The Toxicologist
Supplement to Toxicological Sciences

57th Annual Meeting and ToxExpo™
San Antonio, Texas
March 11–15, 2018
Important Dates and Deadlines

May 15, 2018 | Scientific Session/CE Course Proposal Submission Deadline
July 15, 2018 | Housing and Registration Open
October 9, 2018 | SOT Awards Nomination and Application Deadline
October 19, 2018 | 2019 Abstract Submission Deadline

www.toxicology.org/2019
Preface

This issue is devoted to the abstracts of the presentations for the Continuing Education courses and Scientific Sessions of the 57th Annual Meeting of the Society of Toxicology, held at the Henry B. González Convention Center, San Antonio, Texas, March 11–15, 2018.

An alphabetical Author Index, cross referencing the corresponding abstract number(s), begins on page 561.

The issue also contains a Keyword Index (by subject or chemical) of all the presentations, beginning on page 584.

The abstracts are reproduced as accepted by the Scientific Program Committee of the Society of Toxicology and appear in numerical sequence. Author names which are underlined in the author block indicate the author is a member of the Society of Toxicology. For example, J. Smith.

Scientific Session Types:

- Continuing Education Courses
- Education-Career Development Sessions
- Featured Sessions
- Historical Highlights Sessions
- Informational Sessions
- Roundtable Sessions
- Regional Interest Sessions
- Platform Sessions
- Symposium Sessions
- Poster Sessions
- Workshop Sessions

The 2018 SOT Mobile Event App and Online Planner

The Mobile Event App and Online Planner are available via the SOT website and app marketplaces. These mobile tools enable you, the attendee, to engage with organizers, exhibitors, and each other, and to manage your time and maximize your experience during the Annual Meeting. You also can access ePosters electronically via the Mobile Event App until May 15, 2018.

To cite a 2018 SOT Annual Meeting Abstract, please format as follows: The Toxicologist, Supplement to Toxicological Sciences, 150 (1), Abstract ____, 2018, Title, First Author.

Copies of The Toxicologist are available at $50 each plus shipping ($15 shipping & handling in the USA and $50 for overseas shipments) from:

Society of Toxicology
11190 Sunrise Valley Drive, Suite 300, Reston, VA 20191

All text and graphics are © 2018 by the Society of Toxicology unless noted. For promotional use only. No advertising use is permitted.

This abstract book has been produced electronically by the Society of Toxicology. Every effort has been made to faithfully reproduce the abstracts as submitted. The author(s) of each abstract appearing in this publication is/are solely responsible for the content thereof; the publication of an article shall not constitute or be deemed to constitute any representation by the Society of Toxicology or its boards that the data presented therein are correct or are sufficient to support the conclusions reached or that the experiment design or methodology is adequate. Because of the rapid advances in the medical sciences, SOT recommends that independent verification of diagnoses and drug dosage be made.
Recent advances in genome editing using CRISPR-Cas9 and related technologies have revolutionized the ability to manipulate genes in a rapid, precise, and flexible manner. These advances have spurred an explosion of interest in the possible ways in which genome editing can improve human health. This course will provide an overview of CRISPR-Cas9 systems, the structure and function of CRISPR-Cas9, the repurposing of CRISPR-Cas9 for genome engineering, and recent advances in genome editing and the application of these techniques to toxicology. These include its use in screening the genome in different biological systems for gene pathways related to sensitivity or resistance to chemical toxicity, for elucidating the pathways of biological response to chemical stressors, and other applications related to the understanding of mechanisms and the environment interaction. The Regenerative Science for Environmental Health Decisions (ESEHD) Standing Committee of the National Academies of Science, Engineering, and Medicine serves as an important link between the National Academies and the Society of Toxicology. To foster this collaboration, the ESEHD Committee is pleased to sponsor this course on the use of advanced genome-editing techniques in toxicology, which follows a meeting on gene editing in toxicology and environmental health held at the National Academies’ Headquarters in January 2018.

In the last decade, the fields of toxicology and risk assessment have undergone an extensive shift towards the development of alternative testing methodologies that potentially can be used to assess the safety of chemicals and to reduce animal use in toxicological research. New approaches, including molecular biology, computational and systems biology, high-throughput screening (HTS) assays, automated analytical methods, and robotic implementation, are generating toxicological data at unprecedented speeds. Compared to traditional animal toxicity studies, advanced HTS methods, reach-across approaches, in silico tools, and other alternative methodologies hold considerable promise to define biological activity profiles of chemicals. The first step towards better understanding the application of these new methodologies and tools for safety assessment of chemicals is an interdisciplinary approach which: 1) promotes interaction among scientists from diverse backgrounds (e.g., toxicologists, chemists, biologists, mathematicians, programmers, and risk assessors) and 2) provides hands-on training to demonstrate the utility and challenges associated with the use of these alternative testing methods in different sectors. This course will provide a unique training program to equip attendees with all the necessary knowledge and know-how to use and apply data from HTS assays, in silico tools, and other emerging technologies, such as virtual embryo, in the safety evaluation of chemicals. It is a learning tool aimed at providing training to scientists interested in applying the latest approaches to the safety assessment of chemicals, as well as students and researchers interested in improving the existing methods and developing new alternative methods for toxicological research. The course will include an overview of each of the methodologies (HTS methods, in silico tools, virtual embryo) and case study exercises to demonstrate the use of data from these methods and the use of tools in different sectors, such as pharmaceuticals, consumer products, food, agricultural products, and environmental toxicants.

The immune system has long been a sensitive target of environmental pollutants, industrial chemicals, and pharmacological agents. For example, several federal laws and guidelines have data requirements for immunotoxicity. However, recent studies by an industry trade association and the US Environmental Protection Agency Office of Pesticide Programs determined that no clear signs of immunotoxicity may arise from conventional toxicity studies and that additional immunotoxicity testing may only be recommended if “primary indicators” of immunotoxicity arise from conventional toxicity studies. This approach harmonizes with the “weight of evidence” concept that is discussed in the International Council for Harmonisation of Technical Requirements for Pharmaceuticals for Human Use (ICH) guidelines S8 for human pharmaceuticals and Part 158 for pesticidal substances and certain industrial compounds. This course will provide an overview of the types of immunotoxicity tests often used to meet US data requirements for agents regulated by the US Environmental Protection Agency (EPA) and the US Food and Drug Administration. The course will address the “weight of evidence” concept by defining immunotoxicity, discussing the historic aspects of immunotoxicity testing, highlighting some of the current advances in immunotoxicology assessment, including high-throughput analysis, immunotoxicogenomics, developmental immunotoxicology, and the creation of adverse outcome pathways for immunotoxicity. The second speaker will address the particular data requirements under various laws and guidelines and their applicability to regulatory immunotoxicity. Speaker number three will go into detail about specific required tests under existing laws and guidelines, as well as novel and innovative ways of meeting data requirements. The fourth speaker will provide an overview of the utility of experimental animal models and their predictive value for understanding potential risks toward human health. Finally, the fifth speaker will delve into the information that can be gleaned from human blood samples and how these data can be used to better predict health and disease in exposed/treated humans. Each presentation will include case studies and/or examples of immunotoxicity assessment strategies applied to agents or classes of agents under study, being considered for approval, or under regulatory scrutiny.
tified nonclinically, especially with poorly designed nonclinical studies or irrelevant animal test systems. In addition to addressing the unique aspects of strategies for developing biologics, this will discuss topics such as the selection of relevant species, the role and interpretation of immunogenicity, and the current regulatory challenges. Selection and evaluation of the most relevant species for biologics programs is fundamental. Immunogenicity, the ability of a biologic to elicit an immune response leading to formation of antibodies that can bind to the biologic, can confound and cause concern as to interpretability and translatability of these findings to the clinic. A broad overview will be given of how immunogenicity and other immune responses in animals play a role in the interpretation and assessment of toxicology studies. A brief primer will be offered on current regulatory guidance, in addition to highlighting complex issues that are frequently faced when reviewing applications for biopharmaceuticals. Examples from US Food and Drug Administration submissions will be discussed to illustrate these challenges and to present scientific and regulatory strategies that have been used in the design or review of nonclinical programs that support biopharmaceutical drug development. This course will provide an understanding of the considerations of key issues for advancing these therapeutics safely in the clinic. This requires a strong understanding of the biology of the target and also a good comprehension of the caveats and limits of the current nonclinical models and an ability to design fit-for-purpose, nonclinical safety testing funnels adapted to the test agents being developed.

**1006 AM06: In Vitro Testing: Tales from the Real World**

K. Coleman¹ and A. Clipping⁴, ¹Medtronic PRL, Minneapolis, MN and ⁴PETA International Science Consortium Ltd, Norfolk, VA.

Advances in science and technology have paved the way for a paradigm shift in toxicity testing. We now have the opportunity to more efficiently evaluate substances and better protect human health and the environment by using approaches grounded in human mechanisms rather than animal models. These in vitro tests—namely, skin irritancy, skin sensitization, and systemic (oral, dermal, and inhalation) toxicity—are commonly conducted on medical devices, pesticides, industrial chemicals, pharmaceuticals, cosmetics, and other substances. Thus, it is important to implement rigorous alternative acute toxicity-testing approaches that will protect human health and the environment while reducing the time, cost, and animal use associated with traditional toxicity testing. The goal of this course is to teach attendees about existing in vitro, in chemico, and in silico acute toxicity tests and how they have been successfully applied in integrated approaches to evaluate the toxicity of a wide range of substances. Other approaches, such as the use of waivers or the Globally Harmonized System of Classification and Labeling of Chemicals (GHS) mixtures equation, will be discussed. The presentations will also highlight the remaining challenges that need to be overcome before alternative methods can be implemented globally and accepted by regulatory agencies. This course will be of interest to toxicologists from diverse sectors, including those from the chemical, pharmaceutical, medical device, and personal care product industries, along with others who want to learn more about currently available non-animal tests and how to use them.

**1007 AM07: Physiologically-Based Pharmacokinetic Modeling to Support Modernized Chemical Safety Assessment**

M. Yoon¹ and A. Paini², ¹SciVation, Research Triangle Park, NC and ²European Commission Joint Research, Ispra, Italy.

Physiologically-based pharmacokinetic (PBPK) models have been applied to chemical risk assessment for more than three decades. Extrapolation of toxicity findings to humans has been a major application of PBPK models in risk assessment. Under the proposed new toxicity testing paradigm, which relies on data from human-relevant in vitro toxicity assays interpreted through computational approaches, PBPK models have been redefined as a critical translation tool for quantitative in vitro to in vivo extrapolation. The models would link effect concentrations in cell-based assays to equivalent human exposures. PBPK models provide a biologically relevant integration platform to describe the absorption, distribution, metabolism, and excretion of chemicals based on a wide range of in vitro, in silico, and, if available, in vivo information. This course will provide an opportunity to revisit the basic principles of PBPK modeling with a special focus on supporting chemical risk assessment under the new toxicity testing paradigm. In addition to describing the basics of model construction, recent advances in model parameterization, including in vitro to in vivo extrapolation and in silico predictions, will be presented. Evaluation of model performance and reliability along with use of available human data will be discussed. Development and application of the PBPK models to support risk-based decisions in different tiers of risk assessment will be presented. A hands-on demonstration will be provided, using a free online simulation tool (PLETHEM) to demonstrate the workflow of building and parameterizing a PBPK model, simulating different human populations, and applying the model to translate concentration-effect relationships from cell-based assays or in vivo studies to the dose-response relationship in target human populations to support chemical risk assessment. The course will address continuing challenges and future directions in PBPK modeling.

**1008 AM08: Developmental Neurotoxicity Testing: Current Practices and Latest Advancements**

K. Ryan¹ and S. Makris². ¹NIH, Durham, NC and ²US EPA, Washington, DC.

The potential for neurotoxicity in adults and children remains a high public priority due to concerns that recent increases in the prevalence of neurological disorders may in part be due to chemical effects. Guidance on developmental neurotoxicity studies in rodents currently remain the gold standard for risk assessment. However, these studies are triggered using the current guidelines due to the lack of specific requirements in the guidelines, the subjective nature of these tests causing interlaboratory variability, lack of relevance of some of the assays to human-specific outcomes, and the lack of power to capture subtle deficits. To address these issues there is a significant push to develop alternative strategies for developmental neurotoxicity testing and to recommend strategies for harmonizing guideline studies for use by regulatory agencies. This course is designed to highlight the current state of the science and recent advancements to identify an integrated strategy for developmental neurotoxicity testing. The course will begin with an introductory talk on the current practices with guideline toxicology studies, as well as developments and recommendations for them (US Environmental Protection Agency (US EPA) 870.6300, Organisation for Economic Co-operation and Development (OECD) 426, OECD 443). The next two presenters will focus specifically on the current state and advancements, and recommendations for developmental testing (learning, activity, attention) and neuropathology. The subsequent presenter will then highlight how developmental neurotoxicity is assessed in the clinic, provide case examples, and speak on the parallels between human and rodent studies. The last presenter will provide a practical strategy to rapidly screen for compounds with unknown neurotoxic potential to prioritize for further testing and how to incorporate triggers from those screens in further assessment of in vivo developmental neurotoxicity studies.

**1009 PM09: Consumer Products Safety Assessment: Progress in the Use of Alternatives to Animal Models**

K. E. Page¹ and T. Hartung². ¹The Clorox Company, Pleasanton, CA and ²Johns Hopkins Center for Alternatives to Animal Testing (CAAT), Baltimore, MD.

To meet consumer preferences and changes in the regulatory landscape, the use of animals for the safety evaluation of consumer product ingredients and formulas is decreasing across industries, including cosmetics, personal care products, and household products, and other consumer products companies are soon to follow. The purpose of this course is to provide an encompassing overview of the progress in the field of safety evaluation of consumer products ingredients using alternative approaches. The introductory presentation will map the current landscape of alternative methods for assessing consumer product safety, including highlighting the holes still remaining in the field. Occasional resistance to change by regulatory agencies can be frustrating to the industry at large. However, recent government-industry collaboration has shown the potential for helping the progress. The first presentation will provide insight into the current regulatory landscape of the US Consumer Product Safety Commission (CPSC) animal testing policy, including what methods are approved and recommended, as well as the struggles faced in getting there. A roadmap of where testing and regulations are likely headed will also be presented, including what challenges await. Several alternative methods have been developed and validated to assess product safety and are now considered acceptable by regulatory agencies. However, the path to their integration into safety assessments and communication to scientists-at-large is still a work in progress. The second presentation will showcase available options for alternative testing strategies, as well as struggles and triumphs in getting methods accepted by regul-
latory agencies. The final two presentations will provide case studies of how alternative testing is used in the cosmetics and cleaning products industries, as well as specific examples from L’Oréal as a trendsetter in the field and regarding method development and from Clorox about how to navigate the current regulatory requirements for cleaning products and animal testing. The course will provide a sound understanding of the current and proposed future state of alternatives to animal testing in consumer product safety assessment.

### 1010 PM10: Evaluation of Leachable Substances from Materials with Applications in Foods and Pharmaceuticals: Science- and Risk-Based Approaches

G. L. Erexson1 and K. L. Li2, 1AbbVie, North Chicago, IL and 2Amen Inc., Thousand Oaks, CA.

Polymeric materials commonly used in food and pharmaceutical manufacturing and packaging components are known to leach chemical substances into the final products. The leachable substances may present potential safety risks to consumers and patients. The goal of this course will be to provide an overview of scientific and technical considerations relevant to the assessment of leachable substances covering historical and current context on patient safety and product quality, collaboration between chemists and toxicologists, best practices for deriving chemical-specific safety margins, and use of in vitro and in vivo tools to apply the 3R principle to replace, reduce, and refine animal testing. This course will provide a comprehensive overview of the risk assessment process for leachable compounds from food contact and pharmaceutical materials.

### 1011 PM11: Lead Optimization of Therapeutic Small Molecules: From Drug Target to Clinical Candidate Selection—Strategies and Decision Making

D. Diaz1 and D. Misner2, 1Denali Therapeutics Inc., South San Francisco, CA and 2Atos Biopharma, South San Francisco, CA.

From the decision to drug a chosen target with a small or large molecule to the selection of a lead candidate to take into Good Laboratory Practices (GLP) toxicology studies, discovery toxicologists engage an arsenal of tools and strategies with the objective of selecting molecules with a safety profile that provides an optimal chance of clinical success. This is best achieved by early safety involvement in target selection and target de-risking, selection of the best possible chemical matter with minimal off-target effects through lead optimization, and robust safety characterization and investigation of safety issues as they arise. The premise is that robust and thoughtful early safety involvement would reduce attrition in later phases of drug development. This course will provide a comprehensive overview of the strategies and approaches leading from drug target selection to lead identification, optimization, and selection of clinical candidates for first-in-human studies. The first presentation will address the safety considerations in target selection, to ensure that the intended targets are tractable from a safety perspective, and that the relevant questions are addressed and the proper lead optimization paradigms are in place for the particular program. The second presentation will tackle the critical aspects of selectivity for small molecules, including related and unrelated off-targets, and how to ensure that the molecules that are progressed are screened appropriately to ultimately have minimal off-target effects. The next two presentations will focus on two essential aspects of lead optimization: 1) cardiovascular safety and 2) genotoxicity, for which in vitro models have been particularly effective in minimizing liabilities. The session will continue with a presentation focused on particularly promising in vitro models and strategies to minimize hepatotoxicity: these approaches are becoming increasingly important in drug discovery since preclinical in vivo studies poorly identify human-relevant hepatotoxins. The course will conclude with a presentation that integrates the different aspects of lead optimization discussed previously with in vivo data generated in pilot toxicity studies and will discuss how to incorporate these data into deciding whether to move into GLP toxicity studies. All presentations will focus on the practical aspects of implementing thoughtful de-risking strategies and on how data-driven decisions are made with the data outputs; presenters also will provide relevant examples to illustrate these approaches. The course will provide understanding of how to address safety for small molecules from the inception of a program to candidate selection, into investigative new drug (IND)-enabling studies, and provide to evaluate and integrate relevant data, and how to make good decisions related to compound progression.

### 1012 PM12: NGS-Based Technologies Enable Biomarker Development and Discovery in Toxicology

B. A. Merrick1 and A. B. Nixon2, 1NIHES, Research Triangle Park, NC and 2Duke University Medical Center, Durham, NC.

Next-Generation sequencing (NGS) represents a series of powerful platforms that have revolutionized DNA and RNA analysis. The simultaneous sequencing of millions of DNA molecules can rapidly provide mechanistic insights into toxicology and biomarker discovery. Evolution of NGS technologies has improved the overall sensitivity and accuracy of these sequencing platforms, allowing for the development of new biomarker assays from tissue, blood, and other biofluids. NGS technologies can identify potential molecular indicators at the cellular and toxicopathological level in response to xenobiotics. The goal of this course is to review NGS-based technologies, demonstrate how they can be used as tools for target discovery in tissue and blood, and suggest best practices for optimal sample analysis and processing in the toxicology setting. The technological transition from microarray toward NGS platforms in toxicology will be briefly reviewed. In the first presentation, a broad overview will be provided on the development, validation, and implementation of circulating biomarkers from a clinical perspective. Emphasizing lessons learned from the clinical oncology field, where biomarker development is key to disease treatment, the implementation of NGS and its potential use in toxicology will be discussed. The second presentation will describe the roles of non-coding RNAs as potential biomarkers. RNA-Seq data will be presented on long-noncoding RNAs (lncRNAs) and microRNAs (miRNAs), which are small ~22nt RNAs and represent promising new biomarkers; the isolation, NGS analysis, species, cell and tissue specificity, and toxicological responses in humans and animal models. IncRNAs are an exciting and emerging area in toxicology. The third presenter will focus on another type of noncoding RNA, microRNAs (miRNAs), which are small ~22nt RNAs and represent promising new biomarkers; the isolation, NGS analysis, species, cell and tissue specificity, and toxicological responses in vitro in tissues and biofluids will be discussed. The fourth presentation will highlight best practices for optimal sample collection to ensure success with downstream NGS applications, followed by an introduction to whole exome sequencing (WES) in toxicology. WES provides the coding and noncoding genome to discover new sequence variants. A new WES platform, which is designed for rats, with future directions toward analysis of circulating, cell-free DNA (cfDNA) as a potential biomarker for targeting specific biological processes, such as inflammation, will be described. The final presentation will involve NGS methods in epigenetics, using whole-genome bisulfite sequencing (WGBS), as well as other approaches to assess changes in DNA methylation after chemical exposure. Case studies will include the valuable role of zebrafish as an alternative animal model in chemical toxicity screening for NGS-based environmental epigenetics. This course will be of broad interest to investigators in academia, pharma, and government wishing to explore and expand their interest in novel NGS-based approaches with an emphasis on the development and discovery of biomarkers for the detection of xenobiotic toxicity and exposure.

K. Muldoon Jacobs1 and A. Richarz2, 1NIEHS, Research Triangle Park, NC and 2European Commission Joint Research Centre, Ispra, Italy.

Understanding, describing, and, if possible, quantifying uncertainties is an essential part of risk assessment which needs to be communicated clearly and in an informed decision-making context, with the provision of a transparent statement of the likelihood of possible outcomes as a basis of building confidence in decisions taken. This is particularly true for risk assessments that rely on new toxicological methods with which the risk assessment community does not have the benefit of historical experience. The course will clarify the nature and sources of uncertainties and variability and give an overview of existing initiatives and available guidance for uncertainty evaluation for chemical risk assessment in the regulatory context. Current practice in regulatory review will be discussed, as well as challenges in application for the risk assessor/manager (often the same person) in industry. The importance and challenges of communicating uncertainties also will be addressed. A special focus of the course will be the characterization of uncertainties for alternative methods used for chemical hazard and risk assessment, bearing in mind that the incorporation of new toxicological methods into risk assessment is still happening, and that we still need to describe and assess the associated different uncertainties. The new methods, for example, combine in silico, in vitro, and high-throughput toxicokinetics approaches to predict hazards and to provide quantitative estimates of effect levels and are then combined into models to predict in vivo effect levels, such as lowest-observed-adverse-effect levels (LOAELS).
Approaches will be shown to quantify uncertainty in these individual inputs, as well as methods to combine uncertainty across all inputs in the final models. Furthermore, uncertainty and variability are compared with those in the in vivo databases that are used as benchmarks for the new models. Another example will include consideration of uncertainties for the non-chemical-specific Threshold of Toxicological Concern (TTC) approach as compared to traditional blood-based assessments. The course will further describe state-of-the-art mathematical, statistical, and other methods, such as expert elicitation, to characterize and quantify uncertainty and tiered approaches to handling uncertainty in risk assessment. Examples will illustrate qualitative, deterministic, and probabilistic uncertainty assessment. Two case studies will show how these methods can help risk assessors and support decision-making: 1) the use of Bayesian-belief networks to quantify the uncertainty in the potential of a chemical being a skin sensitizer in the light of competing evidence and 2) a mathematical model for an adverse outcome pathway (AOP)-based risk assessment, defined and parameterized by vitro data sources. Overall, the purpose of the course is to give an overview of the concept of uncertainty and to identify existing resources on uncertainty characterization and reporting in guidance related to hazard assessment, as well as available mathematical methods. Practical examples based on case studies from practice in various sectors will illustrate alternative methods supporting hazard assessment. Thus, the course will present concrete methods to characterize uncertainty in the context of chemical risk assessment, in particular, how to pragmatically apply them in a tiered approach, while gaining more confidence in assessing alternative methods.

**1014 PM14: Xenobiotic Pharmacokinetics during Pregnancy and Lactation**

N. Catlin¹ and A. Slitt², Pfizer, Inc., Groton, CT and ¹University of Rhode Island, Kingston, RI.

Exposure to xenobiotics during pregnancy and lactation is unavoidable and can be either intentional with pharmaceuticals or unintentional as contaminants in air, food, and water. During this critical time period of development, xenobiotic exposure can result in deleterious effects to the developing fetus. A number of critical physiological and molecular changes occur in the pregnant woman or animal that will influence the disposition and toxicity of chemicals, often in a gestational age-dependent manner. These changes range from altered blood flow to changes in metabolic pathways, as well as enhancement of renal filtration. In addition, the placenta is considered a selective barrier to protect the fetus against xenobiotics. However, some pharmaceuticals and toxicants can readily cross this placental barrier through active transport or diffusion, leading to exposure in utero. After birth, lactation represents a new route of xenobiotic exposure for the infant. The goal of this course is to provide participants with an introduction to the maternal and perinatal pharmacokinetics of xenobiotics during pregnancy and lactation. A variety of approaches will be covered, including animal studies, physiologically-based pharmacokinetic (PBPK) modeling, and clinical pharmacology studies in pregnant women. Case study examples will also be discussed in each presentation to illustrate these different approaches. The first presentation will provide an overview of the maternal pharmacokinetics and disposition associated with pregnancy, as well as the metabolic capabilities of fetal and neonatal rodents and humans. The second lecture will discuss placental morphology and the transfer of nutrients and foreign chemicals. The third presentation will cover the application of PBPK modeling to understand how physiological and biochemical processes change, and how they impact xenobiotic disposition in the postpartum period, as well as the early-life stage development. The final presentation will describe clinical pharmacology examples of pharmacokinetic changes during pregnancy and the postpartum period and will provide an overview of xenobiotic transfer through breast milk. This course also will cover changes in pharmaceutical drug labeling related to pharmacokinetics and pharmacology during pregnancy and lactation.

**1015 Advanced Imaging and Microscopy for Retinal Disease and Toxicity**

M. Rios Blanco, Allergan, Irvine, CA.

The three major challenges in the study of acquired and innate diseases, as well as drugs and toxicants that affect the retina in man and experimental animals, are difficulty in early noninvasive detection of decreased visual function and/or loss with conventional tools and techniques; determination of the cellular site(s) and mechanism(s) of action; and monitoring of progression and/or repair following different toxic or therapeutic regimens. Advances in optical coherence tomography (OCT) techniques, for man and experimental animals, provide the ability to noninvasively image individual retinal cells, the optic nerve, and retinal vasculature in living eyes. These new noninvasive techniques enable the clinician and scientist to detect, monitor, and treat retinal disease and injury earlier; to visualize the site of action with greater specificity; and to follow the progress of treatment longitudinally. Moreover, the visualization and determination of the cellular, subcellular, and ultrastructural site and mechanisms of injury in retinas from donated human eyes and experimental animals require a variety of different sophisticated imaging techniques. A variety of new noninvasive and experimental techniques are readily applicable to the study of drugs and toxicants that produce pathophysiological alterations similar to known retinal and neurodegenerative diseases, or that exacerbate such existing conditions. The objective of the session is to present state-of-the-art research approaches to clinical and experimental animal model imaging and their utility in toxicological research and to show how the obtained data can be utilized for translational research. The presentations will cover the study of different cell populations within the retina and of the supporting vascular networks. Each presentation will share the fundamental aspects of the imaging modality, illustrate their application to model organisms, and highlight the utility of imaging other techniques to study this phenomenon in experimental animals. Overall, the session will accomplish three goals. First, it will introduce and educate the scientific community on the use of state-of-the-art approaches to noninvasive ocular imaging for the early detection, assessment, progression, and treatment of retinal damage in man and experimental animals. Second, it will enhance the understanding of retinal sites and mechanisms of action of injury. Third, it will provide a basis for determining the translatability of experimental data to humans. The session will be of interest to basic scientists, clinicians, and researchers engaged in drug development and testing.

**1016 Cellular and Structural Imaging Techniques in Glaucoma Diagnosis and Treatment**

S. McKinnon, Duke University, Durham, NC. Sponsor: D. Fox

Glaucoma is a potentially blinding neurodegenerative disease that affects millions of people worldwide. The disease is diagnosed by assessing function (peripheral visual field testing) and structure (optic nerve appearance). Unfortunately, these standard techniques are subject to large variabilities that make the diagnosis and/or staging of glaucoma a clinical challenge. Imaging modalities such as Optical Coherence Tomography (OCT) and Adaptive Optics (AO) improve glaucoma diagnosis by allowing objective imaging of retina and optic nerve structure. Clinical OCT provides data concerning abnormalities in RGC axonal distribution, and volume images can now be obtained using Swept-Source Spectral-Density (SDOCT) in a matter of seconds. Enhanced Depth Imaging SDOCT can measure retinal nerve fiber layer and axonal loss, allowing earlier risk assessment in glaucoma. Polarization-sensitive OCT (PS-OCT) measures axonal birefringence, providing data concerning microtube stability and structure that are surrogates of RGC health. AO is able to image individual retinal cells, and recently RGCs in monkeys and humans have been imaged for the first time in the near future. AO is highly probable that RGC maps of individual retinal neurons can be created and followed longitudinally for disease progression. Combining AO and OCT allows assessment of retinal vasculature and blood flow using Sensorless AO-OCT Angiography. These seemingly constant improvements in resolution and speed of retinal imaging are changing the way we think about the potential to revolutionize glaucoma assessment and treatment outcomes.
Adaptive Optics Imaging to Study Retinal Degeneration and Response to Treatment

Retinal degenerative diseases cause progressive vision loss, and ultimately blindness. Retinal degeneration can be caused by mutations in over 200 genes, and therefore cause photoreceptor death through a variety of mechanisms that affect photoreceptors, retinal pigment epithelial cells, and choroidal or retinal perfusion to varying degrees. Visual function measures provide information about how the patient experiences the world. In this poster, we present clinical outcomes and how adaptive optics can be utilized to image the retina at cellular and sub-cellular level.

Mitochondria-Mediated Retinotoxicity: Determining Pathophysiological Mechanisms Using Multifaceted Image Analysis and Biochemical Techniques

D. Fox, Robson Forensic, Inc., Philadelphia, PA.

Half of all neuroactive/neurotoxic chemicals adversely affect sensory functions. Of these, the initial and most frequent alterations following chemical exposure occur in the retina, suggesting that the retina is especially vulnerable to chemical insult. Several distinct tissue-, layer- and cell-specific biochemical, metabolic, physiological, and structural, characteristics underlie this vulnerability. The aim of this talk is to provide a comprehensive understanding of the differential pathophysiological responses of rod and cone photoreceptors with intact inner and outer segments that are in contact with retinal pigment epithelial cells. Split detection AO systems utilize non-confocal scattered light to image structures that are not waveguiding, such as photoreceptors that have disrupted or missing outer segments and retinal pigment epithelial cells. Finally, AO can be used to precisely deliver visual stimuli to individual photoreceptors, such that visual function and retinal structure can be studied with cellular resolution. AO imaging offers new insights into retinal cell structure and function on a cellular level, non-invasively, in patients with retinal degenerative diseases. Application and interpretation of these advanced technologies in healthy and diseased retinas is presented.

Cancer Risk Assessment of PAH Mixtures: Current and Future Directions

M. Pratt. US EPA, Washington, DC.

The cancer risk posed by exposures to polycyclic aromatic hydrocarbons (PAH) has long been a public health concern. The two-year rodent cancer bioassay remains the definitive source of information employed for cancer risk assessment, and, using such conventional approaches, the US Environmental Protection Agency (US EPA) is actively working to address the need for an updated and expanded document that serves as the agency’s approach for assessing cancer risk from exposure to PAH mixtures. However, the time and resources required to perform two-year rodent bioassays for the range of environmental PAH mixtures are significant and serve as a disincentive to the development of these kinds of data. Recent trends in toxicology and risk assessment offer opportunities to explore less costly and more rapid alternative approaches using non-apical endpoints for estimating the cancer risk posed by PAH mixtures; however, alternative approaches require critical evaluation to ensure that they represent an improvement from the current approach. The approaches that will be discussed in this session include PAH whole mixtures risk assessment, component-based approaches, use of shorter-term in vitro and in vivo assays to provide cancer-relevant data, and a greater focus on adverse outcome pathways to understand cumulative risk. This will be followed by a panel discussion of the merits of these alternative approaches and what steps are needed to move toward validation. Disclaimer: The views expressed are those of the author and do not necessarily represent the views or policies of the US EPA.
relevant exposure routes, use of tumor bioassay data only, and using an intermediate index chemical to expand the database if benzo[a]pyrene, the index chemical, was not tested concurrently. In addition, methods to compare the cancer potency predicted by the RPF approach with those reported in the few available whole mixtures studies will be discussed. The views expressed are those of the author and do not necessarily reflect the views or policies of the US EPA.

The Genetic Toxicity of Complex Mixtures of Polycyclic Aromatic Hydrocarbons: Evaluating the Dose-Additivity Assumption Using a Transgenic Mouse Model

P. White. Health Canada, Ottawa, ON, Canada. Sponsor: M. Pratt

Over 3,000 federally-owned contaminated sites in Canada contain complex mixtures of polycyclic aromatic hydrocarbons (PAHs). Consequently, the Federal Contaminated Sites Action Plan (FCSAP) funded work aimed at evaluating the assumption of component additivity that is commonly employed for regulatory evaluations of PAH mixtures. Initial work evaluated the excess lifetime cancer risk (ELCR) posed by 10 PAH-contaminated soils using (i) the currently advocated, chemical-specific RPF approach; and (ii) a bioassay-based approach that employs the in vitro mutagenic activity of the soil fractions to determine levels of benzo[a]pyrene (BaP) equivalents and, by extension, ELCR. The results show that ELCR values for the PAH-contaminated fractions, determined using the chemical-specific approach, are generally (i.e., 8 out of 10) greater than those calculated using the bioassay-based approach; most are less than 5-fold greater. Follow-up in vivo work employed subchronic oral exposures of the transgenic Muta Mouse to determine tissue specific mutagenic activities, and, by extension, levels of BaP equivalents in several coal tar derived test articles. Similar to the in vitro work, the results were compared to BaP equivalent levels determined using the RPF approach. The results showed that BaP equivalent concentrations based on experimentally-observed in vivo responses in tissues that are distal from the exposure (i.e., bone marrow), were lower than levels determined using the RPF approach. However, the converse was true for proximal tissues (e.g., small intestine). Nevertheless, in both cases the differences between levels based on experimental observations, and those based on the RPF approach, were within 5 fold. The in vitro and in vivo bioassay-based approaches, which permitted estimation of BaP equivalent concentrations without a prior knowledge of mixture composition, demonstrated that experimentally determined levels are surprisingly close to those determined using the targeted RPF approach that is based on only 7-8 carcinogenic PAHs. The results indicate that the targeted RPF approach for PAH mixtures provides a reasonable estimate of BaP equivalent concentrations, and, by extension ELCR estimates.

Mechanism-Based Classification of PAH Mixtures to Predict Carcinogenic Potential

S. Tilton. Oregon State University, Corvallis, OR.

One of the most difficult challenges for risk assessment is prediction and evaluation of health hazards from environmental chemical mixtures. In particular, polycyclic aromatic hydrocarbons (PAHs) are a major group of over 1,500 chemicals measured in complex mixtures from petrogenic or pyrolytic processes. Humans are primarily exposed to PAHs as mixtures, which include both class 1A (known) and 2A (probable) human carcinogens, through multiple exposure routes. Unfortunately, current reference approaches for assessing PAH risk are inadequate for complex environmental mixtures of unknown composition. To successfully distinguish early regulatory events during initiation and progression, RSP agonism, ER antagonism, and GR antagonism. Based on a comparison of candidate screening assays to in vivo potencies data from the literature, cytotoxicity in diverse cell lines was selected for PAH compounds and prioritized for in vivo testing. A 28-day immunotoxicity study in female B6C3F1/N mice was selected to generate potency data and evaluate application of the relative potency factor approach. The results showed that BaP equivalent concentrations, and, by extension ELCR estimates.

Use of Non-Apical Assay Data in an Integrated Approach to Testing and Assessment of Chemical Mixtures in the Environment: the Advent of Adverse Outcome Pathway Footprinting

J. Lambert. US EPA, Cincinnati, OH. Sponsor: M. Pratt

A key challenge in the risk assessment of environmental chemical mixtures is the availability of sufficient apical endpoint data to inform hazard and dose-response assessment. The virtual absence of whole mixtures data at environmentally relevant exposure levels or proportions, and limited availability of traditional toxicity assay information for individual chemicals present in mixtures, is a challenge for human health risk assessment. This is particularly difficult in the case of cancer risk assessments, where data from two-year rodent bioassays are often not available. With the advent of 21st century toxicity testing and approaches such as adverse outcome pathway (AOP) testing, opportunities to evaluate hazards associated with exposure to “data-rich” mixture chemicals have advanced significantly. Potential health impact(s) of mixture chemicals may be informed using an integrated read-across approach that includes AOP “footprinting” when adverse outcome data derived from traditional bioassays are lacking. In brief, AOP footprinting makes use of key event data to inform qualitative and quantitative relationships between mixture components. This presentation will provide an overview of AOP footprinting and how it complements an integrated approach to testing and assessment (IATA) of both data-poor and data-rich chemicals in environmental mixtures. The views expressed in this abstract are those of the author and do not necessarily reflect the views or policies of the US EPA.

Novel Insights on Chemical-Induced Immunotoxicity: Microvesicles and microRNA Dysregulation

E. Corsini. University of Milan, Milan, Italy.

Eukaryotic cells contain extracellular organelles named microvesicles (e.g., exosomes, nanovesicles) that are released into the microenvironment. Microvesicles and their main content microRNAs are believed to play a central role in many physiological and pathological processes, including inflammation, autoimmunity, atherosclerosis, and cancer. miRNAs, a class of non-protein-coding RNA molecules negatively regulating mRNA translation, have been shown to be involved in several cellular processes, and their role in toxicology is emerging. The miRNA-mediated coordinated control of gene expression has been shown to be crucial in immunity, promoting and finely regulating appropriate immune responses. Both microRNA and microvesicles are very promising tools in identifying early alterations induced by chemical exposure,
which can revolutionize both monitoring and toxicological assessment.

The aim of this session is to provide novel insights on the mechanisms of action of immunotoxic compounds focusing on microRNA and microvesicles. Recently, differential expressions of miRNAs and association with several immunologic and inflammatory disorders have been reported, which have important implications in immunotoxicology assessment. miRNAs influence regulatory mechanisms of inflammation and can induce and contrasting acute and chronic inflammation. In addition, research on microvesicles also is an emerging and developing field. Studies available to date identified several exposures or lifestyle factors able to modify the trafficking of microvesicles, including air pollutants, cigarette smoke, and oxidative stress. The first speaker will guide the audience in the world of microRNAs from discovery to their role in physiological and pathological conditions, with emphasis on tumors and immunosurveillance, to their use as biomarkers. The second speaker will present data showing influences of environmental exposures on EV-encapsulated RNAs and potential links with several adverse health outcomes, including immunotoxicity. The last two speakers will focus on the role of microRNAs in allergic phenomena both in humans and in experimental models. Challenges, limitations, and opportunities in this emerging field in environmental health sciences will be discussed.

**1028 Effects of Environmental Exposures on Microvesicles Release and Their Contents**

A. Baccarelli. Columbia University, New York, NY. Sponsor: E. Corsini

Interest in intercellular communication has risen in recent years, with an increasing awareness of the complexity of its contributions to diverse physiological processes. In particular, the identification of extracellular vesicles (EVs) as novel mediators of intercellular communication has re-focused research efforts in the field. The number of human studies of EVs-using a number of body fluids including blood, urine, saliva, amniotic fluid, and breastmilk, have grown exponentially in the past few years. Several investigations have focused on EV-packaged non-coding RNAs, which are released into EVs by the cell of origin and may reprogram gene expression in recipient cells. EVs have been linked to environmental exposure pathways and the infiltration of the immune system in cancer. MicroRNA and other short or long non-coding RNA alterations are identified in the initiation, progression, and metastasis of human cancer. The main molecular alterations are represented by variations in gene expression, usually mild and with consequences for a vast number of target protein coding genes. The causes of the widespread differential expression of non-coding RNAs in malignant compared with normal cells are still not clear. These findings by the location of these gene in cancer-associated genomic regions, by epigenetic mechanisms, and by alterations in the processing machinery. MicroRNA and other short or long non-coding RNAs expression profiling of human tumors has identified signatures associated with diagnosis, staging, progression, prognosis, and response to treatment. In addition, profiling has been exploited to identify non-coding RNAs that may represent downstream targets of activated oncogenic pathways, or that are targeting protein-coding genes involved in cancer. Recent studies proved that miRNAs and non-coding ultraconserved genes are main candidates for the elusive class of cancer-predisposing genes and that other types of non-coding RNAs participate in the genetic puzzle, giving rise to the malignant phenotype. Last but not least, the shown expression correlations of these new ncRNAs with cancer metastatic potential and overall survival rates suggest that at least some members of these novel classes of molecules could potentially find use as biomarkers or novel therapeutics in cancers and other diseases.

**1029 Circulating microRNAs and Prediction of Airway Hyperresponsiveness**

K. G. Tantisira. Harvard Medical School, Boston, MA. Sponsor: E. Corsini

Airway hyperresponsiveness is a cardinal feature of asthma. While clinically measured via non-specific agents such as methacholine and histamine, other agents, including pollen, smoke, and chemical inhalation, can cause significant airway hyperresponsiveness. Identification of miRNAs associated with airway responsiveness may have biologic, prognostic, and therapeutic relevance. Murine models have identified several miRNAs associated with airway hyperresponsiveness, including miR-126 and let-7. Examination of these murine phenotypes is hindered by the lack of equivalent murine asthma models. MicroRNA expression profiling of human asthma patient samples has revealed a number of the miRNAs with methacholine-induced PC20 changes in a cohort of childhood asthmatics has been reported. Two of these miRNAs, miR-16-5p and miR-30d-5p, form central hubs in miRNA-predicted gene networks and are associated with changes in airway smooth muscle growth and size. MicroRNAs have also been used to provide a prognostic signature for the natural history of asthma with good predictive power for resolution of airway hyperresponsiveness over time. Thus, miRNAs in general, and circulating miRNAs specifically, appear to have an evolving role in the understanding of airway hyperresponsiveness and may shed future light on inhalational and toxicologic lung disorders.

**1030 microRNA in Experimental Models of Chemical Sensitization**

E. Anderson. NIOSH, Morgantown, WV.

Allergic disease is an important occupational health concern, with work-related asthma and allergic contact dermatitis being the most frequently diagnosed occupational illnesses. Understanding the mechanisms behind allergic disease is critical for treatment and prevention. The regulatory potential of microRNAs (miRNAs) has been recognized in a variety of disease states, including allergic disease; however, the roles of miRNAs in chemical sensitization are largely unknown. Increased expression of multiple miRNAs during toluene 2,4-diisocyanate (TDI) sensitization was observed, and several putative mRNA targets identified for these miRNAs were directly related to regulatory T-cell (Treg) differentiation and function, including Foxp3 and Runx3. Specifically, miR-210 expression increased in the mouse draining lymph node (dLN) and Treg subsets following dLN TDI sensitization. Alterations in dLN miRNA and protein expression of Treg-related genes/putative miR-210 targets (foxp3, runx3, cplt, and cdx2) were observed at multiple time points following TDI exposure and in ex vivo systems. A Treg suppression assay, including a miR-210 mimic, was utilized to investigate the suppressive ability of Tregs. Cells derived from TDI-sensitized mice treated with miR-210 mimic had less expression of miR-210 compared to the control, suggesting other factors, such as additional miRNAs, might be involved in the regulation of the functional capabilities of these cells. These novel findings indicate that miR-210 may have an inhibitory role in Treg function during TDI sensitization. Because the functional roles of miRNAs have not been previously elucidated in a model of chemical sensitization, these data contribute to the understanding of the potential immunologic mechanisms of chemical-induced allergic disease.

**1031 Toxicological Implication of Copper in Neurodegenerative Diseases**

M. Kitazawa. University of California Irvine, Irvine, CA.

Copper (Cu) is an essential transition metal and required for many normal physiological functions, including energy production, free radical scavenging, connective tissue production, iron mobilization, and neurotransmission. However, excessive intake due to occupational or environmental exposure to divalent Cu(II) has been implicated as a risk for various human diseases. When administered, almost all Cu ions are bound to ceruloplasmin (Cp), and the remainder, non-Cp-bound Cu (fabile Cu), is bound to albumin, transcuprein, various peptides, and amino acids in plasma. For the normal level of free Cu is tightly controlled by the above-mentioned Cu-binding proteins. Recent studies have clearly indicated that environmental exposure to Cu in adults accelerates cognitive decline and may increase the risk of developing Alzheimer’s disease (AD)-like neuropathology by elevating non-meroplasmin-bound Cu in plasma. This session will bring together the experts who are actively engaging in investigating chemistry of Cu in biological systems, Cu neurotoxicity, and its underlying...
cellular and molecular mechanisms to discuss the toxicological implications of Cu in neurodegenerative diseases. After a brief introduction of Cu in health and human diseases, the first speaker will highlight the mechanisms by which Cu is transported in and out of the brain through the blood-brain barrier (BBB) and blood-CSF barrier and how the altered Cu transport processes in brain barriers may cause Cu dysregulation, leading to Parkinsonian disorders (PD). The second speaker will present new evidence that Cu controls MMP activity and CLUT-1 levels and how these changes lead to BBB dysfunction in the aged brain in conjunction with the role of Cu in regulating the endothelial lipoprotein receptor-related protein 1 (LRP1) as one possible mechanism increasing the risk for AD.

The third speaker will further expand the subject by addressing the immunomodulatory and multifactorial influences of Cu on Aß clearance in the brain and how microRNAs play a critical role in the Cu-mediated down-regulation of LRP1 in the endothelial cells. The fourth speaker will focus on the unique structural chemistry of Cu in its interaction with Aß and how copper positions within the fibrillar structure of Aß promote its assembly by using highly sophisticated nanoscience technology. The final speaker will introduce the role of Cu in adult neurogenesis in the subventricular zone. New data unveiling the mechanism by which Cu regulates the critical steps leading to migration and differentiation of neural stem cells in the SVZ-rostral migratory stream pathway, and possible implication in the involvement of Cu in PD, will also be presented.

Overall, this session will present the latest findings on the structural, genetic, cellular, and molecular mechanisms of Cu neurotoxicity linking neurodegenerative diseases such as AD and PD. The session will capture the broad interest of those engaged in toxicological research of neurodevelopment and neurodegenerative diseases, neuroscience, neurotoxicology, metals biology, and nanoscience.

1032 Regulation of Copper Homeostasis by the Brain Barrier Systems: Implications in Neurodegenerative Diseases

Copper (Cu) is essential to neuronal function; excess or deficiency is known to underlie the pathophysiology of several commonly known neurodegenerative disorders. This delicate balance of Cu in the central milieu is maintained by the brain barrier systems, i.e., the blood–brain barrier (BBB) between the blood and brain interstitial fluid and the blood–cerebrospinal fluid barrier (BCB) between the blood and cerebrospinal fluid (CSF). This talk will provide a concise description on the structural and functional characteristics of the brain barrier systems supported by unpublished and new data. Current understanding of Cu transport across the brain barriers will be examined, with major focus on whether the BBB and BCB coordinate the direction of Cu fluxes between the blood and brain, and the blood and CSF. In particular, the mechanism by which pertinent metal transporters in the barriers, such as divalent metal transporter (DMT1), copper transporter (CTR1), ATP7A/B, and ferroportin (FPN), regulate metal movement across the barriers is explored. Finally, the detrimental consequences of dysfunctional metal transport by brain barriers, as a result of endogenous disorders or exogenous insults, are discussed. Understanding the regulation of Cu homeostasis in the central nervous system aids in the design of new drugs targeted on the regulatory proteins at the brain barriers for the treatment of metal's deficiency or overloading related neurological diseases.

1033 Brain Capillary Copper and the Accumulation of CNS Proteins Associated with Neurodegeneration and Dementia

R. Deane. University of Rochester, Rochester, NY. Sponsor: M. Kitazawa

Excess free Cu, a powerful pro-oxidant, is toxic, and thus, tightly controlled. Imbalance in cerebral Cu homeostasis plays a role in the pathogenesis of Alzheimer’s Disease (AD), and possibly other neurodegenerative diseases and neurotoxicity, by altering APP processing and Aß deposition and clearance. Brain Aß levels are regulated by its rate of production from APP and by its rate of clearance. Clearance of Aß from the brain involves enzymatic degradation by proteases, including insulin-degrading enzyme (IDE) and neprilysin (NEP), bulk flow of interstitial fluid, and mainly transport across the BBB via low-density lipoprotein receptor-related protein 1 (LRP1). LRP1 is expressed in brain endothelium, and a reduced expression is observed in aging rodents and in patients with AD. In the sporadic form of AD, Aß production is unchanged while its clearance is reduced. Thus, faulty clearance in the aging brain is the major contributor to Aß neurotoxicity. In wild type mice, Cu is accumulated in brain capillaries but entry into the brain is restricted. Consequently, this is associated with a reduction in LRP1 levels at the BBB and higher brain Aß levels. These effects can be reproduced by chronic dosing with low levels of Cu via the drinking water without changes in Aß synthesis or degradation. In human brain endothelial cells, Cu, at its normal labile levels, caused LRP1-specific down-regulation by inducing its nitrotyrosination and subsequent proteosomal-dependent degradation due in part to Cu/(cellular pri) protein/LRP1 interaction. However, in APP mice (Tg2576, another mouse model of AD), Cu down-regulates LRP1 in brain capillaries and also increases Aß production and neuroinflammation. These effects are due to Cu accumulation in brain capillaries and, unlike control mice, in the parenchyma, possibly due to the dysfunctional BBB. New data will be presented to include Cu’s role in controlling MMP activity, CLUT-1 levels and CBF, which could explain its contribution to BBB dysfunction in the aging brain. These findings should provide unique therapeutic approaches to control neurotoxicity in the aging brain.

1034 Multifactorial Role of Copper Toxicity on Modulating Amyloid-Beta Clearance via microRNA and Inflammation

M. Kitazawa. University of California Irvine, Irvine, CA.

While copper is an essential transition metal, a growing body of evidence strongly implicates that excessive intake of inorganic copper, particularly through environment, drinking water, and supplements, accelerates cognitive decline and the development of Alzheimer’s Disease (AD). In fact, elevated levels of total non-ceruloplasmin bound free copper levels in serum have been reported among patients with mild cognitive impairment and AD. However, detailed molecular and cellular mechanisms by which excessive copper exerts neurotoxicity remain an open discussion. Here we demonstrate that exposure to copper significantly alters pro-inflammatory responses and attenuates Aß-induced phagocytosis in murine monocyte cells and an animal model of AD. Additionally, copper directly and indirectly reduces the expression of low-density lipoprotein receptor-related protein 1 (LRP1) in primary human endothelial cells via microRNA-200 and -205. Inhibition of these microRNAs markedly prevents copper-mediated loss of LRP1 in endothelial cells. Both microglial phagocytosis and LRP1 have been documented to play a key role in the clearance of Aß in the brain. Our results strongly imply that copper targets these mechanisms to impair Aß clearance and promote accelerated buildup of Aß in the brain. Thus, our finding provides a critical molecular link to copper as a potential environmental risk factor for AD. In this talk, multifactorial mechanisms of Aß clearance by various brain cell lineages, and how copper differentially impacts these processes, will be integrated.

1035 Amyloid-Copper Complexes and Approaches to Heterogeneity in Biological Systems

P. Weiss. University of California Los Angeles, Los Angeles, CA. Sponsor: M. Kitazawa

Many important biomolecular structures and biomolecular assemblies have varied structures and functions. Many are not amenable to crystallography. We have developed novel nanoscale approaches to measuring the structures of these molecules and assemblies that do not rely on averaging and also elucidate the intrinsic heterogeneity of the systems. In Cu-amyloid systems, we determine the binding sites of the metal ions and the effects that this coordination has on the structures. Two binding sites are found in Aß1-42, and assembly structures are changed even when the metal ion sparsely populate these sites. No equivalent information is available through other methods, and these determinations are enabling, in terms of theory and simulation. Additional metal-amylloid structures are being determined, and using approaches from the fields of sparsity and compressive sensing, we have accelerated our measurements and analyses by orders of magnitude. Next, we will study the positions and roles of the molecular modulators that catalyze and induce misfolding in these systems.

1036 Does Copper Play a Role in Adult Neurogenesis in the Subventricular Zone?

W. Zheng. Purdue University, West Lafayette, IN.

Neural stem/progenitor cells (NSPCs) in the adult subventricular zone (SVZ) have the capability to self-renew and to migrate via the rostral migratory stream (RMS) to reach their final destination, i.e., the olfactory bulb, where they mature and integrate into the local neuronal circuitry. Adult neurogenesis plays an important role in the etiology of neurodegenerative diseases. This presentation will provide a concise review on
the current understanding of how Cu plays a role in regulating the adult neurogenesis in the SVZ. The finding of extraordinarily high levels of Cu in the SVZ will be first introduced. To investigate the role of Cu in adult neurogenesis, we have used the intra-cerebral-ventricular (ICV) infusion technique to deliver Cu ions directly into rat brain lateral ventricle. The proliferating cells in the SVZ were then counted and analyzed. Our data indicate that Cu surges after星光出现了 about a 43% increase in proliferating cells in the SVZ. However, infusing Cu to the ventricles significantly suppressed the activated cell proliferation to the level of non-surgical controls, suggesting that a high level of Cu in the CSF may inhibit the proliferation of NSPCs in the SVZ. Our new evidence from in vivo and in vitro further revealed a significant reduction or increased proliferation of NSPCs in the SVZ in the Cu-overloaded or in Cu-deficient animal models, respectively. In summary, these data indicate that the homeostasis of Cu in blood and/or CSF regulates the adult neurogenesis in the SVZ. I will discuss the implication of our recently identified mechanisms by which Cu regulates the adult neurogenesis in Parkinson’s disease and its possible environmental etiopathogenesis.

1037 Understanding the Molecular Mechanisms of Zika Virus Reproductive and Developmental Toxicity

P. Del Valle. US FDA, Silver Spring, MD.

Zika virus (ZIKV) is related to the Yellow fever, West Nile, Japanese encephalitis, and Dengue fever viruses, all classified under the genus Flavivirus that belongs to the family Flaviviridae. Symptoms of infection may include a rash, itching, fever, muscle pain, conjunctivitis, nausea, vomiting, and headaches. ZIKV was isolated from a rhesus macaque in the Marzamemi area in Italy in 1967, from mosquitoes in Uganda in 1974, from pregnant women from Asian countries in the 1960s, and reached the Americas in 2015. Outbreaks have been reported in Micronesia (2007), French Polynesia (2014), and Brazil (2015). By January 2016, autochthonous cases of ZIKV were reported in more than 50 countries in South, Central, and North America, and the Caribbean, with most ZIKV-related outbreaks in the mosquito-borne disease in the United States. ZIKV in pregnant women is reported to cause a wide spectrum of fetal malformations, collectively called congenital Zika syndrome (CZS), that include microcephaly, absent or poorly developed brain structures, retinal damage, hearing deficits, and impaired growth. This session will explore recent findings that have begun to link ZIKV infection with male testicular damage and potential human male infertility and with congenital malformations, microcephaly, and other brain malformations and birth defects. The session will also include an integral discussion of preclinical trials and the role of vector control approaches to reduce/prevent ZIKV infection. The introduction will include a brief overview of the ZIKV infection during outbreaks, with emphasis on the current status of the outbreak in the Americas. ZIKV is primarily spread by the daytime-active female Aedes aegypti mosquito, and several mechanisms of ZIKV replication and tissue tropism have been investigated. Evidence that ZIKV requires the ubiquitin-proteasome system for replication and the hijacking of the host ubiquitin system will be discussed. Understanding the molecular mechanisms of replication is critical to identifying existing or developing new drugs that can prevent or stop viral infection. ZIKV can inhibit the proliferation of NSPCs in the SVZ will be first introduced. To investigate the role of Cu in adult neurogenesis in the SVZ. The finding of extraordinarily high levels of Cu in the SVZ will be first introduced. To investigate the role of Cu in adult neurogenesis, we have used the intra-cerebral-ventricular (ICV) infusion technique to deliver Cu ions directly into rat brain lateral ventricle. The proliferating cells in the SVZ were then counted and analyzed. Our data indicate that Cu surges after星光出现了 about a 43% increase in proliferating cells in the SVZ. However, infusing Cu to the ventricles significantly suppressed the activated cell proliferation to the level of non-surgical controls, suggesting that a high level of Cu in the CSF may inhibit the proliferation of NSPCs in the SVZ. Our new evidence from in vivo and in vitro further revealed a significant reduction or increased proliferation of NSPCs in the SVZ in the Cu-overloaded or in Cu-deficient animal models, respectively. In summary, these data indicate that the homeostasis of Cu in blood and/or CSF regulates the adult neurogenesis in the SVZ. I will discuss the implication of our recently identified mechanisms by which Cu regulates the adult neurogenesis in Parkinson’s disease and its possible environmental etiopathogenesis.

1038 Introduction: A Brief Overview of Zika Virus Infection and Current Magnitude of Infection

P. L. Del Valle. US FDA, Silver Spring, MD.

The ZIKV has been isolated from countries located mainly within the equatorial regions. Imported cases through travelers into other countries in the world occurred occasionally. However, for more than 50 years, ZIKV was only associated with mild cases of infection, and the outbreaks in the French Polynesia, where more than 30,000 cases (11.5% of the population) of ZIKV fever occurred. Severe neurological complications were reported, including association of ZIKV infection with Guillain-Barre syndrome (GBS). It is estimated that 2-5 patients for every 100,000 infected with ZIKV will go on to develop GBS. The outbreak in Brazil attracted the most attention because this country hosted the 2016 Olympic Games. It is estimated that 440,000-1,300,000 suspicion cases of ZIKV disease occurred in Brazil in 2015. Microcephaly was suspected in 5,909 cases reported during the outbreak; however, microcephaly was confirmed in only 641 cases, and it was discarded in 4,222 cases. More than 2,000 cases of pregnant women with any lab evidence of ZIKV infection in the US was 1,793, and in the US territories up to 3,700. The Vital Signs report from the CDC also reported that of the 250 pregnant women who had confirmed Zika infection in 2016, 24, or about 1 in 10 of them, had a fetus or baby with birth defects. These figures and reports illustrate the magnitude of the ZIKV effects on health in the Americas and around the world. Infants born to women with laboratory evidence of ZIKV infection during pregnancy are now subject to a postnatal neuromaging, testing for ZIKV, and a comprehensive newborn physical examination, because the fetus or baby with birth defects of congenital Zika virus infection is not yet known. This presentation will provide updated figures and statistics on ZIKV infection, GBS, and developmental and reproductive adverse outcomes reported for newborn infants to women with ZIKV infection during pregnancy.

1039 The Role of the Host Ubiquitin System in Zika Virus Replication and Tissue Tropism

R. Rajsbaum. University of Texas Medical Branch, Galveston, TX. Sponsor: P. Del Valle

ZIKV is a mosquito-borne, positive-sense single-stranded RNA virus from the genus Flavivirus (family Flaviviridae). ZIKV is closely related to other flaviviruses that cause important human disease, including Dengue virus (DENV), West Nile virus (WNV), and Yellow fever virus (YFV). In contrast to other flaviviruses, there is evidence that ZIKV replicates more efficiently in reproductive tissues, can be sexually transmitted, and is associated with congenital neurologic disorders, indicating that the mechanisms of ZIKV tropism and transmission may be unique. The molecular mechanisms underlying these differences are currently not known. Previous studies suggest that replication of DENV, a close relative of ZIKV, requires the ubiquitin-proteasome system for replication. Similarly, we found that pre-treatment of a placenta-derived cell line (JEG-3) with the proteasome inhibitor MG132 also reduced ZIKV replication, suggesting that the ubiquitin-proteasome system may be important for ZIKV replication and tissue tropism. The host ubiquitin system is a conserved cellular pathway important in many functions, including innate immune signaling and virus replication. By using mass spectrometry analysis of ZIKV infected cells, we identified specific sites of ubiquitination on critical viral proteins. We generated recombinant infectious ZIKV mutants lacking ubiquitination sites and observed reduced virus replication in placenta-derived cell lines, consistent with a role for the ubiquitin system in promoting ZIKV replication and cell tropism. Here, we will provide an overview of ZIKV infections, geographical distribution, and viral pathogenesis, and will discuss potential mechanisms of virus replication and tissue tropism via hijacking of the host ubiquitin system. We will also discuss potential use of US FDA-approved drugs against ZIKV infections and the possibility of targeting the host ubiquitin system to prevent ZIKV replication.
system as a potential therapeutic approach to control ZIKV infections. The identification of host cellular factors required for Zika virus replication may provide novel antiviral targets for future drug development, with a minimal inherent risk of viral escape mutants, and similar antiviral approaches could be used against other flaviviruses.

1040 Zika Congenital Syndrome in Murine Experimental Model
J. P. S. Peron. University of São Paulo, São Paulo, Brazil. Sponsor: P. Del Valle

Brazil has recently gone through an unprecedented public health crisis due to the Zika virus epidemics. As many other flaviviruses, it has never been correlated with human morbidity or mortality. Unfortunately, it has changed dramatically, as the virus is responsible for more than 2,300 babies born with microcephaly. The so-called Zika Congenital Syndrome has, besides microcephaly, many other relevant features, such as retinal damage, intra-uterine growth restriction, and arthropathy. In fact, babies born without microcephaly, but with significant neurologic and retinal lesions, have also been reported. In this context, the development of an experimental model is of great relevance for the studies on the pathogenesis of microcephaly. We demonstrated that the infection of pregnant SJL mice with ZIKV results in severe damage of the pups. Most prominently was the significant reduction in size and weight associated with high viral titers in the brains. This was accompanied by high level of apoptotic cell death, probably of neuronal precursor cells (NPCs). In order to confirm that hypothesis, we infected NPCs and human brain organoids with ZIKV, and observed a significant reduction in the number of NPCs, corroborating the apoptotic cell death hypothesis. Currently we are focused on several aspects of the brain inflammation during microcephaly. Interestingly, many pro-inflammatory cytokines are down-regulated, as well as viral receptors and signaling transduction molecules. This is consistent with clinical findings, showing no sign of inflammation, at least through cerebrospinal fluid protein and cell counts. Our data may indicate that the virus controls inflammation in situ. The elucidation of such a mechanism would greatly contribute to the understanding of the viral biology in the central nervous system and also of the pathogenesis of microcephaly.

1041 Mouse Model of Zika Virus Infection in Testis and Its Potential Relevance to Mechanism of Infection in Human Testis and Male Infertility
P. Esaky. Washington University School of Medicine in St. Louis, St. Louis, MO.

ZIKV in pregnant women causes a wide spectrum of fetal malformations, collectively called CZS, that includes microcephaly, intra-uterine growth restriction and intrauterine death syndrome. Several animal models have been developed to study ZIKV pathogenesis in parents and offspring. We developed a male mouse model of ZIKV infection using a mouse-adapted African strain (Dakar 41519). Results indicate that ZIKV-mediated damage in male reproductive system occurs primarily by destroying testicular germ cells, and noticed that the ZIKV-mediated tissue damage the male reproductive tract, reduced testosterone and inhibit B levels, sperm count, and fertility. In addition to infiltrating inflammatory cells, ZIKV preferentially infected spermatogonia, spermatocytes, and Sertoli cells in the testis, resulting in cell death and destruction of the seminiferous tubules, the basement membrane, and blood testis barrier. Although further studies are needed to monitor ZIKV infection in affected human males, the establishment of a model to evaluate male reproductive tract damage by ZIKV will allow rapid testing of new classes of therapeutic agents to mitigate or prevent disease. As our data has demonstrated an unanticipated clinical manifestation of ZIKV infection, the ZIKV mouse models strongly support the notion that humans are more susceptible than mice. Being the only sexually transmitted arbovirus in humans, ZIKV is well adapted to generate higher levels of viremia, haematospermia, dysuria, and perineal pain. Recent studies have demonstrated the presence of ZIKV on human sperm head that last for more than 30 days in semen, blood, and urine, similar to Ebola virus. Thus, ZIKV persistence in semen relating to viral tropism in male germ cells is a major threat to male fertility. So far, the available experimental, clinical, and epidemiological data lead us to conclude that the effect on fertility caused by non-obstructive azoospermia as demonstrated in animal models could be less of a problem in humans, whereas fertility in men might be at risk mainly owing to transmission of the disease by ZIKV-infected spermatooza during natural conception or assisted reproductive technologies. Our current and future studies are directed toward understanding the translational aspects of ZIKV infection in human subjects with respect to male reproductive health.

1042 Protective Efficacy of Multiple Vaccine Platforms against Zika Virus Challenge in Rhesus Monkeys
R. A. Larocca. Harvard Medical School, Boston, MA. Sponsor: P. Del Valle

ZIKV is responsible for a major ongoing epidemic in the Americas and has been causally associated with microcephaly. The development of a safe and effective ZIKV vaccine is therefore an urgent global health priority. Here we demonstrate that three different vaccine platforms protect against ZIKV challenge in rhesus monkeys. A purified inactivated virus vaccine induced ZIKV-specific neutralizing antibodies and completely protected monkeys against ZIKV strains from both Brazil and Puerto Rico. Purified immunoglobulin from vaccinated monkeys also conferred passive protection in adoptive transfer studies. A plasmid DNA vaccine and a single-shot recombinant rhesus adenovirus serotype 52 vector vaccine, both expressing ZIKV premembrane and envelope, also elicited neutralizing antibodies and completely protected monkeys against ZIKV challenge. These data support the rapid clinical development of ZIKV vaccines for humans.

1043 Integrated Pest Management: A Multifaceted Approach to Vector Control
E. Mendez. US EPA, Washington, DC.

As the Zika virus crisis unfolded, the federal government was faced with the need to swiftly develop a strategy to control the spread of infection. With the Centers for Disease Control and Prevention (CDC) as the lead agency, the coordinated federal response included the Department of Housing and Urban Development (HUD), the Department of Homeland Security (DHS), National Institutes of Health (NIH), the Department of Health and Human Services (HHS), Federal Emergency Management Agency (FEMA), and the US Environmental Protection Agency (US EPA), among others. As the primary mode of Zika virus transmission, mosquito control became a critical aspect of the response to this health crisis. Under the Federal Insecticide Fungicide and Rodenticide Act (FIFRA), the US EPA is charged with regulating the marketing of pesticides in the US; the US EPA conducts a comprehensive evaluation that considers the toxicological profile as well as potential exposure patterns to the chemical in order to assess the potential impact it may have on human health, non-target species, and the environment prior to marketing. The US EPA’s role in responding to this public health crisis, however, goes beyond the regulation of pesticides to incorporate Integrated Pest Management (IPM) strategies. IPM is a comprehensive, sustained effort encompassing a wide-range of mosquito control methods, such as personal protective (e.g., insect repellent), physical control (e.g., breeding environment reduction), larval control (e.g., copepods/fish), biological adulticides (e.g., Wolbachia), and chemical adulticides (e.g., insecticides) measures. This presentation will discuss the risk assessment process undergone by mosquito control methods currently available, as well as new tools under development and their role within an IPM strategy.

1044 Assessing the Dose of Particles in Toxicological Studies: Advances in Dosimetry Models for In Vitro and In Vivo Applications in Light of Risk Assessment
F. Cassee. Rijksinstituut voor Volksgezondheid en Milieu (RIVM) and University of Utrecht, Bithoven, Netherlands.

Emerging hybrid, experimental/computational approaches to cellular dosimetry can be used by particle toxicologists to accurately calculate the delivered dose to cells for various particles and under different in vitro experimental conditions as a function of exposure time. Likewise, in vivo lung dosimetry models allow researchers to estimate the delivered particle dose in any region of the respiratory system, as well as study the implications of particle properties and breathing parameters for diverse animal species. Moreover, knowing the deposited dose also will facilitate the extrapolation from experimental animals (rat, mouse, rabbit, pig, and monkey) to humans of all ages. Most importantly, incorporating such dosimetric methodologies in the study design enables particle toxicologists to bring in vitro and in vivo doses to the same scale, an important step towards the development and validation of in vitro cellular screening assays.
The number of (complex) nanomaterial and other types of particles that are being developed and put on the market is creating a problem for risk assessors as all of these have to be tested for their safety aspects. Standard procedures require mainly in vitro testing, whereas the bulk of the toxicological tests are nowadays performed in vivo. This is partly a result of the societal need to reduce the use of experimental animals. However, it is far from obvious for risk assessors to rely on in vitro data. For particles there is also the issue of the difference between an exposure concentration and the dose that is delivered to the cell in the in vitro model, irrespective of submerged or air-liquid interface systems. The purpose of the session is to bring together risk assessors, modelers, and toxicologists to exchange the needs and possibilities and to funnel down towards an agenda for an efficient development of both in vivo and in vitro that meets the needs of risk assessors and allow for a more accurate read-across and extrapolation of information from experimental studies in human risk assessment. This presentation will focus on the needs from and the data requirements of risk assessors.

A major obstacle in the development of accurate cellular models for investigating nanomaterial interactions in vitro is determination of physiologically relevant measures of dose. Comparison of biological responses to nanoparticle exposure typically relies on administered dose metrics such as mass concentration of suspended particles, rather than the effective dose of particles that actually comes in contact with the cells over the time of exposure. Adoption of recently developed dosimetric methodologies will facilitate determination of effective dose delivered to cells in vitro, thereby improving the accuracy and reliability of in vitro screening data, validation of in vitro with in vivo data, and comparison across multiple datasets for the large variety of nanomaterials currently in the market.

Evidence continues to grow of the importance of in vitro and in vivo dosimetry in the hazard assessment and ranking of engineered nanomaterials (ENMs). Accurate dose metrics are particularly important for in vitro cellular screening to assess the potential health risks or bioactivity of ENMs. To ensure meaningful and reproducible quantification of in vitro dose, with consistent measurement and reporting between laboratories, it is necessary to adopt standardized and integrated methodologies across the ENM dispersion preparation-colloidal characterization-cellular dosimetry. Such integrated methodologies need to include three interconnected steps: (i) Generation of stable ENM suspensions in cell culture media; (ii) colloidal characterization of suspended ENMs, particularly of properties that determine particle kinetics in an in vitro system (size distribution and formed agglomerate effective density); and (iii) robust numerical fate and transport modeling for accurate determination of the ENM dose delivered to cells over the course of the in vitro exposure. Here we will present an integrated comprehensive protocol based on such an integrated methodology for in vitro dosimetry, including detailed standardized procedures for each of these three critical steps/aims.

Respiratory tract deposition and retention kinetics of inhaled particles are determined by their behavior due to physics and chemistry in air, in physiological fluids, and by physiological clearance mechanisms. Dosimetric modeling of deposition requires input of several aerosol characteristics, including density, and modeling retention involves knowledge about particle bio-dissolution. Particle dissolution rates determined in non-cellular in vitro assays using surrogate lung fluids may be applied to estimate overall pulmonary clearance rates. While the importance of dosimetry has long been recognized for inhalation studies, it is essential to be considered and applied as well for cell culture studies. For both in vivo (inhaled) and in vitro (cell cultures) studies, knowledge about Exposure-Dose-Response relationships is key for comparing in vitro and in vivo results on an equal dosimetric basis, and at the same time it provides an opportunity to validate in vitro assays. Ultimately, a careful attention to dosimetric details allows a scientifically justified risk extrapolation of toxicological results from animal studies to humans.

Public exposure generally includes both particles and gases of the same or different species. There is a synergy among various components in the inhaled air. There may be rapid ongoing thermodynamic processes (such as in the case of cigarette smoking), which affect the characteristics of inhaled particles and vapor and thus their fate in the respiratory tract. Mixture characterization is a necessary first step in realistic assessment of the delivered dose to the respiratory tract. A physics-based, mathematical model was developed to study the fate of inhaled mixture of droplets and vapors in the respiratory tract of humans. Droplets contain constituents of different vapor pressures. The dosimetry model accounted for the coagulation of airborne materials at high concentrations and droplet-vapor conversion of different constituents in the inhaled air while traveling through the head and lung airways. Predicted deposition of the droplets and uptake of gases were calculated on a constituent basis to accommodate component-specific risk analysis. The contributions of the droplet and vapor phases to the tissue dose depended on the physicochemical properties of the components in the mixture and lung and therefore the dose of high saturation vapor pressure were absorbed by the tissue via the vapor phase. The dose to the tissue for the low and medium vapor pressure compounds were from droplet deposition. Overall, droplets had a more significant contribution than vapors did. Model development and application for specific scenarios will be presented and discussed.
Drug-induced liver injury is a major reason of failure during premarketing and postmarketing phases of drug development. Drug responsible for more than 50% of all cases of acute liver failure worldwide, drug-induced liver injury is equally of high clinical concern. As such, up to 40% of drug-induced liver injury patients present a cholestatic liver insult pattern. Cholestasis is derived from the Greek words chole and stasis meaning bile and halting, respectively, and denotes any situation of impaired bile secretion with concomitant accumulation of noxious bile acids in the liver or systemic circulation. Drug-induced cholestasis typically, though not uniquely, starts by inhibition of one or more drug transporters directly leading to bile acid retention in the liver. This triggers a deteriorative response associated with oxidative stress, inflammation, and cell death. In parallel, an adaptive response is initiated, which is aimed at restricting bile acid synthesis and influx, while promoting bile acid efflux. In fact, these mechanisms have been embedded recently in an adverse outcome pathway construct in order to further facilitate predictive toxicology. Several additional key events in drug-induced cholestatic liver injury have been identified, including endoplasmic reticulum stress and mitochondrial impairment. Simultaneously, a number of human-based in silico (e.g. DILisym), ex vivo (e.g. precision-cut liver slices), and in vitro (e.g. sandwich cultures of human hepatocytes and two-compartment systems) models have been introduced to mechanistically study drug-induced cholestatic injury. Such alternative animal-free models are cordially welcomed, not only because of ethical reasons, but also given the fact that preclinical animal models are not adequate predictors of human drug-induced liver injuries due to interspecies differences in bile acid profiles, transport, and regulation. These non-animal methods, especially when combined, are able to accurately and quantitatively predict drug-induced cholestatic liver injury, thus emphasizing their overall clinical relevance.

Cholestasis accounts for a majority of cases of drug-induced liver injury. An adverse outcome pathway (AOP) construct has been previously introduced to pinpoint the mechanisms involved in the development of this life-threatening condition. The molecular initiating event in this AOP is the inhibition of the bile salt export pump (BSEP), while the key events that are subsequently triggered include bile acid accumulation, induction of oxidative stress and inflammation, cell death and the activation of the farnesoid X receptor (FXR), the pregnane X receptor (PXR), and the constitutive androstane receptor (CAR). The present study was set up to evaluate the reliability and predictive capacity of this AOP for cholestatic liver injury and to identify new biomarkers reflecting the key events. For this purpose, human hepatoma-derived HepaRG cells were exposed for 1 hour, 24 hours, or 24 hours with 72 hours of wash-out to subcytotoxic concentrations (250 µM, 62.5 µM and 25 µM) of bosentan, a potent BSEP inhibitor known to clinically induce cholestasis. Induction of the molecular initiating event (i.e. inhibition of BSEP) was confirmed using a fluorescent probe. The cellular response to the inhibited toxicity was evaluated by means of transcriptionomics (microarray), proteomics (LC-MS/MS), and metabolomics (NMR) techniques. Most transcriptional changes were induced following exposure of the HepaRG cells to 250 µM bosentan for 24 hours. Pathway analysis identified cholestasis as a major toxicological event. The transcriptionomics results further showed several of the predicted gene changes related to the activation of the nuclear receptors FXR, PXR, and CAR. Induction of oxidative stress was also observed as evidenced by induced expression of anti-oxidant genes. Furthermore, 37 genes could be identified by microarray analysis of samples of cells exposed to all tested concentrations of bosentan. Of those, 10 were also significantly modified at the protein level. Metabolomics analysis indicated changes in the abundance of specific endogenous metabolites related to mitochondrial impairment, including (aceto)acetate, (iso)leucine, lactate, carnitine and 3-methyl-2-oxovalerate. Overall, the outcome of this study underscores the soundness of the established AOP of drug-induced cholestatic injury and demonstrates the power of the experimental in vitro testing for optimizing AOPs.

A major challenge in preclinical safety assessment is accurately prepredictive toxicology for cholestatic injury in humans. One mechanism of drug-induced liver injury (DILI) involves disruption of bile acid homeostasis due to impaired bile acid transport leading to accumulation of toxic bile acids. Preclinical species do not predict bile acid-mediated DILI in humans. Intracellular concentrations of bile acids, drugs and derived metabolites can be quantified in sandwich-cultured human hepatocytes (SCHH). Mechanistic modeling based on data generated in SCHH can be used to assess the impact of transporter-mediated drug interactions on hepatobiliary bile acid exposure. Simulations revealed that in SCHH, a 10-fold decrease in clearance from hepatocytes to bile (CLBile) decreased steady-state concentrations (Chss) of the model bile acid taurocholate (TCA) by about 3-fold, whereas only a 1.3-fold increase in TCA Chss occurred relative to control when basolateral efflux clearance (CLBL) was decreased by 10-fold. Simulations also demonstrated that inhibition of bile acid uptake transporters can attenuate bile acid accumulation, thereby protecting from bile-aid mediated DILI. In separate SCHH studies, induction of CLBL and CLBile (6- and 2-fold, respectively), coupled with a ~2-fold decrease in TCA uptake clearance, reduced cellular TCA to 29 ± 4.8% of control values, demonstrating that bile acid concentrations in hepatocytes are tightly regulated by hepatic transport proteins. A systems pharmacology model (DILisym®) that incorporates drug and metabolite disposition, species-specific bile acid physiology, cellular ATP concentrations, and biomarkers of liver injury can accurately predict the hepatotoxic potential of drugs. When population variability in bile acid and drug/metabolite disposition was incorporated, simulations revealed that this mechanistic model correctly predicted toxicity in human species as well as the incidence and timeframe of DILI reported in humans. Systems pharmacology models for troglitazone and tolbutamidine that integrate physiological information and experimental data demonstrate the clinical utility of this approach to accurately predict the liability for hepatocellular accumulation of bile acids and DILI in humans.

The underlying mechanisms for drug-induced cholestasis (DIC) are not fully understood, and predictive biomarkers are lacking. Therefore, in vitro models that predict the cholestatic potential of drug candidates and that provide insight into the mechanism of DIC are highly needed. The aim of the study was to verify rat and human precision-cut liver slices (PCLS) as an ex vivo model for DIC. PCLS were incubated with cholestasis-inducing drugs, chlorpromazine (18.36 µM), cyclosporine A (1.5 µM) and glibenclamide (120-180 µM) in the presence of a physiological mix at portal vein concentrations of bile acids (BA). Biomarkers as viability, intracellular accumulation of total as well as individual BA and changes in the expression of genes involved in cholestasis reflected various modifications associated with cholestasis, including a decrease in hepatocyte viability up to 50%, accumulation of total BA (up to 2.7-fold), changes in the composition of BA (increase in relative abundance of chenodeoxycholic acid (4-fold to 9-fold), taurochenodeoxycholic acid and glycocoxycholic acid (4-fold)) and changes in the gene expression of the farnesoid X receptor (FXR) (2-fold to 5-fold decrease), bile salt export pump (2-fold decrease) and sodium-taurocholate cotransporting polypeptide (more than 10-fold decrease). Transcriptionomics-based pathway analysis on human PCLS revealed that hepatic cholestasis was among the top 10 regulated pathways and signaling pathways, such as FXR-mediated and liver X receptor-mediated pathways, were significantly affected by all cholestatic drugs. Other significantly affected pathways included unfolded protein response and protein ubiquitination, implicating the role of endoplasmic reticulum stress. Mechanism-based biokinetic modeling of the cholestatic effect using in vitro human data correctly predicted the cholestatic concentration of glibenclamide (120-180 µM) and clinafung (18.36 µM). In conclusion, this study shows that the ex vivo human PCLS model incuated in the presence of a physiological BA mixture correctly reflects DIC in the human liver. These results indicate that PCLS may represent a viable and valuable model to identify cholestatic drugs and to provide insight into the mechanisms underlying potential susceptibility this human PCLS model can be used to identify cholestatic adverse drug reactions of new chemical entities in man early in the development.
**Prediction of Cholestatic Hepatotoxicity: Integration of Transporter Regulation and Adaptive Response**

K. R. Brouwer, Qualyst Transporter Solutions LLC, Durham, NC.

Cholestatic drug-induced liver injury (DILI) in humans has been associated with bile acid pump (BSEP) inhibition. However, in vitro BSEP IC50 concentrations do not correlate with in vivo cholestatic DILI severity. When treated with BSEP inhibitors, sandwich-cultured human hepatocytes respond to the resulting increased intracellular concentrations of bile acids by activation of the farnesoid X receptor (FXR). This results in decreased bile acid synthesis and increased bile acid basolateral efflux, which prevents cholestatic hepatotoxicity. Exposure to tigogenin, a cholestane triterpene, was time-dependent. Parent, as well as metabolites formed, provided hepatocytes. Movement of the test compounds from intestine to liver across a semipermeable membrane. In this way, oral exposure to the test system. Small molecules move into the vasculature model by diffusion intestine compartment. Cyclosporine A (50 µM) and troglitazone (100 µM) were correctly predicted. Unlike using BSEP inhibition data alone, the lower potential for cholestatic hepatotoxicity of pioglitazone, erythromycin estolate, and telmisartan (BSEP IC50 0.3 µM, 13 µM, and 16.2 µM, respectively) was also correctly predicted. Compounds with a high incidence of cholestatic hepatotoxicity, identifying flavonoids, being high BSEP IC50 (100 µM), were also correctly predicted. Additional experiments confirmed the concentration dependency of compounds that demonstrated cholestatic hepatotoxicity. A whole cell assay integrating BSEP inhibition, decreased basolateral efflux by direct inhibition (i.e. acute effect) and/or FXR antagonism (i.e. chronic effect) will more accurately predict cholestatic DILI.

**An Integrated In Vitro Organ Platform to Evaluate Cholestasis**

J. M. McKim, Western Michigan University School of Medicine and IONTOX, Kalamazoo, MI.

The use of adverse outcome pathways (AOPs) to connect key biological events in a causal manner provides a mechanism-based approach for evaluating the effects of chemical and pharmaceutical molecules. When an AOP is evaluated in an integrated multiple organ system, it is possible to develop pharmacokinetic/pharmacodynamic data sets that are more relevant to in vivo risk assessment models. The ability to accurately evaluate new compounds for potential cholestatic liver toxicity would be of value to both the chemical as well as the pharmaceutical industries. In this study, a 2-compartment in vitro system was established using a human intestinal tissue (EpiIntestinal) and Transporter Certified human hepatocytes in a sandwich configuration. These tissue compartments were integrated with a simulated circulatory system. This multiple organ model is unique in that each tissue compartment is completely isolated with respect to growth media. Communication and movement of the test compounds occurs via the simulated blood system. Small molecules move into the vasculature model by diffusion across a semipermeable membrane. In this way, oral exposure to the test compounds can be modelled after application to the apical side of the intestine compartment. Cyclosporine A (50 µM) and tigogenin (100 µM) were applied to the apical side of the intestinal chamber. Samples were collected at 0.5, 1, 2, 4, and 8 hours from the basolateral intestine, simulated blood, and liver compartments and analyzed by LC-MS/MS. Cell viability was assessed by measuring enzyme leakage (lactate dehydrogenase). Activation of the farnesoid X receptor, an indication of bile acid accumulation, was determined by fibroblast growth factor 19 (FGF19) expression, FGF19 mRNA increased 4-fold with the bile salt export pump inhibitor cyclosporine A as bile acids accumulated in the hepatocytes. Movement of the test compounds from intestine to liver was time-dependent. Parent, as well as metabolites formed, provided an indication of first-pass metabolism. By integrating key organs, it is possible to obtain greater insight into chemical activation of AOPs. In conclusion, the mesoscale multiple organ system used here provided a novel means of integrating organs to assess components of the AOP for cholestasis.

**Advancing Exposure’s Profile in Providing the Context for Toxicity Testing and Risk Assessment**

J. Orme-Zavaleta, US EPA, Research Triangle Park, NC.

Exposure is an evolving science that describes the real world and provides the context to translate toxicology into risks; develop the most effective ways to protect health; and address sustainability by describing relationships and interactions among the environment, the stressors it contains, human and ecological receptors, and ultimate biologically-relevant doses. The US National Academy of Sciences, in recent reports on 21st century exposure science and risk evaluation, has extended our perspective of exposure to the internal environment via linking internal marker measurements of exposure such as blood and urine directly to traditional external measures of exposure, which can then be linked to a dose for toxicological sites of action or for clinical analyses. A comprehensive understanding of the impact of exposures is needed to provide information on the most effective ways to reduce negative exposures and decrease risk. The pace of conducting risk assessments is limited by the pace at which both credible and reliable information can be generated on anticipated biological effects, and on expected exposure concentrations. The exposure data landscape (e.g. chemical use data, monitoring data, pharmacokinetic data) for commercial (non-pesticide) chemicals is extremely limited. However, for the last several years under the ExpoCast program for example, US EPA has been generating databases and predictive tools to improve our ability to characterize exposure. Further, non-targeted chemical analyses, new biomonitoring technologies, and advanced modeling and exposure analytics are all new sources of information that can provide new information. The goal is to understand real world risks to humans and ecosystems rather than evaluating a single stressor at a time. Integrating this information into the concepts of the exposome advances our understanding of cumulative risks in the real world and ways to prevent these risks.

**Exposome in Practice: Methods and Results from Exposomics Project**

M. Chadeau, Imperial College London, London, United Kingdom. Sponsor: C. Terry

There are two broad interpretations of the exposome concept and they are complementary. One, called “top-down”, is mainly interested in identifying new causes of disease by an agnostic approach based on omic technologies, similar to what has been applied in genetics with the GWAS design. This first approach is sometimes called “EWAS”, or “exposome-wide association study” (Rappaport, 2016), and utilizes tools such as metabolomics or adductomics to generate new hypotheses on disease etiology. The second general approach is called “bottom-up” and starts with a set of exposures or environmental compartments to identify new causes of disease by an agnostic approach based on omic technologies, similar to what has been applied in genetics with the GWAS design. This first approach is sometimes called “EWAS”, or “exposome-wide association study” (Rappaport, 2016).
determine the pathways or networks by which such exposures lead to disease, i.e. which pathways/networks are perturbed. We have used the latter approach in the EXPOsOMICS investigation (Vinels et al., 2016). In the EXPOsOMICS project we have selected a few priorities for research, with relevant practical implications for policy making and stakeholders: Can we consolidate our knowledge on the health effects of two important environmental factors, air pollution and water contaminants, reinforcing causal assessment? Can we detect variation in exposures in a finer way than with the usual tools of epidemiology? Can we detect the effects of low and very low levels of exposure using ‘omic biomarkers? How can we exploit ‘omic measurements to study mixtures? Can we use improved exposure assessment to calibrate estimates of risk and burden of disease? Finally, methodological aims include to validate a set of five ‘omics measured in the same subjects (for a total number of more than 2,000), and the development of statistical tools to allow the analysis of very complex datasets.
also significantly increased in liver. In addition, PFOA and HFO produced additive effects on hepatomegaly and hepatocytes cell proliferation. After 2 weeks, BrdU labeling in the PFOA + HFO group was 4- and 2-fold higher compared to HFO and PFOA treatment alone. Concordantly, Ccnd1 and cyclc gene expression showed HFO stimulated PFOA- induced cell growth. These results suggest a dual effect of PFOA on NFκB: a decrease in the expression and inhibition of cell proliferation, PPARα activation, and inflammation. Although the exact mechanism underlying this dual effect requires additional study, the decrease may be correlated with the modulation of fatty acid metabolism pathways. For example, hepatic mRNA of Cpt-1a and Apob were increased by PFOA, which may account for an increased lipogenesis and triglyceride accumulation.

100) between uteri from DES-470 differentially expressed genes (P<0.05, 1.5-fold, Intensity Cutoff ≤ EPA, Research Triangle Park, NC; and Podtelezhnikov, K. Tanis, W. E. Glaab, and F. D. Sistare. Co., West Point, PA.

Furthermore, several basal cell-related genes, including that DES-induced SIX1 expression contributes to altered gene expres-

sion. SIX1 levels were downregulated in DES-

and (i.e., apoptosis) implicating a different cellular process. The extent of the fatty liver (duration of HFD treatment) as well as the dose of the PFOA may be important in understanding these results. Finally, it appears the presence of NFκB may impact the poten-
tial risk for hepatic cancer from chemical exposure.

1066 The SIX1 Oncoprotein Mediates Aberrant Uterine Basal Cell Development following Neonatal Exposure to Diethylstilbestrol

A. A. Suen1, W. N. Jefferson2, C. J. Williams3, and C. E. Wood4. US EPA, Research Triangle Park, NC; and 2NIEHS, Research Triangle Park, NC.

Aberrant cellular differentiation early in life can contribute to increased cancer risk later in life. In a classic model of this effect, female mice exposed on postnatal day (PND) 1-5 to the synthetic estrogen diethylstilbestrol (DES) have a high incidence of uterine carcinoma. These cancers are associated with an abnormal population of uterine basal cells that represent the earliest and most prominent precursor lesion. Six1+/− mice (SIX1) is an oncoprotein that is persistently upregulated in the uteri of mice following neonatal DES exposure and localizes to uterine basal cells within all neoplastic lesions. We hypothe-
size that SIX1 is necessary for uterine basal cell differentiation and car-
cinogenesis following neonatal DES exposure. To test this hypothesis, we generated a conditional knockout mouse model was generated in which floxed SIX1 and Cyp1a1 and Cyp1a2, a conditional knockout mouse model was generated in which floxed SIX1 and Cyp1a1 and Cyp1a2 were present throughout the uterine body and horns of DES−/+ mice and 9/12 (75%) DES-exposed SIX1 knock- out (DES−/−) mice but not in controls, indicating that SIX1 is not required for DES-induced uterine carcinogenesis. However, DES−/− mice exhibited distinctive differences in cellular differentiation. Abnormal basal cells expressing Keratin 14 (K14) were present throughout the uterine body and horns of DES−/+ mice but were absent in the uterine horns of the DES−/− mice. Quantitative image analysis indicated a >10-fold decrease in K14 labeling in the uterine horns of DES−/− mice compared to DES−/+ mice, but was similar to controls. Microarray analysis revealed 470 differentially expressed genes (P<0.05, 1.5-fold. Intensity Cutoff ≤ 100) between uteri from DES−/+ and DES−/− mice, suggesting that DES-induced SIX1 expression contributes to altered gene expres-
sion. Furthermore, several basal cell-related genes, including P63, Krt15, Krt14, and Krt13, were downregulated in DES−/+ mice, consistent with morphologic changes. These data indicate that SIX1 acts as a key cellular differentiation factor following early-life estrusogen expression. This abstract does not reflect US EPA policy.

1065 Assessing Ahr Activation Early in Pharmaceutical Development: Applying Gene Expression Signature Thresholds to Predict Tumorigenic Doses in Rats

Ahr activation is associated with carcinogenicity of dioxin (i.e., TCDD) and dioxin-like chemicals, such as polychlorinated biphenyls (PCBs) that are considered non-carcinogens. Cyp1a1 and Cyp1a2 transcripts are commonly monitored for Ahr activity. However, these Cyp can also be induced by many drugs that do not bind Ahr or bind but induce Cyp with low potency and transiently. For example, Hu et al. (Mol. Pharmacol. 2007) noted that 40% of 596 marketed pharmaceuticals can induce Cyp1a1 and/or Cyp1a2 but do not exhibit the dioxin-like effects in rodents or humans following chronic exposures. We hypothesized that with a proper threshold, the liver “Ahr activation” gene expression signature (i.e., Cyp1a1 and 1a2) in a short-term rat study could be used to differentiat-
doxin-like carcinogens from non-dioxin-like Ahr-activating non-carcinogens. We conducted an 8-day rat study with a 4-day peel-off

with 2 typical AhR-activating carcinogens (TCDD and PCB126) at car-
cinogenic vs. non-carcinogenic doses and 3 AhR-activating non-car-
cinogens (omeprazole, mexiletine, and canagliflozin) at related top doses used in 2-year bioassays vs. short-term tolerability study doses. Also included was hexachlorobenzene (HCB), a weak AhR agonist and a rodent carcinogen with controversial carcinogenic mechanisms. This study identified a threshold of “Ahr activation” that could separate a tumorigenic-strength signal from ubiquitous statistically significant inductions, and confirmed the importance of the sustained durability of Ahr activation for carcinogenic potential. Surprisingly, HCB only barely induced Cyp1a1 (up to 11x) but significantly activated CAR at the minimal carcinogenic potency (or threshold) of AhR activation, implying a different mechanism, which is consistent with its different tumor profile from that of TCDD or PCB126 in previous 2-year rat studies. A retrospective survey of internal studies of 489 compounds identified 24% as statistically significant AhR-activators at some doses, but only 7% surpassed the threshold at the highest dose, requiring further deliberation of carcinogenic risk. In conclusion, the potency (or threshold) of Cyp1a1 and Cyp1a2 gene expression induction in rat liver, together with evidence of the sustainability of the induction, could be used early in pharmaceutical development to identify doses of drug candidates that may pose dioxin-like carcinogenic risk.
data from ToxCast/Tox21 database was also considered. Evidence was reviewed for quality, relevance, and activity; data was synthesized using the key characteristics of carcinogens (KCCs) approach. Lines of evidence integrated within and between each KCC were used to identify potential molecular initiating events and key events associated with plausible MoA for the 4-MEI-induced mouse lung tumors. Composite results demonstrated that 4-MEI is not genotoxic, supported by negative findings in endpoints from high quality/relevant in vitro and in vivo studies (e.g., gene mutation chromosome aberrations, micronucleated erythrocytes, lung specific DNA damage). Also, several 4-MEI studies reported no change in gene expression, cell proliferation, or histopathology in mouse lungs following 5, 28, or 90 days of exposure. Thus, 4-MEI is unlikely to operate via a genotoxic, cytotoxic, or mitogenic MoA. The absence of activity within defined KCCs led to further evaluation of contextual data. 4-MEI is structurally similar to histamine and is predicted to mimic the binding of histamine to the active site of carbonyl anhydrase (CA), increasing its activity. Since CA is induced in hypoxic tumor tissue, and since mice have a high rate of spontaneous lung tumors, a plausible MoA was identified whereby activation of CA could augment lung tissue microenvironment, conditions hypothesized to promote the progression of lung tumors late in the lifespan of this species. This systematic evaluation of the 4-MEI database demonstrates that well known cancer MoA cannot explain lung tumors reported in mice chronically exposed to 4-MEI. However, a broader consideration of the scientific literature suggests a plausible alternative MoA for 4-MEI-induced mouse lung tumors that can be tested to elucidate its relevance to humans.

**1068 The Key Characteristics of Carcinogens as an Organizing Principle for Exploring Mechanistic Evidence: Ethylene Oxide and Welding Fumes as Case Studies**

The U.S. Environmental Protection Agency recently characterized ethylene oxide (EtO) as “carcinogenic to humans” following inhalation exposure, and a recent monograph committee from the International Agency for Research on Cancer classified welding fumes (WFs) similarly. While strong epidemiological evidence was heavily relied upon for both agents, evaluation of the animal and mechanistic data was also important in the cancer hazard assessment process. Herein, we explore the key characteristics of carcinogens (KCCs) as a means to categorize and evaluate the weight of evidence for mechanisms of carcinogenesis following diverse inhalation exposures, such as volatile chemicals (EtO), and metal particulates (WFs). A comprehensive literature search was performed to identify evidence relevant to EtO or WFs exposure and association with effects related to cancer. The resulting mechanistic evidence was critically reviewed and organized in a systematic manner by applicability to one or more of the 10 KCCs, evaluated using a weight of evidence approach, and then integrated into hypothesized outcome pathways as appropriate. Following Inhalation, EtO operates as a systemic carcinogen inducing lymphoid and breast cancers in both humans and rodents, as well as other tumors in rodents. Strong and consistent evidence indicates that EtO is both electrophilic and mutagenic, two of the key characteristics of carcinogens, directly adducting DNA and proteins, inducing point mutations and chromosomal damage in humans and/or experimental systems. While WFs may also induce cancers systemically, the strongest association in both humans and rodents is with lung tumorigenesis. Furthermore, strong and consistent evidence links WF exposure to the key characteristics of carcinogens, directly causing inflammation and immunosuppression, with moderate support for the induction of genotoxicity and oxidative stress. The evaluation and discussion of cancer mechanisms relevant to human carcinogenesis arising from exposure to agents with differing physical characteristics can be facilitated by using the key characteristics of carcinogens as a general organizing principle. The views expressed in this abstract are those of the authors and do not necessarily represent the views or policies of the US Environmental Protection Agency.

**1069 Characterization of Mode- and Mechanism-of-Action Data Related to Ethyl Acrylate-Induced Rodent Forestomach Tumors and Their Relevance to Humans**

R. Ellis-Hutchings, L. Finch, S. Murphy, J. Guillani, and K. Wiencz. 1 The Dow Chemical Company, Midland, MI; Arkema Inc., King of Prussia, PA; 2 Sandra Murphy Consulting, Kennett Square, PA; and 3 BASF SE, Ludwigshafen, Germany.

Ethyl acrylate (EA) is a chemical monomer intermediate widely used in industrial production of emulsion-based polymers. EA’s utility in polymerization reactions stems from its conjugated α,β-unsaturated ester bond. This reactivity causes strong irritation to all tissues upon contact. High-dose, chronic gavage bioassay studies resulted in benign and malignant forestomach neoplasms in rats and mice. Despite a lack of other systemic effects following subchronic or chronic EA exposure, and a lack of tumor induction in chronic drinking water, inhalation, and dermal studies, the substance has been classified as “possibly carcinogenic to humans” by the International Agency for Research on Cancer (IARC) since 1986. To aid in an evaluation of the relevance of EA-induced forestomach tumors to humans, the available in silico, in vitro, in vivo, mode- and mechanism-of-action data have been comprehensively evaluated with respect to this adverse outcome. Critical early key events include sustained saturation of glutathione conjugation (detoxification) following high-concentration bolus dosing, resulting in cytotoxicity. Subsequent key events include increased inflammation, regenerative cell proliferation, and hyperplasia of forestomach epithelial cells, with forestomach tumors occurring following greater than 6 months of treatment in a non-specific manner, as indicated by lack of activity in in vivo genotoxicity and mutagenicity studies. Collectively, the evaluated mode- and mechanism-of-action data demonstrate that EA-induced epithelial cell tumors in the rodent forestomach occur by a mode of action that is specific to rodents. The requirement for repetitive long-term EA exposure to a rodent-unique organ at very high concentrations to cause sustained saturation (depletion) of glutathione conjugation are critical early events without relevance to humans. Furthermore, lack of a specific genotoxic and/or mutagenic mechanism of EA for this rodent tumor provides strong evidence that the existing IARC classification should be removed.

**1070 Application of the Key Characteristics of Carcinogens**

K. Z. Guyton, and M. T. Smith. 1 IARC-WHO, Lyon, France; and 2University of California Berkeley, Berkeley, CA.

An international Working Group of experts convened by IARC identified 10 key characteristics, one or more of which are commonly exhibited by established human carcinogens. The key characteristics of carcinogens are distinct from the hallmarks of cancer in reflecting carcinogen mechanisms, including the abilities, for example, to be genotoxic; be immunosuppressive; or modulate receptor-mediated effects. These characteristics provide the basis for an objective approach to identifying and evaluating evidence from pertinent mechanistic studies (Env. Health Perspect. 2016, 124:713). The 10 key characteristics are used to systematically search the literature for evidence on relevant endpoints, and support objective evaluation of the overall strength of mechanistic information. Recent IARC Monograph evaluations demonstrate the applicability of the approach for mechanistically diverse agents. For some compounds, there was strong evidence for only one (2,4-dichlorophenoxyacetic acid) or no (parathion) key characteristics. For others, there was strong evidence of multiple key characteristics of carcinogens. Hydrazine and pentachlorophenol are metabolically activated to electrophilic metabolites, 4-MEI is genotoxic, induce oxidative stress, and altered cell proliferation or death (pentachlorophenol) or nutrient supply (hydrazine). On the other hand, welding fumes are immunosuppressive and induce chronic inflammation. Strong evidence for a distinct set of key characteristics (modulates receptor-mediated effects, is immunosuppressive, and induces oxidative stress) was found for dichlorodi- and trichlorodi- trichloroethane, tetrabromobisphenol A, and tetrachloroazobenzene. These developments lay groundwork for future evaluations where such data may fill important gaps in evidence of carcinogenicity.
We developed a complete panel of flow cytometry biomarkers for characterization of the major populations of porcine peripheral blood mononuclear cells (PBMCs). We subsequently analyzed distributions of these immune cells in blood samples of 4 breeds of minipigs. CD3ε, a marker for T lymphocytes, was shown to identify PBMCs that were distinct from those expressing either CD172a or markers of B lymphocytes (CD21 and B subset). CD8 was selected to identify NK cells in the CD3ε PBMCs, because CD8+ PBMCs were well separated from CD172a- cells and B lymphocytes. There were a number of PBMCs that were CD172a-CD8- in 2-month-old male Sinclair and to 56% in 8-month-old female Yucatan. NK cells were composed of three populations of PBMCs that were CD16+CD8- and γδ TCRs were identified in NKT cells, αβ T cells comprised no less than 75% of NK cells. In summary, a novel flow cytometry approach has been developed to characterize the major porcine PBMCs in one single assay. This assay will facilitate immune investigations during nonclinical pharmacology and toxicology studies.

Interferon-α (IFNα)-Mediated Activation of T Cells from Healthy and HIV+ Individuals Is Suppressed by Δ9-Tetrahydrocannabinol (THC)

J. E. Henriquez, M. D. Rizzo, R. B. Crawford, and N. E. Kaminski. Michigan State University, East Lansing, MI.

Stimulation and maintenance of T cell populations is partially mediated through cytokines. One of the key cytokines in T cell activation and peripheral control of HIV infection is interferon-α (IFNα). Δ9-Tetrahydrocannabinol (THC), the primary psychoactive compound in marijuana, can exacerbate disease progression via suppression of T cell function and secretion of interferons. We have previously shown that THC suppressed secretion of IFNα from plasmacytoid dendritic cells (pDC). The objective of this study was to determine whether THC impairs IFNα-mediated activation of T cells by measuring IL-7 receptor expression, a key homeostatic cytokine for T cells, and the cognate signaling for IL-7R stimulation by IL-7. T cells were stimulated using 100U/ml of recombinant human IFNα. Induction of IL-7Rα mRNA was determined by RT-qPCR. Levels of pSTAT1 and pSTAT5, immediate downstream transducers of IFNα and IL-7R ligation respectively, and surface bound IL-7R were determined by flow cytometric analysis. T cells treated with IFNα had enhanced expression of IL7Rα mRNA which was suppressed by THC. IFNα promoted surface expression of IL7Rα in both CD4+ and CD8+ T cells, which was suppressed by THC. CD8+ T cells from HIV+ donors demonstrated significantly higher expression of IL-7Rα compared to healthy donors in response to IFNα stimulation. Finally, IFNα-induced pSTAT1 and IL-7-induced pSTATs levels were suppressed in a concentration dependent manner by THC. Collectively, these results further support THC as an immunosuppressant.

Aryl Hydrocarbon Receptor Activation by 2,3,7,8-Tetrachlorodibenzo-p-Dioxin (TCDD) Suppresses EBF1 and PAX5 and Impairs Human B Cell Development

The aryl hydrocarbon receptor (AhR) is a ligand-activated transcription factor that mediates biological responses to endogenous and environmental chemical cues. Increasing evidence shows that the AhR plays physiological roles in regulating development, homeostasis and function of a variety of cell lineages in the immune system; however, the role of the AhR in human B lymphopoiesis remains to be elucidated. The objective of this study was to investigate the effects of persistent AhR activation by environmental contaminant TCDD on human B lymphopoiesis. Toward this end, an in vitro human B cell developmental model system was established using human cord blood-derived hematopoietic stem/progenitor cells (HSPCs). Using this model, we found TCDD markedly suppressed the generation of early-B cells and pro-B cells from HSPCs, indicating the impairment of B cell development. Addition of an AhR antagonist reversed the TCDD-elicted reduction of early-B cells and pro-B cells, suggesting that AhR mediates impairment of human B cell development by TCDD. Gene expression analysis revealed a significant decrease in mRNA levels of EBF1 and PAX5, two critical transcription factors directing B cell development. In addition, binding of the ligand activated AhR to putative dioxin response elements in the EBF1 promoter was demonstrated by EMSA and ChIP analyses, suggesting transcriptional regulation of EBF1 by AhR. Taken together, this study for the first time, demonstrates that AhR activation by TCDD impairs human B cell development, and suggests that transcriptional alterations of EBF1 by the AhR are involved in the underlying mechanism. This study was supported in part by NIH ESO002520 and NIH P42004911.

Aryl Hydrocarbon Receptor (AhR) in the Impairment of Immunoglobulin Secretion Involving the Upregulation of Total and Inhibitory Lympocyte-Specific Tyrosine Kinase (LCK) by Human Primary B Cells

J. Zhou, J. E. Henriquz, R. Crawford, and N. Kaminski. Michigan State University, East Lansing, MI.

AHR activation by the high-affinity ligand TCDD is widely established as suppressing the immunoglobulin M (IgM) response in virtually every animal species tested, and has been extensively investigated in various mouse models. In mice, activation of AhR is known to impair B cell to plasma cell differentiation and IgM synthesis. In contrast to mouse B cells, activation of AhR in human primary B cells impairs immunoglobulin secretion in the absence of suppressing IgM synthesis. In recent studies, we have identified the putative involvement of LCK in impaired immunoglobulin secretion by human B cells. LCK is a well-characterized tyrosine kinase that phosphorylates known critical signaling proteins involved in vesicular secretion by T cells. Specifically, phosphorylation of tyrosine residue 505 inhibits the activity of LCK. By contrast, little is known concerning the role of LCK in human primary B cells. For the first time, our studies show that activation of the AhR by TCDD upregulates LCK protein expression, which then leads to impairment of IgM secretion. Treatment with an LCK-specific inhibitor restores IgM secretion by human primary B cells. Additionally, the presence of AhR antagonist reverses the AhR-mediated increase of LCK and the impairment of IgM secretion. We also observe a significant increase in phosphorylation of Tyr-505 LCK with TCDD treatment, indicating that AhR activation increases the level of inhibitory LCK. Taken together, our studies reveal a novel and species-dependent mechanism involving the AhR-mediated impairment of IgM secretion and an increase in total as well as inhibitory LCK in human but not mouse primary B cells. Supported in part by NIH ESO002520 and ESO004911.
The local lymph node assay using 5-bromo-2-deoxyuridine (BrdU) with flow cytometry (LLNA:Brdu-FCM) is a modified LLNA that is used to identify skin sensitizers. This assay measures the proliferation of auricular lymph node cells (LNCs) during the induction phase of skin sensitization and the number of BPA-incorporated LNCs using flow cytometry. This study aims to determine if the LLNA:Brdu-FCM can evaluate skin sensitization potential of the chemicals that were used in the LLNA: DA and the LLNA: Brdu-EISLA but were not listed in OECD TG 429. We selected 20 chemicals including 16 sensitizers and 4 non-sensitizers. After the selection of vehicles and the conduct of a pre-screen test with two phases, solvents and test concentrations for the main test were determined. In the main study, we measured changes in lymph node weight, the number of LNCs and the proportion of BrdU incorporated into lymph nodes, and yielded stimulation indexes (SI). Stimulation Index (SI) values were calculated based on the total number of lymph node cells and BrdU-incorporated LNCs divided by the vehicle and/or control. A threshold value of ΔSI ≥ 2.7 was used to identify potential sensitizers.

In the current study, the objective of the main project of the current study was to evaluate the effects of different sensitizers and the number of BrdU-incorporated LNCs using flow cytometry. This study is a collaborative effort with the NTP, thirteen NIEHS-supported grantees, and the FDA. The LLNA project was established to study the health effects of BPA exposure, a chronic toxicity study using a wide range of BPA doses (2.5 to 25000 μg/kg bw/day) was conducted jointly by the NTP, thirteen NIEHS-supported grantees, and the FDA, which is also supported by the Korean Ministry of Food and Drug Safety in 2016 and 2017. Supported by the grants (161B1NFDS366, 171B1NFDS486) from the Korean Ministry of Food and Drug Safety in 2016 and 2017.

Remarkably, all CRS-inducing IgG1 antibodies promoted significant inflammatory cytokines from human blood cells in vitro. In the present study, the authors used preclinical tools suffer from the limited number of characterized CRS-inducing IgG1 antibodies and the poor understanding of the mechanisms regulating cytokine release. Here, we incubated human whole blood from naive healthy volunteers with monoclonal IgG1 antibodies with different proven or predicted capacity to elicit CRS in clinic and measured cytokine release using a multiplex assay. We found that, in contrast to anti-CD52 antibodies that elicited high level of multiple inflammatory cytokines from human blood cells in vitro, other CRS-inducing IgG1 antibodies induced a more modest cytokine response.
Multiple sclerosis (MS) is an autoimmune demyelinating degenerative disease of the central nervous system, commonly studied by using the mouse experimental autoimmune encephalomyelitis (EAE) model. The severity of EAE can be suppressed by the environmental toxin 2,3,7,8-tetrachlorodibenzo-p-dioxin (TCDD), a ligand of aryl hydrocarbon receptor (AhR). In our previous studies, TCDD upregulated FasL on B cells in EAE mice at day 18. The goal of this study was to investigate the effect of TCDD on FasL in follicular and marginal zone B cell populations in myelin oligodendrocyte glycoprotein (MOG 35-55)-induced EAE mice. We hypothesized that TCDD would upregulate FasL on both follicular and marginal zone B cells. At day 18 in EAE mice, FasL was upregulated with TCDD on follicular B cells. The opposite effect was seen on marginal zone B cells with TCDD inhibiting FasL. The same results were seen in EAE mice at day 10 with FasL being inhibited with TCDD on marginal zone B cells. However, there was only a slight increase in FasL with TCDD on follicular B cells. In vitro studies on B cells with CD40 ligand stimulation show that TCDD upregulates FasL. We have also assessed the effect of 2-(1'H-indole-3'-carbonyl)-thiazole-4-carboxylic acid methyl ester (ITE), an endogenous AhR ligand, on B cells. Our results show that both TCDD and ITE upregulated FasL on B cells. However, ITE induced more FasL expression than TCDD. These results show that exposure to both TCDD and ITE upregulate the expression of FasL, which might trigger apoptosis in Fas positive targets. Supported by MSU CVM and R15ES027650.
showed large infiltration of endothelial cells whereas those containing NiCl2 and Ni-Ti NP exhibited minimal angiogenesis as predicted, since athymic nude mice only express the murine and not human TLR4. The implantation of angioeactators represents a novel method that allows for quantification of angiogenesis in vivo.

Mechanism of Inflammatory Response and the Effect of IL-4 on Th2 Lymphocytes Derived from the Spleen of Zinc-Deficient Rats

T. Kido1, K. Ishiwata1, S. Yogosawa1, W. Yoshioka1, M. Tsunoda2, M. Suka1, and H. Yanagisawa1. 1 The Jikei University School of Medicine, Tokyo, Japan; and 2National Defense Medical College, Saitama, Japan.

Nutritional zinc deficiency leads to dysfunctions of the immune system such as inflammatory diseases. We have previously elucidated the cause of inflammatory reactions related to Th2 lymphocytes and M2 macrophages via the loss of GATA-3 or interleukin (IL)-4. Here, we investigated the inflammatory mechanism resulting from the administration of IL-4 or a change from a zinc-deficient (ZnD) diet to a zinc-control (ZnC) diet. Five-week-old male SD rats were fed a ZnC diet (17 g/day), and two groups were fed a ZnD diet (n = 7 each). Each group was also injected with saline or IL-4 (ZnD/IL-4 ip). The SD rats were also fed a ZnD diet for 6 weeks, but were returned to the ZnC diet for 4 weeks thereafter (ZnD/C). After the dietary manipulation, real-time PCR was performed to determine the mRNA expressions of IL-1β, MIP-1α, IL-4, and IFN-γ. Immunohistochemical staining of the spleen was conducted by using ED-2 (CD163: M2 macrophages), IL-4 (Th2 lymphocytes), and IFN-γ (Th1 lymphocytes) antibodies, and the numbers of positive cells were examined by image analyses. Furthermore, CD4-positive cells from the spleen were extracted and GATA-3 protein expression was measured by western blotting. The IL-1β and MIP-1α mRNA expressions were significantly higher in the macrophages from the ZnD group than in those from the ZnC, ZnD/IL-4 ip, and ZnD/C groups. IL-4 mRNA expression was significantly lower in the T-lymphocytes from the ZnD group than in those from the ZnC, ZnD/IL-4 ip, and ZnD/C groups. The numbers of ED-2- and IL-4-positive cells in the spleen were significantly lower in the ZnD group than in the ZnC, ZnD/IL-4 ip, and ZnD/C groups. GATA-3 protein expression in CD4 cells were significantly lower in the ZnD and ZnD/IL-4 ip groups than in the ZnC and ZnD/C groups. Thus, we concluded that the cause of the inflammatory states resulting from zinc deficiency is related to the effects of Th2 lymphocytes. This study provides data demonstrating that the dysfunction of GATA-3 and decrease in IL-4 levels resulted in reduced numbers of M2 macrophages that are responsible for anti-inflammatory effects. Moreover, the inflammatory states resulting from zinc deficiency were recovered by injection of IL-4 or intake of a ZnC diet.

Cryopreservation Does Not Affect the Immunotoxicological Response Profiles of Blood Immune Cells

M. Martikainen, E. Häkkinen, and M. Roponen. University of Eastern Finland, Kuopio, Finland. Sponsor: M. Viluksela

Freshly isolated peripheral blood mononuclear cells (PBMCs) are rarely used for immune cell analyses in cohort studies, as the use of fresh cells is usually both laborious and impractical due to logistical and scheduling reasons. In cohort studies, several challenges may also hinder the interpretation of the results, i.e., alterations in data acquired during different periods of time and, in multicenter studies, the differences in instrumentation and technical personnel. Cryopreservation of PBMCs and analysis performed in one center in one batch is a widely used answer to these challenges. Few studies, however, have published data concerning the effect of freezing on PBMCs. In this study, we investigated whether cryopreservation affects immune response profiles of PBMCs and functional properties of circulating antigen-presenting cells, namely dendritic cells (DCs) and monocytes. We stimulated fresh and cryopreserved PBMCs of adults (N=6) with different antigens (PI, POLY IC, and 3 doses of LPS) for 18 hours. Expression of functional markers CD80 and CD74 on circulating myeloid DCs (mDCs), plasmacytoid DCs (pDCs), and monocytes were analyzed by flow cytometry. Cytokine production of PBMCs was analyzed by multiplexed ELISA method. The overall response profiles were similar in fresh and frozen cells. Some immune responses, however, were slightly weaker in frozen cells (PI, POLY IC and LPS stimulated expression of CD80 in mDCs, POLY IC stimulated expression of CD80 and LPS stimulated expression of IL74 in monocytes (p<0.05)) than in fresh cells. The response to increasing doses of LPS was lower in frozen cells, measured as the percentage of cells expressing CD80. Preliminary cytokine data are in line with the cellular data (analysis ongoing). Based on the

results, it can be concluded that cryopreservation does not have a critical effect on the response profile of cells, and thus cryopreserved cells can be used in cohort studies reliably. The study suggests, though, that when interpreting and comparing the results of different studies, the possible effects of freezing on the PBMCs should be taken into account.

GAT107, an ago-PAM of α7 Nicotinic Acetylcholine Receptor, Improves Hyperoxia-Compromised Macrophage Function

A. G. Gauthier1, R. Sitapara1, G. Thakur2, and L. Mantell1. 1St. John’s University, Jamaica, NY; and 2Northeastern University, Boston, MA.

Alveolar macrophages are the first line of defense against invading pathogens in the lung. However, exposure to prolonged hyperoxia compromises their ability to phagocytose and kill bacteria. Such exposure can also lead to the release of nuclear HMGB1 into the extracellular milieu, where HMGB1 acts as a potent pro-inflammatory cytokine and suppresses macrophage’s functions. The vagus nerve of the autonomous nervous system regulates anti-inflammatory reflex in part by macrophage α7 nicotinic acetylcholine receptors (α7nAChR), which modulate HMGB1-compromised host defense under hyperoxic conditions. Agonists of α7nAChR at high concentrations may cause desensitization and can disrupt the endogenous tone of the receptor. Ago-PAMs (positive allosteric modulator) of the α7nAChR can synergize and enhance orthorhistic site mediated signaling without disrupting the endogenous signaling. In this study we tested whether GAT107 (a novel ago-PAM) can (1) improve hyperoxia-compromised macrophage phagocytosis and (2) decrease hyperoxia-induced HMGB1 release from macrophages through inhibition of NF-kappaB pathway. RAW 264.7 cells, a macrophage like cell line and murine Bone-Marrow Derived Macrophages (BMDMs), were exposed to different concentrations of GAT107 prior to exposure to 95% O2 (hyperoxia). The results show that GAT107 at concentrations of 1.1 and 3.3μM improved hyperoxia-compromised phagocytic ability of macrophages. In addition, GAT107 effectively inhibits oxidative stress-induced accumulation of HMGB1 in the extracellular milieu through reducing the activation of NF-kappaB. These data indicate that GAT107 can improve hyperoxia-compromised phagocytosis via inhibiting nuclear HMGB1 release into the extracellular milieu. Therefore, targeting α7nAChR using GAT107 may be a possible novel pharmacological agent that can be used to modulate anti-inflammatory reflex in host-defense against pulmonary infection.

Interferon Gamma-Induced STAT3 Serine Phosphorylation Reverses TCDD-Mediated Suppression of IgM Secretion in Primary Naive Human B Cells

L. K. Blevins, R. Crawford, and N. E. Kaminski. Michigan State University, East Lansing, MI.

2,3,7,8-Tetrachlorodibenzo-p-dioxin (TCDD) is a persistent environmental contaminant usually formed as a side product in organic synthesis and burning of organic materials. TCDD has potent immunotoxic effects in B lymphocytes resulting in decreased cellular activation and suppressed IgM secretion following activation with CD40 ligand. Previous work from our lab demonstrated that TCDD treatment of naive human B cells resulted in significant increases in the levels of the tyrosine phosphatase SHP-1, which corresponded with suppression of IgM secretion. STAT3 is a critical B cell transcription factor for B cell activation and suppression of immunoglobulins (Ig). STAT3 dimerizes and translocates to the nucleus following phosphorylation as a result of cytokine receptor signaling. We hypothesized that TCDD-mediated increases in STAT3 serine phosphorylation as early as 12 hours following activation. These results corresponded to decreased phosphorylation of the serine-specific phosphatase PP2a, which is known to be regulated by SHP-1. Further, studies have indicated that interferon gamma (IFNγ), which normally signals through the type II interferon receptor, can non-canonically drive STAT3 serine phosphorylation via Src kinase. Indeed, treatment of human B cells with IFNγ resulted in increased STAT3 serine phosphorylation and reversed TCDD-mediated suppression of IgM secretion. Together, these data highlight a potential mechanism for TCDD suppression of Ig secretion and demonstrate the potential of interferon gamma as a means to reverse this effect in primary human B lymphocytes.

A novel mouse skin sensitization model has been developed which is sufficiently immune for patch testing necessary for immediate hypersensitivity reaction. But there is no useful positive material to detect adjuvant effect in this model. We investigated immunological and histopathological changes of mice transcutaneously sensitized with ovalbumin (OVA) as antigen and cholera toxin (CT) or its nontoxic B subunit (CTB) as positive adjuvant candidate. In experiment 1, CT at a dose of 0.1, 1, and 10 µg with 2 µg OVA was applied in skin patches to the left flanks of 8-week-old BALB/c female mice 3 days a week for 4 weeks, and immune responses were evoked with 1 mg of OVA given via intraperitoneal route. Rectal temperatures, scores on anaphylactic responses, plasma histamine levels, and histopathological changes were evaluated. In experiment 2, 2, 4, and 8 µg OVA with 1 µg CT or 0.7 µg CTB was applied to mice in the same manner as in experiment 1. In the OVA + CT groups and the OVA + CTB group evoked via intraperitoneal injection, increased IgG1 and IgE levels after sensitization and decreased rectal temperature, with augmented anaphylaxis scores and plasma histamine levels after evocation, were noted as compared with vehicle control. In addition, IgG1 and IgE levels in the OVA + CT groups were significantly increased as compared with OVA group. Ki67-positive germinal center in the regional axillary lymph node was observed more frequently in all OVA-treated groups, except OVA + CTB group, than in the vehicle group.

Transcutaneously exposed CT with antigen showed sufficient adjuvant effect in skin sensitization model, and CT is promising positive control material. Because CT is toxic and difficult to handle but same component concentration of non-toxic CTB did not revealed obvious adjuvant effect. Further studies regarding skin toxicity and dose dependency on sensitization of CTB should be analyzed.

Q. Li, M. Kobayashi, and T. Kawada. Nippon Medical School, Tokyo, Japan.

Carbamate pesticides are widely used throughout the world in agriculture as fungicides and insecticides. It has been reported that exposure to carbamate pesticides statistically significantly increased risk of non-Hodgkin’s Lymphoma in humans suggesting that carbamate pesticides may cause impairments of human immune system because natural killer (NK) and T cells provide host defense against tumors. Based on the above background, we investigated immunotoxicity of carbamate pesticides by immune cell lines. Human NK-92CI/MI cells, human Jurkat T cells, and human U937 cells were used to evaluate the effect of carbamate pesticides on NK cells, T cells and monocytes, respectively. These immune cells were treated with carbamate pesticides such as ziram, thiram, maneb, or carbaryl at various concentrations for 2, 4, 8 or 16 h at 37°C in vitro. Therefore, NK and CTL activity was determined in a chromium release assay. To explore the mechanism of carbamate pesticide-induced inhibition of NK activity, intracellular levels of perforin, granulysin and granzymes A/B/3 in NK cells were determined by flow cytometry. In addition, carbamate pesticide-induced apoptosis was determined by FITC Annexin-V/PI staining, intracellular levels of active caspases 3 and mitochondrial cytochrome-c release by flow cytometry. It was found that all carbamate pesticides significantly inhibited human NK and CTL activity and induced a significant apoptosis in all cell lines in a concentration- and time-dependent manner. In addition, ziram and thiram reduced the intracellular levels of perforin, granulysin and granzymes A/B/3 in NK-92CI cells in a concentration-dependent manner suggesting that carbamate pesticide-induced inhibition of human NK activity is at least partially mediated by decrease in the intracellular level of perforin, granulysin and granzymes A/B/3 in NK cells. The strength of the immunotoxicity differed among the pesticides, and the order was thiram > ziram > maneb > carbaryl. These findings indicate that immunotoxicity of carbamate pesticides could be evaluated by immune cell lines in vitro.

A. E. Turley, and C. E. Rockwell. Michigan State University, East Lansing, MI.

Nuclear factor erythroid-derived 2 like-2 (Nrf2) is a transcription factor responsive to cell stressors including reactive oxygen species and electrophilic xenobiotics. Upon activation, Nrf2 up-regulates a battery of detoxification, antioxidant, and metabolizing genes, yielding a cytoprotective response. Nrf2 has been implicated in regulation of the immune system: Nrf2-null mice are more sensitive to inflammatory stimuli, and older female Nrf2-null mice develop a disease similar to lupus. A central component of these responses is the adaptive immune response, which is coordinated and directed by helper (CD4) T cells. In mice, Nrf2 activation skews CD4 T cell differentiation towards a Th2 phenotype, but the role of Nrf2 in T cell activation in primary human CD4 T cells remains undetermined. We have previously shown that the Nrf2 activator tBHQ, a commonly used food additive, inhibits events of T cell activation in primary human CD4 T cells; however, the role of Nrf2 in these events was not determined. To address this gap, we developed a Nrf2 knockout model in primary human CD4 T cells using siRNA, and tested the effects of tBHQ on T cell activation in this model. Nuclear factor with siRNA knocked down Nrf2 protein levels by 85%-90% 12h post transfection, and inhibited induction of Nrf2 target genes in the Nrf2 siRNA transfected cells. tBHQ inhibited T cell activation-induced production of the cytokines IL-2, IFN, TNFa, and GM-CSF in a Nrf2-independent manner. Likewise, tBHQ also inhibited induction of the cell surface markers CD25 and CD69 independent of Nrf2. These studies detail the development of a Nrf2 knockout model in primary human T CD4 cells which can be used to determine the role of Nrf2 in these cells, and demonstrate that the effects of tBHQ on T cell activation are independent of Nrf2 in this model. Supported by NHI grants E5024966 and E5007255.
During toxicology studies in nonclinical species, low food consumption can contribute to toxicity. Data correlating restricted feed or low food consumption to immune responses is limited. Endpoints measuring immunotoxicity include clinical pathology, lymphocytes immunophenotyping, T cell dependent antibody response (TDAR), and histopathology. In the current study, we present TDAR data following Keyhole Limpet Hemocyanin (KLH) administration in feed restricted rats, and compare immunological responses following sheep Red Blood Cells (sRBC) versus KLH administration to immunocompromised rats. Experiment 1 included five cohorts, five rats each. Cohort 1 was fed ad libitum and administered de-ionized water (DI). Cohort 2 was fed ad libitum, administered DI, and immunized with KLH on days 8 and 15. Cohort 3 was fed restricted diet (16 grams of Rodent pellets/day/animal). Cohort 4 was fed restricted diet and immunized with KLH. Cohort 5 was administered Cyclophosphamide monohydrate (CPS) for 5 days and immunized with KLH. In the second experiment 10 rats were immunized with sRBC by intravenous injection, followed by daily oral administration of 5 rats each with either DI or CPS for 5 days. Experiment 1 samples were analyzed for anti-KLH IgG/IgM. Samples from experiment 2 were analyzed for anti-sRBC IgG/IgM. The anti-KLH IgM/IgG responses in experiment 1 were suppressed in CPS treated rats, compared to both DI and restricted feed rats. The restricted feed rats showed a more robust anti-KLH IgM response (mean 7931 ng/mL day 13; 19991 ng/mL day 15) compared to the DI/fed ad libitum cohort (mean 5714 ng/mL day 13; 9134 ng/mL day 15). Mean IgM/IgG concentrations in rats immunized with sRBC were 35364 and 2379 U/mL, respectively, compared to 1735 U/mL IgM and undetectable levels IgG in CPS treated rats immunized with sRBC. The suppression of the immune response correlated with lymphoid organ cell depletion and lower spleen weights. CPS+sRBC rats had lymphoid depletion in all four lymphoid organs examined, while KLH+CPS caused lymphoid depletion in spleen. This finding may have implications for choice of immunogen when designing studies with a T-cell dependent antigen response arm. In conclusion, feed restriction and in extension low food consumption in toxicology studies does not appear to interfere with a normal immune response.

**1093 Challenges of Flow-Cytometry Validations**

C. Dumont, E. Moisan, M. Poirier, M. H. Côté, and M. S. Piché, Charles River Laboratories, Senneville, QC, Canada.

Multi-parametric analysis of thousands of cells per second to adequately identify or functionally characterize complex cell populations of interest can be achieved using flow cytometry platforms. Spanning from basic research, discovery, preclinical to clinical, flow cytometry is a valuable tool, especially with the increasing proportion of biologics in the pipeline. Flow cytometry has proven itself to be an indispensable tool to assess safety, receptor occupancy, or pharmacodynamics. However, the development and validation of flow cytometry-based methodologies can be challenging, given it involves cellular aspects, that standardized cellular reference materials are limited, and that these assays are often used for multiple different purposes. No guidelines for the validation of flow cytometry methods are currently available for the preclinical setting. Various working committees have taken initiatives in the writing of guidance documents describing flow cytometry method validation. However, these recommendations have not yet been integrated in an official document released by the regulatory agencies as it has been done for other analytical methodologies. Validation case studies of various flow cytometry methodologies and designs to overcome current challenges will be presented. Validation approaches that were adapted to address challenges such as sample stability limitations for shipment, inherent variability of functional endpoints, and low frequency populations will be discussed. Generic validation designs are not applicable to flow cytometry assay, and fit-for-purpose approaches are required.

**1094 Candidate Receptors for Metallothionein’s Role as an Immunomodulatory Danger Signal**

S. Bhandari, J. Messina, V. L. Robinson, and M. A. Lynes, University of Connecticut, Storrs, CT.

Metallothionein (MT) is a cysteine-rich stress response protein that lacks a signal peptide and has historically been considered an intracellular protein. As such, MT is important in the management of essential and toxic divalent heavy metal cations, cellular redox potential, and as a scavenger of free radicals. The presence of MT in extracellular fluids and spaces (e.g. serum, urine, milk, prostatic fluids, and bile, and in liver sinusoids, bronchoalveoli, and pancreatic acini) suggests an additional extracellular role for this protein. MT shares some structural motifs and sequence similarities with chemotactic cytokines. We have previously shown that MT is a potent chemotactrant for Jurkat T cells (ATCC TIB-152). This chemotactic activity is pro-inflammatory and can be therapeutically blocked with monoclonal anti-MT antibody (clone UC1M1T), for example, in animal models of inflammatory bowel disease. When Jurkat T cells are pre-incubated with MT, there is a diminished chemotactic response to SDF-1α. Jurkat T cells pre-incubated with SDF-1α will similarly experience a reduced chemotactic response to MT, suggesting a common interaction of these two proteins with SDF-1 α’s cognate receptor CXCR4. The chemotactic response to MT can also be blocked with antagonists of G-protein coupled receptors as well small molecule inhibitors of GPCR-dependent signaling components Arp2/3 and Phospholipase C. To better understand the interaction of MT with its possible receptor, we used 10-mer peptides based on the MT amino acid sequence. Two of these MT peptides (MT1-10 and MT1-12) can interfere with the chemotactic response of Jurkat T cells to SDF-1α. Using in silico analysis we mapped the potential interaction of MT with CXCR4 by threading the intact protein or the MT1-10 peptide over the vMIP-II viral chemokine in a co-crystallized structure with CXCR4. The interaction between vMIP-II and CXCR4 is mediated by four principal contact amino acids, which are also present in peptide MT1-10. MT pre-incubation significantly interfered with the RAW 264.7 cells (ATCC TIB-71) response to CCL2 suggesting that the MT chemotactic effect is not limited to other specific receptor. These data indicate that dysregulation and cellular release of MT during toxicant exposure, chronic inflammation, or autoimmunity disease may represent an important immunomodulatory danger signal, and an opportunity to exploit this phenomenon to develop novel avenues for therapeutic intervention.

**1095 Subchronic Oral Exposure to Cadmium Chloride Inhibits the CDB T Cell Response against Influenza Virus in Mice**

Cadmium is a common environmental toxicant linked to many pathologies, including cancer, cardiovascular disease and osteoporosis. Cadmium is commonly absorbed orally or inhaled and accumulates over the lifetime of an individual. It has also been shown to be a potent agonist of the transcription factor nuclear factor erythroid 2-related factor 2 (Nrf2), which plays a prominent role in the cellular response to electrophiles and oxidative stress. Nrf2 in T cells has been shown to cause an alteration in the cytokine profile, skewing the Th1/Th2 ratio towards the latter. We hypothesized that subchronic oral exposure to cadmium alters the immune response to intracellular pathogens which typically require a Th1-mediated response. In our model, C57Bl/6 mice were exposed to either distilled H2O or H2O with 50ppm CdCl2 through the drinking water for 2 months and then challenged with influenza A/PR/8/34 (H1N1). 10 days post-infection, lungs were collected, homogenized and used to assess immune response. Cytokine expression and virus genome were assessed using qPCR and ELISA. Expression of CD25, CD69, CD44, CD107a, Fasl, and IFNγ were determined by flow cytometry. Overall, the data suggest a decrease in activation and function of CD8, but not CD4, T cells. Specifically, expression of CD25, CD107a and Fasl were decreased by cadmium exposure in CD8 T cells. Moreover, cadmium also caused a decrease in CD8 T cell infiltration in response to influenza. Collectively, the data suggest that cadmium diminishes the CD8 response to H1N1 influenza virus. Supported by NIH grants ES018885, ES024966, and GM092715.
Abacavir (ABC), a nucleoside reverse transcriptase inhibitor (NRTI), highly induces skin rash in patients carrying HLA-B*57:01 allele. It is considered one of the hypersensitivity reactions occurred through the interaction between ABC and the HLA protein. However, little is known about the reason why this type of idiosyncratic adverse drug reaction (IADR) highly occurs in skin. Therefore, we examined immune reactions in keratinocytes (KC) derived from HLA-B*57:01 transgenic mice (B*57:01-Tg), which we had originally constructed. In addition, we investigated how the immune responses in KC from B*57:01-Tg affect acquired immunity. Primary KC were prepared from newborn B*57:01-Tg, the littermate mice or B*57:03-Tg (negative control), and primary hepatocytes were prepared from 8-week-old ones. mRNA expression of proinflammatory cytokines in KC was quantified by real-time PCR. For DNA microarray analysis (3D-Gene, TORAY), total RNA (including mRNA) was collected from primary KC and labeled with Cy5. Bone marrow cells were isolated from B*57:01-Tg mice, then differentiated to dendritic cells (BM-DC) using GM-CSF. BM-DC were cultured in conditioned medium of KC treated with a drug for 24 hours, then the surface expression of CD86 (an activation marker) was evaluated. In KC from B*57:01-Tg, ABC exposure increased the expression of mRNA encoding proinflammatory cytokines, but not in KC from the littermate mice or B*57:03-Tg. DNA microarray analysis further revealed that ABC exposure enhanced stress responses (enhancement of calcium signaling and MAPK signaling) and increased the expression of some immune-modulating factors in KC from B*57:01-Tg. In addition, while ABC did not activate BM-DC directly, conditioned medium of ABC-exposed KC from B*57:01-Tg enhanced the activity of BM-DC. Moreover, conditioned medium of ABC-exposed KC from B*57:03 or hepatocytes from B*57:01-Tg did not activate BM-DC. Immune responses in KC or KC-mediated activation of BM-DC was not induced by other NRTIs (acyclovir or tenoforvir). The immune responses in KC from B*57:01-Tg might activate acquired immunity through activation or secretion of soluble factors secreted from the ABC-exposed KC, eventually inducing IADIR in skin. The interaction between ABC and HLA-B*57:01 induced immune responses in KC, and these responses were necessary for activating DC to mediate innate and acquired immunity.

1099 Using PD-1 Knockout Mice to Test the Potential of Green Tea Extract and (−)-Epigallocatechin Gallate (EGCG) to Cause Idiosyncratic Drug-Induced Liver Injury (IDILI)

Idiosyncratic drug-induced liver injury (IDILI) is an idiosyncratic drug reaction (IDR) that is specific to an individual and can lead to liver failure or even death. The mechanism of IDILI remains poorly understood, but most reactions appear to be immune-mediated. The dominant immune response to drugs that can cause IDILI appears to be immune tolerance, and we have developed the first validated animal model by using a Pd-1 deficient mouse model in combination to anti-CTLA-4 to block immune checkpoints. This was found to mimic characteristics of IDILI in humans. Herbal products have become a significant cause of IDILI. In particular, green tea extract, which is used for weight loss, has been associated with several cases of liver failure leading to liver transplantation or death. Green tea extracts contain a highly variable content of catechins. It is suggested that hepatotoxicity is most likely due to (-)-epigallocatechin gallate (EGCG), the major catechin in green tea formulations and the most toxic in hepatocytes. We hypothesize that the idiosyncratic hepatic injury caused by green tea extract is immunolaboratory, and will be unmasked in Pd-1 deficient mice. Mice were treated with green tea extract (Applied Nutrition® Maximum Strength Green Tea Triple Fat Burner in rodent meal) at a dose of 250 mg/kg or 500 mg/kg for 6 weeks. Neither dose resulted in an increase in ALT in wildtype animals, but a dose of 500 mg/kg caused a 10-fold increase in ALT in Pd-1 deficient mice. This study was funded by the Natural Sciences and Engineering Research Council of Canada (NSERC).
Isoniazid (INH) is associated with a relatively high risk of IDILI. In previous in vitro studies, it was shown that the treatment of mouse hepatocytes with INH was not cytotoxic, but the combination of INH and rotenone caused hepatocyte death. Rotenone is known as a broad-spectrum pesticide and inhibits complex I of the mitochondrial electron transport chain. This is consistent with the hypothesis that mitochondrial injury is important in the mechanism of IDILI at least for INH. However, the in vitro cell death was acute, and IDILI in humans is delayed in onset. We tested whether the combination of INH and rotenone would cause liver injury in vivo in wildtype C57BL/6 female mice or in our IDILI model with impaired immune tolerance utilizing Pd-1 deficient mice treated with anti-CTLA-4. The mice were given either rotenone only (0.1%, 0.05%, 0.02%, and 0.01% w/w in rodent meal), INH only (0.2%), or a co-treatment with both rotenone at the varying doses and INH. A dose of rotenone of either 0.1% or 0.05% combined with INH was lethal; treatment with rotenone or INH alone was not. However, there was no evidence of liver injury in wildtype of the treatment groups. The cause of death is unknown but likely involves the central nervous system. At lower doses of rotenone (0.02% or 0.01%) combined with INH, there was no evidence of liver injury in wildtype animals and rotenone did not potentiate the liver injury of INH in the Pd-1 deficient model. These results suggest that the IDILI caused by INH does not involve mitochondrial injury. Future work will study other agents that affect mitochondrial function such as phenformin and other drugs that cause IDILI. This research was supported by grants from the Canadian Institutes of Health Research (CIHR).

1101 Immunotoxicity and Immunocompetent Response after Drug Exposure in Zebrafish Embryos

The exposure to environmental molecules, pathogens, and other chemicals can disturb the capabilities of the immune system in development organisms. Zebrafish, as mammals, possesses an immune system capable of leading a primary and acquired secondary response after exposure to a potential external agent. During the primary response, neutrophils and macrophages at 48 hpf (hour post fertilization) start to appear, allowing the zebrafish embryo protection. Drug exposure could generate immunological changes over neutrophils and macrophages population, yielding clinical concern from the point of immunological lines. During the present project, two main goals have been addressed: the immunotoxicity derived from drug exposure and the zebrafish immunocompetence after treatment. The main pathways involved in the primary response were evaluated, and specific immunological transcripts directly related to primary immunological response were studied. The transgenic lines MPO:eGFP and mpge1:mcherry, labeling primary immunological response cells, were used to reach these goals. Firstly, a MTC (Maximum Tolerated Concentration) was carried out to determine drug toxicity. After MTC assay, LC25 and NOAEL, using a statistical program R, were determined. LC25 and/or NOAEL were used to evaluate zebrafish immunotoxicity. Fertilized embryos were selected and treated at 5 hpf (hours post fertilization). Embryos were sacrificed at 3 and 4 dpf (days post fertilization) to evaluate immunological changes derived from the treatment at these stages, including two control groups, an untreated group, and a positive group treated with a known inhibitor of the immunological system, Etanercept. Embryos were observed under the microscope; at 3 and 4 dpf, immunological primary cell lines were quantified and immunological markers: Tnf-α, IL-8, IFN-γ, and pu.1, using qRT-PCR, were evaluated. Embryos exposed to reference compounds, known as immune-activation activators, presented a cell deregulation after treatment. Based on the results, we can conclude that the immunotoxicity and immunocompetence study carried out at Biobide can contribute to a better drug understanding and to a better drug risk assessment evaluation.

1102 Effects of Rapamycin (rpm) on *In Vivo* and *Ex Vivo* Cell-Mediated Immune Responses in Cynomolgus Monkeys
P. Ancian, E. Grosdidier, A. Nguyen, S. Sarlang, and J. Descotes. *CiToxLAB, Evreux cedex, France.*

Inconsistent delayed-type hypersensitivity (DTH) responses have been reported in patients, which have prompted us to study alternative cellular immunity endpoints. For this purpose, 3 male and 3 female purpose-bred Cynomolgus monkeys aged 33-36 months received a human dose of tetanus vaccine containing aluminum hydroxide IM on days 1 and 14, and were treated orally with 1 mg/kg/day rapamycin from days 28 to 66. Immunological endpoints were evaluated by an intradermal challenge of tetanus toxoid (TTx) and aluminum hydroxide on days 28 and 63. Injection sites were observed before challenge and after 24, 48 and 72 hours. Then, skin biopsies were taken and stained with anti-Cd3, CD4, CD8, CD68, Ki67, FoxP3 antibodies. Blood was collected on days 0, 28, 31 and 35 to measure anti-TTx IgG using ELISA; on day 0 and then weekly, to study standard hematology; finally, at pre-test and on days 28, 35, 59 and 63, to quantify IFN-γ secreting cells by ELISPOT and cytokine levels using a multiplex assay. No clinical signs were noted. Hematological findings were consistent with known effects of RPM. RPM blood levels measured by LC/MS/MS were within the immunosuppression range. The expected anti-TTx humoral response was seen in all animals prior to RPM treatment, and a 3-8 fold drop in anti-TTx IgG levels was measured after 4 weeks of RPM treatment. DTH reactions in animals prior to RPM treatment were slight and incoherent and DTH inhibition could be observed after RPM treatment. CD4+ and CD8+ T-cells, and CD68+ macrophages infiltrates at the injection site were observed after the first DTH reaction, and markedly decreased after RPM treatment. Despite inter-animal variability, the number of specific anti-TTX IFN-γ secreting cells surged after the first DTH response, and markedly declined at the end of RPM treatment. No clear trend in any cytokine level was noted after the first DTH response, but all levels declined after RPM treatment. This study confirms that DTH in Cynomolgus monkeys requires further study. A better understanding of DTH related events may be gained using ex vivo endpoints (cytokine analysis, immunohistochemistry etc), and in particular IFN-γ ELISPOT.

1103 Characterizing the Immune Response to Carbamazepine: Toward a Biomarker for Idiosyncratic Drug Reactions
A. Jee. *University of Toronto, Toronto, ON, Canada. Sponsor: J. Uetrecht*

Idiosyncratic drug reactions (IDRs) can be serious, life-threatening reactions. The pathogenesis of most IDRs has been shown to be immune-mediated, but it is unknown how drugs induce such an immune response. It has long been observed that the most severe form of an IDR (e.g. Stevens-Johnson syndrome/toxic epidermal necrolysis or liver failure) occurs with a very low incidence, while a similar but milder form of the IDR occurs in response to the same drug in a larger proportion of patients (e.g. skin rash, mild liver injury). Medications that cause IDRs may elicit an even milder, subclinical immune response that spontaneously resolves in an even larger proportion of patients. For example, epinephrine causes an immune response that resolves in over 90% of patients within 24 hours of injection. Further studies in IL-6 and TNFα, but this has never been studied for most drugs. We will study carbamazepine, a widely used anti-epileptic that causes a range of serious IDRs involving the skin, liver, and blood. Our hypothesis is that drugs that elicit IDRs cause a subclinical immune response in most patients that resolves through immune tolerance. An animal model will be used to study the immune response under controlled conditions and in multiple organs. PD-1 knockout mice administered anti-CTLA-4 antibody, a model for idiosyncratic drug-induced liver injury, and wild type mice will be administered carbamazepine and samples from the liver, lymph nodes, and blood will be analysed microscopically and by flow cytometry to determine changes in immune cell populations and cytokine levels. These results will then need to be validated in human patients. Thus far, we have developed a dosing protocol that produces a therapeutic blood level in mice and causes a significant increase in interleukin 12 and PD-1 knockout mice. Further studies will be performed to characterise the cells populations that are involved in this liver injury. Ultimately, we aim to find a biomarker to predict the ability of a drug to cause IDRs, which would save patients’ lives and reduce risk in the drug development process. This research was supported by grants from the Canadian Institutes for Health Research and the AFPC/Merck Canada Inc. Post Graduate Pharmacy Fellowship Award.

1104 Nrf2-Dependent Transcriptional Regulation of GATA3

Tert-butylhydroquinone (tBHQ) is a food preservative and known activator of the transcription factor, nuclear factor erythroid 2-like 2 (Nrf2), which functions to activate cytoprotective genes in response to cellular stress. When exposed to stressors, Nrf2 translocates to the nucleus and binds to an antioxidant response element (ARE) to induce expression of antioxidant genes. We have previously shown that exposure of mice to tBHQ directly influences immune function through polarization of murine CD4+ T cells towards a Th2 phenotype. Immune skewing was evidenced by increased Th2 cytokine (IL-4, IL-5 and IL-13) protein production, as well as increased DNA binding capacity of the master regulator of Th2 helper cell differentiation, GATA3. In a Nrf2-dependent manner, however, the mechanism(s) by which increased GATA3 DNA binding occurs, remains unknown. This study addresses this gap, through ex vivo analysis of
GATA3 expression in response to tBHQ exposure in mouse CD4+ T cells. CD4+ T cells from wild-type (WT) and Nr2f2-null (KO) mice were magnetically isolated and activated with vehicle or tBHQ, followed by T cell specific stimulation for 96 hours. A concentration-dependent increase in GATA3 gene expression was noted with exposure to tBHQ in WT, but not KO mice, indicating Nr2f2-dependent transcriptional regulation. In addition, we identified potential antioxidant response elements within a GATA3 intron as well as in the promoter of the GATA3 gene further suggesting transcriptional modulation. Our data provide insight into the molecular regulation of GATA3 by Nr2f2, and provide additional evidence for the role of Nr2f2 in modulating adaptive immune cell function. This study was supported by National Institute of Environmental Health Sciences (ES024966).

1105 The Nr2f2/Keap1 Axis Modulates Early Events of Human Jurkat T Cell Activation

Nuclear factor erythroid 2-related factor 2 (Nr2f2) is a stress-activated transcription factor. Under basal conditions, Nr2f2 is quickly turned over by interaction with its repressor protein, Keap1. In the presence of stressful stimuli, including reactive oxygen species and electrophilic compounds, Nr2f2 is no longer suppressed by Keap1 and translocates to the nucleus, where it drives the transcription of cytoprotective target genes. Although Nr2f2 is widely considered a master regulator of the antioxidant response, in our recent studies, using CRISPR-Cas9, we demonstrated that activation of Nr2f2 by the synthetic triterpenoid 12-cyano-3,12-dioxooleana-1,9(11)-diene-28-oyl (CDDO-im) suppressed IL-2 secretion in a Nr2f2-dependent manner. One limitation of many Nr2f2 studies is the off-target effects of stress-inducing toxins used to activate Nr2f2. Therefore, using CRISPR-Cas9 gene editing, we have generated both Nr2f2-null and Keap1-null human Jurkat T cell lines. The purpose of the present studies was to use these models to determine the role of the Nr2f2/Keap1 axis in the early events of Jurkat T cell activation. Analysis of wild-type, Nr2f2-null, and Keap1-null genotypes indicate that Nr2f2-null clones secrete significantly more IL-2 than wild type Jurkat T cells, supporting our previous findings that activation of Nr2f2 suppresses IL-2 secretion. Furthermore, Keap1-null clones have a robust increase in caspase activity and subsequent decrease in cell viability, after T cell activation, indicating that Keap1 may play a role in activation-induced cell death. Taken together, our current model demonstrates that the Nr2f2/Keap1 axis plays a role in several key events of human Jurkat T cell activation. This work is funded by NIH grants ES018885, ES024966 and GM092715.

1106 Nr2f2 Induces Blimp-1, a Known Regulator of Th1 Cell Differentiation

R. A. Freeborn, R. C. Kennedy, A. E. Turley, and C. E. Rockwell, Michigan State University, East Lansing, MI.

The cytoprotective transcription factor, nuclear erythroid 2-related factor 2 (Nr2f2), resolves cellular stresses by upregulating cytoprotective genes in response to oxidative and electrophile stresses. One stressor known to activate Nr2f2 is the widely used electrophile food additive, tert-butylhydroquinone (tBHQ). Used to prevent rancidification of fats and oils, tBHQ is found in numerous food products, including cereal, crackers, and frozen fish products. Our lab has previously shown that treatment of T cells with tBHQ results in inhibition of numerous endpoints associated with T cell activation and differentiation. In primary CD4 T cells, tBHQ inhibits IFNγ mRNA and protein expression in a Nr2f2-dependent manner. Moreover, tBHQ causes a Nr2f2-dependent inhibition of the DNA binding activity of T-bet, a transcription factor known to promote Th1 differentiation. Although these findings suggest that Nr2f2 inhibits Th1 differentiation, the mechanism by which this occurs is not known. A protein of interest, B lymphocyte-induced maturation protein 1 (Blimp-1), has been shown to directly inhibit IFNγ, T-bet, and Bcl-6 expression, all of which are involved in Th1 cell differentiation. Notably, Blimp-1 is regulated by an inhibitory transcription factor, Bach2, which belongs to the same family of transcription factors as Nr2f2. To explore the potential link between Nr2f2 and Blimp-1, CD4 T cells were isolated from female wild-type and Nr2f2-null C57BL/6 mice and treated with tBHQ prior to activation. After 96 hours, RNA and supernatants were collected from the cells. Treatment with tBHQ resulted in a Nr2f2-dependent increase in Blimp-1 mRNA. These results provide evidence for a possible mechanism by which Nr2f2 inhibits Th1 cell differentiation. This work was supported by NIH grants ES024966 and GM092715.

1107 Modulation of Type 1 Diabetes in Non-Obese Diabetic Mice following Perinatal Genistein Exposure

G. Huang, University of Georgia, Athens, GA.

Despite many hypothesized benefits of dietary isoflavone genistein intake, its protective effects against type 2 diabetes may stem from soy-based isoflavone exposure. However, the mechanisms surrounding GEN’s immunotrophic effects, especially during developmental exposure, have yet to be answered. Our previous study has shown an exacerbation of T1D in NOD female offspring, as represented by T1D incidence, antibody, and cytokines following perinatal GEN exposure. In the current study, we used a metagenomic approach to identify the gut microbiota trajectories associated with T1D predisposition in vivo and functional metagenomics prediction. NOD mice, a model spontaneously develop autoimmune pancreatitis that resembles human T1D, were orally exposed to GEN [from gestational day 7 to postnatal day (PND) 21] at a physiologically relevant dose of 20 mg/kg body weight. Microbiome analysis of the feces indicated that the postnatal day (PND) 90 gut microbiota from female offspring can be well separated by GEN treatment using weighted UniFrac with an increased level of Enterobacteriaceae (suggesting a pro-inflammatory response), while the similar changes were not found in PND 30 females. For functional metagenomics using Tax4Fun, an R package that analyze the differentially expressed Kegg Ortholog (KO), a total of 6227 KOs were identified, and 969 KOs were significantly different between the vehicle and GEN treated groups based on a critical value of 0.05 by Welch’s t-test, and the potentially involved pathways include 16s RNA methyltransferase and tryptoph-anil-RNA synthetase. In addition, flow cytometric analysis on splenocytes suggested a decreased percentage of CD5+CD4+ subpopulation and increased CD4 CD8+ total cell counts. Taken together, the differential effects of GEN on T1D in male and female NOD mice is unique to the perinatal exposure window, and the strong gender effect is found, which is associated with gut microbiota related mechanism. Supported by NIH R21ES24487.

1108 Assessment of the Accuracy of OECD Toolbox Profilers to Identify Reactive Chemicals Associated with Skin Sensitization

Allergic contact dermatitis is a serious occupational and environmental health hazard. Thus it is prudent to identify potential chemical sensitizers within the early stages of the product development life-cycle. Since the formation of sensitizer-protein complexes involves covalent modification of amine acids by a chemically reactive compound or its metabolite, in silico approaches (e.g. using profilers to identify reactive groups) present a rapid way to screen novel compounds for their sensitization potential without the need for physical research samples. We assessed the predictive capacities of existing chemical profilers in the freely available OECD Toolbox: (Protein binding by OASIS, Protein binding by OECD, Protein binding potency, Keratinocyte gene expression and Cysteine and Lysine direct peptide reactivity assays (DPRAs). We challenged these profilers against a curated database of 581 compounds with local lymph node assay (LLNA) data from the public literature and internal sources both with and without metabolism predicted using the skin metabolism simulator in the OECD Toolbox. The facile chemical reactivity of the parent compounds and predicted metabolites was independently assessed via our in-house KNIME workflow coupled with expert analysis of the results, which was used as the standard for comparison of the Toolbox profilers. Overall, the Protein binding by OASIS and Protein binding by OECD profilers were the most accurate, displaying high sensitivity (97% OASIS and 92% OECD) and overall accuracy (84% OASIS and 88% OECD). The DPRRA profilers for facile alerts within the Toolbox showed 80% sensitivity, 85% specificity and an overall accuracy of 82%. Finally, given the observation that certain profilers displayed limited abilities to identify certain types of false alerts, we demonstrate the utility of a consensus approach in enhancing the sensitivity associated with the profiling of potentially reactive chemicals using existing tools (sensitivity = 98.04% for compounds being flagged by two or more profilers). Assessment and implementation of profilers presents a faster method to screen large, diverse compound libraries for potential interaction with biomolecules and may serve a complementary role in integrated approaches to testing and assessment.
Sulfolane is a widely used industrial solvent detected in groundwater that is employed in liquid-liquid and liquid-vapor extraction of chemicals from petroleum, in fractionalization of wood tars and as a desulfurization agent in the purification of natural gas, gasoline, and diesel fuel. The present studies provide a comprehensive assessment of the impact of drinking water exposure to sulfolane on the immune system. Two models were used, a perinatal drinking water exposure (0, 30, 100, 300 or 1000 mg/L) in Harlan Sprague Dawley rats from GD6 until approximately 13 weeks of age and a 90-day oral gavage exposure (0, 1, 10, 30, 100, or 300 mg/kg) in adult B6C3F1/N mice. Chemical intake in F1 rats based on water intake was calculated to be 0.00 ± 0.01 mg/kg/day for male rats and 0.00 ± 0.01 mg/kg/day for female rats. No effect on NK activity was observed in male F344 rats following developmental exposure. There was a slight, but significant decrease in the percentage of NK cells in the spleen of adult mice following exposure to sulfolane, however this did not impact the killing activity of NK cells. These data suggest that oral exposure to sulfolane affects innate immunity and is influenced by developmental timing of exposure, gender, and species. This work was supported by NIH contract HHSN273201400017C.

In summary, the integration of immunotoxicology and pathology data is necessary to develop a comprehensive understanding of how therapeutics impact the immune system, define adverse effect levels, and mitigate risk to patient populations.
creatinine, infiltration of neutrophils and renal tissue injury than wild-type (WT) mice. Using bone marrow chimeric mice, it was determined that hematopoietic IL-10, rather than IL-10 from renal parenchymal cells, attenuated the nephrotoxic effects of cisplatin, suggesting that IL-10 produced by immune cells reduces cisplatin toxicity. Likewise, we examined the site of IL-10 action in cisplatin toxicity using IL-10R1KO mice. Mice deficient in IL-10R1 showed more renal dysfunction than WT mice. We further used bone marrow chimeric mice to examine the relative role of IL-10R1 expressed on hematopoietic and renal parenchymal cells. The BUN and serum creatinine of IL-10R1 KO chimeric mice with WT hematopoietic cells (WT to IL-10R1 KO) were comparable to WT mice (WT to WT). However, WT chimeric mice with IL-10R1 KO hematopoietic cells (IL-10R1 KO to WT) displayed more renal dysfunction than WT to WT or WT to IL-10R1 KO chimeric mice, indicating that the IL-10R1 of immune cells ameliorates kidney injury in cisplatin nephrotoxicity. Finally, using CD4 T cell transfer studies from WT and IL-10R1KO mice into Rag2 KO mice, it was determined that IL-10R1 on CD4 T cells accounts for endogenous IL-10 protection from cisplatin nephropathy.

1116 Novel Pathway-Linking Particulate Matter (PM) and the Major Histocompatibility Complex Class II: A Possible Biomarker for Oxidative Stress in Bronchial Epithelial Cells

H. Jirau, E. Fuentes-Mattei, and B. Jimenez, University of Puerto Rico MSc, San Juan, Puerto Rico.

The understanding of possible adverse health effects of Particulate Matter (PM) is becoming a high priority for air quality standards by federal and international agencies. Therefore, it is of utmost importance to study and evaluate the toxicological effects of various PM constituents such as ozone, nitrates, sulfates, metals, and biological compounds and their impact on susceptible populations. Oxidative Stress (OS) in lung tissue caused by PM-associated compounds has been correlated with an increase in asthma, airway fibrosis, and COPD in urban populations. Common biomarkers such as glutathione peroxidase (GST/GSSG) and cytokine induction (IL-1b, IL6, ILB, and TNF) have been used to determine stress conditions in bronchial epithelial cells. We recently reported mRNA expression of the MHC class II gene after bronchial epithelial cell exposure to organic PM extract. The major histocompatibility complex responsible for presenting extracellular immune cells had higher expression with PM exposure, even though epithelial tissue is a non-professional antigen-presenting cells (APC), the presence of biological active compounds in PM extracts has been associated with its induction. Induction of MHC class II is known to be dependent on its master regulator CIITA through protein-protein interactions at the promoter region. It is suggested that PMs constituents are responsible for CIITA induction, which subsequently promotes MHC class II expression. The exact mechanisms and related key players in the various pathways have not been yet been identified. Therefore, we propose a possible pathway for MHC class II expression in bronchial epithelial cells exposed to airborne particulate matter. Our data shows that exposure to CuSO4 induces the expression of MHC class II and CIITA. This led us to believe that this expression is related to oxidative stress reactions and kinase induction. Consequently, exposure to PM extract, which is rich in copper, led to a similar expression of these genes, as well as expression in different proinflammatory genes as well. The most striking feature of our study is that MHC class II and its master regulator are being expressed in the absence of its major activator INFγ. We believe that PM constituents work at different levels of MHC class II pathways, which are also essential for inflammatory reactions in the lung.

Inorganic arsenic (iAs) is a common drinking water contaminant, carcinogen and immunotoxicant. Currently, the World Health Organization’s drinking water standard for iAs is 10 ppb, a concentration that is exceeded in the drinking water of an estimated 200 million people worldwide, including >3 million in the US. Environmental exposures such as iAs can increase risk of respiratory infections and are thought to play a role in reduced vaccine efficacy. Vaccine-preventable illnesses such as influenza remain among the top ten causes of death worldwide. Each year 5-10% of adults and 20-30% of children globally experience influenza infections. However, no studies have assessed the effect of iAs exposure on influenza vaccine immunogenicity. The aim of this study was to determine the effect of iAs exposure on influenza A virus (IAV) vaccine immunogenicity in a mouse model. We hypothesized that exposure of mice to iAs suppresses host immune function, resulting in diminished anti-IAV IgG and neutralizing antibody titers compared to control animals. Seven-week-old C57BL/6 female mice were chronically exposed via drinking water to iAs in the form of sodium (meta)
arsenite at 0, 100 or 1000ppb ad libitum. At 2- and 5-wk of exposure, mice were immunized with 20µg (im) of whole killed mouse adapted influenza A/California/4/2009 (H1N1) [ma2009]. At 8-wk of exposure, mice were intranasally inoculated with 10^5 50% tissue culture infective dose (TCID50) of a ma2009 drift variant (ma2009dv) to determine what effect iAs exposure had on vaccine efficacy. Results demonstrate that exposure to 100 or 1000ppb iAs decreased neutralizing antibody titers against the ma2009dv, anti-IAV IgG antibody titers and increased lung histopathology in mice following ma2009dv challenge. Additionally, serum cytokine analysis at multiple time points following immunization as well as infection indicate differential expression of many pro-inflammatory cytokines in iAs-exposed mice compared to control. These preliminary data suggest the potential immunomodulatory effects of iAs in drinking water on viral vaccine immunogenicity. These effects could be devastating for public health and may be a contributing factor to reduced vaccine immunogenicity and efficacy. Future studies will focus on iAs-exposed males and females, as these are the most susceptible populations to IAV infection. Funded by ST32HL07534-35.

**1119 Sodium Methylidithiocarbamate as a Probe of the Role of Oxidative Stress in the Response to Lipopolysaccharide**

S. B. Pruett, M. Gadson, and W. Tan. Mississippi State University, Mississippi State, MS.

The role of reactive oxygen species and oxidation-reduction balance in general in the production of pro-inflammatory cytokines and chemokines in response to inflammatory mediators is often taken for granted. It is typically assumed that reactive oxygen species contribute positively to the grant for processes that lead to the production of pro-inflammatory cytokines and chemokines, but the literature includes many examples of contradictory evidence on this matter. In the present study, we used a widely-used crop fumigant (SMD), which we have previously reported depleted reduced glutathione in macrophages from mice treated with the compound. We compared thioether levels, glutathione redox status, and production of cytokines, chemokines, and growth factors in response to lipopolysaccharide in NF-kappaB reporter mice. The results indicated that SMD at 200 mg/kg depleted reduced glutathione from peritoneal macrophages, and it significantly decreases the production of several pro-inflammatory cytokines and chemokines induced by lipopolysaccharide (60 micrograms/mouse). However, pre-treatment of mice with buthionine sulfoximine (BSO) or N-acetyl cysteine (NAC) to deplete or to restore reduced glutathione, respectively, did not alter the decreased production of cytokines and chemokines in mice treated with SMD. Neither NAC nor BSO had a significant effect cytokine or chemokine production in LPS-treated mice. Treatment with SMD (200 mg/kg) increased production of IL-10 (an anti-inflammatory cytokine), and this was not altered by prior treatment of mice with NAC or BSO. These results demonstrate that oxidative stress does not always have meaningful effects on the production of pro-inflammatory or anti-inflammatory cytokines, chemokines, or growth factors. This work was supported by a grant from NIEHS, R01ES013708.

**1120 Suppression of Antibody Response by Aqueous Film-Forming Foam**

C. Ward, S. Vance, O. Hu, and J. DeVitt. East Carolina University, Greenville, NC.

Aqueous film-forming foams (AFFFs) are mixtures of per- and polyfluoroalkyl substances (PFASs) used extensively as fire suppressants. While several PFASs, notably perfluorooctanoic acid (PFOA) and perfluorooctane sulfonate, have been extensively studied and have been classified as immune hazards to humans, few studies have evaluated effects of AFFF exposure in vertebrate models. We evaluated the ability of AFFF to suppress T cell-dependent antibody responses (TDAR), a functional immune response sensitive to PFAS exposure in male and female rodents, and induce peroxisome proliferation, a biomarker of exposure. Adult female and male C57BL/6 mice were given AFFF (0.188, 3.75, 7.5, 10 mg/kg or 7.5 mg/kg perfluorooctanoic acid positive control) via gavage for 10 days. Body weights were collected daily for 15 days and urine was collected throughout the day after dosing ended, mice were immunized with sheep red blood cells to elicit the antigen-specific IgM antibody response. Five days after dosing ended, blood/sera and organs were collected and frozen for additional analyses. Spleens were immediately prepared for enumeration of B and T cell populations, liver peroxisome proliferation was determined from frozen liver samples, and TDAR was determined by ELISA. Body weights of males exposed to 7.5 and 10 mg/kg of AFFF were reduced by about 15%, on average, compared to the 0 mg/kg group; female body weights did not differ by dose. Relative liver weights were statistically (P < 0.0001) increased 50-200% in males and 37.5-193% in females relative to the 0 mg/kg group. Liver peroxisome proliferation was increased 2- to 12-fold in all dose groups relative to the 0 mg/kg group. Spleen cellularity and splenic lymphocyte subpopulations did not differ by dose. The TDAR was suppressed 18.8% and 11.1% in males and 12.6% and 10.5% in females in the 7.5 and 10 mg/kg of AFFF, respectively, relative to the 0 mg/kg group. We concluded that this PFAS mixture is more potent than single compounds, i.e., PFOA alone, at increasing liver weight, inducing peroxisome proliferation, and suppressing the TDAR and males appear to be more sensitive to effects of AFFF exposure than females for most endpoints evaluated. Additional studies are warranted to determine the most appropriate methods for assessing the human health risks of exposure to AFFF.

**1121 T Cell-Dependent Antibody Response to Clinical-Grade Keyhole Limpet Hemocyanin in Cynomolgus Monkeys**

To provide data to support clinical design, the effect of an antigenic domain antibody (dAb) X on primary and memory TDAR to clinical grade KLH with or without adjuvant was investigated. Previously, dAb X at a single scubcutaneous dose of 5 or 50 µg/kg was shown to suppress the TDAR to research grade KLH (10 mg) without adjuvant in monkeys. In the first adjuvant comparison study, dAb X was administered subcutaneously (SC) at doses of 0, 2, or 20 mg/kg to 2 monkeys/sex/group on Day 1. All monkeys received 1 mg of clinical grade KLH alone or with adjuvant Montanide (1:1 w/w ratio) SC immediately following dAb X administration. DAB X was clinically well tolerated at all doses with no effects on clinical observations or body weight. Addition of adjuvant with clinical grade KLH was critical for increasing the incidence and magnitude of KLH-specific IgM responses in order to assess the suppressive effect of dAb X. Although the effect of dAb X on KLH-specific IgG responses was determined in monkeys administered KLH without adjuvant, addition of adjuvant optimized the magnitude of response. Clinical grade KLH did not elicit ex vivo recall responses, including T-cell activation and cytokine production, to ex vivo KLH stimulation, regardless of whether or not adjuvant was given. Thus, dAb X at doses of 2 and 20 mg/kg was able to suppress the primary TDAR to clinical grade KLH when administered in the presence of adjuvant. In the second study, dAb X was administered SC at doses of 0 or 20 mg/kg to 1-2 monkeys/sex/group previously immunized with KLH. All monkeys received 1 mg of clinical grade KLH with adjuvant SC 7 weeks prior and 1 mg of KLH contains IgG1 constant regions from cytomolgus macaque and variable regions from commercially available drug Simponi. We demonstrate that coadministration of a commercially available drug (Simponi) increases exposure, improves PK parameters and reduces generation of ADA in monkeys and could be potentially used to remove the need to “dose-through” the ADA in toxicological studies.
alone on Day 1 immediately following dAb X administration. A single dose of dAb X at 20 mg/kg had no effect on the robust anti-KLH memory IgG response in this study. It is likely the large magnitude of memory IgG response to clinical grade KLH as compared to the primary IgG response in the first study prevented suppression by dAb X.

### 1123 Role of the AhR in Immunoglobulin Expression and Antibody Isotopic Profile in a Human B Cell Line

V. Enukonda, C. Buckner, N. Alhamdan, and C. Sulentic. Wright State University, Dayton, OH.

B cells play a crucial role in the immune response, but several xenobiotics such as 2,3,7,8-tetrachlorodibenzo-p-dioxin (TCDD) have been shown to affect the function of these cells. In animal models, TCDD inhibits immunoglobulin (Ig) expression and secretion in an aryl hydrocarbon receptor (AhR)-dependent mechanism. The effect of TCDD on human B cells is less clear with studies showing interindividual variation in the effect on IgM secretion. Using a human B cell line (CL-01) and ELISA analysis, we have shown negligible effects of TCDD on stimulation-induced IgM expression, but significantly inhibited IgG expression. Compared to stimulation alone, a co-treatment with the AhR antagonist CH223191 (AhRA) induced significantly higher IgG expression. This effect was antagonized by TCDD co-treatment. The objective of the current study is to determine the role of the AhR in the effects of TCDD and AhRA on IgG secretion and the expression of all eight isotypes (IgM, IgG1-4, IgA1-2, IgE). To evaluate the AhR, we utilized CRISPR/Cas9 gene-editing to generate CL-01 subclones that either have a significant knockdown of AhR expression (AhR KD) or express an AhR with or without a functional transactivation domain (TAD+ or TAD-). The functional status of AhR transactivation was confirmed for each subclone using a luciferase reporter plasmid regulated by six dioxin response elements linked in tandem. The inhibitory effect of TCDD on IgG secretion was similar in both the TAD+ and TAD- subclones. In contrast, IgG secretion was dramatically inhibited in the AhR KD cells. These results suggest that the AhR has a physiological role in IgG secretion and that altered IgG secretion by TCDD involves a nonclassical AhR signaling pathway. Ongoing efforts are focused on evaluating the expression of all antibody isotypes via quantitative real-time PCR in all three CL-01 subclones (AhR KD, AhR TAD+, AhR TAD-). This study will determine how the AhR affects the IgG isotopic profile and the role of classical DRE-mediated signaling vs. nonclassical signaling. Altered expression of specific antibody isotypes could significantly impact immune responses to pathogens or inappropriate immune responses, such as hypersensitivity or autoimmunity disease.

### 1124 Computational Association of Polychlorinated Biphenyl Bioaccumulation in Great Lakes Regions and Potential Risk of Inflammatory Bowel Disease

Polychlorinated biphenyls (PCBs), as industrial byproducts, continue to contaminate the Great Lakes and bioaccumulate in wildlife and humans in areas of Michigan. In addition, certain Michigan populations have increased incidences of inflammatory bowel disease (IBD), a chronic, relapsing intestinal inflammatory disease due to irregular intestinal muscular system activation. This is the current study to determine the potential association of PCB contamination and IBD in specific areas of Michigan where PCB river contamination continues to be problematic. Using a computational systems disease-read across approach incorporating comparative inflammatory-related diseases prevalent in the study region including colorectal cancer (CC), and the two principal types of IBD, inflammatory ulcerative colitis (UC) and Crohn’s Disease (CD), disease-gene networks were developed and common nodes among the disorders were analyzed. Detailed disease incidence maps were developed for the region and genetic susceptibilities through inflammatory cytokine expression was evaluated for both CC and IBD with a focus on local heritage. Of major interest was a SNP of the transporter ABCB1 which is crucial for cellular efflux of chemicals. Potential PCB and ABCB1 interaction was confirmed with a computational chemical/protein docking model. In addition, in this area Mycobacterium avium subspecies paratuberculosis (MAP) infection has been linked to CD. Studies in animals have shown a decrease in MAP IgG after PCB exposure thereby decreasing immunity to IBD. Based on the comparative networks and association analyses, a molecular initiating event for potential PCB-associated-IBD was proposed: PCB induces ABCB1 disruption, which would lead to bioaccumulation of xenobiotics and inflammatory mediators within intestinal cells, exacerbated by MAP infection and resulting in sustained inflammation.

### 1125 Ethanol-Induced Gastric Ulcer: Molecular Ulcerogenic Mechanism

M. W. Ovonikoko, and K. O. Ajeigbe. Igbinedion University, Okada, Benin, Nigeria. Sponsor: C. Alimba

Ethanol is one of the numerous gastrointestinal toxicants to which humans are consciously and deliberately exposed daily. Ethanol-induced gastric ulcer is one of the widely studied experimental ulcers among other ulcer models. The fulcrum for this established fact is due both to pathological semblance of the model with most of the symptoms observed in gastric ulcers and most importantly in alcoholics and easy reproducibility of the method. For instance, many bioactive compounds in different plants have been known to show gastric anti-ulcer potencies against ethanol-induced gastric ulcer. This may be attributed to the ability of these agents to interfere with one or more of the cascade of steps involved in the pathogenesis of gastric ulcer as they have been variably reported to be cytoprotective or gastroprotective. However, despite the plethora of the gastric ulcer method in literature, very little is known about the mechanism involved in its pathogenesis. A thorough literature search through medline was made between year 1997 and 2017 for this purpose and was used as the basis for this review. The review holistically analyse the mechanism, at the molecular level, involved in ethanol induced gastric ulcer model in relation to the healing.

### 1126 In Vitro Cytotoxicity and Inflammatory Responses Elicited by Different Types of Rock Dust: Similarities and Material-Specific Differences

A. A. Shvedova,1,2, A. Menas,1, N. Yanamala1, S. Guppi,2 D. Schweger-Berry1, T. Lee,1 M. Harper1, and E. R. Kisini.1. 1NIOSH, Morgantown, WV; 2West Virginia University, Morgantown, WV; 3NIOSH, Pittsburgh, PA; and 4Zefon International, Ocala, FL.

Rock dusting in underground coal mines helps to prevent the propagation of coal dust explosions. The commonly used rock dust refers to limestone or marble dusts which may be utilized as is or treated to prevent clumping under high humidity conditions. Although potential occupational exposures to rock dust are real, safety or toxicity information on such exposures are largely lacking. The aim of this study was to evaluate the cytotoxicity, cellular damage and inflammatory responses of respirable untreated limestone (UL) and marble (UM) rock dust as well as to examine whether the treatment of dust affects the outcome. Human lung epithelial cells (AS49) were exposed for 24 and 72 h to various concentrations (0 - 1mg/ml) of four rock dust samples. The results showed dose- and time-dependent cytotoxicity and cell damage with the least effect upon exposure to treated limestone (TL). The extent of inflammatory responses evaluated by the number of cytokines produced and released, increased with the concentration of tested materials. Clustering analysis of the inflammatory cytokines/chemokines revealed an overall stronger effect of marble compared to limestone samples. Furthermore, untreated rock dust induced a greater inflammatory response as compared to treated samples in both cases. Similar to the cytotoxic and cell damage results, treated limestone revealed the lowest inflammatory response compared to other samples. Overall, our results unveiled treatment related differences as well as material dependent changes in biological responses.

### 1127 Defining Interstitial Macrophage Populations in Lungs and Changes Based on Nanomaterials

A. T. Lanphear, P. Fletcher, P. Shaw, and C. Migliaccio. University of Montana, Missoula, MT.

Nanoparticles are increasingly utilized in fields such as medicine, agriculture, and industry. Carbon nanotubes have important uses in many of these fields, so understanding their potential for adverse effects is vital. Macrophages are a key component of the immune system and are known to separate into functional subsets that generate distinct responses in the body. Pulmonary macrophages, key regulators of immune responses to respiratory exposures, have yet fully to be sep-
Lightfoot3, J. J. Guers4, S. F. Vatner4, L. McGuinness2, L. J. Kerkohf2, and S. C. Campbell2. 1

Healthy aging, including protection against diabetes, obesity, and cardiovascular disease, we propose to conduct a head-to-head comparison of microbial communities (species and strains) between AC5KO and wild-type (WT) mice to reveal whether there are differences that promote longevity and healthful aging (protect against disease states). Male and female AC5KO and WT mice were fed a normal diet and randomly assigned to exercise or sedentary groups. After 6 weeks, animals were sacrificed, and duodenum/ileum and colon tissues were fixed for immunohistochemistry for intestinal inflammatory marker cyclooxygenase-2 (COX-2). DNA extraction, PCR amplification, and data analysis tools (MiniON) were used to compare the microbial communities of the different groups of mice. Following in vitro polarization of AMs, we detected increased levels of YM1/YM2 in the M2a polarized AMs, we detected increased levels of YM1/YM2 in the M2a polarized cells compared to the controls. We were also able to find marker differences in subsets of pulmonary macrophages following the seven-day exposure. Using Flow Cytometry and in vitro polarization of AMs, we could conclude that macrophages were expressing predicted markers of polarization. The data collected suggests that subsets within the interstitial macrophages do exist and further research is needed to classify them. Being able to separate the macrophages from the seven-day exposure into interstitial and inflammatory interstitial demonstrates differences between interstitial macrophages in the lungs, which needs to be studied further.

1129 Evaluating Intestinal Inflammation and Microbiota in the Healthy Aging AC5KO Phenotype

E. O. Jennings1, R. A. Dowden2, P. J. Winiewski1, L. B. Joseph2, S. Lightfoot1, J. J. Guers3, S. F. Vatner4, L. J. Kerkhoff4, and S. C. Campbell5. 1Ying University, Bristol, TN; 2Rutgers, The State University of New Jersey, New Brunswick, NJ; 3Oklahoma State Health Sciences Center, Tulsa, OK; and 4Rutgers New Jersey Medical School, Newark, NJ.

Healthy aging, including protection against diabetes, obesity, cardiovascular stress, and enhanced exercise tolerance, have been observed in our adenyl cyclase type 5 knock out (AC5KO) mouse model. This is a critical observation, because the aging population would not enjoy extra years if they were accompanied by chronic conditions. Since the gut microbiota has been shown to be an important determinant of age-associated pathological states such as inflammation, diabetes, obesity, and cardiovascular disease, we propose to conduct a head-to-head comparison of microbial communities (species and strains) between AC5KO and wild-type (WT) mice to reveal whether there are differences that promote longevity and healthful aging (protect against disease states). Male and female AC5KO and WT mice were fed a normal diet and randomly assigned to exercise or sedentary groups. After 6 weeks, animals were sacrificed, and duodenum/ileum and colon tissues were fixed for immunohistochemistry for intestinal inflammatory marker cyclooxygenase-2 (COX-2). DNA extraction, PCR amplification, and data analysis tools (MiniON) were used to compare the microbial communities of the different groups of mice. Following in vitro polarization of AMs, we detected increased levels of YM1/YM2 in the M2a polarized cells compared to the controls. We were also able to find marker differences in subsets of pulmonary macrophages following the seven-day exposure. Using Flow Cytometry and in vitro polarization of AMs, we could conclude that macrophages were expressing predicted markers of polarization. The data collected suggests that subsets within the interstitial macrophages do exist and further research is needed to classify them. Being able to separate the macrophages from the seven-day exposure into interstitial and inflammatory interstitial demonstrates differences between interstitial macrophages in the lungs, which needs to be studied further.

1130 Determining the Bio-Distribution and Efficacy of Limonene in Lymph Cannedul, Immunosuppressed Rats with Colitis

Limonene is a naturally occurring terpene that is an effective solvent for cleaning applications and generally regarded as safe (GRAS) by the US Food and Drug Administration. However, the clinical use of limonene as an anti-inflammatory agent is currently being investigated, specifically for inflammatory bowel disease. While using immunosuppressants aids in reducing inflammatory responses, specific treatment for preventing intestinal fibrosis is still unavailable. The use of a lymph cannulated rat colitis model under various immunologic conditions can aid in understanding the pharmacokinetics and efficacy of limonene. Colitis was induced in healthy Sprague-Dawley (SD) rats and athymic nude rats (RNU) by adding L. casei Dextran Sulfate Sodium (DSS) to the drinking water for a period of 7-10 successive days to induce colitis. All rats were then orally dosed Limonene daily for 7-30 days according to their testing groups: (1) 100 mg/kg; (2) 10 mg/kg; (3) 1 mg/kg; (4) control (vehicle only). A reproducible method of lymph collection was established by surgically cannulating a sampling catheter within the thoracic duct into the cysterna chyli of all the rats. Serum and lymph fluid were collected for biochemical analysis and pathological evaluation with tissues collected for histopathology. Induction of colitis by DSS was confirmed based on clinical and histopathologic signs of ulcerative colitis in each testing group. Differences in tumor necrosis factor (TNF) expression and degree of GI inflammation was evident between SD and RNU rats in the various dose groups. Bioanalysis (LC/MS) of serum and lymph fluids was used to determine systemic exposure of Limonene in groups 1 and 2 for both RNU and SD rats. Group 1 revealed a marked reduction in GI inflammation compared to the other groups not treated with either an increase in their unique microbial species or new species present that are a result of exercise training.

1131 Inflammation-Mediated Pathway in Association with Organochlorine Pesticide Levels in the Etiology of Epithelial Ovarian Cancer

T. Sharma. B. D. Banerjee, and K. Guleria. University College of Medical Sciences and GTB Hospital, Delhi University, Delhi, India.

Epithelial ovarian cancer (EOC) is also one of the hormone dependent cancers and begins with the transformation of cells that comprises the ovaries including surface epithelial cells, germ cells and the sex cord or stromal cells. It has been suggested that endocrine disruption, inflammation, exposure to xenobiotic and subsequent oxidative stress may antagonize ovarian cancer and contribute to its pathogenesis. Pesticides exposure has been found to be associated with a range of
human health problems like immune suppression, cancer, etc. Exposure to environmental chemicals and their improper metabolism is one of the factors causing cytokine imbalance and may trigger inflammatory responses. Hence, the present was designed to assess the risk of EOC by analyzing blood OCPs level, gene environment interaction between OCPs levels and mRNA expression of inflammatory genes (IL-6, TNF-α, NFkB and COX-2) in EOC (cases, n=60) and controls n=60. Quantification of OCP levels was done by Perkin Elmer Gas Chromatograph (GC) equipped with 63Ni selective Electron Capture Detector. mRNA expression of IL-6, TNF-α, NFkB and COX-2 were checked by real time qPCR. Levels of β-HCH, endosulfan-I, endosulfan-II, pp’-DDT, pp’-DDE and heptachlor were found significantly high in cases of epithelial ovarian cancer as compared to control. A significant high mRNA expression of IL-6, TNF-α, NFkB and COX-2 was also observed. While performing the regression model testing, a significant increase in CA-125 level was observed when high mRNA expression of IL-6, TNF-α, NFkB and COX-2 are present with high pesticide levels. Results indicate the plausible role of OCPs and inflammatory pathway genes with the pathogenesis of Epithelial ovarian cancer among north Indian population.

1132 Measuring Traumatic Brain Injury in Rat Models Using Tissue Clearing and 3D Histology

K. Bozelli1, T. Villani2, G. Gardner1, M. Johnson1, and J. Goodman1.
1St. John’s University, Jamaica, NY; 2VisiTek Inc., New Brunswick, NJ; and 3City University of New York, Staten Island, NY.

Traumatic brain injury (TBI) is debilitating trauma with myriad clinical presentations that can persist for years after the initial injury. Early stratification of the injury and treatment of secondary injury are critical to optimize recovery. A cascade of inflammatory responses in the brain following the initial injury contributes to the severity and progression of the damage over time. The calcium-binding protein S100b has been extensively examined for its role in TBI as a biomarker of acute astrogial injury and in addition to a damage-associated molecular pattern. In this experiment, we examined levels of S100b in key areas of rat brains following TBI and in controls using whole-mount immunolabeling paired with reversible, solvent-based tissue clearing, enabling the spatial profiling of S100b as a part of the inflammatory cascade resultant from TBI. Observation of the biomarker S100b using confocal microcopy and 3D reconstruction in relation to astrogial injury in the hippocampus, a critical region of the brain whose increased aggregate of S100b is implicated in several conditions resulting from TBI, allows for the extraction of a significant amount of data from each sample and better visualization when compared to the limitations of traditional 2D histology. Profiling of S100b in 3D will provide an unparalleled, well-rounded understanding of a critical alarmin’s pathway in brain injury. A greater understanding of the role S100b plays in TBI will contribute to the development of more effective therapeutic strategies to mitigate long-term injury from TBI.

1133 Neurotoxicity in Mice Exposed to Diesel Exhaust Particles: Inflammation and Impaired Autophagy

T. Cheng1, Y. Wu1, J. Chao1, H. Cheng1, H. Chuang2, and T. Chen1.
1National Taiwan University, Taipei, Taiwan; and 2Taipei Medical University, Taipei, Taiwan.

Epidemiological and toxicological studies have shown that particulate matter (PM) may induce degenerative diseases on the central nervous system (CNS). However, the underlying mechanisms remain unclear. Therefore, an experiment was conducted to explore the CNS toxicity induced by PM. In the first experiment, 8-week-old male C57BL/6J mice were exposed to diesel exhaust particles (DEPs) by intratracheal instillation (IT) twice within two weeks. DEPs of 300µg (high-exposure group), DEPs of 100µg (low-exposure group), or PBS (control group) were administered. Morris water maze (MWM) test was conducted to evaluate the capacity of spatial learning and memory. Pre-inflammatory cytokines, including IL-6, TNF-α, NFkB and COX-2, were measured using western blot analysis. The escape latency in the high-exposure group was significantly longer than the control group on the fourth day (35.4 vs. 14.2 seconds, P < 0.05, Kruskal-Wallis test). Pre-inflammatory cytokines were also increased in the high-exposure group, including TNF-α, IL-1β in the cerebellum (CE), IL-1β in the SP, the medulla (ME), and the cortex (CO); and IL-1β in the ME and the CO. Further study on autophagy expression showed that LC3-II/L-I ratio decreased in cerebral cortex on the third post-exposure day (p<0.05, Wilcoxon rank sum test). However, beclin-1 was not different between exposure and control groups. Our results showed that acute exposure to DEPs caused poor spatial learning together with increased inflammation in the brain. Further, acute exposure to DEPs may impair autophagy in the cerebral cortex. Our study provides information on the possible mechanisms underlying the PM-related degenerative CNS diseases.

1134 In Silico Cardiomyocyte Action Potential Modeling Using GLP Manual Patch Clamp Inhibition Profiles from CiPA Ion Channels

C. Li1, H. Huang1, V. Jacquemet2, R. Forster1, R. Kubaszky1, and S. Authier1. 1CTiToxLAB, Laval, QC, Canada; and 2Université de Montréal, Montréal, QC, Canada.

The Comprehensive in vitro Proarrhythmia Assay (CiPA) calls for multi-ion channel inhibition profiling using high-throughput screening (HTS) and in silico modeling of cardiomyocyte action potential. This study aimed to apply in silico modeling in ion channel inhibition profiling generated with manual patch clamp under conditions applied for GLP studies. IC50 values for CiPA-related cardiac ion channels (Nav-1.5, Kv4.3, CaV-1.2, hERG, KLOQT1, and Kir2.1) were tested with cisapride (1 µM), terfenadine (1 µM), amiodarone (1 µM) and verapamil (10 µM). HEP 293 cells with stable expression were used in manual whole-cell configuration. The O’Hara-Rudy and ten Tusscher models were applied to manual patch clamp inhibition profiles, and the durations of the cardiac action potentials at 90% repolarization (APD90) were calculated during stable pacing of single cells at 60 bpm. In silico O’Hara-Rudy modeling displayed the greatest level of modulation and, from in vitro inhibition profiles obtained from hERG (cisapride 93%, terfenadine 91%, amiodarone 61%, verapamil 92%), CaV-1.2 (cisapride 67%, terfenadine 65%, amiodarone 46%, and verapamil 35%), and NaV-1.5 (cisapride 40%, terfenadine 33%, amiodarone 30%, verapamil 52%) channels. In silico modeling using manual patch clamp data quantitatively predicted increased action potential duration and QT prolongation. A HTS method was used for CiPA-related in silico modeling. Our results suggest that manual patch clamp inhibition profiles obtained using GLP study conditions can be applied to in silico modeling and quantitatively predicts cardiomyocyte APD changes and consequently QT prolongation. The O’Hara-Rudy model, using the 6 cardiac ion channel currents and their respective IC50 values for CiPA-related cardiac ion channels, was used to model the O’Hara-Rudy model with the ultimate goal to estimate ECG effects. The use of truncated panel (i.e., IC50 or IC50, IC50 only) extensively high the high contribution of IC50 in APD estimation with the O’Hara-Rudy model. When using the ten Tusscher model, APD was predicted to increase with a truncated panel using IC50, IC50 only, only indicating the balance of the ion channel balance in this model. Overall, the ten Tusscher model under-performed the O’Hara-Rudy model for pharmacological estimations of drug effects on APD with a full or truncated ion channel panel.

1135 Organ-on-Chip Technology Recapitulates Thrombosis Induced by an Anti-CD154 Therapeutic Monoclonal Antibody

R. Barrille1, A. D. van der Meer2, H. Park1, J. Fraser1, D. Simic1, F. Teng2, D. Congelio3, J. Nguyen4, P. Ng5, S. Barthakur1, C. Belgru1, M. Zhou3, K. Karalis1, D. E. Ingber4, G. A. Hamilton1, and M. A. Otieno1. 1Emulate Inc., Boston, MA; 2University of Twente, Enschede, Netherlands; 3Jansen Pharmaceutical Research and Development, Spring House, PA; and 4Wyss Institute for Biologically Inspired Engineering at Harvard University, Boston, MA.

Blocking of CD40L-mediated signaling represents a validated therapeutic strategy for treatment of several autoimmune diseases; however, development of therapies against this target was stalled for several years because of unexpected thrombotic and cardiovascular events during clinical development of the anti-CD40L mAb HuScB. These side effects were not detected during preclinical testing. Platelet activation assays have been used to test the hypothesis that thrombosis was caused by binding of HuScB1 or FcγRIIb receptors on platelets. To provide additional confidence in the safety of new anti-CD40L mAbs that are designed not to bind FcγRIIa, a micovessel chip was developed that could capture human-relevant endpoints for detection of coagulopathy, providing a patient-specific platform for safety testing. The micovessel chip includes a vascular channel lined by human endothelial cells and perfused with human whole blood at a physiologically relevant shear rate. Treatment with clinical-relevant concentrations of huScB and CD40L, resulted in endothelial injury and platelet activation, platelet aggregation, fibrin clot formation, and increased secretion of thrombin anti-thrombin (TAT) complex. Conversely, these endpoints were atten-
Cardiac safety is one of the leading causes of late-stage compound attrition in the pharmaceutical industry and accounts for 28% of the safety-related withdrawals of FDA-approved drugs from the market. Current cardiac safety preclinical evaluations are heavily focused on approximately 3-7 main ion channels involved in maintaining the cardiac action potential; however, over 70 different types of ion channels are expressed in the heart and participate in the overall cardiac safety-related withdrawals of FDA-approved drugs from the market. These safety testing methods overemphasize electrophysiologic assessment of cardiotoxicity and fail to evaluate cardiomyopathy and other forms of structural cardiotoxicity. Metabolic perturbations are one of the primary mechanisms underlying the cardiotoxicity elicited by pharmaceuticals. Stemina has developed a novel, marker-based assay for evaluating the cardiotoxicity potential of compounds based on changes in the metabolism and viability of human-induced pluripotent stem cell (hPSC)-derived cardiomyocytes. In this study, we exposed hPSC-derived cardiomyocytes to a training set of 57 compounds and a test set of 12 compounds. The cardiotoxic compounds were broken into three categories: structural, functional, and general (compounds that cause both). Metabolomic analysis of spent media identified a set of predictive biomarkers. The biomarker-based model classified the test set with 86% accuracy and the training set with 86% accuracy, based on comparing the concentration where metabolism was perturbed to the therapeutic Cmax. This assay is an attractive new model that can identify both structural and functional cardiotoxic compounds that could be used in conjunction with CIPA and other endpoints to provide a more comprehensive evaluation of a compound’s cardiotoxicity potential.
**1140 Characterization of hiPSC-Derived Cardiomyocytes Formatted into a Physiologically-Relevant High Throughput Screening Platform**

Current approaches on the study of acute cardiac toxicity and safety have been transformed with the availability of human-induced pluripotent stem cell-derived cardiomyocytes (hiPSC-CM). Cardiotoxicity plays an important role in the failure of therapeutic agents in late stages of clinical trials, as well as in the removal of approved drugs from the market. The Comprehensive in vitro Proarrhythmia Assay (CIPA) constitutes a novel screening proposal intended to replace current regulatory strategies that have failed to predict the acute cardiotoxic effects of developing drugs. Through the CIPA initiative, researchers from diverse organizations such as the FDA, academic institutions, and pharmaceutical companies are evaluating hiPSC-CMs as an integral tool for the preclinical assessment of novel therapeutic compounds. Noteworthy key challenges under consideration for the hiPSC-CM system are sub-cellular morphology, sub-cellular structural organization, and overall electrophysiological maturity. As an example, hiPSC-CMs frequently display undefined or disarrayed sarcomeric organization when plated in standard cell cultureware. We have developed a novel high-density screening platform for hiPSC-CMs that is micro-engineered to emulate correct cardiac muscle fiber organization. This platform allows for passive self-alignment of hiPSC-CMs, leading to improved sarcomeric organization, as seen by readily identifiable, correctly patterned myofibrils along the cell body. Concomitantly, directionality of contraction of hiPSC-CM preparations were observed to be increased in this platform. We also observed increased gene expression of ryr2, atr2a2, and α1b, key components of cardiomyocyte calcium handling pathways, which are crucial for cardiac physiology. The expression levels of cardiac ion channel genes were assessed (such as cacna1c, scnn1a, and cngala1), as well as cardiac cell junction components gja1, gja5, and dsp, also showed an increase. Furthermore, a comprehensive analysis of calcium flux in hiPSC-CMs indicated that hiPSC-CM alignment in this platform influences cardiomyocyte physiology, which can be of great importance for the evaluation of compound cardiotoxicity. Altogether we describe a novel hiPSC-derived cardiomyocyte platform with greater physiological relevance that is pre-formatted to high-throughput screening.

**1141 Non-Rodent Isolated Mature Ventricular Cardiomyocytes for Multi-Ion Channel Inhibition during Proarrhythmia Screening**

H. Huang1, M. Accardi2, R. Forster3, F. Duguay4, and S. Authier1,2.

Multiple ion channel inhibition screening on stable expression cell lines is classically used to assess the effects of compounds on early- and late-action potential properties, largely in the assay development stage. To assess therapeutic potential of novel pharmacological tools in a more physiologically-relevant way, we introduced a model with integrated physiological multi-ion channel expression, primary cardiomyocytes may be clinically relevant. The purpose of this study was to evaluate the effects of ion channel blockers on primary cardiomyocytes and compare their torsadogenic potential among three animal models. HEK 293 cells with stable expression were used in manual whole-cell configuration. IC50 values for ion channels (Na v1.5, K v4.3, Ca v1.2, hERG, K vLQT1, and Kir2.1) were tested with various ion channel blockers TTX (IC50 = 5.4 µM in HEK293) at 5 µM. Multiple ion channel inhibition screening on stable expression cell lines may be considered as a tool in proarrhythmic risk assessment.

**1142 Chronic Antiretroviral Treatment Disrupts Mitochondrial Homeostasis and Induces Mitochondrial Genome Instability to Promote Premature Endothelial Senescence**

Y. Chen1, B. Irving2, and T. Dugas3.

1 School of Veterinary Medicine, Louisiana State University, Baton Rouge, LA; and 3 School of Kinesiology, Louisiana State University, Baton Rouge, LA.

Highly active antiretroviral therapy (HAART) has led to a dramatic reduction in morbidity among the human immunodeficiency virus type 1 (HIV-1) infected patients. However, cardiovascular complications have become one of the most prevalent causes of death among HIV-1 infected patients. Nuclear reverse transcriptase inhibitors (NRTI) are the backbone of HAART. The combination of emtricitabine (FTC) and tenofovir disoproxil fumarate (TDF) is considered a potent co-formulation commonly used in current HAART. NRTI was shown to induce a mitophagy-associated endothelial toxicity. In addition, single-dose NRTI treatment induced endothelial dysfunction and increased reactive oxygen species production after 24 h, which was partially rescued by overexpression of the mitochondrial antioxidant enzyme manganese superoxide dismutase. These findings suggest that mitochondrial oxidative stress is involved in the pathogenesis of NRTI-induced endothelial dysfunction. Mitochondrial dysfunction, including a compromised mitochondrial biogenesis, has a causal role in endothelial senescence that can exacerbate cardiovascular disease development. In this study, we evaluated mitochondrial function and integrity in human aortic endothelial cell after chronic FTC (10 µM) and/or TDF (10 µM) treatment for 2-12 passages. High-resolution respirometry showed that mitochondrial respiration was increased in chronically treated cells, suggesting mitochondrial uncoupling. β-galactosidase staining in NRTI-treated cells demonstrated a higher level of senescence. Western blotting indicated a lower expression of Parkin, a mitophagy modulator, in cells treated chronically with NRTI compared to control cells. Using quantitative PCR, mitochondrial DNA (mtDNA) copy number per cell decreased by 20% after treatment, while mtDNA content decreased in senescent NRTI-treated cells compared to equivalent-passage control cells. Our work suggests that long-term use of NRTI impairs mitophagy and depletes mtDNA, resulting in premature endothelial senescence.

**1143 Assessment of Drug Effects on Cardiomyocyte Function: Comprehensive In Vitro Proarrhythmia Assay (CIPA) Results**

C. T. Bot1, K. Juhasz1,2, L. Polonchuk3, M. Martin Traebert4, N. Fertig5, and S. Stölzle-Feix6.

1 Nanion Technologies Inc., Livingston, NJ; 2 Nanion Technologies GMBH, Munich, Germany; 3 Technische Universität München, Munich, Germany; 4 Roche Pharma Research and Early Development, Basel, Switzerland; and 5 Novartis Pharma AG, Basel, Switzerland.

The ongoing comprehensive in vitro pro-arrhythmia assay (CIPA) initiative aims to improve drug safety testing and help more beneficial chemical entities reach the market. The project consists of three main parts, which include 1) electrophysiological investigation of drug effects on human ventricular ion channels, 2) characterization of the in silico cardiotoxicity model predictions, 3) assessment of discrepancies and gaps in fully integrated biological systems (human-induced pluripotent stem cell-derived cardiac myocytes (iPSC-CMs)) and the human ECG). To assess and validate drug effects on hiPSC-CMs in a combined measurement of cardiac excitation and contraction, a subset of compounds which are part of the Phase II CIPA study were tested. A prospective comparison study using combined extracellular field potential (EFP) and impedance technology was conducted across 4 independent laboratories testing 12 reference compounds in 4 independent commercially available hiPSC-CMs. Our data demonstrate that NRTI channel blockers, such as Tatalol and Dofetilide, prolonged field potential duration (FPD) at low concentration and induced arrhythmias as measured by field potential (FP) recording and impedance (IMP) recordings at higher concentrations. The cross-cell comparison displayed different minimal effective concentrations regarding FPD prolongation and cessation of beating. On the contrary, Diltiazem, a calcium channel inhibitor, weakened cell contractile activity and shortened FPD. Multichannel inhibitors, such Quinidine, increased FPD, weakened the contraction force, and induced arrhythmia. Furthermore, validation on low-risk proarrhythmia compounds such as Tamperil and Verapamil and intermediate-risk compounds such as Cisapride and Cholpomazine will be presented. Comparison of the compound effects across the 4 different sites showed the consistent trend of the effect. Taken together, commercially available hiPSC-CMs, in conjunction with combined measurements of ion channel activity and contracility, is a reliable approach for risk assessment of proarrhythmic compounds.
Adult cardiac stem cells (CSC) and progenitor cells (CPC) represent a population of cells in the heart critical for its regeneration and function over a lifetime. The impact of chemicals on adult human CSC/CPC differentiation and function is unknown. Research was conducted to develop an improved assay to assess the impact of chemicals on CPC differentiation and function [3]. CPCs (Cellular Dynamics International), as well as adult-like cardiomyocytes (CM) from murine heart were present in the Biowire™ II tissues. Isoproterenol, a β2-adrenergic receptor agonist, elicited a 7- to 10-fold increase in contractile force. The Biowire™ II tissues displayed adult-like electrical, calcium handling, and contractile function of the Biowire™ II tissues, as well as mature neurovasculature with elevated numbers of perivascular supporting cells. The models were used to screen a library of 38 chemicals with a range of predicted adverse effects on vascular and neural tissue function. Chemicals that facilitated significant changes in total endothelial network area and area overlap between EC and either PC or AC were categorized as “hits” after fluorescent image analysis. The chemicals were assigned low, medium, high, and critical priorities based on the repeatability and magnitude of their effects on EC, PC, and AC behavior over multiple replicates. The highest-priority chemicals were further characterized through multiple measurements of fluorescent images, including EC network area, EC network protrusions, PC/AC area, and PC/AC overlap with EC networks. Dose-response curves generated from these data have demonstrated expected behavior based on the initial chemical screen scores. These were consistent with similar measurements found in the EPA ToxCast™ database. These models promise to identify critical cell types that are affected by chemical exposure, and facilitate the discovery of adverse outcome pathways that compromise the integrity of the neurovasculature.

Heart Failure (HF) can be induced by a range of factors, including genetics and acquired risk factors. It can also be an unwanted consequence of HF drug discovery and cardiac safety testing. The ability of CPC to differentiate into functional CM. This adverse effect may impact the heart in terms of susceptibility to disease and longevity. This abstract does not represent US EPA policy.

Heart Failure (HF) can be induced by a range of factors, including genetics and acquired risk factors. It can also be an unwanted consequence of HF drug discovery and cardiac safety testing. The ability of CPC to differentiate into functional CM. This adverse effect may impact the heart in terms of susceptibility to disease and longevity. This abstract does not represent US EPA policy.
Ginseng and its major active ingredients, ginsenosides, are widely consumed for various health problems including cancer without a special precaution. Previously, we demonstrated that Rg3, one of the ginsenosides with a potent anticancer activity, may cause contractile dysfunction, and structural damage on vascular smooth muscle through apoptotic cell death. However, the mechanism underlying Rg3-induced vascular toxicity was not fully elucidated. Here we demonstrated that the vascular toxicity of Rg3 occurs through actin disruption and Bmf-initiated mitochondrial apoptotic pathway, the mechanism which may contribute to its anticancer effects. In rat primary vascular smooth muscle cells, Rg3 induced apoptosis and contractile dysfunction as determined by caspase-3 activation, TUNEL staining, and insufficient myosin light chain phosphorylation. Rg3 induced actin degradation with Rho A inactivation, which was followed by mitochondrial translocation of Bmf and dissociation of mitochondrial membrane potential (Δψ). Pre-treatment of jasplakinolide, an inhibitor of actin polymerization, significantly blocked Rg3-induced q dissipation and apoptosis. Notably, Rg3 induced actin disruption in hepatoma cell line, HepG2, which could be reversed by jasplakinolide, reflecting that the same mechanism may contribute to the anticancer effects of Rg3 at least in part. Collectively, these results demonstrated that Rg3 may induce vascular toxicity as well as anticancer effects through disrupting actin, which may alert the potential toxicity associated with inadvertent use of ginseng and its products.

1100 Myricetin as an Effective Protectant against Anthracycline-Induced Cardiotoxicity

P. Lum1, K. Kim1, L. Pham2, G. Huang2, A. Magal2, T. Freeman1, R. Gadkari2, C. Armstrong2, S. Elmer1, H. Chang1, and A. Protter1.

1Capella Biosciences, Palo Alto, CA; and 2Stem Cell Theranostics, Redwood City, CA.

Toxic side effects of anticancer drugs are increasingly generating concerns for the US FDA, patients, and researchers. One of the most critical side effects is cardiotoxicity caused by anthracyclines, a class of efficacious chemotherapy drugs that has been used for over 50 years as part of combination therapies to treat various types of cancer. Approaches to predict anthracycline-induced cardiotoxicity have included limiting lifetime cumulative doses, using less cardiotoxic analogs, and optimizing delivery strategies, which are at best, only partial solutions. A potentially more promising approach for reducing cardiotoxicity has been to supplement anthracycline treatment with cardioprotectants. The only clinically approved cardioprotectant is dexrazoxane, which is approved for use only in advanced or metastatic breast cancer patients. Novel cardioprotectants with improved efficacy and safety profiles not only have the potential to significantly reduce drug-induced cardiotoxicity risk, but could also enable higher anthracycline dosing and expanded usage for patients who are excluded from anthracycline therapy due to pre-existing cardiac issues. To this end, we have applied a data-driven algorithmic approach to identifying compounds that could mitigate anthracycline-induced cardiotoxicity and tested the compounds in human iPSC-derived cardiomyocytes. Using this approach, we identified members of the flavonoid class of polyphenolic compounds as having varying degrees of cardioprotection capabilities. Specifically, we identified myricetin as one of the most effective cardioprotectants that mitigated anthracycline-induced cardiotoxicity without interfering with its anticancer activity. Treatment of myricetin provided protection against doxorubicin-induced cardiomyopathy both in human iPSC-derived cardiomyocytes and a mouse model. Ejection fraction and fractional shortening were rescued with the co-dosing of myricetin with doxorubicin in mice. Mechanism of action of myricetin is likely to be in synergy with doxorubicin, reversing expression of genes and pathways that are impaired by doxorubicin in the cardiomyocytes such as hypoxia, oxidative stress, and mitochondrial health. We show that myricetin likely exerts its protective capability in a novel way by binding to TOP2B, in contrast to dexrazoxane, which decreases the protein level.

1149 Adult Human Stem Cell-Derived Cardiomyocytes: An Alternative Model for Evaluating Chemical and Environmental Pollutant Cardiotoxicity

K. Dreher1, V. Long2, and C. Lau1. 1US EPA, Research Triangle Park, NC; and 2Oak Ridge Institute for Science and Education, Oak Ridge, TN.

Heart disease is increasing globally, with a significant percentage of the increase being attributed to chemical and pollution exposures. Currently, no alternative or in vitro testing models exist to rapidly and accurately determine the cardiac effects of chemicals and/or pollutants. This research addresses this need by employing stem cell technology to evaluate the cardiotoxicity of chemicals and pollutants. Adult human stem cell-derived cardiomyocytes (SC-CM) were exposed to either saline or DMSO vehicle, extracts derived from residual oil fly ash (ROFA) or diesel exhaust particles (DEP) at 1-20 µg/ml, suspension of Ag 10 nm nanoparticles (NP, 3 or 6 µg/ml), perfluoroalkyl substances (PFNA, PFOS, PFBS, PFHxS, 25 - 100 µM), or tricosan (TCS, 2.5 - 10 µM) and monitored for viability, beat rate (BR), beating amplitude (BAMP), and beat rate irregularity (BRI) at 0.5, 24, and 48 hr of exposure using the xCELLigence RTCA Cardiac platform (ACEA Biosciences). All SC-CMs cultures were challenged with isoproterenol (ISO) after 48 hr of exposure. No chemical or pollutant examined affected SC-CM viability. ROFA and DEP extracts had no effect on SC-CM BR, BAMP, or BRI. ROFA and DEP extracts inhibited ISO stimulation of SC-CM BR and BAMP, respectively, in a dose-response manner. Ag NP induced a sustained 15% and 30% decrease in SC-CM BR and BAMP at 3 µg/ml, respectively. PFNA exposure induced an immediate and significant dose-dependent change in SC-CM BR and increase in BRI up to 24 hr of exposure while inhibiting ISO stimulation of SC-CM in a dose-dependent manner. PFOS induced an immediate and significant dose-dependent response in SC-CM BRI over the 48-hr exposure period. TCS exposure induced an immediate increase in SC-CM BR and decrease in BAMP over 48 hr of exposure. TCS inhibited ISO stimulation of SC-CM in a dose-dependent manner. These data demonstrate that adult human SC-derived CMs are a viable scalable alternative for in vitro testing model to assess a variety of chemicals and environmental pollutants for cardiotoxicity at low concentrations. This model evaluates critical cardiac physiological endpoints that are easily translatable to animal and human studies. This abstract does not represent US EPA policy.

PCB126 Induces Monocyte/Macrophage Polarization and Inflammation

C. Wang, M. C. Petriello, and B. Hennig. University of Kentucky, Lexington, KY.

Polychlorinated biphenyls (PCBs) are persistent organic pollutants that can contribute to a range of adverse health effects, including inflammatory diseases such as atherosclerosis, which involves macrophages. Although many cells are involved in the initiation and progression of atherosclerosis, macrophages play a key role in the overall inflammatory response and lipid deposition. We hypothesize that dioxin-like PCBs can contribute to monocyte/macrophage polarization and macrophage inflammation. To test this hypothesis, monocytes (THP-1) were differentiated to macrophages, and subsequently exposed to PCB 126. Inflammatory cytokines and genes associated with oxidative stress (e.g., Nrf2 signaling) were studied. Exposure to PCB 126 increased the expression of inflammatory cytokines, such as TNF-α, IL-1β and IL-6, suggesting polarization to the M1 phenotype. In addition, the monocyte chemoattractant protein-1 ( MCP-1) was expressed in PCB-activated macrophages, suggesting induction of chemokines, which regulate immune cell recruitment and migration and infiltration of monocytes/macrophages into vascular tissues. Furthermore, nuclear factor (erythroid-derived 2)-like 2 (Nrf2) and downstream genes, such as glutathione S-transferase (GST) and NAD(P)H quinone oxidoreductase 1 (NQO1), were induced following PCB exposure, indicating induction of xenobiotic-linked defensive mechanisms. Our data demonstrate the involvement of PCB 126 in monocyte/macrophage polarization and inflammation, suggesting another important role of dioxin-like PCBs in the pathology of atherosclerosis. These data have translational implications, suggesting that a compromised cardiovascular system may be able to modulate vulnerability to environmental insults. Supported in part by NIH/NIEHS grant P42ES007380.
Phenotypic Profiling in Human-Based Phenotypic Assays Supports an AOP for CV Toxicity

E. L. Berg, and A. E. Folias. Discoverx, South San Francisco, CA.

Data mining of a large reference database containing drugs, experimental chemicals, and other agents profiled in a human primary cell-based systems has been used to discover novel associations and mechanisms of toxicity associated with certain adverse events. These include acute toxicity, organ toxicity, liver toxicity, skin rash, skin sensitization, and thrombosis-related side effects. Using this approach, an in vitro signature for cardiovascular toxicity comprised of increased cell surface levels of serum amyloid A (SAA) measured in a coronary artery smooth muscle cell-based model of vascular inflammation (BiMAP CASM3C system) was found and was associated with MEF, HDAC, GR/MR, IL-6, pathway, and SIRT1. Since SAA is a clinical biomarker associated with risk of cardiovascular disease in humans, to further understand the regulation of SAA, we performed data mining in the same assay system to identify those agents that reduce the level of SAA. Agents were selected if treatment with that agent for 24 hours at two or more concentrations decrease the cell surface level of SAA without causing overt cytotoxicity. Fewer than 1% of agents in the database were found to decrease level of SAA relative to vehicle control at two or more tested concentrations and with an effect size of ≥ 20% (33/3,800). Notable agents that met these criteria include GLP-1, an endogenous peptide developed as a drug used for treatment of diabetes, roflumilast, a PDE IV inhibitor used for the treatment of chronic obstructive pulmonary disorder, the BCR-Abl inhibitor and oncology drug, imatinib, and a mimetic of ApoA-1, the major lipoprotein of HDL. These represent agents that have been shown to have cardiovascular protective effects in clinical or in vivo studies (some within their class). These results, showing that decreased cell surface levels of SAA in this human primary cell-based phenotypic model are associated with beneficial cardiovascular outcomes, along with the previous finding that increased levels of SAA are associated with cardiovascular toxicity, support the construction of an adverse outcome pathway for cardiovascular toxicity.

1153 Contractility Assessment in Conscious Rats and Guinea Pigs: Comparison from Whole Heart to Whole Body

B. M. Roche, and J. Ross. Charles River Laboratories, Ashland, OH.

Since the inception of ICH S7 B, no drug has been removed from the market for the development of a fatal ventricular polymorphic arrhythmia, Torsades de Pointes. However, drug-induced cardiotoxicity remains a leading cause of drug attrition early in the drug development process, for changes in myocardial contractility needs models that are translatable to the clinical outcome that require minimal amounts of test article. The objective of the study was to evaluate the effects of of ICR isolated guinea pigs (50 mg/kg, SQ) was assessed per the NIST ACM standard as repeatability standard deviation. Rate automated interval detection. Interval measurement repeatability was assessed by average reduction in rSD of 27.4% on the treatment change and drug-related changes in T-wave morphology as assessed by average reduction in rSD of 27.5ms for Lead II and at 30.0 and 33.9ms for sM lead, respectively. Our results demonstrate that a single Lead II ECG is adequate for assessing QT interval prolongation, but may produce different and more variable results for assessment of JTp interval relative to the sM lead derived from multiple ECG lead measurements.

Speckle Tracking with Semi-Automated Strain for Cardiac Contractility Assessments in Dogs, Minipigs, and Non-Human Primates

R. Kubaszy, R. Forster, and S. Authier. CiToxLAB, Laval, QC, Canada.

M-Mode presents significant limitations owing to the unidimensional rectilinear approach with high risks for variations due to changes in ultrasound probe angle. Speckle tracking imaging enables semi-automated contractility evaluation of the entire ventricular circumference with segmental ventricular analysis as well as global integrated contractility assessment. The goal of this study was to demonstrate the performance of this methodology in dogs, minipigs, and non-human primates in the context of drug safety assessment. Echocardiography with speckle tracking imaging was performed on Beagle dogs, Göttingen minipigs, and cynomolgus monkeys at baseline and after pimobendan and itraconazole administration. Dogs and minipigs were evaluated with the right parasternal short- and long-axis views in right lateral decubitus. The transducer (Siemens 4v1c probe) was used for 2D and 3D video image acquisition. Electrocardiogram was taken for systole and diastole for calculation of heart rate, displacement, and stress (peak and time to peak). In dogs, endocardiac circumference strain per ventricular segment for the middle anterior, middle inferolateral, and middle inferoseptal segment were the most stable with the lowest standard deviations at baseline (SD<11%). To assess the evolution of measures with time, the first and last acquisition of multiple sessions were compared, and results showed a non-significant trend toward lower variability at the first capture. Respectively, pimobendan and itraconazole were associated with increased and decreased circumferential endocardiac strain rate at the expected Tmax. As expected, the average of repeat measures showed lower variability than single-cycle measures. Interestingly, standard deviation values were animal dependent, with some animals presenting consistently lower or higher variability than others. The linear proportional correlation for paired standard deviation values between two observers was R2=0.948, supporting a strong animal dependence for variability. In conclusion, the comparison with strain measurements could be considered to assess global or segmental effects on ventricular contractility in non-rodent species, and the average of repeated measures can be used to increase assay sensitivity.

Comparison of QT and JTp Derived from Spatial Magnitude vs. Single-Lead ECG in Beagle Dogs

R. Brockway1, M. Brockway1, B. Brockway1, and R. L. Hamlin2.

1VivaQuant, Shoreview, MN; and 2QTest Labs, Columbus, OH.

The US FDA has recently laid the groundwork for the potential use of J to T-peak (JTP) interval as a biomarker of cardiac arrhythmia liability in human subjects. Johannesen et. al. demonstrated that global JTP is superiour to a number of other biomarkers. As a result of FDA interest in this area, interest in preclinical evaluation of JTP has grown. Preclinical studies often acquire a single-lead ECG, whereas FDA measurements of JTP were derived from a vectorcardiogram (e.g., spatial magnitude) computed using multiple leads. This study compares JTP from a single lead with JTP derived from a spatial-magnitude (sM) ECG. Four beagle dogs were instrumented with 3-lead Holter monitors to acquire continuous surface ECG recordings for three consecutive days. A 24-hour baseline recording was obtained on day 1. On day 2, dogs were given dofetilide (40 mg/kg orally). On day 3, dogs were administered atropine (0.044 mg/kg SQ) followed by dofetilide (40 mg/kg orally) 30 minutes later. The published transform (Hamilin 1960) was used to derive the sM ECG from the 3-lead Holter recordings. The Lead II and sM ECGs were automatically analyzed using the AE-1010 Rhythm Express software (VivaQuant, St. Paul, MN) without manual intervention or editing of the results. The software has been shown to remove up to 95% of in-band noise without distorting ECG morphology and facilitate accurate automated interval detection. Interval measurement repeatability was assessed per the NIST ACM standard as repeatability standard deviation (rSD). JTP and TpTe measured from sM ECG are more robust to changes in posture and drug-related changes in heart rate as demonstrated by average reduction in rSD of 27.5% on the treatment days. Maximum prolongation of QTc and JTP was detected at 22.7 and 25.7ms for Lead II and at 30.0 and 33.9ms for sM lead, respectively. Our results demonstrate that a single Lead II ECG is adequate for assessing QT interval prolongation, but may produce different and more variable results for assessment of Jtp interval relative to the sM lead derived from multiple ECG lead measurements.

Proposed QT-Interval Correction Method for the Influence of Changes in Core Body Temperature Based on Circadian Variations in Conscious Non-Restrained Cynomolgus Monkeys

QT interval lengthening may be related to the inhibition of the hERG channel, decrease in heart rate, or decrease in core body temperature (BT). To discriminate between these causes, QT correction formulas are available for drug-induced changes in BT in several animal species, but no correction formula has been proposed for conscious non-restrained cynomolgus monkeys. This may be especially important for drugs acting on the central nervous system and known to induce at least transient changes in BT in standalone safety pharmacology investigations or
integrated safety pharmacology studies within regulatory toxicology studies in monkeys. In the present study, physiological changes in QT interval duration and BT during dark and light periods were continuously recorded over 26 hours by telemetry in 22 freely moving telemetered monkeys. The relationships between the duration of QT, QTcB (Bazett) or QTcF (Fridericia’s formula) and BT were evaluated. BT ranged from 29.4°C to 31.4°C, with a mean of 30.4°C. For QT, QTcB, and QTcF intervals were 219 ± 25, 250 ± 18, and 293 ± 20 ms, respectively. Plotting QT, QTcB, and QTcF individual values against BT produced linear regressions described as Y = 27X + 125, Y = 15X + 911, and Y = 21X + 1075, respectively. A body temperature value of 38°C for conscious telemetry data was assumed to be normal in monkeys. It was used to correct the duration of QTcB and QTcF intervals for changes in BT: QTcBcT = QTcB - 158 (BT) and QTcFcT = QTcF - 178 (BT). When plotting QTcBcT and QTcFcT individual values against BT, horizontal regression lines were obtained, Y = 0.076X ± 341, Y = 0.349X ± 277, respectively. These results suggest that physiological changes in animals are induced by changes in BT during QTc interval duration. Dark and light periods may be used to estimate QT correction for the influence of drug-induced changes in BT. The correction method should be based on potential effect on heart rate. To confirm the accuracy of these formulas, additional investigations using a larger range of changes in BT are needed. This method is associated with an independent QT correction for BT. Validation of these correction formulas with appropriate reference pharmacological tools in conscious non-restrained cynomolgus monkeys is also required.

**1157 Protective Effect of Dimethyl Fumarate on Diabetic Cardiomyopathy Possibly via Nrf2 Pathway in Type 1 Diabetes Mice**

X. Hu1,2, R. Mohanraj3, Y. Zheng2, and L. Cai1.1 University of Louisville School of Medicine, Louisville, KY; 2The First Hospital of Jilin University, Chang Chun, China; and 3United Arab Emirates University, Maqam, United Arab Emirates.

Oxidative stress and inflammation play key roles in the development of diabetic cardiomyopathy (DCM). We have extensively shown the protective effect by inducing endogenous nuclear factor erythroid 2-related factor 2 (Nrf2) pathway against DCM. Dimethyl fumarate (DMF), an FDA-approved medicine for relapsing multiple sclerosis, has manifested its antioxidant and anti-inflammatory function mostly in the neurotic system. Here we repurpose the use of DMF for testing whether it possesses protective effects on heart disease, and whether it is associated with Nrf2 activation. Method: Type 1 diabetes mouse model was induced using multiple low doses of streptozotocin. DMF or vehicle treatment was given to the mice for 3 months. Blood glucose and body weight were measured regularly throughout 3 months. Cardiac functions were detected by echocardiography. After the animals were sacrificed, the heart weight and tibia length were measured. Cardiac tissues were used for western blot analysis (to quantify target proteins such as 3NT, 4HNE, TNP-α, PAI-1, TGF-β, and CTGF). Real-time PCR (on the RNA transcription levels of genes such as ho-1, nqo-1, cat, and sod-1) and Sirius Red staining were performed to semi-quantitatively calculate collagen accumulation. We demonstrated that diabetic mice showed evident diabetes-induced cardiac dysfunction and structural damage compared to the control group, whereas DMF significantly reduced oxidative stress, inflammatory reactions, and remodeling changes in the heart of diabetic mice, resulting in a prevention of cardiac dysfunction. Furthermore, DMF increased activation of Nrf2 and its downstream phase II antioxidant detoxifying genes. These findings suggest that DMF may be potentially applied in clinics for DCM prevention and treatment, most likely through activation of the Nrf2 antioxidant pathway.

**1158 The Effects of Inhaled Traffic-Generated Pollutant Exposure on Angiotensin II Receptor Expression and Blood-Brain Barrier Integrity in Wildtype Mice on Either a High- or Low-Fat Diet**

U. Suwannasual1, J. Lucero1, J. D. McDonalda2, and A. K. Lund1.1 University of North Texas, Denton, TX and 2Lovelace Biomedical Research Institute, Albuquerque, NM.

Exposure to traffic-generated air pollution has been shown to be a risk factor in cerebrovascular disorders, including stroke, which may be associated with decreased blood-brain barrier (BBB) integrity and permeability. We have previously reported subchronic inhalation exposure to a mixture of diesel and gasoline engine emissions (MVE) promotes BBB disruption in C57BL6 mice on a high-fat diet. While the mechanisms involved have not been fully elucidated, one signaling pathway that has been reported to alter BBB integrity is angiotensin (Ang) II signaling mediated via the Ang II type 1 (AT1) receptors. Thus, we tested the hypothesis that inhalation MVE exposure mediates increased Ang II production and AT1 receptor expression in the cerebral microvasculature of C57BL6 mice, which is exacerbated by consumption of a high-fat diet. 3-month-old male C57BL6 mice on a high-fat (HF, 21% fat) or low-fat (LF, standard chow) diet were randomly assigned to be exposed by whole-body inhalation to either filtered air (FA) or MVE: 70 µg PM/m³ diesel exhaust + 30 µg PM/m³ gasoline exhaust for 6 h/rd for 30d. Treatment with the sodium fluorescein (Na-F) showed a 3-fold increase in Na-F transport from the systemic circulation into the brain parenchyma in MVE+HF animals, compared to MVE+LF or FA+LF controls, indicating increased BBB permeability. This alteration in BBB permeability was associated with a significant increase in plasma Ang II (2-fold) and induced expression of AT1 receptors. Induced expression of AT1 receptors (~20%) in the cerebral microvasculature of MVE+HF C57BL6 mice. Additionally, tight junction protein claudin-5 expression significantly reduced in the cerebral microvasculature of MVE+HF mice, as determined by immunofluorescence. In an in vitro BBB model, when treated with plasma from the study animals, the TEER increased (~30%) in transendothelial electrical resistance (TEER) measurements and TJ protein expression in the endothelial cells treated with plasma from MVE+HF animals, compared to FA+HF controls. Such findings indicate that inhalation exposure to traffic-generated pollutants, combined with a high-fat diet, results in altered BBB integrity, which may be mediated, in part, through Ang II - AT1 signaling.

**1159 Electrophysiological Assessment of Cardiac Conduction in Chronic Diabetic Minipigs**

A. Stricker-Krongrad, J. Liu, and G. Bouchard. Sinclair Research Center LLC, Auxvasse, MO.

Abundant evidence shows that patients with type 1 diabetes are at high risk for several cardiovascular disorders: coronary heart disease, stroke, peripheral arterial disease, cardiomyopathy, and congestive heart failure. Our objective was to assess potential cardiac electro-cardiovascular changes linked to chronic insulin-dependent diabetes in the Yucatan miniature swine. Type 1 diabetes was induced in Yucatan minature swine, and animals were maintained on a daily insulin regimen for 3 to 6 years (total N = 22). Diabetic animals were divided into different groups based on duration of diabetes (Group 1: normal; Groups 2, 3, and 4: diabetes duration of 3-4, 4-5, 5-6 and >6 years, respectively). Cardiac electrophysiological parameters were acquired in conscious diabetic and normal control animals using a standard lead II configuration. Routine measurements of electrocardiograms, including HR (bpm), RR, PR, QRS, QT, and QTc, were done (all in msec). A heart rate correction for the QT interval (QTc) was calculated using the Fridericia method [QTc=QT/(cubed root of RR)]. Mean heart rate was increased for the diabetic Groups 2, 4, and 5 compared to the mean heart rate for normal animals (52, 54 and 54 versus 75 bpm, respectively). The mean PR interval was increased in all diabetic animals compared to normal animals, and the effect increased with the duration of diabetes (132 versus 138, 140, and 172 msec for Groups 1, 2, 3, and 4, respectively). The mean QRS interval was increased for all of the diabetic animals compared to normal animals (47 versus 56, 66, and 64 msec for Groups 1, 2, 3, 4, and 5, respectively). There were no pronounced QTc abnormalities in this study when comparing diabetic to the normal animals, although one animal in Group 3 did have a QTc prolongation of 43 msec. In addition, one animal in Group 5 had a prolonged PR segment (224 msec) associated with frequent ventricular escape complex. This abnormality in rhythm would possibly go along with the duration and severity of the diabetes. In conclusion, chronic diabetes in Yucatan miniature swine manifests with progressive effects on HR, QRS, and QT duration. This indicates that the diabetic minipig could provide a good model to test preventative approaches for progressive cardiac therapies in diabetes, using electrocardiography segments as markers of early heart damage.

**1160 Inhibition of p53 Prevents Diabetic Cardiomyopathy by Preventing Early-Stage Apoptosis and Cell Senescence, Reducing Glycolysis, and Impaired Angiogenesis**

J. Gu1, S. Wang2, H. Guo1, Y. Tan1, C. Zhang1, and L. Cai1.1 University of Louisville, Louisville, KY; 2The First Hospital of Jilin University, Chang Chun, China; and 3Wenzhou Medical University, Wenzhou, China.

Elevated tumor suppressor p53 expression has been associated with heart diseases, including the diabetic heart. However, its precise role in the pathogenesis of diabetic cardiomyopathy (DCM) remains unclear. We hypothesized that the development of DCM is attributed to upregulated p53-mediated both early cardiac cell death and persistent cell...
Mitochondrial morphology was assessed with transmission electron microscopy, and mitochondria isolated from freshly obtained left ventricular tissue were used to measure respiration rate with an XF96 Extracellular Flux Analyzer and susceptibility to mitochondrial permeability transition pore (mPTP) opening in a swelling assay. To determine whether antioxidant treatment could alter any of the effects of radiation, rats were treated with gamma-tocotrienol 24 hours before irradiation. Two weeks after local heart exposure to both a single dose and fractionated radiation, cardiac mitochondrial showed alterations in shape, function, and an increased susceptibility to mPTP opening. When local heart irradiation was combined with daily suntinib for 2 weeks, mitochondrial alterations were more severe than after each treatment alone. While gamma-tocotrienol pretreatment reduced the effects of radiation on cardiac mitochondria, long-term changes in cardiac function and collagen deposition were not altered. In conclusion, local heart irradiation and TKI treatment may worsen each other’s effects on cardiac mitochondrial morphology and function. The role of mitochondrial alterations in cardiac toxicity of cancer treatment is not yet fully understood.

Sex is one of the risk factors in development of cardiotoxicity induced by an anticancer drug, doxorubicin (DOX). In a mouse model developed in our laboratory, adult male hearts showed a greater susceptibility to DOX toxicity compared to females as cardiac lesions were observed only in male mice at 18-27 mg/kg cumulative doses. The left atrium was more vulnerable to DOX toxicity than the right atrium or ventricular myocardium in male mice. DOX toxicity was more pronounced in male mice than in female mice, whereas kidney and liver toxicity were similar in both sexes. Our study suggests that sex is a significant factor in determining the susceptibility to DOX toxicity and underscores the need for sex-specific approaches in the development and optimization of anticancer treatments.

Although epidemiological, human, and animal data have conclusively linked air pollution exposure to adverse cardiovascular outcomes, the severity of the response depends on a number of intrinsic (diet, underlying disease, etc.) and extrinsic (e.g., co-stressors) factors. As such, cardiovascular function is maintained by adequate levels of certain essential micronutrients like vitamin D. Unfortunately, vitamin D deficiency (VDD) has become highly prevalent in the United States, as well as in the world, even affecting otherwise healthy individuals. We previously showed that VDD worsens cardiac arrhythmias and causes autonomic imbalance in mice exposed to acrolein, which is a ubiquitous gaseous air pollutant. A number of studies suggest that vitamin D exerts its effects in the body through a putative anti-aging protein called klotho, which is reduced in VDD. Thus, the purpose of this study was to determine whether klotho treatment would ameliorate the acrolein-induced effects due to VDD. We hypothesized that klotho would decrease arrhythmogenesis and autonomic imbalance during acrolein exposure. Three-week old mice were placed on a VDD or normal diet (ND) for 19 weeks and treated with 1 mg/ml klotho (intraperitoneally) every other day for a month starting at 18 weeks of age. Mice were implanted with radiotelemeters for the measurement of heart rate (HR), electrocardiogram, and heart rate variability (HRV) and allowed 7-10 days to recover from surgery. Mice were...
exposed to filtered air and then acrolein for 3 hours on each separate days. HR and HRV were significantly decreased during acrolein exposure in VDD mice when compared to ND; this response was blocked by klotho treatment. Although arrhythmias were observed in VDD mice treated with klotho during exposure, there was no difference from ND. Acrolein exposure also caused a significant decrease in tidal volume and increase in ventilatory timing (i.e., airway irritation) in VDD mice, which was blocked by klotho. In conclusion, VDD appears to modify the cardiopulmonary response to air pollution through a mechanism involving klotho. Although additional studies are needed to verify these findings, these data suggest klotho treatment could potentially lessen the effects of air pollution in people with VDD. This abstract does not reflect US EPA policy.

**1165 Organophosphate (OP) Toxicity Model in Female Mice: Cardiac Treatment Paradigms**

J. F. Machi, R. Schmidt, L. Salgueiro, N. Klimas, and M. Morris; Nova Southeastern University, Fort Lauderdale, FL.

Gulf War Illness (GWI) is a long-lasting, multi-symptom disorder with features characteristic of a “sickness” behavior. It is strongly tied to the military, particularly to male cohort. However, there are important questions as to how females respond to GWI and how they might be treated. We have developed a chemical toxin protocol that uses DFP (diisopropyl fluoroophosphate) to elicit a syndrome with features similar to GWI. The aim is to use this model in female mice to study the cardiovascular profile using ECHO and to test the role of Tumor Necrosis Factor alpha (TNF-α) using a biological inhibitor (Enbrel). Protocol: Female mice were divided into four groups: control (C), ovariec-tomized (OVX), DFP (OVX+DFP), and OVX+DFP+Enbrel (OVX+DFP+E). The rationale for use of OVX animals is to provide a situation in which cycling of the sex steroids is absent, similar to the male condition. GWI was induced by combined treatment with corticosterone (200 mg/l) followed by DFP exposure (1.5 mg/kg, s.c.). Enbrel (10 mg/Kg/p.o) therapy was administered 2 weeks after DFP. DFP exposure increased end systolic area (ESA). Enbrel produced amelioration of the toxic change produced by DFP (C: 6.00±0.30; OVX: 7.85±0.32; DFP: 11.62±0.70; DFP+E: 6.73±0.39). Systolic function, evaluated by ejec-tion fraction (EF), was reduced in all DFP groups after exposure and remained reduced in the last evaluation in DFP group but not DFP+E (C: 85.21±1.47; OVX: 80.49±1.49; DFP: 58.02±2.66; DFP+E: 84.28±1.70). Fraction Shortening (FS) and Cardiac Output (CO) were reduced after DFP exposure; however, after therapeutic the DFP+E group shows enhanced shortening (C: 25.39±0.76; OVX: 22.77±1.09; DFP: 16.1±1.05; DFP+E: 25.02±1.32, and CO increased (C: 17.71±0.99; OVX: 18.32±1.03; DFP: 13.06±3.34; DFP+E: 20.1±1.14). Systolic function recovery and fractional recovery of EF. Finally, myocardial performance index (MPI) was significantly increased in DFP exposure mice and re-established in Enbrel group after drug ther-apeutic trial (C: 0.35±2.008; OVX: 0.334±0.008; DFP+Enbrel: 0.419±0.01; DFP+E: 0.315±0.009). Results demonstrate that DFP exerts a negative impact on cardiac function in female mice, while Enbrel prevents most of the dys- functions produced by DFP. This suggests that a therapeutic trial could be a feasible strategy for treatment of veterans with GWI.

**1166 Bisphenol A and Phthalates Escape from Medical Devices and Induce the NLRP3 Inflammasome in Murine Cardiac Infarcts and Suture Wounds**

L. Chalifour1, J. Shahg2, J. Corriev3, J. Gagnon2, P. Dumus2, and A. Leblanc4; 1Lady Davis Institute/McGill University, Montreal, QC, Canada; 2Lady Davis Institute, Montreal, QC, Canada; 3Jewish General Hospital, Montreal, QC, Canada; and 4INSPO, Quebec, QC, Canada.

Most medical devices, including perfusion pumps, catheters, and IVs, have plastic parts. Yet it is unclear how much of the incorporated bisphenol or phthalates escape into patients or whether any exposure modulation contributes to wound healing. To define exposure, we quantified the metabolites of 6 bisphenols and 10 phthalates in 9 men before, and immediately after, cardiac surgery. Exposure levels were measured using a biological inhibitor (Enbrel). Protocol: Female mice were divided into four groups: control (C), ovariec-tomized (OVX), DFP (OVX+DFP), and OVX+DFP+Enbrel (OVX+DFP+E). The rationale for use of OVX animals is to provide a situation in which cycling of the sex steroids is absent, similar to the male condition. GWI was induced by combined treatment with corticosterone (200 mg/l) followed by DFP exposure (1.5 mg/kg, s.c.). Enbrel (10 mg/Kg/p.o) therapy was administered 2 weeks after DFP. DFP exposure increased end systolic area (ESA). Enbrel produced amelioration of the toxic change produced by DFP (C: 6.00±0.30; OVX: 7.85±0.32; DFP: 11.62±0.70; DFP+E: 6.73±0.39). Systolic function, evaluated by ejec-tion fraction (EF), was reduced in all DFP groups after exposure and remained reduced in the last evaluation in DFP group but not DFP+E (C: 85.21±1.47; OVX: 80.49±1.49; DFP: 58.02±2.66; DFP+E: 84.28±1.70). Fraction Shortening (FS) and Cardiac Output (CO) were reduced after DFP exposure; however, after therapeutic the DFP+E group shows enhanced shortening (C: 25.39±0.76; OVX: 22.77±1.09; DFP: 16.1±1.05; DFP+E: 25.02±1.32, and CO increased (C: 17.71±0.99; OVX: 18.32±1.03; DFP: 13.06±3.34; DFP+E: 20.1±1.14). Systolic function recovery and fractional recovery of EF. Finally, myocardial performance index (MPI) was significantly increased in DFP exposure mice and re-established in Enbrel group after drug ther-apeutic trial (C: 0.35±2.008; OVX: 0.334±0.008; DFP+Enbrel: 0.419±0.01; DFP+E: 0.315±0.009). Results demonstrate that DFP exerts a negative impact on cardiac function in female mice, while Enbrel prevents most of the dys- functions produced by DFP. This suggests that a therapeutic trial could be a feasible strategy for treatment of veterans with GWI.

**1167 An Automated Heart Rate Detection Platform in Wildtype Zebrafish for Cardiotoxicity Screening of Fine Particulate Matter Air Pollution**

Exposure to air pollution-derived particulate matter (PM) causes adverse cardiovascular health outcomes, with increasing evidence implicating soluble components of PM; however, the enormous number of unique PM samples from different air sheds far exceeds the capacity of conven-tional in vivo approaches to characterize potential health impacts. The zebrafish (Danio rerio) is a vertebrate model widely used to evaluate heart function in vivo given the high degree of functional conservation with humans. The purpose of this study was to develop a rapid cardiotoxicity screen for PM. Here, we present an assay that relies on measure-ment of a simple health metric, i.e., heart rate (HR), acquired quickly from hundreds of zebrafish embryos without the use of drug anesthetics, restraint, fluorescent labeling, or confocal microscopy. Short videos acquired using bright-field imaging of 2-day-old wild-type zebrafish were processed using an original algorithm and scripts that derived HR from heart contraction patterns. To examine the utility of this approach in the cardiotoxicity testing of PM, we compared the effects of treatment (5.5 h) with organic extracts of PM collected from compressor-generated diesel exhaust (C-DEP), low sulfur diesel (B0), soy biodiesel (B100), and a 1:1 blend of B0 and B100 (B50). Epinephrine, a drug known to increase HR, caused dose-dependent increases in HR (peak increase = 14%, 177 beats per minute (bpm) vs. vehicle control (155 bpm)); whereas cloni-dine, a drug known to decrease HR, and all PM extracts caused decreases in HR (peak decreases of 10% for clonidine (120 bpm), 20% for C-DEP and B0 (125 bpm), and 8% for B100 (143 bpm), vs. vehicle (155 bpm, p < 0.001 for all). Preliminary screen for potential drug candidates of the PM samples indi-cated C-DEP = B0 > B100. Analysis of B50 is in progress. Taken together, this approach may help expedite relative cardiotoxicity determinations of PM, drug candidates, and other chemicals and mixtures This abstract does not reflect US EPA policy.

**1168 PON1 Status and HDL Characteristics in Patients with Cardiovascular Diseases**

N. Ponce Ruiz1, F. Murillo-González1, A. Rojas-García2, B. Barrón-Vivanco1, J. Ponce-Gallegos3, Y. Bernal-Hernández1, C. González-Arias1, M. Torres-Tamayo4, J. Jorge-Galarza5, G. Cardoso-Saldaña6, M. Hernández-Ochoa7, and I. Medina-Díaz1; 1Universidad Autónoma de Nayarat, Tepic, Mexico; 2Hospital Puerta de Hierro, Tepic, Mexico; 3Instituto Nacional de Cardiología, Mexico, Mexico; and 4CINVESTAV, Mexico, Mexico.

Serum paraoxonase 1 (PON1) is a high-density lipoprotein-associated enzyme capable of hydrolyzing a wide spectrum of substrates including oxidized lipids. Some evidence indicates that the genotype and phe-notype of PON1, as well as HDL concentrations and HDL subclasses, could associate with development of cardiovascular diseases. The aim of this study was to evaluate between HDL concentration and lipid profile in patients with cardiovascular diseases (CVD) or cardiovascular risk factors (CRF), or who were healthy. A case-con-trol study was conducted in 69 volunteers from an institution of health in Nayarat, Mexico. The study was approved by the local Institutional Ethics Committee. A written informed consent was obtained from each patient in compliance with good clinical practices, and the research
according to the principles in the Declaration of Helsinki. Blood samples were obtained to evaluate lipid profile, HDL subclasses by SDS-PAGE, and PON1 concentration by ELISA. T-Cholesterol, LDL-C, and ApoB levels were higher in the healthy group compared to the CVD and CRF groups. Among the groups, the CVD group had the lowest PON1 concentration (3.21, 2.76-3.94 µg/mL). Respect to HDL subclasses, HDL2a and HDL3a were found in higher proportions in CVD and CRF groups vs. the healthy group, whereas HDL3b and HDL3c were found in lower proportions. The healthy group had HDLs with the smallest average diameter (8.53 ± 0.07 nm). A logistic regression model found that if PON1 increases one unit, it decreases 1.86 the odds (p=0.00) to fit in the cardiovascular disease group. On the other hand, if the diameter increases one unit, it increases 17.89 the odds (p=0.00) to fit in the cardiovascular disease group. Lower proportions of small HDL (3c) and PON1 concentration were found in CVD group. Our data suggest that the study of PON1 status and HDL characteristics could be assessed to predict susceptibility for development of CVD.

**1169** Effect of Ethanol on IL-6-Mediated Effect on Human Angiotensinogen Using Human Hepatocytes: An In Vitro Model

R. A. Ansari, and S. A. Brettler. Nova Southeastern University, Fort Lauderdale, FL.

Human angiotensinogen (hAGT) is an acute-phase reactant type II (APR II) protein modulated by interleukin-6 (IL-6). Angiotensinogen is the source of angiotensin II that is a vasoactive peptide. AGT plays a significant role in blood pressure regulation, and increased levels of AGT are found among hypertensives. AGT participates in fibrinotic transformation of liver after hepatocellular carcinoma. Among chronic alcoholic patients, the immune system is downregulated while levels of circulating cytokines, like IL-1β, IL-6, and IL-8, are increased. In a cell-based model using HepG2 and Huh7 cells, the effects of alcohol on IL-6 mediated effects on secreted and cellular AGT levels were determined from 24 hrs to 72 hrs. It was observed that IL-6 and alcohol (50 and 100 µM) both increased the levels of secreted AGT from both HepG2 and Huh7 cells from 24-72 hrs. The cellular levels of AGT were also increased concomitantly to the secretions after IL-6 and alcohol treatment. The effects of alcohol and IL-6 combination treatment were additive in both cells. It was observed that HepG2 was more sensitive to treatment with IL-6 and alcohol as compared to Huh7 cells.

**1170** Qualification of a Thrombin-Anthrombin Complex Quantification Assay for the Detection of Hypercoagulable Conditions in Rats

F. Poitout1, S. Cotton1, S. Martin1, D. Poulin1, D. Culing2, C. Bédard2, and R. Samaddar1. 1Charles River Laboratories, Sennesville, QC, Canada; and 2Université de Montréal, St-Hyacinthe, QC, Canada.

The purpose of this study was to qualify an assay for the measurement of thrombin-antithrombin (TAT) complexes for the detection of hypercoagulable/pro-thrombotic conditions in rats due to a continuous low-grade activation of coagulation factors. Such conditions are difficult to identify in preclinical studies, as continuously evaluated coagulation times are not sensitive indicators. In hypercoagulable conditions, the low-grade activation of the coagulation factors leads to the formation of thrombin, which is inhibited by antithrombin present in blood, inducing the formation of TAT complexes. Quantification of such complexes is considered a sensitive and specific indicator of thrombin activation in human medicine and indicative of hypercoagulability. TAT complexes were measured using a qualified ELISA method (Rat TAT, Elasbiene) in a rat model study of inflammation. Rats were administered once intraperitoneally with a low dose of lipopolysaccharides (LPS). Injection of LPS triggers proinflammatory cytokines and upregulates the expression of tissue factor, and leads to the activation of the coagulation system. Range of response was 0.50 to 16.00 ng/mL in plasma EDTA. Selectivity: % Recovery was within ± 25% for 4 out of 5 lots tested. Long-term TAT stability in plasma was proven for 43 days at -20°C. Short-term stability: 6 hours at ambient room temperature or 4°C. Freeze-thaw stability: 2 freeze-thaw cycles at -20°C. Level of TAT obtained were higher (~50%) with EDTA versus citrated plasma. In an in vivo study, a 2.5-fold TAT increase was observed following initiation of coagulation cascade after addition of neoplastic and calcium. During the in vivo study, rat blood samples were collected from the jugular vein in EDTA tubes, prior to LPS administration and 3, 8, 24, and 48 hrs post-dose. Increases in TAT concentration were observed at 3 hrs, peaked at 8 hrs (up to 6 folds), and gradually decreased at 24 and 48 hrs post LPS administration. Such changes indicated an excessive generation of thrombin and hypercoagulability, which gradually reversed. Based on the results observed, the quantification of TAT complexes is an interesting marker for the evaluation of hypercoagulable conditions in rats.

**1171** PBDEs Exaggerate Adrenal Epinephrine Content in Salt-Loaded Rats Showing Hypertension: Involvement of Sympathetic and Renin-Angiotensin-Aldosterone Systems

B. D. Chinthilla. University of California Riverside, Riverside, CA. Sponsor: P. Kodavanti

Polybrominated diphenyl ethers (PBDEs) are organobromine compounds that are used as flame retardants in a wide array of products, including electronics and home furnishings. Our earlier studies revealed that developmental exposure to the penta-PBDE mixture, DE-71, exaggerates blood pressure responses to Na+ loading with sensitivity to the autonomic ganglion blocker (GB), pentolinium tartrate (19.2 mg/kg, s.c.), and renin-angiotensin-aldosterone system (RAAS) blockers captopril (CAP; 15 mg/L, drinking water, 2 weeks) and spironolactone (SPIRONO; 40-50 mg/Kg, oral gavage, 5-7 days) (Shah et al, 2011; Spurgin et al 2014), suggesting sympathetic nervous system (SNS) and RAAS involvement. Since PBDEs can enhance catecholamine release from adrenal chromaffin cells (Dingemans et al, 2007), we examined the activity of the sympathoadrenal axis (SAS) in hypertensive and normotensive rats perinatally exposed to DE-71 or corn oil vehicle infused cefetra toxins given to dam mothers (30.6 mg/kg/day; GD6-PND21). At PND50-70, adult male offspring were treated with hypertonic NaCl (3.5%; i.p.; Hyper) or normotonic NaCl (0.9%; i.p.; Norm). PBDE hyper rats were injected with Oil, Hyper, PBDE Hyper + Oil, PBDE Hyper + CAP, PBDE Hyper + SPIRONO. Adrenal content of catecholamine (CA) was measured via trihydroxyindole method and fluorometric detection at pH 7 (Kelner et al, 1985). Epinephrine (Epi) was measured at pH 2. Results showed a significant increase in both total CA and Epi in response to hypertensive treatment, but the effect on Epi was greater in PBDE-exposed rats (p<0.05 - .01, n=6-10). The elevated adrenal Epi content in PBDE Hyper was prevented by pretreatment with GB, CAP, and SPIRONO (p<0.001, n=6-10), suggesting involvement of SNS and RAAS. These blockers also reduced basal Epi content. Using ELISA, plasma levels of hyperosmotic-stimulated Epi were similar in PBDE and Oil rats, and only trend to GB (p<0.05, n=4-8). These results indicate that PBDE exaggerates the rise in adrenal Epi content under hypertensive stress. Our findings show that developmental exposure to PBDEs increases SAS, and RAAS activity under sodium loading may lead to hypertensive responses. Supported by UCMEUS (KS) and COR from UC Riverside (MCC).

**1172** Evaluation of Hypertension in Schoolchildren Exposed to Inorganic Fluoride in Chihuahua, Mexico

L. M. Del Razo1, A. Pérez-Galicia1, L. Arreola-Mendoza2, G. Aguilar-Madrid3, M. I. Jiménez-Córdova1, A. Herrera-Hernández2, L. C. Sánchez-Peña1, and M. C. Gonzalez-Horta4. 1CINVESTAV-IPN, Mexico City, Mexico; 2CIEMAD-IPN, Mexico City, Mexico; 3IMSS, Mexico City, Mexico; and 4Universidad Autónoma de Chihuahua, Chihuahua, Mexico.

Inorganic fluoride (F) is an abundant element in nature, its main source of human exposure being drinking water. Epidemiological and experimental studies have shown that fluoride exposure is related to adverse cardiovascular effects such as hypertension, with limited reports in children. We evaluated the relationship of fluoride exposure with the presence of hypertension in children. A cross-sectional study in 366 schoolchildren at 5-12 years old were selected from two schools, located in two communities of Chihuahua, Mexico, with 0.32±0.5 mg/L and 1.38±1.1 mg/L in drinking water. Concentration of fluoride in water and urine were measured by fluoride ion-selective electrode. Fasting blood glucose and lipid levels were evaluated using a chemical autoanalyzer. Resting blood pressure was measured in triplicate using a mercury sphygmomanometer in a sitting position. Hypertension and prehypertension were defined using national guidelines. Children that showed systolic and diastolic blood pressure greater than 95% and between 90th and 95th percentiles, respectively, for age, sex, and height. The mean urinary fluoride levels were 2.5±1.2 mg/L (0.67-6.75 mg/L). The prevalence of obesity (15.3%) was lower than overweight (17.9%). A total of 9.6% (n=35) of children had prehypertension, and a further 10.7% (n=39) of children had hypertension; both were related with body mass index (OR = 9.96, 95% CI = 4.70-21.10) and plasma atherogenic index (OR = 2.28, 95% CI = 1.37-3.80), but unre-
lated to urinary fluoride concentration (OR=0.90, 95% CI=0.70-1.17). Our results indicate that the prevalence of hypertension in these children is not related to fluoride exposure. Our finding also emphasizes the importance of the prevention of obesity and overweight. Supported by CONACYT-Mexico, Children’s Environmental Health Network #280296.

1173 Dioxin-Like PCB 126 Increases Systemic Inflammation and Accelerates Atherosclerosis in Lean LDLR Receptor-Deficient Mice

M. Petriello, J. Hoffman, J. Barney, B. Wahlang, B. Hennig, and A. J. Morris. University of Kentucky, Lexington, KY.

Exposure to dioxins and related persistent organic pollutants likely contributes to cardiovascular disease (CVD) risk through multiple mechanisms, including modulation of chemokine expression. Epidemiological studies have shown that leaner individuals may be more susceptible to the detrimental effects of lipophilic toxics because they lack large adipose tissue depots that can accumulate and sequester these pollutants. This phenomenon complicates efforts to study mechanisms of pollutant-associated atherosclerosis in experimental animal models where high-fat feeding and adipose expansion limit the bioavailability of lipophilic pollutants. Here, we investigated whether a model dioxin-like pollutant, PCB 126, could increase inflammation and accelerate atherosclerosis in Ldlr-/- mice fed a low-fat atherogenic diet. We fed Ldlr-/- mice the Clinton/Cybulsky diet (10% kcal fat, 0.15% cholesterol) and sacrificed mice at 8, 10, or 12 weeks post PCB (2 doses of 1 μmol/kg) or vehicle gavage. To characterize this novel model, we examined the effects of PCB 126 on markers of systemic inflammation, hematological indices, fatty livers, and atherosclerotic lesion size. Mice exposed to PCB 126 exhibited significantly increased plasma inflammasome cytokine levels, increased circulating biomarkers of CVD, altered platelet and red blood cell counts, increased accumulation of hepatic fatty acids, and accelerated atherosclerotic lesion formation in the aortic root. PCB 126 also increased circulating neutrophils, monocytes, and macrophages as determined by flow cytometry analysis. Exposure to dioxin-like PCB 126 increases inflammation and accelerates atherosclerosis in mice. This low-fat atherogenic diet provides a useful tool to study the mechanisms linking exposure to lipophilic pollutants to increased risk of CVD.

1174 Differential Responses in Maternofetal Vasculature after Engineered Nanoparticle Inhalation

The continued development of engineered nanomaterials (ENM) across a broad range of fields has given rise to concerns over the potential mechanisms, including inflammation. Exposure to titanium dioxide nanoparticles (nano-TiO2) has been shown to impair fetal development and impact the health of surviving offspring. Given the inherent heterogeneity of the maternofetal vasculature, the purpose of this investigation was to assess the impact of a single ENM exposure at 3 time points during gestation on vascular reactivity at 4 distinct anatomic levels. Timed-pregnant Sprague-Dawley rats were exposed to nano-sized titanium dioxide (TiO2) aerosols (10-15 μg/m3) for 4 hours, 4 times/week, from gestational day 4, 12, or 17. Rats were euthanized on GD 20. Pregnancy parameters (fetal number, implantation sites, fetal and placental weights) were recorded. Wire myography (DMT-Liga) was used to evaluate active tension generation in the thoracic aorta, uterine artery, umbilical vein, and fetal thoracic aorta in response to chemical stimuli to assess endothelium-dependent (EDR) [methacholine (10-6-10-4 M)], -independent (IER) [spasmic/NONOate (SP, 10-6-10-4 M), and vascular smooth muscle (VSM) (phenylephrine (10-6-10-4 M)] reactivity. A single pulmonary exposure to nTiO2 early in gestation (GD 4) resulted in a greater number of reabsorption sites (2.3±1.9 vs. 0.6±0.2) and significant increase in placental weight (p=0.001) with no differences in litter size or pup weight. Pulmonary exposure to nTiO2 significantly impaired EDR in the thoracic aorta by 78.5±1.1% compared to control. EDR of the uterine artery, umbilical vein, and fetal aorta after exposure were not significantly different. Following ENM exposure, EDR was impaired in the thoracic aorta (75.6±23.0%, SPR 10-4M) and fetal aorta (160.8±38.3%) compared to controls, while significance was not noted for other vessels. There were no significant differences in VSM responses. Together, these results indicate a susceptibility of critical maternofetal vasculature to a single pulmonary exposure of nTiO2 during gestation. Additionally, gestational age at time of exposure influences fetal development, thereby identifying windows of fetal susceptibility to ENM. 1175 Effects of Orally-Administered Entresto on Systemic and Left Ventricular Pressures in Telemetered Normotensive St. Kitts Green Monkeys

S. Liddie1, M. Dunn3, X. Morton1, D. Moddelrelle1, A. Banerjee1, J. Torello1, L. Morton1, and M. Lawrence1. 1RxGen, New Haven, CT; and 2Regeneron Pharmaceuticals Inc., Tarrytown, NY.

The St. Kitts green monkey (Chlorocebus sabaeus) is a primate species with close physiological and genetic homology to humans. It is gaining attention as a highly clinically translatable species for drug development, specifically in discovery and safety pharmacology testing. In the current study, we investigated the effects of orally administered Entresto (sacubatril/valsartan) on systemic and left ventricular pressures in telemetered normotensive St. Kitts green monkeys to evaluate respective pharmacodynamics and characterize the employed telemetry system. Following pole and collar training for 7 days, 3 monkeys with intubating Stellar TSE PPBTA-XL catheters were dosed via nasogastric intubation with either Entresto or vehicle for 7 days using a crossover design. Baseline pressures were relatively stable, although one monkey presented as hypertensive (systolic BP >150 mmHg). Entresto reduced systemic blood pressures by ~15-18 mmHg with minimal effects on heart rate (HR). Baseline left ventricular pressures (LVP), although relatively consistent through time, were outside of physiologically relevant ranges, reflecting calibration drifts in LVP signals. Entresto administration resulted in relative drops in LV systolic, diastolic, and mean pressures. This experiment highlights the potential utility of employing radio telemetry in St. Kitts green monkeys to evaluate cardiovascular pharmacodynamics and safety pharmacology testing with novel telemetry with other modalities, including ultrasound and circulating serum biomarkers, allows for the comprehensive evaluation of test article-induced cardiovascular effects in the highly clinically translatable St. Kitts green monkey.

1176 Group II Innate Lymphoid Cells and the Microvascular Response to Pulmonary Titanium Dioxide Nanoparticle Exposure

The reproductive and cardiovascular effects of pulmonary exposure to engineered nanomaterials (ENM) are poorly understood. Inflammation remains the most frequently explored mechanism. However, the key mediators remain to be uncovered. The purpose of this study was to determine the uterine inflammatory and vascular effects of pulmonary exposure to titanium dioxide nanoparticles (nano-TiO2). We hypothesized that pulmonary nano-TiO2 exposure initiates a Th2 inflammatory response mediated by Group II innate lymphoid cells (ILC2), which is associated with an impairment in uterine vascular reactivity. Female, virgin Sprague-Dawley rats (8-12 weeks) were exposed to 100 μg of nano-TiO2 via intratracheal instillation 24 hours prior to vascular assessments. Blood samples were obtained at 0, 1, 2, and 4 hours post-exposure for multiplex cytokine analysis. ILC2 numbers present in lungs were determined via flow cytometry 4 hours post-exposure, and bronchoalveolar lavage was performed for cytokine analysis. ILC2 cells were isolated by magnetic bead separation, and phospho-NF-kB levels were measured by ELISA. Immunohistochemistry of lung tissue for interleukin (IL)-33, a marker for epithelial cell damage, was also performed. Wire myography was used to evaluate uterine artery active tension generation, while pressure myography was used to assess vascular reactivity of radial and basal arterioles. Uterine vasculature was treated with cumulative concentrations (1×10-6-1×10-4 M) of phenylephrine, acetylcholine, and sodium nitroprusside. Four hours after nano-TiO2 exposure, a 2-4 fold increase in IL-18, 4, 5, and 13, and TNF-α was observed, indicative of an innate Th2 inflammatory response. ILC2 were significantly increased in lungs from exposed animals (1.7±0.2%) compared to controls (0.3±0.6%). Phosphorylation of NF-kB in isolated ILC2 was also increased by nano-TiO2 exposure (129±14% of controls), and pre-liminary data show a marked increase in lung IL-33. Radial and basal arteriolar endothelium-dependent reactivity was impaired by (27±12%), while endothelium-independent dilation (7±4%) and alpha-adrenergic sensitivity (8±2%) were not affected. These results suggest that pulmonary nano-TiO2 exposure may trigger an innate systemic Th2 inflammatory effect within 4 hours by stimulating lung resident ILC2. Supported by NIH R01-ES015022 (TRN), NSF-1003907 (TRN, ABA).
Neonatal rats are valuable models for the evaluation of cardiovascular development and associated toxicities. However, despite evidence for immature vascular α-adrenoceptors and a cardiac dominance of fast myosin isoforms in neonatal rats, few data exists on the normal cardiovascular state of this transitioning system. This study characterized systemic/left-ventricular hemodynamics, vascular responsiveness, and functional indices in rats ranging from the neonate period (10–14 days, n = 34) to young adulthood (>8 weeks of age, n = 7). Neonatal and young adult Sprague-Dawley rats were anesthetized with isoflurane (1.5–2%) and instrumented for aortic and left-ventricular pressures via carotid artery catheterization; in a subset of animals, 2D-guided M-mode echocardiography was also performed. Hemodynamic data were obtained before and after pharmacological vascular challenges with sodium nitroprusside (SNP, 25 μg/kg IV) and/or phenylephrine (PE, 10 μg/kg IV) in order to assess both cardiovascular state and responsiveness. When compared to adult physiology (at a matched-anesthetic plane), neonatal rats had marked cardiovascular differences, characterized by low arterial pressures (MAP: 44±1 vs. 100±3 mmHg in adults) and normal heart rates (HR: 372±4 vs. 366.8 bpm in adults). Neonates also had lower peak rates of LV pressure development (dP/dt max: 4058±123 vs. 9478±231 mmHg/s in adults), but faster-estimated velocities of shortening (CI: 152±3 vs. 144±5 1/s in adults) and preserved ejection fraction (EF 78±0.5% vs. 81±0.4% in adults). Moreover, the α-AR pressor capacity was incompletely developed in neonates, demonstrated by blunted responses to PE (ΔMAP: +12.2% vs. +37.2% in adults); however, NO-mediated vaso- relaxation was intact, as SNP resulted in an acute hypotension (ΔMAP: -25.2% vs. -30.2% in adults), albeit reflexive tachycardia was blunted (ΔHR: +21% vs. +12.2% in adults). These data confirm and document a maturing cardiovascular system in neonatal rats, characterized in vivo by hypotension, immature vascular α-AR responsiveness, and blunted cardiac baroreflexes, as well as by preserved systolic function and increased left-ventricular shortening velocity. These observations are consistent with the known neonatal ex vivo vascular adrenoceptor profile as well as with the predominance of the fast, but load-intolerant, alpha-myosin isoform in neonatal hearts.

**Exposure to Environmentally Persistent Free Radicals Leads to Decreased Vascular Responsiveness**

A. C. Harmon, A. Noel, B. Subramanian, M. Jennings, Y. Chen, A. Penn, K. Varner, and T. Duong. Louisiana State University, Baton Rouge, LA.

Environmentally persistent free radicals (EPFRs) are formed during the combustion of waste at Superfund sites when pollutants are chemisorbed to redox-active transition metals. In vitro studies have demonstrated that cells exposed to EPFRs produce increased IL-6, TNF-α, and ROS, indicating inflammation, which is an initiator of vascular dysfunction. In addition, in vivo data demonstrate that adult C57BL/6 mice exposed to 1.5 mg/m³ of the EPFR DCB230 for either 4 hours or for 10 consecutive days exhibit significantly reduced NO and increased ET-1, suggesting endothelial dysfunction. However, analysis of BALF and lung tissue for inflammation was unremarkable, indicating the vasculature as a direct target of injury after EPFR exposure. Therefore, we hypothesized that at an intermediate time point, DCB230 exposure will lead to systemic inflammation, resulting in a decrease in vascular responsiveness. Adult C57BL/6 mice were subjected to whole-body inflation of 1.5 mg/m³ DCB230 for 4 hours a day for 3 consecutive days prior to flow cytometry and vessel reactivity analysis. DCB230-exposed mice demonstrated significantly reduced monocytes in circulation and increased lymphocytes versus the air-only control group. Analysis of aortic segments indicated a significant reduction in maximum relaxation in DCB230 versus control mice. Together these data demonstrate that EPFRs lead to alteration of the peripheral inflammatory cell milieu and reduced vascular responsiveness, which may ultimately culminate in the development or exacerbation of cardiovascular disease.

**Intravenously Injected Polyethylene Glycol (PEG)-Coated Liposomes Result in Microvascular Dysfunction**

V. C. Minarchick, J. M. Brown, and D. Simberk. University of Colorado Denver, Aurora, CO.

Polyethylene glycol (PEG) is a coating often used to improve biodistribution and safety of small molecules and liposomes for drug delivery. Despite PEG being commonly used, the microvascular impacts are largely unknown. Therefore, we hypothesize that PEG-coated liposomes will negatively impact microvascular function following intravenous (IV) injection. Balb/C mice were IV injected with either PEG-coated or non-PEG-coated liposomes (SmM), and mesenteric arterioles were harvested three days post exposure. Endothelium-dependent and -independent reactivity was assessed with acetylcholine (ACH, 10⁻⁴ M), and sPentine NONOate (SPR, 10⁻⁴ M) via pressure myography. Vascular smooth muscle vasoreactivity was assessed with phenylephrine (PE, 10⁻⁶ M). Following assessments, superoxide and hydrogen peroxide were scavenged in the presence of the superoxide dismutase mimetic 2,2,6,6-tetramethylpiperidine-N-oxyl (TEMPOL, 10⁻⁴ M) and catalase (50 U/mL). The contribution of nitric oxide (NO) was evaluated by inhibiting nitric oxide synthase with N°-monomethyl-L-arginine (L-NMMA, 10⁻⁴ M). Following PEG-coated liposome delivery, endothelium-dependent dilatation was significantly attenuated (-3.9 ± 24% vs. control 69 ± 4%), and this impairment was not present following non-PEG-coated liposome delivery (55 ± 10% vs. control 69 ± 4%). Furthermore, there was no significant impairment in endothelium-independent dilation for the two liposome groups (PEG, 2 ± 6% vs. non-PE, 70 ± 6%). Taken together, these results indicate that PEG-coated liposomes induce microvascular dysfunction that is present up to three days following injection, and these impairments may be due to changes in oxidative stress and/or endothelial cell signaling. Furthermore, this is the first report of adverse microvascular effects associated with PEG-coated liposomes. Since liposomes are being increasingly used as a therapeutic delivery method, establishing these negative microvascular effects is essential since they may contribute to adverse cardiovascular responses.

**Intranasal Administration of Amiodarone Causes Pulmonary Fibrosis and Triggers Recruitment of Immature Macrophages to the Lung in C57BL/6 Mice**

Amiodarone (AD) is an antiarrhythmic drug that causes pulmonary toxicity in 10-17% of patients. Pulmonary fibrosis associated with AD is characterized by the presence of foamy macrophages and hyperplasia of type II alveolar epithelial cells. The precise role of the innate immune system in the development of AD-induced pulmonary toxicity is unknown, and this represents the focus of the present studies. AD administration (16 mg/kg intranasally every 5 d) to 8-12-week-old male and female C57BL/6 mice resulted in the development of pulmonary fibrosis 25 d post exposure. This was characterized by collagen deposition around the airways and in the lung parenchyma, as assessed by Masson’s Trichrome staining, which was associated with an accumulation of macrophages in the lung in histologic sections. To analyze the phenotype of these cells, we used techniques in flow cytometry; two macrophage populations were analyzed. The population that was scavenged by bronchoalveolar lavage, and tissue-associated macrophages selected from a collagenase-mediated whole-lung digest by magnetic selection of F4/80+ cells. We found that the ratio of F4/80+SiglecF-CD11C++CD11B+ to F4/80+SiglecF-CD11C++CD11B- populations of tissue-associated macrophages increased from 1.12 in sham animals to 1.77 and 1.90 in PBS and AD-exposed animals, respectively. In contrast, there were no changes in alveolar macrophages. Immunohistochemistry demonstrated that inflammatory (CD11B-) macrophages were mainly present in areas of collagen staining in lung tissue. The increased ratios of F4/80+SiglecF-CD11C++CD11B+ to F4/80+SiglecF-CD11C++CD11B- populations may be due to changes in oxidative stress and/or endothelial cell signaling. Furthermore, this is the first report of adverse microvascular effects associated with PEG-coated liposomes. Since liposomes are being increasingly used as a therapeutic delivery method, establishing these negative microvascular effects is essential since they may contribute to adverse cardiovascular responses.
Vanadium is a transition metal that can be found in respirable particulate matter in occupational and environmental settings. Here, we investigate the effects of vanadium administered via pulmonary exposure on respiratory function, bronchial ring contraction, and inflammatory response. C57BL/6 mice were treated with 0, 0.1, 1, 10, 30, or 90 µg of VOSO₄ dissolved in saline by pharyngeal aspiration. A forced oscillation pulmonary function system (Flexivent, Scireq Inc.) was used to assess airway resistance and compliance 24 hours post-exposure. This included administering increased doses of methacholine (0–50 mg/ml) by inhalation to induce bronchoconstriction, to characterize lung damage. Additionally, a comparison study between VOSO₄ and VO₂O₄ was conducted to examine inflammatory responses in the lung with 0, 0.1, 1, or 10 µg VOSO₄ or VO₂O₄ by pharyngeal aspiration. Bronchoalveolar lavage fluid (BALF) and serum samples were collected 24 hours post-exposure. BALF samples were stained via basophilic staining, followed by counting the number of macrophages and neutrophils, and a Bradford protein assay was used to measure protein concentration. Bronchial rings were isolated from naïve mice and treated ex vivo with VOSO₄ to examine the impact on contraction to methacholine using a myograph. Pulmonary function data showed negligible differences among exposure groups, although dose-related differences in methacholine-induced bronchial rings were evident. Both VOSO₄ and VO₂O₄ did not affect macrophage percent, but a slight increase in neutrophils was seen with high-dose VO₂O₄ treatment. Bronchial rings treated with VOSO₄ were more sensitive to methacholine-induced contraction than naïve rings. Soluble VOSO₄, even at high levels, did not produce substantial impacts on pulmonary function, although age-related differences in methacholine-induced reactivity were observed. C57BL/6 mice were treated with 0, 0.1, 1, 10, 30, or 90 µg of VOSO₄ or VO₂O₄, and these exposure groups were compared using age-matched naïve control animals. Exposure to 2,4-DB acid or to MCBP acid caused laryngeal effects at doses of 0.02 mg/L and above. These effects recovered partially following 1 week of recovery. These studies add to the weight of evidence characterizing laryngeal squamous metaplasia in the rat by providing additional information on the degree of recovery that may be anticipated after shorter recovery periods. Given that herbicide use patterns often require several weeks between applications, such information is relevant for determining the appropriate use of rodent toxicity data in a human health risk assessment context. This poster will present the results of these studies and discuss their contribution to the overall weight of evidence on interpretation of the adversity and human health significance of laryngeal squamous metaplasia in rodent inhalation studies.
Potassium titanate whisker (PTW) is one of the man-made mineral fibers and used for an alternative to asbestos. There is a report that a certain type of PTW was positive for mesotheliomagenesis in intraperitoneal injection study. As the particles of PTW are respirable in size, inhalation studies are essential for the assessment of its respiratory toxicity. A rat study has been reported with a low lung burden for a mass concentration of the aerosol, suggesting the presence of a large proportion of non-respirable agglomerates in the aerosol. In order to establish an inhalation exposure condition of PTW for a precise hazard assessment with better dosimetry, we conducted a mouse short-term whole-body inhalation study of a commercially available PTW in Japan, using our dispersion method and inhalation system designated as Taquann Method and Taquann Direct-Injection Whole Body Inhalation System (J Tox. Sci. 2013). In our study, the mass concentration was 4.1 mg/m³, and relative concentration was 7.575 mg/mL measured by condensation particle counter (Model 3776, TSI). MMAD on aerosol in the chamber was 1.348 nm measured by MOUDI (Model 125, Kanomax). The fiber length of PTW aerosol was 4.3±3.7 micrometer (max. 23.8), and the fiber diameter was 338±171 nm (max. 990), observed by scanning electron microscopy (VE-9800, Keyence). Male C57BL/6 mice, 12 weeks old, were exposed for two hours per day for five consecutive days. Mice in control group inhaled clean air in the same manner. The lung burden of mice immediately after the last exposure (Day 0) was 15 micrograms per animal, and the length of PTW recovered from the lung was virtually identical to the last exposure (Day 0) was 15 micrograms per animal, and the length of PTW recovered from the lung was virtually identical to the last exposure. Pulmonary densities of B (CD45R+), T (CD3+) and 2) assess the impact of the dietary ω-3 polyunsaturated fatty acid docosahexaenoic acid (DHA) on cSiO₂ triggering of ectopic lymphoendothelial structures (ELS) in the lungs of mice genetically prone to develop lupus. ELS are tertiary lymphoid organs, associated with autoimmunity, that develop in areas of chronic inflammation and are characterized by the formation of organized B cell and T cell aggregates and germinal centers with follicular dendritic cell networks. The goal of this study was to 1) determine the kinetics of cSiO₂-induced ELS development in the lungs of lupus-prone mice and 2) assess the impact of the dietary ω-3 polyunsaturated fatty acid docosahexaenoic acid (DHA) on cSiO₂ triggering of ectopic lymphoendothelial structures (ELS). Cohorts of 6-week-old lupus-prone female NZBWF1 mice were nasally instilled with 1 mg cSiO₂, or saline vehicle alone, once per wk, for 4 consecutive wks. Animals were sacrificed 1, 5, 9, or 13 wks after the last cSiO₂ instillation. Pulmonary densities of B (CD45R+, T (CD3+) and follicular dendritic (CD21+/CD35+) cells were immunohistochemically and morphometrically determined. Lymphoid cell densities significantly increased over time in the lungs of cSiO₂-treated mice. DHA supplementation markedly attenuated cSiO₂-triggered B and T cell, but not follicular dendritic cell, infiltration over the entire 13-wk post-exposure period. These results suggest that the development of ELS in the lung may be an early indicator of cSiO₂-induced autoimmunity and that dietary DHA may effectively prevent development of these aberrant structures. Research funded in part by NIH grant ES027353, Lupus Foundation of America grant 362470, and the Dr. Robert and Carol Diebel Family Endowment.

From an occupational standpoint, exposure to silica can have devastating consequences. An estimated 2.3 million workers in the US are exposed to dust containing crystalline silica, annually. In addition, of the 140 million people over the age of 20 employed in the US, 30% are obese. If and how diet-induced obesity modifies silica-induced pulmonary toxicity is unknown. Therefore, the objective of this study was to determine the effect of diet-induced obesity, if any, on silica-induced pulmonary toxicity. Rats (Fischer 344, male) were fed either a regular-fat diet (RFD; 18% kcal as fat) or a high-fat diet (HFD; 60% kcal as fat) and exposed by whole-body inhalation to either air or crystalline silica (15 mg/m³, 6 hours/day, 5 days). At designated post-exposure time intervals (1, 3, 6, and 9 months), pulmonary toxicity was determined. Toxicity parameters including lactate dehydrogenase (LDH) activity, oxidant production, cell counts (including infiltrating neutrophils and alveolar macrophages), inflammatory cytokine levels (IL-1β, IL-10, TNF-α, MCP-1, and MIP-2), and lung histopathology were assessed. Body weights and serum triglyceride levels, indicators of diet-induced obesity, in the HFD rats were higher compared to those in RFD rats. The results showed that silica particles were seen in lung sections from the exposed animals. Silica inhalation resulted in pulmonary toxicity, which progressed across all post-exposure time points, as evidenced by enhanced neutrophil infiltration, increased LDH activity, oxidant production, and increased inflammatory cytokine levels. The incidence and severity of silica-induced lung pathology was similar between the two diet groups up to 6 months post-exposure. However, by 9 months post-exposure, silica-induced pathology tended to be slightly more severe in animals fed a RFD compared to those fed a HFD. In summary, our results indicated that certain pulmonary toxicity parameters induced by silica inhalation were modified by diet-induced obesity in rats.

Humans exposed to asbestos and/or asbestiform fibers are at high risk of developing many lung diseases, including asbestosis, lung cancer, and malignant mesothelioma. However, the disease-causing potential and related processes associated with various asbestos/asbestiform fiber exposures in triggering the different (non-)carcinogenic outcomes is still largely unknown. In this study, we investigated whether exposure to different asbestos/asbestiform fibers leads to differences in inflammatory responses and gene expression profiles at acute/sub-acute phases that can be related to pathological outcomes observed at extended time points of post-exposure. We exposed mice to asbestos (crocidolite, tremolite asbestos), asbestiform fibers (erionite), and a low-pathogenicity mineral fiber (wollastonite) using oropharyngeal aspiration. We observed some shared inflammatory and tissue damage responses, albeit to different extents, at day 1 and 7 post-exposure. In addition, exposure to different fibers also exhibited distinct changes in the regulation and release of a number of inflammatory mediators. Further, a detailed comparison of gene regulation changes in the lungs on day 7 post-exposure also suggested differential biological responses that were consistent with histopathological changes at day 7 and 56 post-exposure. Taken together, these results suggest clear differences in the magnitude of various pulmonary responses and gene regulation that were consistent with pathological alterations upon exposure to the four asbestos/asbestiform fibers studied. Further mechanistic studies focusing on long-term endpoints are critical for understanding how early biological responses are associated with pulmonary exposures to asbestos/asbestiform materials and their ability in triggering different carcinogenic outcomes, i.e., lung cancer versus mesothelioma.
Evaluation of the Dose-Response and Fate in the Lung and Pleura of Chrysotile Containing Brake Dust Compared to Chrysotile or Crocidolite Asbestos in a 28-Day Inhalation Toxicology Study

D. M. Bernstein, B. Tóth, R. A. Rogers, P. Kunzendorf, and H. Ernst. Consultant in Toxicology, Geneva, Switzerland; 2GiToxLab, Veszprém, Hungary; 3Rogers Imaging, Needham, MA; 4GSA mbH, Ratingen, Germany; and 5Fraunhofer Institute, Hannover, Germany.

This study was designed to provide an understanding of the biokinetics and potential toxicology in the lung and pleura following inhalation of brake dust (from brakes manufactured with chrysotile) in a 28-day repeated multi-dose inhalation toxicity study (6 h/d, 5 d/wk, 4 wk) followed by 28-days of exposure-free recovery and served as a range-finding study for a subsequent ongoing 90-day repeated-dose inhalation toxicology study with lifetime recovery. Comparative fiber control groups were included of a similar grade of commercial chrysotile as used in the brakes and a commercial crocidolite asbestos sample. The aerodynamic fiber distribution of the chrysotile and crocidolite asbestos was similar (Fibers L = 20 µm/cm²; Chry-LD 42, Chry-HD 62; Croc-LD 36, Croc-HD 55; WHO f/cm³ Chry-LD 192, Chry-HD 219; Croc-LD 211, Croc-HD 255). The total number of particles in the aerosol of the brake dust groups was similar to that in the chrysotile groups (Part/cm³: 211, Croc-HD 255). A macrophage dose response to the brake dust groups was observed with no fiber-related effects. In the fiber control groups, the study differentiated between similar exposures to chrysotile and crocidolite asbestos. The chrysotile exposure resulted in a dose-dependent particle-laden macrophage response characterized by Wagner Grade 1 to 3. In contrast, following crocidolite exposure there was a dose-response accumulation of fiber-laden macrophages and interstitial fibrosis during exposure (Wagner score Grades 3 to 4), which increased in incidence following exposure (Wagner score Grade 4). Confocal microscopy images obtained from chestwalls deep frozen at sacrifice revealed no difference between the air control, brake dust, and chrysotile high-dose exposure groups and no difference in the visceral or parietal pleura thickness at 28 or 56 days. The crocidolite exposure resulted in more than double the thickness of the visceral pleura and parietal pleura, with associated extensive inflammatory response and collagen development observed, including adhesions between the visceral and parietal surfaces. These results provided a basis for the design of the 90-day study. Study funded by Honeywell International Inc.

Endocannabinoids Attenuate Staphylococcal Enterotoxin B (SEB)-Mediated Acute Lung Injury through Regulation of microRNA That Target the Induction of Myeloid-Derived Suppressor Cells and T Regulatory Cells

M. A. Sultan, M. Nagarkatti, and P. Nagarkatti. University of South Carolina School of Medicine, Columbia, SC.

Acute Lung Injury (ALI) is still a significant cause for morbidity and mortality in the human population, with a high incidence of over 200,000 cases/year in the US. In this study, we used a single dose of Staphylococcal enterotoxin B (SEB) (50µg) intranasally to induce ALI. The inhalation of SEB, a category B agent as defined by the CDC, leads to robust activation of T cells and a cytokine storm that causes significant damage to the lungs. In the current study, we induced SEB-mediated acute lung injury in C57BL/6 mice and investigated if treatment with an endocannabinoid (AEA) would attenuate ALI. Our data demonstrated that a dose of (40mg/kg) of AEA significantly improved the lung function tests in mice with SEB-induced ALI when compared to vehicle controls, as determined by plethysmography. Analysis of mononuclear cells in lung of SEB-AEA mice showed significant increase in myeloid-derived suppressor cells (MDCSs) that were CD11b+Gr1+ and anti-inflammatory. Our results also demonstrated induction of T regulatory cells that were CD4+FOXP3+. Microarray analysis of miRNA in lung-infiltrating cells in SEB+AEA group revealed that miR-23a-3p and miR34a-5p were downregulated when compared to controls. These miRNA targeted TGF-β1, TGF-β2, and FOXP3, as shown by transfection of splenocytes activated by SEB with mock, mimic, or inhibitor of both miR 23a-3p and miR34a-5p separately, which resulted in specific alterations in the target genes. The expression of all miRNAs and target genes involved were validated by RT-PCR. Together, our data demonstrated that endocannabinoids can attenuate ALI and inflammation mediated by SEB through modulation in the expression of miRNA which induce immunosuppressive MDCSs and Tregs. Supported by NIH grants P01AT003961, R01AT006888, R01AI29788, R01AI123947, R01MH94755, P20GM103641 to PN and MN, and HCED Iraq to MS.

Role of microRNA in Tetrahydrocannabinol (THC)-Mediated Amelioration of SEB-Induced Acute Lung Injury

A. K. Mohammed, H. K. Alghetaa, P. Nagarkatti, and M. Nagarkatti. University of South Carolina, Columbia, SC.

Staphylococcal enterotoxin B (SEB) produced by Staphylococcus aureus may cause food poisoning, acute respiratory distress syndrome, and multiple organ failure, and could be fatal. Tetrahydrocannabinol (THC) is the main ingredient found in marijuana cannabis, which has psychotropic effects and is used to treat anorexia and nausea, as well as used as an analgesic. In the current study, we investigated the therapeutic potential of THC on immune cell apoptosis and inhibition of nuclear factor kappa B (NF-κB). To this end, acute lung injury was induced by a dual dose of SEB in C57/HeJ mice, which were treated with vehicle or THC. SEB caused expansion of a large number of T cells and massive release of inflammatory cytokines such as TNF-α. Furthermore, stimulation through its receptor led to activation of the MAP kinase (MAPK) complex, which causes activation of general stress response factor NF-κB. Apoptosis, a process of programmed cell death, was detected by the TUNEL & DIO6C staining. Moreover, we had identified that THC caused cell cycle arrest in G2 and apoptosis. In order to determine the epigenetic mechanisms of THC-induced effects, we performed high-throughput microRNA microarrays with lung-infiltrating mononuclear cells from vehicle and THC-treated mice. Ingenuity Pathway Analysis software was used to analyze the microarray dataset. The analysis showed that THC treatment led to immunosuppression through several mechanisms, including downregulation of miR-185 that may be responsible for increased expression of Runx, NKRA5, IL10, and Foxp3, while upregulation of miR-21 led to decreased NF-κB and Stat-3. Furthermore, validation of the expression of miR-185 and miR-21 by RT-PCR using lung mononuclear cells confirmed our data from high-throughput analysis. Together, THC plays a major role through epigenetic mechanisms that modulate immunological pathways that suppress SEB-induced acute lung injury. Supported by P01AT003961, R01AT006888, R01MH94755, P20GM103641, R01AI129788, R01AI123947, and M01ESR for AKM.

Infiltrating Monocyte-Derived Macrophages Contribute to the Development of Radiation-Induced Pulmonary Fibrosis

The lung is a radiation (RT)-sensitive organ, and the development of chronic inflammation that progresses into pneumonitis and pulmonary fibrosis (PF) is often observed in exposed individuals. RT induces an injury response involving the recruitment of immune cells to execute inflammatory and wound healing programs. However, RT can alter the lung microenvironment, dysregulating immune responses and preventing the return to homeostasis. This leads to chronic inflammation, pneumonitis, and PF. The extent to which recruitment of inflammatory monocytes, which are bone marrow derived and express CCR2, contribute to RT-induced PF has not been fully investigated, and we hypothesized that RT-induced PF is reliant on this population. To test this, CCR2-/- mice were exposed to 12.5 Gy thoracic RT. PF development was evaluated, and alterations in pulmonary macrophage subpopulations were assessed by flow in immune cells enriched from lung digests collected at 12 - 18 wk following RT. In CCR2-/- recipient mice that received C57Bl/6j bone marrow (WT > CCR2-/-) and WT syngeneic mice, fibrotic foci were observed in the periphery of the lungs by 12 and 16 wk following exposure, respectively. In contrast, in mice that received bone marrow lacking CCR2 (CCR2-/- > WT and CCR2-/- > syngenic mice), no PF was observed for at least 22 wk post-exposure and correlated with decreased numbers of infiltrating and interstitial macrophages compared to controls, and reduced proportions of proinflammatory Ly6C+ macrophages, observed at 12 - 18 wk following exposure, suggesting CCR2+ macrophages contribute to radiation-induced pulmonary fibrosis. Reduced proportions of CD206+ lung macrophages, indicative of an alternatively activated phenotype, were present at this time in CCR2+/WT recipient chimeric mice, regardless of AEA mouse bone marrow type, suggesting this resident phenotype is influenced by CCR2. In all chimeras, RT decreased the percentage of F4/80+ cells, expressed on mature macrophages and monocytes, suggesting the presence of less mature macrophages following RT exposure. These results suggest infiltrating monocytes influence resident macrophage phenotype and play a role in the development of RT-induced PF.
Comparing the RMVs against the Alexander equation during restraint gave values of 13.3 breathes/min, 132 mL/min, and 1.73 L/min at Day 16. 5 min prior to dosing. The values from 2 to 21 hrs post-dose markedly increased to 40.9 breathes/min, 124 mL/min, and RR, TV, and RMV from 16.1 breathes/min, 130 mL/min, and 2.04 L/min. The average TV for Day 8 was 193 mL/min, decreased to 142 on Day 16. The average RR on Day 8 was 25.4 breathes/min, which decreased to 20.1 after Day 10 and 14 showed a general decrease in RR. The RR, TV, and RMV values, which may mask potential effects in duration. The aim was to minimize stress-related elevations in respiratory minute volume (RMV) values, which may mask potential effects of administered test material. Pre-dose measurements of tidal volume (TV), respiratory minute volume (RMV), and activity, are potential strategies for the treatment or prevention of DNA damage, as well as mitigation of ROS production and activity, are potential strategies for the treatment or prevention of these persistent toxic, lethal effects of pulmonary radiation injury.

The minipig is increasingly being used as a species of choice for toxicological and pharmacological studies due to improved animal welfare considerations and increased ethical scrutiny of using non-human primates. However, this is not the case for inhalation studies. Prior to the inhalation dose values with pre-dosing values (-1 to -0.67 hr), the values at Days 10 and 14 showed a general decrease in RR. The RR, TV, and RMV values for the females were higher than the males. Comparing the inhalation dose values with pre-dosing values (-1 to -0.67 hr), the inhalation restraint procedure gave a marked average decrease in RR, TV, and RMV from 16.1 breathes/min, 130 mL/min, and 2.04 mL/min. These values markedly increased to 40.9 breathes/min, 124 mL/min, and 6.11 mL/min 5 min prior to dosing. The values from 2 to 21 hrs post-dose gave values of 13.3 breathes/min, 132 mL/min, and 1.73 mL/min at Day 16. Comparing the RMVs against the Alexander equation during restraint procedures found that this dataset produced RMV values that were up to 70% higher than predicted based on the bodyweight, suggesting that this equation overestimates the RMV for minipigs and RMV values should be ascertained prior to every study. However, it must be noted that no equivalent data were used in that equation’s derivation. In conclusion, the RR, TV, and RMV decreased with the number of acclimatized exposures (4%) but were considerably higher than observed pre- and post-exposure. The RMV of minipig is 70% lower than predicted by the Alexander et al. RMV equation, an RMV determination should be undertaken prior to every study, and a species-specific RMV equation is necessary.
In 2016, the American Conference of Governmental Industrial Hygienists lowered the 8-hr threshold limit value-time-weighted average (TLV-TWA) for toluene disocyanate (TDI) from 5 ppb to 1 ppb, and the 15-minute short-term exposure limit (STEL) from 20 ppb to 5 ppb, to protect against respiratory effects. However, the human evidence indicates that maintenance of 8-hr average TLV-TWA concentrations less than or equal to 5 ppb and peaks less than 20 ppb (i.e., the previous 8-hr TLV-TWA and 15-minute STEL) is protective of occupational asthma (OA) in most workers, and is also protective of lung function decrements and other respiratory effects. Some of the available studies that suggest occupational asthma cases at TWA concentrations less than 5 ppb were likely affected by very high peak exposures, well above 20 ppb. Advances in industrial hygiene measures have reduced peak exposures and the incidence of upset conditions such as spills and accidents, so these high peak exposures are unlikely to occur in modern TDI manufacturing facilities. The animal literature supports the human evidence and indicates that TDI-induced asthma is a threshold phenomenon. The evidence does not indicate that the lower TDI TLVs will result in a lower incidence of respiratory effects, including OA.

### 1197 Critical Evaluation of Thresholds for Respiratory Effects of Toluene Disocyanate

1Gradient, Cambridge, MA; and 2Gradient, Seattle, WA.

Prolonged exposure to hyperoxia (>95% O2) has been shown to contribute to the accumulation of HMGB1 in the airways of patients receiving oxygen therapy. Excessive production of intracellular reactive oxygen species (ROS) during prolonged hyperoxia exposure can compromise innate immunity, predisposing patients receiving ventilation to the development of ventilator-associated pneumonia (VAP). Nuclear factor (erythroid-derived 2)-like 2 (Nrf2) is a transcription factor that regulates the expression of endogenous antioxidant proteins. The present study investigates whether sulforaphane (SUL) and resveratrol (RES), Nrf2 inducers, can ameliorate hyperoxia-compromised macrophage functions. RAW 264.7 cells, a murine macrophage-like cell line, and bone marrow-derived macrophages (BMDM) were exposed to hyperoxia for 24 hours in the presence or absence of different concentrations of SUL or RES. SUL treatment ameliorated the increase of intracellular levels of reactive oxygen species (ROS) as well as hyperoxia-induced compromised phagocytic function. In addition, SUL was found to rescue HMGB1-compromised macrophage phagocytosis. Furthermore, both SUL and RES were found to inhibit HMGB1 release, activate Nrf2, and increase levels of the endogenous antioxidant compound HO-1. This increase in macrophage phagocytic function in the presence of Nrf2-inducing compounds suggests that enhanced antioxidant capacity through the activation of the Nrf2 pathway can improve innate immunity, providing a therapeutic approach to the treatment of VAP.

### 1198 Evaluation of the Toxicity of Sodium Dodecyl Sulfate (SDS) in the MucilAir Human Airway Model In Vitro

C. S. Rooper, J. L. Vinall, and J. B. Welch. Charles River Laboratories, Edinburgh, United Kingdom. Sponsor: S. Buleria

MucilAir™ is an in vitro airway model with morphology and functions mirroring the trachea-bronchial epithelium. MucilAir™ units comprise cells derived from human airway biopsies cultured at the air interface on permeable membranes by Epithelix. This model is increasingly used in asthma research and early development of inhaled drugs.

To investigate the toxicity of sodium dodecyl sulfate (SDS) in the MucilAir model, cells derived from human airway biopsies were cultured at the air interface in vitro. SDS was added to the culture medium at different concentrations (0-10 mM) for 24 h (37°C; humidified 5% CO2 atmosphere). Monolayer integrity was assessed using metabolic competence (resazurin reduction), membrane integrity (lactate dehydrogenase release), and other parameters such as trans-epithelial electrical resistance (TEER) and lactate content. After 24 h, histology demonstrated that pseudo-stratified epithelial morphology did not recover, recovery of basic cellular functions was limited, and cytokine release was increased. These results indicate that SDS is a potent toxin in the MucilAir model, providing a therapeutic approach to the treatment of VAP.

### 1199 Effects of Cationic Disinfectants on Surface Activity of Pulmonary Surfactant Monolayers

1Nagoya City University Graduate School of Medical Sciences, Nagoya, Japan; 2National Institute for Environmental Studies, Tsukuba, Japan; and 3St. Marianna University School of Medicine, Kawasaki, Japan.

Institute for Environmental Studies, Tsukuba, Japan; and 3St. Marianna University School of Medicine, Kawasaki, Japan. Quaternary ammonium compounds (QAC), such as benzalkonium chloride (BAC) and cetetylpyridinium chloride (CPC), constitute a group of cationic surfactants, widely used as disinfectants, preservatives, and detergents, for personal hygiene and medical use. It has been reported that inhalation of aerosols of BAC or CPC increases pulmonary inflammation in rats. Therefore, BAC or CPC deposited in the alveolar region could alter pulmonary function directly when humans inhale those aerosols. We investigated the effects of BAC, CPC, and pyridinium chloride (PC, as a control) on surface activity of the pulmonary surfactant monolayer using both Surfacten (Mitsubishi Tanabe Pharma), a modified bovine lung surfactant, and 1,2-dipalmitoyl-sn-glycero-3-phosphocholine (DPPC), a major component of the lung surfactant. One mM DPPC or Surfacten dissolved in chloroform was spread dropwise on a subphase in the trough filled with distilled water containing designated concentration of BAC, CPC, or PC. To examine the effect of BAC, CPC, or PC on the surfactant, we compared the features of surface pressure/roughness area (n-A) isotherm by the Langmuir-Wilhelmy method and atomic force microscopy (AFM) topographic images of lipid monolayer transferred onto the mica disc. The n-A isotherms showed that addition of BAC or CPC to the subphase expanded the isotherm at lower pressures to much greater areas, suggesting a reduced packing density of monolayer. The collapse pressure diminished with increasing concentration of CPC in subphase. Conversely, addition of PC (control) into subphase affected neither DPPC nor Surfacten monolayer isotherm. The compressibility modulus (Cs) of each n-A isotherm was also measured. The higher Cs value reflects the higher rigidity of the model membrane. The maximum Cs value of both DPPC and Surfacten monolayers decreased with increasing concentration of BAC or CPC in the subphase. Topographic images indicated that the presence of BAC or CPC in the subphase resulted in smaller condensed lipid domains compared to those on the subphase of distilled water or water containing PC. These results suggest that the deposition of BAC or CPC aerosols on the pulmonary surface may be related to dysfunction of surfactant activity in the lung.

### 1200 Nrf2 Inducers Ameliorate Hyperoxia-Compromised Macrophage Functions

To further investigate the role of Nrf2 in hyperoxia-compromised macrophage functions, we tested the effect of sulforaphane (SUL) and resveratrol (RES) on macrophage viability, apoptosis, and cytokine release in a hyperoxia model. RAW 264.7 cells, a murine macrophage-like cell line, and bone marrow-derived macrophages (BMDM) were exposed to hyperoxia for 24 hours in the presence or absence of different concentrations of SUL or RES. SUL treatment ameliorated the increase of intracellular levels of reactive oxygen species (ROS) as well as hyperoxia-induced compromised phagocytic function. In addition, SUL was found to rescue HMGB1-compromised macrophage phagocytosis. Furthermore, both SUL and RES were found to inhibit HMGB1 release, activate Nrf2, and increase levels of the endogenous antioxidant compound HO-1. This increase in macrophage phagocytic function in the presence of Nrf2-inducing compounds suggests that enhanced antioxidant capacity through the activation of the Nrf2 pathway can improve innate immunity, providing a therapeutic approach to the treatment of VAP.
1201 Two Novel Models for Study of Particle-Induced Alveolar Macrophage Toxicity: ASC-Transfected Raw 264.7 Cells and Max Planck Institute Cells
K. A. Wierenga1, M. A. Bates1, P. Akbari1, J. Wee2, K. N. Gilley1, M. Gavrill2, A. Holian3, J. R. Harkema1, and J. J. Pestka1. 1Michigan State University, East Lansing, MI; 2Ohio State University, Columbus, OH; and 3University of Montana, Missoula, MT.
Both human epidemiological and mouse experimental studies reveal that lung exposure to crystalline silica triggers autoimmunity. Silicosis-induced pathogenesis has been linked to NLRP3 inflammasome activation in alveolar macrophages (AM), which drives caspase-1 activation, extracellular release of mature IL-1beta, and pyroptotic cell death, thereby activating and recruiting additional immune cells to the lung. In vitro elucidation of early silica-triggered molecular events is limited by low numbers of AM that can be obtained from a single mouse (≈10^5). To address this, we compared two new in vitro AM models relative to silica-induced inflammasome activation. In the first model, RAW 264.7 murine macrophage cells were stably transfected with the ASC protein (adaptor protein essential for inflammasome assembly). Following priming with LPS for 2 h, RAW 264.7 + ASC cells were highly sensitive to silica-induced cell death and showed over a ten-fold increase in the release of IL-1beta as compared to non-transfected RAW 264.7 cells. In the second model, Max Planck Institute (MPI) cells were used. MPI cells are self-renewing macrophages, derived by culturing fetal mouse livers in GM-CSF-supplemented medium and are phenotypically similar to murine AM. Both cytokotoxicity and IL-1beta release were evident in LPS-primed silica-treated MPI cells. Taken together, the responses of silica-treated RAW 264.7 + ASC cells were reflective of responses seen in vivo upon exposure to inhaled silica. Both types of cells might be suitable in vitro alternatives to primary AM for characterizing the up- and downstream events associated with silica- triggered activation of the NLRP3 inflammasome in AM. Supported by NIH grant ES027353, the Institute for Integrative Toxicology NIEHS Training Grant T32ES070255.

1202 Long-Term Culture of Nasal, Tracheal, Bronchial, and Small-Airways Human Airway Epithelia at Interconnected and Dynamic Liquid Flow Conditions
S. Constant1, M. Caulfty1, G. Fischer2, S. Huang2, L. Wiszniewski1, A. Roux1, and S. Stoppini1. 1Epithelix, Plan-les-Ouates, Switzerland; and 2Hepia, Geneva, Switzerland.
We herein report the first interconnection of four fully differentiated epithelia reconstituted from primary human cells from different anatomical origins, namely the nose, the trachea, and the bronchial and small airways (SmallAir™). The system is composed of a culture plate allowing 3D models grown in transwells to be (i) interconnected via the basal compartment through meso-fluidics (0.3 μl/min of a common culture medium) and (ii) maintained at the Air-Liquid Interface. Stability in terms of morphology and function of the four fully differentiated human airway epithelia was evaluated. Endpoint measurement included longitudinal tissue integrity assessment (TEER); cilia activity (Cilia Beating Frequency), and histological evaluation (%Eucalcian blue staining). Quantitative immune-histological analysis didn’t reveal major differences in cell proliferation (Ki67) or ciliation (FoxJ1) between interconnected and static conditions. The study concluded that minor differences are observed for all tested endpoints after 6 weeks of culture at interconnected and dynamic liquid flow conditions; therefore, this model allows testing the toxicity of the chemical compounds simultaneously on several anatomical regions of the respiratory tract, as well as the interplay of different organs/tissues in vitro.

1203 Respiratory Irritants Cause Reversible Up-Regulation of Pro-Inflammatory Cytokines on Human Nasal Mucosa Reconstituted In Vitro
S. Huang, S. Constant1, F. Hussein, B. Boda, and L. Wiszniewski. 1Epithelix, Plan-les-Ouates, Switzerland.
Respiratory irritants are considered as substances of higher risk, at the same level as carcinogens, mutagens, and toxic chemicals for reproduction. Respiratory irritation is defined as a non-corrosive effect inducing a reversible local inflammation on the mucosa. However, until now there is no validated in vitro cell model for identifying the respiratory chemical irritants. The aim of this study is to develop an in vitro cellular assay for identification of respiratory chemical irritants based on human 3D nasal airway epithelium (MucilAir™). Epithelia were reconstituted with primary human nasal cell pooled from 14 donors. MucilAir™ is not only morphologically and functionally differentiated; it can also remain at a homeostatic state for more than one year, allowing repeated-dose and long-term toxicity testing. 11 chemical compounds, belonging to 3 classes (irritants “H35”, highly toxic “H350”, and highly toxic chemicals through inhalation), were tested. As testing strategy, 30 μl of chemical solution were applied on the apical surface of the epithelium. In order to monitor recovery, endpoints were recorded 1, 2, 5, and 7 days post-exposure. Effect on tissue integrity was monitored by Trans-Epithelial Electrical Resistance (TEER), cell viability through LDH release, high-molecular-weight, effect on cilia motion by monitoring Cilia Beating Frequency, and morphological changes through visual inspection. Proinflammatory cytokines IL-8 and IL-6 were used as biomarkers for discriminating these molecules. Interestingly, at subtoxic doses, only the respiratory irritants upregulated reversibly the secretion of IL-8 and IL-6 upon acute challenge. As conclusion, this standardized human nasal epithelium model MucilAir™ is a promising in vitro platform for identifying the respiratory irritants, and IL-8 seems to be a reliable biomarker.

1204 Low-Molecular Weight PAH-Induced Early Signaling in Lung Epithelial Cells Involves Eicosanoids
K. J. Siegrist1, D. Romo1, K. Velmurgun1, B. L. Upham2, M. L. Armstrong1, K. Quinn1, M. R. Elle1, N. Reisdorph1, and A. K. Bauer1. 1University of Colorado Denver, Aurora, CO; and 2Michigan State University, East Lansing, MI.
Low-molecular weight (LMW) polycyclic aromatic hydrocarbons (PAHs) are more prevalent in the environment and occupational settings, as well as secondhand smoke (SHS), when compared to their high-molecular-weight counterparts, such as benz[a]pyrene (B[a]P). Previously, we demonstrated that SHS-prevalent LMW PAHs activate p38-MAPK-dependent dysregulation of gap junctional intercellular communication (GJIC), which may be involved in inflammatory lung diseases. However, there is little known about the early mechanistic events leading to inflammation, specifically those mediated through lipid signaling and eicosanoids. Secondhand smoke is a complex mixture, and to model this feature in vitro we examined the effects of a binary mixture of 1-methylnaphthacene (1-MeA) and fluoranthene (Fltn) in C10 cells, a mouse, non-tumorigenic alveolar type II cell line for the ability to dysregulate GJIC (scalpel-loaded/dye transfer assay) via activated phospholipase C’s (pPLA2)) and induce cyclooxygenase-2 (COX-2), downstream prostaglandins, and pro-inflammatory mediators via immunoblotting, focused metabolomics approaches, and quantitative RT-PCR from 30 min-8 hr. Specific inhibition of pPLA2 led to significant reversal of dysregulated GJIC in response to the binary PAH mixture after only 30 min. COX-2 mRNA and protein was also significantly induced in response to these PAHs following activation of the lipases as early as 2 hr. The subsequent downstream effects were significant prostaglandin production (PGE2, and PGE1) and pro-inflammatory cytokine mRNA induction, including IL1β, IL6, CCL2, and Kc. These effects were all prior to PAH metabolism, determined via GC/MS analysis. Our results represent a mechanistic pathway of inflammatory lung disease from exposure to a more relevant real-world binary mixture of LMW PAHs through the early induction of lipid-mediated GJIC dysregulation and downstream production of eicosanoids and pro-inflammatory cytokines. Funded by R15 ES 024893-01 (AKB) and the Flight Attendant Medical Research Institute (FAMRI) CIA 130022 (AKB).

1205 In Vitro Model of the Hepatic Contribution to Lung Epithelial Cell Toxicity Induced by Ethylbenzene, Styrene, and Naphthalene
J. S. Kelty1, X. Ding2, and L. S. Van Winkle1. 1University of California Davis, Davis, CA; and 2SUNY Polytechnic Institute, Albany, NY.
Ethylbenzene (EB), styrene (ST), and naphthalene (NA) cause toxicity in the lung, but this is thought to require metabolic activation by cytochrome P450 monooxygenases (P450s) in either the liver or the lung. To date, we are developing an in vitro approach to determine whether hepatic bioactivation of these aromatic hydrocarbons can contribute to lung toxicity. We hypothesize that hepatic enzymes are capable of escalating the lung epithelial cell damage caused by EB, ST, and NA. Airway epithelial cells from either female mouse trachea (MuEC) or the human bronchiolar epithelial cell line, HBE1, were grown and differentiated at the air-liquid interface in transwell inserts. Cells were exposed to 5μM or 10μM EB, 5μM or 10μM ST, or 5μM to 3mM NA, in media containing female mouse liver microsomes. Liver microsomes were boiled to inactivate P450s for negative control experiments. Lung epithelial cell toxicity was
assessed by measuring cell permeability and cell density. MuEC cells exposed to 10μM EB with liver microsomes present resulted in a 50% decrease in cell density. No significant MuEC cell death occurred with 10μM EB and boiled liver microsomes. The 5μM EB exposure did not result in significant cell death for MuEC cells. MuEC exposed to ST or NA at 5μM and 10μM resulted in no significant cell death with or without active liver microsomes. For a higher dose of NA, 20μM, MuEC cell death was observed, but the extents were similar in the active and boiled microsome groups (~50% decrease in cell density). No significant cell death was detected in HBE1 cells exposed to 5μM to 3μM NA without active liver microsomes present. With the active microsomes present during exposure to 3 and 0.3μM of NA, a significant (20%) drop in HBE1 cell density was detected. Liver microsome-generated EB metabolites are more potent than liver microsome-generated NA or ST metabolites in causing toxicity in the mouse trachea epithelial cells. MuEC, which are primary mouse trachea cells, had apparently greater intrinsic ability to generate toxic NA metabolites, and were more susceptible to NA toxicity, compared to the HBE1 cells. Supported by R01 ES020867, P30 ES023513, NIOSH 2U54OH007550, and T32 HL007013.
to examine effects of DEP exposure on cell types beyond the epithelium. To this test, we developed a transwell-based organotypic airway model where bronchial epithelial cells are grown on a collagen matrix on the apical side of a porous membrane, and lung fibroblasts are grown in the basolateral compartment. We conducted exposures by adding DEP to the confluent epithelial cell layer and assayed changes in the expression of interleukin-8 (IL-8) and heme oxygenase-1 (HMOX1), markers of pro-inflammatory and oxidative stress, respectively, in both cell types. Exposure of epithelial cells in the organotypic model resulted in a 25- and 5-fold induction of HMOX1 and IL-8, respectively, which was greater than the 15- and 4-fold inductions observed in matched exposures lacking fibroblasts. Further, despite a lack of direct exposure, HMOX1 and IL-8 were induced by 3.300- and 3-fold, respectively, in fibroblasts in the basolateral compartment. Our findings indicate that toxic exposures can have effects outside of the directly exposed cells, suggesting this organotypic airway model can elucidate aspects of exposure response not well-addressed by traditional monoculture models. Utilizing this model in future studies could facilitate understanding the role that fibroblasts play in local and systemic adverse health effects of toxic exposures.

1210 Effects of Acute Exposure to an Environmental Electrophile on Human Platelet Bioenergetics

W. Shen1, H. Tong1, K. S. Lavrich2, A. Ghio2, D. Diaz-Sanchez2, and J. Samet3. 1US EPA/ORISE, Chapel Hill, NC; 2US EPA, Chapel Hill, NC; and 3University of North Carolina at Chapel Hill, Chapel Hill, NC.

Exposure to air pollution is a global public health problem associated with cardiovascular morbidity and mortality. Exposure to particulate matter (PM) has been reported to activate circulating platelets in vulnerable populations (patients with type 2 diabetes or coronary heart disease) within hours of exposure. 1,2-naphthoquinone (1,2-NQ) is an oxidative environmental stressor found associated with diesel exhaust particles. Given the dependence of platelet function on cellular bioenergetics, we investigated the effect of exposure to 1,2-NQ oxygen consumption rates (OCR) in human platelets using extracellular flux technology. Human platelets (HP) were isolated from venous blood collected from healthy male subjects using IRB-approved protocols. HP (30 million per well, n=3-4 per treatment group) were isolated from a blood sample collected on the day of the assay and subjected to a mitochondrial stress test using an extracellular flux analyzer (Seahorse platform) in order to assess indices of mitochondrial respiration inferred from changes in oxygen consumption rates (OCR) in response to specific inhibitors. Treatment of HP with a concentration of 1,2-NQ as low as 3 µM decreased the mitochondrial basal respiration, maximal respiration, and spare respiratory capacity in HP, while a dose of 10 µM of 1,2 NQ increased non-mitochondrial respiration, possibly associated with redox cycling, compared to vehicle-treated controls. These findings provide insights into the mechanisms through which exposure to environmental contaminants can affect cellular bioenergetics and suggest potential effects of air pollution exposure on hemostasis and cardiovascular health. This abstract of a proposed presentation does not necessarily reflect US EPA policy.

1211 Air Pollution-Mediated Alterations in CYP Enzyme Expression Dependent Upon Age and Diet in the Brains of C57B16 Wild-Type Mice

C. Kennedy1, J. Lucero1, J. D. McDonald2, and A. K. Lund1. 1University of North Texas, Denton, TX and 2Lovelace Biomedical Research Institute, Albuquerque, NM.

Inhalation exposure to traffic-generated air pollutants has been reported to have deleterious effects to the central nervous system (CNS), including blood-brain barrier (BBB) disruption and neuroinflammatory, and neurodegenerative diseases. Cytochrome P450 enzymes (CYPs) are one of the main classes of biotransforming enzymes present in the body, which mediate reactions of thousands of endogenous and exogenous substrates. Altered expression of certain CYP enzymes are associated with neurodegenerative disorders. We chose to investigate the effects of inhaled traffic-generated air pollutants on the expression of these enzymes in the CNS on the BBB. Young (2 mo) or aged (18 mo) male C57B16 wild-type mice were placed on either a “Western” high-fat (21% fat by content) or low-fat diet, and subsequently exposed to either 300 µg/m³ of mixed exhaust (MVE: 250 µg/m³ PM diesel engine + 50 µg/m³ PM gasoline engine emissions) or filtered air (FA, controls) for 6 hr/day, 7 days/wk, for 50 days. Brain tissue was collected at the end of the exposure period, and prepared for either real-time RT-qPCR or double immunofluorescence, to detect variation in CYP enzyme expression in the cerebrum and/or BBB. MVE exposure resulted in significant increases in CYP2D (~1.5-fold), CYP2E1 (~2-fold) enzymes, with trending increases in CYP1B1 enzyme expression in the CNS of aged mice on a low-fat diet, while the expression of these same enzymes had the opposite trends in expression (decreased with MVE exposure) in the CNS of young C57B16 mice on a low-fat diet. There was no statistical change observed in expression of CYP1A1 in either young or old mice. In the high-fat fed C57Bl6 mice, we observed a significant decrease in CYP1B1, with trending decreases in CYP2D, CYP2E1, and CYP3A1 mRNA in the aged mice. Inverse (increasing) trends in expression in CYP2D, CYP2E1, and CYP3A1 were observed in the young mice on a high-fat diet, compared to FA controls. Thus, our preliminary findings suggest that inhalation exposure to traffic-generated pollutants alters cerebral expression of CYP enzymes in the young vs. aged differently (typically inversely), which is further complicated with concurrent consumption of a high-fat diet. Research funded by NIHES R00ES0126586 and UNT RIG Grant GA9306 (AKL).

1212 Examining the Association of Environmental Degradation and Poor Cardiovascular and/or Respiratory Health Outcomes in a Disadvantaged Community

K. Kantaria, and H. Jeng. Old Dominion University, Norfolk, VA.

The objective of the study was to examine whether residential proximity to multiple environmental air pollution sources [two TRI industries (Industry 1 and Industry 2) and freeway] and individual-level risk factors (age, gender, and body mass index [BMI]) were associated with the poor cardiovascular and/or respiratory health outcomes of residents in the Southeast Community of Newport News, Virginia. Surveys were employed to collect demographies and health outcomes data of the Southeast Community residents. Geo-referencing was used to plot the locations of residents on a map for assessing the proximity to the pollution sources. Lakes Environmental Screen View™, which is a user-friendly interface for the US EPA SCREEN3, was used to predict the ground-level concentrations of pollutants released into the air from TRI reporting facilities. Exposure to air pollutants from the industries was defined by the distance between each geocoded residential address and industries. The distance of residence from the industry and freeway were grouped into two categories: <1 mile and ≥1 mile based on the observed increased predicted concentrations of pollutants measured, we considered a valuab...
2.51-fold increases in CB exposure group and recovery group, compared with the control. The comet assay showed that nanoscale CB particles could induce DNA damage significantly in lung cells of rats. The levels of interleukin-6, interleukin-8, interleukin-17, and tumor necrosis factor alpha in lung tissue but not in serum were significantly increased in CB exposure group compared with the control. The cell counts of white blood cell, monocytes, and neutrophils had 1.72-, 3.13-, and 2.73-fold increases in CB exposure group compared with the control. The percentage of cluster of differentiation (CD) 4+ lymphocytes and the rates of CD4+/CD8+ in CB exposure group were statistically increased, compared with the control. The stimulation indexes of the peripheral blood cell, monocytes, and neutrophils had 1.72-, 3.13-, and 2.73-fold increases after CB treatment compared with the control. CD4+/CD8+ in CB exposure group were statistically increased, compared with the control. The peripheral blood cell, monocytes, and neutrophils had 1.72-, 3.13-, and 2.73-fold increases after CB exposure for 90d, thymus and spleen displayed slightly morphologic changes. The early apoptotic thymocytes had a 2.36-fold increases after CB treatment compared with the control. CB induces the pulmonary toxicity, which includes the localized effect and the non-targeted adverse cardiovascular response of exposure to CB. Both directly and systemically, immune responses are interlinked, and thus toxicity can be considered as a combined effect of them.

**1214 Low Vitamin D Levels Are Associated with Increased Cardiovascular Responses following Diesel Exposures in Healthy Subjects**

J. Mirowsky1, K. Stratford3, M. Maddox3, S. Harder1, B. Devlin1, and M. Hazari4. 1

Cardiovascular disease accounts for over 17 million deaths per year. There is a large body of evidence suggesting that vitamin D deficiency is associated with cardiovascular disease after risk factors. Vitamin D deficiency might be associated with elevated cardiovascular responses in healthy people. Before, after, and 18 hrs following each exposure, blood samples were collected. Nine participants were males (69%), the average age of the participants was 27 years, and the majority of the participants were white (62%). The average vitamin D concentration before clean air exposures was 22.3 ng/mL, and the average vitamin D concentration before diesel exposures was 23.4 ng/mL (paired t-test; p = 0.44). Four participants were considered vitamin D deficient (vitamin D < 20 ng/mL), 7 participants had inadequate vitamin D levels (vitamin D between 21-29 ng/mL), and 2 were vitamin D sufficient (vitamin D > 30 ng/mL). Positive and significant associations were observed between baseline vitamin D concentrations and tPA (β = 6.93, 95% CI = -0.30, 13.57) and IL-4 (β = 0.01, 95% CI = 0.00, 0.01), while a negative and significant association was found with plasminogen (β = 2.84, 95% CI = 0.07, 0.61). At 0 hrs post- exposure, there were significant negative associations between baseline vitamin D concentrations and D-dimer (β = 0.02, 95% CI = -0.04, 0.00) and IL-8 (β = -0.03, 95% CI = -0.06, 0.00). Additionally, at 18 hrs post-exposure negative associations were found between baseline vitamin D concentrations and PAI-1 (β = -0.03, 95% CI = -0.07, 0.01) and TNF-α (β = -0.03, 95% CI = -0.06, 0.00). This suggests vitamin D deficiency might be associated with elevated cardiovascular responses in this cohort.

**1215 Effects of Asian Dust on Respiratory Symptoms in Children in Nagasaki and Fukuoka**

Y. Tateishi1, T. Nakamura2, Y. Nishiwaki2, K. Hashimoto3, H. Morichi4, T. Kitajima5, K. Komori5, K. Tashiro6, K. Ueda7, A. Shimizu8, A. Takeuchi9, H. Odajima10, and M. Hashizume1. 1

Asian dust (AD) originates from inland China and is carried to Japan by the Westerlies, and anxiety over its effect on human health has been expressed. We evaluated the potential effects of AD on respiratory symptoms and allergy rates in children with and without bronchial asthma in Nagasaki and Fukuoka. In Nagasaki, 110 children with bronchial asthma under outpatient care at 4 hospitals were investigated annually in March-May from 2014 to 2016. In Fukuoka, 29 children with bronchial asthma receiving outpatient care at 6 hospitals and 137 children at 2 elementary schools were surveyed in April-June 2013. The peak expiratory flow (PEF) values measured daily in the morning and evening, information collected from diaries and medical interview forms were analyzed. The exposure to AD was quantified as the values indicated by the light detection and ranging system. In Nagasaki, no association was observed between AD and respiratory symptoms (including asthma attacks) in children with asthma. In Fukuoka, also, no decrease in PEF due to AD was noted. The results concerning the effects on the health of children with asthma were consistent between Nagasaki and Fukuoka. Many of the asthmatic children in this study used anti-asthmatic drugs over a long period, and so the symptoms may have been controlled adequately. Therefore, when the analysis was restricted to the asthmatic children not on long-term anti-asthmatic medication, a decrease (about 1%) in PEF associated with AD was observed. In children without asthma, also, a decrease in PEF (about 1%) coinciding with the arrival of AD was observed. The views expressed in this article are those of the authors and do not necessarily reflect those of the Ministry of the Environment, Japan.

**1216 Diesel Exhaust Particles Downregulate PI3K/Akt/mTOR Signaling and Mitochondrial Bioenergetics in a Novel Organotypic Model of the Airway Microenvironment**

S. C. Faber. University of North Carolina at Chapel Hill, Chapel Hill, NC.

The pathophysiological importance of oxidative stress generation and induction of cytokines in diesel exhaust particle (DEP)-mediated inflammatory responses in fibroblasts, play a key role in maintaining tissue health and have the potential to play a central role in mediating bioenergetic and inflammatory endpoints following chemical exposure. Utilizing a novel 3D organotypic model of the human airway, we investigated whether DEP disrupts pulmonary and metabolic homeostasis in the airway microenvironment by impacting normal fibroblast functions through generation of oxidative stress and activation of the p38 MAPK pathway, a central mediator of cellular function. Confluent monolayers of bronchial epithelial HBEC grown on a collagen substrate in permeable Transwell inserts were exposed to DEP while healthy fibroblasts were present in the adjacent basolateral compartment. Here we show that an in vivo-like DEP exposure of airway epithelial cells strongly enhances phosphorylation of p38 as well as upstream MKK3/6 and downstream effectors MAPKAPK2, HSP27, and p35 in adjacent fibroblasts. Activation of the p38 pathway in fibroblasts was accompanied with the induction of the pro-inflammatory and oxidative stress genes interleukin-8 (IL-8) and heme oxygenase 1 (HMOX-1), respectively, which were attenuated by treatment with LY222820, an inhibitor of p38 kinase activity. We also examined the potential crossstalk between MAP kinases and the PI3K/Akt/mTOR pathway, known for regulating protein synthesis, bioenergetic, and tissue regeneration. DEP exposure decreased phosphorylation of PI3K, Akt, and mTOR in the fibroblasts while increasing phosphorylation of cell cycle regulator p27kip1 and Rb. Maximal mitochondrial respiratory rate was reduced in fibroblasts; however, these changes were not associated with alterations in gross morphology or cytotoxicity.
Silicosis is an inflammatory and fibrotic pulmonary disease caused by inhalation of silica particles. Lung macrophage plays a key role in the development and progression of inflammation and fibrosis process caused by silica particles. Bixin is a compound that is widely used as a natural food additive. And our previous studies have demonstrated that bixin could stimulate Nrf2 signaling pathway and alleviate inflammation in ventilation-induced acute lung injury as well as UV exposure-caused skin damage. To date, the mechanism of bixin in protecting silica-induced lung inflammation and fibrosis has not yet been studied. In this study, a murine silicosis model was established through silica intratracheal instillation. To elucidate the effects and mechanisms of bixin in silica-induced pulmonary inflammation and fibrosis, we treated the mice with bixin following silica instillation. Our results indicated that bixin treatment attenuated the accumulation of inflammatory cells, which significantly ameliorated pathological inflammation and fibrotic development in the lung. In addition, intraperitoneal (i.p.) injection of bixin in mice led to upregulation of Nrf2 response in the lung. The mechanism was further studied in the in vitro THP-1 cell model, where we showed that bixin activated Nrf2 signaling pathway via blocking KEAP1-mediated ubiquitination and degradation of Nrf2. Our work has brought insights into exploring anti-silicosis activities in daily consumption of natural products. In addition, our study also inspires the discovery of new beneficial effects of bixin and its application in the treatment of other inflammatory disease.

Air pollution has become a major factor concerning life expectancy and well-being. WHO estimated that 92% of the world population is affected by air pollutant concentrations that are above WHO air quality limits. An important factor in air pollution is particulate matter (PM), which has been focused heavily in many studies but often neglecting PM below 100 nm. We measured a non-road diesel engine emission effect simultaneously on A549 alveolar epithelial cell line in an air-liquid interface (ALI) exposure system and on a mouse inhalation exposure unit. Our ALI uses thermophoresis to deposit PM into cell. We used A549 that has been cultivated in inserts for 72 hours in 5% CO2 atmosphere and at 37°C. 24 h before exposure cells are allowed to form ALI Exposure was done in cells 1 h at 100% humidity with serum-free cell culture medium containing HEPES buffer. Instantaneously after exposure, medium was collected for cytotoxicity assays and cells were allowed to recover 24 h in fresh medium before further analysis. Mice were exposed in inhalation exposure chamber with 30% humidity. Control mice were at laminar airflow in an animal transfer station. Exposures for mice lasted for 4 h per day and were done for three consecutive days. Mice were euthanized and bronchoalveolar lavage fluid (BALF) were collected for analysis. A549 cells and mice BALF were analyzed with cell vitality using Dapi coloring, inflammatory response, and comet assay. Cell vitality staining showed no viability decrease in ALI samples. Whereas mice BALF cells showed significant decrease in vitality in exposed mice compared to unexposed. Inflammatory effect was at a significant level in A549 medium, but in BALF and mice serum the effect was mild. Comet assay showed that diesel emissions caused significant DNA fragmentation on A549 cells and in BALF when compared to controls. These results indicate that parallel ALI and animal inhalation exposure methods complement each other when toxicity of diesel engine emissions is assessed.

Exposure to particulate matter (PM), including mineral particles as well as organic particles/components may be linked to respiratory diseases, including asthma. This study assessed co-exposure effects of lipopolysaccharide (LPS) or Aspergillus fumigatus hyphae fragments (AFH) with mineral particle quartz (Min-U-Sil). The pro-inflammatory properties of these particles both individually and upon co-exposure were examined in human THP-1 monocytes (THP-1 Mo) and phorbol 12-myristate 13-acetate (PMA)-differentiated THP-1 (THP-1 Macrophages; THP-1 Ma). Combined effects of AFH and Min-U-Sil were further investigated in two primary macrophage models; human airway macrophages (AM)/sputum macrophages and peripheral human blood monocyte-derived macrophages (MDM), and in one human bronchial epithelial cell line (BEAS-2B). Exposures of either LPS and AFH alone increased the release of the pro-inflammatory cytokines interleukin-1 beta (IL-1β) and tumor necrosis factor alpha (TNF-α) in THP-1 Mo and THP-1 Ma at low doses, while Min-U-Sil induced IL-1β release only in THP-1 Ma. LPS or AFH co-exposed with Min-U-Sil showed both an enhanced/synergistic effect on IL-1β release from THP-1 Mo and THP-1 Ma. In contrast, the effect on TNF-α release was unchanged. There was no correspondingly increased mRNA expression of pro-IL-1β upon combined exposure. The AFH co-exposed with Min-U-Sil showed similar profound synergistic effects in AM, MDM, and BEAS-2B. The repression of mRNA expression of pro-inflammatory cytokines exposed to organic components, such as bacterial and fungal components, are more sensitive and give a stronger response to air pollution particles such as mineral particles when compared to unexposed cell. The synergistic response was caused by an enhanced release of IL-1β due to Min-U-Sil-induced activation of the inflammatory, and subsequent cleavage of LPS/AFH-induced pro-IL-1β to IL-1β.

Supporting a prominent functional role for fibroblasts in maintaining airway fibroblasts induces mitogenic crosstalk and overall downregulation of nutrient response, protein translation, and cell cycle progression, a pro-apoptotic ER stress response gene, were greater among donor with the I585I/V genotype (n=6) versus wild-type (I585I/I) donors with worse asthma symptom control. It was found that TRPA1 mRNA was expressed at higher levels among two donor samples of primary human lung epithelial cells with the I585V polymorphism of TRPV1 affected asthma symptom control. Specifically, the I585V variant was less responsive to the particle agonist coal fly ash, but heterozygosity for TRPV1 I585V was uniquely associated with worse asthma symptom control. It was found that TRPA1 mRNA was expressed at higher levels among two donor samples of primary human lung epithelial cells with the I585V/g genotype, which correlated with differences in IL-8 gene expression and secretion compared to wild-type expressing cells treated with coal fly ash (n=2). This study expanded upon these initial results and showed that the TRPA1 I585V/g genotype both increases the relative levels of TRPA1 expression as well as the relative sensitivity of primary human lung epithelial cells to diesel exhaust particles. Specifically, increases in the expression of mRNA for IL-8 and growth arrest and DNA damage-inducible transcript-3 (DDIT3), a pro-apoptotic ER stress response gene, were greater among donor cells with the I585V/g genotype (n=6) versus wild-type (I585I/I) donors (n=7). This work implies that the expression of TRPA1 in lung epithelial cells may contribute to the observed differences in asthma symptom control among subjects with the TRPA1 I585V/g genotype. Supported by ES017431 and GM121648.
Coal Fly Ash (CFA) is a byproduct of burning coal. It is found in building materials and is present in particulate air pollution. Exposure to CFA has adverse effects on human health. Transient receptor potential melastatin-8 (TRPM8) is activated by the chemical agonist menthol and also by CFA. CFA stimulates pro-inflammatory cytokine production by human primary bronchial epithelial cells via activation of TRPM8, but this finding was not replicated in mouse lungs. We constructed HEK-293 cells stably overexpressing human TRPM8, mouse TrpM8, and rat TrpM8. All three cell lines responded to the prototypical chemical agonist menthol. However, neither the mouse nor the rat TrpM8 overexpressing cells responded to CFA or a similar particle agonist, calcium oxide (CaO) nanoparticles. Reduced responses to CFA and CaO was also observed in cells stably overexpressing chicken and X. tropicalis TrpM8. Amino acid sequence alignment of human, mouse, rat, chicken, and X. tropicalis TrpM8 indicated several potentially important differences in the amino acid sequence of the extracellular pore-loop domain, which is important for TRPM8 tetramer formation and activation of human TRPV1 by CFA. We hypothesized that specific amino acids in the pore-helix region would regulate the species-specific activation of TRPM8 by CFA and related calcium-rich particles. Mutagenesis of amino acids of the human and mouse TRPM8 channels revealed that specific residues of the pore-loop domain did indeed determine species-specific activation. Mouse serine 927 and human threonine 932 were identified as important residues in the response of TRPM8 to CFA. Our results provide new insights on how particles activate human TRPM8 and provide clues for how insoluble particles may activate other TRP channels. This will aid in the development of better models for studying particle effects such as health risks associated with CFA or similar materials. Support: ES017431.

First responders and Lower Manhattan residents exposed to the World Trade Center dust (WTC dust) have been plagued by upper and lower respiratory ailments. Using anti-inflammatory drugs, this study explored the molecular pathways involved in these WTC dust-induced pulmonary ailments. WTC dust (63µg) suspended in saline was intranasally instilled in male C57BL/6 mice. Immediately post-exposure, mice were injected intraperitoneally with saline, dexamethasone (0.1mg/kg), or Drug-X (5mg/kg). Drug X is a quinolone antibiotic, which was used to treat urinary tract infections and chancroid. Drug X was found to be a highly selective IRAK1 kinase inhibitor with low cytotoxicity. New indications of Drug X have been identified for treating inflammation. Left lungs were lavaged 24 hr post-exposure for evaluation of inflammation (PMN number), and right lungs were used for RNA sequencing analysis. WTC dust-exposed mice had increased PMN infiltration (17.4±1.7%), and increased inflammatory IL1α, IL12, IL10, IL12, IL17A, and TNFα. Dexamethasone exposed mice had increased PMN infiltration (17.4±1.7%), and increased inflammatory IL1α, IL12, IL10, IL12, IL17A, and TNFα. Dexamethasone and Drug X decreased PMN in the lungs by 22 and 42%, respectively. Using a Poisson regression model, Drug X was 26% more effective in reducing WTC-induced lung inflammation (95% CI: 3.43%; p<0.001). Preliminary dynamic compound-target-pathway network analysis revealed that WTC lung inflammation most likely involved CDC-like kinase 1 (Ck1, involved in pre-mRNA processing), and the cell cycle-regulated proteins cyclin-dependent kinase 1 (Cdk1) and aurora kinase B (Aurkb). In addition, serine/threonine-protein kinase Chk1 (Chek1) and Mgc proto-oncogene protein (Myc) were also affected. Thus, WTC dust exposure may enhance cell proliferation and potentially cause lung cancer, and may help to explain the higher rate of adverse respiratory health effects being observed many years after the WTC dust exposure.
Large cities in the world are known to have many sources of air pollution and thus elevated pollutant levels. Although previous studies have looked at health effects of rapid changes in air pollution on residents, no studies have looked into the impact on the respiratory and cardiovascular systems when individuals travel abroad to cities with air pollution levels different from their home city. Travelers are exposed to varying levels of air pollution in a new environment within minutes to hours, which may lead to adverse health outcomes. This study’s goal was to examine the impact on the respiratory and cardiovascular systems due to a change in the environment when traveling to a city in another country, with a main focus on changing air pollution levels. The study recruited subjects traveling from NYC to cities abroad including London, Beijing, Shanghai, Prague, and Mexico City. Participants were pre-trained to measure lung function, blood pressure, and heart rate for 1 week before departure, during the stay, and after returning from the city abroad. Participants also carried an “Airbeam,” a portable, low-cost PM2.5 monitoring instrument, to measure personal exposure levels. The Airbeams were tested against a PDR DataRam 1500 monitor and the standard gravimetric filter method for comparison and calibration. Results from the pilot study have shown that overall, subjects who traveled to cities that were more polluted than NYC had a significant decrease in lung function as compared to their pre-travel values, whereas there was no significant difference in subjects who traveled to “clean” cities (total n=20). The maximum mean reduction in FEV1 and PEF for subjects traveling to “polluted” cities were 8% and 20%, respectively, when compared with NYC means. Systolic blood pressure levels were significantly increased in some subjects who traveled to cities whose PM levels were significantly higher than NYC. Levels in the travel abroad city were correlated with changes in lung function. The Airbeam low-cost sensors showed inter-instrument variability and required calibration of individual units. The results of this pilot study show that travel to cities with significantly higher pollution than one’s home city can have acute impacts on the cardiopulmonary system and support a concern for the potential for adverse health effects due to air pollution while traveling abroad.

Inhalation Exposure to Traffic-Generated Pollutants Results in Increased Plasma Angiotensin II and Angiotensin II Type 1 Receptor Expression in the Vasculature, Kidneys, and Adipocytes of C57Bl/6 Wildtype Mice

L. Schneider1, J. Lucero1, J. D. McDonald2, and A. K. Lund1.
1University of North Texas, Denton, TX; and 2Loveland Biomedical Research Institute, Albuquerque, NM.

Multiple studies in the literature have revealed a clear association between exposure to traffic-generated air pollution and exacerbation of cardiovascular disease (CVD). More recently, a few studies have shown that obesity exacerbates the association between chronic exposure to air pollution and prevalence of CVD. Additionally, exposure to traffic-generated pollution has been shown to induce or exacerbate obesity in both children and adults. To date, very limited information exists on the effects of inhaled pollutants on adipocytes/adipocyte signaling. The renin-angiotensin system (RAS), when dysregulated, is known to mediate pathogenesis in the renal and cardiovascular system, as well as in adipocytes, primarily through angiotensin (Ang) II signaling via the Ang II Type 1 (AT1) receptor. Thus, we hypothesize that MVE-exposure in adipocytes, primarily through angiotensin (Ang) II signaling via the AT1 receptor, results in altered RAS signaling and altered AT1 receptor expression. Ang II Type 1 (AT1) receptor. Thus, we hypothesize that MVE-exposure in adipocytes, primarily through angiotensin (Ang) II signaling via the AT1 receptor, results in altered RAS signaling and altered AT1 receptor expression. Therefore, we investigated the effects of inhaled ubiquitous air pollutants—wood smoke (WS) or mixed diesel and gasoline vehicle exhaust (MVE)—on alterations in inflammation, and on microbiota profiles in the intestine of atherosclerotic apolipoprotein E knockout (ApoE−/−) mice. Male 8-week-old ApoE−/− mice on a high-fat diet were exposed to either MVE (300 µg/m³ PM: 250 µg/m³ PM diesel engine + 50 µg/m³ PM gasoline engine emissions), WS (~450 µg/m³ PM), or filtered air (FA) for 6 hr/d, 7d/wk, for 50 d. RT-qPCR was used to quantitate expression of inflammatory factors tumor necrosis factor (TNF)-α and interleukin (IL)-1β in the intestines. Plasma cortisol levels were assessed via ELISA from ApoE−/− mice on a separate study that saw the same diet and MVE exposure conditions/durations, which was statistically increased in MVE-exposed mice, compared to FA controls. Microbial profiling of the intestine was done using Illumina 16S sequencing of V4 16S rRNA PCR amplicons. We observed a significant increase in TLR-4 mRNA in the intestines of MVE and WS-exposed (1.5-fold and 2.5 fold, respectively), and IL-1β mRNA expression (~1.4-fold induction for both exposures), while only WS exposure resulted in significantly increased TNF-α mRNA expression (~1.5-fold), compared to FA controls. Both WS and MVE-exposure resulted in decreased intestinal bacterial diversity, as well as alterations in microbiota profiles, including the Bacteroidites:Firmicutes ratio at the phyla level. Our findings show inhalation exposure to either MVE or WS have degrading effects on mouse mucosal integrity while altering microbiota profiles and diversity, which are associated with local and systemic inflammation. Supported by UNT RIG Grant GA9306 (AKL) for the analysis assays and NIH/NIEHS Grant ES014639 (MJC) for the mouse exposures/tissue.

Characterization of the Murine Alveolar Macrophage Response to In Vitro Ozone Exposure

The University of North Carolina at Chapel Hill, Chapel Hill, NC.

Exposure to ambient ozone is associated with numerous adverse health effects including airway inflammation, decreased respiratory function, and exacerbation of existing respiratory disease. Controlled exposure studies in humans have established that the response to ozone is characterized by large inter-individual and minimal intra-individual variation, suggestive of gene-environment interactions; however, the molecular basis of this variation is incompletely understood. Alveolar macrophages (AMs), a critical resident immune cell, are known to mediate aspects of ozone response. Though previous studies have extensively characterized the mouse strain-dependence of ozone response, little has been done to investigate how natural genetic variation may modify these responses through the modulation of AM function. Hence, we sought to develop an in vitro system to facilitate an analysis of the AM contribution to strain-specific ozone responses. More specifically, we developed a platform to perform an unbiased, genome-wide survey of the transcriptional responses induced by ozone in AMs. We obtained primary AMs from BALB/cJ mice, cultured them at air-liquid interface, and then exposed them to ozone (0.4 ppm x 4 h) or filtered air alone. Twenty-four hours after exposure, media and RNA were collected for cytokine measurements and whole-transcriptome RNA-seq, respectively. We detected increased MIP-1α at the protein level, and increased TNF expression at the mRNA level. Future studies will extend this approach to AMs from Collaborative Cross, a new mouse genetic reference population, in order to assess the contributions of AM to gene-environment interaction, and we will also compare the effect of in vitro vs. in vivo exposure.
Lipid Hydroperoxides as Mediators of Ozone-Induced Oxidative Changes in Human Airway Epithelial Cells

E. Corteselli1, and J. Samet1. 1University of North Carolina at Chapel Hill, Chapel Hill, NC; and 2US EPA, Chapel Hill, NC.

Despite strict regulatory measures, millions of Americans are exposed to concentrations of tropospheric ozone (O3) that are associated with an increasingly broad range of health effects. The respiratory tract is the main target of ozone exposure, causing pulmonary function decrements and airway inflammation, which are thought to occur through oxidative mechanisms. While it is known that ozone oxidizes carbon-carbon double bonds in polyunsaturated fatty acids to produce lipid hydroperoxides, hydrogen peroxide (H2O2), and various aldehydes, the role of these intermediates in downstream responses is still not well understood. Previous studies have observed an increase in the glutathione redox potential (EGSH), a marker of intracellular oxidative state, in human airway epithelial cells (HAEC) exposed to ozone. In this study we investigated the role of lipid hydroperoxides as a key mediator in ozone-induced oxidative responses in HAEC. We hypothesized that lipid hydroperoxides contribute to increases in the glutathione redox potential (EGSH) during ozone exposure. We utilized live-cell confocal imaging and the fluorogenic sensor roGFP to monitor EGSH in BEAS-2B cells exposed to the lipid hydroperoxide HpODE in real time. Exposure to HpODE induced a rapid, dose-dependent increase in EGSH. Overexpression of catalase was effective in blunting EGSH changes induced by H2O2, but not those induced by HpODE. shRNA-mediated knock-down of glutathione peroxidase 4 (GPx4), the primary enzyme responsible for reduction of lipid hydroperoxides, suppressed the HpODE-induced EGSH changes in HAEC, indicating this enzyme is critical in reducing lipid hydroperoxides at the expense of reduced glutathione. Taken together, these results suggest that lipid hydroperoxides contribute to redox changes induced by ozone exposure of HAEC. This abstract of a proposed presentation does not necessarily represent US EPA policy.

Bittersweet: Real-Time, Dynamic Changes in Blood Glucose Levels during an Acute Ozone Exposure in Rats

S. J. Snow1, W. Cheng1, A. R. Henriquez2, A. K. Farraj1, M. Hazari1, R. Conolly1, and U. P. Kodavanti1,2, 1US EPA, Research Triangle Park, NC; and 2University of North Carolina at Chapel Hill, Chapel Hill, NC.

In humans and rats, acute exposures to ozone have been shown to activate the sympathetic-adrenal-medullary and hypothalamic-pituitary-adrenal axes to induce multi-organ metabolic alterations, including impaired glucose homeostasis. These findings have largely been gleaned from one-time snapshots of responses measured after exposure. The complexity of such responses, however, requires a multidimensional view of in-life, dynamic biomolecular changes across time for accurate elucidation of etiology. The purpose of this study was to use new radio-telemetry technology capable of providing real-time quantitative glucose and core body temperature data to assess the impacts of ozone exposure across time and exposure level. We hypothesized that ozone exposure will impair normal circadian glucose rhythms in a concentration-dependent manner. Male, 13-week-old Wistar-Kyoto rats (n=8), implanted with telemeters capable of monitoring glucose and body temperature in conscious and unrestrained rats, were exposed to 0.0, 0.2, 0.4, and 0.8 ppm ozone for 4h/day, 1 day/week for 4 consecutive weeks. A crossover design was used wherein all 8 implanted animals were exposed to each concentration with continuous monitoring of blood glucose levels, core body temperature, and locomotor activity prior to, during, and following ozone exposure for the entire 4-week period. Exposure to 0.8 ppm ozone caused a precipitous increase in blood glucose levels as core body temperature simultaneously decreased, approximately 1.5h after the beginning of exposure. Glucose tolerance testing performed immediately after exposure to filtered air and 0.8 ppm ozone further revealed ozone-induced glucose tolerance. These data for the first time demonstrate the real-time temporal dynamics of ozone-induced hyperglycemia and glucose intolerance, which can be more reliably used to establish biological plausibility for epidemiologic findings and develop more predictive computational models of the biological effects of environmental stressors. This abstract does not reflect US EPA policy.

Ultrafine PM and O3 Act Synergistically to Induce Airway Injury in Aged Rats with Cardiovascular Disease

Elderly individuals with cardiovascular disease (CVD) have increased risk for adverse events precipitated by air pollutant exposure. In order to model this effect, the present investigation examined the interaction of ultrafine particulate matter (UFPm) and ozone (O3) in aged normotensive and hypertensive rats. Normal (NW) and spontaneously hypertensive (SH) aged (10-14 mos) male Wistar-Kyoto rats (350-700 g) were used in this study. Four exposure regimens included (1) filtered air (FA); (2) 1.0 ppm O3; (3) 250-300 μg/m³ UFPm, and (4) 1.0 ppm O3 and 250-300 μg/m³ UFPm (UFPm+ O3). Flame-generated particles (mean aerodynamic diameter = 74,0 nm) utilized were described previously (Lee et al., J Appl Physiol [1985], 2010 Oct;109[4]:1115-24). The experimental protocol was (1) 60-minute control period, (2) 6-hour exposure period, and (3) 8-hour recovery period. Rats were then euthanized and lungs were formalin fixed by intratracheal instillation. Standard, paraffin-embedded, hematoxylin, and eosin histopathology sections were evaluated for large airway epithelial loss (EL), epithelial necrosis (EN), and exudate (Ex) in the terminal bronchioles, macrophage infiltration (MOI), edema (Ed), and neutrophils (N) in the alveolar ducts and intravascular fibrin-neutrophil complexes (IVFNc) in parenchymal vessels in a blind fashion by a board-certified pathologist using a semiquantitative grading scale (0-5). Data were analyzed using a Kruskal-Wallis test with Dunn-Bonferroni post-hoc comparisons. Within NW groups there were significant (p ≤ 0.001) effects of UFPm+ O3 compared to FA for all pathology endpoints except for IVFNc. Within SH groups there were significance effects of UFPm+ O3 compared to FA for all pathology endpoints (p ≤ 0.001) except for IVFNc. There were significant differences between NW and SH strains for EN in the O3 exposure group (p = 0.04) and IVFNc in the UFPm+ O3 exposure group (p = 0.006). There was a synergistic interaction between UFPm and O3 exposure in both strains. The SH group was uniquely susceptible to intravascular inflammation with UFPm+ O3. The increased presence of IVFNcs in the SH group is consistent with increased thrombus formation and increased cardiovascular risk in an aged population with preexisting CVD.
Air pollutant exposure has been associated with excess cardiac mortality in elderly individuals with cardiovascular disease (CVD). In order to model this effect, the present investigation examined the synergistic interactions of ultrafine particulate matter (UFPM) and ozone (O3) in aged normotensive and hypertensive rats. Normal (NW) and spontaneously hypertensive (SH) aged (10-14 mos) male Wistar-Kyoto rats (350-700 g) were used in this study. Four exposure regimens included: (1) filtered air (FA); (2) 1.0 ppm O3; (3) 250-300 μg/m³ UFPM, and (4) 1.0 ppm O3 and 250-300 μg/m³ UFPM (UFPM+O3). Flame-generated particles (mean aerodynamic diameter = 74.0 nm) utilized were described previously (Lee et al., J Appl Physiol. 2010;109(4):1115-24). At least two weeks prior to exposure, rats were surgically implanted with telemetry units. Experimental protocol: (1) 60-minute control period, (2) 6-hour exposure period, and (3) 8-hour recovery period. Rats were then euthanized and hearts formalin fixed. Standard, paraffin-embedded, hemoxylin and eosin histopathology sections were evaluated for organized necrosis (ON), acute cellular necrosis (ACN), and hypercontractility (HC) in a blind fashion by a board certified pathologist using a semiquantitative grading scale (0-5). Data were analyzed using a Kruskal-Wallis test with Dunn-Bonferroni post-hoc comparisons. Heart rate variability (HRV) was evaluated using time and frequency domain measures. Data were analyzed using mixed model three-way analysis of variance with repeated measures followed by Bonferroni post-hoc comparisons. UFPM+O3 induced significant ON, ACN and HC in SH rats compared to FA. Within the NW groups there were significant effects of UFPM+O3 compared to FA for HRV parameters. Within the SH groups there were significant effects of O2 and UFPM+O3 compared to FA and between the NW and SH strains with O3 for HRV parameters. UFPM+O3 and PM alone induced myocardial injury in rats with CVD. There was a synergistic interaction between UFPM and O3 exposure on HRV in the NW strain. The myocardial injury and HRV responses to oxidant stress in the SH rats indicates that CVD results in increased susceptibility to air pollutants.
1237 Long-Acting β2 Adrenergic Agonists Potentiate Ozone-Induced Lung Injury and Inflammation
1University of North Carolina at Chapel Hill, Chapel Hill, NC; and 2US EPA, Durham, NC.

Ozone (O3), a ubiquitous air pollutant, disproportionally affects asthmatics. We have shown (1) that O3-induced lung injury and inflammation are associated with increased circulating epinephrine and corticosterone, and (2) that antagonists of β-adrenergic receptors (BAR) and glucocorticoid receptors (GR) attenuate many of the O3-induced effects. Agonists of both BAR and GR are used to reduce asthma-associated bronchoconstriction and inflammation, respectively. We hypothesized that treatment of healthy rats with long-acting β2 agonist (LABA; clenbuterol; CLEN; and GR agonist (dexamethasone; DEX)) would further increase O3-induced changes in lymphoid tissues, and exacerbate pulmonary vascular leakage and inflammation. Male 12-week-old Wistar-Kyoto rats were injected daily with saline, CLEN (0.004 [low dose] or 0.02 [high dose]) mg/kg, i.p., or DEX (0.02 [low dose] or 0.1 [high dose]) mg/kg, i.p.. Dual therapy was often prescribed in patients, a subset of rats received both drugs (CLEN+DEX; at 0.005 [low dose] or 0.02 [high dose]) mg/kg, i.p.). Drug treatment began one day prior to and each day before start of air or 0.8 ppm O3 exposure, 4hr/day x 2 days. O3, DEX, and CLEN+DEX, but not CLEN alone, reduced thymus and spleen weights and circulating lymphocyte numbers. However, drug treatmentalone had no significant pulmonary effects in air-exposed rats. High dose CLEN exacerbated O3-induced pulmonary protein leakage and neutrophil influx in bronchoalveolar lavage fluid (~4-fold), whereas DEX-alone did not modify O3-induced lung injury or inflammation. When both CLEN+DEX were administered, O3-induced injury and inflammation were increased only ~2-fold. In conclusion, our results show that systemic administration of DEX resulted in depletion of lymphoid tissues and circulating lymphocytes, not unlike that induced by O3 exposure, but DEX treatment did not modify O3-induced pulmonary protein leakage or neutrophil influx. However, LABA monotherapy potentiated O3-induced pulmonary protein leakage and inflammation in rats. When dual therapy was used, this potentiation was reduced to nearly half. By extension, it is possible that those individuals receiving LABA or a combination of LABA and steroids may be more sensitive to air pollution-induced pulmonary vascular leakage and inflammation. This abstract does not reflect US EPA policy.

1238 Scavenger Receptor B-I Mitigates Ozone-Induced Pulmonary Inflammation through Efferocytosis
M. X. Hodge1, S. Reece1, B. Kilburg-Basnay1, B. Luo1, J. Madenspacher1, and K. Gowdy1
1East Carolina University, Greenville, NC, and 2NIHES, Research Triangle Park, NC.

Ozone (O3) is a criteria air pollutant known to increase lung injury and exacerbate pulmonary diseases. After injury, the tissue resolution in the lung is driven in part by macrophage efferocytosis to restore homeostasis. Efferocytosis is the phagocytosis of apoptotic cells, which prevents secondary necrosis and upregulates anti-inflammatory cytokine production. Scavenger Receptor B-I (SR-BI) is a class B scavenger receptor that mediates macrophage (Mφ) efferocytosis through Src/PI3K/Rac1 activation in multiple models of cardiovascular disease. Currently, it is unknown if O3 exposure impairs efferocytosis and whether SR-BI is critical in mediating pulmonary efferocytosis. We hypothesize that O3 exposure induces efferocytosis and SR-BI attenuates the inflammatory effects of O3 on the lungs by mediating efferocytosis through the Src/PI3K/Rac1 pathway. To assess the pulmonary effects of SR-BI on O3 exposure, we exposed C57Bl/6J (WT) male mice and SR-BI-/- mice to filtered air (FA) or 1 ppm O3. Mice were necropsied 24 hrs post exposure, lungs were lavaged for bronchoalveolar fluid (BAL) to analyze protein, cytokines, and immune cell infiltration. To evaluate the effects of SR-BI on efferocytosis following O3 exposure, WT or SR-BI-/- mice were exposed to FA or 1 ppm O3. Apoptotic thymocytes were instilled oropharyngeally (o.p.) 24 hrs post exposure. The phagocyte index (PI) was calculated by counting the number of BAL Mφs that phagocytosed thymocytes compared to the number of Mφs without apoptotic cell uptake. O3 exposure in SR-BI-/- mice increased BAL GR+ cells, IL-6, G-CSF, MIP-2, KC, and neutrophil cell counts in the BAL compared to the WT mice 24 hrs post exposure. Exposure to O3 impaired efferocytosis by displaying a decreased PI compared to the FA control 24 hrs post exposure. SR-BI-/- mice displayed further impairment of efferocytosis when compared to WT controls. SR-BI protects against the pro-inflammatory effects of O3 exposure and mediates pulmonary Mφ efferocytosis of apoptotic cells. Data from this project will bridge the knowledge gap about the harmful effects of O3 inhalation and how SR-BI mitigates pulmonary inflammation. Future studies will define the molecular mechanisms by which SR-BI mediates efferocytosis.

1239 Alveolar Macrophages but Not Exudative Macrophages Are Increased following Acute Ozone Challenge
R. M. Tighe1, A. Birukova, R. L. Cummings, and Y. Yu
1Duke University, Durham, NC.

Ozone (O3) alters the pulmonary immune system, which is important to subsequent lung injury development and immune responses. Pulmonary macrophages are essential to these processes in the lung as either alveolar, interstitial, or inflammatory monocyte-derived (also known as exudative) populations. Clear identification of pulmonary macrophages is, therefore, critical to understanding their unique functional roles. To perform this, we used a recently developed flow cytometry panel and characterized the macrophage cell populations following O3 exposure. We exposed 10-12-week-old male and female C57BL/6J mice to 2ppm O3 or filtered air (FA) for 3h. At 24, 48, and 72h following exposure, the mice underwent tissue harvest to obtain single-cell solutions. Cells were stained and flow cytometry was performed using a BD LSRII. The data were analyzed using Flojo software. Flow cytometry of lung tissue following O3 identified all the major immune cells in a single reaction. Macrophages were defined as alveolar (CD45+ Ly6G+ Ly6C+ CD44+ CD11b+ Siglec F-), interstitial (CD45+ Ly6G+ Ly6C+ CD44+ CD11b+ Siglec F+) or exudative (CD45+ Ly6G- Ly6C- CD11b+ Siglec F+). At 24h post-O3 exposure as a percentage of live CD45+, Ly6-G (non-PMNs) cells, there were increased alveolar and interstitial macrophages in male and female mice without evidence of exudative macrophages. At 48 and 72h following exposure, alveolar macrophages continued to be elevated in the male and female mice, though the differences between FA and O3 were greater in the female mice. Intersitial macrophages were non-statistically elevated at 48h and had returned to baseline by 72h post-exposure. No significant evidence of exudative macrophages presence was evident at either of these time points. Alveolar and interstitial macrophages increased following O3 exposure without significant contribution of inflammatory monoocyte-derived exudative macrophages. This supports focus on these specific macrophage populations as potential modulators of O3 responses. Furthermore, this highlights the potential of detailed flow cytometry characterization of the pulmonary immune cell compartment as a tool for evaluating toxicant responses.

1240 Suppression of Ozone-Induced Macrophage Activation and Oxidative Stress by Valproic Acid
V. Sunil, K. Vayas, A. Murray, A. Venosa, A. Gov, J. Laskin, and D. Laskin
Rutgers, The State University of New Jersey, Piscataway, NJ.

Ozone is a ubiquitous urban air pollutant known to damage the lung, causing alveolar epithelial barrier dysfunction, inflammation, and oxidative stress. This is associated with an accumulation of proinflammatory/cytotoxic and anti-inflammatory/wound repair macrophages in the lung, which have been implicated in the pathogenic response to ozone. Valproic acid (VPA) is a short-chain fatty acid with anti-inflammatory and antioxidant activity. In these studies we assessed the ability of VPA to mitigate ozone-induced oxidative stress and inflammatory macrophage activation. Mice were treated with air or ozone (0.8 ppm, 3 h) in whole-body exposure chambers, followed by VPA (300 mg/kg/day, i.p.) or PBS control beginning 30 min later. Bronchoalveolar lavage and lung tissue were collected 48 h later and analyzed for markers of macrophage activation and oxidative stress. Ozone exposure resulted in increased numbers of macrophages in the lung. Flow cytometric analysis revealed that these cells consisted of CD11b+Ly6G/F4/80+Ly6C+ pro-inflammatory and CD11b+Ly6G/F4/80+Ly6C+ anti-inflammatory macrophages. CD11b+Ly6G/F4/80+Ly6C+ monocytic myeloid-derived suppressor cells (MDSC) were also identified in the lung after ozone exposure. Treatment of mice with VPA resulted in decreased numbers of pro-inflammatory macrophages in the lung, with no change in anti-inflammatory macrophages or monocytic MDSC. VPA-mediated decreases in pro-inflammatory macrophage populations were associated with downregulation of ozone-induced expression of heme oxygenase-1, 1, a marker of oxidative stress. Ozone-induced increases in the generation of 4-hydroxynonenal, a lipid peroxidation end product, were also reduced by VPA. These data...
Dietary DHA Mitigates Ozone-Induced Pulmonary Inflammation and Reductions in Specialized Pro-Resolving Mediators

B. Kilburg- Başyan1, S. Reece1, M. Hodge1, B. Luo1, M. Yaeger1, M.R. Odom1, C. Psaltis1, M. L. Armstrong1, J. L. Hannan1, N. Reisdorph2, R.M. Tighe2, S. R. Shaikh4, and K. M. Gowdy1. 1East Carolina University, Greenville, NC; 2University of Colorado, Denver, CO; 3Duke University Medical Center, Durham, NC; and 4University of North Carolina at Chapel Hill, Chapel Hill, NC.

Ozone (O₃), a criteria air pollutant, causes significant pulmonary morbidity and mortality annually. Obesity and metabolic disorders increase the susceptibility to the health effects of O₃. Currently, it is unknown why these populations are more susceptible. Our previous studies indicate O₃ exposure decreases pulmonary specialized pro-resolving mediators (SPMs), which promote resolution of immune responses. In obesity, the SPMs and, specifically, docosahexaenoic acid (DHA)-derived SPMs are decreased. Therefore, this could serve as a link between obesity and altered immune responses. Obesity is associated with consumption of a western diet (WD). We hypothesize that DHA supplementation increases pulmonary SPM levels, mitigating ozone-induced pulmonary inflammation. 5-week-old C57Bl/6J male mice were fed a normal diet (ND), a WD (45% fat) or a WD+DHA (43%+2% DHA). After 6 weeks, mice were exposed for 3 hr to filtered air (FA) or 1 ppm O₃. Pulmonary tissue lipid mediators were quantified using LC-MS/MS. In the ND group, O₃ exposure significantly increased BAL macrophages (Mₚ), pulmonary mRNA pro-inflammatory cytokine expression, and total BAL protein. This was associated with a decrease in pulmonary levels of SPMs 14(S)-hydroxy DHA (14-HDHA) and resolvins D and E (RvD, RvE) in the WD group. O₃ exposure increased BAL Mₚs, cytokine expression, and BAL protein. O₃ exposure did not change pulmonary 14-HDHA levels. In O₃-exposed mice, DHA significantly reduced pulmonary CCL2, CCL3, IL-6, and IL-1β expression. Compared to WD, DHA reduced BAL total protein and increased pulmonary 14-HDHA and resolvins DS levels, which are known to reduce pro-inflammatory cytokine expression. Unexpectedly, WD and ND have the same impact on O₃-induced inflammation. DHA increases pulmonary SPMs and SPM precursors, resulting in a decrease in pulmonary pro-inflammatory cytokine expression. These data support the novel idea that a DHA-supplemented diet may mitigate O₃-induced pulmonary responses by increasing pulmonary SPMs.

Suppression of Ozone-Induced Inflammation and Oxidative Stress by Ethyl Nitrite

S. Taylor, A. Murray, E. Abramova, M. Francis, A. Gow, J. Laskin, and D. Laskin, Rutgers, The State University of New Jersey, Piscataway, NJ.

Ozone (O₃) is a pulmonary irritant known to cause lung injury, oxidative stress, and altered pulmonary mechanics. We previously showed that this is associated with an accumulation of pro-inflammatory macrophages in the lung, which contribute to ozone toxicity. Macrophage activation toward a pro-inflammatory phenotype is dependent on NF-κB. Nitric oxide is known to downregulate NF-κB, either through direct nitrosylation of the p65 subunit or indirectly through suppression of translocation. We hypothesized that administration of the NO+ donor ethyl nitrite (ENO) would reduce NF-κB signaling through increased nitrosylation and hence limit O₃-mediated inflammation via reduced pro-inflammatory macrophage activation. Female mice were exposed to 0.8 ppm of O₃ or air for 3 hr; this was followed 1 hr later by 0.0125% ENO (50 µL) intranasally. Mice were euthanized 48 hr later. Alveolar and tissue-associated macrophages were collected by bronchoalveolar lavage and lung digestion followed by magnetic sorting for F4/80+ cells, respectively. Left lung lobes were either inflation fixed for histology or snap frozen. Flow cytometric analysis demonstrated that administration of ENO reduced O₃-induced expression of the proinflammatory marker Ly6C in both alveolar and tissue-associated macrophages; O₃-induced upregulation of Ym1, a marker of anti-inflammatory macrophages, was also reduced. This was associated with reduced epithelial cell damage, lipid peroxidation, and expression of downstream inflammatory signals, including cytochrome b5, 4-hydroxynonenal, and I1L-1β. These data suggest that nitric oxide can play a protective role in the toxicity of O₃ by limiting inflammatory macrophage activation. Supported by NIH grants ES004738, ES005022, and HL086621.

Ozone Exposure Results in Altered Lung Microbiome Diversity and Growth Pattern

L. Kerkhof, V. Sunil, K. Vayas, L. McGuinness, D. Laskin, and A. J. Gow, Rutgers, The State University of New Jersey, Piscataway, NJ.

The lung contains a significant microbiome within its lining fluid, which may be important in disease and potentially the response to inhaled toxicants. We analyzed the effects of inhaled ozone on the lung microbiome, exposing C57Bl6/J mice to air or 0.8 ppm ozone for 3 hr in whole-body chambers; bronchoalveolar lavage fluid (BAL) was collected 24, 48, and 72 hr later. Changes in the microbiome were assessed using an Oxford Nanopore (ONT) MinION system, which is accurate up to 97%. Bacterial rRNA operons were amplified using domain-specific forward primers in the 16S rRNA subunit, domain-specific reverse primers within the 23S rRNA subunit, and a High Fidelity Taq polymerase. This rRNA operon profiling approach yields an amplicon containing both ribosomal subunits for phylogenetic assignment (4,200 bp of sequence). Plus the ITS region (500+ bp) containing species/strain information. Replicate bacterial rRNA operon profiles were run. The rRNA operons were barcoded and sequenced in a 12-hr run on the MinION. We obtained 87,238 raw reads, and 11,788 were identified by MinKnow software. Sequences were analyzed using a simplified data analysis pipeline based on DMetaBlast against an NCBI 16S rRNA database via Genious software. Analysis using the Simpson diversity index showed a decrease in microbial diversity 24 hrs post-ozone, from 3.8 to 2.2, a time that we have demonstrated is associated with accumulation of pro-inflammatory macrophages. Subsequently, coordinate with the appearance of anti-inflammatory macrophages, microbial diversity rebounded to levels greater than control (5.6 vs 3.8); this was maintained for 72 hr. We speculated that the initial loss of diversity results from loss of normal microbes as a consequence of inflammation and oxidative stress; the later increases result from altered growth conditions within the lung lining fluid, and expansion of previously under-represented species. Thus, we assessed the active bacteria using a single isotope-labeling protocol. We found that only BAL from ozone-exposed animals is capable of incorporating 14C into the archael carrier band upon 16S rRNA amplification, consistent with our hypothesis that ozone alters the available carbon sources. We speculate that these alterations in the microbiome lead to increased susceptibility to disease. Supported by NIH grants HL 086621, ES005022 and ES004738.

Maternal Exposure to Polycyclic Aromatic Hydrocarbons in South Texas

A. Van Cleve1, J. Pulczinski2, Y. Luo2, L. Myatt3, K. Rychlik4, and N. M. Johnson3. 1Texas A&M University, College Station, TX; 2Johns Hopkins University, Baltimore, MD; and 3Texas A&M University School of Public Health, College Station, TX.

In this study, we characterized personal exposure to polycyclic aromatic hydrocarbons (PAHs) in pregnant women residing in Hidalgo County, where childhood asthma prevalence and hospitalization rates are among the highest in the state of Texas. Participants (n=17) in their third trimester of pregnancy were recruited from Rio Grande Regional Women’s Clinics located throughout Hidalgo County. Individuals provided three non-consecutive urine samples for biomarker analysis. We developed an isotope dilution liquid chromatography mass spectrometry method to quantify 1-hydroxypyrene (1-OHP), a common phenoil metabolite of pyrene that is often used as a biomarker to assess overall PAH exposure. In our study, 1-OHP was detected in 88% of the samples at a limit of detection (LOD) of 0.01 ng/mL urine. Individual concentration values were normalized by creatinine concentrations. Mean 1-OHP levels were 0.310 ± 0.395 (SD) with a median level of 0.213 ng/mg creat. Results illustrate that the measurement of the study population had a measurable exposure to PAHs. Values were in range of those in previously published studies for non-smoking individuals. Further analysis is ongoing to correlate urine biomarkers with additional measures of PAH and particulate matter level exposure collected from active sampling.
At present, no effective therapies exist to reduce the high mortality associated with dialysis-dependent acute kidney injury (AKI-D). Given the anuria associated with such patients, serum biomarkers may be useful in understanding the pathophysiological processes involved with AKI and assessing the severity of injury, and may point to novel therapeutic targets. In this study, Slow Off-rate Modified Aptamers (SOMA) can proteomic platform was used to profile 1,305 proteins in serum samples of patients enrolled in the Veterans Affairs-National Institutes of Health (VA/NH) Acute Renal Failure Trial Network (ATN) study. Study day-1 serum samples from 100 patients, and day-8 samples from 107 patients were analyzed by SOMAscan. From day-1 samples, 33 proteins were increased and 21 proteins were decreased when comparing samples of patients who died in the first 8 days versus patients who survived > 8 days. From day-8 samples, 76 proteins were increased and 78 proteins were decreased in patients who died between 8-28 days as compared to patients who survived >28 days. Higher serum levels of fibroblast growth factor 23 (FGF23), tissue plasminogen activator (tPA), neutrophil collagenase (MMP8), and soluble uricase plasminogen activated receptor (suPAR) on day 1, when stratified by tertiles, associated with higher mortality before and after adjusting for other potential risk factors including age, gender, cardiovascular SOFA score, congestive heart failure, and presence of diabetes. Upper tertile levels of FGF23, tPA and interleukin-6 (IL-6) on day 8 were associated with increased mortality. Ingenuity Pathway Analysis of the day-1 data revealed increased inflammation and increased coagulation in patients who died early (<8 days), and identified IL-6 as one of the top upstream regulators of inflammatory proteins. On day 8, mortality was associated with pathways of increased cell death and inflammation. The results indicate these serum proteins that may not only be important in the pathogenesis, but also helpful to discriminate AKI-D patients with high mortality.

Incidence of kidney failure is on the increase; unfortunately, traditional renal function markers are equivocal, especially at the early stage until end-stage renal disease, when a kidney transplant becomes inevitable. Hence, the need for early and more sensitive markers of renal damage indicating the presence of covert renal damage in occupational lead toxicity is imperative. This work is proposing diagnostic methods that could predict the development of chronic renal failure (CRF), especially in occupational lead-exposed subjects combining results of conventional and new biomarkers of kidney damage based on renal operating characteristics (ROC) area under the curve (AUC). Traditional renal function markers (plasma creatinine, urea, and uric acid) (TRF) were determined in one hundred each of lead-exposed subjects (LES) and non-exposed, non-nephrotic adults (control) along with sixty chronic renal failure patients (CRF) (all age-matched) using standard spectrophotometric methods. Blood lead level (Pb) was determined in one hundred each of lead-exposed subjects (LES) and control and non-exposed, non-nephrotic adults (control) along with sixty chronic renal failure patients (CRF) (all age-matched) using standard spectrophotometric methods. Blood lead level (Pb) was determined in one hundred each of lead-exposed subjects (LES) and non-exposed, non-nephrotic adults (control) along with sixty chronic renal failure patients (CRF) (all age-matched) using standard spectrophotometric methods. Blood lead level (Pb) was determined in one hundred each of lead-exposed subjects (LES) and non-exposed, non-nephrotic adults (control) along with sixty chronic renal failure patients (CRF) (all age-matched) using standard spectrophotometric methods. Blood lead level (Pb) was determined in one hundred each of lead-exposed subjects (LES) and non-exposed, non-nephrotic adults (control) along with sixty chronic renal failure patients (CRF) (all age-matched) using standard spectrophotometric methods. Blood lead level (Pb) was determined in one hundred each of lead-exposed subjects (LES) and non-exposed, non-nephrotic adults (control) along with sixty chronic renal failure patients (CRF) (all age-matched) using standard spectrophotometric methods. Blood lead level (Pb) was determined in one hundred each of lead-exposed subjects (LES) and non-exposed, non-nephrotic adults (control) along with sixty chronic renal failure patients (CRF) (all age-matched) using standard spectrophotometric methods. Blood lead level (Pb) was determined in one hundred each of lead-exposed subjects (LES) and non-exposed, non-nephrotic adults (control) along with sixty chronic renal failure patients (CRF) (all age-matched) using standard spectrophotometric methods. Blood lead level (Pb) was determined in one hundred each of lead-exposed subjects (LES) and non-exposed, non-nephrotic adults (control) along with sixty chronic renal failure patients (CRF) (all age-matched) using standard spectrophotometric methods. Blood lead level (Pb) was determined in one hundred each of lead-exposed subjects (LES) and non-exposed, non-nephrotic adults (control) along with sixty chronic renal failure patients (CRF) (all age-matched) using standard spectrophotometric methods.

Diesel exhaust (DE) as the major source of vehicle-emitted particle matter in ambient air impairs lung function. The objectives were to assess the contribution of local (e.g., FeNO and serum CC16) and systemic (e.g., serum CRP and IL-6) inflammation to DE-induced lung function impairment using a unique cohort of diesel engine testers (DET, n=137) and non-DETs (n=127). Urinary metabolites, FeNO, serum markers, and spirometry were assessed. A 19% reduction in CC16 and a 94% increase in CRP were identified in DETs compared to non-DETs (all P<0.001), which were further corroborated by showing a dose-response relationship with internal dose for DE exposure (all Ps<0.04) and a time-course relationship with DE exposure history (all Ps<0.005). Mediation analysis showed that 43% of the difference in FEV1 between DETs and non-DETs can be explained by circulating CC16 and CRP (permuted P<0.001). An inverse dose-dependent relationship between FeNO and systemic markers does not support a single mechanism for DE-induced lung toxicity. A range of 95% lower bounds of benchmark dose (BMD) of 0.315 to 0.9676 μg/g creatinine for urinary pheranths was recommended for regulatory risk assessment. Local and systemic inflammation may be a key process that contributes to the subsequent development of obstructive lung disease in DE-exposed populations.

Exposure to Pyrethroid and Organophosphate Insecticides among Adolescent Applicators and Non-Applicators

B. C. Okeke1, A. A. Ismali1, J. R. Olson2, M. R. Bonner3, G. Rasouli1, O. Hendy1, K. Wang1, and D. S. Rohlman1. 1University of Iowa, Iowa City, IA; 2SUNY at Buffalo, Buffalo, NY; and 3Menoufa University, Menoufa, Egypt.

Agricultural practices commonly include the application of several pesticides throughout a season, however, research seldom examines the impact of these multiple exposures. Previous studies have hypothesized a organophosphate (OP) mediated inhibition of the detoxification of pyrethroids (PYR) as a result of OPs inhibiting carboxylesterases responsible for hydrolyzing PYRs, resulting in PYR bioaccumulation. Exposures to PYR and OP insecticides were examined as part of a longitudinal study and metabolites (MTB) from three pesticides, λ-Cyhalothrin and α-Cypermethrin, class II PYRs, and chlorpyrifos (CPF), an OP, were examined before, during, and after the PYR application period. The goals of this study were to investigate if the urinary δ-glucuronide (D7 and D10) and trans-DCCA levels increased during the PYR application cycle and to examine the interaction between PYR and OP exposure on MTB levels. Urine samples from nine test sessions before, during and after the PYR application cycle were analyzed from adolescents employed (n=40) and not employed (n=58) by the Ministry of Agriculture (MOA). Negative ion chemical ionization gas chromatography mass spectrometry was used to analyze the samples for five MTBs: λ-Cyhalothrin (λ-Cyhal), MTB for λ-Cyhalothrin; cis-trans-3-(2,2-dichlorovinyl)-1,2-dimethylcyclopanecarboxylic acid (trans-DCCA), MTB for α-Cypermethrin; 3-phenoxypyridinol (3-PBO), a non-specific PYR MTB; and 3,6-trichloro-2-pyridinol (TCPy), MTB for CPF. Applicators had significantly higher MTB levels for all pesticides compared to non-applicants (p-values < 0.01). 3-PBO and trans-DCCA levels increased during the PYR application cycle and then continued to increase after spray ended. TCPy levels were significantly higher than the four PYR MTB (p-values < 0.0001) in both groups. TCPy and the four PYR MTB levels were examined to determine if there was inhibition in PYR biotransformation; however, higher TCPy levels were associated with higher PYR MTB levels, not demonstrating inhibition (p value < 0.001). PYR levels never returned to baseline in both groups which could be due to prior OP exposure slowing OP biotransformation and resulting elimination of PYR metabolites or to continued exposure. Further investigation into the interactive effects between PYRs and OPs are needed.

Evaluation of Prodromal and Reversibility Effects on Novel Biomarkers of Nephrotoxicity in Cynomolgus Monkeys Treated with Gentamicin

J. C. Gautier1, X. Zhou1, T. Gury1, Z. Qu2, M. Slaoui1, Y. Yang2, O. Poetzi3, C. Sommersdorf3, T. Joes4, J. F. Léonard1, P. Delitieux1, and B. Li1. 1Sanofi, Vitry-sur-Seine, France; 2National Institutes for Food and Drug Control, Beijing, China; 3Sanofi, Bridgewater, NJ; 4Signatope GmbH, Reutlingen, Germany; and 5Natural and Medical Sciences Institute at the University Tübingen, Reutlingen, Germany.

Very few studies have been published on kidney safety biomarkers in Cynomolgus monkey. This study was conducted to further evaluate the ability of novel biomarkers of nephrotoxicity to monitor the onset, progression, recovery of drug-induced kidney lesions, and to explore potential prodromal effects in this species. Groups of 4 or 6 males were given intramuscular daily injections of gentamicin at 10 mg/kg/day for 3 or 10 days and were sacrificed on Day 4, 11 or 25. Blood samples and 16-hour urine samples were collected on Day −7, −3, 2, 4, 7, 9, 11, 18 and 25. In parallel to conventional parameters, the urinary kidney biomarkers N-acetyl-β-D-glucosaminidase (NAG), microalbumin, retinol-binding protein 4 (RBP4), cystatin C, α1-microglobulin, clusterin and osteopontin were evaluated. Kidney microscopic findings consisted of minimal to mild tubular cell alteration, hyaline droplet formation and/or tubular cell degeneration/necrosis in 4/6 monkeys treated for 10 days on Day 11. There were no kidney lesions on Day 4 or 25. No increases in serum creatinine, blood urea nitrogen, urinary total protein and microalbumin were observed, except in 1/6 treated animals with mild tubular cell degeneration/necrosis on Day 11. NAG, RBP4 and clusterin were increased at similar levels from individual monkeys (2- and 3-fold, respectively), and almost returned to baseline levels during the recovery phase. On Day 4, similar NAG and RBP4 fold-increases were noted in the absence of kidney microscopic changes. A trend increase in osteopontin was noted from Day 7 and was followed by a partial decrease after treatment cessation. In this study, no significant cystatin C and α1-microglobulin changes were observed. These results indicate that the urinary NAG and RBP4 are sensitive biomarkers of nephrotoxicity in monkeys with potential prodromal added value, and which could be used to monitor the reversibility of drug-induced kidney lesions.

Kidney Injury Protein Biomarker Quantification in Canine Urine by Novel Multiplex-Immunoprecipitation Mass Spectrometry Assay

M. Sonee1, Y. Chen2, W. Naboulsi3,4, S. Bryant1, C. Johnson1, L. Nguyen2, B. Scott2, T. Joes4, O. Poetzi3, and J. E. McDuffie2.

In this 10-day (D) study, tobramycin nephrotoxicity was monitored in male beagle dogs where normal renal urinary tubular injury biomarkers were analyzed and compared with histopathology and classical parameters. For this, caninespecific sandwich immunoassays were used along with a novel multipleximmunoprecipitation mass spectrometry (IP-LC/MS) assay which can be used across species. Animals received tobramycin (60 mg/kg, n=6) or vehicle (n=3) for ten days. Urine/serum were collected at pre-dosing (D-4) and on D1, D3, D7, and D10. Plasma was collected at 0.25, 0.5, 1, 2, 4, 6 and 24h post the first last administrations. There were no deaths/cclinical observations. Tobramycin plasma exposures with respect to mean Cmax, mean AUC4-24 and mean AUC× more were higher when compared to D1. The Tmax ranged from 0.3 to 1 hours and 0.5 to 2 hours on D1 and D9, respectively. Tobramycin-induced kidney lesions were characterized by minimal to marked proximal cortical tubular necrosis and interstitial fibrosis; minimal to slight acute interstitial inflammation and hyaline casts; and minimal mononuclear cell infiltration. No significant increases in urea nitrogen and serum creatinine were detected. When normalized to urinary creatinine, increases in urinary GGT (D7 and D10) and N-acetylβ-D-glucosaminidase (D10) were detected in dogs. Dogs versus controls were used to manufacture the powders indicating that TTTCA is likely a product of glucosinate metabolism in cruciferous plants. Our data strongly suggest that TTTCA is not only an exposure biomarker of CS2 but is also a promising biomarker of cruciferous vegetable intake in clinical trials. Furthermore, consumption of cruciferous vegetables should be taken into consideration as a confounder in CS2 monitoring within high-risk populations. This work was supported by P50 CA097190 and R35 CA197222.
outperformed by selected novel urinary biomarkers, indicating that the innovative multiplex IPLC/MS assay is a valuable platform for simultaneous detection of urine-based proximal cortical tubule injury biomarker changes in dogs and potentially in other species.

1253 Sex Differences in Excretion Levels of Urinary Biomarkers of Nephrotoxicity in Rats

Urinary biomarkers have been used widely in preclinical toxicity studies to detect dysfunctions and injuries of the kidney caused by drugs under development. While they have been well-studied for evaluating nephrotoxicity, knowledge of sex differences in excretion levels of urinary biomarkers remains inadequate. We conducted experiments focused on effects of endogenous sex hormones on urinary biomarkers using intact and castrated male and female rats. Comparisons of the urinary biomarker excretion levels between intact male and female rats at 5, 7, and 9 weeks of age revealed higher excretion levels of leucine aminopeptidase (LAP), γ-glutamyl transpeptidase (GGT), total protein, liver-type fatty acid-binding protein (L-FABP), cystatin C (Cys-C) and β2-microglobulin (β2-MG), and lower excretion level of kidney injury molecule 1 (Kim-1), in male rats as compared to female rats. Orchidectomized male rats showed lower urinary excretion levels of alkaline phosphatase (ALP), GGT, N-acetyl-β-D-glucosaminidase, cystatin C, total protein, L-FABP, Cys-C, β2-MG and neutrophil gelatinase-associated lipocalin, and higher urinary excretion levels of clusterin and Kim-1 than sham-operated male rats. On the other hand, no significant differences in the urinary biomarker excretion levels excluding ALP were observed between ovariectomized and sham-operated female rats. In the present study, we demonstrated the existence of sex differences in excretion levels of urinary biomarkers that are universally used in preclinical toxicity studies, and also that these differences, especially in relation to the urinary excretions of ALP, LAP, GGT, total protein, L-FABP, Cys-C, and β2-MG, may closely relate to the endogenous testosterone.

1254 Evaluation of Urinary Renal Safety Biomarkers in Non-Human Primates with Six Model Kidney Toxicants

Certain classes of drugs (e.g., antibiotics like aminoglycosides or cephalosporins, chemotherapeutic agents, and antivirals) are known to cause drug-induced kidney injury (DIKI) in patient populations. Due to the close evolutionary relationship with humans, non-human primates (NHP) are an important nonclinical model for assessing drug-induced injuries. NHP models afford an opportunity not only to study the type of injury induced by such drugs but also to evaluate the performance of translational safety biomarkers that may be useful for monitoring similar injuries in humans. Novel urinary kidney safety biomarkers have been shown to be more sensitive than the conventional renal function biomarkers, blood urea nitrogen (BUN) and serum creatinine (Scr). To characterize the types of kidney injury caused by common drugs and to assess the relative performance of a growing list of novel kidney safety biomarkers, studies were run in NHP using six compounds that are classified as non-class A, antivirals, amino-naproxen, cyclosporine, naproxen and cyclosporine. A comprehensive evaluation of nine urinary biomarkers (albumin, creatinin, cystatin C, Kim-1, lipocalin-2 or NGAL, N-acetyl-β-D-glucosaminidase (NAG), osteopontin (OPN or SPP1), retinol binding protein 4 (RBP4) and total protein) was performed on urine collected from these studies. Treatment with each of the six compounds resulted in kidney proximal tubule injury of various severities, and the performance of the urinary biomarkers was determined relative to the microscopic histomorphologic changes observed. Among the kidney injury biomarkers analyzed, Kim-1, creatinin, and albumin showed the highest overall performance for detecting drug-induced renal tubular injury in the NHP, and the majority of the biomarkers were able to detect the injury earlier than BUN or Scr. This comprehensive evaluation of six common nephrotoxic drugs characterized the histopathological changes in the kidney and demonstrated the monitoring of such changes using novel safety biomarkers, and provided additional supporting evidence for translating these biomarkers for use in clinical settings to further ensure patient safety.

1255 Alterations in the Expression of Shelterin Complex Genes in Crystalline Silica Exposed Rat Lungs

Occupational exposure to silica can result in a variety of pulmonary fibrosis and lung carcinoma through several complex mechanisms. Therefore, it is imperative to identify the key biomarkers of silica-induced pulmonary toxicity for the intervention of lung pathologies. Telomerases (the nucleoprotein structures with repetitive (TTAGGG) sequences at the end of chromosomes) are a molecular "clock of life" and alterations are associated with several chronic diseases. Shelterin complex protection of telomerase1 (POT1), telomeric repeat binding factor1 (TRF1), telomeric repeat binding factor2 (TRF2), TRF1-interacting nuclear factor2 (Tin2), TRF2-interacting telomeric protein (Rap1), and POT1 and Tin2-organizing protein (TPP1) play an important role in maintaining telomere length and integrity and any alteration in telomeres activate DNA damage machinery resulting in telomere attrition. The goal of this study was to assess the effect of crystalline silica exposure on the regulation of shelterin complex genes in an animal model. Male Fisher 344 rats were exposed by inhalation to Min-U-Sil 5 silica for 3, 6, and 12 weeks at a concentration of 15 mg/m³ for 6 hours/day for 5 consecutive days/week. After the final day of exposure the right lung was homogenized, total RNA was isolated and reverse transcribed to obtain cDNA, and expression of shelterin complex genes was assessed. At all time points after exposure, mRNA expression of POT1, TRF1, TRF2, Tin2, Rap1, and TPP1 were significantly decreased (p<0.05) in the silica-exposed animals compared to air controls, and the decrease observed were exposure time dependent. POT1 and TPP1 which mediates telomerase-dependent telomere extension were significantly decreased in exposed animals. In conclusion, our results suggested that silica inhalation promoted shelterin complex instability. This study indicated that measurement of expressions of shelterin genes involved in telomere regulation may serve as a potential biomarker for silica-induced pathology including carcinogenesis. In addition, changes in shelterin complex could potentially promote telomere end-to-end fusions and cancer formation.

1256 Evaluation of Di-Docosahexaenoyl Phosphate (22:6 BMP) as a Biomarker of Drug-Induced Phospholipidosis in Rodents

Drug induced phospholipidosis (DIP), a lysosomal phospholipid storage disorder, has been known as a side effect of cationic amphiphilic drugs. Recently di-docosahexaenoyl (C22:6)-bis(monoacglycerol)phosphate (22:6 BMP) has been proposed as a noninvasive and specific biomarker to monitor DIP in animals and human. In this study, amiodarone (AMD), a well-known phospholipidosis inducer, was administrated to rats to evaluate onset, dose-response and reversibility of 22:6 BMP in serum and urine. We also evaluated the specificity of 22:6 BMP by the analysis of rats treated with tetracycline (TC), a negative compound for DIP. In the 1st study, AMD was orally administered to male Crl:CD(SD) rats at dose of 150 mg/kg/day for 3, 7 or 10 days. Additional animals were dosed 150 mg/kg/day of AMD for 10 days followed by 13 days recovery period. In the 2nd study, AMD and TC were orally administrated for 7 days at doses of 16, 50 and 150 mg/kg/day of AMD or 2000 mg/kg/day of TC to male rats. In both rat studies, urine was collected overnight via metabolic cages after last dosing or at the end of recovery period. Blood and tissues were collected at the necropsy, and the tissues were used for microscopic examinations. Serum and urine 22:6 BMP were measured by LC/MS/MS. DIP-related histopathological changes were observed after administration of 150 mg/kg/day of AMD for 3, 7 or 10 days, which caused the increase of 22:6 BMP in both serum and urine. AMD-induced histopathological changes and the increase of 22:6 BMP were returned to normal after the recovery period. There were no histopathological changes at doses of 16 and 50 mg/kg/day of AMD for 7 days, and serum and urine 22:6 BMP were not increased significantly. Regarding the TC dosing group, slight to moderate fatty changes of hepatocyte were observed, but serum and urine 22:6 BMP were not increased. Serum and urine 22:6 BMP are considered to be enough sensitive, reversible and specific markers for DIP. They only increase significantly when the histopathological changes related to DIP are observed.
Cardiovascular diseases are the number-one cause of death worldwide. Much is known about cardiovascular diseases risk factors, including hypertension, high cholesterol, obesity, diabetes, physical inactivity, tobacco exposure, and unhealthy diets. Additionally, epidemiological and clinical data in the last ten years positively related air pollution exposure with cardiovascular diseases. More specifically, chronic air pollution, mostly originated from diesel exhaust, has been found to increase cardiovascular disease mortality and have significant effect on atherosclerosis. So far, little is known about molecular mechanism and biomarkers of diesel exhaust particle (DEP) effects on atherosclerosis development. In this study we applied in silico approach to a gene expression profile of human macrovascular endothelial cells (HMEC) treated with DEP to predict candidate biomarkers of air pollution-induced cardiovascular effects. From the whole-genome analysis, 528 significantly dysregulated genes were selected for further analysis. For the prediction of hypotheses, our expert knowledge system utilizes a network-based approach that considers manually curated prior knowledge of genes, proteins, and chemicals and their associations with each other and to thousands of pathologies. This expert knowledge system reports that DEP dysregulated genes play a role in cardiovascular pathologies, including atherosclerosis, hypertension, cardiotoxicity, endothelial cell testing, and vascular smooth muscle toxicity. Network analysis of atherosclerosis revealed involvement of 34 genes from DEP gene expression data. Centrality analysis ranked 14 of these genes by the importance in the mechanism of atherosclerosis development. Among these 14 genes, further testing on annotated public data readily identified 6 known and potential biomarkers for atherosclerosis and cardiovascular diseases, the highest ranked being DUSP1, TNFAIP3, and MMP10. These tests support validation of a systems biology approach to discovery of biomarkers for DEP effects on the cardiovascular system.

1258 Serum 14,15-DHET, a Metabolite of Soluble Epoxide Hydrolase, Is an Early Biomarker to Predict Doxorubicin (DOX)-Induced Cardiotoxicity in Rats

Over 2.8 million women in the US in 2015 were subjected to breast cancer chemotherapy, which increased 5-year survival rate. However, chemotherapy anthracyclines, e.g., doxorubicin (DOX), cause cardiotoxicity and heart failure (34% of the patients). Early diagnosis followed by medical intervention is critical to prevent cardotoxicity. The aim of this study is to find whether serum hypertension biomarkers, 14,15-DHET (metabolite of soluble epoxide hydrolase), 20-HETE (metabolite of cytochrome P450 4A4/4F) and 8-isoprostane (non-enzymatic oxidative stress product) are early biomarkers to predict DOX-induced cardiotoxicity. Female Sprague-Dawley rats (n=6 per group) were treated with and without DOX (3 mg/kg /week, i.v. for 2 weeks) (no recovery group) and with a 2-week recovery period (2 week recovery group). Decreased ANP and BNP mRNA levels in the myocardium is a marker of hypertrophy. Whereas no increases of heart ANP and BNP mRNA levels were detected by RT-PCR after 2 weeks of DOX treatment, mRNA levels increased ~3-fold and 2.5-fold, respectively, after 2 week recovery. A hypertrophy and vacuolization study of heart tissues of the rats revealed that no damage occurred after the 2-week recovery. The qualitative and mRNA analyses after DOX treatment suggested that the rats in the 2-week recovery group did not experience cardiotoxicity. Early increase of the BNP mRNA level without cell hypertrophy followed by decreased BNP mRNA levels after extended recovery period with cell damage were correlated with DOX-treated rats. The results demonstrated that the fatty acids were not affected after two weeks of DOX treatment (no recovery). However, after 2 week recovery, when cardiotoxicity was still not detected, levels of 14,15-DHET (p<0.05) and 8-isoprostane (p<0.05), but not 20-HETE levels, were increased compared to the control group. The results suggest that 14,15-DHET and 8-isoprostane are early biomarkers to predict DOX-induced cardiotoxicity.

1259 Air Pollution-Induced Cardiovascular Effects: Bioinformatics Approach to Biomarker Identification

The aim of these studies was to determine the utility of candidate biomarkers in the assessment of platelet activation and stress; two endpoints adding to the interpretation of preclinical toxicology studies. Platelet activation is usually measured in vitro, using whole blood, by flow cytometry. This requirement for special sampling and instrumentation limits the use of these assessments for in vivo studies. This study qualified the performance of assays for fibrinogen, d-dimer, p-selectin, and 14,15-DHET, biomarkers that reflect in vivo platelet activation and clot formation and are present in plasma, which is readily collected and analyzed. Samples taken from cynomolgus monkeys and human donors were incubated with activators ADP, TRAP-6, and thrombin, processed to platelet lysates and incubated with an immunoassay for fibrinogen, d-dimer, and 14,15-DHET. The results for both species reflect fibrinogen and d-dimer are potential biomarkers of clot formation and breakdown. A cynomolgus monkey cross-reactive p-selectin assay was not identified. For stress biomarkers, IL-6 and cortisol were examined in plasma. Salivary cortisol levels, which are potentially less stressful to collect, were also measured to determine if those levels accurately reflect plasma levels. The following stressors were evaluated: cynomolgus monkeys during acclimatization following shipment, and beagle dogs before and during facility transfer. The stressors failed to elicit an increase in IL-6 to above the lower limit of quantification for either species. For monkeys, there was no relationship between cortisol levels and acclimatization, nor between individual plasma and saliva cortisol values. This could be due to rapid acclimatization and the effects of social dominance. For dogs, both plasma and saliva cortisol levels increased roughly 2-fold on the day that they were moved, and then decreased back to baseline levels. The results for both species reflect veterinary observation. In summary, these data suggest that fibrinogen and d-dimer are potential biomarkers of clot formation and breakdown in vivo in cynomolgus monkeys, and that plasma and salivary cortisol are potential biomarkers of stress in beagle dogs, but not cynomolgus monkeys, using the given stressors. The qualification of the assays used in this study enables their use in toxicology studies to provide additional interpretation to other findings.
1261 Changes in Whole Blood Gene Expression Due to Exposure to Bromobenzene or Allyl Alcohol

M. G. Permenter1, D. M. Kumshner2, J. Koontz2, and V. T. Divito2.
1 EXCEAT at USAECHE, Ft. Detrick, MD; and 2 US Army Center for Environmental Health Research, Ft. Detrick, MD. Sponsor: M. Madejczyk

Exposure to toxic industrial chemicals resulting in organ injury is an occupational hazard for many workers, community members, and military personnel. Bromobenzene and allyl alcohol are two such chemicals which may cause injury to the liver and kidney. Peripheral blood is an accessible biofluid containing a wealth of information. Transcriptomic analysis of blood has shown that gene expression changes are reflective of physiological and pathological events in different tissues. Here, we examined gene expression in the whole blood of rats exposed to bromobenzene or allyl alcohol to elucidate the mechanisms of toxicity, as well as to identify potential biomarkers of steatohepatitis induced by bromobenzene or fibrosis induced by allyl alcohol. Rats (n=5) were treated with 78.5, 157, or 314 mg/kg of bromobenzene, 45 mg/kg of allyl alcohol, or vehicle control daily for up to 5 days. Blood samples were collected at days 2-5 after the final exposure. Whole blood transcriptomics were assessed by next-generation sequencing. Differential gene expression was determined using edger and enrichment analyses were performed. Exposure to the toxicants induced gene expression changes at each time point. Interestingly, more genes were changing in the early time points due to exposure to bromobenzene than after 5 days, while more genes were differentially expressed at the later time points due to exposure to allyl alcohol. Many of the same canonical pathways, such as actin cytoskeleton signaling and acute phase signaling, were enriched by both chemicals, however the chemicals differed in whether they activated or inhibited the pathway. The transcriptomic analysis also suggests that both chemicals inhibit PPARα/RXRα activation. In conclusion, we tested rats for steatohepatitis and fibrosis inducing chemical and measured gene expression changes in whole blood daily for four days. We identified modulated molecular pathways and functions common and unique to each chemical, providing insight into the molecular difference between steatohepatitis and fibrosis as well as identifying potential biomarkers specific to these different liver injuries. Research was conducted in compliance with the Animal Welfare Act, and all other federal requirements. The views expressed are those of the authors and do not constitute endorsement by the US Army.

1262 Expression and Release of Hepatic Biomarkers from Primary Human Hepatocyte Spheroids

C. C. Bell1, C. A. Johansson1, J. Dear2, D. P. Williams3, and M. Söderberg1. 1 AstraZeneca, Gothenburg, Sweden; 2 University of Edinburgh, Edinburgh, United Kingdom; and 3 AstraZeneca, Cambridge, United Kingdom.

Drug-induced liver injury is a major obstacle to the development of new medicines, and is associated with significant patient risk. Detection of hepatic liabilities is complicated by species differences in drug metabolism as well as a lack of mechanistic biomarkers. In vitro systems which better mimic human liver physiology may serve to bridge this gap. In the current study we therefore sought to determine how emerging clinical biomarkers were regulated in a spheroid model. Spheroids generated from cryopreserved primary human hepatocytes were treated with acetaminophen (APAP) or staurosporine (STA), which induce cell death via predominantly necrotic or apoptotic mechanisms respectively. Media and cells were harvested at 1, 2, 4, 4h, 24h and 72h and a panel of hepatic biomarkers including cytoketeron 18 (both full length (CK18) and a caspase-cleaved fragment (ccCK18)) and mir-122 were measured and compared to levels of cellular ATP. In addition, the expression and localization of these biomarkers was monitored via immunohistochemistry. Both compounds induced a time and dose dependent reduction in cellular ATP. This was followed by elevations in mir-122 and CK18 which were both detected in cell culture media at later time points (24-72h), suggesting a leakage of cellular contents. APAP treatment resulted in minimal production of ccCK18, whereas it was increased up to 5-fold after treatment with STA, confirming that the spheroids can be used to distinguish between apoptosis and necrosis. Detection of ccCK18 was improved significantly when analyzing cellular lysates rather than culture medium, likely due to very low constitutive amounts of the fragment present in healthy cells. At the same time increased expression of active caspase 3 in STA-treated spheroids was observed via immunohistochemistry, allowing the identification of specific apoptotic cells. Wider analysis of clinically relevant miRNA candidates as well as transcriptomic profiling will be now be performed in order to identify toxicological signatures of different drug-induced pathologies. The addition of non-parenchymal cells such as Kupffer and stellate cells will also be investigated as a possible route to better mimic in vivo physiology and model adverse reactions where multiple cell types are involved.

1263 Quantitative, Accessible, and Translational Biomarkers of Gastrointestinal Toxicity

Drug-induced toxicities to the gastrointestinal tract (GIT) encompass diverse pathologies, reflecting the heterogeneity in physiological function in this system. Clinically, adverse drug reactions include: upper GIT erosions from non-steroidal anti-inflammatory drugs (NSAIDs) and dose-limiting lower GIT safety concerns such as diarrhea or colitis due to chemotherapeutics and immuno- oncology therapies. Qualification of quantitative and accessible GIT injury biomarkers with a mechanistic association to the injury and with translational relevance will enhance the ability to use preclinical toxicity studies to predict adverse clinical outcomes. Here we compare the performance of mechanistically diverse biomarkers of GI injury in multiple models for the first time with a two week mechanistic toxicity study in rats with the NSAID indomethacin (INDO) (up to 3 days), the chemotherapeutic methotrexate (MTX) (6 days) and the mucosal solvent dextran sulfate (DSS) (6 days) to respectively, evaluate the performance of plasma and fecal biomarkers of GIT injury due to: epithelial perforation, disruption of intestinal villus turnover and colitis. The biomarkers evaluated were plasma citrulline, intestinal fatty acid-binding protein, CD14 and lipopolysaccharide-binding protein and fecal lipocalin-2. These measurements were accompanied by terminal histopathology and genomic analysis and by standard clinical observations (COs), measurements of body weight (BW) and fecal hemoglobin (Hb). Standard measurements showed: significant BW loss and fecal Hb for INDO-treated animals by Day 3 and before Day 6. Watery feces, with slight BW loss, for MTX-treated animals (Day 6 on), accompanied by increased morbidity without recovery. No GIT-related COs or BW loss in the DSS-treated animals. However, a dose-dependent, mechanistically-coherent and organ-specific increase in histopathological findings and genomic expression was observed due to all treatments, demonstrating low sensitivity of standard in life measurements for specific GIT toxicities. In contrast, accessible biomarker responses matched the type, onset, severity, incidence and recovery of histopathology findings; consistent with the mechanistic link between biomarkers and injury. The biomarkers evaluated are clinically translatable and add sensitive, quantitative, mechanistic information to standard measurements of GIT injury.

1264 Mechanism of the Phenylhydrazine-Induced HbA1c Reduction in Rats

K. Matsuyama1, Y. Katou1, T. Aoki2, H. Kanno2, and T. Iwasaki2. 1 Shionogi & Co. Ltd., Osaka, Japan; and 2 Tokyo Women’s Medical University, Tokyo, Japan. Sponsor: Y. Tomomura

Hemolytic anemia affects glycated hemoglobin (HbA1c) levels, which are widely used as an indicator of glucose control in patients with diabetes. However, there are limited experimental data examining the mechanism underlying HbA1c changes in hemolytic anemia. We examined HbA1c levels in three animal models of Sprague-Dawley rats (hemolysis model, blood loss model, and aplastic model) and compared old and young rat erythrocyte sensitivity to phenylhydrazine (hemolysis model, blood loss model, and aplastic model) and compared old and young rat erythrocyte sensitivity to phenylhydrazine in vitro. Based on the specific HbA1c decreases in the hemolytic model, the change in HbA1c was not affected by the change in the percentage of reticulocytes. Additionally, the in vitro study indicated that phenylhydrazine induced greater methemoglobin formation in old erythrocytes than that in young erythrocytes due to decreases in methemoglobin reductase activity. These findings indicate that the mechanism of decrease in HbA1c induced by phenylhydrazine is attributable to hemolysis, specifically occurring in old erythrocytes. These data suggest that HbA1c can be a sensitive biomarker for hemolysis, particularly hemolysis induced by oxidative stress. Importantly, these findings contribute to the understanding of the glycosylated hemoglobin process and the correct use of HbA1c as a screening tool for hemolysis and diabetes.
A new safety testing paradigm that relies on gene expression biomarker panels was developed to easily identify drug-induced tissue injuries prior to drug candidate selection. The approach has yielded positive impact on early compound de-risking, enabling drug advancement while reducing later probability of attrition. Further, defining doses associated with tissue injury has provided additional perspective to advancing dose and development of emerging mechanistic biology that may be impacted as a consequence of organ toxicity. Here we describe the development, qualification, and implementation of gene expression signatures that diagnose tissue degeneration/necrosis for use in early rat Safety Lead Optimization (SLO) tolerability studies. Microarray data were used to first identify approximately 400 genes that were discovered as being shared consistently across 4 prioritized tissues (liver, kidney, heart, skeletal muscle), following injuries induced by known toxicants and so were termed ‘universal’. Quantitative PCR on ~100 of those genes followed, and the approach was extended across 5 other tissues (pancreas, spleen, GI, bladder, and testes) where early toxicities are historically less common. The most consistent and robustly responding transcripts were selected, resulting in a final 12-gene set for each of 9 tissues, with some tissues supplemented with transcripts specific for a given tissue (e.g., Kim-1 for kidney). Mathematical algorithms were generated to convert each tissue’s gene expression fold changes for the 12 genes into a single metric, scaled between 0 and 1, and a positive threshold was set using a training set of approximately 60 compounds. Performance for all tissue signatures on an independent test set of approximately 30 rat studies yielded approximately 90% sensitivity and 100% specificity. Bundled together, we have incorporated these gene expression signature panels into a 5 day rat SLO derisking study, that provides rapid objective assessment of compound liabilities, benchmarks toxic doses, and guides selection of lead candidates to improve attrition without the necessity to perform time-consuming histopathology, which can be reserved for advancing more optimized compounds at later GLP development stages.

Impact of Stress on Histology, Hematology, Clinical Chemistry, and Biomarkers of Inflammation and Muscle-Injury in Rat

Stress may affect results and complicate data interpretation in safety assessment studies. Prednisone is a short-acting corticosteroid, which is known to mimic characteristics of a physiological stress response in animals. Studies with vehicle vs prednisone-treated rats were conducted to examine the impact of chemically-induced stress on the histology, hematology, clinical chemistry, and biomarkers of inflammation and muscle-injury. In the 1st study, rats received 2 or 4 doses of prednisone at 0.03 or 10 mg/kg. Blood was collected 24 hours after the final dose. No changes in the clinical chemistry or biomarker results for cardiac troponin I (cTnI), myosin light chain 3 (Myl3), monocyte chemotactic protein-1 (MCP1), thrombospondin-1 (TSP1), N-terminal pro cardiac troponin I (cTnI), myosin light chain 3 (Myl3), monocyte chemotactic protein-1 (MCP1), thrombospondin-1 (TSP1), N-terminal pro-cardiac troponin I (cTnI), myosin light chain 3 (Myl3), monocyte chemotactic protein-1 (MCP1), thrombospondin-1 (TSP1), N-terminal pro-cardiac troponin I (cTnI), myosin light chain 3 (Myl3), monocyte chemotactic protein-1 (MCP1), thrombospondin-1 (TSP1), N-terminal pro-cardiac troponin I (cTnI), myosin light chain 3 (Myl3), monocyte chemotactic protein-1 (MCP1), thrombospondin-1 (TSP1), N-terminal pro.
1269 Identification of Candidate Genes Associated with Breast Cancer Using Multiple High-Throughput Analysis

S. Yequivapalli1, R. Pamanji2, and K. Chitrala3. 1University of South Carolina School of Medicine, Columbia, SC.

Breast is one of the common cancer types prevalent in women worldwide. Molecular profiling of breast tumors may lead to the identification of gene sets or signatures that are associated with higher risk of metastasis and poor disease outcome for the patients. In the present study, we aim to analyse these gene signatures using high throughput put analysis. Breast cancer samples from the patients who haven’t sought chemotheraphy and underwent breast conservation surgery or total mastectomy were collected from Sri Venkateswara Medical College, Tirupati. Sub classification of the breast specimens were done by immunos- taining for estrogen receptor, progesterone receptor and human epi- dermal growth receptor. Gene expression analysis was performed using microarray analysis. Microarray profile for the patient samples were compared with the gene expression profile data available at the public domain databases Gene Expression Omnibus and Array express. Results from microarray analysis of the samples with a fold value of 0.6 showed that 4162 genes were up regulated and 9629 genes were down regu- lated. Among them, up regulated cancer pathway genes were 84 and down regulated cancer pathway genes were 140. Among the genes conferring high susceptibility to breast cancer, BRCA1 (fold value = 0.86), BRCA2 (fold value = 1.12), TP53 (fold value = 1.20), STK11 (fold value = 1.03), CDH1 (fold value = 9.09) were found to be up regulated whereas PTPN11 (fold value = 1.31) was found to be down regulated. In the case of moderate and low penetrance genes, ATM (fold value = 0.69), CHEK2 (fold value = 1.33), BRI1 (fold value = 2.28), TOX3 (fold value = 2.95), MAP3K1 (fold value = 0.68), FAM84B (fold value = 2.31), NEK10 (fold value = 0.83), CASP8 (fold value = 1.07), ES1 (fold value = 1.95) were found to be up regulated whereas PALB2 (fold value = -0.04), FGFR2 (fold value = 0.34), LSP1 (fold value = -1.08), COX11 (fold value = -0.93), TPNI1 (fold value = -0.20), NOTCH2 (fold value = -0.76), RAD51B (fold value = -0.14), FGR10 (fold value = -0.42) were found to be down regulated. Overall, results from the present study may provide fundamental aspects early prognosis and therapeutic strategies in breast cancer.

1270 Anti diabetic Activity of NR4A1 Ligands in C2C12 Muscle Cells

K. Mohankumar. Texas A&M University, College Station, TX.

Research in this laboratory has identified 1,1-bis (3'-indolyl)-1-(p-hydroxyphenyl) methane (DIM-C-pPhOH) as an NR4A1 ligand that acts as an antagonist and inhibits pro-oncogenic NR4A1-dependent, growth, survival, and migration of cancer cells and tumors. A series of butyrenes (3 or 3, 5-substituted) analogs of DIM-C-pPhOH have been prepared, and this second generation set of NR4A1 ligands typified by the 3-chloro- 5-methoxy analog (DIM-C-pPhOH-3-Cl-5-OCH3) is 4 to 10 times more potent than DIM-C-pPhOH. In this study we used C2C12 muscle cells to investigate the antidiabetic activity of NR4A1 ligands, which includes induction of GLUT4 and glucose uptake and induction of glycolytic gene expression. Treatment of C2C12 muscle cells with metformin or the NR4A1 ligand DIM-C-pPhOH induced NR4A1 and GLUT4 mRNA and protein expression. Similar results were observed with butyrenes (3 or 3, 5-substituted) analogs of DIM-C-pPhOH including DIM-C-pPhOH-3-Cl-5-OCH3, and the butyrenes analogs were more potent than metformin or DIM-C-pPhOH as inducers of NR4A1 and GLUT4 mRNA levels. Metformin and the bis-indole substituted analogs also induced expres- sion of several glucose synthesis genes and Rab4, which has previously been linked to enhancing cell membrane accumulation of GLUT4 and overall glucose uptake in C2C12 cells, and these responses were also observed after treatment with metformin and the NR4A1 ligands. The role of NR4A1 in mediating these responses was also confirmed by knockdown of NR4A1, which attenuated not only the bis-indole NR4A1 ligand but also the metformin-induced responses. Our results demon- strate for the first time that the bis-indole-derived NR4A1 ligands rep- resent a novel class of anti diabetic drugs that enhance glucose uptake in C2C12 muscle cells, and we also show that the antidiabetic effects of metformin in this cell line are NR4A1-dependent.

1271 Enzymatic Activities of PON1 as Predictors of Cardiovascular Disease: Which is the Ideal Biomarker?

F. Murillo-González1, N. Ponce-Ruiz1, A. Rojas-García1, S. Rothenberg Lorenz2, J. Ponce-Gallojos3, L. Hernández-Ochoa4, B. Barrón-Vivanco1, Y. Bernal-Hernández1, C. González-Arias1, and I. Medina-Díaz1. 1Universidad Autónoma de Nayarit, Tepic, Mexico; 2Instituto Nacional de Salud Pública, Cuernavaca, Morelos, Mexico; 3Hospital Puerta de Hierro, Tepic, Mexico; and 4CINVESTAV-IPN, Mexico, Mexico.

Paraoxonase 1 (PON1) has been extensively studied in the field of toxicology and more recently it has been well established as a cardioprotective agent in cardiovascular diseases (CVD). PON1 is a high density lipoprotein-associated enzyme that has antioxidant and anti-inflammatory activities towards organophosphate triesters, alylesters, lactones, among others. The aim of this study was to demonstrate which of the enzymatic activities of PON1 predict CVD the best. A case-control study was conducted in 356 volunteers from Institutes of Health in Nayarit, Mexico. The Case group was divided in two subgroups: cardiovascular risk factors group (CRF) and cardiovascular disease group (CVD). The study was approved by the Institutional Ethics Committee. Written informed consents were obtained from patients in compliance with Good Clinical Practice. PON1 activities were assessed in plasma samples using 4-chloromethylphenyl- nitrate (CMCPase), dihydroucamarin (LACase) and ethyl-paraoxon (PONase) as substrates. Our results showed that the LACase activity was 12 U/mL, 13 U/mL, and 9 U/mL in control, CRF and CVD groups, respectively. The CMCPase activity was 22.06 U/mL, 21.73 U/mL and 14.18 U/mL in control, CRF and CVD groups respectively. Comparing LACase and CMCPase activities, there were significant differences between control and CVD (p<0.0001), and between CRF and CVD (p<0.0001). No significant difference in PONase activity was found. Logistic anal- yses showed that the risk of having CVD decreases (RRR = 0.85, 95% CI 0.79-0.91) as the CMCPase activity increases. Also, the increase in LACase activity diminishes the risk of belonging to the CVD (RRR = 0.56, 95% CI 0.47-0.67). CMCPase or LACase activities had no influence on the risk of having CRF. Further, PONase activity had no influence on the risk of having CVD or CRF. These data together showed that LACase activity was the best predictor of CVD, followed by the CMCPase activity of PON1.

1272 DTMBA Metabolite as a New Biomarker of Exposure to Vinclozolin

Vinclozolin (V) is a fungicide with anti-androgenic properties whose metabolism is not fully understood, and data on urinary elimination of either V or its metabolites are limited. M3 metabolite has been used as biomarker of V exposure; nonetheless, it is a non-metabolite of V and would be generated during the processing of samples for analysis. Furthermore, there is no quantitative information about its generation from the metabolism of V by humans. Therefore, the kinetics of urinary elimination of V and its metabolites, after an oral dose (100 mg/kg) in adult male rats were investigated. V and its metabolites were extracted from urine, then enzymatically hydrolyzed using β-glucuronidase/sul- fate of H. pomatia, and analyzed by HPLC/DAD. Urinary pharmaco- kinetic parameters were calculated using the analute concentrations adjusted by creatinine levels. V and its metabolites DTMBA (formerly denoted as M5), M1, M2 were efficiently detected. The mean urine concentration of DTMBA was the best predictor of CVD, followed by the CMCPase activity of PON1.
Recently, study on circulating microRNAs (miRNAs) as potential biomarkers of drug-induced liver injury (DILI), has received increasing attention. It has been demonstrated that miR-122 and miR-192, which are liver enriched, could be potential biomarkers of DILI. However, these miRNAs cannot discern types of injuries. In this study, we identified plasma miRNAs that can distinguish different types of DILI, hepatic, biliary, or mixed cholestasis and steatosis, using deep sequencing. Male 6-week-old Sprague Dawley rats were treated with acetaminophen (APAP, 1500 mg/kg, p.o.) and thioacetamide (TAA, 100 mg/g, p.o.) for hepatic DILI models, o-naphthylisothiocyanate (ANIT, 150 mg/kg, p.o.) and 4,4'-methyleneedianiline (MDA, 250 mg/kg, p.o.) for cholestasis models, and carbon tetrachloride (CCL4, 300 mg/kg, p.o.) and dexamethasone (DEX, 15 mg/kg, p.o.) for steatosis models. Blood was collected at several time points, and miRNA was extracted from plasma for comprehensive expression analysis of small RNAs, in which more than 300 miRNAs were identified in each DILI model. The expression level was normalized with DESeq package of R software. To compare the expression profiles between different injury models, hierarchical clustering was performed, and we defined early, middle, and late stage of injury based on the cluster patterns. Through differential analysis, we characterized miRNAs that were specifically up- or down-regulated in each DILI model with traditional biomarkers, such as ALT and T-Bil, were observed in the late stage of injuries, whereas miRNA profiles were dramatically changed earlier than those traditional biomarkers. For example, in APAP-induced hepatocellular injury model, miR-let-7b-5p was up-regulated as early as 3 h after dosing, while significant change in ALT level was observed 24 h after. Thereafter, we focused on the DILI type-specific miRNAs which were up-regulated at early stage of injury, and performed RT-qPCR validation. As a result, miR-let-7b-5p for hepatic cellular injury models, miR-143-3p for cholestasis models, and miR-302-3p for steatosis models have been shown increase in the early stage of injuries. Our study suggests potential miRNA biomarker candidates which can detect early stage of DILI in type-specific manners.

Exosomes are nanovesicles present in many body fluids including urine. In the kidney they are secreted by different cell types and contain microRNAs (miRNAs) which change in number and profile depending on pathophysiological processes. They are therefore considered as promising urinary biomarkers for kidney injury. Yet a consensus on a standard method for exosome isolation and exosomal miRNA analysis is still lacking. Currently available isolation methods cause differences in miRNA yield and profile, and in microvesicle (MV) contaminations. Furthermore some require rather large urine volumes. We compared three exosomal miRNA isolation kits regarding their performance in small urine volumes from a rat disease model: (1) Size exclusion chromatography (SEC) columns (Izon) combined with the miRNeasy kit (Exiqon), (2) the precipitation-based mirCURRY Exosome and miRNA Isolation kit (Exiqon) and (3) the Urine exosome RNA isolation kit (Norgen Biotek). Single miRNAs were quantified using the mirCURRY LNA Universal miRNA PCR kit (Exiqon), and Mouse&Rat miRNome Panel I (Exiqon) was used for profiling. The amount of exosomes was quantified by western blotting (WB) for the exosomal proteins Alix and TSG101. Contamination with microvesicles (MV) was addressed with the ER marker protein calnexin, which is also present in MVs. Our results show that it was possible to isolate exosomal miRNA with all three methods: The miRNA yield was highest for the Norgen kit, followed by mirCURRY, but considerably lower for the SEC protocol. According to the WB results, the greatest amount of exosomes was obtained with the miCURRY kit, followed by SEC. MV contamination was present in both preparations to the same degree. WB evaluation of Norgen kit preparations was technically not possible, due to a component in this kit which prevented appropriate protein separation by gel electrophoresis. Based on the best performance in miRNA qPCR and WB, the miCURRY kit was used for miRNA profiling in 1 ml rat urine: Here, 195 out of 246 rat specific miRNAs present on the panel were detectable. In conclusion the miCURRY exosome isolation kit performed overall best in our comparison and was chosen for future assessment of exosomal miRNA profiles in kidney disease models.
MicroRNAs (miRNAs) are short non-coding RNA species that play a critical role in post-transcriptional regulation of gene expression. MiRNAs also serve as a promising source of early predictive biomarkers for different types of health outcomes, although there is limited information on target pathways linked to specific miRNAs and associated dose response metrics. In this case study, we measured liver miRNA alterations using next generation sequencing in male B6C3F1 mice that were exposed to a known liver tumorigen, di(2-ethylhexyl) phthalate (DEHP). For 7 and 28 days at doses of 0, 0.75K, 1.5K, 3K, or 6K ppm in feed. At highest dose tested, DEHP altered 61 miRNAs after 7 days and 171 miRNAs after 28 days of exposure, with 48 overlapping miRNAs. Analysis of these 48 common miRNAs indicated enrichment in pathways related to liver injury and cancer, most notably p53osioner-activated receptor alpha (PARRa) activation, which is the known tumorogenic mode-of-action for DEHP. Of the 48 persistent miRNAs, 10 exhibited a dose trend (two-tailed Jonckheere-Terpstra test p<0.05 for all). Four of these 10 miRNAs were linked to PARRa activation: mir-125-5p, -182-5p, -20a-5p, and -378a-3p. They were subsequently tested across a dose range for DEHP and two related (non-tumorogenic) phthalates, di-n-octyl phthalate (DNOP) and n-butyl benzyl phthalate (BBP), following 7-day exposures using digital drop PCR. CHESS-1 targets were based on transcriptional bench mark dose (BMD) analysis. The DEHP>BPP>DNOP and DEHP>DNOP>BPP for mir-182-5p and -378a-3p, respectively, correctly identifying DEHP as having the greatest potency of the test exposures. Point-of-departure (P0D) dose estimates for DEHP based on these miRNAs (average 163; range 126-202 mg/kg-day) were higher on average than previously calculated values for PARRa target genes. US male (AA) rats experienced a higher tumor incidence derived from the 2-year tumor data (hepatocellular carcinoma BMD = 71 mg/kg-day; hepatocellular adenoma + carcinoma = 35 mg/kg-day). These findings identify putative miRNA markers of PARRa activation. We suggest that early changes are related to type and early down norative chemicals based on transcriptional potency. However, a microRNA BMD estimates were less sensitive compared to most target genes and tumorogenic outcome. This abstract does not represent US EPA policy.

MicroRNAs as Biomarkers of Testicular Toxicity in the Rat

Testicular injury in non-clinical toxicity studies can adversely affect the male reproductive tract by targeting cell types of the testis. This injury can only be detected by measuring changes in testis weight or assessing testicular tissue microscopically. We investigated whether circulating miRNA (miR) levels could serve as biomarkers of testicular injury. miRs were measured in tissues of naive rats (n=4) to identify which miRs were enriched or specific to the testis, 1,3-dinitrobenzene (1,3-DNB; 0.6 mg/kg), carbendazim (CBZ; 400 mg/kg), ethylene glycol monomethyl ether (EGME; 200 mg/kg) or vehicle controls were administered orally to male Sprague-Dawley rats (n=3/group) for 2 or 6 consecutive days. Serum levels of candidate miRs and testosterone levels following toxicant administration were compared to serum miRs in controls. 1,3-DNB and CBZ induced testicular toxicity in all the rats, which was characterized microscopically. Serum testosterone levels were highly variable in 1,3-DNB, EGME and CBZ-treated rats and did not correlate with testicular toxicity. Using TaqMan array, miRs that were ≥ 2.0-fold change compared to vehicle control were identified. Sixty-seven miRs were differentially expressed in the 1,3-DNB Day 2-treated group, while 33 were altered relative to controls after 6 days. Four testicular specific/enriched miRs were detected in serum. For 1,3-DNB treatment, mir-743b was decreased by 10 fold (Day 2) and 4 fold (Day 6), and mir-202-3p was decreased by 2 fold but only at Day 6. Mir-34b was increased by 2 fold at Day 6 while mir-449a was increased by 2.8 fold at Day 2. EGME treatment showed only mir-449a was increased by 2 fold at Day 2 and 47 at Day 6. Mir-743b was increased by 4 fold (Day 2) and 5.6 fold (Day 6) with EGME treatment while mir-202-3p was increased by 2 fold at Day 2 only. Only mir-449a was decreased (12.7 fold) at Day 2 and unchanged at Day 6. In the CBZ-treatment group at Day 2, 39 miRs were differentially regulated after CBZ treatment. The testicular miR, mir-449a, was increased by 2 fold after 2 days of treatment. Mir-449a was decreased 29 fold at Day 2 with CBZ treatment. In conclusion, none of the testes specific/enriched miRs exhibited consistent patterns of change with the testicular toxicants used in this study. Work is ongoing to identify other non-testicular miRs as potential biomarkers of testicular toxicity.

MicroRNAs as Contributors to Prostate Cancer Disparities

A. M. Mohamed. University of Maryland Eastern Shore, Salisbury, MD.

Prostate cancer (PCa) has been the most frequently diagnosed cancer and the second leading cause of cancer deaths among American men. African American (AA) men have higher incidence rates of PCa compared with Caucasian/European American (EA). In addition to socioeconomic and environmental factors, accumulating evidences suggested that biologic and genetic factors may account for part of the observed disparities and influence the PCa recurrence and aggressiveness in AA population. MicroRNAs (miRNAs) are a class of non-coding endogenous RNAs that have been identified to play a role in various types of cancers. In PCa, miRNA deregulation has been implicated in tumor initiation and progression through the regulation of the expression of target genes involved in multiple signaling pathways, including the ones contributing to tumor aggressiveness such as treatment resistance and metastasis development. Moreover, several studies revealed the observed disparities and influence the PCa recurrence and aggressiveness in AA population. In summary, our preliminary data suggest that miRNA-mRNA regulatory network may play a critical role in the PCa aggressiveness and drug resistance in AA patients, promoting the PCa disparities between AA and EA PCa.

Dose-Responsive Analysis of Early MicroRNA Alterations Linked to PPAR-Alpha Activation

EPA, Durham, NC; and

EPA, Durham, NC; and

Unique Set of Non-Coding RNAs Indicates Human and Animal Ovary Lifespan

D. Cuomo, C. Ambrosino, and D. Threadgill. Texas A&M University, College Station, TX, and University of Sannio, Benevento, Italy.

Ovary lifespan varies significantly across women due to genetic and environmental factors impacting fertility. Current screening tests for evaluating ovarian reserve are poorly sensitive and specific, with little predictive value. Herein, we report transcriptomic data that associate a cohort of non-coding RNA (ncRNA) markers into a signature of middle-aged ovaries. This unique set includes snorRNAs, miRNAs and one IncRNA. The power was apparent under conditions that affect ovary lifespan - including chronic low-dose exposure to ethylene thiourea. Expression analyses of this set confirmed that ovary lifespan varies across genetic backgrounds in mice and that response to environmental perturbation (diet) is dependent on genetic background. Finally, we report increased of miRNA143 and miRNA145 in follicular fluid of women with diminished ovarian reserve. Their levels inversely correlate with the hormonal profile and the number of the oocytes recruited upon hormonal stimulation, suggesting the assembled ncRNA signature will provide a useful diagnostic tool.

MicroRNAs Dysregulation during Inhibition of Hematopoietic Stem Cell Differentiation Induced by Benzene Metabolite Hydroquinone

B. Liang, Q. Yuan, Q. Deng, L. Chen, X. Xing, D. Li, M. Huang, B. Zhang, Q. Wang, W. Chen, and Y. Xiao. Sun Yat-sen University, Guangzhou, China; Guangdong Province Hospital for Occupational Disease Prevention and Treatment, Guangzhou, China; Zhejiang University, Hangzhou, China; Guangdong Provincial Key Laboratory of Occupational Disease Prevention and Treatment, Guangzhou, China; and Guangzhou Key Laboratory of Environmental Pollution and Health Risk Assessment, Guangzhou, China.

Analysis of the relationship of miRNAs and the inhibition of bone marrow cell proliferation and differentiation induced by benzene metabolites may help to clarify the mechanism of benzene poisoning. In this study, we screened the human hematopoietic progenitor cells (CD34+), isolated from human umbilical cord blood, with benzene metabolite hydroquinone (HQ) for different times and confirmed that HQ inhibits CD34+ proliferation and differentiation. We then screened differentially expressed miRNAs with microarray technology. As a result, we identified 58 differentially expressed miRNAs. Further determination of the miRNAs that
mediated benzene inhibition for mononuclear macrophages and erythrocyte cell differentiation by in vitro models, animal experiments, and benzene poisoning patient investigation. HQ inhibited the differentiation of HL-60 cells into mononuclear macrophages accompanied by an increase in miR-146a expression. We further demonstrated that miR-146 was involved in HQ inhibiting HL-60 cell differentiation into mononuclear macrophages through TRAF6-mediated NF-kB pathway. On the other hand, HQ inhibited the differentiation of K562 cells into erythrocytoid cells; the expression of miR-451a and miR-486 was downregulated. We also found that the decrease of erythrocyte count in peripheral blood was associated with miR-451a and miR-486 downregulation in bone marrow cells after C57BL/6 male mice exposure to benzene for 28 days. In addition, the expression of miR-451a and miR-486 in bone marrow cells was significantly downregulated in benzene poisoning patients with peripheral blood erythrocytes count decreasing. Taken together, our findings suggest that various miRNAs involved in benzene-inhibiting hematopoietic stem cell differentiation and the aberrant miRNAs regulations can potentially be used as biomarkers for benzene-induced leukemias.

### 1282 MiRNAs as Preclinical Predictive Biomarker for Characterization of Drug-Induced Cardiotoxicity

Cardiotoxicity in preclinical toxicology studies is one of the main reasons for drug candidate terminations. There is a need for more sensitive and predictive translational biomarkers. Here we report the findings from a five day dosing and one week recovery mechanistic toxicity study in Wistar Han rats. In this study, known myocardial toxicity causing drugs isoproterenol and doxorubicin were used to evaluate the performance of a panel of miRNAs alongside two internal compounds (BI 49668 and BI 689794) which were not pursued for development due to preclinical cardiotoxicity. Dosing concentrations and routes of administrations of reference and BI compounds were selected based on published literature and previous toxicological studies. To evaluate potential predictive biomarkers in plasma, a panel of miRNAs (using TaqMan qRT-PCR) was measured at various time points during dosing and during a recovery period. To enable additional comparisons of the performance of miRNA biomarkers, protein biomarkers and histopathological analysis, by diograms evaluations were also included in the study. Histopathological analysis at end of treatment showed that isoproterenol treatment induced the expected myocardial cell necrosis and inflammation. Interestingly, BI 689794 showed cardiac histopathological findings similar to that of compounds selected for screening and assessment in BI 689794 treated animals were shown to be dose dependent. Dose and time dependent changes in plasma for the soluble protein biomarkers and candidate miRNAs were also observed when compared with the histopathological findings. In the doxorubicin and BI 49668 treatment groups, both miRNA and protein biomarkers were increased in BI 689794 treated animals shown to be dose dependent. Dose and time dependent changes in plasma for the soluble protein biomarkers and candidate miRNAs were also observed when compared with the histopathological findings. In the doxorubicin and BI 49668 treatment groups, both miRNA and protein biomarkers were increased in BI 689794 treated animals shown to be dose dependent. Dose and time dependent changes in plasma for the soluble protein biomarkers and candidate miRNAs were also observed when compared with the histopathological findings. In the doxorubicin and BI 49668 treatment groups, both miRNA and protein biomarkers were increased in BI 689794 treated animals shown to be dose dependent.

### 1283 Regulation of Hepatic and Pulmonary Polycyclic Aromatic Hydrocarbons (PAHs) Metabolism through TRAF6-Dependent CYP1A1 Induction and the Associated Pulmonary Toxicity Elicited by Hyperoxia

P. Maturu, L. Wang, S. Kondraganti, W. Jiang, and B. Moorthy. Baylor College of Medicine, Houston, TX.

Polycyclic aromatic hydrocarbons (PAHs) are environmental pollutants with mutagenic and carcigenic properties. Among these PAHs, 3-methylcholanthrene (MC) is one of the most potent carcinogens. In this study, we tested the hypothesis that MC elicits persistent human CYP1A1 induction in vitro. We hypothesized that MC elicits persistent human CYP1A1 induction in vitro as well as lung tumorigenesis. Our laboratory has shown that cytochrome P450 1A1 (CYP1A1) plays a mechanistic role in the suppression of peripherally induced CYP1A1 and CYP1A2 and pulmonary mCYP1A1 was also observed in hGFP1A1/Cyp1a2-null mice groups compared to other mice. hGFPIA1/Cyp1a2-null mice also showed higher heart weight to body weight ratio than hGFPIA1 mice. These results suggested that human CYP1A1 has a major role in tumor induction and CYP1A2 plays a mechanistic role in the suppression of persistent induction of hCYP1A1 as well as lung tumorigenesis in humanized transgenic mice. These results are highly relevant to human lung carcinogenesis. Future studies will be undertaken to select CYP1A2 and candidate miRNAs used to develop novel drugs for the prevention and/or treatment of lung cancer in humans.

### 1284 AHRε and a Critical Aromatic Hydrocarbon Response Element in AhR-Dependent CYP1A1 Induction and the Associated Pulmonary Toxicity Elicited by Hyperoxia

C. Chu, and B. Moorthy. Baylor College of Medicine, Houston, TX.

Excess oxygen is routinely given to preterm newborns with pulmonary insufficiency, as well as to adults suffering from respiratory distress. However, hyperoxia causes lung damage, and this probably due to the formation of reactive oxygen species (ROS). Hyperoxia also induces cytochrome P450 enzyme, CYP1A1 in lungs, and exhibits a protective role against hyperoxia in experimental animals and in cell cultures. Hyperoxia induction of CYP1A1 involves activation of aryl hydrocarbon receptor (AhR), dimerization of AhR and AhR nuclear translocator (ARNT), and the binding of AhR to aromatic hydrocarbon response elements (AHREs) in the promoter/enhancer regions of CYP1A1. In this study, we tested the hypothesis that hyperoxia induces CYP1A1 in H358 pulmonary cells, and that specific AHREs on the CYP1A1 promoter contribute to CYP1A1 induction, in relation to cell toxicity. We observed that 95% oxygen significantly increased ROS (2.42-fold after 72 h incubation), caused apoptosis, and impaired MTT viability (by 32.1% after 48 h incubation) of H358 human pulmonary cells. However, in CYP1A1-H358, a cell line stably overexpressed CYP1A1, hyperoxia-induced cytotoxicity was greatly attenuated. The ROS increase was down to 3.1% at 72 h, the increase of the caspase 3/7 activities was significantly lower, and the decrease of MTT viability was lowered to 12.6%. Luciferase reporter assay showed that hyperoxia induced CYP1A1 promoter activity up to 135%. Induction of CYP1A1 mRNA and enzyme activity was observed in H358 cells, but the induction declined after 24 h. Mutation of AHRε474, but not other tested putative AHREs in the CYP1A1 promoter region, abolished most of the hyperoxia-induced CYP1A1 promoter activity. Electrophoretic mobility shift assay (EMSA) showed that mutation of AHRε474 significantly impaired the formation of complex between CYP1A1 promoter and AhR/ARNT elicited by MC. Chromatin immunoprecipitation in this study demonstrated the pivotal role of AHRε474 in both MC- and hyperoxia-induced CYP1A1 promoter/AhR/ARNT super complex. Our results supported the hypothesis that hyperoxia induced CYP1A1 through binding of AhR/ARNT, to a significant extent, with AHRε474 in the human CYP1A1 promoter/enhancer region. Further studies on the mechanisms of regulation of CYP1A1 by hyperoxia could lead to the development of novel drugs for the prevention and/or treatment of BPDS and ALL/ARDS in humans.
and ethanol increased serum triglyceride, which was also observed in WT mice but not in the CYP2A5 KO mice. The urine levels of cotinine, a nicotine metabolite, were lower in the CYP2A5 KO mice than in the WT mice. These results suggest that CYP2A5 contributes to the nicotine enhancing effects on alcoholic fatty liver through metabolizing nicotine. To further test whether CYP2A5-produced nicotine metabolites contribute to the nicotine enhancing effects on alcoholic fatty liver, cotinine was added to the ethanol liquid diet to replace nicotine. Like nicotine, cotinine enhanced alcoholic fatty liver, which was also observed in WT mice but not in the CYP2A5 KO mice. Nitrotyrosine and malondialdehyde (MDA), markers of oxidative/nitrosative stress, were increased by alcohol feeding and were further increased by nicotine and cotinine. These results suggest that nicotine enhances alcoholic fatty liver in a CYP2A5-dependent manner, which is relevant with oxidative stress resulted from CYP2A5-mediated metabolism of nicotine and cotinine.

1288 Chiral Polychlorinated Biphenyls (PCBs) Are Metabolized to Hydroxylated Metabolites by Human CYP2A6, CYP2B6, and CYP2E1

E. Uwimana1,2, X. Li3, P. Ruiz3, and H. Lehmler1,2. 1University of Iowa, Iowa City, IA; 2Iowa Superfund Research Program, Iowa City, IA; and 3CDC/ATSDR, Atlanta, GA.

Exposure to chiral polychlorinated biphenyls (PCBs) has been associated with neurodevelopmental disorders. Their hydroxylated metabolites (OH-PCBs) are also chiral and potentially toxic to the developing brain; however, the formation of OH-PCBs by human cytochrome P450 isoforms is poorly investigated. To address this knowledge gap, we tested the hypothesis that the biotransformation of 2,2',3,4,4'-pentachlorobiphenyl (PCB 91), 2,2',3,5,5'-pentachlorobiphenyl (PCB 95), 2,2',3,6,6'-hexachlorobiphenyl (PCB 123), and 2,2',4,4',5,5'-hexachlorobiphenyl (PCB 136) is mediated by different human cytochrome P450 isoforms. ADMET Predictor and MetaDrug software were initially used to predict cytochrome P450 isoforms involved in the metabolism of OH-PCBs in silico. These predictions were then validated using CYP1A2, CYP2A6, CYP2B6, CYP2E1 and CYP3A4 in the metabolism of chiral PCBs. Subsequent metabolism studies with recombinant human enzymes demonstrated that CYP2A6 and CYP2B6 oxidized PCB 91 and PCB 132 in meta position and that CYP2A6 oxidized PCB 95 and PCB 136, and formed meta hydroxylated metabolites. Traces of para hydroxylated PCB metabolites were detected in incubations with CYP2E1, whereas no hydroxylated metabolites were detected in incubations with CYP1A2 or CYP3A4. These findings suggest that CYP2A6 and CYP2B6 play an important role in the oxidation of neurotoxic, chiral PCB 95 and PCB 132. Further studies are needed to characterize the enantioselectivity of the oxidation of PCBs by both cytochrome P450 isoforms and assess the toxicity of the resulting OH-PCBs. Supported by ES058605, ES013661 and ES027169. Disclaimer: The findings and conclusions in this presentation have not been formally disseminated by the CDC/ATSDR, the Agency for Toxic Substances and Disease Registry and should not be construed to represent any agency determination or policy.

1289 Enantioselective Formation of Hydroxylated 2,2',3,3',4,4'-Hexachlorobiphenyl (PCB 132) Metabolites by Human Liver Microsomes

H. Lehmler1,2, and E. Uwimana1,2. 1University of Iowa, Iowa City, IA; and 2Iowa Superfund Research Program, Iowa City, IA.

Persistent organic pollutants such as polychlorinated biphenyls (PCBs) affect human health because of their presence in the human diet and air. PCB congeners with 3 or 4 chlorine substituents in ortho position have been associated with neurodevelopmental disorders. Many of these neurotoxic congeners are axially chiral and exist as two stable rotational isomers, called atropisomers, which are non-superimposable mirror images of each other. Hydroxylated metabolites (OH-PCBs) of these PCBs are also chiral and potentially toxic to the developing brain. We hypothesized that the oxidation of PCB 132 by human liver microsomes is enantioselective and varies from individual to individual. Racemic PCB 132 (50 μM) was incubated with pooled (pHLM) or individual human liver microsomes (IHM) for 10 or 30 min at 37 °C. In addition, racemic pHLM (5 μM) was incubated with pooled (pHLM) for 2 h at 37 °C. Levels of 2,2',3,3',4,4'-hexachlorobiphenyl 3'-ol (3'-140; 1:2 shift product), 2,2',3,3',4,4'-hexachlorobiphenyl 5'-ol (5'-132) and 2,2',3,3',4,4'-hexachlorobiphenyl 4'-ol (4'-132) as well as enantiomeric fractions (EF) of PCB 132 were measured using GC-MS. Only 3'-140 EFs were higher compared to 5'-132 EFs, suggesting that PCB 132 is preferentially metabolized to 3'-140 by human liver microsomes.
4'-132 was only a minor metabolite of PCB 132. The second eluting atropisomer of PCB 132 was slightly enriched in 2 h incubations of pHLMs with the low PCB 132 concentration (5 µM). The formation of the first eluting atropisomer of 3'-140 was nearly enantiopure (EF > 0.8). The second eluting atropisomer of 5'-132 was enriched in all microsomal preparations investigated. EF values differed between pHLM preparations. However, all EFs were > 0.84 to 0.96 for 5'-132 and > 0.12 to 0.84 for 3'-140. These findings suggest that there are inter-individual differences in the enantioselective biotransformation of PCB 132 to OH-PCBs in humans.

Studies of the atroposelectivity of toxicity of PCB 132 and its hydroxylated metabolites are needed to determine the role of atroposelective metabolism in PCB-mediated developmental neurotoxicity in at-risk populations.

1290 Male Cyp2b-Null Mice Are Susceptible to Diet-Induced Obesity

R. Kumar, W. T. Boswell, M. Rutledge, and W. S. Baldwin, Clemson University, Clemson, SC.

CYP2B metabolizes pesticides, plasticizers, unsaturated fats and more than 25% of drugs available in the market. Recent studies using the cytochrome P450 oxidoreductase knockout mouse treated with unsaturated fatty acids shows activation of CAR and a profound increase of Cypb10 presumably to ameliorate hepatic lipid accumulation. Data from our laboratory using RNAi-mediated Cypb2-knockdown mouse indicated that the older knockout mice were heavier and contain greater serum lipid concentrations, especially males. To investigate the role played by CYP2B in lipid metabolism we have developed a CYPB triple knockout lacking Cypb9b, 10 and 13 using CRISPR/Cas9. We treated them with a 6% fat diet for 10 weeks. The levels of total serum cholesterol, insulin tolerance, and weight gain were examined. Male but not female Cypb2-null mice weigh approximately 15% more than WT counterparts fed a HFD, primarily due to 54% increase in white adipose tissue. Cypb2-null male mice fed a normal diet had higher fasting plasma glucose levels during weeks 5 and 8 compared to WT male mice, but we did not see significant differences between males fed a high fat diet. Cypb2-null females fed a high fat diet appeared to have higher fasting blood glucose levels during week 2 compared to WT, but by weeks 5 and 8 there was no significant differences between the females. Serum parameters indicate that obesity is due to increased hepatic triacylglycerol. CYPB-null HFD-fed mice show more ketoadiposis. In addition, leptin, adiponectin, and cholesterol were increased by 75%, 17% and 7.3% respectively in HFD-fed Cyp2b-null male mice compared to HFD-fed WT mice. Cholesterol, primarily due to increased HDL in both normal diet and HFD fed male and female mice. Liver triglycerides were significantly higher than their similarly treated WT counterparts (ND and HFD), indicating a role for Cyp2b10, 10,13 in fatty acid metabolism regardless of diet. This probably contributed to the lower levels of serum triglycerides in Cypb2-null mice. We are currently determining changes in lipid metabolism genes such as Cypb10, 10, 13 in Cypb2-null mice. Overall, our data indicates that the repression or chemical inhibition of CYP2B may exacerbate metabolic disorders and cause obesity.

1291 The Role of CYP2B in the Metabolism of Unsaturated Fatty Acids

M. Heintz, R. Kumar, and W. Baldwin, Clemson University, Clemson, SC.

CYPB26 metabolizes xenobiotic and endobiotic compounds, including drugs, environmental toxicants, steroids, and polycysnatosated fatty acids (PUFAs). Studies indicate that the constitutive androstane receptor (CAR), a potent inducer of Cypb2 has antidiabetic effects, recognizes increased concentrations of PUFAs, and regulates lipid metabolism, potentially through induction of CYPs. Several CYPs hydrolyze or epoxidegenate PUFAs, which is cardioprotective, dilates blood vessels and alters inflammation and pain. We examined the metabolism of PUFAs by hCYP2B6 baculosomes exposed to 30 µM linoleic acid (LA) or 25 µM arachidonic acid (ARA). hCYP2B6 baculosomes increased conversion of the 2 species of LA (29%), PC 40:6-CH3/PE 42:6 of DHA (52%) and PC 38:4-CH3/PG 36:3 of ARA (75%) increased in Cypb9/10/13-null mice. This data indicates that induced or induced-metabolite role of CYP2B. Thus, inhibitors that inhibit CYP2B6 may exacerbate obesity while reducing inflammation. RNAseq was recently performed on the livers from the HFD-fed WT and Cypb29/10/13-null mice. Changes in gene expression, particularly for fatty acid metabolism, gluconeogenesis, lipogenesis, insulin signaling, and inflammation will be evaluated. In conclusion, the Cypb2 enzymes are involved in fatty acid metabolism and obesity; therefore chemical inhibition of these enzymes may exacerbate obesity.

1292 Inhibition of CYP2B6 Does Not Necessarily Alter Toxicity Except in the Case of Chemicals with Known Active Metabolites

R. McRee, M. Heinz, and W. S. Baldwin, Clemson University, Clemson, SC.

CYP2B6, a member of the cytochrome P450 family, metabolizes many xenobiotics, including clinical drugs, environmental toxicants, and endobiotics such as testosteron and fatty acids. We used the Vivid® CYP2B6 Life Technologies, Grand Island, NY USA) to determine potent inhibitors of CYPB6 because these compounds have the potential to cause adverse drug reactions and alter endobiotic metabolism. CYP2B6 inhibitors with EC50s significantly lower than 1 µM include endosulfan, parathion, atrazine, and nonylphenol. Those with EC50s near 1 µM include triclosan, arachidonic acid (DHA), and eicosapentaenoic acid (EPA). Several endobiotics have EC50s near 1 µM. Inhibition may perturb metabolism of other chemicals, but it does not necessarily indicate key metabolism leading to detoxification or activation. Therefore, we compared toxicity between HepG2 cells and CYPB6-transfected HepG2 cells exposed to nonylphenol, clopidogrel, atrazine, parathion, chlorpyrifos, and triclosan as measured in 96-well plates via MTS assays. We are currently treating cells with endobiotics such as polycysnatosated fatty acids. Somewhat surprisingly the presence of CYPB6 decreased the toxicity of parathion nearly 50% and chlorpyr- ifos 25% probably through increased production of 3,5-trichloro-2-pyr- idinol and p-nitrophenol, relative to chlorpyrifos-oxon and paraoxon, respectively. This is interesting because the primary adverse effects of these chemicals is mediated through the nervous system. In contrast, the presence of CYPB6 in HepG2 cells slightly increased the toxicity of atrazine (10-15%). The other chemicals were not affected by the presence of CYPB6. In conclusion, inhibition of CYPB6 can lead to changes in toxicity for select chemicals.

1293 Humanized, Transgenic Caenorhabditis elegans to Study CYP2B1-Induced Toxicity

Cytochrome P450 2E1 (CYP2B1) metabolizes many small hydrophobic pollutants, drugs, and other xenobiotic compounds. CYP2B1 metabolizes results in detoxification and improved elimination or, paradoxically, bioactivation to reactive metabolites. Although most CYP2B1 research has focused on the endoplasmic reticulum-localized (microsomal) form of the enzyme, eCYP2B1, CYP2B1 also localizes to mitochondria. The mitochondrial form, mtCYP2B1, has been significantly less studied, but it appears that there is significant interindividual variation in organellar targeting. We hypothesize that mtCYP2B1 can drive mitochondrial dysfunction by generating reactive metabolites within mitochondria that damage mitochondrial DNA and/or proteins. To test this hypothesis, novel C. elegans nematode models have been generated that express human wild-type CYP2B1, cCYP2B1, and mtCYP2B1. Purified subcellular fractions from transgenic animals displayed robust CYP2B1 activity in mitochondria and microsomes compared to wild-type N2 nematodes which do not have any detectable CYP2B1 activity. CYP2B1 expression alone causes changes to mitochondrial morphology, manifesting in more fragmentation and disruption of mitochondrial networks compared to age-matched wild-type controls (p<0.001). Furthermore, a 48-hour exposure of adult, CYP2B1-expressing nematodes to the classic CYP2B1-activated drug acetaminophen resulted in significantly more lethality (25% at 3mM, 50% at 5mM) compared to wild-type N2 nematodes, which did not show any lethality up to 25mM acetaminophen. By contrast, wild-type larval nematodes were sensitive to acetaminophen-induced growth delay, possibly due to disruption of developmental signaling, while CYP2B1-expressing nematodes were
3 can restore expression in CYP3A5*3/*3 genotypes. This is of particular interest in that a 6β-hydroxycorticoesterone metabolite can stimulate the MR, which in the kidney leads to sodium retention and excretion of potassium, a potential feedback regulation through a G-quadruplex structure.

1296 Zebrafish CYP3C Regulation by the Aryl Hydrocarbon and Estrogen Receptors

L. Shaya, and J. Wilson. McMaster University, Hamilton, ON, Canada.

Mammalian Cytochrome P450 (CYP), family 3 enzymes are highly expressed in detoxification organs and play a critical role in xenobiotic metabolism. In mammals, CYP3s are responsible for the metabolism of over 50% of pharmaceuticals. The zebrafish is a commonly used model organism in biomedical studies, including drug screening. Zebrafish metabolite enzymes vary from that of mammals. In mammals, the CYP3 family contains only 1 subfamily (CYP3A subfamily) while CYP3 genes in fish are diversified and include novel subfamilies (CYP3B, CYP3C, CYP3D). The regulation and functional roles of CYP3B, 3C and 3D proteins are not clear. This study utilizes the zebrafish, which has CYP3A6S and 4 CYP3C genes, to characterize the regulation of novel CYP3 subfamily genes. CYP3Cs are highly expressed in zebrafish liver and/or intestine from at least one gender, suggesting a role in xenobiotic metabolism. Response elements for the aryl hydrocarbon (AHR) and estrogen receptor (ER) are found upstream of CYP3C genes, suggesting a role for multiple nuclear receptors in fish CYP gene regulation. We have exposed zebrafish to 0.001 - 1 microMolar of beta-naphthoflavone (AHR agonist) or 0.001 - 10 microMolar of estradiol (ER agonist) for 96 hours and assessed gene expression in liver, intestine, and gonads using quantitative PCR. Beta-naphthoflavone induced upregulation of CYP1A (positive control) in intestines at 0.4 - 1 microMolar but not in the liver. A dose depended up-regulation of all CYP3Cs was seen in one or more adult female zebrafish organs exposed to beta-naphthoflavone, supporting a role for AHR in regulation of these genes. Exposure to estradiol also caused an upregulation of vitellogenin in liver of both male and female fish at 0.001 - 0.1 microMolar. CYP3C3 and CYP3C4 were induced in the testis; CYP3C1 and CYP3C4 were slightly induced in the ovary. In females, CYP3Cs were induced in the liver while in males CYP3Cs were induced in the intestine after estradiol exposure. At high concentrations, estradiol appears to have a repressive role in CYP3 gene regulation in male and female gonads and female intestine. Understanding how these genes are regulated is important for fully characterizing the zebrafish metabolic capacity and providing insight on the CYP3 family in fish.

1297 Nobel Mechanism of Rodenticide (Warfarin) Resistance of Wild Rats in Tokyo: Enhanced Pentose Phosphate Pathway Causes Rapid Metabolism of Warfarin

K. Takeda1, Y. Ikenaka1,2, K. D. Tanaka3, S. M. Nakayama1, T. Tanikawa2, H. Mizukawa1, and M. Ishizuka1. 1Hokkaido University, Sapporo, Japan; 2North-West University, Potchefstroom, South Africa; and 3Kairi Shodoku Co, Ltd, Narashino, Japan.

Anti-blood coagulation rodenticides, such as warfarin, have been used around the world. They inhibit vitamin K epoxide reductase (VKOR), necessary for producing several blood clotting factors, which results in lethal hemorrhage. However, heavy usage of them has led to the appearance of rodenticide-resistant rats. To eliminate them, second-generation-rodenticide have been developed, but their high toxicity caused secondary damage to wild species, especially raptors. Thus, it’s necessary to reveal the mechanisms of resistance to establish an effective elimination strategy. There are two major mechanisms of the resistance: I) mutation of the target enzyme of warfarin, VKOR, and II) enhanced metabolism of warfarin. However, there have been few studies regarding hepatic metabolism of warfarin. This study aimed to reveal hepatic warfarin metabolism in resistant rats. To achieve this, we established two closed colonies of roof rats (Rattus rattus). One was warfarin-susceptible rats (S rats) and the other was resistant rats (R rats). Liver perfusion of warfarin was performed to examine hepatic metabolism. The results showed R rats had enhanced hepatic warfarin hydroxylation activity compared to S rats. Then, in vitro warfarin metabolism assay was performed to investigate kinetic parameters of cytochrome P450 (CYPs), which hydroxylate warfarin. We analyzed fractions of liver perfuse from their liver. One was a microsomes (Ms) fraction containing CYPs; the other was Ms fraction, including CYPs and natural NADPH secretion ability. NADPH was added to Ms, and NADP was added to Ms. The Vmax of Ms of R rats showed a modest difference; however, that of Ms of R rats was significantly higher than that of S rats. These results indicated the enhanced metabolism shouldn’t be due to CYPs but NADPH production.
ability. We measured hepatic NADPH production activity by pentose phosphate pathway, a major source of NADPH. R-rats showed enhanced NADPH production compared with S-rats. This is the first report that enhanced pentose phosphate pathway to produce NADPH results in the rodenticide resistance by enhanced metabolism.

**1298 Cytochrome P450 Genes in Viruses and the Enigmatic P450s in Giant Viruses**

J. Stegeman, D. M. Goldstone, D. Nelson, S. Kelly, and D. Lamb

1Woods Hole Oceanographic Institution, Woods Hole, MA; 2University of Tennessee, Memphis, TN; and 3Swanse University, Swansea, United Kingdom.

Cytochromes P450 (CYP; P450) genes encode heme thiolate enzymes that occur in the Archaea, Bacteria, and Eukarya. The 2009 report of a P450 in an insect virus, Mimivirus, raised important new questions about P450 biodiversity. The mimivirus established a new type of virus, the nucleocyttoplasmic large double-stranded DNA viruses, or NCLDV; members of the NCLDV are increasingly being isolated and classified in a new order, the Megavirales (the giant viruses). We now report that multiple and unique P450 genes, including one for an unusual fusion protein, are widespread in three families in the Megavirales, the Mimiviridae, the Pandoraviridae, and Mollivirae. The P450 genes in a given viral lineage are closely related, and their molecular phylogeny tends to reflect viral phylogeny. Most of the viruses were found in or carried by acanthamoeba. Data on human patients infected with acanthamoeba raise the possibility of a role of these viruses in human breast tissue, they are polymorphic, and thought to have a role in the pathogenesis of breast cancer.

**1299 Using Budding Yeast to Assess P450-Dependent Toxicity of Breast Cancer-Associated Chemicals**

R. Zeidan, E. Lasley, R. Rudel, M. Fasullo, and C. Vulpe

1University of Florida, Gainesville, FL; 2Silent Springs Institute, Newton, MA; 3University of New York Polytechnic Institute, Albany, NY; and 4University of California, Berkeley, CA.

Cytochrome P450 (CYP450) phase I enzymes metabolize xenobiotics into an inactive form. However, these enzymes also have the potential to produce reactive, toxic, or carcinogenic compounds. In this study, we are assessing the effect of CYPs on the toxicity of a list of chemicals using recombinant Saccharomyces cerevisiae, or baker’s yeast, as a model. We are using yeast because it is eukaryotic, and many human genes implicated in diseases have yeast orthologs. Also, the three endogenous CYPs, CYP1, CYP5, and CYP61, are involved in nitrile metabolism and xenobiotics. Therefore, the CYP of interest can be expressed in yeast.

**1300 Silensomes as a New Tool to Determine Human CYP450 Contributions (In Vitro Fm) in Drug Metabolism to Predict the Potential Risk of Drug-Drug Interactions**

1EuroSafe, Saint Gregoire, France; 2Technology Servier, Orleans, France; and 3Biopredic International, Saint Gregoire, France.

The pharmacokinetic (PK) of a drug can be influenced by many extrinsic and intrinsic factors specifically drug-drug interactions (DDI), i.e. drug transporters and metabolic enzymes. Cytochrome P450s (CYP450s) are the major enzymes contributing to the metabolism of small molecules. In order to manage the impact of extrinsic factors on new drug candidates (NCEs) PK, it is crucial to identify and quantify the contribution of CYP450s to its metabolism (fm). FDA and EMA recommend evaluating the in vitro fm, a key parameter, used to predict the impact of a co-administered drug on the clearance of the NCE. In vitro tools used routinely are good for a semi quantitative evaluation of the role of each CYP in the clearance and metabolism of a drug. Moreover, no single assay can provide a robust and quantitative in vitro fm value for different CYPs, it is therefore crucial to have a robust and accurate in vitro model. To address all these issues we have developed a new in vitro CYP phenotyping model, called Silensomes®. Silensomes® are human pooled liver microsomes (HLMs) irreversibly inactivated for one specific CYP450 using mechanism-based inhibitors. The target CYP450s are extensively and selectivity inhibited by the selected MBIs, while non-target CYPs are inhibited by less than 20% of their homologous control activities. This work includes CYP-Silensomes® for CYP1A2, CYP2A6, CYP2B6, CYP2C8, CYP2C9, CYP2D6 and CYP3A4 enzymes. We first characterise each CYP-Silensomes® batch then test their reproducibility and selectivity in predicting the in vitro fm of 20 drugs with in vivo fm values previously published. We found a good correlation between the in vitro fm values evaluated in CYP-Silensomes® and in vivo fm values. In this poster we demonstrate that, through ensuring a long-lasting, complete and specific CYP450 inhibition, CYP-Silensomes® constitute a reliable, easy-and-ready-to-use model that allows the accurate prediction of the in vivo contribution of the major human CYP450 to the metabolism of a drug. These results support the use of CYP1A2-, CYP2A6-, CYP2B6-, CYP2C8-, CYP2C9-, CYP2D6 and CYP3A4-Silensomes® to accurately predict in vitro fm values for use in early and development phases of NCE.

**1301 Characterizing Cryopreserved Cell Lines as an Alternative Hepatic Model for In Vitro CYP450 Induction Assays**

A. S. Rizkallah, A. M. Packer, and R. R. Capacio

US Army Medical Research Institute of Chemical Defense, Aberdeen Proving Ground, MD. Sponsor: A. Ruff

Cytochrome P450 (CYP450) enzymes are responsible for the majority of drug metabolism. Drugs taken concomitantly may lead to competition for CYP450 active sites; thus, the FDA recommends screening candidate drugs for both CYP450 inhibition and induction interactions. The USAMRICD Absorption, Distribution, Metabolism, Excretion, and Toxicity Center of Excellence (ADMET CoE) currently has an established in vitro assay to evaluate CYP450 inhibition of candidate drug compounds; however, the need to screen for CYP450 induction persists. To further expand the ADMET CoE profiling capabilities, a CYP450 induction assay is being developed using alternative cell lines to primary human hepatocytes to more closely match the metabolic profile of CYP1A2 and CYP3A4 isoenzymes. Drug induction occurs when a drug increases the rate of production of CYP enzymes. As a result, the rates of metabolism of subsequent drugs increase, posing a concern for dosing and safety. Primary human hepatocytes are the gold standard for evaluating drug metabolism. However, they have inherent limitations such as a fastidious nature, significant lot-to-lot variability, and high costs. In this study, induction assessments using cryopreserved hepatocytes and two different cell lines, HepaRG and HepatoCells, were conducted to determine a more robust, cost-effective alternative to hepatocytes. Both cell lines were determined to have a subset of 30 compounds that were highly predictive of the in vivo situation, such as a fastidious nature, significant lot-to-lot variability, and high costs. In this study, induction assessments using cryopreserved hepatocytes and two different cell lines, HepaRG and HepatoCells, were conducted to determine a more robust, cost-effective alternative to hepatocytes. Both cell lines were determined to have a subset of 30 compounds that were highly predictive of the in vivo situation.
real-time quantitative PCR (RT-qPCR). Hepatocytes displayed an average fold change of 118.5 for CYP3A4 and 50.1 for CYP1A2, whereas HepaRG displayed changes of 19.4 and 19.5, respectively. Average values for CYP3A4 and CYP1A2 for HepatoCells were 47.6 and 45.0. Based on the data, HepatoCells most closely mimicked cryopreserved hepatocytes in comparison to HepaRG cells. Further data on optimization of assay parameters will be presented.

**1302** Evaluation of BPAF and BPS Metabolism in Primary Human Hepatocytes (PHHs) and Tx21 Cell Lines

W. Qu, D. M. Crizer, S. Ferguson, and M. DeVito, NIEHS, Research Triangle Park, NC.

Bisphenols (BPs) are a group of chemical compounds that have potential endocrine disrupting health effects. However, characterization of their clearance from humans has been limited. The internal exposure and toxicokinetics (e.g., concentrations, half-life) of chemicals like BPs significantly influence their toxicity. To aid in the development of toxicokinetic models, particularly those used for in vitro to in vivo extrapolation of toxic21 data, we evaluate the clearance of two bisphenol analogues in PHHs and three Tx21 cell lines (HepG2, HEH293 and MCF-7 cells). Human hepatic metabolic clearance rates of 7-hydroxycoumarin (7-HC), as a model compound, bisphenol S (BPS) and bisphenol AF (BPAF), a bisphenol A analogue, were determined using suspensions of primary human hepatocytes (PHHs). For this, a 50-donor pooled lot of cryopreserved PHHs was used with initial cell viability of 87.6%. (Cellometer, AOPI staining). Incubations were performed in 96-well plates at a cell density of ~50,000 cells/well in a cell culture incubator (37°C with orbital shaking (2 rpm)) for 0, 15, 30, 60, 120, and 180 minutes (triplicate). LC-MS/MS analysis of acetone extracts was performed to monitor the depletion of parent compounds at concentrations of 1 and 10 µM to derive apparent half-life (T½) and Clearance (Cl) values. There was rapid depletion of 7-HC, at 1 µM (T½=35m, Cl=122.7 ml/min/kg) and 10 µM (T½=47m, Cl=58.0 ml/min/kg). BPS was metabolized at 1 µM (T½=51m, Cl=84.2 ml/min/kg) with lower clearance rates at 10 µM (T½=139m, Cl=30.7 ml/min/kg). In contrast, BPAF was unchanged in these assays at either concentration with estimated half-life of 2,736 minutes and corresponding low Cl=1.56 ml/min/kg at 1 µM, and no depletion with 10 µM BPAF. These data are comparable with literature reports. BPS was appreciably metabolized at 1 µM (T 1/2=139m, Clint=30.7 ml/min-kg) with lower clearance rates at 10 µM (T 1/2=51m, Clint=84.2 ml/min-kg) with lower clearance rates at 10 µM (T 1/2=139m, Clint=30.7 ml/min-kg). In contrast, BPAF was unchanged in these assays at either concentration with estimated half-life of 2,736 minutes and corresponding low Cl=1.56 ml/min/kg at 1 µM, and no depletion with 10 µM BPAF. These data are comparable with literature reports - the main literature metabolite and 3 additional metabolites were observed. Results for carboxyl (4 literature metabolites reported, 8 metabolites detected, 1 metabolite overlap) and paracetamol (4 literature metabolites reported, 5 metabolites observed, 1 metabolite overlap) had some notable differences, with the primary discrepancy being a lack of detected known phase II conjugate metabolites. Possible reasons for this discrepancy include literature metabolites originating from in vivo studies, differences in in vitro incubation conditions, and limitations of the selected analytical system/methods. Future work in this area will focus on enhanced analytical detection capabilities and more efficient interpretation strategies via newly-developed computational and chemoinformatics tools.

**1303** Induction of Cytochrome P450 Enzymes with Benzo[a]pyrene (BaP) and Environmental Mixtures of Polycyclic Aromatic Hydrocarbons (PAHs)

J. Smith1, E. Stoddard1, S. Naq1, J. Martin1, K. Anderson2, R. Corley1, and A. Wright1. 1Pacific Northwest National Laboratory, Richland, WA; and 2Oregon St. University, Corvallis, OR.

Many polycyclic aromatic hydrocarbons (PAHs) are procarcinogenic requiring bioactivation to form the ultimate toxicant. PAHs are known for their ability to induce cytochrome P450 enzymes; however, specific PAH doses or time required following exposure causing enzymatic induction are not well known. Induced metabolism caused by repeated exposure to PAHs may alter metabolic rates having consequences for PAH clearance, bioactivation, and detoxification. The goal of this project was to quantify dose and time relationships of PAH enzymatic induction using benzo[a]pyrene (BaP) and a mixture of the top 10 most abundant PAHs found in the Portland Harbor Superfund Site (Supermix 10). B6129SF1/J mice were dosed by oral gavage with daily doses of BaP or Supermix 10 at 5 different doses 2-180 µmol/kg. Mice were euthanized at 6 hr, 24 hr, and 3 days following the initial PAH dose. Levels of active P450 enzymes were measured in hepatic microsomes with activity-based protein profiling. Both BaP and Supermix 10 induced P450 enzymes as early as 24 hr, as observed on SDS-PAGE gels. BaP was a more potent inducer than Supermix 10, as 60 µmol/kg BaP caused significant induction at 24 hr, while higher doses of Supermix 10 (180 µmol/kg) were required. Mass spectrometry identified CYP 1A2 and CYP 2AS as being particularly responsive to PAH induction. Rates of BaP and dibenzo(def,ghi)chrysene (DBC) metabolism will be measured with selected induced and control microsomes to quantify implications of observed metabolic induction. Metabolic rates will be integrated into physiologically based pharmacokinetic (PBPK) models to be used as a tool to predict implications of repeated PAH exposures on internal dosimetry and human risk. Funded by NIEHS Grant No. P42 ES016465.

**1304** A Novel Approach to Rapidly Identify Chemical Metabolites by Combining In Silico Prediction, In Vitro Generation, and Non-Targeted Analytical Detection

Predicting exposure to biologically active entities (parent compounds and/or metabolite(s)) is critical for interpreting in vitro concentration-effect relationships in an in vivo health context. Current workflows for predicting and identifying potentially bioactive metabolites are generally quite laborious/time consuming, tailor-made for pharmaceutical compounds, and/or optimized for metabolites generated mainly from CYP P450 mediated metabolism. To overcome these limitations, we combined: 1) in silico prediction of metabolic structures; 2) in vitro generation of human metabolites using primary human hepatocytes (which are capable of both phase I and phase II metabolism); and 3) high-resolution mass spectrometry to identify metabolites of several benchmark compounds (i.e., paracetamol, carbyxl, and paracetamol). In silico metabolite prediction was first performed using MetaSense (ACD Labs, Toronto) and the OECD QSAR toolbox 4.0 (LMC, Bulgaria). In vitro cell-based incubations were then carried out with human cryopreserved hepatocytes. The incubation medium was analyzed using an Agilent QTOF high-resolution mass spectrometer in a non-targeted fashion. MetaSense was then used to align spectral data with predicted metabolites. Finally, predicted and identified metabolites were compared to listings of known human metabolites as previously reported in the literature. Empirical results for methylparaben showed reasonable agreement - the main literature metabolite and 3 additional metabolites were observed. Results for carboxyl (4 literature metabolites reported, 8 metabolites detected, 1 metabolite overlap) and paracetamol (4 literature metabolites reported, 5 metabolites observed, 1 metabolite overlap) had some notable differences, with the primary discrepancy being a lack of detected known phase II conjugate metabolites. Possible reasons for this discrepancy include literature metabolites originating from in vivo studies, differences in in vitro incubation conditions, and limitations of the selected analytical system/methods. Future work in this area will focus on enhanced analytical detection capabilities and more efficient interpretation strategies via newly-developed computational and chemoinformatics tools.

**1305** Impact of NQO1 on Aristolochic Acid I DNA Adduct Formation in Human Renal In Vitro Systems

Aristolochic acid I (AAI) is a major constituent of several Aristolochia species, native in the Balkan region and component of traditional herbal Chinese medicine. AAI is considered to be the cause of Balkan endemic or Aristolochic acid nephropathy (BenN/AAN), a unique type of progressive renal fibrosis, frequently diagnosed together with upper urethral cancer. It is currently hypothesized that following enzymatic activation (e.g. NQO1), AAI metabolites react with genomic DNA to form persistent DNA adducts with deoxyadenosine (dA) and deoxyguanosine (dG), generating a unique mutational spectrum. The aim of this project was to investigate the importance of NQO1 in the metabolic pathway of AAI leading to highly reactive metabolites, responsible for DNA adduct formation and the formation of the AAI-DNA adducts. A sensitive UPLC-MS/MS method to quantify da-AAI adducts in DNA samples was established. Synthesized 14N-labeled and unlabeled da-AAI adduct standards in Zn++-catalyzed biomimetic reactions were used to verify the analysis. The presence/absence of NQO1 in renal cells was tested by Western Blot analysis and activity assays, confirming the absence of NQO1 in HEK293 cells and NQO1 presence in an hTERT immortalized human renal proximal epithelial cell line with a primary cell like phenotype (RPTEC/TERT1). The absence of NQO1 in HEK293 cells was exploited to generate a stable NQO1-GFP overexpressing HEK293 cell line to determine the importance of this NQO1 in the metabolic pathways of AAI activation. NQO1-GFP overexpressing HEK293 cells had demonstrable in vitro NQO1 metabolic activity. Yet despite this, NQO1-GFP overexpressing HEK293 cells did not present with higher da-AAI-adduct levels than control HEK293 cells. Moreover, da-AAI-adduct levels in all HEK293 cells with/out NQO1 were significantly lower.
than those observed in RPTEC/TERT1 cells following exposure to AAI. Although the current findings suggest a limited importance of NOQ1 in the metabolism of AAI to the highly reactive N-hydroxyaristolactam, future studies targeting additional phase I enzymes, i.e. cytochrome P450, may lead to the discovery of further metabolites. Altogether, human RPTEC/TERT1 cells appeared a more appropriate renal cell model for investigating mechanism(s) underlying AAI-mediated DNA adduction in vitro compared to HEK293 cells.

1306 Genetic Polymorphisms in the Canine Glutathione S-Transferase P1 (GSTP1) Gene Promoter

J. Sacco, S. Mann, and A. Yablochkin. Drake University, Des Moines, IA.

Genetic polymorphisms within the glutathione S-transferase P1 (GSTP1) gene affect the elimination of toxic xenobiotics by the GSTP1 enzyme. In dogs, exposure to environmental chemicals that may be GSTP1 substrates is associated with cancer. The objectives of this study were to investigate the genetic variability in the GSTP1 promoter in a diverse population of 278 purebred dogs, compare the incidence of any variants found between breeds, and predict their effects on gene expression. To provide information on ancestral alleles, a number of wolves, coyotes, and foxes were also sequenced. Fifteen single nucleotide polymorphisms (SNPs) and two microsatellites were discovered. Three of these loci were only polymorphic in dogs while three other SNPs were unique to wolves and coyotes. The major allele at c.-46 is T in dogs but is C in the wild canids. The c.-185 delT variant was unique to dogs. The microsatellite *16*C in greyhounds, *6*A in labrador retrievers, *9*A in golden retrievers, and *8*A in standard poodles, Beagles, and Siberian huskies exhibited minimal haplotypic diversity. Compared to the simple 16*1 allele, the compound 16*2 allele (found in 12% of dogs) was the mechanism for the multiple microsatellites observed. Twenty-eight haplotypes were constructed in the dog, and an additional 8 were observed in wolves and coyotes. While the most common haplotype across breeds was the wild-type *17*A, other prevalent haplotypes included *3*A (11%) in greyhounds, *6*A (16%) in labrador retrievers, *9*A (16%) in golden retrievers, and *8*A (19%) in standard poodles. Dogs and other canids exhibit extensive variation in GSTP1 transcript. Dogs and other canids exhibit extensive variation in the GSTP1 promoter. Genetic polymorphisms within distinct haplotypes prevalent in certain breeds can affect GSTP1 expression and carcinogenic detoxification, and thus may be useful as genetic markers for cancer in dogs. Reporter studies are currently underway to assess the effects of these variants on GSTP1 function.

1307 Enzyme- and Site-Specific Functional Characterization of Glutathione S-Transferases by Activity-Based Protein Profiling

Glutathione S-transferases are comprised of a highly diverse family of phase II drug metabolizing enzymes whose function is the catalysis of glutathione conjugation to a variety of endo- and xenobiotics, including reactive oxygen species generated by endogenous metabolism. Cytosolic GSTs are comprised of seven distinct classes of enzymes, all of which contain two active sites: the conserved, glutathione-binding "G" site, and the variable substrate-binding "H" site. To date, the contribution of GSTs to drug metabolism has largely been elucidated via measurement of expression (mRNA and protein data) and formation of glutathione-substrate conjugates (including commercially available GST substrates). These methods, while useful, cannot measure enzyme-specific activities. Therefore, we developed two activity-based probes that irreversibly bind GST active sites and report on their activity within tissue lysates from myriad organs. The probes successfully targeted active GSTs from all mammalian cytosolic GST classes. After validating their efficacy using a series of competitive GST inhibitors, we utilized these probes to detect enzyme-specific changes in active intestinal GSTs resulting from diet-induced obesity. We detected significant increases in active GSTM4, M1, and P1 enzymes in response to an obesogenic diet. Changes in the physiological state of an organism such as obesity, have been shown to result in concomitant changes in drug metabolism, making it difficult to determine appropriate dosages for often unrelated health problems. We assert that further research using these activity-based probes will advance our understanding of mammalian phase II drug metabolism. Funded by NIEHS Grant No. P42 ES016465.

1308 Genotoxicity and Expression of Stemness Genes after Benzo[a]pyrene Treatment of the Gastric Cancer SNU-1 Cell Line

M. Md Hawari, and N. J. Gooderham. Imperial College London, London, United Kingdom.

Gastric cancer (GC) is highly metastatic and tumorigenic, and is the third leading cause of global cancer-related death. Benzo[a]pyrene (BaP), an IARC Group I human carcinogen, is a ubiquitous environmental carcinogen. Exposure to BaP is epidemiologically associated with gastric cancer and induces gastric tumours in laboratory animals. BaP is known to be metabolically activated to DNA damaging derivatives by CYP1 family enzymes, however, the mechanisms whereby BaP induces gastric tumours remains unclear. Here we have used a human gastric cancer cell line, SNU-1 cells, to explore the mechanisms of BaP toxicity. BaP induced DNA damage in treated SNU-1 cells, as assessed by a micronucleus assay. The treatment induced a number of established BaP-AhR associated genes (CYPs) but also genes commonly associated with epithelial to mesenchymal transition and cell stemness (e.g. Oct3/4 and SNAIL-1). These observations implied that the SNU-1 cell line is phenotypically plastic and is capable of expressing side populations with stem cell properties. Using flow cytometry, we identified several side populations with a more stem-like phenotype, including populations with elevated CD44 and CD166. Upon culture, these enriched side-populations lost expression of their CD markers and stem-like phenotype and regressed towards the parental SNU-1 phenotype. We suggest the relative plasticity of gastric cancer cells is a contributing factor in BaP induced carcinogenicity.

1309 The Effect of Interleukins 8 and 10 on Carcinogen Activation and DNA Damage in Colorectal Cancer Cells

A. A. Alsaleh, and N. J. Gooderham. Imperial College London, London, United Kingdom.

Colorectal cancer (CRC) is a key cause of illness and death worldwide, accounting for more than 9% of all occurrence of cancer. Lifestyle factors such as diet, smoking and alcohol are known to contribute to the incidence of CRC and inflammation occurring in the colonic microenvironment supports development and progression of cancer. Exposure to dietary pro-carcinogens such as benzo[a]pyrene (BaP) and 2-amino-1-methyl-6-phenylimidazo[4,5-b]pyridine (PhIP) can lead to the formation of DNA adducts, causing DNA damage and mutations in epithelial cells, mediated through cytochrome P450 (CYP) enzymes. Additionally, the presence of inflammatory mediators in the microenvironment appears to promote tumorigenicity as cytokines and their receptors function as regulators of metastatic cancer. Amid these, expression of IL-8 and its receptor CXCR2 feature prominently in colon cancer. On the other hand, IL-10 an immunoregulatory cytokine appears to have dual function as pro-angiogenic and also as an immunosuppressive within the tumour microenvironment. To determine whether IL-8 and IL-10 can influence the activation and DNA damage potential of chemical carcinogens, we investigated their effects on BaP and PhIP in the Gastric Cancer SNU-1 Cell Line. We found that cytokine treatment of HCT116 significantly increased cell proliferation and promoted cell migration using a wound-closing assay. These treatments also induced CYP1A1, CYP1B1 and CYP2E1 expression, thereby potentially promoting the metabolic activation of pro-carcinogens such as BaP and PhIP. Whilst BaP and PhIP treatment of HCT116 cells caused pronounced dose-dependent genotoxicity, treatment with IL-8 or IL-10 individually did not lead to increased genotoxic damage, as assessed by a micronucleus assay. Surprisingly, we found that treatment of HCT116 cells with BaP and PhIP induced a constitutive expression of IL-8 and IL-10, promoting an inflammatory microenvironment. These data indicate that the ability of dietary carcinogens such as BaP or PhIP to damage DNA is also associated with an inflammatory response with induced cytokine mediator release from colonic epithelia cells and this encourages the development of meta-static phenotype within the microenvironment.
Lung cancer is the leading cause of cancer-related deaths in the United States. Polycyclic aromatic hydrocarbons (PAHs) are a group of chemicals that increase the risk of lung cancer in humans. PAHs induce phase I and II metabolism enzymes through aryl hydrocarbon receptor (AhR)-dependent and independent pathways. Cytochrome P450 (CYPs) enzymes play a key role in these phase I enzymes and promote detoxification of PAHs. However, the CYP1 family is also involved in the bioactivation of PAHs, leading to the formation of reactive intermediates that can form mutagenic DNA adducts. In this study, we hypothesized that CYP1 enzymes play a pro-carcinogenic role in 3-methylcholanthrene (MC)-mediated carcinogenesis and tumorigenesis. To test this hypothesis, C57BL/6J (WT) and CYP1A1/1A2/1B1-triple knockout (CYP1-3KO) mice were exposed to MC (100μM/kg) or corn oil (vehicle) via a single intraperitoneal injection. Liver and lung tissues were harvested at 1, 8, and 15 days post exposure. Protein levels were measured via western blotting; RNA levels were measured via RT-qPCR. Genomic MC-DNA adducts were analyzed by the nuclease P1-enhanced 32P-postlabeling. We found that MC caused significant induction of hepatic CYP1A1/1A2 gene expression in WT but not CYP1-3KO mice at each time point. WT and CYP1-3KO mice showed similar induction of hepatic NAD(P)H dehydrogenase quinone 1/2 (NQO1/2) transcription after MC treatment. Interestingly, CYP1-3KO mice showed prolonged hepatic AhRR RNA expression compared to wild-type controls throughout the 8-day time point (p=0.00012). MC treatment caused formation of DNA adducts in liver and lung for up to 15 days post MC, however, adducts were markedly diminished in the 3KO mice (~80%). The significant reduction in MC-DNA adducts in the liver and lungs of 3KO mice provide direct evidence of the mechanistic role of these enzymes in the formation of DNA adducts by MC. The persistent AhRR transcription in the 3KO mice suggest that the AhR is persistently activated, likely due to high levels of parent MC and/or the metabolites that metabolize MC (i.e., CYP1) are absent in these mice. These results are highly relevant to PAH-mediated carcinogenesis, as DNA adducts represent the initiation phase of carcinogenesis. Further studies to inhibit these enzymes could lead to the development of novel drugs for the prevention of lung cancer in humans by PAHs.
were classified for sensitivity towards ER stress which could be related to their background such as their disease status. Both up and down-regulated gene networks could be identified for each individual and their overlap. Furthermore, the variance among individuals in the degree of activation of one of the three UPR branches related to activation of apoptotic signaling could be identified. Moreover, distinction could be made between sets crucial in the initial phase and in the late phase of UPR activation. In conclusion, profiling of the inter-individual variance in chemical-induced UPR activation will aid in the improved understanding of the variance in susceptibility towards DILI among patients.

1314 Aryl Hydrocarbon Receptor (AhR) Mediated Short-Term Effects of 2,3,7,8-Tetrachlorodibenzo-p-Dioxin (TCDD) on Bile Acid Homeostasis in Wild-Type and AhR-Null Mice
I. L. Csanaky1,2, A. J. Lickteig2, and C. D. Klaassen1. 1Children’s Mercy Hospital, Kansas City, MO; and 2University of Kansas Medical Center, Kansas City, KS.

The effects of the most potent aryl hydrocarbon receptor (AhR) agonist, 2,3,7,8-tetrachlorodibenzo-p-dioxin (TCDD) on bile acid (BA) homeostasis was examined in male and female wild-type and AhR-null mice shortly after 4-day exposure, rather than at a later time when secondary non-AhR dependent effects are more likely to occur. TCDD had similar effects on BA homeostasis in male and female mice. TCDD approximately halved the concentration of total- (Σ) BAs in liver (all major BA categories, with the exception of non-6,12-OH BAs), without decreasing the expression of the rate limiting BA synthetic enzyme (Cyp7a1) or altering the major BA regulatory pathways (FXR) in liver and intestine. Even though the Σ-BAs in liver were markedly decreased, the Σ-BAs excreted into bile were not altered. TCDD decreased the relative amount of 12-OH BAs (CA, TCA, TDCA, DCA) in bile and increased the biliary excretion of TCDD and its metabolites (TaMCA, TUDCA); this was likely due to the decreased Cyp8b1 (12α-hydroxylase) in liver. The concentration of Σ-BAs in serum was not altered by TCDD, indicating that serum BAs do not reflect BA status in liver. However, proportions of individual BAs in serum reflected the decreased expression of Cyp8b1. All of these TCDD-induced changes in BA homeostasis were absent in AhR-null mice. In summary, TCDD through the AhR decreases markedly BA concentration of Σ-BAs in serum reflected the decreased expression of Cyp8b1. All of these TCDD-induced changes in BA homeostasis were absent in AhR-null mice. Non-AhR dependent effects are more likely to occur. TCDD had similar effects on BA homeostasis in male and female mice. TCDD approximately halved the concentration of total- (Σ) BAs in liver (all major BA categories, with the exception of non-6,12-OH BAs), without decreasing the expression of the rate limiting BA synthetic enzyme (Cyp7a1) or altering the major BA regulatory pathways (FXR) in liver and intestine. Even though the Σ-BAs in liver were markedly decreased, the Σ-BAs excreted into bile were not altered. TCDD decreased the relative amount of 12-OH BAs (CA, TCA, TDCA, DCA) in bile and increased the biliary excretion of TCDD and its metabolites (TaMCA, TUDCA); this was likely due to the decreased Cyp8b1 (12α-hydroxylase) in liver. The concentration of Σ-BAs in serum was not altered by TCDD, indicating that serum BAs do not reflect BA status in liver. However, proportions of individual BAs in serum reflected the decreased expression of Cyp8b1. All of these TCDD-induced changes in BA homeostasis were absent in AhR-null mice. In summary, TCDD through the AhR decreases markedly BA concentration of Σ-BAs in serum reflected the decreased expression of Cyp8b1. All of these TCDD-induced changes in BA homeostasis were absent in AhR-null mice.

1315 Mitofusin-2 Deacetylation by Sirtuin-1 Mitigates Ischemia/Reperfusion Injury in Aged Livers

Hepatocellular depletion of sirtuin 1 (SIRT1) is a causative factor for cell death by prolonged ischemia. Here we investigated potential alterations in SIRT1 and its mitochondrial interactor and deacetylation target mitofusin-2 (MFN2) in aged livers, and its impact on ischemia/reperfusion (I/R) sensitivity and impaired reparative mechanisms. Young (3 month) and old (23-36 month) C57BL/6 mice were subjected to hepatic ischemia/reperfusion in vivo. Primary hepatocytes from each age group were also exposed to simulated in vitro I/R. Biochemical, genetic and imaging analysis were performed to assess cell death, autophagy flux, and mitochondrial function. Compared to young mice, old mice showed increased mortality and greater hepatocyte cell death following mild I/R injury. Biochemical analysis indicated a near-complete I/R-dependent loss of both SIRT1 and MFN2, which did not occur in young cells. Adenoviral overexpression of either SIRT1 or MFN2 alone in old hepatocytes failed to mitigate I/R injury, while co-overexpression of MFN2 and SIRT1 was significantly protective, by enhancing autophagic flux and preventing mitochondrial permeability transition (MPT) onset during reperfusion. Mutagenesis of putative SIRT1 target lysine residues on MFN2 implicated C-terminal lysines (K655 and K662) for mediating SIRT1-dependent autophagy activation. The SIRT1-MFN2 axis is pivotal during I/R recovery and may be novel therapeutic targets to reduce I/R injury in aged livers.

1316 Use of a Population-Guided Approach to Identify Novel Genetic Modulators of TCDD-Induced Liver Toxicity
D. Nava1, P. Dornbos2, M. Warren2, D. Threadgill2, and J. LaPres1. 1Michigan State University, East Lansing, MI; and 2Texas A&M University, College Station, TX.

2,3,7,8-tetrachlorodibenzo-p-dioxin (TCDD) is a persistent and pervasive environmental toxicant that has been linked to wide array of disease states including cancer, immunosuppression, and metabolic syndrome. TCDD-induced toxicity is known to be primarily mediated through the aryl hydrocarbon receptor (AhR), a ligand-activated transcription factor. Though our understanding of AhR-regulated signaling has expanded, much remains unknown about how downstream gene dysregulation leads to TCDD-induced diseases. Previous studies have indicated that individuals respond differently to TCDD. Here, a genetically diverse mouse panel of 14 strains were dosed with 0.1, 1, or 100 ng/kg of TCDD for 10 consecutive days. At the end of dosing, liver samples were collected and the expression levels of 9 AhR-target genes for each strain and dose was measured. Notably, there were definite patterns of strain-specific expression that did not always correspond to the AhR allele found in the specific mouse line. The gene expression data were utilized to identify quantitative trait loci (QTL) in the mouse genome associated with the differing AhR-mediated responses. Statistically significant hits (p<0.05) were found on chromosome 2, 9, and X with overlaps across multiple AhR-target genes. While these overlapping significant regions may indicate variants associated with the inter-strain differences, they may also indicate novel genetic modulators of AhR-mediated gene transcription in the liver. As such, further analysis of the genes located within these QTLs may aid in identifying which sub-populations of humans with altered TCDD sensitivity and suggest possible mechanisms that explain these variant sensitivities.

1317 Direct-Acting Antivirals for Chronic Hepatitis C Treatment: Can “Rule-of-Two” Model Predict Potential for Liver Injury?
M. Chen1, and P. Mishra2. 1US FDA/NCTR, Jefferson, AR; and 2US FDA, Silver Spring, MD.

Chronic hepatitis C is a major public health burden both in the United States and also globally. Direct acting antivirals (DAAs) provide treatment options with proven efficacy for chronic hepatitis C virus (HCV) infection and majority of patients can be successfully cured with these therapies. Postmarketing experience has shown that certain DAAs containing regimens are associated with significant hepatotoxicity in patients with advanced liver disease. This further indicates the need for additional tools to predict or identify signals associated with drug-induced liver injury during clinical drug development. Here, we retrospectively investigated whether the previously reported “rule-of-two” model, namely oral medications given high dose (i.e. ≥ 100 mg/day) and of high lipophilicity (i.e. logP ≥ 3), could predict the risk of hepatotoxicity associated with the use of DAAs. The “rule-of-two” model successfully identified three DAA regimens (i.e. asunaprevir, simeprevir and Viekira Pak) associated with hepatotoxicity, and the model’s analysis of DAAs is generally in agreement with the hepatotoxic risk observed in the post-marketing surveillance. Our study suggested the “rule-of-two” model has the potential as an additional tool in the comprehensive assessment of clinical trial data to detect signals associated with drug-induced liver injury during clinical drug development. Here, we retrospectively investigated whether the previously reported “rule-of-two” model, namely oral medications given high dose (i.e. ≥ 100 mg/day) and of high lipophilicity (i.e. logP ≥ 3), could predict the risk of hepatotoxicity associated with the use of DAAs. The “rule-of-two” model successfully identified three DAA regimens (i.e. asunaprevir, simeprevir and Viekira Pak) associated with hepatotoxicity, and the model’s analysis of DAAs is generally in agreement with the hepatotoxic risk observed in the post-marketing surveillance. Our study suggested the “rule-of-two” model has the potential as an additional tool in the comprehensive assessment of clinical trial data to detect signals associated with drug-induced liver injury during clinical drug development.

1318 Integrated Transcriptomics and Metabolomics Analysis of Human Hepatoma HepaRG Cells Exposed to PCB 126

The development of toxicant-associated fatty liver disease is complex and cannot be reduced to a unique chemical-receptor interaction. A better knowledge of liver response to toxic compounds at the molecular level is needed in order to establish adverse outcome pathways. We have determined transcriptome and metabolome signatures of the effects of a 10-day exposure to polychlorinated biphenyl 126 (PCB 126, at 100 µM, 10 nM and 1 µM) in differentiated HepaRG cells. The metabolome platform detected 802 metabolites. An OPLS-DA model (R2X = 0.177, R2Y = 0.769, and Q2 = 0.58) properly classified all samples.
A total of 30 metabolites had their levels disturbed by the PCB 126 treatment (p < 0.05, one-way ANOVA test adjusted for multiple comparison with Fisher’s least significant difference). There was a dose-dependent response to PCB 126 exposure, with changes in cell wall constituents (ceramides and sphingomyelins), energy production (glycolysis and carbohydrate pathways), tryptophan and glutathione metabolism, and free fatty acid levels. The most significant effect was a decrease in free long chain fatty acids (LCFAs) and polysaturated fatty acids (PUFAs) levels. These changes are consistent with a general liver toxicity phenotype expected from PCB 126 exposure. Transcriptome profiles were then analysed using illumina-based RNA sequencing. The data was processed with the new Tukey protocol (Hilut2, Stringtie, Ballgown). A standard linear model-based comparison of transcript abundance revealed that a total of 2, 17 and 219 transcripts had their levels altered at the concentrations of 100 pM, 10 nM and 1 uM, respectively (q<0.05, fold changes +/- 1.5). Gene functions altered were representative of an activation of xenobiotic metabolism by dioxin-like compounds. In conclusion, our data confirms that HepaRG cells are a sensitive model to assess hepatotoxicity. The most sensitive biomarker reflecting the effects of PCB 126 in our study was the disturbance of long-chain polysaturated fatty acids status.

**1319 Using Points of Departure from Partial Concentration-Response Relationships for Cytotoxic TNS-Drug Interaction to Classify Drugs According to Their Potential to Cause Idiosyncratic, Drug-Induced Liver Injury**

S. L. Hession, A. R. Maiuri, P. E. Ganey, and R. A. Roth, Michigan State University, East Lansing, MI.

Idiosyncratic, drug-induced liver injury (IDILI) typically affects a small fraction of patients when it occurs, although the effects can be serious and include death. Recent results suggest that tumor necrosis factor-alpha (TNF) interacts with drugs that cause IDILI to kill hepatocytes. Using a set of 24 drugs, we demonstrated previously that cytokotixity in the presence of TNF is used to classify drugs into voltage dependent regions. To confirm the sensitivity of the approach in preclinical evaluation of drug candidates, we hypothesized that successful classification could be accomplished using only data from the low end of the CRRs. We tested this hypothesis using the same data set as previously modeled; however, concentration-response data were censored above the EC50 to conduct CRR modeling using only the low-dose region. Multiple curve-fitting models were compared for their ability to fit the low-dose region for each CRR. Akaike Information Criteria (AIC) were used to select an optimal fitting model for each drug to be used to estimate a point of departure (POD) for the CRR. PODs were estimated for each drug in the absence and presence of TNF coexposure (covariates 1 and 2). These PODs, the difference between PODs (covariate 3), and the ratio of PODs for vehicle and TNF-treated cells (covariate 4) were used to create statistical classification models. Performance of the models was evaluated using receiver operating characteristic (ROC) analysis. Individually, covariates 1 through 4 yielded areas under the ROC curves (AUCs) of 0.72, 0.79, 0.83, and 0.83, respectively. The classification model incorporating both PODs (i.e., covariates 1 and 2) classified drugs with high selectivity and specificity and an AUC of 0.96. These results suggest that models employing covariates comprising PODs estimated from incomplete CRRs can accurately classify drugs according to their IDILI potential. Supported by NIH grant R01 DK112695.

**1321 Methionine Alleviates Cholesterol-Induced Increases in Inflammatory Markers in Sprague-Dawley Rats**

A. Kumar1, R. Pathak2, H. A. Pfalrey3, T. W. Gettys2, and S. N. Murthy1, 1Southern University and A&M College, Baton Rouge, LA; and 2Pennington Biomedical Research Center, Baton Rouge, LA.

Cardiovascular disease (CVD) is the leading cause of death worldwide. Western diets are mainly composed of meat and meat-based products which are rich in both cholesterol (Cho) and methionine (Met). Homocysteine (Hcy) is an intermediate in the metabolism of Met and consumption of high levels of Met has been shown to increase circulating levels of Hcy. Both Cho and Hcy are documented risk factors for CVD/atherosclerosis, an inflammation-based disease. The goal of the present studies was to test whether the combination of Met+Cho exacerbated the inflammatory effects of Met or Cho individually. After 35 days of ad libitum consumption of diets high in either Met or Cho, or a combination of both, body weight, energy intake and serum leptin were significantly lowered in the rats fed Met or a combination of Met+Cho. In the liver, genes for pro-inflammatory cytokines (IL-1, TNF, Mip-1) and Klf-2 were upregulated in rats fed the Cho diet compared to controls and the other dietary groups. In contrast, Met alone or Met+Cho had no detectable effect on expression of inflammatory markers in the liver. Moreover, maximum hepatic accumulation of triglycerides was seen in rats fed Cho diet which was reduced in rats fed either Met or Met+Cho. Thus, based on hepatic accumulation and bile control of hepatic inflammatory markers, our findings make a strong case that Cho alone represents a more significant risk factor than high Met. Further, high dietary Met ameliorates the adverse effects produced by Cho alone.

**1322 Chronic Polychlorinated Biphenyl (PCB) Exposure Disrupts Hepatic, Xenobiotic, and Intermediary Metabolism and Increases Hepatic Inflammation/Injury**

H. Shi, J. Hardesty, J. Jin, H. Clair, C. Falkner, R. Prough, and M. Cave, University of Louisville, Louisville, KY.

Polychlorinated biphenyls (PCBs) are endocrine and metabolism disrupting chemicals. Epidemiological studies have shown that PCB exposure is associated with steatohepatitis and diabetes. The aim of this study was to investigate whether chronic PCB exposure could disrupt hepatic metabolism and cause liver injury in a two-hit mouse model. Eight week old male C57BL/6 mice were fed a high fat diet (42% fat) and treated with either Aroclor 1260 (20 mg/kg p.o), a NDL PCB mixture, or PCB126 (20 mL/kg p.o), a single DL PCB congener, or vehicle control for 12 weeks. The mixture and doses used were based on human bio-accumulation patterns which show high levels of heavily chlorinated NDL PCBs and relatively low levels of DL PCBs. After euthanasia, tissues were obtained for analyses. As anticipated, AhR target gene, Cyp1a2 was induced by PCB126 exposure, while the constitutive androstane receptor (CAR) target gene, Cyp2b10 was induced in mice treated with Aroclor 1260. Neither body weight nor liver weight was changed with PCB treatment, but the epididymal fat weight was increased in the Aroclor 1260 group. Histological data showed that the extent of hepatic steatosis, triglycerides and lipid levels were similar in all groups. ALT was increased by Aroclor 1260 exposure, while AST was decreased by cholestatic liver injury. In this model, impaired bile flow elicits hepatocyte injury and inflammation, leading to myofibroblast activation and collagen deposition in the periportal and portal regions of the liver. The goal of this project was to determine how AhR activation by TCDD impacts the progression of liver fibrosis in BDL mice. We hypothesized that TCDD treatment would increase inflammation and myofibroblast activation in BDL mice and exacerbate the development of fibrosis. To test this, male C57BL/6 mice were treated with TCDD (20 μg/kg) or peanut oil (vehicle) one day prior to BDL or sham surgery. Mice were euthanized 3, 7, or 14 days post-surgery. Results indicate that TCDD treatment exacerbated liver injury and inflammation in BDL mice, based on elevated collagen content levels of alanine aminotransferase and increased inflammatory cell infiltration to the liver. TCDD was found to prolong and increase liver damage and inflammation 14 days after BDL surgery. Furthermore, exposure to TCDD increased mRNA levels of myofibroblast activation markers, aSMA, Col1α1, and Colα1. Despite these increases, TCDD collagen content levels of liver fibrosis was similar in vehicle- and TCDD-treated BDL mice. These results support the notion that TCDD increases myofibroblast activation in vivo, yet whether this occurs through a direct or indirect mechanism remains unclear. In addition, the finding that TCDD increased collagen transcript levels but not hepatic collagen content raises the possibility that TCDD enhances extracellular matrix turnover, which would presumably limit collagen deposition despite increased liver injury and inflammation.
PCB126 exposure. Ar126 treated animals had increased lobular inflammation and expression of pro-inflammatory cytokines (Tnfa and Cxcl8). Hepatic genes related to fatty acid synthesis (Srebp1, Fasn, and Scd1) and lipoxigenase (Lipox) expression were increased in Ar126 treated animals. Glucose and insulin tolerance were not affected by PCB exposure. However, mice treated with PCB126 had lower fasting blood glucose associated with decreased expression of the glucose regulatory gene, Gck1. Chronic PCB exposure disrupts hepatic xenobiotic and intermediary metabolism, to influence hepatic inflammation and injury. These data suggest that DI and NDLC PCB exhibited slightly different effects which could be due to, in part, to differential receptor activation.

1323 TCD2 Alternates Polysaturated Fatty Acid Metabolism and Eicosanoid Biosynthesis in Female Sprague Dawley Rats

C. Doxsey, R. Nault, K. Fader, T. Lydic, A. Jones, and T. Zacharewski, Michigan State University, East Lansing, MI.

2,3,7,8-tetrachlorodibenzop-dioxin (TCD2) is a potent aryl hydrocarbon receptor (AhR) agonist that elicits a broad spectrum of dose-dependent effects in the liver, including hepatic lipid accumulation coupled with inflammation at higher doses. We hypothesized that changes in polysaturated fatty acid (PUFA) metabolism would be coupled with dysregulation of inflammatory lipid mediators and play an integral role in TCD2-mediated hepatotoxicity in female Sprague-Dawley (SD) rats. Female SD rats were gavaged with sesame oil vehicle or TCD2 (0.01-10 µg/kg) every 4 days for 28 days. The integration of hepatic RNA-Seq data with untargeted metabolomics identified dose-dependent changes in linoleic acid (LA) and arachidonic acid (AA) metabolism. AA and LA are metabolized via cyclooxygenase, lipoxigenase, and cytochrome P450 epoxidiase/hydroxylation pathways. TCD2 elicited dose-dependent hepatic gene expression changes in all eicosanoid biosynthetic pathways with corresponding changes in PUFA and their eicosanoid metabolites. Overall, there was a dose-dependent increase in total ω-6 PUFA’s, while total ω-3 PUFAs decreased resulting in a dose-dependent increase in the hepatic ω-6:ω-3 PUFA ratio, as reported in human NAFLD. More specifically, TCD2 increased pro-inflammatory eicosanoids, including leukotriene (LT) B4 (3-fold), LTb (5-fold), and LTC4 (1.3-fold) and decreased cysteinyl LTs (CysLT, 13-fold) and LTb (2-fold) and decreased AA utilization by lipoxygenases. Accordingly, phospholipase A2 (P2a) was induced 6-fold consistent with increased AA biosynthesis, while AA utilization by lipoxygenases Alox5 (2-fold), Alox12 (2-fold), and Alox15 (10-fold) for the synthesis of LTs also increased. Hypothesized that TCD2 activates AhR, which mediates the toxic effects of environmental pollutants such as dioxins. AhR has also important endogenous functions, notably in vascular remodeling and THPS toxicity but not THP toxicity was significantly increased in the absence of amino acids in the medium. However, when methanal was added to the medium with amino acids, the toxicity of both THPS and THP was reduced. The hypothesis that conjugation of THPS with amino acids occurs only in the presence of methanal and protects against toxicity, possibly by decreasing the free THPS concentration. Morphological examination revealed the presence of microvillus in the cell cytoplasm without any obvious zone-specificity. The metabolism of glutathione peroxidase and superoxide dismutase 1 and 2 was not altered, indicating that other mechanisms than oxidative stress lead to liver toxicity and morphological changes observed. In conclusion, our results indicate that THPS toxicity might be due to THP’s and their acid conjugation mediated by methanal protects against this toxicity.

1324 Flutamide Interaction with Bile Acid and Tumor Necrosis Factor-Alpha in Human Hepatocytes: Implication for the Pathogenesis of Cholestatic Drug-Induced Liver Injury

G. P. Rice, N. Hibbard, R. A. Murphy, R. A. Roth, P. F. Ganey, and J. M. McMinn, 1ONTOX LLC, Kalamazoo, MI; and Michigan State University, East Lansing, MI.

Drug induced liver injury (DILI) is a major cause of acute liver failure in the United States and a primary reason for regulatory actions, such as drug recall or withdrawal. In most cases of DILI, patients are idiopathic (IDILI), and many appear to involve an immune response. Several IDILI-associated drugs interacted synergistically with tumor necrosis factor-alpha (TNF-α) to cause cytokite toxicity in HepG2 cells (Maiuri et al., JPET 362: 459, 2017), but the response appeared more robust with drugs that cause hepatic rather than systemic toxicity. For example, flutamide (FLUT) causes cholestatic IDILI and showed no synergy with TNF-α in HepG2 cells. FLUT can inhibit transport of bile acids (BAs). It has been suggested that drug-induced cholestatic injury involves inhibition of BA transport, and it seemed possible that the lack of responsive changes in FA transport was due to the absence of transport of BAs. Accordingly, we hypothesized that intrahepatic accumulation of bile acids caused by FLUT initiates cell stress that interacts with TNF-α, resulting in cytokitotoxicity. To test this hypothesis, FLUT cytokitotoxicity was evaluated in human hepatocytes in sandwich culture in the presence and absence of TNF-α and/or the BA, glycochenodeoxycholic acid (GCDA). Cytokitotoxicity was measured as lactate dehydrogenase (LDH) release and decreased intracellular ATP. Hepatocytes were exposed for 24 hr to various concentrations of FLUT (0-100 µM) and to vehicles or TNF-α (15ng/mL) and/or GCDA (300 µM). These concentrations of TNF-α and GCDA were nontoxic by themselves. FLUT alone caused no cytokitotoxicity; however, modest but statistically significant cytokitotoxicity occurred from FLUT in the presence of the TNF/GCDA combination, and the effects of the cytokine and the BA appeared to be additive. These data support the hypothesis that drug-induced accumulation of BAs in hepatocytes causes cell stress that adds to TNF-α-induced activation of stress pathways resulting in liver injury. Supported by a grant from IONTOX and by NIH grant R01 DK12665.

1325 Mechanism of Liver Toxicity of the Biocide Tetrakis(Hydroxymethyl)Phosphonium Sulphate

V. Starkokozhko, J. Stam, G. Steiblen, G. M. Groothuis, and I. A. De Graaf, 1University of Groningen, Groningen, Netherlands; and 2Solvay, Saint-Fons, France. Sponsor: E. Russel

The biocide tetrakis(hydroxymethyl)phosphonium sulphate (THPS) is associated with hepatotoxicity according to several animal studies, but the mechanisms behind are still unknown. In water, THPS exists in a reversible equilibrium with tris(hydroxymethyl)phosphine (THP). Also, THPS is known to degrade rapidly and spontaneously in biological material. The biocide tetrakis(hydroxymethyl)phosphonium sulphate (THPS) and other downstream metabolites, and can also form conjugates with amino acids. The goal of this study was to identify the ultimate culprit of THPS-induced liver toxicity. Therefore we tested the toxicity of THPS, THPO and THP on rat perfusion-liver slices (PCLS). The slice viability was determined by means of Alamar Blue and LDH leakage. The morphological examination was performed on paraffin sections stained with hematoxylin and eosin. The expression of genes known to play a role in oxidative stress was studied. THPS showed hepatotoxicity with a TC50 between 70µM and 100µM. THSP showed only moderate toxicity (TC50 200 µM) as did THPO and was not toxic up to 124µM. It was hypothesized that THPS actively binds to plasma proteins and amino acids with methanal acting as a linker in this reaction. Accordingly, THPS toxicity but not THP toxicity was significantly increased in the absence of amino acids in the medium. However, when methanal was added to the medium with amino acids, the toxicity of both THPS and THP was reduced. The hypothesis that conjugation of THPS with amino acids occurs only in the presence of methanal and protects against toxicity, possibly by decreasing the free THPS concentration. Morphological examination revealed the presence of microvillus in the cell cytoplasm without any obvious zone-specificity. The metabolism of glutathione peroxidase and superoxide dismutase 1 and 2 was not altered, indicating that other mechanisms than oxidative stress lead to liver toxicity and morphological changes observed. In conclusion, our results indicate that THPS toxicity might be due to THPS and/or THP and that amino acid conjugation mediated by methanal protects against this toxicity.

1326 Gender-Specific Role of the Aryl Hydrocarbon Receptor in Cellular Senescence during Liver Aging

C. Duval, S. Baron, C. Rouault, V. Nivet-Antoine, R. Barouki, and X. Coumoul, 1Paris Descartes University, Paris, France; and 2Pierre et Marie Curie University, Paris, France.

Cellular senescence is a fundamental cellular stress response limiting the proliferation of damaged cells but also driving inflammation with potential deleterious consequences in age-related liver diseases. The Aryl Hydrocarbon Receptor (AhR) is a ligand-activated transcription factor that mediates the toxic effects of environmental pollutants such as dioxins. AhR has also important endogenous functions, notably in vasculature and liver development, as it can influence cell biological endpoints such as growth or differentiation. The goal of the present study was to gain new insights into the potential role of AhR in liver aging and cellular senescence through the characterisation of AhRKO and WT mice of both gender at different ages (26, 39 and 52 weeks). Contrary to WT mice, AhRKO mice did not gain weight with aging. AhRKO mice display smaller liver weight and lower alanine amino transferase serum levels than WT littermates, as previously reported, regardless of the age. Liver histology confirmed the presence of a mild periportal fibrosis in AhRKO mice. Accordingly, hepatic mRNA levels of pro-fibrotic markers (Col1α1, Act2) were higher in AhRKO than in WT mice, though they decreased with aging. Strikingly, plasma profiles of pro-inflammatory cytokines were exacerbated in AhRKO females compared to WT littermates or males, and proned to age-dependent modulation. Also, liver inflammation was more severe in aged-AhRKO females than in males. Remarkably, hepatic gene expression of oxidative stress markers (Nox2,
1327 Sitagliptin Exacerbates Expression of Inflammatory Markers in Sprague Dawley Rats Fed a High-Cholesterol Diet

R. Pathak1, A. Kumar1, H. A. Palfrey1, T. W. Gettys2, and S. N. Murthy1. 1Southern University and A&M College, Baton Rouge, LA; and 2Pennington Biomedical Research Center, Baton Rouge, LA.

Sitagliptin, a dipeptidyl peptidase IV inhibitor, is an anti-diabetic drug. Independent of its hypoglycemic effects, sitagliptin is reported to reduce inflammation in addition to other health benefits. However, recent studies have demonstrated a risk of pancreatitis, hepatic injury and cardiac fibrosis associated with sitagliptin. Since hypercholesterolemia is responsible for the development and progression of atherosclerosis (an inflammation-based disease), studies were conducted in adult male Sprague Dawley rats to investigate whether sitagliptin exacerbates the effects of hypercholesterolemia. Using rats fed either a control or high cholesterol (Cho) diet, and gavaged daily with vehicle or sitagliptin, we found that high Cho increased hepatic expression of pro-inflammatory cytokines (Il1β, Tnf α, Mcp-1), and surprisingly, sitagliptin further increased the mRNA expression of each of these genes. High levels of Il1β were also seen in the serum of rats fed Cho and given sitagliptin. Analysis of serum metabolites revealed changes in purine metabolism. Reduced levels of uric acid (urate) and guanosine in sitagliptin-fed rats fed Cho is further suggestive of inflammation. Moreover, the high Cho produced a significant increase in serum Cho which was unaffected by sitagliptin. Serum triglycerides were reduced approximately 50% by sitagliptin in rats on Con diet but the effect was lost in rats on high Cho diet. Thus, sitagliptin increased expression of inflammatory markers in rats fed high Cho, in a manner that was independent of food intake or body weight. The diet x sitagliptin interaction with respect to inflammatory markers and lipid levels provides several interesting avenues for future studies.

1328 Bile Salt Supplementation for Detecting Drug-Induced, Cholestatic Liver Injury in Rats

F. Yang1, S. Oda1, K. Tsuneyama2, and T. Yokoi1. 1Nagoya University Graduate School of Medicine, Nagoya, Japan; and 2Institute of Biological Science, Tokushima University Graduate School, Tokushima, Japan.

Drug-induced liver injury (DILI) is a problem that complicates clinical pharmacotherapy and drug development. Many clinical drugs are associated with inhibition of bile acid export pump (BSEP), which induces hepatic bile acid retention and leads to liver injury. In drug development process, conventional experimental animals hardly detect cholestatic liver injury of marketed drugs, probably due to species differences in bile acid compositions and susceptibility to cholestatic drugs between humans and rodents. In this study, we aimed to establish an animal model to detect liver injury of BSEP-inhibiting drugs. Five-week-old female Sprague-Dawley rats were orally treated with chenodeoxycholic acid (CDCA) sodium salt at a nontoxic dose every 24 hours together with typical cholestatic drugs, ketoconazole (KTZ) for 4 days or itronavir (RTV) for 5 days. The plasma alanine aminotransferase (ALT) and aspartate aminotransferase (AST) levels were measured as biomarkers. Liver samples were collected on day 5 for KTZ group and day 6 for RTV group. Then hematoxylin-eosin staining was conducted. We confirmed that CDCA alone treatment did not result in biomarker increases and histological changes. In KTZ and CDCA-co-treated group, ALT levels were elevated ranging from 200 to 400 U/L while hepatic inflammations, necrosis, and lipid droplet were observed. The ALT levels were increased in the liver of 52 weeks-old AhRKO females. Our study provides new evidence that AhR could protect from cellular senescence associated with age-related liver diseases in a gender-specific manner. Established a rat model of liver injury that is susceptible to cholestatic drugs with the oral bile acid supplementation. This model would be useful in nonclinical safety studies to examine cholestatic property of drugs which alone do not cause liver injury in experimental animals in vivo.

1329 Alcohol Metabolism in Non-Alcoholic Steatohepatitis

H. Li, E. Toth, and N. J. Cherrington. University of Arizona, Tucson, AZ.

Alcohol metabolism is a well-characterized biological process that is dominated by the alcohol dehydrogenase (ADH) and aldehyde dehydrogenase (ALDH) families. Nonalcoholic steatohepatitis (NASH) is the stage of nonalcoholic fatty liver disease (NAFLD), and is known to alter the metabolism and disposition of numerous drugs. Hepatic ADH and ALDH play critical roles in alcohol metabolism and other cellular metabolism processes, as well as the metabolism of clinical drugs. Therefore, the purpose of this study was to investigate the alterations of alcohol metabolism in a mouse model of NASH with focus to human NASH pathology. Expression and function of individual ADH and ALDH enzymes were examined in normal, steatosis, NASH (fatty) and NASH (not fatty) human liver samples. ALDH4A1 mRNA was significantly decreased in both NASH groups, while no significant changes were observed in the mRNA levels of other ADH and ALDH genes. The protein levels of ADH1A, ADH1B and ADH4 were each decreased in the NASH groups, which was consistent with a decreased overall ADH activity as measured by the oxidation of ethanol. In NASH, protein levels of ALDH2 and ALDH4A1 were significantly increased, but unchanged for ALDH1A1 and ALDH2B1. Interestingly, ALDH activity measured by multiple substrates was variable. There was no significant change in ALDH-mediated acetaldehyde oxidation, but ALDH-mediated hexanal oxidation was decreased in both NASH groups and octanal oxidation was decreased in the NASH (fatty) group. Furthermore, the significant accumulation of 4-hydroxynonenal (4-HNE) protein adduct was observed in NASH, indicating significant oxidative stress and a potential reduction in ALDH activity. Collectively, the alterations in ALDH expression and function indicate distinct regulatory mechanisms in NASH. ADH and ALDH expression and function are profoundly altered in the progression of NASH, which may have notable impact on the ADH and ALDH associated cellular metabolism processes and lead to significant alterations in drug metabolism mediated by these enzymes.

1330 A Novel Fibroblast Growth Factor 1 Variant Reverses Non-Alcoholic Fatty Liver Diseases in Type 2 Diabetes

Nonalcoholic fatty liver disease (NAFLD) is the most common chronic liver disorder and is strongly associated with type 2 diabetes (T2D). Our recently engineered FGF1 partial agonist, carrying triple mutations (FGF1ΔHBS) exhibits greatly reduced proliferative potential, while preserving the full metabolic activity of wild-type FGF1 (FGF1 WT) (Cell Rep. 2017; 20:1717-28). This study tests the therapeutic effects of FGF1ΔHBS on NAFLD in T2D and explores potential mechanisms. The results showed that pharmacological administration of FGF1ΔHBS on 9-month-old male db/db mice for 3 months almost completely normalized the blood glucose levels, insulin sensitivity, liver weight, hepatic lipid deposition and inflammation and liver function. Mechanistically, FGF1ΔHBS treatment prevented diabetes-induced hepatic oxidative stress by promoting nuclear translocation of the antioxidant transcription factor Nrf2 (nuclear factor erythroid 2-related factor 2) and elevating the expression of multiple enzymes. Nrf2 knockdown inhibited the expressions of hepatic hexokinase genes including FXS, SREBP-1, SCD-1, and reversed the suppressed activity of hepatic fatty acid oxidation pathways, including elevated expressions of PPARα and PGC-1α, and enhanced phosphorylation of AMPK and ACC. Hep2 cells treated with palmitate (Pal) mimicked the diabetic phenotype of hepatic oxidative damage and disordered lipid metabolism seen in db/db mice, all of which could be reversed by supplementing with FGF1ΔHBS. Knockdown of Nrf2 by siRNA completely abolished the anti-oxidative capacity of FGF1ΔHBS, but did not affect the beneficial effects of FGF1ΔHBS on Pal-induced lipid metabolic disorder. Furthermore, inhibition of AMPK by the inhibitor Compound C completely abolished FGF1ΔHBS ability to prevent Pal-induced hepatic lipotoxicity and lipid metabolic disorder, along with the inhibition of Nrf2-mediated anti-oxidative signaling pathway. Our findings demonstrate that, in addition to its ability to restore glucose-lowering and insulin-sensitizing effects, FGF1ΔHBS can reverse NAFLD in T2D, by its ability to up-regulate AMPK-mediated lipid metabolism and Nrf2 anti-oxidative pathway.
Mechanisms of Polyhexamethylene-Biguanide-Induced Mouse Liver Hemangiosarcomas
Z. Wang, X. Li, and J. E. Klaunig. Indiana University, Bloomington, IN.

Chronic exposure of mice to polyhexamethylene biguanide (PHMB) resulted in an increased incidence of liver hemangiosarcomas. The underlying mechanism for these PHMB tumors appears to be through a nongenotoxic mechanism. The present study examined several key pathways for hemangiosarcoma formation in PHMB-treated mice including hypoxia, macrophage activation, increased angiogenic growth factors, epigenetic modifiers and preclinical animal species. For example, Prescott and Wright1, demonstrated that PHMB activate Ppar-γ, induce hypoxia/oxidative stress which in turn activate Kupffer cells, producing increased vascular growth factors, which stimulate endothelial cell progenitor cells differentiation, and promote endothelial cell proliferation. Male C57BL6 mice were treated to PHMB via diet at doses of 0 (control), 400, 1200 or 4000 ppm for 7, 14, and 28 days. Real-time PCR gene expression analysis revealed that PHMB at the high dose induced Hif1α after 14 days and Hmgb1, a known marker of hypoxia, after 14 and 28 days. Kupffer cells (macrophages) activation was indicated by increased expression of Tnfα and Il6 at the high dose group. Though not all statistically significant, vascular growth factors Vegf, Angpt (angiopoietin) and Tgf-β, as well as Vegf receptors 1 & 2 were consistently increased following PHMB exposure. Similarly, eNOS, an angiogenesis inducer was also increased following treatment with PHMB. The endothelial differentiation /progenitor marker Cd34 and VE-cadherin were also significantly induced by PHMB at the medium and high dose levels after 14 and 28 days. In addition, Ppar-γ receptor and the Ppar-γ regulated gene, Cd36 was induced by PHMB in a dose-responsive manner. Tumor proliferation rate was determined by gene expression, and BrdU staining (ongoing). PHMB administration induced a dose-related increase of cMYC expression. What’s more, gene expression data were suggestive that oxidative stress (increased Nrf2, Sod1, and Hmox1) and nuclear receptor CAR (elevated Cyp2b10) might also be involved. PHMB also failed to induce hemolysis as determined by red blood cell numbers and hemoglobin (Hb) levels after treatment for up to 28 days. Together, the present study along with literature information suggested that PHMB activate Ppar-γ, induce hypoxia/oxidative stress which in turn activate Kupffer cells, producing increased vascular growth factors, which stimulate endothelial cell progenitor cells differentiation, and promote endothelial cell proliferation and finally development of hemangiosarcomas.

Assessment of Acetaminophen Glutathione Depletion under In Vivo-Like Pharmacokinetic Concentration Profiles Enabled by a Microfluidic Addition and Removal Device
M. Shaeri, S. Snow, T. Kostrzewski, and D. Hughes. CN Bio Innovations Ltd, Welwyn Garden City, United Kingdom. Sponsor: M. Gaca

The pharmacokinetic (PK) profile is a determining factor in both the safety and efficacy of a drug or therapeutic regimen. PK profiles can vary significantly between patients and between humans and preclinical animal species. For example, Prescott and Wright1, demonstrated patients who suffer liver damage after acetaminophen (APAP) overdose exhibited an increase in both APAP plasma concentration and half-life. The plasma half-life for those with and without liver damage were 7.2 ± 0.7 hr and 2.9 ± 0.3 hr respectively. To model this effect using standard in vitro tests in which drug is added as a bolus is challenging as i) the concentration profile of the drug poorly mimics in vivo PK ii) the concentration of drug in the well may change in ways which are difficult to control due to cellular metabolism, binding to plasticware or degradation in solution. To provide a realistic in vitro model of APAP overdose profiles we developed a microfluidic device, known as the Microformulator (Viibre, Vanderbilt University), capable of precision addition and removal of medium from the wells, was used to create PK like concentration profiles in the wells of a microtiter plate. PK like concentration profiles were created by sequential addition and removal, where the duration of each step is set equal to the half-life. The accuracy of the profiles was verified using fluorescent probes. APAP was dosed onto primary human hepatocytes seeded in 96 well plates, either as a bolus or with PK like concentration profiles with a rise time of 4 hr and a decay half-life of either 7.2 or 2.9 hr. The maximal concentration reached was varied between 2 and 50mM. After 48 hr the cells were lysed and glutathione (GSH) levels measured. Bolus additions always resulted in greater GSH depletion than PK like profiles when comparing the maximal concentration in the PK profile to the concentration added as a bolus. For example at 20mM the GSH depletion was bolus 100%, PK 7.2 hr 94%, PK 2.9 hr 64%. Plotting the data against AUC, unified the database, indicating GSH depletion by APAP is AUC driven. This study demonstrates, the utility of a new tool for the generation of PK like concentration profiles in microtiter plates, and models clinical APAP overdose profiles in vitro. 1 Prescott LF, Wright N. The effects of hepatic and renal damage on paracetamol metabolism and excretion following overdosage. A pharmacokinetic study. Br. J. Pharmac (1973), 49, 602-613

HDAC3 Inhibition Prevents Liver Damage and Increases FGF21 Synthesis and Secretion to Aortic Protection in Diabetic Animals
J. Zhang1, Z. Xu1, J. Gu1, J. Freedman1, J. Sun1, Y. Tan1, and L. Cai2. Kosair Children Hospital Research Institute, Louisville, KY; and 2The First Hospital of Jilin University, Changchun, China.

Vascular complications are common pathways associated with type 1 diabetes. Drugs are effectively lowering the incidence of microvascular complications, they are less effective in the treatment of macrovascular diseases, including atherosclerosis. In recent years, histone deacetylase enzyme (HDAC) inhibitors have been found to be successful in preventing atherosclerosis. To investigate the role of HDAC3 inhibition in preventing diabetic aortic pathologies, male OVE26 type 1 diabetic mice and age-matched wild-type mice were given the HDAC3 specific inhibitor RGFP966 or vehicle for 3 months. At this time, mice were sacrificed or maintained for additional 3 months without RGFP966 treatment. Levels of aortic inflammation and fibrosis, plasma and hepatic FGF21 levels were then determined. Additionally, hepatic miR-200a and Keap1 expression, Nrf2 nuclear translocation and antioxidant gene expression were measured. We found that HDAC3 inhibition significantly reduced aortic fibrosis and inflammation in OVE26 mice at both 3 and 6 months. Plasma FGF21 levels were significantly higher in RGF966 treated OVE26 mice compared to vehicle-treated OVE26 mice at both time-points. Because the liver is the major organ for FGF21 synthesis and secretion in diabetic animals, the effects of HDAC3 inhibition on hepatic FGF21 synthesis was examined. RGFP966 treatment significantly reduced hepatic pathologies associated with diabetes and increased FGF21 mRNA and protein expression. Furthermore, our data found that HDAC3 inhibition reduced miR-200a expression that was associated with a reduction of Keap1 protein levels. This resulted in an increase of Nrf2 nuclear translocation and an upregulation of antioxidant genes and FGF21 transcription. Our results indicate that HDAC3 inhibition promotes Nrf2 function to prevent diabetes-induced liver injury preserving hepatic FGF21 synthesis. The preservation of hepatic FGF21 synthesis and secretion ultimately leads to a reduction in diabetes-induced aorta pathologies.

Late Protective Effect of Netrin-1 in the Murine Acetaminophen Hepatotoxicity Model
L. Duan, A. Ramachandran, B. Woolbright, and H. Jaeschke. University of Kansas Medical Center, Kansas City, KS.

Acetaminophen (APAP) hepatotoxicity is the leading cause of acute liver failure in the United States; the current treatment option for APAP overdose is administration of N-acetylcysteine (NAC), which facilitates hepatic and renal damage on paracetamol metabolism and excretion following overdose. A pharmacokinetic study. Br. J. Pharmac (1973), 49, 602-613

The pharmacokinetic (PK) profile of a drug is a determining factor in both the safety and efficacy of a drug or therapeutic regimen. PK profiles can vary significantly between patients and between humans and preclinical animal species. However, NAC has a short early therapeutic window and novel strategies are needed for patients who typically present late to the hospital. This is relevant, since the recovery and regeneration capacity of the liver, which typically occurs late after injury, plays a critical role in patient survival after an APAP overdose. Netrin-1 is a laminin-related protein initially identified as a chemotactic agent for axon guidance, and recent work has demonstrated that Netrin-1 also promotes hepatic repair and regeneration during liver ischemia/reperfusion injury. The role of Netrin-1 in acetaminophen hepatotoxicity is unknown and this study evaluated this in vivo in a mouse model of APAP overdose. Male C57BL/6J mice were co-treated with exogenous Netrin-1 vehicle control, along with 300mg/kg APAP and euthanized at 6h and 24h. Significant elevations in ALT indicative of liver injury were seen in control mice at 6h, however, this injury was not significantly affected by Netrin-1 administration. Also, Netrin-1 treatment did not affect mitochondrial translocation of phospho-JNK, though translocation of Bax to the mitochondria and release of Smac and cytochrome c were blunted at 6h. Interestingly, however, Netrin-1 administration attenuated liver injury as seen by ALT levels and histology at 24h, at which time significant elevations in mRNA for the adenosine A2B receptor, one of the Netrin-1 receptors, was also seen. Thus, our data indicate a previously unrecognized role for Netrin-1 in attenuation of APAP hepatotoxicity, which could be mediated by prevention of mitochondrial dysfunction through the adenosine A2B receptor.
Diethylene glycol (DEG) is an industrial solvent, generally found in brake fluid and cooling fuel, that has been implicated in mass poisonings worldwide. The predominant metabolites of DEG are 2-hydroxythoxyacetic acid (2-HEAA) and diethylene glycol (DEG). Although proximal tubular necrosis is characteristic of DEG poisoning, hepatotoxicity has also been observed. DEG has been implicated as the metabolite responsible for the renal and hepatic toxicity seen during these poisonings due to its accumulation in these target organs. DEG has also been shown to increase intracellular levels of reactive oxygen species (ROS). We hypothesize that treatment with DGA would impact the ratio of reduced and oxidized glutathione (GSH/GSSG) in the target organs, particularly in the liver. GSH is an important antioxidant that helps to protect against damage caused by ROS, and changes in the ratio of GSH/GSSG can be indicative of oxidative stress. To test this hypothesis, an in vivo dosing study was conducted. Rats were divided into control, low dose (100 mg/kg of DGA by oral gavage), and high dose (300 mg/kg) groups. The liver of each animal was collected by flash freezing in liquid nitrogen, homogenized in acid-containing solutions, and analyzed via HPLC. There were no significant differences seen in the amount of GSH, GSSG, or in the GSH/GSSG ratio among the three dose groups, even though there was marked toxicity observed in the high dose animals. The results suggest that oxidative stress is not a mechanism by which DGA causes toxicity to the liver in vivo.

**1338 Perfluoronanoic Acid (PFNA) Activates Nrf2 by Suppressing Autophagy in Mouse Liver and Human Hepatoma Cells**

Y. Le, and X. Cheng. St. John’s University, Queens, NY.

Perfluorinated compounds (PFCs) are persistent environmental pollutants, which are commonly detected in human serum. Epidemiologic studies showed positive associations between higher serum levels of PFCs and greater risk of liver diseases, endocrine disorders, and immunotoxicity. Nuclear factor erythroid 2-related factor (Nrf2), which plays important anti-oxidative roles, can be activated by oxidative stress and/or autophagy repression to protect liver cells. Our preliminary data showed that perfluoronanoic acid (PFNA) activated Nrf2 in mouse liver and cultured human hepatoma cells. However, the underlying mechanism is unknown. The present study was designed to investigate whether PFNA activates Nrf2 signaling via oxidative stress and/or autophagy suppression. Our results showed that PFNA increased mRNA expression of Nrf2-targeting genes, such as glutamate-cysteine ligase catalytic subunit (Gclc), NAD(P)H:quinone dehydrogenase 1 (Nqo1) and heme oxygenase (Ho-1), and the nuclear level of Nrf2 protein in mouse liver as well as in cultured human Hep3B hepatoma cells. Seashore and flow cytometry analysis demonstrated that in cultured human Hep3B hepatoma cells, PFNA (10μM) did not induce apparent mitochondrial stress or oxidative stress. Therefore, PFNA-induced Nrf2 activation is not due to oxidative stress. We next determined the impact of PFNA on autophagy progression. PFNA time-dependently decreased the conversion of microtubule-associated protein 1 light chain 3 beta (LC3B-I) to LC3B-II in mouse liver, indicating that autophagy was repressed by PFNA exposure. Furthermore, in mouse liver and cultured human Hep3B hepatoma cells, PFNA largely increased p62 protein level in the cytosol. In summary, this study demonstrated that PFNA activates Nrf2, maybe mediated by autophagy suppression and subsequent cytosolic accumulation of p62 protein.

**1339 Absence of Mrp4 Impairs Lipid Homeostasis following Two-Thirds Partial Hepatectomy**

O. Adelabolokun. University of Connecticut, Storrs, CT.

The regenerating capacity of the liver is critical for tissue recovery and survival following chemical-induced injury. The Multidrug-resistance associated protein 4 (Mrp4), an ATP-binding cassette (ABC) efflux transporter, plays an important role in regulating both hepatotoxicity and adaptive changes during liver injury in mice. Hepatic Mrp4 expression is low under basal conditions, with remarkable induction reported during acetaminophen (APAP)-induced hepatotoxicity and cholestasis liver injury. Furthermore, previous work from our laboratory has shown that Mrp4 up-regulation is localized to proliferating hepatocytes following APAP overdose. However, the role of Mrp4 in liver regeneration has not been studied recently, with emphasis placed on lipid accumulations transient regeneration-associated steatosis (TRAS) in models that underwent two-thirds partial hepatectomy (PH), a model for liver regeneration. The present study evaluated the gene expression profile of several cell cycle markers and lipid homeostasis genes in both WT and Mrp4 KO mice at 24, 48 and 72 hr after PH. Hepatocyte proliferation was evaluated by measuring the gene expression of cell proliferation markers such as Ki67, cyclin D1 and D2. Induction of Ki67 mRNA was observed in both genotypes after surgery with no significant differences between

**1337 Mechanisms of Protein Adduct Release during Acetaminophen Hepatotoxicity: Role of Exosomes**

A. Ramachandran, L. Duan, J. Akakpo, J. L. Weemhoff, B. L. Woolbright, and H. Jaeschke. Kansas University Medical Center, Kansas City, KS.

Acetaminophen (APAP) hepatotoxicity is the leading cause of acute liver failure in the United States, and formation of adducts between the reactive APAP metabolite N-acetyl-p-benzoquinone imine (NAPQI) and cellular proteins are a critical feature of pathophysiologic. In addition, circulating protein adducts are biomarkers of APAP hepatotoxicity and have recently been the focus of a rapid bioassay for identification of an APAP overdose in humans. In spite of their clinical significance however, mechanisms of release of APAP-protein adducts from hepatocytes into the circulation are not well understood. Studies in hepatocytes in vitro show significant release of APAP-protein adducts into the medium prior to elevations in ALT, suggesting that adduct release occurs before extensive hepatocyte necrosis. Exosomes are discrete membrane bound vesicles, which package cellular cargo and function in extracellular transport. Clarification of their role in transport of APAP adducts is relevant since adduct packaging within these membrane bound vesicles could shield them from detection by anti-body based methods, resulting in under-estimation of circulating adduct levels. Hence, this study evaluated exosome release after APAP overdose in vivo in mice, in primary mouse hepatocytes and human HepaRG cells in culture from APAP overdose patients and examined their role in transport of APAP-protein adducts. Exosomes were isolated by ultra-centrifugation and characterized by size and protein composition, following which level of APAP-protein adducts were measured by HPLC. Significant elevations in circulating exosome numbers were observed 6 hours after APAP overdose in vivo and by 4 hours in primary mouse hepatocytes in culture. Circulating exosomes were also elevated in media from HepaRG cells by 24 hours after APAP exposure, an effect recapitulated in APAP overdose patients, where exosome numbers were elevated compared to healthy controls. Though APAP-protein adducts were elevated in circulation and media parallel to the increased exosome release, no detectable adducts were observed within exosomes. This suggests that though APAP overdose enhances exosome release from hepatocytes in mice and humans, it is not a significant mechanism of release of APAP-protein adducts into circulation.

**1336 Loss of Liver-Specific and Sexually Dimorphic Gene Expression by Aryl Hydrocarbon Receptor Activation in C57BL/6 Mice**

The aryl hydrocarbon receptor (AhR) is a highly conserved transcription factor that mediates a broad spectrum of species-, strain-, sex-, age-, tissue-, and cell-specific responses elicited by structurally diverse ligands including 2,3,7,8-tetrachlorodibenzo-p-dioxin (TCDD). Dose-dependent effects on liver-specific and sexually dimorphic gene expression were examined in male and female mice gavaged with TCDD every 4 days for 28 or 92 days. RNA-seq data revealed the coordinated repression of 181 genes predominately expressed in the liver including albumin (Alb; 3.7-fold), methane dioxygenases (Kat la; 4.5-fold) α-fibrinogen (Fga; 14.5-fold), and β-fibrinogen (Fgb; 17.4-fold) in males with corresponding AhR enrichment at 2 hr. Liver-specific genes exhibiting sexually dimorphic expression also demonstrated diminished divergence between sexes. For example, male-biased Gsp1 was repressed 3.0-fold in males and induced 4.5-fold in females, which were confirmed at the protein level. Disrupted regulation was consistent with impaired GHR-JAK2-TAT5 signaling and inhibition of female specific CUX2-mediated transcription, as well as the repression of other key transcriptional regulators including Ghr, Stat5b, Bcl6, Hmna4, Hnf6, Foxa1/2/3, and Zhh2. Attenuated liver-specific and sexually dimorphic gene expression was concurrent with the induction of fetal genes such as alpha-fetoprotein (Afp; 15.0-fold). The results suggest AhR activation causes the loss of liver-specific and sexually dimorphic gene expression producing a functionally “de-differentiated” hepatic phenotype.
3340 Regulation of Long Non-Coding RNA Dino-Mediated P53 Activation by an Orphan Nuclear Receptor Nr2e3 in Acetaminophen-Induced Hepatotoxicity

K. Kim, and T. Khanal. University of Cincinnati, Cincinnati, OH.

A damaged induced non-coding gene (DINO) is a unique long non-coding RNA that interacts with, and stabilizes p53 protein for proper activation of p53 signaling pathways. Here, we have newly revealed that by an orphan nuclear receptor NR2E3 play a role in maintaining active epigenetic status of DINO gene promoter by forming protein complex with Sp1 transcription factor. On the contrary, NR2E3 loss induced repressive DINO epigenetic status by recruiting histone demethylase LSD1 that turn off active histone mark H3K4me2, subsequent led to impaired DINO expression and p53 signaling pathway activation. In acetaminophen-induced animal liver injury model, Nr2e3 knockout mice recently generated in our laboratory exhibited more severe liver damage than wild type mice accompanied by increased necrosis with less apoptosis mainly due to defective DINO-p53 signals activation. Also, the liver damage in Nr2e3 knockout mice was not successfully reversed by antioxidant N-acetylcysteine treatment, comparing to an efficient reversal in wild type mice, indicating that DINO-p53 signaling axis is critical for the antioxidant-mediated recovery from acetaminophen-induced hepatotoxicity. Collectively, our new findings demonstrated that NR2E3 is an essential player for maintaining proper activation of p53 signaling pathways by sustaining active DINO epigenetic status and expression. The findings will provide fundamental scientific information that can be translationally applied for the improvement of prognosis and therapeutic strategies in various p53-related human diseases.

3342 Chronic TCDD Treatment Elevates Liver Fibrosis in Hepatocyte-Specific Ahr Knockout Mice

S. Rayavara Veerabhadraiah. Boise State University, Boise, ID. Sponsor: K. Mitchell

Accumulating evidence implicates a role for the aryl hydrocarbon receptor (AhR) in the development of liver fibrosis, which is a pathological wound healing response that is characterized by excessive synthesis of extracellular matrix molecules. During liver fibrosis, chronic injury and inflammation drive the activation of myofibroblasts, which produce collagen type I. We have previously reported that exposure to the exogenous AhR ligand 2,3,7,8-tetrachlorodibenzo-p-dioxin (TCDD) increased HSC activation in vitro and in mice treated with carbon tetrachloride. Furthermore, recent literature reports demonstrate that chronic TCDD administration alone elicits liver fibrosis. It is possible that AhR activation in HSCs alone can drive the activation of myofibroblasts and fibrogenesis. Therefore, we hypothesize that AhR activation by the exogenous agonist 2,3,7,8-tetrachlorodibenzo-p-dioxin (TCDD) increased HSC activation in vitro and in mice treated with carbon tetrachlore. Hence, exacerbated liver fibrosis.

3343 Exogenous AhR Activation Increases Myofibroblast Fibrogenic Activity in Mice with a Hepatocyte-Specific Ahr Deletion

G. N. Cholico, and K. Mitchell. Boise State University, Boise, ID.

The aryl hydrocarbon receptor (AhR) is a soluble, ligand-activated transcription factor that has been implicated in fibrosis, which is a pathological wound healing response that is characterized by excessive synthesis of extracellular matrix molecules. During liver fibrosis, chronic injury and inflammation drive the activation of myofibroblasts, which produce collagen type I. We have previously reported that exposure to the exogenous AhR ligand 2,3,7,8-tetrachlorodibenzo-p-dioxin (TCDD) increases HSC activation in vitro and in the liver of mice chronically treated with carbon tetrachloride (CCL4). The goal of this project was to distinguish between the direct effects of TCDD on HSC activation and indirect effects that could occur through TCDD-induced hepatocyte damage. Cre-LoxP recombination was used to generate hepatocyte-specific AhR knockout mice (AhR∆hep). To elicit liver injury and fibrosis, these mice or control mice (AhRfl/fl) were treated with 1.0 ml/kg CCl4 every four days for 5 weeks. TCDD (100 μg/kg) or peanut oil vehicle was administered during the fifth week. Based on serum alanine aminotransferase levels, TCDD increased liver damage in CCl4-treated AhRfl/fl mice but had no effect in AhR∆hep mice. In addition, TCDD treatment increased hepatic inflammation in CCl4-treated mice on both backgrounds, but the number of inflammatory foci was twice as high in AhRfl/fl mice than in AhR∆hep mice. TCDD also increased markers of HSC activation in CCl4-treated mice, based on increased expression of α-smooth muscle actin and Colla1, but expression levels were approximately 3-fold lower in AhR∆hep mice compared to AhRfl/fl mice. Nevertheless, despite discrepancies in liver damage, inflammation and HSC activation, collagen content was remarkably similar in CCl4/DDC-treated AhRfl/fl and AhR∆hep mice. Collectively, these results indicate that hepatocyte damage augments - but is not absolutely required for - the increased myofibroblast activation observed in TCDD-treated mice. Data support the notion that TCDD either directly activates HSCs or else exacerbates inflammation, which subsequently leads to HSC activation.
Potential Cross-Talk between FXR and FGF19 Signaling Pathways in the Human Hepatic Stellate Cell Line LX-2

J. D. Schumacher, B. Kong, J. Wu, J. Shen, and G. L. Guo, Rutgers, The State University of New Jersey, Piscataway, NJ.

Fibroblast growth factor 15 (Fgf15; FGF19 - human ortholog) is an endocrine FGF produced in the ileum in response to the activation of the nuclear receptor farnesoid X receptor (FXR) by its endogenous ligands, bile acids (BAs). BAs also activate other receptors and pathways including TGR5. Fgf15 acts as a crucial feedback factor on BA production by suppressing the hepatic expression of genes encoding BA synthesizing enzymes, Cyp7a1 and Cyp8b1. Our lab has previously shown that Fgf15 deficiency was protective against liver fibrosis in a high fat diet (HFD)-induced non-alcoholic steatohepatitis (NASH) mouse model. Despite the observed decrease in fibrosis in Fgf15 deficient mice with NASH, there was severe steatosis and inflammation indicating that Fgf15/19 may directly activate hepatic stellate cells (HSCs). FXR activation in HSCs has been shown to reduce the expression of collagen thus inhibiting fibrosis. Therefore, Fgf15 deficiency may protect against the development of hepatic fibrosis by increasing the total BA pool size and subsequently increasing FXR activation in HSCs. To differentiate the effects of Fgf15 signaling from FXR signaling, we treated the human hepatic stellate cell line, LX-2, with a BA that is a FXR agonist, chenodeoxycholic acid (CDCA), and/or recombinant FGF19. Effects on gene expression at mRNA and protein levels for HSC activation and proliferation were determined. We found that FGF19 induced the phosphorylation of hyperplipidemic messenger of fibroblast growth factor receptor (FGFR), STAT3, indicating that FGF19 could directly activate FGFRs in LX-2 cells. However, FGF19 treatment did not alter the gene expression of the HSC phenotypic marker genes, including COL1A1, aSMA, or PPARγ. As expected, CDCA up-regulated the expression of the chenodeoxycholic acid receptor, FXR, and its response genes, CYP3A7, ABHD5, and ATGL. Treatment with FGF19 led to decreased expression of the BA receptors, FXR and TGR5, while CDCA treatment increased the expression of the FGF19 co-receptor FGFR1 and β-KLOTHO. These findings indicate potential cross-regulation and feedback between these pathways in HSCs. As Fgf15 decreases the total BA pool size and leads to down-regulation of FXR in HSCs, we postulate that the partial protective benefit offered by FGF15 deficiency on the development of hepatic fibrosis may be due to increased FXR activity in HSCs.

Hepatotoxic Effects of Gugulipid® 2.5% following In Vivo Exposure in Sprague Dawley Rats and In Vitro Exposure in Human Liver Microsomes

Gum guggul extract (GGE), derived from the resin of Commiphora mukul, is marketed in the United States as a dietary supplement purported to treat hyperlipidemia, arthritis, obesity, and acne. The active constituents of GGE, the sterioisomers E- and Z-guggulsterone, are known to alter the activity of cytochrome P450 (CYP) enzymes, suggesting concern for herb-drug interactions following GGE exposure. GGE is also not recommended for use in individuals with liver disorders. Due to concerns for liver toxicity and inhibition of CYP activity following exposure to GGE, the National Toxicology Program (NTP) selected a dietary supplement currently on the market, Gugulipid® 2.5% granules, for toxicity evaluations. The subchronic effects of Gugulipid® 2.5% exposure were determined by targeted gene expression array in Sprague Dawley rats and the effects of Gugulipid® 2.5% or E- and Z-guggulsterones on enzyme and transporter activity were determined in vitro in human liver microsomes (HLM). Male and female SD rats were administered Gugulipid® 2.5% by oral gavage at 0, 62.5, 125, 250, 500, and 1000 mg/kg for 13 weeks. At study termination, rats were evaluated for general toxicity including liver weights, CYP activity, and clinical pathology. Exposure to 500 or 1000 mg/kg Gugulipid® 2.5% resulted in increased liver weights, dose-dependent increases in CYP3A4 and CYP2B1 activity, and decreased serum alkaline phosphatase (ALP) levels in both male and female rats. Serum bile salts were also decreased in female rats. Incubation of HLM with Gugulipid® 2.5% (normalized to 10 μM guggulsterones) caused marked inhibition of multiple CYP activities. E- or Z-guggulsterone alone inhibited CYP activity as well, albeit not to the same extent. When evaluated for effects on transporter activity, Gugulipid® 2.5% inhibited sodium/bile acid co-transporter Na+taurocholate (NTCP) activity and increased P-glycoprotein (Pgp) activity, suggesting Pgp as a key pump for xenobiotic compounds. Overall, in vivo and in vitro exposure to Gugulipid® 2.5% modulated hepatic enzymatic activity in both SD rats and HLM.

Perfluorooctanesulfonic Acid (PFOS) Worsens Hepatic Steatosis and Induces Fatty Acid Uptake in Mice Fed a High-Fat Diet and High-Fat to Low-Fat Diet Switch

Perfluorooctanesulfonic acid (PFOS) is part of a class of bio-accumulative pollutants, called perfluoroalkyl substances (PFAS). In mice, PFOS administration has been shown to increase liver weight and induce hepatic lipid accumulation. The aim of the study was to evaluate potential mechanisms of PFOS induced liver lipid accumulation. Mice were fed a standard chow low fat diet (LFD) or 60% Kcal high fat diet (HFD) for 12 weeks to establish significant body weight and food intake tolerance. Mice were then divided into two main groups; diet alone or diet containing 0.0003% PFOS. Furthermore, each group was subdivided into 3 groups: mice fed LFD, mice fed HFD, or mice fed HFD that were switched to a LFD to mimic the therapeutic treatment. The end study design resulted in a total of 6 treatment groups: (i) LFD, (ii) HFD-LFD, (iii) HFD, (iv) LFD + PFOS, (v) HFD-LFD+PFOS, and (vi) HFD+PFOS. For 10 weeks, mice were fed the new diets, and body weights were monitored. Serum lipids levels were measured in fasting blood. Liver lipid were isolated via chloroform: methanol extraction, and mRNA expression was determined by targeted bead array. HFD feeding for 14 weeks increased body weight, liver weight, white adipose tissue weight, serum lipids and liver lipids. HFD-LFD mice lost body weight and had similar tissue weights, serum lipids, and liver lipids as LFD mice at the end of the study. PFOS exposure in LFD mice reduced body weight and overall weight gain, decreased white adipose tissue weights, and increased liver triglycerides. PFOS exposure in the HFD-LFD group increased liver weight, decreased serum cholesterol, and increased free fatty acids. PFOS exposure in the HFD caused less overall weight gain, increased liver weight, decreased serum cholesterol, and increased liver lipids compared to HFD controls. Liver mRNA expression data shows that PFOS exposure modulates several genes: liver fatty acid translocase (Cd36 or Fat), cell death activator CIDE-A (Cidea), fatty acid binding protein 4 (Fabp4), glutathione S-transferase M3 (Gstm3), and 3-hydroxy-3-methylglutaryl-CoA synthase 1 (Hmgcs1). Western blot data shows PFOS exposure increased Cd36 and Fabp4 expression. The data suggests that PFOS exposure acts on liver lipid uptake, and exacerbates hepatic steatosis in mice induced by high fat diet feeding.

Low-Dose Perfluorononanoic Acid (PFNA) Alters Hepatic Gene Expression in a Mouse Model of Diet-Induced Obesity and Hepatic Steatosis

Perfluoronoctonanoic Acid (PFNA) is classified as a synthetic perfluorinated carboxylic acid with a nine-carbon backbone, that has been shown to cause adverse liver and insulin-signaling effects in rodents, and little is known about its effects on the human liver. PFNA is a member of the perfluoroalkyl substances family, which is a group of man-made compounds that are highly stable and of significant toxicological concern. The aim of this study was to evaluate whether PFNA exposure in combination with a moderately high-fat diet caused serum lipid changes and increased biomarkers of hepatic steatosis. For this study, 5-week-old male mice were fed a 10% Kcal (LFD) or 45% Kcal high fat diet (HFD) alone or in combination with PFNA (0.0003% in chow; LFD-PFNA and HFD-PFNA, respectively) for 12 weeks. The HFD increased body weight by 30%, white adipose tissue (WAT) by 100% and liver weight by 30%. The administration of PFNA slightly decreased body weight in the HFD mice by 85% and in the HFD mice by 82%. PFNA significantly decreased WAT tissue mass in both the LFD and HFD mice. HFD feeding increased hepatic total lipids and triglycerides, however no change was observed in cholesterol or NHEA. Hepatic total lipid content, NEFA, and cholesterol content were similar between controls and both PFNA treated groups. PFNA did not significantly decrease triglyceride content in the HFD fed mice. PFNA significantly increased liver weight and interacted with the HFD. A targeted gene expression array revealed that PFNA altered the expression of genes involved in hepatic lipid deposition. The fatty acid uptake genes Cd36, Lpl, Slc27a1 and Sreb1 were all significantly induced by PFNA administration in both HFD and LFD mice. This data suggests that an environmentally relevant dose of PFNA (0.0003%) may impact hepatic lipid accumulation. 

1344 Potential Cross-Talk between FXR and FGF19 Signaling Pathways in the Human Hepatic Stellate Cell Line LX-2

1345 Hepatotoxic Effects of Gugulipid® 2.5% following In Vivo Exposure in Sprague Dawley Rats and In Vitro Exposure in Human Liver Microsomes

1346 Perfluorooctanesulfonic Acid (PFOS) Worsens Hepatic Steatosis and Induces Fatty Acid Uptake in Mice Fed a High-Fat Diet and High-Fat to Low-Fat Diet Switch

1347 Low-Dose Perfluorononanoic Acid (PFNA) Alters Hepatic Gene Expression in a Mouse Model of Diet-Induced Obesity and Hepatic Steatosis
1348 The Role of Hepatocyte-Specific Farnesoid X Receptor (FXR) and Lipocalin 2 (Lcn2) in the Acute Phase Response

L. E. Armstrong, S. Chung, B. Kong, and G. Guo, Rutgers, The State University of New Jersey, Piscataway, NJ.

Farnesoid X receptor (FXR) has emerged as a key nuclear receptor in regulating bile acid homeostasis, liver lipid metabolism, and most notably, liver inflammation. Specifically, FXR has been shown to be a key regulator of members of the lipocalin family of proteins. Lipocalins (Lcn) act as acute phase proteins (APPs) that are expressed and secreted by hepatocytes in response to systemic or local innate inflammatory response, collectively known as the hepatic acute phase response (APR). This study aims to define the role of hepatic FXR and Lcn in the APR using a mouse model with acute bacterial infection. Wild-type (C57BL/6), hepatocyte-specific FXR KO (FXR hep-/-), Lcn2 KO (Lcn2 hep-/-), and double knockout (DKO) mice were intraperitoneally injected with an acute dose of Escherichia coli (E. coli) or sterile phosphate buffered saline (PBS). In vivo bacterial counts in whole blood, liver and spleen were determined 24 hrs post-infection. Serum levels of liver injury markers were determined, and liver and spleen were collected for tissue-specific gene expression. It is hypothesized that hepatic FXR and Lcn protect against liver inflammation; therefore, deficiency of these genes will result in altered APR defined by either worsened bacterial infection and/or increased liver inflammation. All genotypes had significant increase in bacterial load with E. coli compared to their PBS controls. Liver injury was only noted in infected FXR hep-/- mice with significantly increased ALT (87.9 ± 35.1 U/L) and AST (70.4 ± 17.4 U/L) compared to Lcn2 hep-/- (109 ± 8 mg) and DKO (116 ± 20 mg) mice. Most significantly, DKO mice had lower ALT (13.7 ± 10.2 U/L) and AST (57.4 ± 17.4 U/L) compared to FXR hep-/- mice, suggesting Lcn2 may contribute to worsened liver injury in FXR hep-/- mice. These findings suggest a protective role of FXR in regulating the hepatic APR and/or APPs, overall supporting a larger role of FXR in the spectrum of disease known as nonalcoholic fatty liver disease (NAFLD). Chronic activation of the APR and dysregulation of APPs are factors of liver inflammation associated with the disease pathology of nonalcoholic steatohepatitis (NASH), in which FXR activation could protect against.

1349 Activation of Kupffer Cells and Bone Marrow-Derived Macrophages by the Fibrinolytic Enzyme, Plasmin

M. Rodriguez, K. Roth, and B. Copple, Michigan State University, East Lansing, MI. Sponsor: C. Rockwell

Studies have shown that inhibition of the fibrinolytic enzyme, plasmin, prevents macrophage activation after toxin-induced liver injury in mice. This decreases cytokine production and macrophage-mediated phagocytosis resulting in impaired liver regeneration. The mechanism by which plasmin regulates the activity of macrophages in the liver remains unknown. In the present studies, the hypothesis was tested that plasmin directly activates macrophages. To test this hypothesis, macrophages were isolated from mice and treated with plasmin. Treatment of bone marrow-derived macrophages and Kupffer cells with plasmin increased expression of tumor necrosis factor-a, Cxcl1 and Cxcl2. Upregulation of cytokines was inhibited by the plasmin inhibitor, tranexamic acid. Plasmin stimulated formation of extensive pseudopodia, and activated Erk1/2, Jnk, NF-kB and p38, while inhibiting activation of Akt. Previous studies have indicated an important role for the damage-associated molecular pattern molecule, high-mobility group B1 protein (HMGB1), in activation of macrophages after liver injury. Interestingly, in the present studies, HMGB1 alone did not directly activate macrophages, but it did synergistically enhance activation of macrophages by plasmin. Further, necrotic hepatocytes from wild-type mice enhanced activation of macrophages by plasmin whereas necrotic hepatocytes from hepatocyte-specific HMGB1 knockout mice had no effect on activation of macrophages by plasmin. Collectively, these studies indicate that plasmin is a key activator of macrophages in the liver after injury. Supported by NIH grant DK073566.

1350 A Novel In Vitro Liver Cell Culture Flow System Allowing Long-Term Metabolism and Hepatotoxicity Studies

M. Stosik1, S. Buesch1, J. Schroeder1, M. Bunge2, and T. D’Souza2.

1Lonza Cologne GmbH, Cologne, Germany; and 2Lonza Walkersville Inc., Walkersville, MD.

Hepatotoxicity is a concern when developing new small molecule pharmaceutical compounds. One of the major reasons for the withdrawal of a drug from the market is hepatotoxicity that typically does not appear immediately but after patients have had prolonged and repeated exposure to a drug. Animal models can be suitable for the detection of hepatotoxicity including long-term and repeat dosing studies to replicate this long-term phenomenon. However, animal models often do not accurately predict toxicity in humans due to species differences, e.g. differences in compound metabolism. In vitro models based on primary human hepatocytes (PHH) may be suitable to predict acute toxicity in humans. However, in vitro PHH undergo a rapid de-differentiation over the course of the first 7 days in culture that limits the ability to develop long-term repeat dosing models in vitro. Here we present an alternative in vitro model that is based on the culture of PHH in the Quasi Vivo Q900 flow system. The Q900 flow system consists of 6 chambers that can be connected in flexible configurations. A peristaltic pump generates a cell culture medium flow that mimics blood flow and ensures a steady supply of nutrients, growth factors and oxygen as well as removal of waste products and continuous dosing with test compounds. When culturing PHH in the Q900 flow system, we observed good cell viability and sustained albumin production for up to 14 days in culture. Healthy hepatocyte morphology was well maintained during the analysis period as assessed by phase contrast microscopy. In comparison to non-perfused cultures, the basal activity of the drug metabolism enzymes Cyp3A4, Cyp1A2 and Cyp2B6 was increased, e.g. by up to 10-fold for CYP1A2, as measured by mass spectroscopic analysis of the conversion of phenacetin to acetaminophen. After 72 h of rifampicin treatment, induced CYP3A4 activity was comparable between perfused and non-perfused cultures (assessed by luciferase assay and analysis of hydroxymidazolam formation). Furthermore, this system enabled fewer media changes as typically required in static cultures to enable build-up of potential toxic metabolites that would not be detected when media is refreshed daily. In summary, we present an in vitro liver cell culture flow system that improves longer-term stability of drug metabolism enzymes in PHH for a more human relevant in vitro system for repeat dosing of hepatotoxicants.

1351 Human Liver and Kidney Slices Maintained for Multiple Dosing and Recovery from Injury

A. Vickers1 and R. Fisher1. 1Human Translational Models, Irvine, CA; and Vitron Inc., Tucson, AZ.

The extended viability of multi-cellular 3-dimensional human liver and kidney slices for up to 7 days expands the use of this in vitro model for studying pathways of injury and repair following multiple dosing. Human tissue was obtained from procurement agencies, according to accepted medical and ethical standards, as outlined by the Uniform Anatomical Gift Act. In culture, the organ slices are supported on a tita- nium mesh roller-insert, and the medium is replaced daily to mimic multiple dosing. The slices remain differentiated, are metabolically active, synthesize ATP and glutathione, while organelle integrity is maintained. By 72 hr of culture the organ slices begin to exhibit pathways of repair. Global gene expression profiling using U133A Affymetrix gene chip arrays revealed similarities in human liver and kidney slices, including the upregulation of extracellular matrix constituents, the proteolytic cascade IGFBP-5, and an up-regulation of growth factors. The up-regulation of several collagens, led to an increased deposition of collagen IV protein in both tissues. Differences in kidney slices included an up-regulation of the collagen catabolism matrix metalloproteinases. In this study, there was an up-regulation of genes encoding EGF, FGF-regulin and TGF-β1 in the human liver slices, and TGF-β1 in the human kidney slices. Activation of stellate cells in the liver was evident by the up-regulation of early (HSP47 and ß-crystallin) and late markers (αSMA and procollagen 1a1) of stellate cells. Kidney slices exhibited an up-regulation of markers of DNA synthesis and cell cycle progression, such as MCM, minichromosome maintenance, and the microtubule associated kinesins, as well as an up-regulation of cytokine IL-24 which is linked with wound healing, cell survival and proliferation. Morphological changes in liver slices included evidence of regeneration by day 3, anisokaryosis and scattered multinucleate hepatocytes that continued through day 6, with no evidence of progressive necrosis or fibrosis. Additionally,
bile production was evident in the liver slices. The human kidney slices exhibited progressive necrosis in spite of gene changes indicative of repair. These 3-dimensional multi-cellular organ slices maintain tissue architecture and function to predict pathways of injury and repair for several days and following multiple dosing.

### 1352 Non-Coding RNAs Function as Regulators in Acetaminophen-Induced Liver Injury: An Integrative Approach

D. Yu, S. Chen, Y. Zhao, L. Wu, W. Tolleson, B. Knox, L. Guo, Y. Zheng, and B. Ning. 1. Qingdao University, Qingdao, China; and 2. US FDA/NCTR, Jefferson, AR.

Acetaminophen (APAP) overdose is the leading cause of acute liver failure. MicroRNAs (miRNAs) and long non-coding RNAs (lncRNAs) are families of non-coding RNAs (ncRNAs) that control gene regulatory mechanisms epigenetically. To elucidate the roles of ncRNAs in APAP-induced pediatric liver injury, we systematically analyzed the gene and ncRNA expression profiles in APAP-treated HepaRG cells, and selected candidate ncRNAs that target the key drug metabolizing enzymes, transporters (DMETs) and DME regulators—nuclear receptors, and then investigated the underlying mechanisms by a series of biochemical or biological assays. We identified 2,757 genes, 47 miRNAs and 1,340 IncRNAs differentially expressed in APAP-treated HepaRG cells. The hsa-miR-224-5p, hsa-miR-320a, hsa-miR-449a, and hsa-miR-877-5p were predicted to target the CYP3A4, CYP3A4, and NR1I2 and the endogenous expression of these genes were suppressed by the transfection of corresponding miRNAs. RNA electrophoresis mobility shift assays and miRNA pull-down assays displayed direct interactions between miRNAs and their cognate mRNA transcripts. Importantly, experimental transfection of these miRNAs or antisense oligonucleotides (ASOs) for cognate miRNAs exhibited progressive necrosis in spite of gene changes indicative of repair. These 3-dimensional multi-cellular organ slices maintain tissue architecture and function to predict pathways of injury and repair for several days and following multiple dosing.

### 1353 Novel Liver Spheroids for High-Throughput Drug-Drug Interaction Screen by Next-Generation Sequencing

N. Dianat1, P. Ibanez2, R. Ayata3, L. Chamayou4, A. Perreard Dumaine5, M. Pardon6, N. Bremond7, G. Sanderink8, A. Griffiths9, and J. Bibette1. 1. ESPCI, PSL Research University, Paris, France; and 2. Fluofarma, Pessac, France; and 3. Cytorex, Alderley Park, United Kingdom. Sponsor: B. Wetmore

For ADME, early prediction of Drug-drug interaction (DDI) risk prediction is needed, but available datasets don’t reach FDA approval. However, no accurate high throughput screen (HTS) assay is available for induction of Cytochrome P450 (CYP), the main family of drug-metabolizing enzymes and key players in DDI. Primary Human Hepatocytes (PHH) in 2D usually used in DDI screens feature loss of tissue-specific architecture, mechanical and biochemical cues, cell-to-cell and cell-to-matrix interactions and cell-metabolizing enzyme activities. This affects their metabolic functions and assays leading to relatively poor DDI risk reliability. We have developed “HepatoPearl”, a PHH 3D model produced in micrometric alginate capsules. Their architecture and function to predict pathways of injury and repair for several days and following multiple dosing.

### 1354 Diversity of Primary Hepatocytes Models Allow for Choosing the Best Tools for Hepatotoxicity Assessments

G. Froget1, L. Ekue2, P. Kitchener3, and F. Simon3. 1. Parasol SAS, Fluvofarma, Le Genest Saint Isle, France; and 2. Fluvofarma, Pessac, France.

Hepatotoxicity is a major issue for pharmaceutical companies due to it being a frequent cause of attrition of drug candidates. One of the major reasons for failures is the lack of accurate and predictive models of hepatoxicity in the early stages of drug development. There is therefore a need for in vitro hepatotoxicity screening models that are valid, robust and amenable to high throughput. An array of specific and representative read-outs, using high content imaging and flow cytometry, were established for analyzing compounds’ effects. Cytolysis was followed kinetically as a phenotypic readout of hepatotoxicity, while mitochondrial membrane potential, GSH depletion, or lipid contents measured by flow cytometry, help decipher hepatotoxicity mechanisms with excellent sensitivity. Hepatocyte primary cultures from three different species were used for different ADME studies. For example, this approach revealed that the human hepatocytes from rats is highly amenable to large screening campaigns. Primary human hepatocytes are also available in high numbers from deceased patients and constitute an excellent model for testing hepatotoxicity, with a higher cost. We have compared and validated selected hepatocytes against the three most reactive APAP hepatocytes in our array of specific readouts with the same compounds. We exemplify how the use of fresh rat hepatocyte based assays, in combination with the single cell level of analysis, represents a quality predictive model with a high level of sensitivity and specificity. However, primary human hepatocytes are only used for different ADME studies and they are highly relevant for modeling APAP-induced hepatotoxicity as mechanisms are similar in human and mice. Mice primary hepatocytes were used for screening potential protective compounds against APAP by using the GSH content readout and comparing with the effect of N-Acetylcysteine. We have therefore developed fully validated primary hepatocyte models from different species, combined with specific readouts, which allow for choosing the best model for a particular question.

### 1355 Utilization of Human-Focused 3D Liver Models in Conjunction with Multi-Parametric Cell Health Approaches for the Prediction of Drug-Induced Liver Injury

C. Dilworth. Cytorex, Alderley Park, United Kingdom. Sponsor: C. Strock

Recent pharmaceutical strategies to address drug induced liver injury (DILI) have focused primarily on multi-parametric approaches utilising conventional 2D cell culture methods with primary human hepatocytes (PHH) or HepG2 or HepaRG cells. A recent study has been published using a strategy for the prediction of human DILI utilising PHH 3D liver microspheres. Their approach compared responses in 2D versus 3D models to reference DILI compounds utilising a single biochemical endpoint, cellular ATP. We have further developed this DILI approach and developed a comprehensive panel of PHH and HepaRG 3D liver microspheres (MTs) utilising, in addition to ATP, a multiparametric confocal high content screen measuring a range of endpoints such as mitochondrial membrane potential, reactive oxygen species formation and GSH content. CYP450 characterisation microspheres showed significantly higher activities in HepaRG MTs compared to PHH MTs (CYP: 2.10 pmol/min/MT HepaRG, 80 pmol/mn/MT PHH). Following characterisation 40 DILI reference compounds (30 positive, 10 negative) were screened through each model and confocal high content was used in addition to ATP activity to measure cellular function. Prediction of human DILI was improved in the HepaRG MT when compared to the overall response in the human hepatocyte MTs. In addition prediction of DILI was increased further when a multiparametric approach was taken when compared to measurement of ATP. Compounds such as diclofenac and bosentan were not flagged as DILI positive (within 5-fold of Cmax) when ATP was used as the predictive marker, however using a multi-parametric approach these
were shown to be DILI positive. In addition a DILI positive response for fialuridine was only observed in the HepaRG model. The data presented here builds upon the current strategies to address human DILI. We have demonstrated that 3D MTs consisting of HepaRG cells gives an increased prediction of DILI. In addition the prediction of DILI is also significantly improved by the utilisation of multi-parametric approaches when compared to measuring ATP alone. These in vitro models are amendable to high throughput screening, are cost effective and as such could play an important role in mitigating DILI risk early in drug discovery. 1 Chem. Res. Toxicol. 2012 2067-82 2 Toxicol. In vitro 2016 33,63-70 3 Toxicol. In vitro 2015 30, 429-437 4 Arch. Toxicol. 2017 91, 2849-2863

1356 Assessment of the Gene Expression Signatures of Hepatotoxic and Non-Hepatotoxic Endothelial Receptor Antagonists in Primary Human Hepatocytes
J. E. Moscovitz, Y. Weng, and A. S. Kalugtukar. Pfizer, Inc., Cambridge, MA.

Impairment in the hepatobiliary elimination of bile acids (via inhibition of bile salt export pump (BSEP)) has emerged as a leading mechanism for clinical drug induced liver injury (DILI) associated with the structurally diverse endothelial receptor antagonists (ERAs) bosentan and sitaxsentan. In addition to BSEP inhibition, sitaxsentan is also known to undergo oxidative bioactivation by cytochrome P450 (CYP) 3A4 to yield protein reactive metabolites, which may represent an additional causative factor of clinical DILI. In contrast, evidence to date suggest little risk of DILI with the marketed ERAs ambrisentan and macitentan, which are used to treat pulmonary arterial hypertension. Incidentally, ambrisentan does not inhibit BSEP but macitentan inhibits the transporter with potency comparable to that of bosentan and sitaxsentan, and yet is not hepatotoxic. While the propensity for direct inhibition of hepatobiliary transporters by ERAs has been described using human hepatocytes, corresponding examination of the up- and/or down-regulation of major human drug metabolising enzyme (CYPs, UGTs, drug transporters (OATP, NTCP, MRP, BCRP, MDR)) and oxidative stress response ( NRF2 pathway) genes remains to be addressed. We recently reported the use of a custom TaqMan Gene Expression Array Card to differentiate nuclear receptor- mediated transcriptional regulation of drug metabolizing enzymes and transporters. In the present work, we have extended this methodology towards the comparison of the gene signature profile for the hepatotoxic and non-hepatotoxic ERAs in human hepatocytes. Varying concentrations of the test compounds were incubated with sandwich-cultured cryopreserved human hepatocytes (n=3 donors) for 48 h. Full dose-response curves were generated to enable differentiation by rank-ordered maximal effect (Emax) and/or half maximal concentration (EC50) for target genes. The results obtained from this analysis demonstrate unique gene signatures for structurally diverse ERAs with a trend towards differentiation of hepatotoxic and non-hepatotoxic molecules. This framework, in addition to the suite of existing in vitro trend towards differentiation of hepatotoxic and non-hepatotoxic molecules. This framework, in addition to the suite of existing in vitro tests. The liver is one of the first and most exposed organ to chemical damage, and thus can serve as a marker of potential systemic or target-specific toxicity elicited from repeated chemical exposure. This study provides an update on our understanding on mechanisms of toxicity elicited by selected commonly used chemical classes. It is focused on the construction of a hepatotoxicity decision tree based on more than 1300 different chemicals, their possible MOAs (including receptor binding activities), and their core chemical structural alerts (including reactive metabolites). Based on these principles, we have created a decision tree where we have grouped these chemicals into 30 different categories and more than 120 subcategories. This decision tree includes: 4 chemical categories associated with 9 different receptors, 10 chemical categories associated with reactive metabolites (RMs), as well as 14 chemical categories associated with similar structural features/MOA. We propose that this decision tree can be used to screen and identify potential liver toxicants based on their core structural alerts/features, and/or their reactive metabolites (RMs). The steps in the decision tree are very transparent, and could be used as a component of weight of evidence decisions based on SAR by identifying high quality suitable analogs, and thus toxicity data usable in read-across evaluations. This information can also be used to integrate chemical structure and MOA information within chemical classes, with the mechanistic explanations where possible, which could be used to improve the accuracy and consistency of SAR read across methods.

1357 Identifying Chemicals Based on Mode-of-Action/Metabolism/Structural Features Associated with Potential to Elicit Hepatotoxicity

A better understanding of mode of action (MOA) of chemicals of interest is important in the design/support of non-animal alternative methods, for example in supporting relevance of analogs used in Structure Activity Relationship (SAR)-based assessments, or for choosing appropriate in vitro tests. The liver is one of the first and most exposed organ to chemical damage, and thus can serve as a marker of potential systemic or target-specific toxicity resulting from repeated chemical exposure. This study refines an update on our understanding on mechanisms of toxicity elicited by selected commonly used chemical classes. It is focused on the construction of a hepatotoxicity decision tree based on more than 1300 different chemicals, their possible MOAs (including receptor binding activities), and their core chemical structural alerts (including reactive metabolites). Based on these principles, we have created a decision tree where we have grouped these chemicals into 30 different categories and more than 120 subcategories. This decision tree includes: 4 chemical categories associated with 9 different receptors, 10 chemical categories associated with reactive metabolites (RMs), as well as 14 chemical categories associated with similar structural features/MOA. We propose that this decision tree can be used to screen and identify potential liver toxicants based on their core structural alerts/features, and/or their reactive metabolites (RMs). The steps in the decision tree are very transparent, and could be used as a component of weight of evidence decisions based on SAR by identifying high quality suitable analogs, and thus toxicity data usable in read-across evaluations. This information can also be used to integrate chemical structure and MOA information within chemical classes, with the mechanistic explanations where possible, which could be used to improve the accuracy and consistency of SAR read across methods.

1358 Primary Human Hepatocyte 3D Spheroid Model for Predicting Drug-Induced Liver Injury

Primary human hepatocytes (PHHs) are considered the "gold standard" for liver biology and also the main target of drug induced liver injury (DILI). Drug development failures and post-launch withdrawals highlight the need for more physiologically relevant in vitro human models to improve liver toxicity prediction accuracy. Emerging 3D cell culture technologies can potentially fill the gap between preclinical tests and clinical observations by better mimicking the in vivo scenarios. In comparison to other 3D cell culture technologies, hepatoid culture is cost-effective and more compatible with high throughput toxicity screening in the early stages of drug discovery. More importantly, 3D spheroid culture has been shown to prolong the viability and functionality of PHHs up to several weeks and therefore allows for in vitro chronic hepatotoxicity tests with repeated dosing. In this presentation, we have tested more than 30 lots of cryopreserved PHH for 3D hepatotoxicity using Corning® Ultra-Low Attachment spheroid plates (96-well or 384-well format). About 50% of the PHH lots tested produced spheroids that can be used for 3D spheroid based assays. Three lots of 3D spheroid qualified PHH were used for both 2D (24 hour single dose) and 3D hepatotoxicity assays (three repeated dosing over 2 weeks) with known DILI liability (amiodarone, nefazodone, troglitazone etc.) and control compounds. Serial dilutions of testing compounds were applied and dose response curves were generated following bioluminescent ATP viability measurements. In comparison to 2D monolayer culture from the same lots of PHHs, 3D PHHs consistently increased the sensitivity (2-10 fold lower IC50 values than those from 2D culture) to the treatment of DILI compounds. Using a margin of safety (MOS) analysis comparing IC50 to clinical Cmax values of tested compounds confirms that 3D hepatotoxicity assays have superior prediction to 2D assay addition, high confidence based 3D assays are being developed with PHH spheroids for mechanistic insights into DILI with model compounds. Together, our results demonstrate 3D PHH spheroids as a superior in vitro model to predict DILI with high throughput capacity.

1359 Liver-Chip Model Identifies Mitochondrial Dysfunction, Oxidative Stress, and Inflammasome Response as Potential Pathways of Toxicity for the GPR40 Agonist TAK-875

Drug-induced liver injury (DILI) is a major reason for safety-related attrition in the pharmaceutical industry. There is continued search for in vitro models that can be used to consistently and reliably select compounds with reduced liability for liver injury. 3D liver models have the potential to revolutionize in vitro liver toxicity testing. We describe a microfluidic Liver-Chip model that contains primary hepatocytes, sinusoidal endothelial cells, stellate, and Kupffer cells in a spatial configuration that mimics their organization in the liver. Albumin secretion and abundant CYP450s activities are maintained in culture for ≥2 weeks. The model can detect diverse liver pathophysiology, including hepatocellular injury, lipid accumulation, and stellate activation. The fluidic component allows for ease of sampling of effluent for detection of cytokines and DILI biomarkers (miR122, α-GST, CK-18, ccCK18, and total HMGB1). These endpoints were characterized with tool compounds including APAP, fialuridine, and methotrexate. The model was also used to investigate the mechanism of DILI by the GPR40 agonist TAK-875 following daily treatment at 3, 10, and 30 μM for ~2 weeks. There was significant turnover of TAK-875 and formation of its reactive acyl glucuronide metabolite (TAK-875AG) on Day 1 (16%) and on Days 7/14 (44%) compared to 1% turnover obtained in human hepatocytes. The oxidative metab-
olite (M-I) was formed at 4% in the Liver-Chip compared to reports of 10% found in humans. Inhibition of MRPI expression, perturbation of mitochondrial membrane potential, and formation of reactive oxygen species and inflammatory cytokines were observed at concentrations bridging the clinical Cmax (10 μM). Interestingly, hepatic lipid accumulation and stellate cell activation were also observed at 10 μM. These data suggest that accumulation of a reactive TAK-875AG, cell stress, and an innate immune response are possible triggers for TAK-875-mediated liver toxicity. In summary, the Liver-Chip is amenable for microscopical, biochemical, and DilI biomarker evaluation and will be useful for prediction and mechanistic investigation of DilI.

Liver fibrosis is the excessive accumulation of extracellular matrix proteins such as collagen, which can lead to cirrhosis, liver failure and transplantation. Anti-fibrotic therapies aim at inhibiting the induction of fibroblasts (HSC), preventing the deposition of extracellular matrix proteins (ECM). Beside the HSC, presence of other liver cell types as opposed to a 2D monolayer greatly decreases the number of cells required per well and likely increases the physiological relevance of the model. In liver spheroids exposed to the Cyp2e1 substrate acetaminophen for 6 days (p<0.05) compared to scrambled control, however, the functional effect of knockdown could not be confirmed as no cytotoxicity was observed in non-transfected PMH spheroids exposed to the Cyp2e1 substrate acacetaminophen for 6 days at concentrations up to 10 mM (p>0.05 for ATP and albumin compared to control). Efforts to quantitate Cyp enzyme activity and transporter levels in PMH spheroids are ongoing. Taken together, our results demonstrate the successful long-term culture of PMH in 3D spheroids—methodology that can now be expanded to CC strains that will enable rapid and cost-effective implementation of this approach at all stages of drug development. The objective of this study was to evaluate 3D spheroid methodology for the long-term culture of primary mouse hepatocytes (PMH) to support an initial focus on drug-induced liver injury (DILI). Cypreserved hepatocytes from C57BL/6 mice were seeded on ultra-low attachment 96-well plates and allowed to spontaneously self-aggregate. PMH spheroids were then cultured in 96-well plates for 5 days. ATP levels were maintained, while albumin production was significantly higher on culture Day 13 compared to Day 6 (p<0.05). Transfection of Cyp2e1-targeting siRNA performed on culture Day 0 resulted in an 85% reduction of Cyp2e1 mRNA levels in PMH spheroids and a 70% reduction of Cyp2e1 mRNA in PMH spheroids at Day 4 (p<0.05 compared to scrambled control). The successful long-term culture of liver fibrosis, suitable for high-throughput efficacy and safety screening of anti-fibrotic drugs.

Drug-induced liver injury (DILI) remains a major cause of drug attrition during drug discovery and development. As there is a significant need for more predictive models for DILI, a microengineered Liver-Chip was developed to include all relevant cell types more representative of the in vivo tissue. To ensure hepatic function, we recapitulate in vivo metabolic capabilities, that has potential for long term maintenance of cell viability to enable repeated drug exposures, has well characterized toxicology endpoints sensitive for cell-specificity over time, and is capable of demonstrating the diverse mechanisms of DILI. Advanced engineering fabrication techniques were applied to achieve a high level of control over the chip microenvironment. The model incorporates relevant cell-ECM interactions, a hepatocyte and liver sinusoidal endothelial cell interface, with relevant cytoarchitecture and physiological flow. In addition to the human Liver-Chip, rat and dog models were developed to enable characterization of species differences with respect to pharmacokinetics, toxicity and mechanism of action. Liver-specific functions were measured for all three species and demonstrated maintenance of in vitro relevant levels of functionality including albumin secretion, CYP450 enzyme activity, and expression of transcriptomic profile that demonstrated functional diversity over conventional 2D models. We evaluated Liver-Chips for each of the three species to evaluate non-clinical to clinical translation of experimental findings with Bosantan, an endothelin receptor antagonist and BSEP transport inhibitor that has clinical to clinical translation of experimental findings with Bosantan, an endothelin receptor antagonist and BSEP transport inhibitor that has been used in clinical trials. We also demonstrated that this model of liver fibrosis, suitable for high-throughput efficacy and safety screening of anti-fibrotic drugs.

Liver fibrosis is a major fibrotic disease that occurs in a variety of organs as a consequence of chronic injury. It is characterized by the excessive accumulation of extracellular matrix proteins (ECM) in liver, which can lead to cirrhosis, liver failure and transplantation. Anti-fibrotic therapies aim at inhibiting the induction of fibroblasts (HSC), preventing the deposition of ECM. Beside the HSC, presence of other liver cell types as opposed to a 2D monolayer greatly decreases the number of cells required per well and likely increases the physiological relevance of the model. We demonstrated the successful long-term culture of PMH in 3D spheroids—methodology that can now be expanded to CC strains that will enable rapid and cost-effective implementation of this approach at all stages of drug development. The objective of this study was to evaluate 3D spheroid methodology for the long-term culture of primary mouse hepatocytes (PMH) to support an initial focus on drug-induced liver injury (DILI). Cypreserved hepatocytes from C57BL/6 mice were seeded on ultra-low attachment 96-well plates and allowed to spontaneously self-aggregate. PMH spheroids were then cultured in 96-well plates for 5 days. ATP levels were maintained, while albumin production was significantly higher on culture Day 13 compared to Day 6 (p<0.05). Transfection of Cyp2e1-targeting siRNA performed on culture Day 0 resulted in an 85% reduction of Cyp2e1 mRNA levels in PMH spheroids and a 70% reduction of Cyp2e1 mRNA in PMH spheroids at Day 4 (p<0.05 compared to scrambled control). However, the functional effect of knockdown could not be confirmed as no cytotoxicity was observed in non-transfected PMH spheroids exposed to the Cyp2e1 substrate acetaminophen for 6 days at concentrations up to 10 mM (p>0.05 for ATP and albumin compared to control). Efforts to quantitate Cyp enzyme activity and transporter levels in PMH spheroids are ongoing. Taken together, our results demonstrate the successful long-term culture of PMH in 3D spheroids—methodology that can now be expanded to CC strains. The use of 3D spheroids as opposed to a 2D monolayer greatly decreases the number of cells required per well and likely increases the physiological relevance of the in vivo model. The ability to perform siRNA knockdown in PMH spheroids will enable rapid validation of candidate risk factor genes identified by our CC platform.
we treated the human hepatocytes in both models with inducers like Omeprazole, Phenobarbital and Rifampycin and examined the metabolic cytochrome P450 (CYP) capabilities. For hepatocytes in RAFT™ Culture System the response was both stronger and more stable over 17 days in culture compared to the sandwich cultures, improved stability of P450s by culturing hepatocytes in 3D could enable long-term and repeat dosing for toxicity analysis using primary human hepatocytes.

1366 Expanded Primary Human Liver Sinusoidal Endothelial Cells as a Tool to Complement Hepatotoxicity Studies
A. Rae Kark1, A. Noerenberg2, D. Brauer3, M. Klett3, A. Schober3, and T. Johannsen2. 1Biojump, Hillsborough, NJ; 2Upcyte Technologies, Hamburg, Germany; and 3Technical University Ilmenau, Ilmenau, Germany. Sponsor: P. Hewitt

Liver sinusoidal endothelial cells (LSECs) are highly specialized endothelial cells lining the walls of hepatic sinuses. Their key roles include the transfer of substances between blood and liver parenchyma, rapid internalization of blood-borne macromolecules, liver regeneration and immune tolerance. Despite their substantial contribution to liver homeostasis, LSECs are often overlooked during hepatotoxicity assays due to insufficient cell numbers and a limited proliferation capacity. To address this issue, we employed our previously described upcyte® technology for expansion of primary LSECs by lentiviral transduction of human 3D liver microtissue (hLiMT) assay to understand whether cell viability and overall cell numbers were stable in 2D and 3D culture formats. Future investigations will focus on acute and chronic exposure to hepatic toxic model compounds in both 2D and 3D cultures. Taken together, our data suggest that upcyte® LSECs combine many characteristics of primary LSECs with the advantage of an extended lifespan, facilitating their use in hepatotoxicity assays under reproducible and standardized conditions.

1368 Co-Culture of Primary Human 3D Hepatic Spheroids with Non-Parenchymal Cells Allows for Detection of Immune-Related Drug-Induced Liver Injury Compounds
J. Harney1, J. Roy1, M. Aleo1, and S. Messner2. 1Pfizer, Inc, Groton, CT; and 2InSphero AG, Schlieren, Switzerland.

Idiosyncratic drug induced liver injury (IDILI) remains a major cause of pharmaceutical drug failure. As a component of the innate immune system, the liver contains non-hepatocyte cells such as natural killer T cells (NKT) and Kupffer cells (KCs) among others. Here we used an in vitro human 3D liver microtissue (LiMT) assay to understand whether co-culturing non-parenchymal cells (NPCs) could detect known IDILI compounds. When human NPCs were incorporated into LiMTs and treated with 1 µg/mL LPS, increases in cytokines were detected in the media, compared to non-LPS treatment. Additionally, some NPC lots displayed greater levels of CD68+ and KCs among others. Generated upcyte® LSECs expressed typical endothelial cell markers (CD31, von Willebrand factor), LSEC-specific receptors (mannose receptor, LYVE-1 and L-SIGN) and showed uptake of several macromolecule ligands (e.g. serum albumin, aggregated IgG). Since LSECs are involved in drug-induced liver injury, we investigated acetaminophen-induced cytotoxicity. Interestingly, LSECs showed a significant decrease in IC50 when compared to upcyte® hepatocytes, indicating that these cells are a promising tool to complement hepatotoxicity methods. Experiments were conducted with primary human hepatocytes and compared different 2D and 3D culture approaches. Among 8 different medium formulations tested, the most appropriate medium was a mixture of hepatocyte and LSEC medium, as demonstrated by high preservation of macrophages markers (e.g. albumin, CD31). Cell viability and overall cell numbers were stable in 2D and 3D culture formats. Future investigations will focus on acute and chronic exposure to hepatic toxic model compounds in both 2D and 3D cultures. Taken together, our data suggest that upcyte® LSECs combine many characteristics of primary LSECs with the advantage of an extended lifespan, facilitating their use in hepatotoxicity assays under reproducible and standardized conditions.
presence of LPS (NCP-1: 69.0 +/- 0.2 µM versus NCP-3: 319.6 +/- 1.7 µM). DCF showed 2-fold greater cytotoxicity with the NCP-1 lot compared with NCP-3, independent of LPS co-treatment. LPS alone for 72 h stimulated IL-2, IL-6 and IL-8 from NCP-1 compared with NCP-3, however there were no significant differences between TVX treatment with or without LPS in either NCP lot. Our results demonstrate that incorporation of low cultured immune cells into 3D hLiMTs can help to drive in-vitro detection of liver-toxic compounds as measured by cytotoxicity endpoints. Due to donor specific variability, characterization of NPC lots, by identification of markers for the inherent cell types present and their reactivity towards LPS-co-treatment, could enable more sensitive detection of DILI compounds.

1369 A 3D Human Microtissue Model of the Liver

M. A. Traore, A. Feldmann, G. Pegg, and D. Thompson, MilliporeSigma, St. Louis, MO.

Drug-Induced Liver Injury (DILI) contributes to drug failures, drug withdrawals and acute liver failures. Moreover, the liver is known to strongly interact with other organ systems and in some instances the metabolites secreted by the liver are responsible for other organs injury. Engineered 3D liver models may increase the physiological relevance of drug toxicity assays by maintaining the expression levels of key cytochrome P450 enzymes and the metabolic activity in liver cells. The objective of this study was to create a three-dimensional (3D) microtissue model of the human liver. A human hepatoma cell line (HepaRG) was used to create the 3D microtissue liver model. These cells express the major xenobiotic sensors, drug transporters, phase I and II drug metabolizing enzymes. A 3-chamber microfluidic device (DAX-1, AIM Biotech) was used to create the liver 3D tissue. The device consists of a single chamber that is connected to two adjacent fluidic channels used to feed the microtissue. Briefly, liver cells at a concentration of 50 million cells per mL were mixed in either a collagen type 1 solution (7 mg/mL concentration) or fibrin solution (10 mg/mL). Then added to the central chamber of the microfluidic device. The gel and cell mixture was subsequently left to polymerize in the central chamber. This microfluidic device facilitates the generation of an interstitial fluid flow through the porous microtissue and thus enables feeding of the microtissue but also allows sampling of metabolites in the low pressure microfluidic channel. To evaluate both the viability and the ability of HepaRG liver cells to respond to compounds in the microfluidic chip, testosterone at 50 µM concentration was added to the central chamber. This microtissue model enabled feeding of the microtissue but also allows sampling of metabolites secreted by liver cells. Moreover, our results also suggest that the seeding matrix is an important factor in the metabolism of HepaRG liver cells. The metabolite concentration was three times higher when liver cells were seeded in collagen type 1 versus fibrin gel. We have therefore developed a microtissue model and demonstrated that this model can be used to assess the functionality of CYP 3A4 in HepaRG cells and quantify their secretion of metabolites. In the future, we plan to use this model system to investigate liver–kidney interactions.

1370 Up-Regulation of Fibroblast Growth Factor (Fgf) 21 by Cisplatin in Mouse Liver and Hepatoma Cells

Y. Zhang, and X. Cheng, St. John’s University, Queens, NY.

Cisplatin (cis-diaminedichloroplatinum, CDDP) is one of most widely used chemotherapeutic drugs. Numerous adverse effects have been noted during cisplatin therapy, which largely limit its clinical applications. Cisplatin has only been sporadically reported that cisplatin causes liver dysfunction. Fibroblast growth factor (Fgf) 21 is an important regulator of glucose, lipid and energy metabolism. Recent studies demonstrated that Fgf21 also plays an important cytoprotective role against chemical-induced toxicities, such as of dioxins, acetaminophen and endotoxins. This study was designed to determine the regulation of Fgf21 by cisplatin in mouse liver and cultured mouse hepatoma cells, as well as the underlying mechanisms. Our data demonstrated that cisplatin increased the mRNA and protein expression of Fgf21 in wild-type (WT) mouse liver and in cultured mouse Hepa1c1c7 hepatoma cells. In addition, both mouse liver and cultured mouse Hepa1c1c7 hepatoma cells, cisplatin increased mRNA expression of manganese superoxide dismutase (MnSOD), which is generally induced in the presence of mitochondrial stress. Seahorse study further demonstrated that cisplatin concentration-dependently induced mitochondrial stress in cultured mouse Hepa1c1c7 cells. Moreover, in mouse liver, cisplatin increased activating transcription factor (ATF) 4 mRNA expression, which is generally activated by mitochondria stress and subsequently up-regulates Fgf21 expression. In conclusion, cisplatin induced Fgf21 expression in mouse liver and cultured mouse hepatoma cells, maybe via activation of mitochondria stress-ATF4 signaling.

1371 Microcystin-Lr Hepatic and Renal Toxicity in Non-Alcoholic Fatty Liver Disease

T. Arman1, K. Lynch1, M. Gastecki1, M. J. Goedken2, and J. Clarke3.

1Washington State University, Spokane, WA; and 2Rutgers, The State University of New Jersey, Piscataway, NJ.

Microcystin-Lr (MCLR) is a hepatotoxin produced by blue-green algae and is transported into cells by organic anion transporting polypeptides (Oatp). Non-alcoholic fatty liver disease (NAFLD) is an increasing chronic liver disease in the United States and is a risk factor for chronic kidney disease (CKD). Previous data showed that rodent models of NAFLD decreased expression of hepatic Oatps and caused increased plasma concentrations of Oatp substrates. We hypothesize that MCLR will exacerbate liver disease in NAFLD and, due to increased plasma concentrations, increase kidney toxicity in NAFLD. Three rat diets were used: control (healthy), methionine and choline deficient (MCD) diet (NAFLD), and a high fat/high cholesterol diet (HFFC) (NAFLD). Dose groups included vehicle, 10µg/kg and 30µg/kg MCLR via i.p. injection every other day for 4 weeks. Liver pathological incidence and severity score results indicate increased fibrosis in all high dose MCLR groups, greater inflammation, fibrosis and biliary hyperplasia in the low dose MCLR MCD group, and dose-dependent decreased steatosis in both NAFLD groups, suggesting MCLR drives NAFLD towards lower lipidosis and more fibrosis. Kidney pathology scores showed elevated protein casts and glomerular pathology in MCLR treated healthy and HFFC groups. Biochemical analyses indicate that high dose MCLR increased plasma alanine transaminase (ALT) and urinary kidney injury molecule-1 (KIM-1) in both healthy and HFFC groups. With high dose MCLR, plasma glucose decreased in both healthy and HFFC groups but insulin increased only in the HFFC. At both MCLR doses plasma triglycerides decreased only in healthy animals, while plasma cholesterol increased only in HFFC animals. We also observed decreased hepatic and renal mRNA expression of several Oatp isoforms with MCLR exposure. These data suggest that MCLR exposure exacerbates pathological features of NAFLD in both the liver and kidney and alters key metabolic features of disease. Funded by 4R00ES024455.
mitochondrial fatty acid beta-oxidation. Most non-DILI compounds were not detected in any of the assays. These results indicate that each assay has its own advantages and limitations, thus, a combination of these assays is useful for estimating the DILI potential of compounds. 1) J. Toxicol. Sci., 42, 349-357, 2017

1373 A Sensitive Donor Is Identified in a Multi-Donor Evaluation of the Toxicity of the Fialuridine and Clevudine Nucleoside Analogues in the In Vitro Human Hepatocap® Model

A. G. Aslamkhan¹, L. Liu¹, J. Gaffney², H. Suemizu¹, Y. Ohashi¹, Z. Wang³, K. Vlasakova³, M. Kuhlis³, P. Lane¹, A. Podtelezhnikov¹, S. Pacchione¹, Q. Xu¹, K. Pearson¹, R. Evers¹, F. D. Sistare¹, W. E. Glaab¹, and J. Lebrón¹. ¹Merck Research Laboratories, West Point, PA; ²Ascendence Biotechnology, Boston, MA; and ³Central Institute for Experimental Animals, Kawasaki, Japan.

FIAU is a nucleoside analogue that was under development for Hepatitis B but was discontinued in clinical trials following development of acute liver failure and death hypothesized to be related to mitochondrial dysfunction. Conventional preclinical testing did not predict such findings. FMAU is a nucleoside analogue similar in structure to FIAU, except that the iodo group is replaced by a methyl group. This compound also did not manifest preclinical findings. However, a small percentage of patients developed severe myopathy with mitochondrial changes after multiple months of treatment leading to termination of FMAU development for several countries. We evaluated both FIAU and FMAU for a 12-day treatment period in the in vitro HepatoPac® model in five human donors of varying ages (i.e., pediatric vs. adult), genders, and ethnicities to assess potential for differential donor sensitivity using assays for mitochondrial and nuclear DNA levels, urea production, lactate dehydrogenase (LDH) release, and transcriptional profiling with RNA-seq (FIAU) only. For FIAU, mtDNA declines were similar across donors with IC_{50}s of ~0.1 µM. However, nuclear DNA, reflecting general cytotoxicity, was more significantly impacted for two donors (Donors 4-S, D4-S) with IC_{50}s ~5 µM; whereas the other donors had IC_{50}s >10 µM, including a donor (D3) which manifested no nuclear DNA decline up to the highest concentration tested (30 µM). One of the donors (D4) with greater sensitivity to the nuclear DNA change also manifested the earlier and more robust declines in urea production and increases in LDH release. D4 also had the most robust mtDNA decline (~67%) with 30 µM FMAU treatment (top dose). The other endpoints were insensitive for all donors treated with FMAU. RNA-seq analysis showed that D4 had the most significant mitochondrial fatty acid beta-oxidation. Most non-DILI compounds were not detected in any of the assays. These results indicate that each assay has its own advantages and limitations, thus, a combination of these assays is useful for estimating the DILI potential of compounds. 1) J. Toxicol. Sci., 42, 349-357, 2017

1374 Examination of Drug-Induced Liver Injury in Uptcye Hepatocytes

J. P. Vanden Heuvel¹, S. M. Maalouf¹, and B. Sheff¹. ¹INDIGO Biosciences, Inc., State College, PA; and ²Penn State University, University Park, PA.

Liver toxicity is a major cause of drug failure in clinical trials as well as market withdrawal of approved drugs. In addition, due to species differences in drug metabolism, it is often difficult to extrapolate the results obtained from preclinical animal models to humans. The ucpcyte® cells are proliferating human hepatocytes that retain important drug metabolizing enzymes, such as cytochrome P450 3A4 (CYP3A4), which make them an attractive model system to examine drug-induced liver injury (DILI). In this study, we examined the cytotoxicity in ucpcyte® cells for 10 compounds known to be bioactivated in liver. The potency for inducing toxicity was compared to that of a cell line that has reduced expression of CYP3A4. Several compounds had higher toxicity in ucpcyte® than in the cells with lower CYP3A4 expression. These studies show that using ucpcyte® hepatocytes to study DILI can potentially reduce attrition due to metabolism-mediated toxicity and improve safety of drug candidates.

1375 Cyp Silenced Human Hepatocytes for Metabolite Assessment in a Toxic Response

R. Li¹, B. Bouaita¹, K. Rondel², D. Steen³, F. Roschchina¹, and C. Chese¹. ¹Biopredic International, Saint Gregory, France; and ²Biopredic US, Kansas City, KS.

It is important to identify the role of a given metabolite and of the corresponding CYP(s) involved in its formation in the toxic response of the human liver to a xenobiotic. The metabolite assessment could anticipate hepatotoxicity, DDIs, and the inter-individual variation in the drug safety. The current approach used for CYP reaction phenotyping consists of i) incubating the hepatocytes with either reversible CYP inhibitors such as ABT or more irreversible inhibitors such as azamulin; and ii) comparing the response to the test compound in the conditions with/without inhibitors. These conventional studies are done ex tremoraneously, and thus our goal is to prepare a performance-controlled, frozen and ready-to-use cell-based assay system for fm measurement and metabolite assessment. Primary human hepatocytes would be evaluated from different donors were pre-incubated separately with three specific inhibitors to generate three targeted major CYP-silenced PHH, in which a single CYP was chemically and irreversibly inactivated. The potent inhibition of fresh and thawed CYP-silenced PHH batches and related controls was evaluated using CYP-specific probe substrates. The results showed the targeted CYP activity was specifically and significantly inhibited in specific CYP-silenced PHH. For example, around 80% of CYP3A4-mediated metabolism of testosterone was inhibited in CYP3A4-silenced PHH inactivated by azamulin even the optimization of MBI conditions could further increase silencing efficiency. It has been reported that bioactivation of aflatoxin B1 and lapatinib to reactive metabolites by CYP3A4 contributed importantly to hepatotoxicity in PHH and HepaRG™ cells. Therefore, both of CYP3A4-silenced PHH and control cells were incubated with aflatoxin B1 or lapatinib at different concentrations, and then the formation of MBI was measured and analyzed by LC-MS/MS. The preliminary results of this study showed that the concentration levels of both aflatoxin B1 and lapatinib metabolites dropped by 60-80% correspondingly, compared to the controls. Those ready to use cytopreserved hepatocytes with specific CYP silencing allow a direct evaluation of metabolic liabilities. The cell-based assay is relevant for conducting the metabolite assessment in an integrated functional environment, taking into account the interplay between transporters and phase I and II metabolism.

1376 Fasiglifam (Tak-875): Investigating Drug-Induced Liver Injury Utilizing In Vitro Mechanistic Assays

P. Walker. Cyprotex, Alderley Park, United Kingdom. Sponsor: C. Strock

Fasiglifam (TAK875, a GPR40 agonist) developed for the treatment for type 2 diabetes mellitus was withdrawn from Phase III clinical trials due to drug-induced liver injury (DILI). Rodent and human in vitro liver models were used to investigate the potential hepatotoxic mechanism of action. TAK-875 is 99.84% protein bound, with an estimated free plasma concentration of 14 nM. Therefore, exposure conditions with and without serum were used throughout. High-content screening (HCS) revealed effects on mitochondrial membrane potential in HepG2 cells, primary human hepatocytes and 3D human liver microtissues (HLIMT) at a range of time points, implicating mitochondria have a potential role in TAK-875-induced liver injury. The mitochondrial potential was uncoupled at 5.6µM in HepG2 cells in the absence of serum; however, no response in MMP was observed with serum up to a concentration of 100µM. Further using the mitochondrial glutamate (GLU) assay in serum and serum-free conditions showed no significant shift between Glu and Gal conditions up to 400µM (+serum) even though cytotoxicity was observed. In the absence of serum, a positive 3.67-fold shift was shown with a galactose AC_{50} of 27.5µM. Using the Seahorse XF96 analyzer to determine mitochondrial oxygen consumption rates (OCR) and reserve capacity. The OCR AC_{50}s of TAK-875 in HepG2 cells were 16.9, 2.8, and 4.1 µM at 0hr, 1hr, and 24hrs, respectively. The reserve capacity AC_{50}s of TAK-875 in HepG2 cells were 12.2, 4.66, and 0.97µM at 0hr, 1hr, and 24hrs, respectively. In human hepatocytes the OCR and reserve capacity AC_{50}s values at 0hr were determined to be 86.4 and 116 µM. This indicates hepatocytes and HepG2 cells respond comparably to TAK-875 mitochondrial liability would have been flagged as a concern using in vitro models of hepatotoxicity, thus demonstrating the valuable role of in vitro screening for hepatotoxicity in drug discovery strategies.
Acetaminophen (APAP)-induced liver injury after an overdose is the major cause of acute liver failure in the USA. APAP hepatotoxicity is mediated by formation of a highly reactive intermediate, N-acetyl-p-benzoquinone imine (NAPQI), which depletes hepatic GSH and initiates hepatoocyte injury. While treatment with N-acetylcysteine (NAC) to replenish GSH is the current standard of care for APAP overdose, anecdotal evidence suggests that co-administration of NAC with 4-methylpyrazole (4MP) is beneficial in the clinic. The current study examined the influence of 4MP on APAP induced cell signaling and attempts to uncover the basis for this protection. Co-treatment of 4MP at a dose of 50 mg/kg to male C57Bl/6 mice administered APAP (300 mg/kg) showed significant protection against elevations in plasma ALT levels at 6 hours. This protection was confirmed by histology, which showed attenuated centrilobular necrosis and DNA fragmentation. Moreover, APAP-induced activation of JNK, mitochondrial translocation of phospho-JNK and Bax were all prevented by 4MP co-treatment. Release of mitochondrial inter-membrane proteins AIF and Smac into the cytosol were also blocked. Investigation of the mechanism behind these effects revealed significant inhibition of cytochrome P450 activities by 4MP in vitro. In addition, 4MP treated animals showed 95% reduction in APAP protein adducts at 6 h and a 66% attenuation of hepatic GSH depletion at 30 min after APAP treatment. Analysis of APAP metabolites revealed that the APAP-GSH conjugate and its metabolites (APAP-Cys, APAP-NAC) were reduced by 80-98.3% by 4MP treatment while generation of the glucuronide conjugate, which represents 95% of the total metabolites, was not affected. APAP-sulfate levels, which represent 6% of the total metabolites, were reduced by 49%. The relevance of these findings for humans was assessed in primary human hepatocytes. Similar to the findings in mice, co-treatment of 4MP (2 mM) with APAP (10 mM) eliminated cell death in human hepatocytes at 24 h. Together, these findings indicate that 4MP is highly effective in protecting against APAP in both murine and human hepatocytes by blocking the generation of the reactive metabolite through inhibition of cytochrome P450 enzymes. 4MP can complement NAC in preventing mitochondrial dysfunction and the progression of liver injury.

Drug-induced Liver injury (DILI) is one of the major impediments in drug development. Acetaminophen (APAP)-induced liver injury is a classic model of DILI. Flavin-containing monoxygenase 3 (FMO3) is an enzyme involved in metabolism of several xenobiotics, such as amphetamine and its analogs. In a rodent model of APAP autoprotection, dramatic increases in hepatic Fmo3 mRNA and protein expression have been observed. Fmo3 induction is seen in association with highly increased serum levels of methionine sulfoxide (MSO), an endogenous metabolite of this enzyme. In female mice, pharmacological inhibition of Fmo3 results in greater susceptibility to APAP-induced liver injury compared to males. Moreover, in vitro overexpression of Fmo3 confers partial, yet significant protection from APAP cytotoxicity. Although these studies are suggestive of a potential hepatoprotective role of Fmo3 in APAP hepatotoxicity, the molecular mechanism of this protective function is still unknown. In this study, we investigated the capacity of MSO to protect against APAP cytotoxicity using two immortalized hepatocyte cell lines, HepaRG and HC04 cells. Additionally, we evaluated the role of MSO in the hepatic differentiation of HepaRG liver progenitor cells. Our results show that MSO treatment by itself at a wide range of concentrations does not produce any cytotoxicity. As expected, APAP treatment produced cytotoxicity in both cell lines in a dose-dependent manner, as evidenced by LDH release into media. However, MSO treatment (pre-as well as co-treatment) did not afford any protection against APAP cytotoxicity in either cell line. Furthermore, addition of MSO to both growth and differentiation media did not alter the expression of FMO3 in HepaRG cells. Hepatocyte differentiation status was determined by gene expression analysis of prototypic drug metabolizing enzymes such as CYP2E1 and 3A4. Overall, these data indicate that the dramatic increases in serum MSO levels observed in our mouse model of APAP autoprotection, does not appear to be the mechanism by which Fmo3 induction confers protection against APAP toxicity.
1381 Bile Acid Profiling in a Cyp7a1 and Cyp27a1 Double-Knockout Mouse Model

D. Rizollo1, K. Buckley1,2, B. Kong1, L. Zhan1, J. Shen1, A. Brinker1, M. Stefan1, B. Buckley1, and G. Guo1.1 Rutgers, The State University of New Jersey, Piscataway, NJ; and 2Indiana University, Bloomington, IN.

Bile acids (BAs) are a diverse population of amphipathic molecules that are synthesized through the enzymatic oxidation of cholesterol in the liver. The synthesis of BAs has traditionally been shown to occur via two pathways. Cholesterol 7 alpha-hydroxylase (Cyp7a1) performs the initial and rate-limiting step in the classical pathway while sterol 27-hydroxylase (Cyp27a1) initiates the hydroxylation of cholesterol in the acidic pathway. These two pathways are believed to be responsible for the vast majority of BA synthesis, roughly 75% and 25% of total BA production, respectively. While the role of individual BA species as physiological detergents is relatively ubiquitous, their endocrine function as signaling molecules and role in disease pathogenesis has been found to be BA species specific. In order to better understand the pharmacologic and toxicologic roles of individual BA species in an in vivo model, Cyp7a1 null mice (Cyp7a1-/-) were crossed with Cyp27a1 null mice (Cyp27a1-/-) to create double null mice (Cyp7a1-/-/Cyp27a1-/-) that are deficient in both enzymes. Wild type, Cyp7a1-/-, Cyp27a1-/-, and Cyp7a1-/-/Cyp27a1-/- mice were euthanized at 4 months of age. Serum, gallbladder, liver, and small intestine were collected for BA analysis. BAs were quantified by LC-MS to create a synthesis profile. We found that there was an increase in Cyp27a1 gene expression (11.3 x) in Cyp7a1-/- mice, which may be an attempt to compensate for the loss of Cyp7a1, while there was no change in the mRNA levels of Cyp7a1 in Cyp27a1-/- mice. In the Cyp7a1-/- mice, we observed a reduction of BAs in the gallbladder (86.3%) and in the liver (74.9%) as compared to wild type mice. In the ileum of Cyp7a1-/-/Cyp27a1-/- mice, the gene expression at mRNA levels of fibroblast growth factor 15 was reduced 77.7%, suggesting a decrease in FXR activity in response to low BA levels. It is also important to note that there were no differences in serum biomarkers or gross signs of liver injury among these four strains of mice. In summary, the two genes, Cyp7a1 and Cyp27a1, are critical in mice for BA homeostasis, and generation of the double null mice may serve as a useful model to study the functions of individual BA species. Funding: NIH ES050522, ES007148, R01GM104037.

1382 Comprehensive Examination of Induction of Drug Metabolizing Enzymes in Human Upcyte® Hepatocytes

S. W. Maloof1, J. P. Vanden Heuvel1, B. Sherf2, and Z. R. Abedin2. 1INDIGO Biosciences, Inc., State College, PA; 2Penn State University, University Park, PA; and 3PrimBio Research Institute, Exton, PA.

Drugs that induce xenobiotic metabolizing enzymes (XMEs) responsible for their own metabolism or that of a co-administered drug are a major source of concern in drug discovery. Human upcyte® hepatocytes are proliferating hepatocytes that retain many characteristics of primary human hepatocytes and are an important model for studying drug-drug interactions (DDI). We conducted a comprehensive examination of altered gene expression in upcyte® cells treated with a selection of reference XME inducers. Cells were treated with prototypical agonists of Pregnan X Receptor (PXR, rifampicin), Constitutive Androstane Receptor (CAR, rifampicin), Aryl Hydrocarbon Receptor (AhR, MeB), Farnesoid X Receptor (FXR, GW4064), Liver X Receptor (T0901317), Peroxisome Proliferator-Activated Receptor Alpha (PPARA, GW509735), Nuclear factor (erythroid-derived 2)-like 2 (Nrf2, Sulforaphane) or Liver Receptor-Homology 1 (ML179). Next-Generation sequencing (NGS) was used to quantify the altered gene expression induced by these drugs with a focus on XMEs that can affect the availability of biomarkers of drug metabolism and the characteristic induction of XMEs makes upcyte® hepatocytes suitable for DDI screening, as well as more in-depth mechanistic investigations.

1383 Utilization of a 3D Bioprinted Liver Tissue Model to Evaluate the Antifibrotic Effects of an ALK5 Inhibitor in a TGFβ-Induced Model of Hepatic Fibrosis

Compound induced chronic liver injury can lead to initiation of profibrotic processes resulting in sustained production of growth factors and profibrotic cytokines where inflammation, tissue remodeling and repair pathways are activated simultaneously to counteract the injury. Evaluation of potential antifibrotic therapies are limited using conventional non-human animal models, due to their inability to accurately reflect complex in vivo human biology, while 2D models lack the multicellular complexity and life span required to study fibrosis progression and regression. Utilization of a human 3D-bioprinted liver tissue model (ExVive® Human Liver Tissue) comprised of primary hepatocytes, hepatic stellate cells (HSCs), and endothelial cells, which can model TGFβ induced fibrosis, enables a mechanistic interrogation with an anti-fibrotic compound. In this study, galunisertib, a small molecule ALK5 (TGFβRII kinase) inhibitor, was used to evaluate pathway-specific blockage of TGFβ-induced fibrogenesis. The co-administration of galunisertib with TGFβ prevented the characteristic features of TGFβ-induced fibrosis, including upregulation of collagen deposition, phosphorylated SMAD2/3, and TIMP-1. Increased HSC activation was observed only in the TGFβ-induced fibrosis model, demonstrated by α-smooth muscle actin (αSMA) labeling and upregulation of ACTA2 transcript. Tissue and hepatocellular health remained stable following treatment with galunisertib, as shown by LDH release, viability, and albumin production which remained similar to vehicle levels, suggesting prevention of TGFβ induced tissue damage. These results demonstrate that a progressive in vitro model of liver fibrosis can be utilized to interrogate disease-associated pathways, and establish proof of concept for application of the model for preclinical evaluation of certain classes of anti-fibrotic drugs.

1384 A Common Genetic Variant Associated with the Risk of Idiosyncratic Liver Injury Due to a Variety of Drugs Is Identified via Hepatic Gene Expression-Based Clustering Analysis

M. Mosedale1,2, B. Foley3, P. Nicoletti4, E. T. Cirulli5, M. B. Black2, R. S. Thomas6, and P. B. Watkins1,2. 1University of North Carolina at Chapel Hill, Chapel Hill, NC; 2The Hamner Institutes for Health Sciences, Research Triangle Park, NC; 3Columbia Center for Computational Biology and Bioinformatics, New York, NY; and 4Duke Center for Applied Genomics and Precision Medicine, Durham, NC.

Genome-wide association studies (GWAS) to identify common risk factors for idiosyncratic drug-induced liver injury (IDILI) have been largely unsuccessful. The objective of this study was to explore the possibility that clustering drugs by underlying mechanisms of toxicity might increase the power to detect gene variants associated with IDILI susceptibility. Terminally differentiated HepaRG cells were treated with a single subtoxic concentration (5X Con) of 30 IDILI drugs or vehicle control for 8 and 48 h. (N=3 triplicates on day 6 and time point). Microarray gene and cellular pathways were used to cluster drugs into groups with similar transcriptional responses. GWAS performed using Caucasian genotype data from IDILI cases enrolled by the Drug-Induced Liver Injury Network and the International Severe Adverse Events Consortium as well as matched population controls identified a significant association in the region of microRNA-4750. It is also associated with cis-eQTLs for poly-nucleotide kinase 3 phosphate and PTOV1 antisense RNA2. PrediXcan, a method to impute gene expression profiles based on genetic data, permitted the possible expression differences in DILI cases for two genes near rs78137368: zinc finger protein 234 and V-set and immunoglobulin domain containing 10 like (p<0.0056 in blood). In conclusion, this study demonstrates a unique approach to improve the power for genetic studies of adverse drug response, which was utilized here to identify a pathway with the risk of IDILI associated with a common genetic variant. Ongoing efforts will explore the biological significance of these associations.

1385 Regulation of Steatosis in Upcyte® Cells by Nuclear Receptor Agonists

B. Sherf1, S. W. Maalouf1, K. John1, Z. R. Abedin2, and J. P. Vanden Heuvel1,2. 1INDIGO Biosciences, Inc., State College, PA; 2PrimBio Research Institute, Exton, PA; and 3Penn State University, University Park, PA.

Steatosis, typified by excessive accumulation of intracellular lipids, is a common liver disease triggered by various factors, including certain drugs and environmental chemicals. Nuclear receptors (NRs) are important transcriptional regulators that drive lipid metabolism and homeostasis, amidst other functions. The upcyte® human hepatocyte system has recently emerged as a good alternative to traditional non-human animal models, due to their inability to accurately reflect complex in vivo human biology, while 2D models lack the multicellular complexity and life span required to study fibrosis progression and regression. Utilization of a human 3D-bioprinted liver tissue model (ExVive® Human Liver Tissue) comprised of primary hepatocytes, hepatic stellate cells (HSCs), and endothelial cells, which can model TGFβ induced fibrosis, enables a mechanistic interrogation with an anti-fibrotic compound. In this study, galunisertib, a small molecule ALK5 (TGFβRII kinase) inhibitor, was used to evaluate pathway-specific blockage of TGFβ-induced fibrogenesis. The co-administration of galunisertib with TGFβ prevented the characteristic features of TGFβ-induced fibrosis, including upregulation of collagen deposition, phosphorylated SMAD2/3, and TIMP-1. Increased HSC activation was observed only in the TGFβ-induced fibrosis model, demonstrated by α-smooth muscle actin (αSMA) labeling and upregulation of ACTA2 transcript. Tissue and hepatocellular health remained stable following treatment with galunisertib, as shown by LDH release, viability, and albumin production which remained similar to vehicle levels, suggesting prevention of TGFβ induced tissue damage. These results demonstrate that a progressive in vitro model of liver fibrosis can be utilized to interrogate disease-associated pathways, and establish proof of concept for application of the model for preclinical evaluation of certain classes of anti-fibrotic drugs.
primary hepatocytes to examine liver diseases in vitro, including steatosis. In this study, upcyte cells were used to examine the role of NR to affect lipid accumulation and modulate gene expression. Prototypical activators of the pregnane X receptor (PXR, rifampicin), constitutive androstane receptor (CAR, CITCO), aryl hydrocarbon receptor (Ahr, Mebio), farnesoid X receptor (FXR, GW4064), liver X receptor (T0901317), peroxisome proliferator-activated receptor alpha (PPARA, GW300735) or nuclear factor (erythroid-derived 2)-like 2 (Nrf2, sulforaphane) or liver receptor homology 1 (ML179) were examined. Examination of lipid accumulation and altered gene expression from steatotic upcyte cells would provide insights into potential use of nuclear receptors as therapeutic targets to treat liver disease.

1386 An Optimized Process for Isolation, Culture, and Freezing of Human Kupffer Cells and Hepatic Stellate Cells to Develop Liver Co-Culture Models for Toxicological Studies

R. Li1, A. Jamin1, D. Steen1, P. Roshchina1, N. Rougier1, and C. Chesne2
1Biopredic International, Saint Gregoire, France; and 2Biopredic US, Kansas City, KS.

The use of hepatic non parenchymal cells (NPCs) has recently increased for the development of liver co-culture models to study liver toxicity. The NPCs are composed of Kupffer cells (KCs), hepatic stellate cells (HSCs) and sinusoidal endothelial cells. The KCs are the resident macrophages of the liver and play a key role in immune response to injury, and the HSCs are delicate to isolate, to cryopreserve and to retain their functionality after thawing. The aim of the present study was to establish a robust protocol for isolation, culture and cryopreservation of high quality functional human KCs and HSCs. Primary hepatic cells were isolated from liver resection of different donors. The different types of NPCs were recovered and separated with a Percoll gradient. Following specific binding step, the KCs were purified, cultured and frozen by optimized process. In parallel, other fraction of cells were seeded to induce HSCs proliferation. After the second to the fourth passage in culture, HSC were also freezing. Characteristics of fresh and thawed KCs and HSCs were tested 1 to 4 days post-seeding. The results showed that KCs expressed CD68 macrophage marker and were able to phagocytize FITC-latex beads (1 µm). Both fresh and thawed HSCs up to 9 subcultures expressed only αSMA showing an activated state. However, fresh HSCs from rare donors were quiescent with desmin expression and positive red oil staining of αSMA showing an activated state. However, fresh HSCs from rare donors were quiescent with desmin expression and positive red oil staining of retinol storage. However KCs and HSCs are very sensitive to isolation, culture and cryopreservation of high quality functional human KCs and HSCs. The NPCs are composed of Kupffer cells (KCs), hepatic stellate cells (HSCs) and sinusoidal endothelial cells. The KCs are the resident macrophages of the liver and play a key role in immune response to injury, and the HSCs are delicate to isolate, to cryopreserve and to retain their functionality after thawing.

C. Jamison, and K. McMartin. LSU Health Sciences Center - Shreveport, Shreveport, LA.

Diethylglycol (DEG) is an organic compound that can be found in consumer goods, including brake fluid, but can also be an adulterant in medicines by acting as a counterfeit solvent. DEG poisons affect the liver and nervous system, but have been characterized predominantly by acute kidney injury and necrosis of the proximal tubule cells. Diethylglycol is metabolized to two primary metabolites: 2-hydroxyethoxyacetic acid (2-HEAA) and diglycolic acid (DGA). In human proximal tubule (HPT) cells, DGA alone has been shown to be the metabolite that produces concentration-dependent cell death by decreasing the production of ATP and substrates involved in the electron transport chain, downregulating this energy-producing pathway. DGA has also been shown to chelate free calcium in a similar strength as known calcium chelator EGTA. To determine the effects of DGA on intracellular calcium levels in whole cells, a time-point study with subtoxic concentrations of DGA were conducted using primary human proximal tubule cells. DGA-treated cells were harvested and analyzed via spectrophotometry using the ratiometric calcium indicator dye Fura 2-AM. A higher ratio of emission from the dual excitation wavelengths, 340/380, would indicate a higher amount of calcium in the cell. Additionally, HPT cells were treated in a DGA dose response and analyzed for oxygen consumption rate (OCR) and extracellular acidification rate (ECAR), a measurement of glycolysis, using the Seahorse XF24 Analyzer. The measured 340/380 ratios from fresh and DGA incubated cells at timepoints between 2-48 hours showed a significant increase in intracellular calcium at the 25mM DGA concentration at 36 and 48 hours. DGA also decreased OCR and increased ECAR in a dose-dependent manner, lending more support to the effects of DGA on energy production. These data suggest that DGA appears to increase total intracellular calcium levels, but studies using other calcium sensing techniques need to be performed to determine the location of this effect.

1388 Effects of Lead on Calcium Oxalate Crystallization in an Insect Model of Nephrolithiasis

A. Branco, and G. M. Landry. Massachusetts College of Pharmacy & Health Sciences, Boston, MA.

Calcium oxalate (CaOx) accounts for 75-80% of kidney stone composition, and CaOx-containing stones are highly recurrent. Genetic predisposition, gender, geographic region, diet, and low fluid intake all contribute to disease pathogenesis. However, an important cause of renal CaOx formation that remains insufficiently studied is environmental exposure to pollutants, specifically nephrotoxic metals. Lead (Pb2+) is of particular interest as epidemiological data indicates that low-level Pb2+ exposure and blood Pb2+ levels (0.48µM-3.85µM) in humans increase kidney stone formation. Using our Drosophila melanogaster (fruit fly) model, we sought to determine the effects of exogenous Pb2+ on CaOx crystallization. This physiologically simple, yet evolutionarily conserved model allows us to mimic and easily visualize and quantify CaOx formation within intact Malpighian tubules (MT, insect renal structures). We found that MTs were isolated from wild-type flies (w1118), and treated with oxalate (5 mM) + Pb2+ acetate (2 µM) for 1h. Following exposure, MTs were imaged using differential interference microscopy (DIC), and crystals quantified (crystal number, total crystal area, and average size/crystal) using ImageJ. CaOx crystal number and total crystal area were significantly increased (~50-fold) in Pb2+-oxalate-exposed MTs when compared to oxalate alone treated controls. Furthermore, MTs exposed to Pb2+ alone had no crystallization indicating a role for Pb2+ in the increased formation of CaOx, and not PbOx. Our data indicate that exogenous Pb2+ plays a role in CaOx crystallization, which in turn could correlate to a higher propensity for CaOx stone formation and a worsening of nephrolithiasis pathology. Additionally, this model could be used as a high throughput assay for testing a variety of nephrotoxic agents to determine their effect on crystal formation. Future studies will determine whether flies reared on a Pb2+-containing diet mimic the same increases in CaOx crystallization parameters described above, as well as effects of Pb2+ on MT calcium levels.

1389 Early Screening for Nephrotoxicity Employing Transporter Over expression Cell Lines

S. Lu1, T. Sung1, M. Varma2, M. B. Monteiro3, S. Ramm1, and Y. Will2
1Pfizer, Inc., San Diego, CA; 2Pfizer, Inc., Groton, CT; and 3Harvard Medical School, Boston, MA.

Transporters play a significant role in regulating various physiological pathways. They can also mediate active uptake of drugs resulting in drug sequestration in the cells leading to potential toxicity. The kidney maintains total body homeostasis by conserving essential nutrients and eliminating potentially toxic xenobiotics, xenobiotic metabolites, and metabolic wastes. Proximal tubules contribute to the regulatory and secretory process via multiple membrane transporters in the basolateral and luminal membrane. Many drugs associated with kidney proximal tubule toxicity are hydrophilic - suggesting that active uptake via transporters drive the cell accumulation for such low permeable drugs. However, cells commonly used in vitro toxicology as lack transcellular expression which can lead to false negative results. Here we used OAT1, OAT3 and OCT2 over-expressing HEK293 cells to see whether they could improve our predictivity for nephrotoxic compounds. Transfected cells were treated with Cidofvir, Tenofovir (substrate of OAT1 and OAT3) and Cisplatin (OCT2 substrate) and kinetic impedance was measured as an indicator for cytotoxicity. In the parental HEK293 cell line both Cidofvir and Tenofovir did not cause any impedance change compared to control. However both OAT1-HEK293 and OAT3-HEK293 cells exhibited toxicity with the compound treatment (more severe toxicity observed with OAT1-HEK293). This result correlates with the compound uptake data (much greater uptake in OAT1 over
expression cells compared to that of OAT3 over expression cells). Similar differential toxicity profiles were also demonstrated with cisplatin using OCT2 over expressing cells compared to the parental cells. Inhibition of OAT1 and OAT3 (using probenecid) and OCT2 (using quinidine) reduced the toxicity associated with test compounds indicating that the increased toxicity is associated with increased cell accumulation. Both Cidofovir and Tenofovir were further examined in the microfluidic titer plate OrganoPlate® seeded with ciPTEC or RPTEC provides a promising drug screening platform as it allows multiplexing of biomarker analysis upon exposure to drugs of different classes.

1390 Drug Toxicity Screening in a High-Throughput Kidney-on-a-Chip

1Radboudumc, Nijmegen, Netherlands; 2University of Applied Sciences Northwestern Switzerland, Muttenz, Switzerland; 3MIMETAS, Leiden, Netherlands; and 4Utrecht Institute for Pharmaceutical Sciences, Utrecht, Netherlands. Sponsor: F. Russel

Kidneys-on-a-chip have the potential to reduce animal experimentation and improve predictivity of drug-induced kidney injury during drug development. Here, two human immortalized proximal tubule epithelial cell lines (ciPTEC and RPTEC) cultured in a multi-compartment microfluidic titerplate (Organoplato®) were evaluated as an high-throughput tool to assess drug-induced kidney injury. ciPTEC (Radboudumc) and RPTEC (Sigm Aldrich) were cultured in Organoplato® (MIMETAS B.V.) onto a collagen-I matrix and exposed to twelve compounds known for their nephrotoxic potential (including cisplatin, tenofovir, tobramycin and cyclosporin A) for 24 and 48h. Cell viability was assessed with a WST-8 assay and through biomarkers released into supernatant (LDH, NAG and mRNA's). Barrier integrity of RPTEC monolayers was evaluated by measuring diffusion of labeled dextran from the apical to the basal compartment. Finally, intracellular RNA was extracted from the kidneys-on-a-chip for gene expression analysis. Upon 10 days of culture under flow conditions, ciPTEC and RPTEC formed tubule structures in the Organoplato®. Significantly decreased cell viability and claudin-2 gene expression as well as increased release of LDH and NAG (9 compounds at 48h exposure) were detected in treated ciPTECs. Under the same experimental conditions, secretion of specific mRNAs into the perfusion buffer was increased in 11 out of 12 compounds at 24h exposure. Barrier integrity of RPTEC was reduced for 7 compounds as assessed by dextran diffusion. The microfluidic titerplate Organoplato® seeded with ciPTEC or RPTEC provides a promising drug screening platform as it allows multiplexing of biomarker analysis upon exposure to drugs of different classes.

1391 Cisplatin-Mediated Renal Cytotoxicity: The Protective Effect of Cinnamaldehyde, Kaempferol, and Resveratrol

M. Valentino, K. C. Brown, M. Dial, and A. Lamyaithong. Marshall University School of Medicine, Huntington, WV.

The cancer chemotherapeutic agent cisplatin is used clinically in patients with testicular, ovarian and cervical cancer. The primary serious effects include neurotoxicity and nephrotoxicity. Interventions to reduce cisplatin (CIS) cytotoxicity rely on hydration and diuresis. Agents that may reduce the renal cytotoxicity but not impact the cancer chemotherapy would improve cancer cure rate and benefit patient quality of life. This study examined the protective effect of three natural products: cinnamaldehyde (CIN), kaempferol (KAM) and resveratrol (RES) to reduce CIS cytotoxicity. The overall hypothesis of this project is that these agents will reduce cisplatin nephrocytotoxicity by maintaining mitochondrial function. Human proximal tubular cells were plated and allowed to equilibrate for 48h followed by a 1h pretreatment with vehicle (DMSO), 0-40 uM CIS, 0-20 uM KAM and 0-10 uM RES followed by a 24h treatment with 0-50 uM CIS. All studies were conducted as a minimum of 3 independent experiments. Viability was assessed by MTT leakage and by trypan blue exclusion. CIS was cytotoxic within 24h relative to vehicle control. CIN, KAM and RES did not affect MTT or Trypan Blue exclusion when compared to vehicle control (p>0.05). CIS induced a concentration dependent decline in viability after a 24h exposure to 0-50 uM relative to vehicle control. CIN, KAM and RES provided protection for CIS cytotoxicity to HK-2 cells. RES provided the best protection at the lowest concentration. Further studies examined mitochondrial function following a 24h exposure to cisplatin in cells treated with vehicle or RES using a Seahorse Xp analyzer. Optimization of cell number, FCCP and glucose were conducted prior to treatments. Basal and maximal or uncoupled mitochondrial function were assessed using the Mito Stress Kit. A separate series of studies conducted the Glucose Stress test and following a 24h exposure to CIS in the presence of RES or vehicle. Leakage of the mitochondrial protein, cytochrome c was evaluated 24h after CIS exposure in the presence of vehicle or RES. CIS induced cytochrome c leakage as detected by Western analysis. CIN, KAM and RES were protective for CIS cytotoxicity based on viability. RES reduced CIS cytotoxicity at the lowest concentrations compared to CIN and KAM. RES preserved mitochondrial basal and maximal oxygen consumption following CIS exposure which may be part of its protective effects. Supported by NIH Grant 5R01DK110343.

1392 Podocyte Culture-Based Screening Method Provides New Screening Approach for Nephrotoxicity

T. V. Damodaran1 and M. P. Winn2. 1Northwest University College, Durham, NC; and 2Duke University Medical Center, Durham, NC.

Podocyte integrity, an important determinant for the pre selective properties of the glomerular filtration barrier, is impaired in individuals with type 1 and type 2 diabetes as well as in individuals with known or unknown exposure to chemicals / radiation. We have established a primary podocyte culture model that will rapid screening of multiple chemicals for toxicity. We provide data from our podocyte culture method from wild type and mutant animal model (TRPC6-KO mice) that shows differential regulation of cell division and apoptosis. We have used the following assays to establish the differential response of primary podocytes: a) Annexin-PI assay to distinguish apoptosis and necrosis, b) Mitot assay to assess the mitochondrial involvement, c) Caspase-3 assay, d) UV-irradiation assay to identify P-S3 related pathways and f) Serum free growth assay for stress related pathways. We exposed the podocytes to the following chemicals: a) PAN, b) STZ, c) OAG, d) hyperforin, and e) UV-irradiation. In general, the TRPC6-KO mice manifested lower rate of apoptosis and higher level of DNA synthesis / cell division. There are dose dependent changes in the increased DNA synthesis and decreased cell death rates for various chemicals and radiation. This rapid screening approach for multiple chemicals or toxicants provides plenty of data regarding cell death and cell proliferation that can be effectively used for further dissection of distinct pathways of toxicant exposure related kidney dysfunction.

1393 Persistence of Bromate-Induced Epigenetic Changes in Kidney Cells

B. S. Cummings, R. T. Kolli, S. P. Kaur, and T. C. Glenn. University of Georgia, Athens, GA.

Bromate (BrO3) is a water disinfection byproduct we’ve previously shown to induce nephrotoxicity in vitro and in vivo. We also showed that the epigenetic inhibitors 5-aza-2-deoxycytidine (5-Aza) and trichostatin A (TSA) increased BrO3- nephrotoxicity while altering the expression of the cyclin-dependent kinase inhibitor p21 expression. In this study we used a novel approach called targeted genome bisulfite sequencing (TGBS) to determine the percent methylation at the p21 promoter in human embryonic kidney (HEK293) and rat normal kidney (NRK) cells. Treatment of the cells with 5-Aza decreased DNA methylation at 35% at the s5-inducible element (SIE-1), a transcription factor binding site in human p21 promoter, but did not alter methylation at the rat p21 promoter. We also observed differences in the basal promoter methylation between rat and human p21, suggesting that the rat and human p21 are differentially regulated by DNA methyltransferases. In contrast, sub-chronic BrO3- exposure failed to alter this methylation in both human and rat renal cells. In contrast, sub-chronic exposure of NRK cells to similar concentrations of BrO3 altered histone acetylation, as determined by chromatin immunoprecipitation (ChIP) assays. Changes in histone acetylation correlated to changes in p21 protein expression. Changes in histone acetylation were not observed in HEK293 cells. The persistence of these epigenetic changes was assessed by discontinuing exposure to BrO3 or the epigenetic inhibitors. 5-Aza-induced promoter demethylation remained stable after the withdrawal; however, TSA- and BrO3-induced histone hyperacetylation recovered back to basal levels after 3 days of withdrawal. These data suggest that BrO3 regulates the renal expression of p21 using mechanisms that alter histone acetylation, and by not inducing de-methylation of its promoter. The data also show species- and time-dependent difference in the epigenetic regulation of p21. These data suggest that epigenetic changes in rat p21 expression cannot be directly extrapolated to human p21, especially when assessing the risk of renal toxicants in humans.
Evaluation of the Epithelium Lining the Renal Papilla in Rats That Are Normal or with Chronic Progressive Nephropathy: It Is Not Urothelium

1UNESP - São Paulo State University, Botucatu Medical School, Botucatu, Brazil; and 2University of Nebraska Medical Center, Omaha, NE.

Chronic progressive nephropathy (CPN) is a common disease in rats, especially in the F344 and Sprague-Dawley strains. It is more common and more severe in males than females. One of the manifestations of high grade CPN is proliferation of the lining of the renal papilla, which is currently designated as urothelial hyperplasia in the INHAND classification. However, the true urothelium is the lining of the kidney pelvis that leads into the ureter. The present study was to design to evaluate whether the epithelium lining the renal papilla is truly urothelial and whether the CPN-associated hyperplasia represents urothelial proliferation. The differentiation of the lining of the papilla in aged and young male rats was assessed by immunohistochemical staining of uroplakin, a group of urothelial specific proteins. Kidney tissue from 8 aged male F344 rats and 5 young male Sprague-Dawley rats was used for the study. All of the aged rats had CPN, with 4 of the F344 rats having hyperplasia of the epithelium lining the papilla. Four of the aged rats did not have this proliferation. The kidneys from the 5 young Sprague-Dawley rats were normal. No uroplakin cytoplasmic staining was observed in the cells lining the renal papilla in any of the rats, whether hyperplastic or not, indicating that these cells are not urothelial. Furthermore, mitotic figures were not observed in this epithelium, even with hyperplasia. Based on these findings, we recommend that the epithelium lining the renal papilla not be classified as urothelial, and that the proliferation of this epithelium associated with CPN be designated as hyperplasia of the epithelium lining the papilla. Furthermore, this proliferation should be separated in diagnostic systems from true urothelial hyperplasia of the kidney pelvis.

Microcystin Exposure Modulates NOX-2, miR21 Axis in Ectopic Glomerular Toxicity in Underlying Non-Alcoholic Fatty Liver Disease

F. Alhasson1, V. Chandrashekarana, D. Dattaraoy1, R. Seth1, M. Albadrani1, G. Scott1, S. Raychowdhury2, M. Nagarkattil, P. Nagarkattil, and S. Chatterjee1.

University of South Carolina, Columbia, SC, and 2Benedict College, Columbia, SC.

NAFLD often results in cardiovascular, intestinal and renal complications. Previous reports from our laboratory exhibited NAFLD induced ectopic inflammatory manifestations in the kidney that gave rise to glomerular inflammation. Extending our studies, we hypothesized that existing inflammatory conditions in NAFLD could make the kidneys more susceptible to environmental toxins. Our results showed that exposure of Microcystin-LR (MC) in NAFLD mice caused a significant increase in mesangial cell activation as evidenced by increased a-SMA in the extracellular matrix surrounding the glomeruli. Renal tissue surrounding the glomeruli also had increased NOX2 activation as shown by increased co-localization of P47 Phox and its membrane component gp91 that. To show whether NOX2 activation and subsequent NOX2-miR21 axis were key to microcystin exposure and exacerbation of renal toxicity, experiments were designed in vitro with immortalized mesangial cells of mouse origin. The cells incubated with (a) apocynin and (b) nitroven spin trap DMPO and (c) miR21 inhibitor showed significantly decreased a-SMA, miR21 levels and proinflammatory cytokine release in the supernatant. In parallel, mice lacking miR21, a proinflammatory miR, known to be activated by NOX2, when exposed to MC in NAFLD showed decreased mesangial cell activation. Mechanistically, phenyl boronic acid incubated cells that are exposed to MC showed significantly decreased mesangial cell activation showing that peroxynitrite might be the major reactive species involved in mediation the activation process, release of proinflammatory micro RNAs and cytokines that are crucial for renal toxicity. Thus, in conclusion, MC exposure causes NOX2 activation that leads to mesangial cell activation and toxicity via release of peroxynitrite and miR21.

Drug Interaction Screening in a Microfluidic Human Renal Proximal Tubule

1Radboud Institute for Molecular Life Sciences, Nijmegen, Netherlands; 2Mimetas B.V., Leiden, Netherlands; 3University of Applied Sciences Northwestern Switzerland, Muttenz, Switzerland; and 4Utrecht Institute for Pharmaceutical Sciences, Utrecht, Netherlands.

A kidney-on-a-chip resembling in vivo conditions allows screening for functionally relevant compounds at a low cost. A human renal conditionally immortalized proximal tubule epithelial cell line overexpressing organic anion transporter 1 (CIPTET-OAT1) in a microfluidic titerplate (OrganoPlate®). CIPTET-OAT1 was cultured under fluid shear stress in the OrganoPlate®. Gene expression of P-glycoprotein (Pgp), organic cation transporter 1 (OCT1) and organic cation transporter 2 (OCT2) was assessed. Calculation of AUC and CMFDA were used to measure activity of P-gp and MRP2/4, respectively. PSC833 and a mixture of PSC833, MK571 and CO143 were used to inhibit P-gp and MRP2/4, respectively. A blinded screening for drug interactions of 12 potentially nephrotoxic compounds (e.g. cispilatin, tenofovir and cyclosporine A) was performed to evaluate their activity in this human renal epithelial cell line model. Drug treatment with cyclosporine A increased the fluorescent signal. In the blinded screening, five compounds (including cyclosporine A) caused a significant interaction with P-gp. For MRP2/4, four compounds (including cyclosporine A) caused a significant interaction. Comparison with in vitro and in vivo data of these compounds should further validate our model. We demonstrate a kidney-on-a-chip, composed of CIPTET-OAT1 in the OrganoPlate®, suitable for high-throughput screening at the pre-clinical phase in drug development.
Human immunodeficiency virus (HIV)-infected patients have higher prevalence of chronic kidney disease (CKD) than the general population. Both conditions are associated with decreased gluteal availability, which impairs the detoxification of electrophiles through the mercapturative pathway. This route is almost exclusive of kidney tubular cells, generating cysteine-S-conjugates, upon uptake and subsequent acetylation by N-acetyltransferase 8, form mercapturate and coenzyme A (CoA) that are eliminated in urine. The aim of the study was to compare urinary mercapturates of cysteine-S-disulfides (uNAC) and CoA (uCoA) between HIV-infected patients with a decrease in kidney function and those that remained stable during 1-year of follow-up. Urine samples were collected at admission (T0) and 12 months after (T12). Estimated glomerular filtration rate (eGFR) was calculated by CKD-EPI equation using creatinine, expressed in mL/min/1.73m². Patients were stratified according to their eGFR baseline values: normal control (NC)≥90, early kidney dysfunction (EKD): 60≤eGFR<90 and CKD<60; and eGFR evolution: non-progression (NP) with stable eGFR; progression (P) with decreasing kidney function≤10% from T0. uNAC and uCoA were quantified by HPLC-FD, presented as % of T0. HIV-patients (n=105) were 68% men; 75% Caucasian; median [interquartile range, IQR] age 50 [44-58]; 49 were NC, 46 were EKD and 10 were CKD. eGFR was 88 [76-98] at T0 and 81 [67-90] at T12 (p=0.007). At T12, 52% of patients were P. uNAC was lower in P vs NP, particularly for EKD-P (mean±SD 64±26%, p<0.05) and CKD-P (70±18%, p<0.001) (Two-way ANOVA). Among NP group, was lower in P vs NP, particularly for EKD-P (mean±SD 64±26%, p<0.05)

The incidence of type 1 diabetes (T1D), as well as its associated risk of chronic kidney disease (CKD) or end-stage renal disease (ESRD), are on the rise. T1D is an autoimmune disease in which insulin-producing beta cells are destroyed. T1D is manifested as increased expression of inflammatory proteins, elevated glucose concentrations, and decreased insulin levels. Increased incidence of T1D has been suggested to be a result of environmental factors such as exposure to polycyclic aromatic hydrocarbons (PAH). 2-aminoanthracene (2AA) is a PAH that has been associated with the onset of early diabetic symptoms. This study was conducted to identify if 2AA dietary ingestion would induce T1D renal injuries. To accomplish the research objective, three-week-old male Sprague-Dawley rats were assigned into three 2AA dietary ingestion groups (0 mg/kg, 50 mg/kg, and 100 mg/kg) for 12 weeks. Animals were evaluated for their food intake, body weight, total body, and kidney weight after euthanasia. Further experiments involving the analysis of serum glucose, creatinine concentration, albumin-creatinine ratio, and expression of inflammatory and renal injury gene markers were performed. The Sprague-Dawley rats in the 100 mg/kg group lost 5% less weight than the other treatment groups and converted roughly 3% more of their food intake into body mass. The kidney weight per body weight of the 100 mg/kg treatment group was 30.1% greater than the control group. Creatinine concentration of the 100 mg/kg group was 46.2% greater than the control group. FABP1 and SPP1 expression were elevated in treated groups. These results suggest that 2AA may induce the early diabetic renal injuries of hyperfiltration and microalbuminuria; however, further studies utilizing urine analysis, glomerular filtration assessment, greater 2AA concentrations, different delivery methods, longer trials, and ELISA should be conducted to further assess the effect of 2AA on diabetic kidneys.

Ellagic acid-artesunate hybrid molecule on selected kidney function parameters in mice. Recently through rational drug design approach, single hybrid molecules with multiple functionality and molecular targets have been developed as a novel treatment for many diseases, e.g., the ellagic acid-artesunate hybrid molecule, which has been demonstrated to possess high antimalarial activity. However, there are growing concerns about the toxic effects of these synthesized molecules on physiological systems. The aim of this study, therefore, was to investigate the effect of novel ellagic acid-artesunate hybrid molecule on selected kidney function parameters in mice. Thirty mice were randomly distributed into six groups of five mice each (A-F). Group A was orally administered 5% DMSO, while groups B, C, D, E, and F were administered 5, 10, 20, 40, and 80 mg/kg body weight of the hybrid molecule, respectively, for 28 days, after which the kidney function indices were determined. The results revealed that hybrid molecule caused no significant change (p>0.05) in plasma concentrations of chloride, calcium, bicarbonate, and phosphate ions at various doses compared to controls. However, the hybrid molecule significantly (p<0.05) reduced plasma concentrations of sodium ion at doses higher than 10 mg/kg and plasma potassium ion concentration at all doses compared to controls. The hybrid molecule produced no alteration (p>0.05) in plasma creatinine and urea concentration. Renal alkaline phosphatase activity was significantly increased (p<0.05) compared to controls upon treatment with the hybrid molecule. However, plasma alkaline phosphatase activity, and renal and plasma γ-glutamyl transferase activities were not significantly (p>0.05) altered at all doses administered compared with controls. Furthermore, Na⁺, K⁺ - ATPase activity in the kidney was significantly reduced (p<0.05) at doses higher than 5 mg/kg body weight, while Ca⁺⁺, Mg²⁺ -ATPase, and Mg²⁺ -ATPase activities were not altered as a result of administration of the hybrid molecule. The findings suggest that the hybrid molecule may adversely affect reabsorption of sodium ion in the kidney after prolonged administration at higher doses.

Chlorinated benzenes are commonly used as chemical intermediates in the manufacture of a wide range of commercial products and are found as environmental contaminants. Toxicity induced by chlorobenzenes includes neurotoxicity, hepatotoxicity and nephrotoxicity. While nephrotoxicity of some di- and trichlorobenzenes is associated with rat α2u-globulin, it is less clear if these halogenated benzenes have direct effects on the kidney. The purpose of this study was to examine the in vitro nephrotoxic potential of the three trichlorobenzenes (1,2,3-, 1,2,4-; and 1,3,5-trichlorobenzene [TCB]) using isolated renal cortical cells (IRC) from male Fischer 344 rats. IRC (~4 million cells/ml; 3 ml) were incubated with shaking at 37°C under a 95% oxygen/5% carbon dioxide atmosphere with a TCB (0 - 1.0 mM) or vehicle (dimethyl sulfoxide) for up to 60 min. General cytotoxicity was determined by determining trypan blue exclusion of IRC and measuring changes in lactate dehydrogenase (LDH) release. In some experiments, IRC were pretreated with an antioxidant or cytochrome P450 (CYP) inhibitor before 1,2,3-TCB (1.0 mM) or vehicle. 1,2,3-TCB proved to be the most potent nephrotoxicant of the three TCBs, inducing an increase in LDH release at 0.25 mM within 30 min. Both 1,2,4- and 1,3,5-TCB required TCB concentrations of 1.0 mM to induce cytotoxicity at 30 min. 1,2,3-TCB cytotoxicity was accompanied by reduced ATP levels but not increased levels of protein carbonyls. 1,2,3-TCB cytotoxicity was also reduced by both antioxidant and CYP inhibitor pretreatments. These results indicate that 1,2,3-TCB is the most nephrotoxic TCB in IRC and that CYP-mediated oxidation contributes to TCB nephrotoxicity. Mitochondria appear to be targets for TCB (and/or its metabolites), but lipid peroxidation is not the mechanism of cell death. Supported in part by NIH grant P20GM103434.
from a new high content screening assay we developed, with drug exposure information, in order to predict the risk for nephrotoxicity. We developed a high content screening assay, using 5 fluorescent dyes to score parameters associated with nuclei, cell morphology, mitochondrial function, actin cytoskeleton and cell membrane permeability, in conditionally immortalized proximal tubal epithelial cells that were transfected with the drug transporter OAT1 (ciPTEC-OAT1). We scored how 48 hour incubation with 38 nephrotoxic and 24 non-nephrotoxic drugs affected the endpoints in the assay. First, we confirmed that ciPTEC-OAT1 was more sensitive to the nephrotoxic substrates for OAT1 than parent ciPTEC. Next, by manual data analysis, we found that parameters related to cellular and nuclear structure and mitochondrial health were more sensitive than nuclei counts. In order to access the full predictive power of the assay, we built a mathematical model integrating all 250 parameters we derived from the high content image analysis, as well as human exposure information (Cmax). This model was able to correctly classify 35 of 58 nephrotoxic drugs (60% specificity, 92%) and 23 of 24 of non-nephrotoxic drugs (specificity: 96%). As the assay can be performed in a relatively high throughput (3 day assay protocol, 96 well format, cost effective), and has good predictivity, it is compatible with implementation in an early drug discovery setting.

1405 Characterization of the Dose- and Time-Response of miRNA and mRNA Profiles in the Serum and Kidney of F344 Rats Recovering from a Nephrotoxic Co-Exposure to Melamine and Cyanuric Acid

We reported previously that a 28-day exposure to nephrotoxic doses of melamine and cyanuric acid (MEL&CYA) modulated the serum miRNome of male and female F344 rats. To confirm and expand these findings, we have now assessed the changes in the serum miRNome induced by a nephrotoxic dose of MEL&CYA in F344 rats upon 90-days of exposure and during 90-days of recovery. We further assessed molecular changes (miRNA and mRNA) in the kidney of these animals, and compared their dose- and time-responses with kidney histopathology, serum creatinine, and blood urea nitrogen. Serum samples were screened (n = 5 per sex, 0 and 5 mg/kg body weight (bw)/day each MEL&CYA) using quantitative real-time RT-PCR (qPCR). The levels of several serum miRNAs were decreased by treatment, including some that we had previously identified in the 28-day exposure study (e.g., mir-106b-5p and mir-128-3p). In addition, a subset of these miRNAs was found to be modulated in the kidneys of these animals, although the direction of the effect was reversed in most cases. The expression of putative target genes of the modulated kidney miRNAs, as identified using miRWalk 2.0, and of several genes included in a Rat Nephrotoxicity Panel (TaqMan® Array) was also different in treated versus control rats. Characterization of the dose- and time-response of these effects showed that the serum and kidney miRNAs were not affected by non-nephrotoxic doses of MEL&CYA (1.25 and 2.5 mg/kg bw/day each), while the miRNAs modulated by the 5 mg/kg bw/day MEL&CYA dose returned to baseline upon 90 days of recovery from treatment. Taken together, these results suggest that exposure to a nephrotoxic dose of MEL&CYA induces miRNA and miRNA changes at the serum and kidney levels that correlate with the histopathological changes observed in the kidneys of the same animals. This work was sponsored under an interagency agreement between the FDA/NCTR and the NIH/NTD FDA IAG # 224-12-0003/NIEHS IAG # AES12013.

1406 Effect of Juvenile Chlorpyrifos Exposure on Novel Object Recognition in Adolescent Rats

Chlorpyrifos (CPF) is an organophosphate insecticide that is widely used in agricultural regions in the United States. Developmental exposure has been hypothesized to lead to long-term behavioral effects in children, and exposure has been correlated with decreased cognition and attention deficit/hyperactivity disorder (ADHD). In previous studies, we have reported that developmental exposure to CPF inhibits fatty acid amide hydrolase (FAAH), an enzyme which breaks down endocannabinoids in the brain. This inhibition occurs at exposure levels that do not result in the inhibition of acetylcholinesterase, the canonical target for CPF. In this study, the effects of developmental exposure to low levels of CPF on novel object recognition memory were investigated. From postnatal day 10 (PND10) to PND16, rat pups were orally exposed...
A. M. Lewis, J. A. Mosier, N. E. Rowbotham, and R. L. Carr. Mississippi State University, Mississippi State, MS.

Childhood exposure to chlorpyrifos (CPF), an organophosphorus insecticide, results in negative long-term neurologic effects. We have previously reported that low-level developmental exposure of rats to CPF disrupts endocannabinoid (EC) degradation through fatty acid amide hydrolase (FAAH) inhibition and leads to increased social play behavior once adolescence is reached. Increased activity in the EC system may be responsible for the observed altered behavior. Phosphorylation of the cannabinoid receptor (CB1R) is an indicator of EC activation. This study compared the phosphorylation of the CB1R in brain regions of control and treated rats immediately following behavioral testing. On postnatal day (PND) 10, rats were exposed orally to either corn oil, 0.5 mg/kg CPF, 0.75 mg/kg CPF, 1.0 mg/kg CPF or 0.02 mg/kg PF-04457845 (a specific FAAH inhibitor) daily for 7 days. On PND 36, social behavior was monitored and all treated groups spent more time playing than did controls. Western blotting was used to quantify the amount of CB1R and phosphorylated CB1R proteins in the hippocampus, amygdala, prelimbic cortex, agranular insular area, and nucleus accumbens. There were no significant effects of treatment on the amount of CB1R protein in any of the five brain regions. Increased CB1R phosphorylation occurred in all brain regions following social play, but no effects of CPF treatment were observed. This suggests that increased EC activation is not a causative factor in the increased social play observed in CPF treated rats. It remains unclear whether developmental CPF exposure induces an alteration in EC tone or an alteration in other neurotransmitter systems that could explain the observed changes in social behavior. Funded by NIH R15ES023162.

1408 Increased Expression of c-Fos in Brain Regions following Repeated Developmental Exposure to Low Levels of Chlorpyrifos

W. Jones, S. Guo-Ross, and R. L. Carr. Mississippi State University, Mississippi State, MS.

Chlorpyrifos (CPF) is an organophosphate insecticide that acts primarily through the inhibition of acetylcholinesterase (AChE) and the subsequent accumulation of acetylcholine. At higher levels of exposure, this accumulation leads to overstimulation of postsynaptic receptors leading to neuronal excitation. However, neurotoxic effects have been reported following repeated developmental exposure to CPF at levels that do not inhibit AChE. It is not clear if low level repeated exposure to CPF will induce neuronal excitation. c-Fos is a transcription factor that plays a part in many cellular events such as cell proliferation, differentiation, and survival. The induction of c-Fos has been used as a marker of increased neuronal activity. In our study, we focused on determining if exposure to low levels of CPF induces neuronal excitation and, if it does, determining the regions of the brain in which this occurs. For this purpose, juvenile rats were orally exposed daily to either corn oil, 0.5, 0.75, or 1.0 mg/kg CPF from postnatal day 10 (PND10) to PND16. Rats were sacrificed 12 hours after the final treatment and brains were collected and sliced using a microtome to isolate specific regions of the brain. Immunohistochemistry was then performed on these specific regions to determine c-Fos expression. Staining revealed increased expression of c-Fos in the caudate putamen (CPu) and lateral septal nucleus (LSD) regions of the brain following treatment with low levels of CPF. These data suggest that exposure to low levels of CPF can induce neuronal activity resulting in the increased expression of c-Fos. Funded by NIH R15ES023162.

1409 Effects of Alpha-Cypermethrin and Prenatal Stress on Embryonic Brain Development

B. A. Elser, H. Lehmler, and H. E. Stevens. University of Iowa, Iowa City, IA.

Alpha-cypermethrin is a type II pyrethroid that has been recommended for use by pregnant women to prevent mosquito-borne transmission of the Zika virus. As such there is high probability for prenatal exposure to the developing embryo. Previously, we have shown that prenatal stress is a risk factor for disrupted embryonic brain development and delays the migration of GABAergic progenitor cells in the developing forebrain in a mouse model. In addition, several studies have suggested that psychological stress may influence chemical toxicity through alterations in metabolism and tissue distribution. As such, the present study examined the effects of prenatal exposure to alpha-cypermethrin on mouse embryonic brain development, alone and in combination with maternal stress. CD1 dams were administered alpha-cypermethrin at doses of 0 mg/kg, 3 mg/kg, or 10 mg/kg daily throughout the first 14 days of pregnancy (E0-E13). In addition, half of the mice were subjected to restraint stress under bright light (3x45 min) on the 12th and 13th days of gestation (E12-E13). No overt signs of maternal toxicity (decreased body/organ weights) were observed in any dams. Embryonic body and placenta weights were unchanged among all treatments in several cases of abnormal development including exencephaly, growth retardation, and early stage embryonic death were observed in a small fraction of high dose cypermethrin treated embryos but were absent in controls. In mice, an increased incidence of placental fusions was observed in high dose cypermethrin treated litters. Neurodevelopmental endpoints including GABAergic progenitor migration, forebrain volume, and volume of the ganglionic eminence proliferative zone were assessed at E14. High dose cypermethrin resulted in a trend delay in GABAergic progenitor migration. No other endpoint was significantly changed by either prenatal stress or cypermethrin, alone or in combination. This suggests an unintended stress buffering mechanism due to our experimental method, which is currently being addressed in ongoing experiments. In conclusion, although several neurodevelopmental endpoints were not affected, these findings suggest potential adverse outcomes on embryonic development as a consequence of prenatal exposure to cypermethrin at doses below the threshold for maternal toxicity.

1410 Transcripntional Analysis of Alternative Flame Retardant Exposures in hESC-Derived Neural Precursors

Due to their persistence in the environment and suspected ability to cause neurotoxicity in humans, polybrominated diphenyl ether (PBDE) flame retardants (FRs) are being phased out of the marketplace. Alternative FRs, including organophosphorus and polybromobenzene forms, are being introduced in their place and have recently been detected in human maternal/fetal biological matrices. While the developmental health effects associated with alternative FR exposures in utero remain undefined, in vitro assessments suggest similar risks with legacy FRs. Human embryonic stem cells (hESCs) have tremendous potential as a model of in utero xenobiotic exposure. We have previously demonstrated hESC-derived neural precursor cells (NPCs) to be particularly sensitive to PBDEs, which induce significant concentration-dependent cytotoxicity and gene expression changes in pathways related to neurodevelopment and stress. Therefore, in this study we expanded our assessments to include 12 FRs currently being used in consumer products. In a blinded investigation, we discovered 9 of the 12 tested FRs (0-30μM) produced significant cytotoxicity in NPCs, with select alternative FRs showing similar potencies to BDE-47. To identify possible common mechanisms underlying FR toxicity, we profiled NPCs using RNA sequencing. NPCs were exposed to either BDE-47 or alternative FRs: IPP (isopropylated phenyl phosphate), EHPD (2-ethylhexyl diphenyl phosphate), or TBBPA (tetrabromobisphenol A) at 3 or 10 μM. Significant alterations in gene expression were observed for all four compounds (p<0.0001): BDE-47 (277), IPP (1968), EHPD (482), and TBBPA (211). Sixty genes were commonly differentially expressed with all four FRs, including factors suspected of driving neuronal migration.
Autism spectrum disorder (ASD) is considered to be one of the most heritable components of the complex neurodevelopmental disorders (NDD). However, the sharp increase in rates of ASD in recent decades has prompted the search for genetic and environmental interactions that influence individual risk for ASD. PCBs, a class of persistent organic pollutants, have been implicated as environmental risk factors for NDDs, and immune system abnormalities are frequently observed comorbidity in ASD. Therefore, the goal of this study was to examine how genotype and sex influence serum cytokine responses to PCBs. Mice were developmentally exposed to a mixture of PCB congeners (MARBLES mix) present in the serum of a woman who is at high risk for having a child with ASD at four dose groups: low, intermediate, high, and control. In the maternal diet through gestation and lactation. Four genotypes were studied: knock-in mice expressing a human y nanodeoxyribo nucleic acid receptor (RyR) gene of function mutation (T482E-RyR1), the X-linked FMR1 CGG repeat expansion (PCGCG) with 170 repeats) or both mutations (double mutation, DM), and congenic wildtype (WT) mice. At postnatal day 28, serum was collected and analyzed for 23 cytokines and chemokines using a Lumexin multiplex assay. Genotype affects the serum cytokine responses to PCBs, with WT mice exhibiting a non-monotonic dose response for most of the cytokines tested that was not observed for the other genotypes. Sex differences were observed in many cytokine profiles, with data analysis suggesting that circulating serum cytokines in males are more responsive to PCB dose than females. This sex difference is most pronounced in WT and PCGCG animals. These data suggest that male immune responses may be more susceptible to modulation by environmental factors implicated in ASD pathogenesis. Supported by NIEHS (R01 ES014901 to PJL and INP, F32 ES070739 to SS, P01 ES01269 to JVDW and PJL, P01 ES035691 to HUL), NICHD (U54 HD079125 to JVDW, INP and PJL, F32 HD088016 to KPK), and US EPA (RD83542501 to JVDW, INP and PJL).
STX inhibits voltage-gated sodium channels, affecting the propagation of action potentials. Humans are among the species most sensitive to PSP, and neurological symptoms of exposure range from tingling of the extremities to severe paralysis. To protect humans against PSP, there is a ban on harvesting of seafood where the STX levels reach 80 μg/100 g of shellfish tissue. However, shellfish with toxin levels below this regulatory threshold are consumed for consumption. Our objective is to understand the potential health effects of exposure to low levels of STX during sensitive windows of development. Zebrafish embryos were exposed to STX (24 or 48 pg) or vehicle (0.3 mM HCl) at 6 hours post-fertilization (hpf) via microinjection. There was no overt toxicity, but at 10 days post fertilization (10 dpf) there was temporary lack of pigmentation in STX-injected embryos, which resolved by 72 hpf. Using HPLC, we found that STX was retained in embryos up to 72 hpf in a dose-dependent manner. We examined transcriptional profiles in embryos at 24, 36, and 48 hpf. There were no differentially expressed genes (DEGs) in STX-injected embryos at 24 hpf, but at 36 and 48 hpf there were 3547 and 3356 DEGs, respectively, in response to STX. KEGG pathway analysis revealed significant enrichment of genes related to focal adhesion, adhesion junction, and regulation of actin cytoskeleton, suggesting that cell-cell and cell-extracellular matrix interactions were affected by STX. The genes affected are critical for axonal growth and the development of functional neural networks. We also observed differential expression of axon guidance factors (neurins, semaphorins, and ephrins), which can control axon outgrowth. We are currently using immunohistochemistry to confirm these findings. Overall, these results suggest that STX exposure might affect axon outgrowth by modulating cell adhesion molecules. NIH P01ES021923 and NSF OCE-1311462.

The zebrafish clock1a gene regulates Bisphenol A-induced neurodevelopmental toxicity
J. Zhang, and Y. Guo. School of Public Health, Sookhoo University, Suzhou, China. Sponsor: J. Li
Bisphenol A is one of the most important EDCs, possibly inducing the developmental toxicity through multi-mechanisms. The present study had shown that circadian clock gene, clock1a, could be disturbed by BPA. Fluorescein reporter assay confirmed BPA promoted the binding of estrogen receptor to the estrogen-response elements (EREs) of clock1a promoter. Then we used clock1a-/- zebrafish to detect the developmental toxicity after 96 h treatment of BPA in different concentrations of BPA (0, 1, 5, 25 μM). The results revealed the increase of malformation rate and death rate, the decrease of the total distance and total trace with a dose-dependent and the reaction to the dark stimulus was weakened in light and dark alternating experiment, apoptosis has increased after BPA treated. Furthermore, all these changes are more pronounced in clock1a-/- groups. Nrf2 as a clock-controlled gene downstream of clock1a, its promoter contains the E-box sequence, its expression is rhythmic and the rhythm changes after BPA treatment.Taken together, clock1a and Nrf2 are important genes that regulate the BPA induced neurodevelopmental toxicity.

Exploring the role of host-associated microbiota as mediators of Bisphenol A chemical toxicity in zebrafish
Exposure to Bisphenol A (BPA), a widespread environmental contaminant, has been associated with adverse endocrine and neurodevelopmental effects. Growing public concern over the safety of BPA has resulted in swift replacement with a suite of alternatives that uniformly lack adequate testing data. Because the microbiota play important roles in nervous system development and harbor the ability to bioactivate or detoxify xenobiotics, we hypothesized that developmental exposure to BPA compounds may influence microbiota structure leading to colonization-dependent neurotoxicity. To test this, a semi-static system was used to expose conventionally colonized zebrafish to BPA, Bisphenol AF (BPAF), Bisphenol B (BPB), Bisphenol F (BPF), or Bisphenol S (BPS). The classic estrogen receptor agonist 17beta-estradiol (E2) was used as a positive control. At 10 days post fertilization (dpf) larvae were assessed for mortality and a range of phenotypes was observed: BPB > E2 > BPF > BPA > BPAF. To evaluate potential chemical-dependent shifts in microbiota structure in 10 dpf conventionally colonized zebrafish, 16S rRNA gene sequencing was performed. Concentration-dependent disruption of microbiota was observed with exposure to BPA, BPF, and BPS, while exposure to E2, BPB, and BPAF, the most overtly toxic compounds, did not alter microbiota structure. To assess whether neurobehavioral toxicity was mediated by microbiota, we exposed three cohorts of zebrafish to all six compounds: conventionally colonized, axenic (microbe-free), and axenic colonized with zebrafish facility water at 1 dpf. At 10 dpf, neurobehavioral effects were assessed using an established light/dark assay. Hypoactivity was observed in colonized larvae only with E2 exposure. While some BP compounds caused neurobehavioral toxicity in one or more cohorts, the effect was colonization-dependent. Overall, these data demonstrate that the least overtly toxic BP compounds cause the most significant alterations in microbiota structure in 10 dpf zebrafish. These differential chemical effects suggest that current hazard identification strategies have the potential to misestimate risk if chemical-microbiota interactions are not considered. This abstract does not necessarily reflect US EPA policy.

Zebrafish Larvae Require Specific Strains of Bacteria for Neurobehavioral Development
There is an increasing appreciation of the relationship between gut microbiota and nervous system development and function. We previously showed that axenic (microbe-free) larvae are hyperactive at 10 days post fertilization (10 dpf) relative to conventionally colonized larvae. Interestingly, while exposure to heat-killed bacteria or microbe-associated molecular patterns failed to block hyperactivity in axenic larvae, colonization of axenic larvae with Aeromonas veronii or Vibrio choleae produced locomotor hypoactivity relative to colonized controls. These data suggest that there is a developmental requirement for certain types of microbes to modulate host behavior. To address this hypothesis, we exposed three cohorts of zebrafish larvae with 100 cells/ml of each of Actinetobacter, Vibrio, Comamonas, and Comamonadaceae at 1 dpf. Finally, Vibrio-related hypoactivity was found to persist in 10 dpf larvae. These data suggest that specific bacterial taxa are needed to drive normal neurobehavioral development while colonization with other strains may result in behavioral hypoactivity and raise the possibility that environmental chemicals may disrupt neurobehavioral development by selecting for specific classes of host-associated microbes. This abstract does not necessarily reflect US EPA policy.

Sex differences in neurotoxic effects and neurotoxic effects on sex differences
E. Levin, A. Hawkey, H. White, L. Yao, E. Yazdani, and B. Kenou. Duke University, Durham, NC.
The most common genetic polymorphism is sex. The most obvious sex differences are in reproduction but other sex differences exist. As with factors like height, sex differences in non-reproductive behaviors are not dichotomous but have overlapping continuous distributions. Most studies have shown that neurotoxicants can have differential effects in females and males. In some cases, these effects diminish or reverse normal sex differences in neurobehavioral function. In rats, we have found that exposure to the organophosphate insecticide chlorpyrifos (CPF) significantly reduces normal sex differences in working memory and activity in a radial-arm maze task. Males typically have fewer working memory errors than females. Low-dose neonatal CPF exposure (1 mg/kg/day, postnatal days 1-4) to rats reduces errors in females and increases them in males, eliminating this normal sex difference. Neurotoxic diminution of normal sex differences is not limited to insecticides. A recently completed study investigated the relevance of sex differences to the effects of two teratogenic components of cigarette smoke: nicotine and polycyclic aromatic hydrocarbons (PAHs). Developmental exposure of rats to a low dose (0.03 mg/kg/day throughout gestation) of the PAH benzo-a-pyrene (BaP) causes a significant reversal of a normal sex difference in locomotor activity in which female rats are normally more active than male rats. Prenatal BaP exposure causes hyperactivity in males but not females, eliminating the normal sex difference in locomotor behavior. Sex-selective effects are also seen with nicotine and BaP exposures in emotional and cognitive tests, with each compound eliminating sex differences in anxiety-like behavior in a novel environment. Intriguingly, BAP exposure...
1420 Brain Growth Spurt Alcohol Exposure Does Not Alter the Dynamics of Microglia, Dendritic Spines, or Their Interactions in Adolescent Mouse Somatosensory Cortex

Patients with fetal alcohol spectrum disorder (FASD) suffer from a wide range of cognitive disabilities throughout life. Auditory, visual, and tactile sensory information processing is often impaired in FASD patients, contributing to learning disabilities and difficulty navigating social scenarios. Rodent studies have shown that alcohol exposure during the brain growth spurt (BGS), when synapses are initially formed, can drive acute neuronal apoptosis and immunological activation of microglia in the somatosensory cortex. It remains unclear to what extent microglia and the excitatory synapses that microglia interact with in the healthy brain still function normally later on in life. We administered 3.6g/kg alcohol subcutaneously during the peak of the BGS (postnatal day 4 through 9 (P4-P9)). Control littersmates were injected with saline vehicle or handled. At P28, we used in vivo two-photon microscopy to image microglia and dendritic spines (structures representing postsynaptic sites of excitatory synapses) in the living, intact somatosensory cortex. We found that microglial process motility was not changed by prior alcohol exposure. While microglia in somatosensory cortices of mice previously exposed to alcohol tended to respond faster and more robustly to tissue injury compared to the response in control mice, the difference failed to reach significance. Neither dendritic spine density nor the proportion of spines falling into distinct morphological categories was affected by prior alcohol exposure. Tracking the same dendritic spines three times over 7 days revealed that spine stability, remodeling, and morphology were also similar among the alcohol and control groups. Quantifying the physical interactions between microglia and dendritic spines in P28 somatosensory cortices, we revealed no alcohol-induced differences in contact frequency, contact duration, or the size of spines more likely to be contacted by microglia. Together, these findings support the surprising conclusion that, without further perturbation, the physiological functions of surviving microglia and excitatory neurons in the mouse somatosensory cortex are intact and not affected long-term by BGS alcohol exposure.

1421 Identifying Sex Differences in Growth Responses to Ethanol in Fetal Neural Stem Cells

H. A. Muhisen, A. Tseng, A. Mahnke, and R. Miranda. Texas A&M University, College Station, TX. Sponsor: S. Safe

Fetal Alcohol Spectrum Disorders (FASDs) result from prenatal exposure to alcohol, and are the leading non-genetic cause of developmental disabilities. Neural stem cells (NSCs) generate a majority of neurons in the adult brain during the mid-first to second trimester of gestation during which they are particularly susceptible to the teratogenic effects of alcohol. Ethanol exposure loss of NSC number and capacity in NSCs but does not cause increased cell death. One cellular mechanism through which ethanol exerts its effects on NSCs is through its actions on miR-9, a critical regulator of NSC differentiation. Ethanol exposure increases methylation at the miR-9 locus and subsequently reduces its expression in NSCs. Interestingly, previous studies have shown sexual dimorphism in cellular behavior, such as miRNA expression, within endogenous stem cells. Our study is the first to investigate sex-differences in the NSC response to ethanol. Using ex vivo cultures of NSCs derived from gestational day 12.5 C57BL/6j mouse fetal telencephalon and maintained as neurosphere cultures, we assessed the effect of ethanol on NSC sphere formation and sphere size separately in male and female-derived cultures. Preliminary data indicate that ethanol decreases neurosphere formation, and that fetal male-derived cultures are more sensitive to low dose ethanol exposure than female-derived cultures. Further studies characterizing these sex differences in the NSC response to ethanol will help elucidate the pathophysiology of FASD and lead to the development of novel therapeutics. Research supported by grant # R01AA024659.

1422 Identification of Molecular Bioindicators of Thyroid Hormone Action in the Fetal and Neonatal Rat Brain

K. L. O’Shaughnessy1,2, C. Wood1, R. L. Ford1,2, M. G. Hotchkiss1, P. A. Kosian1, S. J. Deagt2, and M. E. Gilbert1. 1US EPA, Research Triangle Park, NC; 2Oak Ridge Institute for Science and Education, Oak Ridge, TN; and 3US EPA, Duluth, MN.

Adverse neurodevelopmental consequences remain a primary concern when evaluating the effects of thyroid hormone (TH) disrupting chemicals. Though the developing brain is a known target for TH insufficiency, the relationship between THs in the serum and the central nervous system is not well understood. When and how hypothyroidism exerts a neurotoxic influence on brain development is also unknown due to a lack of described phenotypes induced by mild hypothyroxinemia. To begin to address these outstanding issues we performed a series of dose response experiments in pregnant rats, using low to moderate levels of the goitrogen propylthiouracil (PTU, dose range 0.1 - 10 ppm). THs were quantified in both the serum and brain of offspring at gestational day 20 (GD20) and postnatal day 14 (PN14), two developmental stages recommended in OECD and EPA regulatory guidelines. From this dose response data, quantitative relationships of THs between the serum and brain were described. Next, targeted gene expression analyses that a transcriptional readout could serve as a molecular bioindicator of brain TH status, in lieu of T4/T3 measurements within the tissue. Our results show that the GD20 fetus exhibits a significant reduction of THs in both the serum and brain at low doses of PTU; yet very few of the proposed TH-sensitive candidate genes were significantly altered in the cortex at any dose tested. In the PN14 pup, significant reductions in both serum and brain THs were also observed at several doses of PTU. However, twelve transcriptional targets were identified in the neonate that mirrored the TH insufficiency within the brain. Interestingly, many of these genes encode proteins critical for maintaining future development and organization, which are processes known to cause phenotypic alterations in the brain following developmental hypothyroxinemia. These results inform the quantitative relationship between TH status in the periphery and the developing brain, and offer several target genes that could serve as pragmatic readouts of TH dysfunction in the PN14 rat cortex. This work does not reflect US EPA policy.

1423 Thyroid Hormone Insufficiency and Cortical Heterotopia Induced by Ammonium Perchlorate in Rodent Brain

M. E. Gilbert1, K. L. O’Shaughnessy1, C. R. Wood1, S. Thomas1,2, M. Hotchkiss1, R. L. Ford1,2, and J. Ford1. 1US EPA, Research Triangle Park, NC; and 2Oak Ridge Institute for Science and Education, Oak Ridge, TN.

A morphological defect, a cortical heterotopia, has been observed in the brains of rat pups exposed to utero to moderate doses of the thyroid hormone (TH) synthesis inhibitor propylthiouracil (PTU). TH insufficiency during late gestation/early postnatal period is required to induce this defect, and its magnitude and incidence are dose-dependent. The present study extends these observations to the environmental contaminant ammonium perchlorate. Pregnant LE rat dams were placed on an iodine-controlled diet on gestational day (GD)2. On GD6, perchlorate (0 1 30 1000 1000 ppm) was administered to the dam via the drinking water. In one group, blood and thyroid glands were collected from dams on GD20, and blood, brain, and thyroid glands were taken from the fetuses. In a second group, pups were sacrificed on PN0, PN2, PN14, and blood and brains were collected. Increases in thyroid gland weights were seen in dams on GD20 and PN14. Expression of gene transcripts (Nis, Tpo) was increased in the thyroid gland of the dam and the fetus. Induction of the thyroid hormone (TH) responsive genes (Camk4, Klf9, Bdnf, Sema7a) was not changed in the fetal brain. Histological analysis of the PN14 brain revealed heterotopia in 0%, 30%, 70% and 100% of animals at 0, 30, 300 and 1000 ppm dose, respectively. Heterotopia were also largest at the highest dose of perchlorate, but consistently smaller in size than the observed hypothyroidism. Preliminary findings are consistent with prenatal TH insufficiency as essential for heterotopia formation, but further suggest that ‘perinatal’ hypothyroxinemia may be necessary for its full expression. Direct pup dosing studies are currently underway to address this hypothesis. These findings support the hypothesis that this morphological defect may serve as a brain-based biomarker of neurodevelopmental insult associated with moderate developmental TH disruption. This abstract does not necessarily reflect US EPA policy.
Human-Based Primary and Induced Pluripotent Stem Cell-Derived Neural Progenitor Cells as Promising In Vitro Models for a Developmental Neurotoxicity Testing Battery

Brain development underlies strictly controlled highly complex mechanisms, which makes the developing brain particularly vulnerable to a chemical insult. However, for the majority of chemicals that are in use the developmental neurotoxic potential is not characterized. Currently, developing brain function and neurotoxicity (DNT) testing is done according to an OECD or EPA in vivo guideline study. These studies are insufficient for large scale DNT testing as they consume high amounts of animals, time and money and bear the issue of species extrapolation. It is therefore generally accepted that an alternative strategy for DNT testing is needed and the use of an in vitro testing battery for compound screening and prioritization is currently under discussion at the OECD level. Our group has developed two in vitro models that represent major processes of embryonic as well as fetal brain development. With high readiness we use human second trimester (fetal) neural stem/progenitor cells growing as 3D cell aggregates called neurospheres. The ‘Neurosphere Assay’ mimics specific neurodevelopmental key events, e.g. proliferation, migration and differentiation into neural effector cells (astrocytes, neurons and oligodendrocytes). We also developed neurospheres from rodents, which can be used for knowledge driven species extrapolation according to the parallelogram approach. In development and with low readiness we use human induced pluripotent stem cells (hiPSCs) which are made from human fibroblasts and reprogrammed to regain a human stem cell-like character. Recently, we established hiPSC-derived neural progenitor cells, cultured as 3D neurospheres, to cover the embryonic development. These hiPSC-derived neurospheres were compared to our primary human neurospheres. We found hiPSC-derived NPC mimic neural development similar to primat NPC. A special property of these hiPSC-derived neurospheres is the ability to differentiate to a functional neuronal network consisting of neurons and glia cells that exhibit spontaneous electrophysiological activity on microelectrode arrays (MEAs). In summary, our assays represent an array of major neurodevelopmental key events and are a promising part of a modular DNT testing battery.

Comprehensive Gene Expression Analysis and Neurotoxicity Testing of Human iPSC-Derived Neural Progenitor Cells and Neurons

D. Yin. ATCC, Gaithersburg, MD.

Human induced pluripotent stem cells (iPSC)-derived neural progenitor cells (NPCs) and neurons are an attractive in vitro model to study neurodevelopmental, neurotoxicity and to model diseases. However, there is a lack of validated NPCs and media that support differentiation into multiple types of neurons for disease modeling, drug screening, and toxicity screening. Here, we investigated the expression of genes associated with the differentiation of NPCs during three weeks in dopaminergic differentiation media. Known early neuron markers, MAP2 and TuJ1 genes reached peak expression at two weeks while expression of dopaminergic neuronal genes (TH, Nurr1, VMAT2, AADC) was significantly increased in a time-dependent manner (p < 0.05) in two types of normal NPCs. Furthermore, expression of genes associated with GABAergic (GABRB3) and glutamatergic (VGLUT1, vGLUT2, GLS2) neurons was also induced and peaked at the end of three weeks. This suggests that our NPCs and dopaminergic differentiation media are capable of producing GABAergic and glutamatergic neurons, in addition to dopaminergic neurons. To validate that our NPCs and dopaminergic neuron differentiation media are suitable for drug screening, we conducted neurotoxicity screenings in three types of NPCs (non-reporter NPCs, MANo-NanocL-HaloTag reporter NPCs, and Parkinson’s disease NPCs) and NPCs-derived neurons using Reliable™ cell viability reagent assay and high content imaging analysis. We found that paclitaxel, a microtubule-stabilizing chemotherapeutic agent, significantly induced neurotoxicity (p < 0.001) in the three types of NPCs evaluated, but not in NPC-derived neurons. Vincristine, amiodarone, and chlorhexidine significantly decreased viability of both NPCs and neurons, whereas piperoxane, cisplatin, and hydroxyurea did not induce any significant neurotoxicity in either NPCs or neurons. This study demonstrates that our iPSC-derived NPCs and dopaminergic differentiation media are suitable for studying neurological development and neurotoxicity screening.

Development of a Dysmyelination Test to Study Developmental Neurotoxicity of Environmental Chemicals in a Human Brain Microphysiological System

M. Chesnutt, H. Hogberg, T. Hartung, and D. Pamies, Johns Hopkins Bloomberg School of Public Health, Baltimore, MD.

Neurodevelopment is highly sensitive to perturbations caused by environmental exposure. Disruption of myelin formation is a key neurodevelopmental event. Dysmyelination, or the failure to form or maintain myelin, can disrupt neuronal signal transmission, trigger degradation of axons, and lead to impaired cognitive function. Chemical disruption of myelin formation has been demonstrated in animal studies, but there are very few in vitro human cell-based models that have shown de novo myelination or classified chemicals using endpoints associated with myelination. Thus, there is a need to develop new methods that have the ability to evaluate myelination impairment as an endpoint for in vitro developmental neurotoxicity (DNT) testing. Our center has recently developed a reproducible human brain microphysiological system (BMPS) derived from induced pluripotent stem cells (iPSCs) that models key neurodevelopmental events, and the wrapping of axonal structures by oligodendrocyte processes was confirmed with confocal and electron microscopy. The objective of this study is to develop a test method which utilizes myelination as an endpoint for classification of developmental neurotoxicants in the BMPS. Using immunocytochemistry, we visualize the co-localization of myelin basic protein (MBP) and neurofilament (NF) and computer-assisted evaluation of myelin formation, we have been able to quantify axon myelination in BMPS. Preliminary data has also demonstrated that the organophosphate flame retardant DNT (1,3-dichloro-2-propyl) phosphate (TDCPP), Bisphenol A (BPA), and Cuprizone (CPZ), which have been demonstrated to cause dysmyelination in animal studies, cause dose-dependent reductions in myelin formation in BMPS at non-cytotoxic concentrations, indicating that the model has potential as a novel DNT test system to study dysmyelination.
We established a test system (finger maze test) for evaluating learning and memory ability in infant cynomolgus monkeys. The system using a puzzle as enrichment is an experimental method that evaluates learning and long-term memory in a relatively short time (5-week training phase, 2-day learning test, and 2-day memory test which is conducted 2 months after the learning test). In this study, we investigated 1) long-term memory retention capacity, 2) spatial cognitive ability, and 3) sex and age differences to expand the scope of finger maze test for pre-clinical learning and memorization researches. In Exp. 1, a memory test was conducted once every 2 months after the learning test to assess long-term memory retention capacity in 1-year-old infants. The success rate at the 2nd memory test (93.6% ± 4.0% mobility after learning test) was comparable to the learning test and 1st memory test (2 months after the learning test), suggesting the infants could memorize what they had learned 4 months ago and that long-term memory of over 4 months was assessable. In Exp. 2, an inverted version of the maze was used to examine if they had simply memorized the correct pattern or were using spatial cognitive ability to recognize the structure of the apparatus. Two months after the learning test, a 2-day memory test with the previously learned task (positive task) was conducted, and a memory test opposite to the previous learned (opposite task) was then conducted for 4 days. The time taken for the test was longer in the opposite task than the positive task (194 vs 274 sec) in Day 1 but the success rate was comparable (86.4% vs 80.0%). The duration for each test decreased over 4 days (274 to 101 sec) and the high success rate continued on Days 2-4 (92.1% to 95.0%). These results indicated that animals recognized the 3D structure of the maze and had the ability to carry out new tasks based on learned memories. In Exp. 3, the finger maze test was given to male and female monkeys of various ages (<1 year, <3 years, >5 years) to examine age and sex differences. Although all generations completed the learning and memory task without sex differences, young adults (<3 years) performed the best and had the shortest training periods. These results show that the finger maze test is useful for assessing short- and long-term memory in cynomolgus monkeys, since they have advanced spatial cognitive ability. The test could be applied to pre-clinical learning and memorization assessment.

N. Alugubelly1, M. J. Edelmann2, A. N. Mohammad1, B. Nanduri1, and R. L. Carr1. 1University of Florida, Gainesville, FL; and 2University of Florida, Gainesville, FL.

Organophosphorus insecticides (OPs) are the most widely used class of insecticides. Developmental exposure to OPs has long lasting negative impacts, including abnormal emotional behavior. These negative impacts of OPs are observed at levels that cause only minimum inhibiting effects of acetylcholinesterase, the canonical target of OPs. However, exposure to these levels results in the inhibition of endocannabinoid metabolizing enzyme fatty acid amide hydrolase (FAAH) but it is not clear what the long term effects of this inhibition are. In an study, the male rat pups were exposed orally to either corn oil, 0.75 mg/kg chlorpyrifos (CPF), or 0.9 mg/kg PF-04457845 (PF; a specific inhibitor of FAAH) daily from postnatal day 10 (PND10). The brain levels of FAAH were determined using a label free shotgun proteomic approach. The analysis determined FAAH levels against neurofilaments (NF), glial fibrillary acidic protein (GFAP), and myelin basic protein (MBP) were determined NAb (IgM and IgG) levels against neurofilaments (NF), glial fibrillary acidic protein (GFAP), and myelin basic protein (MBP) were determined. Multiregression modeling indicated anti-NF IgG were positively associated with indoor levels of MTBE, which is a byproduct of burning diesel fuel. Organic air pollutants are linked to the nervous system. The Mechanistic Indicators of Childhood Asthma (MICA) study in Detroit, Michigan used a participant-based approach for collection of indoor and outdoor residential air sampling data. This MICA-Air subset of participants conducted a residential sampling of VOCs which included: MTBE, hexane, styrene and BTEX (benzene, toluene, ethylbenzene, and m/p- and o-xylene) using Perkin-Elmer tubes packed with Supelco Carpack B adsorbent. Indoor samples were collected in the bedroom of the participating child. From these samples, blood of children (n=39; 9-13 years old) was collected on the day of their clinical visit, 24 hours after the sampling period. Serum NAb (IgM and IgG) levels against neurofilaments (NF), glial fibrillary acidic protein (GFAP), and myelin basic protein (MBP) were determined by ELISA. Results were analyzed non-parametrically for association with measured levels of a pollutant sources. IgM levels for NAb were inversely and significantly correlated with levels of VOCs. However, anti-NF IgG were positively associated with indoor levels of MTBE, Styrene and BTEX (r=0.25, p<0.02). Multiregression modeling indicated that indoor toluene was the major positive determinant of anti-NF, anti-GFAP and anti-MBP IgG titers (r²=0.2; p<0.05), while two or more BTEX constituents were significant determinants of anti-NF, anti-GFAP and anti-MBP IgG titers (r²=0.2-0.4; p<0.05). The discrepancy between nega-
tive individual pollutant associations with IgM and positive associations with IgG suggests Ig class switching and the development of immunological memory. However, it should be noted that children in this study also had heavy metal exposure, which may be a contributing factor in the NAB response, as previously reported. It should be noted that these associations were independent of the children’s asthma status, the focus of this study, and gender. While collected air samples do not reflect historical conditions, or internal dose, they do indicate exposure risk. These results further indicate that ambient indoor air pollutants impact on the nervous system, as indicated by NAB, in environmentally vulnerable populations. This abstract does not necessarily reflect US EPA policy.

**1432 Developmental Neurotoxicity Resulting from Pharmacotherapies Used in Preterm Labor, Modeled In Vitro**

F. J. Seidler, S. Skavicus, A. Ko, and T. A. Slotkin. Duke University Medical Center, Durham, NC.

Preterm labor is frequently treated with terbutaline (to inhibit uterine contractions) and dexamethasone (to promote fetal lung maturation), drugs that are suspected to have an adverse impact on fetal brain development. We evaluated these two agents, separately or together, for effects on critical stages of neurodevelopment in two cell models that simulate key decision points in neural development: the emergence of neurons and glia from embryonic neural stem cells (NSCs), and the selection of neurotransmitter phenotype in neurotypic PC12 cells undergoing neurodifferentiation triggered by nerve growth factor. In NSCs, terbutaline reduced cell numbers and diverted neurodifferentiation in favor of the formation of glia; these effects reflected actions at β-adrenergic receptors, since they were blocked by propranolol. The in vivo effects were developmental. We injected pregnant mice with terbutaline in vivo, which produces glial activation. Dexamethasone likewise reduced NSC cell numbers but in contrast, suppressed the formation of glia; dexamethasone also suppressed NSC differentiation into neurons, to a greater extent than its effect on glia. The combination of terbutaline + dexamethasone produced outcomes similar to those of dexamethasone alone. In the PC12 model, terbutaline suppressed the emergence of both dopamine and acetylcholine phenotypes; dexamethasone, on the other hand, enhanced the dopaminergic phenotype at the expense of the cholinergic phenotype. Again, treatment with both drugs produced an outcome resembling that of dexamethasone alone. Our results provide clear evidence that the drugs used in preterm labor have a direct, adverse effect on multiple stages of neurodifferentiation, but that the effects of dexamethasone are more profound than those of terbutaline and can override those of the β-agonist. Since both of these agents have been implicated in neurodevelopmental teratology, the present findings provide a potential underlying mechanism for epidemiological associations of these therapies with increased risk of learning disabilities and autism spectrum disorders. Supported by NIH ES010356.

**1433 Role of the Gut Microbiome on the Ontogenesis of the Enteric Nervous System**

S. Rodriguez González1, and B. Gulbransen2. 1University of Puerto Rico at Cayey, Cayey, PR; and 2University of Rochester Medical Center, Rochester, NY.

The enteric nervous system (ENS) is a complex network of neurons and glial cells organized in two plexuses that function to coordinate the gastrointestinal tract development occurring within a constantly changing environment, which, after birth, ends in the establishment of the gut microbiome. The gut microbiome has been linked with the development of the ENS and the physiology of the gut. However, how altering the microbiome affects the development of the ENS is not clear. We hypothesized that depleting the microbiome by exposure to antibiotics during prenatal and postnatal development impairs the maturation of the ENS. We will test our hypothesis by assessing the effects of antibiotics on the activity and anatomy of the ENS in mice expressing the genetically encoded calcium indicator GCaMP5g and the fluorescent reporter tdTomato in glia. Gial expression will be driven by crossing reporter mice Sox10CreERT2 mice. Pregnant females will receive an antibiotic cocktail in drinking water after breeding and throughout pregnancy. Control females will receive normal drinking water. Samples of the colon and ileum will be harvested from pups at postnatal days 1, 7, and 14 to image spontaneous activity of glial cells using GCaMP5g fluorescence. We will analyze the architecture of the ENS by imaging tdTomato fluorescence in neurons and glia. We anticipate that the results from our study will provide important insight into the effects of antibiotics on the neural control of the digestive tract.

**1434 Alterations in Developmental Serum Testosterone Concentrations and Adult Social Deficits Produced by Early-Life Exposure to Ultraviolet Particulate Matter**

Air pollution is a worldwide environmental health concern. Recent epidemiological evidence suggests that poor air quality may contribute to the etiology of sex-biased neurobehavioral disorders such as Autism Spectrum Disorders (ASDs). Our previous studies indicate that male, but not female, mice exposed during the neonatal period to concentrated ambient ultrafine particles (<100 nm diameter; CAPS) had significantly enlarged lateral ventricles, a characteristic of ASD and schizophrenia. Additionally, CAPS reduced corpus callosum size and corresponding myelin basic protein morphology in males, but not in females, with preliminary evidence suggestive of decreases in serum testosterone concentrations. To expand on these previous findings, neonatal mice were exposed to terbutaline (10-20 fold) ambient ultrafine particles using the Harvard Ultralfine Concentrated Ambient Particle System (HUCAPS). Twenty-four hours following the final exposure, P14 mice showed CAPS-induced reductions in serum testosterone, while no significant effects were seen in females. Furthermore, there were significant social behavior deficits in adulthood, with CAPS-exposed males showing significantly fewer nose-to-nose interactions with novel male mice, identified using the social novelty paradigm. Again, females showed no significant changes. Following another independent breeding and CAPS exposure, animals were tested for deficits in social behavior utilizing the social conditioned place preference paradigm. Again, CAPS-exposed males, but not females, showed deficits. CAPS males had significantly fewer entries into the social conditioned compartment, with increases in the isolation compartment. These data suggest that early development exposure to CAPS alters early endocrine signaling pathways, leading to lifelong social behavior, including social preference and communication. Taken together, these data represent three experimental studies that indicate CAPS produces developmental neuropathology, preferentially in males, that is consistent with features of sex-specific neurodevelopmental disorders like ASDs. Supported by R21 ES019105.

**1435 Influence of Genetic Background on Polychlorinated Biphenyl (PCB) Developmental Neurotoxicity**

S. Sethi1, K. P. Keil1, H. Lehmler1, J. N. Pessah1, and P. J. Lein1.

1University of California Davis, Davis, CA; and University of Iowa, Iowa City, IA.

The prevalence of many neurodevelopmental disorders (NDDs) is on the rise, and while there is strong genetic predisposition for many NDDs, there is evidence that environmental factors contribute to individual risk. PCBs have recently been identified as possible NDD risk factors. Experimental studies have shown that a subset of environmentally relevant PCBs may alter neuronal function by sensitizing receptor tyrosine kinases (RyRs), thereby modifying calcium-dependent signaling pathways important in activity-dependent dendritic growth. This study tested the hypothesis that neurodevelopmental outcomes following developmental exposure to PCBs are influenced by heritable mutations that alter the fidelity of Ca2+ signals. Transgenic mice expressing a human RyR gain-of-function mutation (T4826I-RyR1), the X-linked FMR1 CGG repeat expansion (170-200 repeats; CGG), or both mutations (DM), and congeneric wildtype (WT) mice were exposed to MARBLES PCB Mix at 0, 0.1, 1.0, and 6.0 mg/kg/day in the maternal diet throughout gestation and lactation. The MARBLES PCB Mix mimics the proportions of the top 12 PCB congeners found in the serum of mothers in high risk for having a child with a NDD. One male and female pup from each litter was examined at postnatal day (PND) 26-29 for grooming as a measure of repetitive behavior, and at PND 28-31 for sociability using an automated social approach assay. Genotype alone influenced outcome: Relative to sex-matched WT controls, T4826I-RyR1 and DM females spent significantly more time grooming, and the DM males and females exhibited decreased sociability as evidenced by failure to spend more time with a novel mouse compared to a novel object. PCBs significantly increased grooming in the 0.1 mg/kg group and increased social behavior in the 1.0 mg/kg group to the same extent as observed in DM mice. These findings suggest that (1) PCBs can cause NDD-relevant phenotypes but that the outcome is modulated by genetic background; and (2) sex differences in the prevalence and/or severity of NDDs may be due to sex-specific responses to environmental factors. Supported by NIEHS R01 ES014901, P50 and INP; T32 ES007059, SS; P01 ES013661, HUL; and NICHD (F32 HD088016, KPK).

Evolution of Autism Research: The Role of Environmental Health Sciences

A. C. Haugen, A. E. Garton, and C. P. Lawler. NIEHS, Research Triangle Park, NC. Sponsor: M. Humble

The phenotypic and genetic heterogeneity of Autism Spectrum Disorder (ASD) suggests both genetic and environmental factors are involved in its etiology. Xenobiotic contributors may impact gene expression via GxE interactions and epigenetic modifications, or even modify metabolic or immune pathways. To understand the current state of the science and evolution of environmental health science (EHS) research in ASD, a network analysis of the exposures, genes, and mechanisms investigated in over 20 years of grants funded by NIEHS—a major supporter of EHS research—was conducted. Temporal analysis reveals a diverse portfolio comprised, in the beginning, of projects researching a few metals (e.g., lead and mercury) as well as brominated (e.g., PBDEs) and chlorinated compounds (e.g., PCBs). Over time, the portfolio expanded to include a wide variety of xenobiotic exposures and endocrine disruptors as well as more recent categories like air pollutants. Many projects also considered the varied contexts of and pathways linked to health-related endpoints that include neurodevelopment and, eventually, also the immune system, metabolic disease, and the microbiome. Of about 140 genes, 29% are included in the SFARI gene list—a curated database of autism susceptibility genes. GO enrichment analysis of these genes reveals categories related to synapse assembly/potentiation, brain development, and social behavior. Further network analysis shows non-SFARI gene-connectedness to identified autism genes and is representative of researchers’ interest in genes not previously associated with autism. Many known response genes to environmental factors that interact with biological processes (e.g., oxidative stress, immune response, cell signaling). Furthermore, immune-related genes appear central in a co-occurrence network and connected to gene categories involved in metabolic disease, cell signaling, and synaptic function. Bipartite network analysis displays how these groups of genes most associate with studies on exposures such as pesticides, brominated compounds, metals, air pollutants, and hormonal mimics, several of which have produced key advances in environmental risk research on ASD. Finally, the results reflect the increasing understanding of the complexity of the genetic etiology of ASD, but also increased awareness of the toxicology community regarding a broad range of exposures that may impact neurodevelopment.

Building a Community: An Application of Social Network Analysis to Collaboration in NIEHS-Funded Environmental Autism Research

A. E. Garton, A. C. Haugen, and C. P. Lawler. NIEHS, Research Triangle Park, NC. Sponsor: M. Humble

Collaborative and interdisciplinary research is a vital strategy for translating environmental health research from observations in humans to mechanistic toxicology and impetus to future studies, as well as to health interventions and public health impacts. One way to measure and visualize collaboration is through co-author networks, which allow for the calculation of metrics that reflect the structure and dynamics of the network. In this analysis, environmental autism research is used as a rich case study in an area that has been prioritized for funding by NIEHS. This field includes multiple disciplines such as toxicology, epidemiology, and neuroscience as well as multiple posited exposures that may contribute to autism development, among them air pollution, heavy metals, and persistent organic pollutants. Using autism-related publications linked to NIEHS grants and co-author networks generated over time to demonstrate the growth of research in the field and integration of new groups within the network. We reviewed 208 autism-related articles published between 2004 and August 2017, with 540 unique authors. The analysis shows significant growth in both the number of publications and authors in this field since 2004. However, the network’s density, a measure of the overall connectedness of the network, has remained quite low over time. By 2016, the network showed nine weakly connected components: one large sub-network that is institutionally and regionally based, supported by multiple PIs, and eight smaller sub-networks headed by single PIs. It is clear that the network size and density have increased, and that these groups are publishing independently of each other, even in cases where they are working with similar models or on related toxicants. Specific individuals remain key gatekeepers of communication and act as bridges within and between groups, however, new authors and fields are beginning to play a larger role in the network. The incorporation of new authors and fields in the network reflects the active engagement by NIEHS and other funding organizations, e.g., targeted workshops, but the continued low density of the network may indicate that additional steps are warranted. This type of analysis could be used in other areas of toxicology to understand the growth of and opportunities for interdisciplinary collaboration.

Neonatal Hyperoxia Followed by Concentrated Ambient Ultrafine Particle Exposure Leads to Cumulative Learning Deficits in C57Bl/6J Mice

Advances in neonatal care have drastically increased the survival of preterm infants, who are exposed to a unique set of environmental conditions during a vulnerable stage of neurodevelopment. The etiology of neurodevelopmental disorders is multifactorial and includes genetic and environmental factors. The polycomb gene complex, which includes Rbfox3, Dnmt1, and Dnmt3a, is critical for neurodevelopment in the central nervous system of animals and may also affect neurodevelopment in humans. A previous study showed that mice exposed to a single episode of hyperoxia and CAPS (cerebellar peduncle-ablated pups) exhibited deficits in multidimensional learning compared to WT mice exposed to hyperoxia followed by CAPS. This study aimed to determine the cumulative effects of hyperoxia followed by CAPS at different time points, as well as the effects of exposure to ambient ultrafine particles (CAPS). Hyperoxia exposure impaired multidimensional learning as early as 2 days of age, and CAPS exposure at 3 days of age. The combination of hyperoxia and CAPS exposure led to cumulative learning deficits in C57Bl/6J mice. These results suggest that exposure to ambient ultrafine particles may impact neurodevelopment, and that further research is needed to understand the mechanisms underlying these effects.
deficits on an extinction paradigm in which reinforcement was subsequently withheld. Further elucidation of specific behavioral and pathological underpinnings of the unique effects of the combined insults will provide important insights into the potential for enhanced adverse outcomes in premature infants exposed to air pollution.

**1440 Combined Neurodevelopmental Pyrrolizidine Pesticide and Stress Hormone Exposure in Mice Affects the Dopaminergic Pathway in ADHD**

A. Vester, C. J. Marsit, and W. M. Caudle. Emory University, Atlanta, GA.

Attention-Deficit Hyperactivity Disorder (ADHD) is one of the most common neurodevelopmental disorders, with the dopamine circuit playing a critical role in disease etiopathogenesis. While genetic variation contributes to incidence of ADHD, more recent work identifies exposure to environmental toxicants, specifically pyrethroid insecticides, as a neurodevelopmental risk factor. These findings are in line with our previous work, which shows neurodevelopmental exposure to deltamethrin (DM) is associated with changes in pre- and postsynaptic dopaminergic signaling and ADHD-like hyperactivity and inattention behaviors in a mouse model. In addition to elevated pesticide exposure, children of low socioeconomic status have higher levels of stress hormones, which can affect the dopamine circuit. ADHD is also more prevalent in low socioeconomic status groups. While these exogenous risk factors intersect at the dopamine circuit, their potential interaction has not been evaluated. Thus, we hypothesized that combined exposure to DM and the stress hormone corticosterone (CORT) would result in additive molecular, behavioral, and epigenetic effects in the dopamine system compared to each individual exposure. In our study, C57/Bl6 pregnant dams were exposed to 3 mg/kg DM during gestation and lactation until weaning of offspring at postnatal day (PND) 21. Thereafter, offspring were exposed to 25 mg/mL CORT in their drinking water until adulthood at PND 60. Controls included vehicle-only, DM-only, and CORT-only groups. Alterations to dopamine signaling in male and female offspring were evaluated by neurobehavioral, neurochemical, and epigenetic assessments focused on elucidating dysfunction in pre- and postsynaptic elements of the dopamine circuit. Results show that dual exposure to DM and CORT during neurodevelopment is associated with alterations in expression and function of critical dopaminergic synaptic proteins in the striatum accompanied by deficits in ADHD-relevant neurobehaviors. This is the first study to a) examine the combined effects of two environmental exposures that affect the dopamine system in the context of ADHD and b) integrate both epigenetic and molecular alterations with neurobehavioral assessments in a mouse model. Results from this study indicate that it is imperative to study multiple neurodevelopmental exposures at once to elucidate pathophysiological mechanisms of ADHD.

**1441 Gene Environment Interaction in 3D iPSC-Derived Autism Model**

Autism is a main concern of developmental neurotoxicity. The recent dramatic increase of autism cannot be explained solely by genetics or exposure to environmental chemicals, but rather as interplay between environmental toxicants, specifically pyrethroid insecticides, as a neurodevelopmental risk factor. These findings are in line with our previous work, which shows neurodevelopmental exposure to deltamethrin (DM) is associated with changes in pre- and postsynaptic dopaminergic signaling and ADHD-like hyperactivity and inattention behaviors in a mouse model. In addition to elevated pesticide exposure, children of low socioeconomic status have higher levels of stress hormones, which can affect the dopamine circuit. ADHD is also more prevalent in low socioeconomic status groups. While these exogenous risk factors intersect at the dopamine circuit, their potential interaction has not been evaluated. Thus, we hypothesized that combined exposure to DM and the stress hormone corticosterone (CORT) would result in additive molecular, behavioral, and epigenetic effects in the dopamine system compared to each individual exposure. In our study, C57/Bl6 pregnant dams were exposed to 3 mg/kg DM during gestation and lactation until weaning of offspring at postnatal day (PND) 21. Thereafter, offspring were exposed to 25 mg/mL CORT in their drinking water until adulthood at PND 60. Controls included vehicle-only, DM-only, and CORT-only groups. Alterations to dopamine signaling in male and female offspring were evaluated by neurobehavioral, neurochemical, and epigenetic assessments focused on elucidating dysfunction in pre- and postsynaptic elements of the dopamine circuit. Results show that dual exposure to DM and CORT during neurodevelopment is associated with alterations in expression and function of critical dopaminergic synaptic proteins in the striatum accompanied by deficits in ADHD-relevant neurobehaviors. This is the first study to a) examine the combined effects of two environmental exposures that affect the dopamine system in the context of ADHD and b) integrate both epigenetic and molecular alterations with neurobehavioral assessments in a mouse model. Results from this study indicate that it is imperative to study multiple neurodevelopmental exposures at once to elucidate pathophysiological mechanisms of ADHD.

**1442 Role of Benzyl Salicylate in the Development of Autism**

A. G. Ransom, and O. Bagasra. Claflin University, Orangeburg, SC. Sponsor: A. Baines

Benzyl salicylate is a naturally occurring compound found in plants and plant extracts. It is often a major ingredient in numerous cosmetic products and serves as a fragrance/tick agent in food. It is commonly used as a fragrance additive/solvent and UV light absorber. The International Fragrance Association has placed a restriction on its use in consumer goods due to risk of causing sensitization and allergic reactions. Benzyl salicylate is an endocrine disruptor and is suspected to be an environmental toxin. Overall, studies confirm it is a known human immune system toxicant or allergen. It is hypothesized that if found present in the blood-stream of a pregnant adult female, benzyl salicylate could potentially cause damage to the developing brain of a fetus. This investigation examined the effects of various concentrations of benzyl salicylate on the neurons of two neuroblastoma cell lines, CRL-2266 and CRL-2267, which served to represent a developing fetal brain. The cell lines were extensively analyzed for any morphological abnormalities in comparison to a control group. These abnormalities included deviation in axonal length, central chromatolysis, synctia formation, and axonal degeneration. Analyses indicated that neurons from both male and female cell lines that were exposed to benzyl salicylate underwent substantial modifications, specifically synctia formation (P<0.0248) and chromatolysis (P<0.0444). It was concluded that exposure to benzyl salicylate could potentially cause serious neurological damage to a developing fetal brain and therefore possibly lead to autism development.

**1443 Does Raising Perinatal Serotonin Availability Rescue Sociability via Oxytocin Signaling in the BTBR Mouse Model of Autism?**

Autism is a lifelong disorder with prominent social behavior deficits and exaggerated restrictive-repetitive habits that confers staggering costs for families and to society. Clinical and basic research evidence suggests that serotonin (5-HT) system dysfunction or low 5-HT availability in brain contribute to the etiology of some forms of autism, which may underlie social behavior impairments. Recent studies have shown that 5-HT availability in fetal brain depends more on available maternal tryptophan (TRP), the precursor to serotonin. Given this, we hypothesized that either maternal dietary TRP supplementation or administration of a selective serotonin reuptake inhibitor such as Prozac (fluoxetine) that inhibits 5-HT transporters (5-HT Transporter) during gestation/lactation could potentially protect a developing fetal brain otherwise at risk of developing autism. To test this, we utilized black and tan brachyury tufted (BTBR Itpr3T+/tf) mice, as the strain exhibits dominant and reliably hereditary impaired social interactions and restricted behavior phenotypes that persist across their lifespan; impaired serotonin system development and function is also evident in this strain. BTBR mouse dams were administered diets either with control TRP levels (2.1 g/kg, daily requirement for mic) or 5X enhanced TRP (12.6 g/kg) throughout pregnancy/lactation. While it is still early in the study and data collection is strongly perturbed by CPF in CHD8+/− organoids vs. CHD8+/+ control. Perturbation of WNT/beta-Catenin pathway was previously shown to be associated with CHD8 mutation. Beta-Catenin level was induced by both CHD8 mutation and CPF exposure, while GSK3β was similar in both lines. Oxidative stress was higher in CHD8−/− organoids and was further induced by CPF exposure. Thus, we identified a potential synergy of CHD8 mutation and the pesticide CPF in perturbation of neural development and functions. Further experiments are being conducted to identify molecular mechanisms of potential synergy between CHD8 genetic background and chlorpyrifos exposure.

KO organoids. In addition synaptogenesis and neurite outgrowth were strongly perturbed by CPF in CHD8−/− organoids vs. CHD8+/− control. Perturbation of WNT/beta-Catenin pathway was previously shown to be associated with CHD8 mutation. Beta-Catenin level was induced by both CHD8 mutation and CPF exposure, while GSK3β was similar in both lines. Oxidative stress was higher in CHD8−/− organoids and was further induced by CPF exposure. Thus, we identified a potential synergy of CHD8 mutation and the pesticide CPF in perturbation of neural development and functions. Further experiments are being conducted to identify molecular mechanisms of potential synergy between CHD8 genetic background and chlorpyrifos exposure.
spring of fluoxetine treated dams have significantly greater preference for social interaction than saline treated dams (p<0.05, N=3-5). Behavior data from male offspring of fluoxetine treated dams haven’t been analyzed yet. Male burying data showed no significant changes in restrictive repetitive behaviors among groups.

1445 Quantitative Measurement of Neural Autoantibodies to Map-2, Tau, Tubulin, and Gfap Proteins by Elisa in the Seria of Patients with Gulf War Illness (GWI)

M. V. Brahmajothi1, L. A. Conboy2, E. Kokkotou3, K. Sullivan3, N. Klimas1, and M. B. Abou-donia1. 1Duke University Medical Center, Durham, NC; 2Harvard Medical School, Boston, MA; and 3NOVA Southeastern University, Davie, FL.

For Gulf War Veterans (GWW), the effects of war continued long after they returned home. In addition to the psychological ramifications, veterans and civilian workers showed exacerbated effects of medically unexplained chronic multi-system disorders. The causality of illness may be due to the compounds they were exposed to, which include acetylcholine (ACh) or modulate the pharmacokinetics of substances that control the metabolic activation or breakdown of ACh inhibitors. Such compounds include chloropyrifos, sarin, sulfur sarin, sulfur mustard, pyridostigmine bromide, DEET, opiates as therapeutics and the enzymes responsible for drug metabolism such as cytochrome P450 reductases, liver microsomal oxidases, etc. Inaccessibility of the nervous system has impeded the evaluation of cellular and molecular changes that result in neurodegeneration. Discharges of neural proteins during this process can induce autoimmune response that can be measured by novel biomarkers.

When we screened for novel nervous system biomarkers in the sera of GWVs from our pilot study, we found 2 to 9 fold increase of autoantibodies to the neuronal specific proteins. We have now developed ELISA to determine and quantitate serum autoantibodies against microtubule associated proteins (MAP-2), microtubule associated protein tau (Tau), tubulin and glial fibrillary acidic protein (GFAP). This method quantitatively distinguishes IgG levels of the autoantibody titers at 0.1 microgram level of the specific neuronal proteins. Determination of specificity was achieved by absorption studies to estimate the threshold level. We performed dose response to determine the optimum concentration of each protein. Supported in part by DOD Contract No. W81XWH-15-1-0641.

1444 Manganese (Mn) Exposure Differentially Alters Expression of SLC30A10 and S100A9 in a Mouse Model of Huntington’s Disease

J. M. Wilcox, A. C. Pfaffer, J. Sepulveda, S. Magee, and A. B. Bowman, Vanderbilt University, Nashville, TN.

Huntington’s Disease (HD) is an autosomal dominant neurodegenerative disorder resulting from an expanded CAG repeat in the Huntingtin (Htt) gene. Despite its monogenetic etiology environmental factors strongly modify age-of-onset and progression. Mn is an essential nutrient and co-factor for several enzymes regulating antioxidant status, urea cycle metabolism, and neurotransmitter synthesis. In vitro and in vivo models of HD have demonstrated reduced Mn bioavailability in the brain suggesting significant perturbations in Mn biology. To understand differences in the transcriptional response to Mn exposure, male and female YAC128Q (HD) mice as well as wild-type (WT) littermates were given a single subcutaneous injection of 50 mg/kg MnCl2•(H2O)4 and sacrificed immediately, 1 hour (h), 4 h, 12 h, or 24 h after. Select brain regions (cortex and striatum) and spleen were collected at each time point, and mRNA expression of Mn responsive genes by qRT-PCR and oxidative stress markers (WT only). The Mn-transporter SLC30A10 and S100 calcium binding protein 9 (S100A9) were differentially expressed after Mn exposure in WT animals only. In the cortex, SLC30A10 mRNA was downregulated 15% 12 h post injection (p = .0032) while there was no change for HD mice. Interestingly, basal cortical SLC30A10 mRNA was significantly lower in HD compared to WT (p = .048), S100A9 was upregulated 16% by 4 h post injection (p = .043) and 36% by 12 h post injection (p = .0002) in WT cortical tissue. However, in HD cortical tissue, S100A9 increased 8.18% only at 1 h post injection (p = .032). In the striatum, S100A9 increased 30% in WT mice 12 h post injection (p = .0032) while there was no change for HD mice. Similarly, hepatic S100A9 increased 24% 1 h post injection (p = .026) and sustained a 18% increase 4 h post injection (p = .0231) in WT mice with no significant changes in HD mice. These Mn-induced transcriptional alterations occurred without inducing oxidative stress (measured by thiobarbituric acid reactive substances, total glutathione, and vitamin C levels). The differential transcriptional response to Mn in HD compared to WT provides further evidence that Mn biology plays a critical role in the pathophysiology of HD. Supported by NIH T32 ES7028 (JMW, ACP, ABB) and RO1 ES016931 (ABB).

1446 Biomarkers for Chronic Fatigue Syndrome (CFS) and Irritable Bowel Syndrome (IBS) Compared to Gulf War Illness (GWI) in Gulf War Veterans

M. B. Abou-Donia1, M. V. Brahmajothi1, L. A. Conboy2, E. Kokkotou3, E. Jacobson2, N. Klimas3, and K. Sullivan4. 1Duke University Medical Center, Durham, NC; 2Harvard Medical School, Boston, MA; 3NOVA Southeastern University, Davie, FL; and 4Boston University, Boston, MA.

Approximately one third of the American military personnel who served in the Gulf War from August 1990 to June 1991 experienced chronic symptoms of GWI. Other Gulf War Veterans’ illnesses included CFS and IBS. CFS is characterized by debilitating fatigue, unrestful sleep, neuropsychological decrements and chronic pain. IBS is characterized by recurrent abdominal pain and bowel difficulties. In the present study, we used our newly developed biomarkers using western blot assay to screen serum for the presence of autoantibodies (AA) against the following neural proteins: neurofilament triplet proteins (NFNP), tubulin, microtubule associated tau protein (tau), microtubule associated protein-2 (MAP-2), myelin basic protein (MBP), myelin associated glycoprotein (MAG), calcium-calmodulin kinase II (CaM-II) and glial S100 protein. Serum reactivity was measured as arbitrary chemiluminescence units. The study included 50 CFS, 50 IBS, 68 GWI and 26 non-veteran asymptomatic served as controls. None of the patients showed any significant increase in AA against S100B. Patients with CFS showed statistically significant increase in AA only against four proteins over controls, presented in descending order: MAP-2 (2.90) > GFAP (2.88) > Tubulin (2.05) > CaMkII (1.51) > MBP (1.48) > SNCA (1.42) > NFP (1.21) > MAG (1.176) > Tau (1.04). IBS patients exhibited the following pattern: MAG (3.20) > MBP (3.19) > S100CL (1.39). GWI patients showed the following pattern: MAP-2 (4.81) > MBP (3.93) > NSF (3.63) > Tubulin (3.48) > Tau (3.17) > MAG (3.14) > S100CL (3.03) > GFAP (2.68) > CaMkII (2.48). These results showed that patients with CFS and IBS have less levels of AA against fewer neural proteins, indicating that the levels of AA against neural proteins in these patients are at the threshold levels that accompany brain injury in contrast to patients with GWI and in agreement with absence of neurological symptom complaints in these patients. Supported in part by DOD Contract No. W81XWH-15-1-0641.

1447 Copper-Induced Upregulation of miRNA Directs the Suppression of Endothelial LRPL1 in Alzheimer’s Disease

Reduced expression of low density lipoprotein receptor-related protein 1 (LRP1) in brain capillary with age is one of putative risk factors for the pathological buildup of Aβ in the brain and development of Alzheimer disease (AD). The exact mechanism of accelerated loss of LRPL1 in the brain capillary, however, remains unanswered. We and others have previously reported that copper-mediated downregulation of LRPL1 was proteasome-dependent, while the pro-inflammatory cytokine-induced loss of LRPL1 was proteosome- or lysosome-independent. In this study, we extended our investigation to examine whether microRNA, a small non-coding RNA involved in post-transcriptional modifications, mediates the repression of endothelial LRPL1. Three putative microRNAs, miR-205-5p, miR-200b-3p and miR-200c-3p, targeting LRPL1 mRNA were found to significantly increase in human primary microvascular endothelial cells (MVECs) after copper or IL-1β exposure. Application of these microRNA mimics to MVECs alone significantly reduced LRPL1 levels, and pharmacological inhibition of these microRNAs effectively reversed the loss of LRPL1 by copper or IL-1β. In J20 AD mouse model of AD, we found that 1.3 ppm copper drinking water for 9 months developed a marked reduction of LRPL1 in brain capillaries and increased amyloid-β burdens when compared to control J20 mice. Taken together, our findings support the pathological impact of copper-induced inflammatory responses and Aβ clearance in the brain, at least in part, by upregulating microRNAs miR-205-5p, miR-200b-3p and miR-200c-3p and further down-regulating endothelial LRPL1. Our findings provide a possible underlying mechanism by which environmental risk factors contribute to the development of AD neuropathology.
Alzheimer's disease (AD), the most common neurodegenerative disorder and disproportionately affects females, with >60% of those diagnosed with AD being female. Pathologically, AD is characterized by amyloid-beta (Aβ) plaques and neurofibrillary tangles (NFTs). Aβ plaques are comprised of extracellular aggregates of peptide fragments (Aβ38, Aβ40, Aβ42), sequentially cleaved by secretases from the amyloid precursor protein (APP). NFTs are formed by the aberrant phosphorylation and folding of the microtubule associated protein tau (MAPT). Though aging, family history, and the APOE ε4 genotype have been shown to play prominent roles in AD risk, little is known about environmental contributions to disease etiology. As such, a multitude of environmental and biological factors are likely important in astrogliosis of late-onset AD. Previously, we identified that serum levels of dichlorodiphenylchloroethylene (DDE), a metabolite of the pesticide dichlorodiphenyltrichloroethane (DDT), was significantly higher in the serum of patients compared to age-matched controls. These results suggested that DDT may be a potential risk factor for AD. Early acute studies indicated a high concentration of DDT decreased oxidative respiration in isolated rat heart and liver mitochondria. However, little is known about the effects of DDT on mitochondrial bioenergetics in the brain. Thus, the aims of the present study were to determine the role of DDT in the brain and to delineate the potential impact of increased Aβ burden on mitochondrial bioenergetics. Mitochondria exert a wide variety of cellular functions including generation of ATP by oxidative phosphorylation, secretion of cytokines, and detoxification of reactive oxygen species. Mitochondrial dysfunction has been widely implicated in neurodegenerative diseases such as Alzheimer's disease (AD) and Parkinson's disease. Previously, we reported significantly higher levels of dichlorodiphenylchloroethylene (DDE), a persistent metabolite of the pesticide dichlorodiphenyltrichloroethane (DDT), in the sera of AD patients compared to age-matched controls. This work provides insight into potential mechanisms that may contribute to the association between DDT exposure and increased risk of AD. Supported in part by NIH R01ES026057.

**1448 Sex-Specific Effects on Alzheimer's Disease-Related Proteins after Exposure to DDT in 3xTG Mice**

Northeast Ohio Medical University, Rootstown, OH.

Alzheimer’s disease (AD), one of the most debilitating neurological diseases that impair sensory, motor, as well as cognitive functions. An early detection method for AD has gained tremendous importance recently. An exploration of olfactory pathway alterations at sequential stages of plaque deposition in rodent model potentially describes a spatiotemporal pattern of Aβ deposition related to early olfactory loss. In the present studies a styrylbenzene derivative, fluoro-styrylbenzene (FSB) was used to detect amyloid plaques and Fluoro Jade C (FJC) was used to detect degenerating neurons in the olfactory bulb (OB) of Tg AD rats ranging from age 4-20 months. FSB has the affinity to stain both amyloid plaques and tangles in the human AD brain. Non-Tg rats did not show any amyloid plaques or FJC degenerating neurons. At 4 months of age, very few nonfibrillar amyloid plaques were seen in the olfactory bulb and 1-2 amyloid plaques were observed in the piriform cortex in a 25 um coronal section, however, at 6 months of age, moderate amount of plaques in the Tg AD rats were confined to the olfactory nerve layer (ONL). Neurons were more involved in the ONL compared to the olfactory bulb and piriform cortex. Axonal degeneration was seen in the glomerular layer of the OB, but not in the hippocampal CA1 or CA3 regions. In aged Tg AD rats, FSB stained fewer amyloid plaques and tangles. At 20 months, FSB stained fewer amyloid plaques and tangles. At 20 months, FSB stained fewer amyloid plaques and tangles. Thus, these results demonstrate that DTT causes mitochondrial dysfunction in cultured primary astrocytes at relatively low concentrations. These data further suggest that greater cognitive deficits may be observed in the aged as compared to adult mice. Supported by NIH R01ES026057, R01ES027481, and R01ES021800.

**1449 Age-Related Hippocampal Vulnerability to Adult Neurogenesis following Pyrethroid Exposure**

M. M. Hossain, R. Rabbani, and J. R. Richardson.
Northeast Ohio Medical University, Rootstown, OH.

Over 16 million people in the United States are living with cognitive impairment (CDC, 2009). Environmental factors, including pesticide exposure, are thought to be significant contributors to neurodegeneration and cognitive dysfunction in some populations. There is growing evidence that adult neurogenesis in the hippocampus is important for learning and memory. Recent studies demonstrate that adult born neurons in the dentate gyrus (DG) in the hippocampus can functionally integrate into the existing neuronal circuitry and contribute to hippocampal-dependent learning and memory. Furthermore, disruption of adult neurogenesis can lead to deficits in hippocampal-dependent learning and memory. We previously reported that repeated exposure to deltamethrin resulted in reduction of progenitor cell proliferation in the DG of hippocampus and learning deficits in young mice. Here, we examined the impact of age on hippocampal neurogenesis in mice of different ages following deltamethrin exposure compared to age-matched control. Data revealed that deltamethrin decreased bromodeoxyuridine (BrdU)-positive cells in the DG of the hippocampus by 39% in young (3 month-old), 45% in adult (6 month-old), and 70% in aged (13 month-old) mice, while Ki67+ cells was reduced by 47% in young, 45% in adult and 67% in aged mice, indicating potential impairment of cellular proliferation. In addition, deltamethrin exposure decreased the number of nestin-expressing neural progenitor cells by 44% in young, 49% in adult, and 62% aged mice. Together, these findings suggest that deltamethrin-induced disruption of hippocampal neurogenesis is a significant contributor to the magnitude of deltamethrin-induced disruption of hippocampal neurogenesis. Based on the importance of hippocampal neurogenesis in the regulation of cognitive function these data further suggest that greater cognitive deficits may be observed in the aged as compared to adult mice. Supported by NIH R01ES026057, R01ES027481, and R01ES021800.
1452 Downregulation of 14-3-3 Protein Levels in an Animal Model of Neurodegeneration and in Human Alzheimer’s Brains

The 14-3-3 proteins are among the most abundant proteins expressed in the brain, comprising about 1% of its total soluble proteins. They bind to specific phospho-serine and phospho-threonine-containing motifs found on a variety of signaling proteins (kinases and transcription factors, among others) to regulate a wide array of cellular processes including cell cycling, apoptosis, and autophagy. We have examined the expression of 14-3-3 and its different isoforms in frontal cortex of kainic acid-treated and control rats, as well as in frontal cortex of post-mortal Alzheimer’s disease (AD) patients and age-matched control subjects. Among the different 14-3-3 isoforms in control rats, the relative abundance of expression is in the following order: 14-3-3-eta > tau > a > gamma > b > d > e > delta; whereas in human control samples the sequence of relative abundance is 14-3-3-eta > gamma > tau > epsilon > sigma > zeta/delta > alpha/beta. While 14-3-3-eta is the most abundant isoform in both rat and human frontal cortex, its relative proportion among all the isoforms is less than 50% in rat but nearly 90% in human, suggesting a more predominant role for it than all other 14-3-3 isoforms in human frontal cortex. Twenty-four hours following a kainic acid injection (10 mg/kg i.p.), there was a significant decrease in the total protein levels of 14-3-3 as well as the isoforms eta, tau, epsilon and gamma, when compared to those in control animals. AD samples, there was a significant decrease in total 14-3-3 levels and the eta and gamma isoforms, and no difference in 14-3-3-tau levels between AD and control brains. Together, these results demonstrate an abundance of several 14-3-3 isoforms in the frontal cortex and that a downregulation of total 14-3-3 protein levels and specific 14-3-3 isoforms is associated with neurodegeneration. Given the known function of 14-3-3 proteins as inhibitors of apoptosis, the observed decreased levels of 14-3-3 proteins could be early molecular events leading to increased activities in cell death signaling and eventually neurodegeneration. Based on these results and available evidence from other neurodegenerative diseases and animal models, 14-3-3 proteins may serve as an early biomarker of neurodegeneration and a potential target of therapeutic intervention for neurodegeneration.

1453 Effects of the mGluR Agonist CHPG in a Mouse Model of Alzheimer’s Disease

T. M. Planas-Fontanez1,2, J. Z. Honeywell2, and C. F. Dreyfus2.
1Rutgers, The State University of New Jersey, Piscataway, NJ; and 2Robert Wood Johnson Medical School, Piscataway, NJ.

Previous work in our laboratory indicated that stimulation of metabotropic glutamate receptors (mGluRs) by injection of the agonist ACPD or 2-Chloro-5-hydroxyphenylglycine (CHPG) elicits an increase in myelin proteins and BDNF (brain derived neurotrophic factor) following a cuprizone elicited demyelinating lesion (Fulmer et al., 2014 and personal communication). More recently, we found that this effect of CHPG can also be elicited by an intraperitoneal (i.p.) injection to a cuprizone treated mouse. Based on the neuroprotective effects of CHPG observed in the demyelination model, we sought to determine if mGluR agonists could have similar protective effects in an Alzheimer’s Disease (AD) mouse model, in which pathologies include neuronal and oligodendrocyte degeneration. Levels of BDNF and myelin proteins were measured in triple transgenic (3xTg) AD and control brains at several stages of development. Examination of the basal forebrain (BF) demonstrated that at 12 months 3xTg-AD mice exhibit a significant decrease in BDNF compared to control mice as well as a decrease in the myelin proteins myelin basic protein (MBP) and myelin associated glycoprotein (MAG). These deficits were reversible after administration of exogenous BDNF (0.5ug/ul) into the lateral ventricle. To determine if the myelin proteins and BDNF would also be reversed by an i.p. injection of CHPG, we injected CHPG (40 mg/kg) three times a week for one week. Statistically significant increases in BDNF (257%), MAG (172%) and MBP (167%) were detected in the BF of 3xTg-AD mice suggesting that a similar mechanism is present in mice with an ongoing demyelinating lesion in pituitary; however, in the presence of an ongoing demyelinating lesion, it is possible that the effects of CHPG are not as pronounced. These studies suggest that CHPG may have a protective effect on demyelination in multiple models of neurodegeneration. Future experiments will assess the role played by BDNF and provide an understanding of the cellular mechanisms underlying these effects. Furthermore, these results may shed light on a feasible therapeutic approach to control the progression of AD. Mice were provided by F. LaFerla (UC Irvine); Supp. NIH HD23315 and NS036647.

1454 The Metabotropic Glutamate Receptor Agonist 2-Chloro-5-Hydroxyphenylglycine (CHPG) Increases BDNF and Myelin Proteins after Cuprizone-Induced Demyelination

K. S. Saitta1,2, L. D. Lercher2, Y. Huang2, and C. F. Dreyfus2.
1Rutgers, The State University of New Jersey, Piscataway, NJ; and 2Robert Wood Johnson Medical School, Piscataway, NJ.

Treatment with the demyelinating agent cuprizone causes a decrease in brain-derived neurotrophic factor (BDNF) and myelin proteins with an upregulation of metabotropic glutamate receptors (mGluRs) within the lesion site. Similarly, many patients with multiple sclerosis not only have a decrease in myelin proteins, but also have enhanced expression of mGluRs within active chronic lesions and decreases in BDNF. Therefore, an intriguing therapeutic approach for these types of demyelinating diseases may be to enhance the endogenous source of BDNF. The aim of this study was to enhance endogenous BDNF through the selective mGluR Group I agonist CHPG by using the clinically relevant approach of a peripheral injection. Cuprizone or identically processed control feed was fed to mice for 4 or 6 weeks prior to intraperitoneal (ip) injections of saline or CHPG (20 or 40 mg/kg). Western blot was used to analyze the levels of BDNF, myelin proteins, and oligodendrocyte progenitor cell (OPC) markers after cuprizone treatment. CHPG increased levels of BDNF and myelin proteins 24 hours after injection. Cuprizone also caused an increase in OPC markers NG2 and PDGF-Rα, which were reduced by 40 but not 20 mg/kg CHPG. Interestingly, CHPG did not alter these proteins or myelin proteins in control-fed mice. Furthermore, preliminary data suggests that BDNF and myelin proteins remain elevated following ip injections of CHPG every other day for 2 weeks, suggesting that CHPG’s effects are maintained over time. To begin to elucidate the receptor responsible for CHPG’s actions, the selective mGluR5 antagonist 2-methyl-6-(phenylethynyl)pyridine (MPEP) was injected directly into the lesion site prior to ip injection of CHPG. When MPEP was injected with ip CHPG myelin proteins or BDNF were not enhanced. Preliminary data indicates that these effects are reduced when MPEP is administered before CHPG, suggesting both a role of mGluR5 in mediating the actions of CHPG and that CHPG injected peripherally acts within the lesion site. Taken together, these data suggest that selective mGluR Group I agonists such as CHPG may be a therapeutic approach for treating demyelinating diseases by increasing the levels of BDNF and myelin proteins. Supported by NIH NS0336647, T32ES0507148, F31NS098642 and NMSS RG 425784/1.

1455 Med64-Quad II System Accelerates the Studies of the Roles of NMDA Receptor in Synaptic Plasticity and Epileptogenesis in Acute Mouse Hippocampal Slice

S. Yasuoka1, R. Avant2, and G. Cheng2.
1Alpha MED Scientific Inc., Osaka, Japan; and 2Alpha MED Scientific Inc., Berkeley, CA. Sponsor: Lantz

Micro-electrode arrays (MEAs) have been widely utilized to measure neuronal activities in vitro. The MEA technology offers many unique advantages to investigate neuronal circuitry, interaction, models of learning and memory, development, aging, disease and neurotoxicity. While several high-throughput platforms have been utilized for drug screening with cultured cell applications in recent years, there have been limited platforms designed for acute slice applications. Here we present the capabilities of the highly sensitive Med64-Quad II system, a novel medium-throughput MEA designed specifically for acute or cultured slice applications. We demonstrate the reliability and reproducibility of inducing LTP and spontaneous spike recording simultaneously in 4 acute hippocampal slices from 6-7 weeks old male ICR strain mice. Following theta burst stimulation, amplitude and slope were monitored for an additional 60 minutes. Pretreatment of NMDA receptor antagonist APV at 50uM in bath solution blocked LTP development. Bath application of NMDA at 10uM produced transient depression of fEPSP rather than enhancement of fEPSP. NMDA induced synchronized burst. The synchronized burst was inhibited by APV. NMDA induced synchronized burst can be useful as a cellular epilepsy model to study epileptogenesis and NMDA receptor can be a therapeutic target for epilepsy treatment. The results indicate that Med64-Quad II system can accelerate LTP mechanism study, studies for epilepsy disease model and therapeutic drug discovery. This system provides a useful tool for disease model research, drug discovery, target validation, compound screening for antiepileptic drug targets and pharmacological studies in acute brain slice applications in vitro.

2018 SOT Annual Meeting
Glutamate is one of the major neurotransmitters in the central nervous system where it binds and activates ligand-gated ion channels and metabotropic glutamate receptors. Glutamate-evoked excitotoxicity plays a role in neuropathological conditions including ischemic stroke (IS) and traumatic brain injuries (TBI), and has been implicated in the etiology of degenerative diseases such as Alzheimer’s disease (AD), and Parkinson’s disease (PD). There are currently no cures for these conditions. Therefore, drugs with the potential to cure these diseases or delay their onset are highly desirable. In this study, we developed an automated high throughput screen (HTS) cell based assay to screen a collection of highly diverse chemical molecules to identify compounds which would inhibit HT22 cells from glutamate toxicity. Cells were treated with cell-permeable compound (HT22) to convert to resazurin, a non-fluorescent molecule to resorufin, a highly red fluorescent compound in a variety of cells, including HT22. We validated the assay by screening accleration of 1280 compounds in the Prestwick library of pharmacologically active compounds. A total of 25 compounds were identified as actives in the primary screen. These compounds are currently undergoing confirmation. In addition, we screened a library of Kinase inhibitors consisting of 32 chemical molecules in dose response. Of the 32 compounds, 10 molecules exhibited inhibitory activities against glutamate toxicity, with IC 50 ranging from 500 nM to 5 uM. These confirmed compounds from the kinase set are currently under study to identify the mechanism of neuroprotection and the potential to repurpose these compounds as medicines for glutamate induced neuropathological conditions. In the future, we plan to screen a subset of 450,000 compounds from a proprietary library of chemical molecules in our collection to discover novel chemical structures with the potential to be developed as treatment of neurodegenerative diseases.

**A Serum-Free Human iPSC-Motoneuron Schwann Cell Myelination Model**

C. Lorance1, J. W. Rumsey1, C. J. Long1, M. L. Shuler1,2, and J. J. Hickman1, *Hesperos, Inc, Orlando, FL,* and *Cornell University, Ithaca, NY.

Schwann cell myelination is a critical step during development of the peripheral nervous system (PNS). Myelin protects the axons of motor and sensory neurons from damage, and greatly increases the efficiency and rate of action potential conduction along the Nodes of Ranvier that form between myelin segments. Damage to myelin segments by auto-antibodies is common etiology in peripheral demyelinating diseases that affect millions of people in the U.S. Current human cell-based models fail to recapitulate myelination of motoneurons by Schwann cells under serum-free conditions which is especially important for studying auto-immune diseases where patient sera must be present to mimic pathology. Here we describe a serum-free, human-based myelinating co-culture model composed of iPSC-derived motoneurons (hMNs) and Schwann cells (hSCs). We used immunocytochemistry and confocal microscopy to determine myelination based on myelin basic protein (MBP), neurofilament heavy chain (NF-H), and S100b protein marker co-localization. Myelin segments were quantified by counting the number of myelin expressing hSCs (myelin segments) relative to the total number of aligned Schwann cells. This model is the first human-based, serum-free myelinating system, and represents a milestone in tissue engineering that has utility for basic research into the molecular pathways that influence axon myelination and screening of drug candidates to treat demyelinating diseases. This serum-free system is especially relevant for studying auto-immune demyelinating diseases where added patient serum is critical for mimicking the disease phenotype.

**An In Vitro NMJ Model for Studying the Pathology and Treatment of ALS**

Amyotrophic lateral sclerosis (ALS) is a fatal neural disease that is characterized by the dysfunction of the neuromuscular junction (NMJ). Pathological hallmarks of ALS include motoneuron degeneration and impaired energy metabolism which has been linked to mitochondrial dysfunction and glutamate toxicity. Although most ALS cases are sporadic, familial ALS accounts for up to 10% of cases with 20% of such cases identifying mutations in the superoxide dismutase (SOD) 1 gene. Despite extensive research, no consensus on the main toxicity of these mutants has emerged. *In vitro* modeling of the NMJ would represent a powerful tool to delineate events leading up to the formation and subsequent disruption of the NMJ. We have developed a serum-free, compartmentalized in vitro NMJ model system capable of isolated stimulation of either muscle or motoneuron (MN), and selective treatment of either muscle, motoneurons or both. Induced skeletal muscle contraction was monitored by pixel subtraction video recordings. This system has been validated with 3 different neurotransmitters, for which not only dose response curves were generated, but also different mechanisms were revealed. This analysis provided a physiologically relevant tool to assess the pharmacology of neuromuscular blocking drugs. This functional system was extended to a disease model by using induced pluripotent stem cell (iPSC) derived SOD1 motoneurons co-cultured with human skeletal myoblasts to investigate MN-induced ALS pathology. From this study, we have identified structural and functional perturbations in SOD1-MN NMJs including decreased synchronous contractions, reduced NMJ stability and increased motoneuron varicosities compared to wild-type NMJ systems to develop a specialized “fingerprint” associated with several SOD1 mutations. We later treated these systems with compounds to alleviate the SOD1-induced deficits. Specifically, we observed increases in synchronous contraction and NMJ stability. This functional system can be used to study other ALS therapeutics including efficacy and toxicity, and through simple housing or cellular modifications, study other diseases of the NMJ including myasthenia gravis and muscular dystrophy and be used as a toxicological screen for toxic side effects.

**Use of Peptides to Disrupt NO Synthase Recognition by the Hsp90/Hsp70 Chaperone Machinery**

D. Felker, M. Lau, Y. Morishima, A. Davis, H. Zhang, R. J. Richardson, and Y. Osawa. *University of Michigan, Ann Arbor, MI.*

The Hsp90/Hsp70 chaperones are upregulated during stress and regulate the quality control of proteins during toxicant injury. Although it is clear that chaperones specifically recognize damaged proteins in a sea of proteins in their native conformations, it remains unknown exactly how this occurs. We utilized neuronal NO synthase (nNOS) as a model Hsp90/Hsp70 chaperone client to study this process. Specifically, we utilized synthetic peptides (8-12 mer) that correspond to important domains on nNOS to block recognition by chaperones. Such an approach successfully identified a domain recognized by chaperones on the neuronal growth factor receptor that is exposed only on the monomeric protein. We chose sites near the heme domain that are thought to become exposed upon damage and subsequent monomerization of nNOS. To assess the extent to which peptides interfered with chaperone action, we utilized a convenien assay that measures the chaperone-mediated insertion of heme into the heme-deficient monomeric form of the nNOS. Thus, by simple measurement of reduced nNOS and SH-SY5Y human neuroblastoma cells supplemented with galactose-supplemented media to mimic the cell-type and cellular processes, we could readily assess chaperone recognition of nNOS. We tested 20 peptides and found that targeting three regions within the nNOS dimerization interface (the BH4 cofactor binding site, the Zn2+ binding loop, and the active site cleft opening) interfered with chaperone action on nNOS. As a control, peptides with novel chemistries derived from regions outside the dimerization interface did not affect the heme insertion. We are currently testing the peptides to see if they directly block association of Hsp90 and Hsp70 to nNOS. Identifying the site of binding will greatly aid in understanding how chaperones recognize damaged nNOS and may provide a useful method to pharmacologically control levels of nNOS.

**Heterocyclic Amine-Induced Bioenergetics Alterations**

R. M. Foguth, Z. S. Agim, and J. R. Cannon. *Purdue University, West Lafayette, IN.*

Environmental factors have been repeatedly implicated in Parkinson’s disease (PD) etiology. Pesticides have been extensively studied. Emerging data also suggests that dietary toxins should be considered. Heterocyclic amines (HCAs) are primarily produced during high temperature meat cooking. Our group has extensive data showing that several HCAs cause dopaminergic neurotoxicity in primary midbrain cultures. To date, we tested 1100 compounds and found numerous HCA subclasses. Since some of these HCAs are structurally very similar to known mitochondrial complex I inhibitors, we hypothesized that HCAs of dietary relevance will inhibit mitochondrial function. To test our hypothesis, we used SH-SY5Y human neuroblastoma cells supplemented with galactose-supplemented cells, more closely mimicking in vivo physiology. We tested the effect HCA exposure [12-amino-9H-pyrido[2,3-b]indole}
**1461 Novel Keap1 Inhibitors Protect against Neuroinflammation In Vitro**

X. Wen1, Y. Zhou1, V. Mangipudy1, D. Abed1, L. Hu1, J. R. Richardson2, and L. M. Alekseus1. 1, Rutgers, The State University of New Jersey, Piscataway, NJ; and 2Northeast Ohio Medical University, Rootstown, OH.

NF-E2-related factor 2 (Nrf2) is a critical cytoprotective transcription factor. Under basal conditions, Nrf2 is bound to a Nrf2-interacting protein Kelch-like ECH-associated protein 1 (Keap1) and targeted for proteasomal degradation. Keap1 can be covalently modified allowing the release and translocation of Nrf2. The activation of Nrf2 can induce the transcription of cellular defense genes such as heme oxygenase 1 (Ho-1) and NAD(P)H quinone dehydrogenase 1 (Nqo1). Thus, specific inhibitors of the Keap1-Nrf2 protein-protein interaction may represent potential therapeutic agents to treat neurodegenerative diseases. Here, we sought to evaluate whether novel direct Keap1-Nrf2 inhibitors (designated LHs) for their ability to (1) activate Nrf2 signaling, (2) up-regulate Ho-1 and Nqo1 mRNA and proteins and (3) protect against inflammation caused by lipopolysaccharide (LPS) in mouse microglia BV-2 cells. BV-2 cells were treated with LH compounds (10 µM) or the indirect Nrf2 activator DMF. At 6 h, DMF induced Ho-1 and Nqo1 mRNAs by 2- and 5-fold, respectively. The LH compounds significantly increased Nqo1 mRNA levels in microlglial cells between 2- and 20-fold at 24 h. LH385 was the most potent Keap1 inhibitor that significantly induced Nqo1 mRNA expression (up-regulation of Nqo1 proteins in BV-2 cells. In addition, LH385 significantly decreased LPS-induced proinflammatory cytokines IL-1 beta, TNF alpha and nitric oxide synthase (iNOS) mRNAs by 70 to 90%. LH385 also attenuated LPS-induced increases in IL-1 beta and TNF alpha proteins at 6 h. Of note, all eight LH compounds had no effect on cell viability when used at high concentrations (up to 50 µM) in BV-2 microglial cells. Based on these data, LH385 may be a potential therapeutic agent to reduce neuroinflammation by activating the Keap1-Nrf2-ARE pathway. Supported by NIH ES021800, ES005022 and Liberty Science Center Partners Program.

**1462 Sex-Specific Effects of Lead and Prenatal Stress on miRNA Expression in Mouse Frontal Cortex and Hippocampus**

V. Singh1, G. Varma1, M. Sobolewski1, J. Schneider1, and D. Cory-Slechta2. 1Thomas Jefferson University, Philadelphia, PA; and 2University of Rochester School of Medicine, Rochester, NY.

Environmental lead (Pb) and prenatal stress (PS) are co-occurring environmental and neurotoxicants, known to cause cognitive/behavioral disturbances and to impair learning and memory. Here, we sought to determine how subtle structural difference influence HCA mechanisms of neurotoxicity.

**1463 Enriched Environment Alters Hippocampal, Epigenetic, and Gene Expression Profiles and Mitigates Lead-Induced Memory Deficits**

G. Varma, V. Singh, and J. Schneider. Thomas Jefferson University, Philadelphia, PA.

Being raised in an enriched environment is a potential social intervention strategy to mitigate cognitive/behavioral deficits associated with exposure to developmental neurotoxicants. However, molecular mechanisms related to environmental enrichment that may underlie structural/functional effects on the brain remain poorly understood. Developmental exposure to lead (Pb) results in behavioral/cognitive impairments and no current therapies have been effective in reversing the deficits. Epigenetic alterations induced by Pb exposure provide a window into possible epigenetic mechanisms underlying these deficits. The purpose of this study was to investigate the extent to which environmental enrichment could mitigate memory consolidation/recall deficits and further modify epigenetic marks and gene expression profiles altered by developmental Pb exposure. Following an early postnatal exposure (EPN) to Pb (birth through weaning), female Long Evans rats were randomly housed under non-enriched (standard housing, 3 rats/cage) or enriched (large enclosures, 6 rats/cage, equipped with variety of toys, running wheels etc., changed 3 times/week) conditions. Non-Pb-exposed controls were housed under similar conditions. At PDN55, the animals were tested for associative memory deficits using a trace fear conditioning paradigm. Memory deficits were observed only in non-enriched EPN females. Enriched EPN females performed similar to non-Pb controls suggesting that living in the enriched environment mitigated the cognitive deficit induced by Pb exposure. To gain insight into possible epigenetic mechanisms underlying these results, we examined global DNA methylation (mC) and hydroxymethylation (hmC) levels in the hippocampus (CA1). Non-enriched EPN females had globally reduced mC and hmC levels. Enriched EPN females and controls had similar mC and hmC levels. Exposure to Pb differentially altered expression level of DNA methylation-related genes in non-enriched animals and environmental enrichment normalized these levels. RNA-seq analysis showed transcriptional profiles in non-enriched EPN females to be significantly different from that in enriched females. The interaction of Pb and enriched environment influenced numerous biological processes related to DNA methylation and chromatin modification. Studies aim to further understand gene level function and networks/molecular mechanisms modified by Pb exposure and early life experiences are in progress. Supported by R01 ES015295.

**1464 Early-Life Lead Exposure Produces Sensorimotor Gating Deficits Consistent with a Schizophrenia Phenotype**

Epidemiological studies have demonstrated detrimental effects of chronic early life Pb exposure (CELE) on children’s intelligence, learning ability and neuropsychological development. Additional studies indicate CELE is associated with the onset and progression of neurological disorders including major depression, anxiety, delinquent behavior, and schizophrenia (SZ). Previous studies from our lab have shown that rats developmentally exposed to Pb express key features observed in SZ including: (1) loss of parvalbumin-positive GABAergic interneurons in relevant brain regions, (2) hyperdopaminergic hyperactivity and (3) increased dopamine receptors in the striatum (Biansfield et al., 2015).
Pre-pulse inhibition (PPI) is widely used to assess sensorimotor gating and deficits are well described in SZ and other neuropsychiatric disorders. In the present study we are investigating sensorimotor gating in Pb2+ exposed rats using a life course approach. Long Evans rats were chronically exposed to control diet or diet containing 1500ppm PbAc from gestation until late adolescence (postnatal day 50, PN50) or adulthood (PN120). This exposure results in blood Pb2+ levels of 0.7 ± 0.6 (control) or 17.9 ± 1.8 μg/dL (Pb2+-exposed). At PN50 and PN120, acoustic startle reactivity (120 dB bursts) and PPI (5 prepulses) were tested in control and Pb2+-exposed male and female rats. In PN50 male rats (Control n=21; Pb2+-exposed n=17), there was a significant effect of prepulse dB, F(3,117.3) = 59.1, p<0.0001, and an overall effect of Pb2+ treatment, F(1,36) = 11.7, p=0.002. In PN50 female rats (Control n=13; Pb2+-exposed n=9), there was a significant effect of prepulse dB, F(2.4,48.3) = 41.7, p<0.0001, and a near significant effect of Pb2+ treatment, F(1,20) = 4.02, p=0.059. In PN120 male rats (Control n=7; Pb2+-exposed n=7), there was a significant effect of prepulse dB, F(1,31,5.3) = 15.7, p=0.001, and an effect of Pb2+ treatment, F(1,12) = 5.0, p=0.045. No significant effects of Pb2+ were observed on acoustic startle response in male or female rats at either age. Taken together our data suggest a Pb2+-dependent impairment on PPI, reproducing behavioral changes present in SZ. Our findings combined with previous studies support the hypothesis that exposure to environmental toxins may contribute to the expression of mental disease later in life. Supported by NIEHS ES006189 to TRG.

1465 Cortical-Hippocampal Circuit Dysfunction Bridging the Cellular to Cognitive-Behavioral Effects of Chronic Early-Life Lead Exposure in Rats

Chronic early-life lead exposure (CELLE) causes neuronal and synaptic dysfunctions in the developing brain leading to learning deficiencies and behavioral abnormalities; but the circuit-level consequences of CELLE that tie cellular effects with cognitive impairments are not well understood. CELLE is known to disrupt the subunit composition of NMDA receptors, undermining synaptic plasticity, and leads to loss of parvalbumin (PV)-positive GABAergic interneurons (PVGI) in the hippocampus (HC) and medial prefrontal cortex (mPFC). These effects are thought to impair the excitatory-inhibitory (E-I) interactions of principal neurons in HC and mPFC within interneuronal networks and consequently disrupt gamma oscillations (30-150 Hz) that depend on E-I coupling as a mechanism for local computation. It remains unknown how lead’s neurotoxic effects actually impact circuit rhythms underlying cognitive functions. Local-field potential (LFP) recordings, reflecting local synaptic and neuronal synchrony, provide a powerful means for evaluating rhythmic coordination within and between brain regions. We recorded LFP simultaneously from HC and mPFC while adult rats (~100 days old) navigated an open environment. In addition to gamma, we observed the theta rhythm (4-12 Hz) that is prominent in HC and mediates interactions throughout the distributed cortical circuitry for navigation and decision making. Whereas theta recorded from control rats showed the same frequency in HC and mPFC, lead-exposed (1500ppm in diet) rats exhibited a theta frequency elevation in mPFC relative to HC consistent across running speeds (1-100 cm/sec). Both theta and gamma coherence in local HC-HC and mPFC-mPFC electrode pairs, as well as distal HC-mPFC electrode pairs, were disrupted in lead-exposed rats reflecting disrupted processing both within and between regions. Notably, gamma-band coherence was diminished both within mPFC and between HC and mPFC. In lead-exposed rats, we also observed a weakening of the relationship between HC theta frequency and animals’ running speeds indicating abnormal coupling of neural circuit dynamics to behavior. These initial observations provide a foundation for bridging the cellular and cognitive-behavioral effects of CELLE. Supported by NIH ES006189 to TRG.

1467 Developmental Manganese, Lead, and Barren Cage Exposure Have Adverse Long-Term Neurocognitive, Behavioral, and Monoamine Effects in Sprague-Dawley Rats

Developmental stress can induce dysregulation of the hypothalamic-pituitary-adrenal axis. Stressors such as low socioeconomic status (SES) may result in adverse long-term neurocognitive and behavioral effects. Children in lower SES households experience more stress and are more likely to be exposed to environmental pollutants (EPA 2008). Lead (Pb) and manganese (Mn), exposure to stress, Pb, and Mn during development may increase the risk of CNS dysfunction. Sprague-Dawley rats were used with one male/female pair within each litter assigned as follows: 0 (vehicle), 10 mg/kg Pb, 100 mg/kg Mn, or 10 mg/kg Pb + 100 mg/kg Mn (Pb-Mn). Treatment was from postnatal day (P) 4-28 with half the litters reared in cages with standard bedding and half with no bedding (Barren). Offspring were tested as adults. Mn and Pb-Mn groups had decreased anxiety, reduced acoustic startle, transient hypoaactivity, increased activity following (+)-methamphetamine, egocentric learning and memory deficits in Cincinnati water maze (CWM), and deficits in latent inhibition. Pb increased anxiety and reduced open-field activity. Barren-reared rats had decreased anxiety, CWM deficits, increased startle, and transient hyperactivity. The Mn, Pb-Mn, Barren-reared groups also had impaired Morris water maze performance. Pb altered corticotropin releasing hormone (CRH) and norepinephrine (NE) S-HT in males + Barren-reared increased noradrenergic S-HT, and Barren-reared decreased noradrenergic dopamine in males. The most pronounced effects were in the Mn and Pb-Mn-exposed groups, indicating that Mn exposure drove most of the adverse effects on behavior and neurotransmitters. Few interactions between Mn and Pb with barren cage rearing stress were found.

1468 Neuroprotective Effect of EGCG on Aluminum Altered Hippocampal NMDA Receptor 1 and 2A/2B Expression in Rats

S. S. Palabiyik1, N. D. Zeybek1, E. Akpinar1, E. B. Zirh2, H. Sipahi3, and Z. Halici1. 1Atatürk University, Erzurum, Turkey; 2Hacettepe University, Ankara, Turkey; and 3Yeditepe University, Istanbul, Turkey. Sponsor: H. Orhan

Aluminum (Al) is a neurotoxic metal and has been associated with chronic neurodegenerative diseases. N-methyl-D-aspartate receptors (NMDARs) contribute to neuronal development. Chronic Al exposure can affect the glutaminergic system through the NMDARs. Changes caused by Al also affect the development of chronic neurodegenerative diseases. Epigallocatechin gallate (EGCG) has a well-known antioxidant effect and is the most important component of green tea; it is also a subject of research interest in recent years. The purpose of this study was to investigate the effect of Al on hippocampal neuronal
development through the NMDAR 1 and 2A/B expressions and the protec-
tive role of EGCG in Al-induced changes through the NMDARs on
the hippocampus, which is known to be the most affected region in
chronic Al toxicity. In this study; 120 male Sprague-Dawley rats were
randomly divided into 10 groups (n=12). Control (C) was given 1 mL/
day saline orally; 100 mg/kg bw aluminum chloride (AlCl3) was admin-
istered for 8 weeks to AlCl3 group; 20 mg/kg EGCG was given for 4 and
8 weeks as EGCG C groups. AlCl3 was administered with two different
doses of EGCG (10mg/kg and 20mg/kg) and 0.15mmol/kg/bw deferox-
amine as study groups. For the other two groups, after 4 weeks pre-ad-
ministration of AlCl3, two different doses of EGCG (10mg/kg and 20mg/
kg) were added to the administration for the last 4 weeks. NMDAR 1 and
2A/B mRNA levels of these parameters were assessed with real-time
PCR and also evaluated immunohistochemically. Al downregulated
NMDAR subunits’ mRNA expression, which is apparent and statistically
significant in NMDAR1 and 2B subunits (p<0.05). Both doses of EGCG
treatment upregulated these changed mRNA expression levels dose-
dependently, but the simultaneous administration is more effective.
These changes are also confirmed with h-score analysis of immunore-
activity. The present study showed Al can induce neurotoxicity through
the NMDARs, and the EGCG has a protective role. In the light of this
study, EGCG application or consumption will be a new approach for the
prevention of neurodegenerative diseases probably induced by Al. This
work was supported by TUBITAK (project number 1155333).

1469 Lead-Induced Auditory Dysfunction and Potentiation of Noise-Induced Hearing Loss

R. Rosati, and S. Jamesdaniel. Wayne State University, Detroit, MI.

Environmental exposure to lead, a neurotoxicant, is unavoidable in
urban communities with older infrastructure. Though exposures at low
levels are often overlooked because their adverse health effects are
not obvious immediately, their interaction with other environmental stresses
cannot be ignored. A potent risk factor for lead neurotoxic manifestation,
such as acquired hearing loss, which significantly affects the quality of
life and productivity in 15% of American adults. Lead exposure disrupts
the structure as well as the function of the auditory system. Despite
the overwhelming evidences indicating the ototoxic effects of lead, the
underlying mechanism and its interaction with other ototoxicants
are yet to be fully understood. The aim of this study is to delineate
the mechanism underlying lead-induced auditory dysfunction and its
potential interaction with noise exposure. Young-adult C57BL/6 mice
were exposed to: 1) control conditions; 2) 2 mM lead acetate in drinking
water for 28 days; 3) 90 dB broadband noise 2 hours/day for two weeks;
and 4) both lead and noise. Blood lead levels were measured by induc-
tively coupled plasma mass spectrometry analysis (ICP-MS), lead-in-
duced cochlear oxidative stress signaling was assessed using targeted
gene arrays, and the hearing thresholds were assessed by recording auditory brainstem responses. Chronic lead exposure downregulated
cochlear Sod1, Gpx1, and Gstk1, which encode critical antioxidant
enzymes, and upregulated ApoE, Hspa1a, Ercc2, Prnp, Ccl5, and Sqstm1,
which are indicative of cellular apoptosis. Isolated exposure to lead or
noise induced 8-12 dB and 11-25 dB shifts in hearing thresholds, respec-
tively. Combined exposure induced 18-25 dB shifts, which was signif-
cantly higher than that observed with isolated exposures. This study suggests
that chronic exposure to lead induces cochlear oxidative stress and
additively potentiates noise-induced hearing impairment, possibly
through parallel pathways.

1470 Role of Aluminum-Induced Cytotoxicity in Neurodegeneration of Human Neuroblastoma Cells

M. Webb. University of Maryland Eastern Shore, Princess Anne, MD. 
Sponsor: A. Ishaque

Aluminum (Al) has gained considerable attention due to its neurotoxic
effects. The widespread and extensive use of products made from or
containing aluminum provides easy and continuous exposure to humans.
Several pieces of epidemiological and clinical evidence have linked Al
with neurodegenerative disorders, including Alzheimer’s disease (AD).
The neuropathological characteristics associated with AD include the
accumulation of amyloid plaques and neurofibrillary tangles (NFTs).
The cleavage of amyloid precursor protein (APP) by the proteases
β-secretase (BACE1) and γ-secretase, respectively, generates the peptide amy-
loid-beta (Aβ), which then progresses to oligomerization and forms the
final product amyloid plaques. In addition, there are a large number of
studies providing evidence for the presence of Aβ within neurons on post-
mitotic and transgenic mouse brains. Our aims were to test the
effect of aluminum on β-secretase activity and to examine the differen-
tial effects of Aβ1-40 or Aβ1-42 peptides on cellular toxicity in human
neuroblastoma cells. Also, we examined the interactions of Al and Aβ
peptide subtypes with cells. SH-SYSY cells were exposed to different
exposure periods to various concentrations of aluminum chloride in the
presence and absence of Aβ peptides. Cell proliferation, viability and
β-secretase activity were assessed. Exposure to Al at a concentration
range of 0.001 mM to 1 mM did not show marked effect on SH-SYSY cell
proliferation whereas a significant reduction in cell proliferation and via-
bility was observed in a dose dependent manner after exposure to more
than 1 mM of aluminum. Significant increase in the β-secretase activity
was observed after exposure to Al at a concentration range of 0.01μM to
100μM. Treatment of SH-SYSY cells for three days with Aβ1-40 or Aβ1-42
even at micro molar quantities of aluminum concentrations did not
suggest that exposure to AI may contribute to neurodegeneration and AD pathogenesis. Supported by Title III.

1471 Arsenic Exposure Induces Apoptosis in Hippocampal Neurons and Cognitive Impairment in Rats via Upregulated Bmp-2-Dependent Bdnf/ptrkb Signaling Pathway

Arsenic stimulates apoptosis in the brain cells and induces cognitive
deficits. However, mechanism promoting arsenic-mediated neuronal
apoptosis and cognitive impairment is less investigated. Bone morpho-
genetic proteins (BMP) are expressed in the hippocampus, which controls
cognitive performances, and we hypothesized that a deregulated BMP
signaling might affect the hippocampal neuronal apoptosis and cognitive
functions. We first validated an arsenic-mediated dose-dependent
loss in the hippocampal neurons, through Western blotting (WB) and
Nissl’s staining. Increased Terminal deoxynucleotidyl transferase deUTP
nick end labeling (TUNEL)-reactivity in the NeuN cells and an enhanced
cleaved Poly ADP-ribose polymerase (c-PARP) and c-caspase-3, detected
through Immunofluorescence (IF) and WB, verified As-induced neuronal
apoptosis. Investigating the mechanism through in vivo and in vitro studies revealed that arsenic promoted Bone Morphogenetic protein-2
(BMP2) expression, and a downstream BMP Receptor2 (BMPR2) level
and p-SMAD1/5 signaling in the hippocampal neurons. Interestingly,
a BMP antagonist, noggin, reduced the arsenic-induced TUNEL reac-
tivity and neuronal loss, proving the participation of increased BMP2
signaling suppressed Brain-Derived Neurotrophic Factor (BDNF) expres-
sion levels and BDNF/Tbrk signaling in the arsenic-treated hippocampal
neurons. This decreased BDNF/Tbrk pathway appeared essential for
neuronal apoptosis, as evident from a TrkB inhibitor (K252a)-mediated
abrogation of noggin-induced protection to the hippocampal neurons.
Ultimately, we verified cognitive impairments in the arsenic-treated rats
through Passive avoidance test and Y-Maze test and proved a resto-
rative following noggin treatment. The overall present study confirms
that arsenic induces apoptosis in the hippocampal neurons through a
BMP2/p-SMA1/5-dependent BDNF/Tbrk pathway, affecting normal
cognitive performances.

1472 Protective Effect of Mir-124 Against As-Induced Endoplasmic Reticulum Stress and Implications in Neurodevelopmental Outcomes in Children

H. Park1, R. A. Panganiban1, M. Shumyatcher2, R. Sun1, B. E. Himes2, D. Christians1, and Q. Lu1. 1Harvard School of Public Health, Boston, MA, and 2University of Pennsylvania, Philadelphia, PA.

As a pervasive environmental contaminant, Arsenic (As) poses a great
public health concern attributing to a myriad of diseases including adverse neuronal outcomes. Exposure to As during the early stages of
brain development has disastrous lasting effects on the hippocampal
functions. Although epidemiological studies report that prenatal As exposure is associated with impaired neurodevelopment in children, the
molecular mechanisms underlying the susceptibility of early brain develop-
ment to As exposure remain poorly understood. Endoplasmic reticulum
(ER) is the organelle where membrane and secreted proteins are synthe-
sized. Challenges to ER function lead to protein misfolding and a state
of irreversible ER stress, which significantly affects the structure as well as the function of the neuronal cells. Despite the overwhelming evidences
indicating the ototoxic effects of lead, as a known neurotoxicant, we
investigated the mechanism underlying lead-induced auditory dysfunction and its interaction with other ototoxicants such as lead acetate and noise.
Young-adult C57BL/6 mice were exposed to: 1) control conditions; 2) 2 mM lead acetate in drinking
water for 28 days; 3) 90 dB broadband noise 2 hours/day for two weeks; and 4) both lead and noise. Blood lead levels were measured by induc-
tively coupled plasma mass spectrometry analysis (ICP-MS), lead-in-
duced cochlear oxidative stress signaling was assessed using targeted
gene arrays, and the hearing thresholds were assessed by recording auditory brainstem responses. Chronic lead exposure downregulated
cochlear Sod1, Gpx1, and Gstk1, which encode critical antioxidant
enzymes, and upregulated ApoE, Hspa1a, Ercc2, Prnp, Ccl5, and Sqstm1,
which are indicative of cellular apoptosis. Isolated exposure to lead or
noise induced 8-12 dB and 11-25 dB shifts in hearing thresholds, respec-
tively. Combined exposure induced 18-25 dB shifts, which was signif-
cantly higher than that observed with isolated exposures. This study suggests
that chronic exposure to lead induces cochlear oxidative stress and
additively potentiates noise-induced hearing impairment, possibly
through parallel pathways.
early brain development. Our genome-wide CRISPR screen using an ER stress reporter cell line identified novel suppressors of As-induced ER stress including microRNA(miR)-124. We showed that miR-124 directly targets IRE1 pathway, one branch of UPR signaling via direct binding to the 3′UTR of ERN1 (gene for IRE1). We further demonstrated that miR-124 overexpression reduces As-induced ER stress/UPR signaling.

In addition, As treatment inhibited cell proliferation in human NSCs or neuroblastoma cells with concomitant activation of ER stress/UPR signaling. Furthermore, miR-124 overexpression reduced As-induced growth inhibition in SH-SY5Y cells. Using data from existing genome-wide association studies of an environmental epidemiological cohort, we found that miR-124 polymorphisms were associated with neurocognitive outcomes, though the mechanisms involved are unknown. In a previous study, we hypothesized that miR-124 is a potential target for preventative and therapeutic interventions against detrimental effects of As exposure in children.

**1473** Heterozygous Huntingtin Promotes Cadmium Neurotoxicity via Caspase Activation, Impaired Metal Transport, and Erk- and PKC-δ-Dependent Oxidative Signaling Mechanisms: Relevance to Pathogenesis of Huntington’s Disease

G. Kwakye, J. A. Jiménez, B. A. Kingsley, and E. M. Korley. Oberlin College, Oberlin, OH.

Expression of Huntingtin gene (Htt) encoding Huntingtin protein (Htt) leads to striatal neurodegeneration in Huntington’s disease (HD). HD is functionally linked to environmental factors, including metal dysmetabolism and diet use. Interestingly, one of the most abundant heavy metals in cigarettes is cadmium (Cd), which also accumulates in the striatum and causes neurotoxicity upon exposure. Thus, we hypothesized that heterozygous Htt, found in most HD patients, in combination with Cd exposure may exhibit disease-toxicant interactions revealing cellular pathways that mediate neurodegeneration. We report that heterozygous Htt significantly increased Cd cytotoxicity as compared to wild-type cells upon 48 h exposure. The heterozygous Htt x Cd-induced cytotoxicity led to a NADPH oxidase (NOX) mediated oxidative stress that was attenuated by ascorbic acid and apocynin, a NOX inhibitor. Heterozygous Htt in tandem with Cd exposure caused increased expression of protein kinase C (PKC) and other key oxidative stress proteins without altering Akt protein levels. Additionally, heterozygous Htt caused increased caspase-9 and caspase-3 activation and blocked the overexpression of estrogen receptor kinase (Erk) upon Cd exposure. Inductively coupled plasma-mass spectrometry (ICP-MS) analysis revealed an increase in Cd uptake and intracellular accumulation in heterozygous Htt-expressing cells upon Cd exposure and no significant changes in the levels of other essential metals. Moreover, Cd exposure decreased expression of divalent metal transporter 1 (DMT1) protein in the striatal cells. We demonstrate that the enhanced Cd cytotoxicity phenotype in heterozygous Htt can be ameliorated with non-toxic levels of zinc, manganese and iron. Collectively, these results demonstrate that heterozygous Htt exhibits neurotoxic properties upon Cd exposure to cause cell death via caspase activation, impaired metal transport, and regulation of Erk and PKC-δ dependent oxidative signaling mechanisms.

**1474** Metastatic M1 Receptor Partially Modulates Higher Sensitivity to Cadmium-Induced Cell Death in Primary Basal Forebrain Cholinergic Neurons: A Cholinesterase Variants-Dependent Mechanism

Cadmium is a toxic compound reported to produce cognitive dysfunctions, though the mechanisms involved are unknown. In a previous work we described how cadmium blocks cholinergic transmission and induces greater cell death in primary cholinergic neurons from the basal forebrain. It also induces cell death in SN56 cholinergic neurons from the basal forebrain through M1R blockage, alterations in the expression of AChE variants and GSK-3b, and an increase in Ab and total and phosphorylated Tau protein levels. It was observed that the silencing or blockage of M1R altered ChAT activity, GSK-3b, AChE splice variants gene expression, and Ab and Tau protein formation. Furthermore, AChE-S variants were associated with the same actions modulated by M1R.

Accordingly, we hypothesized that cholinergic transmission blockage and higher sensitivity to cadmium-induced cell death of primary basal forebrain cholinergic neurons is mediated by M1R blockage, which triggers this effect through alteration of the expression of AChE variants. To prove this hypothesis, we evaluated, in primary culture from the basal forebrain region, whether M1R silencing induces greater cell death in cadmium does, and whether the native AChE variants are involved in the mechanisms described so as to play a part in the cadmium induction of cholinergic transmission blockage and cell death in this cell line through alteration of the expression of AChE variants. Our results prove that M1R silencing by cadmium partially mediates the greater cell death observed in basal forebrain cholinergic neurons. Moreover, all previously described mechanisms for blocking cholinergic transmission and inducing cell death on SN56 cells after cadmium exposure are partially mediated by M1R through the alteration of AChE expression. Thus, our results may explain cognitive dysfunctions observed in cadmium toxicity.
oxidative stress in fish brain, after exposure to mercuric chloride. The present study suggests the toxicity of mercuric chloride by inducing the oxidative stress and adverse alterations in the brain metabolism and possible interference in brain coordination processes and the protective effect of lotus over the mercury induced changes.

1477 Methylymercury Modulates the Autophagic Response in Mice

C. L. Gonçalves1, B. F. Villahoz1, F. M. Gonçalves1, A. B. Bowman2, and M. Aschner1. 1Albert Einstein College of Medicine, Bronx, NY; and 2Vanderbilt University Medical Center, Nashville, TN.

Methylmercury (MeHg) is a global, highly lipophilic environmental pollutant that causes damage to various organs specially on the central nervous system (CNS). It has been known that MeHg induces oxidative stress through an increase in intracellular reactive oxygen species (ROS) and a particular affinity for thiol groups of proteins. In this context, autophagy prevents the accumulation of misfolded or damaged proteins and organelles in the cytoplasm and is regulated by cellular stress responses. Since, the molecular mechanisms underlying MeHg toxicity are not clear, the understanding of autophagy implication in MeHg toxicity could prove to be very useful for the understanding and developing of detoxication strategies. Thus, the aim of this study was to evaluate the autophagic response induced by systemic MeHg exposure in cerebellum and cortex of adult mice. Adult male C57BL mice (3 months old) were exposed to MeHg (0.5 mg/L and 5 mg/L; diluted in drinking water; ad libitum) during 30 days. After 24 hours the animals were killed by decapitation, the brain was removed, and the cerebellum and cerebral cortex were isolated to posterior analysis. Western blot analysis showed a significant decrease in the levels of the autophagic-related proteins p62, ATG4A and ULK-1 in cerebellum and cortex of MeHg-exposed mice compared to control mice (5 mg/L). The levels of other important markers for autophagy pathway, such as, mTOR, LC3-II, Beclin-1 are under analysis. Importantly, this is the first study to evaluate the effects of MeHg in an autophagic response in an animal model. In summary, MeHg seems to modulate/impair the levels of autophagic proteins probably via ROS production.

1478 Recovery Effect of Fasudil, a ROCK Inhibitor, on Axonal Degeneration in Spineoneural System of Methylmercury-Intoxicated Rats

Methylmercury (MeHg) is an environmental neurotoxicant that induces neuropathological changes in the spineoneural system as well as the cranial nerve system, such cerebral cortex and cerebellum. Our previous study demonstrated that MeHg exposure (20 ppm MeHg in drinking water for 4 weeks) induced neuropathological changes in both spinoneural and cranial nerve systems in rats. Furthermore, pretreatment of Fasudil, a ROCK inhibitor, prevented axonal degeneration in the spineoneural system, including dorsal column of spinal cord and dorsal root nerve. However, our understanding in the recovery effect of Fasudil on MeHg-induced axonal degeneration is unknown due to the difficulties in maintenance for a long-term survival of MeHg-intoxicated animals. In the present study, we established a new MeHg-intoxicated rat model. Short-term exposure to MeHg (20 ppm MeHg in drinking water for 3 weeks) induced sufficient axonal degeneration in the spineoneural system, but not in the cranial nerve system. Six weeks after MeHg withdrawal, MeHg-intoxicated animals had still maintained those axonal degenerations and the expression of infiltrated microglia without inducing individual death. Moreover, the expression of ROCK was observed in infiltrated microglia of spinal cord. Post-treatment of Fasudil for 6 weeks restored those axonal degenerations and hind limb crossing sign, a characteristic MeHg-intoxicated behavior. Fasudil also suppressed the expression of inflammatory factors such as TNFα and iNOS, which come from infiltrated microglia. These results suggest that Fasudil, a ROCK inhibitor, recovers MeHg-induced axonal degeneration in the spineoneural system through the suppression of inflammatory factors, and is effective for the cure of MeHg-induced neural dysfunction.

1479 Autophagy and Sequestosome1/p62 Play a Protective Role against Low-Dose Methylmercury-Induced Cytotoxicity

Methylmercury (MeHg) is a widespread environmental pollutant and causes serious health problem all over the world. MeHg inhibits learning and memory and causes a serious hazard to health worldwide. However, molecular mechanisms underlying MeHg toxicity remain elusive. Autophagy plays a major and highly conserved degradative pathway in eukaryotes, prevents the accumulation of misfolded or damaged protein aggregates and damaged organelles in the cytoplasm. Here we focus on the role of autophagy against low- dose MeHg exposure. We show that MeHg induced mouse embryonic fibroblasts (MEFs) viability in a dose-dependent manner. Furthermore, MeHg treatment increased levels of autophagy marker LC3-II and SQSTM1/p62. MeHg exposure elevated the number of LC3 puncta in stable GFP-LC3 MEFs and the number of autophagic vacuoles. The accumulation of LC3-II and p62 was much increased by co-treatment of MeHg with autophagy inhibitors. This additive effect of MeHg on LC3-II accumulation in the presence of inhibitors suggests that MeHg stress activates autophagy and promotes autophagosome/LC3-II accumulation. To establish the impact of autophagy in alleviating MeHg toxicity, we assessed MeHg sensitivity in autophagy-related gene 5 deficient (Atg5KO) MEFs. Atg5KO significantly decreased viability of the cell following 24 h of MeHg treatment. The enhanced MeHg-induced cytotoxicity in Atg5KO cells suggests that autophagy protects cells from MeHg-induced cell death. This finding could reveal that autophagy is necessary for protective mechanisms in eliminating intracellular MeHg-induced damaged materials. Moreover, we examined MeHg sensitivity in p62-deficient (p62KO) MEFs. p62KO MEFs exhibited higher sensitivity to MeHg exposure compared to their wild-type (WT) counterparts. Interestingly, an earlier and higher level of accumulation of ubiquitinated proteins was observed in MeHg-treated p62KO MEFs when compared with WT MEFs. Taken together these results suggest that, in addition to autophagy, p62 is crucial for cytoprotection against MeHg and required for MeHg-induced ubiquitinated proteins clearance.

1480 Acute Methylmercury Exposure Alters Immunofluorescence of the Renshaw Cell Area in C57BL/6J Mice

A. Suazo1, M. Rios-Cabanillas2, and W. Atchison2. 1Northern New Mexico College, Espanola, NM; and 2Michigan State University, East Lansing, MI.

Methylmercury (MeHg) affects a number of membrane targets and synaptic processes, including excitatory and inhibitory neurotransmission; the latter is affected earlier than the former. Disrupting the ratio of inhibition/excitation can cause excitotoxicity, an effect we reported for acute exposure to MeHg in cerebellum and chronic exposure in a mouse model of amyotrophic lateral sclerosis (ALS). For ALS, a region of particular interest for MeHg neurotoxicity is the spinal cord, especially motor neurons (MN). In this study, we targeted the spinal and their recurrent inhibitory partners, the Renshaw Cells (RCs) of C57BL/6J adult mice. MeHg-induced toxicity was compared using immunohistochemistry after acute exposure (1 h) of lumbar spinal slices to MeHg (5, 10, 20 or 50 μM), or untreated as control. The RC and MN areas were identified by the presence of gephyrin clusters, calbindin d28k, d28k 2B2K immunoreactivity and the presence of cholinergic contacts. Primary antibodies against gephyrin, which anchors inhibitory transmitter receptors including glycine and GABAa to the cytoskeleton of the postsynaptic membrane, calbindin d28k a Ca2+-binding protein expressed in Renshaw and choline acetyl transferase (ChAT), the biosynthetic enzyme for ACh, were found in MNs, respectively. In summary, for all three antibodies underwent a similar MeHg concentration-based pattern of activity. At 20 μM MeHg, immunofluorescence for all markers was markedly increased from control (calbindin 0.11, ChAT 0.41, gephrin 0.18; relative increase) but at 50 μM MeHg immunofluorescence decreased. Pretreatment with strychnine or mecamylamine (MEC), glycine and nicotinic receptor antagonists alone, respectively, decreased immunofluorescence (calbindin 0.17, 0.20 and gephrin 0.29 0.41: relative reduction, respectively), suggesting a block of excitatory nicotinic cholinergic or inhibitory glycnergic transmission. The combination of 20 μM MeHg with strychnine or MEC, markedly decreased immunofluorescence for all markers from the MeHg alone group (calbindin 0.11, ChAT 0.41, gephrin 0.18; relative change). Results (N=6-8) suggest that these proteins are affected during MeHg toxicity through inhibitory and excitatory pathways. Understanding how MeHg-mediated neurotoxicity affects spinal MN pathways, especially inhibitory pathways, is important in assessing its role in MN toxicity in a mouse model of ALS.
Studies have demonstrated that methylmercury (MeHg) produces motor neuron cell death at the lumbar spinal cord region. In many cell types, a key MeHg neurotoxicity marker is dysregulation of intracellular calcium (Ca^{2+}) homeostasis. Spinal cord alpha motor neurons (aMNs) send excitatory signaling onto Renshaw interneurons, which in turn send inhibitory neurotransmitter back to the same aMNs, ultimately modulating their signaling. The effects of Ca^{2+} concentration ([Ca^{2+}]_{i}) during MeHg exposure at the lumbar ventral spinal recurrent inhibition have never been studied. The aim of this project is to determine the effects of acute MeHg-mediated ([Ca^{2+}]_{i}) during the excitatory and inhibitory signaling of recurrent inhibition between aMNs and Renshaw cells. Lumbar sections of adult C57BL6J mice were exposed to 20 μM MeHg during 15 min through a real-time perfusion system. Ca^{2+} changes were recorded using Fluo4-AM at 15 min of MeHg exposure. The role of the acetylcholine (ACh), glycine and GABA receptors, all cytoine-containing ligand gated channels, mediators of recurrent inhibition, was determined using a pharmacological approach. ACh receptor antagonists: mecamylamine (MEC), dihydro-ß-erythroidine hydrobromide (DHIE) and glycine and GABA receptors antagonists: strychnine and bicuculline (BCC), were used as a pretreatment and during MeHg treatment. It is hypothesized that MeHg neurotoxicity produces a differential disruption of Ca^{2+} signaling in these cell types that could potentially lead to hyperexcitability of the Renshaw area. Results show (N = 11) that MeHg treatment alone significantly increases ([Ca^{2+}]_{i}) at 15 min and 1 hr (0.27 and 0.21 relative fluorescence, respectively). Presence of MEC, DHIE, strychnine and BCC during MeHg treatment significantly decreases ([Ca^{2+}]_{i}) at (0.21, 0.18, 0.19 and 0.14, relative fluorescence, respectively) from baseline. Determining the role of MeHg-induced disruption in Ca^{2+} homeostasis through these receptors could potentially elucidate the possible mechanisms of MeHg-mediated ([Ca^{2+}]_{i}) neurotoxicity during recurrent inhibition. Supported by NIH grant R01ES024064.

**Methylmercury Causes Intracellular Calcium Dysregulation in Spinal Cord Slices from SOD1^{G93A} Mice That Is Reduced by Riluzole Treatment**

B. A. Brauer, J. M. Bailey, and W. D. Atchison, Michigan State University, East Lansing, MI.

Amyotrophic lateral sclerosis (ALS) is a neurodegenerative disease that affects upper and lower motor neurons (MNs). Mice that overexpress the humanized superoxide dismutase-1 gene mutation (SOD1^{G93A}) are used to model ALS; they reliably exhibit an ALS-like phenotype as they age. Previously we showed that methylmercury (MeHg), an environmental neurotoxicant, hastens the onset of the ALS-like phenotype in these mice. Overexpression of Ca^{2+} signaling in aMN neurons is a possible mechanism by which riluzole treatment produces its beneficial effects in the clinical population. These data also demonstrate a possible mechanism by which riluzole treatment produces its beneficial effects in the clinical population.

1481 Effects of Acute Methylmercury-Induced Calcium Changes in the Ventral Lumbar Spinal Cord Region of the C57BL6J Mouse

M. Rios-Cabanillas, and W. Atchison, Michigan State University, East Lansing, MI.

Astrocytes provide neuronal protection from excitotoxicity by eliminating glutamate from the synapses through the excitatory amino acid transporter 1 and 2 (EAAT1 and EAAT2). Mercury and reactive oxygen species reportedly inhibit EAAT1 and EAAT2 re-uptake of extracellular glutamate. In the spinal cord, where motor neuron degeneration occurs, the role of spinal cord astrocytes (SCA) in MeHg toxicity has not been fully characterized. We hypothesized that MeHg could induce down-regulation of EAAT1 and EAAT2 mRNA expression in mouse SCAs. Mouse SCA cultures were exposed to 0.5μM MeHg for 30 min, or 1-12h. RNA samples from SCA were collected at 30 min. Increase EAAT3 mRNA levels were increased at 3h of MeHg exposure ~ 2.8- and 2.2-fold relative to control respectively. Both subsequently declined back to control levels. The increase and later decrease of EAAT1 and EAAT2 mRNA, thus SCAs may initially attempt to buffer the glutamate-mediated excitotoxicity; the subsequent reduction of these mRNAs expression could exacerbate MeHg-induced excitotoxicity. The potential effect of MeHg on EAAT3 mRNA expression was examined in the motor neuron cell line (NSC-34). The predominant role of EAAT3 in neurons is not for glutamate uptake, but for intracellular glutathione synthesis, to protect neurons from oxidative stress. Expression levels of EAAT3 mRNA following 2 μM MeHg exposure was determined from 30 min, 1h and from 3-24h at 3h intervals. EAAT3 mRNA levels were 2.4-fold higher than control mRNA at 30 min. Increase EAAT3 mRNA levels gradually declined after 1h of MeHg exposure; they were significantly lower than NSC34 cells controls with more than a 2-fold decrease at 24h. Thus, MeHg affects EAAT1-2 mRNA expression in SCAs but also affects glutathione-precursor transporter mRNA expression in NSC-34 motor neuron-like cells. Thus, degeneration of spinal cord cells by MeHg exposure could be partially due to alteration of synaptic glutamate clearance-transporter expression in astrocytes and loss of antioxidant precursor transporter expression in neurons. This research was supported by NIH grant R01ES024064, and R25NS090988; ENDURE Program.

1483 Expression of Excitatory Amino Acid Transporter-1 and Glutathione Synthetase in Primary Spinal Cord Astrocytes during Methylmercury Exposure

K. A. Rivera-Caraballo, D. Wiwatratana, and W. D. Atchison, Michigan State University, East Lansing, MI.

Astrocytes provide neuronal protection from excitotoxicity by eliminating glutamate from the synapses through the excitatory amino acid transporter 1 and 2 (EAAT1 and EAAT2). Mercury and reactive oxygen species reportedly inhibit EAAT1 and EAAT2 re-uptake of extracellular glutamate. In the spinal cord, where motor neuron degeneration occurs, the role of spinal cord astrocytes (SCA) in MeHg toxicity has not been fully characterized. We hypothesized that MeHg could induce down-regulation of EAAT1 and EAAT2 mRNA expression in mouse SCAs. Mouse SCA cultures were exposed to 0.5μM MeHg for 30 min, or 1-12h. RNA samples from SCA were collected at 30 min. Increase EAAT3 mRNA levels were increased at 3h of MeHg exposure ~ 2.8- and 2.2-fold relative to control respectively. Both subsequently declined back to control levels. The increase and later decrease of EAAT1 and EAAT2 mRNA, thus SCAs may initially attempt to buffer the glutamate-mediated excitotoxicity; the subsequent reduction of these mRNAs expression could exacerbate MeHg-induced excitotoxicity. The potential effect of MeHg on EAAT3 mRNA expression was examined in the motor neuron cell line (NSC-34). The predominant role of EAAT3 in neurons is not for glutamate uptake, but for intracellular glutathione synthesis, to protect neurons from oxidative stress. Expression levels of EAAT3 mRNA following 2 μM MeHg exposure was determined from 30 min, 1h and from 3-24h at 3h intervals. EAAT3 mRNA levels were 2.4-fold higher than control mRNA at 30 min. Increase EAAT3 mRNA levels gradually declined after 1h of MeHg exposure; they were significantly lower than NSC34 cells controls with more than a 2-fold decrease at 24h. Thus, MeHg affects EAAT1-2 mRNA expression in SCAs but also affects glutathione-precursor transporter mRNA expression in NSC-34 motor neuron-like cells. Thus, degeneration of spinal cord cells by MeHg exposure could be partially due to alteration of synaptic glutamate clearance-transporter expression in astrocytes and loss of antioxidant precursor transporter expression in neurons. This research was supported by NIH grant R01ES024064, and R25NS090988; ENDURE Program.

1484 The Expression of Glutamate Transporter-1 and Glutamine Synthetase in Primary Spinal Cord Astrocytes during Methylmercury Exposure

K. A. Rivera-Caraballo, D. Wiwatratana, and W. D. Atchison, Michigan State University, East Lansing, MI.

Expression of excitatory amino acid transporter (GLT-1) and glutaminase synthetase (GS) plays an important role in cytoplasmic glutamate and the glutamine cycle between astrocytes and neurons. The expression of GLUT1-2 mRNA, thus SCAs contribute both to neuronal survival and degeneration. For MeHg, astrocytes have been demonstrated to be a target of toxicity, with increased oxidative stress and impaired glutamate uptake, yet astrocytes also protect neurons from MeHg-induced generation of oxidative damage through production of glutathione. Astrocytes protect over-extracellular glutamate through re-uptake of the glutamate by way of excitatory amino acid transporter (EAAT). The EAAT type 2 or glutamate transporter 1 (GLT-1) plays a pivotal role in maintaining non-toxic levels of extracellular glutamate while glutamine synthetase (GS) plays an important role in cytoplasmic glutamate and the glutamine cycle between astrocytes and neurons. GS in astrocytes converts glutamate into glutamine, then recycles back to the synapses as a neuronal glutamate precursor. In this study, the MeHg toxicity to primary spinal cord astrocytes (SCA) were examined as a function of time and concentration of MeHg exposure. The degree of MeHg toxicity to SCA was greater in the highest range of MeHg concentration in our study, using 0.1, 0.5, 1, 2 and 5 μM MeHg. The concentration response curve indicated a decrease in IC50 with longer times of exposure to MeHg. The time function of MeHg toxicity indicated a left shift of the concentration response curve in which IC50 decreased for longer MeHg exposure and increased hillslope value. The high limit threshold is 12 h of MeHg exposure with a concentration of 0.3 μM MeHg would cause 50% of SCA to degenerate. The degree of susceptibility of SCA to MeHg also depends upon SCA structure and size. The large flat astrocytes were more resistant, whereas small process bearing astrocytes are more susceptible to MeHg. The mechanism involved in MeHg induced SCA degeneration may be alteration of oxidative stress and impaired glutamate uptake, yet astrocytes also protect neurons from MeHg-induced generation of oxidative damage through production of glutathione.
exposure, there was an increase of population of SCA expressing GLT-1 greater than the SCA control. The level of G5 appeared to decrease for longer exposures to MeHg and this alteration appears to be associated with the GLT-1 expression level. This research is supported by NIH grant R01 ES024064.

**1485** Methylmercury In Vivo Preferentially Potentiates AMPA-Mediated Currents in Brainstem-Hypoglossal-Motorneurons from Mice Expressing the Human Superoxide Dismutase 1 (hSOD1) G93a Gene Mutation

Y. Yuan, J. M. Bailey, J. B. Spitsbergen, and W. D. Atchison. Michigan State University, East Lansing, MI.

Gene-environment interactions are believed to contribute to development of Amyotrophic Lateral Sclerosis (ALS), a progressive and fatal disease of motor neurons (MNs). We previously showed that chronic exposure of mice overexpressing the human superoxide dismutase 1 (hSOD1) gene mutation (hSOD1G93a) A mouse model for ALS, to methylmercury (MeHg), accelerated the onset of ALS-like phenotype. In vitro, we also showed that MeHg altered AMPA receptor expression when present with our previous in vitro results: [Ca2+]i at 15 min and 1 hr (0.52, 0.66 relative fluorescence, respectively) in MNs from G93A mice. Conversely, neither AMPA- nor GABA-A receptor-evoked currents were examined in whole cell recording techniques. Untreated littermates were sacrificed at the same time points to serve as controls. AMPA and GABA-evoked currents were examined at two holding potentials. At -50 mV, AMPA and GABA evoked inward and outward currents respectively. However, at a holding potential of -80 mV, which approximates the reversal potential for GABA under our conditions, only AMPA-meditated currents were evoked. MeHg exposure significantly increased amplitude of AMPA-meditated currents, simultaneously reducing GABA-mediated currents in hypoglossal MNs from G93A mice. Conversely, neither AMPA- nor GABA-evoked currents in MNs of SOD1 WT or WT were affected. Thus, consistent with our previous in vitro studies, gene-MeHg interactions appear to contribute to MN excitotoxicity, thereby facilitating development of ALS-like phenotype. Supported by NIH/NIH grant ES024064 and NIH/NIH T32 ES0075250.

**1486** Role of Inhibitory and Excitatory Receptors in Mediating Calcium Changes during Acute Methylmercury Exposure on the C57BL6j Mouse

R. González-Pons1, M. Ríos-Cabanillas2, and W. Atchison2. 1University of Puerto Rico, Cayey, PR; and 2Michigan State University, East Lansing, MI.

Lumbar spinal cord excitatory motor neurons (MNs) and inhibitory Renshaw cells (RCs) interact with each other in a negative feedback mechanism called recurrent inhibition. Interruption of this mechanism by MeHg can result in epileptiform activity. Neurons use glutamate (excitatory) and GABA (inhibitory) neurotransmitters to communicate with each other in either excitatory or inhibitory processes. The effects of MeHg on the Renshaw cells of rats have been studied extensively. However, MeHg alters recurrent inhibition in the absence or presence of strychnine, bicuculline, mecamylamine (MEC) or DhβE. Results show (N=11) that MeHg treatment alone significantly increases [Ca2+]i at 15 min and 1 hr (0.52, 0.66 relative fluorescence, respectively) from baseline. MEC, an excitatory nAChR antagonist, pretreatment fol-

**1486a** Short-Term Effects of Gulf War Illness-Related Chemical Exposure on Brain Monoamines: Modulation by the Neoglycoconjugate LNFPIII

J. M. Carpenter, J. J. Wagner, D. A. Herrn, and N. M. Filipov. University of Georgia, Athens, GA.

Of the 700,000 veterans from the 1990-1991 Gulf War (GW), 25-30% suffer from Gulf War Illness (GWI), a complex disease that includes neurological symptoms, such as disruption in movement, memory and mood that might originate from GW-related chemical exposures. Neuroinflammation is a prominent GWI feature. A neoglycoconjugate of Lacto-N-fucopentaose III (LNFPIII), a human breast milk component, has potent immunomodulatory properties. Using a mouse (male C57BL/6) model of GWI (Pyridostigmine bromide + Permethrin) and LNFPIII treatment (both for 10 days), this study sought to determine the short-term effects of the GWI treatment on brain monoamines and the potential protection LNFPIII affords. Six or 48 hr post treatment, brain monoamines were analyzed using high-performance liquid chromatography with electrochemical detection (HPLC-EC) in the prefrontal cortex (PFC), nucleus accumbens (NA), striatum (STR), amygdala (AMY), dorsal hippocampus (dHipp), ventral hippocampus (vHipp), and cerebellum (CER). The GWI chemical treatment resulted in fairly wide spread perturbation of serotonin (5HT) homeostasis that was most notable by 48 hrs and it manifested itself with increased 5-HIAA (a 5-HT metabolite) and trends for decreased 5-HT. LNFPIII treatment maintained 5-HT levels in the NA, STR, and CER, thus, counteracting the GWI chemicals effects. In GWI treated groups, dopamine (DA; 6 h) and its metabolite HVA (6 and 48 h) increased in the PFC and vHipp, with this effect not seen in the mice that were also treated with LNFPIII. Overall, the data indicate that, in the short term, this GWI treatment causes a more widespread serotonergic perturbation and a more focused dopaminergic dysfunction in brain areas that include the ones associated with locomotion, cognition, and mood. At multiple instances, chemical effects were not seen if animals were given LNFPIII, suggesting that this is a treatment option worth further pursuing. Supported by a grant number W81XWH-16-1-0586 (DoD).

**1486b** Comparative Effects of Methylmercury on Nrf2-Keap1 mRNA Expression in Primary Spinal Cord Astrocyte Cultures

J. A. Rios-Arce1, D. Wiwatratana2, and W. D. Atchison2. 1University of Puerto Rico in Arecibo, Arecibo, PR; and 2Michigan State University, East Lansing, MI.

Loss of redox homeostasis is involved in methylmercury (MeHg)-induced cell death. In the central nervous system, astrocytes are the first cells exposed to MeHg and accumulate mercury more than neurons. Neurons, however, are more susceptible to MeHg than astrocytes. Astrocytes play an important role in neuronal protection by supplying antioxidant glutathione (GSH) to neurons, especially during oxidative stress. A master regulator of antioxidants in cells, called nuclear factor erythroid 2-related factor 2 (Nrf2), controls the expression of several antioxidant genes including GSH precursors. Nrf2 is negatively regulated by Kelch-like ECH-associated protein 1 (Keap1) by undergoing ubiquitin proteosome degradation during normal physiology. Once oxidative stress occurs, these cytoprotective proteins are dissociated. The disso-

1487 Application of Multiple Methods for GFP Detection in Histological Sections in Animal Toxicity Studies

G. Bondarenko, S. Sorden, S. Webster, Z. Antionio, E. Budzynski, B. Christian, and A. Sharma. Covance, Madison, WI.

Green Fluorescent protein (GFP) is widely used as a gene expression reporter and a molecular and cellular tag in biomedical research. Detection of GFP in histological sections is critically important for the visualization of tagged proteins and transfected cells in animal toxicity and efficacy studies. Analysis of GFP reporter gene expression in tissue sections is currently a leading method for evaluation of vector system effectiveness in gene therapy in target tissues such as the eye. Multiple sensitive methods for GFP detection within formalin-fixed paraffin-embedded (FFPE) tissue utilizing direct fluorescent (DF), immunofluorescent (IF), immunohistochemical (IHC) and in situ hybridization (ISH) techniques were established. FFPE sections of known positive (GFP transfected) and negative (naïve) tissue and cell lines were used as controls and to evaluate the specificity of the methods. While IHC and IF staining with commercially available antibodies are the primary methods used for revealing the presence of GFP in cells and tissues, DF detection of GFP in unstained FFPE sections allowed preliminary screening of study slides to find samples with visible signal. Our data showed a direct correlation of signal intensity between DF and IHC/IF staining, although some reports suggest that GFP may lose fluorescence during tissue fixation and processing. The relative simplicity and reliability of the DF visualization significantly decreased the time required for method validation/optimization and enabled rapid identification of samples with low positive signal. Establishing IHC/IF with different species of anti-GFP antibodies (e.g. mouse monoclonal and rabbit polyclonal) permitted the use of varied detection techniques on tissue from a wide variety of animal models used in toxicity studies (mouse, rat, rabbit, primate etc.) in single and multiplex (double) staining protocols. Chromogenic ISH utilizing an RNAscope® protocol designed to detect GFP (enhanced GFP) mRNA expression patterns in FFPE tissue is invaluable in cases in which GFP signal is below the limit of detection for IHC/IF.

1488 Oral Cyclosporine A Immunosuppressive Therapy Leads to Systemic Toxicity in the Royal College of Surgeons Rats

The Royal College of Surgeons (RCS) rats are a widely used model of reces-

18 hrs, it had been reduced to ~ 25% of control levels. Despite reduc-

tion of Keap1 expression, and loss of negative control of Nrf2, there was no concomitant increase in Nrf2 expression in spinal cord astrocytes in response to MeHg. This research is supported by NIH grant R01 ES024064, and R25 Summer Undergraduate Research Program R25 ESI5025060.

1489 The Dual-Effect of Melatonin on Type I Diabetic Retinopathy

J. Y. Chang, L. Shi, M. Ko, and G. Ko. Texas A&M University, College Station, TX.

Diabetes is a fast-growing global problem, and diabetic retinopathy (DR) is the leading cause of blindness among Americans over 40 years old. Nearly all patients with type I diabetes and more than 60% of those with type II diabetes will develop DR. Diabetic retinopathy is a dual disorder with microvascular complications and retinal degeneration. Oxidative stress is one of the major culprits in development of DR vascular lesions and photoreceptors death. Scavenging reactive oxygen species may be a potential strategy to delay the DR progression. Here we use melatonin as a potential treatment based on its antioxidative properties for DR complication and screen its effect on microvascular and retinal neuron separately. STZ-induced type I diabetic mouse model was used in this study. STZ mice were separated into two groups, and one of them were given daily melatonin injections while the other group were monitored regularly. Retinal light responses by electoretinography (ERG) measurement and fluorescein angiography (FA) were used to assess changes in retinal neurons and retinal vasculature. Ocular tissues were harvested and analyzed for molecular changes by immunofluorescent staining. There is no significant difference in the body weight among the control, control treated with melatonin, STZ, and STZ treated with melatonin mice, but melatonin treatment seems to increase systemic glucose levels. Melatonin has no significant effect on retinal light responses on control mice. But the STZ mice given daily melatonin had compromised retinal light responses, which was worsened over time compared to the STZ mice without melatonin. However, melatonin treatments reversed STZ-induced changes in mitochondrial dynamics and neovascularization in the retina. Melatonin treatment for three months worsens the retinal light responses, but it might improve diabetes-induced changes in mitochondrial dynamics and retinal neovascularization.

1490 Evaluation of Streptozotocin-Induced Lens Opacities by Using Retro-Illumination Camera in Rats

In the ophthalmologic examination of non-clinical toxicity study, slit lamp is usually used to evaluate the optic media including lens. To monitor and evaluate drug-induced cataract, objective and reproducible method for documenting the cataract formation is important. Photograph taken by slit lamp has the limitation of producing a single section through the lens. Even if the photos of multiple sections are taken by slit lamp, it still gives an incomplete statement of the total amount of lens opacity. Retro-illumination photography can be used in visualization of lens opacity and the use of the retro-illumination camera in documenting cataract is well established in human clinical setting, but not in experimental animals. In this study, the development of cataract in streptozotocin-induced diabetic rats (n = 15) was documented with a retro-illumination camera (Lovex Co., Ltd.) once a week after intravenous injection of streptozotocin (50 mg/kg) during a 13-week period and the applicability of this camera system in rats was evaluated. As a result, lens opacity was noted in all the streptozotocin-induced diabetic rats between 1 and 4 weeks after the injection of streptozotocin. As the early morphological changes, small vacuoles or short radial opacities appeared at the lens equator, or featherly or net-shaped opacities, which are difficult to take photographs by slit lamp, were observed under the retro-illumination camera clearly documented by the retro-illumination camera. Several courses of cataract development were successfully and easily documented and it was suggested that the retro-illumination camera is a useful tool to visualize cataract formation.

1491 Cadmium-Induced Changes in Gene Expression in Human Lens Epithelial Cells

K. Srinivasan, M. J. Jenny, and A. G. McArthur. 1McMaster University, Hamilton, ON, Canada; and 2University of Alabama, Tuscaloosa, AL.

Vision is a crucial aspect of life for humans and animals, and cataracts are a leading cause of impaired vision and blindness. Although cataracts may form as a process of aging, several environmental and life-style factors increase the risk of this disease, such as cigarette smoking, oxidative stress and steroid treatments. The toxic metal cadmium (Cd), a major contributor to cigarette-related cataract formation, and other related risk factors are known to activate the metal regulatory transcription factor 1 (MRTF-1). Previous research [O’Sheilds et al., Biochim Biophys Acta 2017] showed that the early expression of MTF-1 in human lens epithelial cells (HLE) was induced by the toxic metal cadmium. Here, we used a microarray approach to investigate the gene expression profile of HLE cells exposed to CdCl2. Using this approach, we identified a number of genes that were differentially expressed following CdCl2 exposure. These genes were primarily involved in the processes of apoptosis, cell cycle regulation, and cellular response to stress. The results of this study suggest that cadmium exposure may induce changes in the expression of genes involved in the development and progression of cataracts.
An Approach for Assessing Mild Irritants with the Bovine Corneal Opacity and Permeability Test Method

H. Kojima1, M. Furukawa2, K. Itoh2, T. Sakakibara2, and M. Matsuura1. 1National Institute of Health Sciences, Tokyo, Japan; 2Safety Research Institute for Chemical Compounds Co, Ltd, Sapporo, Japan.

The bovine corneal opacity and permeability (BCOP) test method (OECD TG 437) is an in vitro test method that uses isolated bovine cornea from cattle slaughtered for commercial purposes to identify test chemicals that are possibly and severe irritants (UN GHS Category 1). At present, neither the BCOP test method nor any other alternative eye irritation test method is capable of identifying test chemicals as UN GHS Categories 2A or 2B, and efforts to develop such a test are continuing. As part of this effort, we investigated whether or not test chemicals could be identified as GHS Categories 2A or 2B using a modified version of the BCOP test method that includes a histopathological examination. We tested 85 substances to determine an in vitro irritancy score (IVS) and histopathological findings for corneal changes in the corneal epithelium and stroma. IVS values were calculated based on the corneal opacity and permeability values following exposure to a test chemical per OECD TG 437. The corneas were then fixed in 10% buffered formalin solution, stained with hematoxylin and eosin, and subjected to a histopathological examination. Fifteen of the 85 test chemicals are known to be UN GHS Category 2B, and for thirty-one of these, high IVIS values were calculated based on the corneal opacity and permeability values following exposure to a test chemical per OECD TG 437. The corneas were then fixed in 10% buffered formalin solution, stained with hematoxylin and eosin, and subjected to a histopathological examination. Fifteen of the 85 test chemicals are known to be UN GHS Category 2B, and for thirty-one of these, high IVIS values were calculated based on the corneal opacity and permeability values following exposure to a test chemical per OECD TG 437.

Laser-Induced Choroidal Neovascularization as a Model of Age-Related Macular Degeneration in the Minipig

Choroidal Neovascularization (CNV) is a known cause of Age-Related Macular Degeneration (AMD). Lucentis’ (ranibuzumab) is a marketed treatment for AMD, and is hypothesized to function by binding to vascular endothelial growth factors (VEGF) and preventing aberrant vascular growth. Ocular similarities between humans and miniature swine make it a useful large animal model ocular therapies, and this study aimed to validate the miniature swine model of laser induced CNV. In this study, Choroidal Neovascularization was generated in Sinclair minipig using retinal photoocoagulation. After laser induction of CNV, animals received a single 25 µL intravitreal injection of either Lucentis' (n=4), or vehicle (n=4). Eyes examinations and fluorescein angiography were performed to assess hemorrhaging and formation of CNV lesions. CNV lesions developed as expected, as hypofluorescent spots and hemorrhages caused by laser tissue damage were observed during weeks 1 and 2. Grade 1 through 3 CNV lesions were present in weeks 1 and 2. Ocular opacities prevented fluorescein imaging in 2/4 vehicle treated animals compared to 1/4 Lucentis’ treated animals. By week 6 all hypofluorescent spots and hemorrhages had resolved and clinically significant Grade 4 CNV lesions were present, defined by bright hyperfluorescence at the mid-time point and late leakage beyond the treated area during fluorescein angiography. Grade 4 lesions were present at a lower prevalence (25% of observed lesions) in Lucentis’ treated animals compared to vehicle treated animals (33% of observed lesions). Based on vitreous opacities, and anterior segment inflammation, vehicle treated animals developed more severe ocular changes than Lucentis’ treated animals. Lucentis’ treatment demonstrated an anti-angiogenic effect, validating the Sinclair minipig as a model of wet AMD.

Validating a Scoring Methodology for Drug-Induced Anterior Segment Inflammation in Non-Human Primate Eyes

R. Goody, A. Banerjee, and M. Lawrence. RxGen, New Haven, CT.

The eye of the African green monkey (AGM; Chlorocebus sabaeus) shares significant anatomic and physiologic similarity to the human eye. As such, this Old World nonhuman primate species has been increasingly employed as a preclinical ophthalmic test system for safety and efficacy studies. In this study, an ophthalmic inflammation scoring system, adapted from reported clinical and preclinical scales, was validated in eyes receiving intracameral concanavalin A (con A), a mitogen that induces anterior uveitis when introduced into the aqueous chamber. Six adult male and 6 adult female AGMs were evaluated. Following baseline slit lamp exam, laser flare photometry, tonometry, and pachymetry, monkeys received intracameral injection of con A (20 µl of 2.5 µg/µl; a dose titrated to induce mild reversible inflammation). Follow up ocular exams were performed 1, 2, 4, 6 and 8 days later. Anterior chamber flare and cell was scored and clinical pathology recorded by direct external inspection and slit lamp biomicroscopy. Exams consisted of evaluation of the eyelids, palpebral and bulbar conjunctiva, cornea, anterior chamber cell and flare, cell deposits on the corneal endothelium, lens and vitreous, IOP, pupillary diameter, intraocular pressure, and 90 diopter lens with scoring of inflammatory changes within discrete anatomical regions. The scoring regimen was established to cover the full spectrum of potential ocular inflammatory changes, though the con A dose employed to model moderate anterior uveitis the lower end of each scale was primarily applied. Additionally, an evaluation of visual acuity was also conducted prior to sedation for clinical exams to confirm retention of visual function throughout the study and laser flare photometry was also performed. Topical dexamethasone (Dex) was used as a positive control. Intracameral con A induced ocular changes consistent with the clinical spectrum of pathology observed in anterior uveitis and potential test article-associated inflammatory changes, including conjunctival swelling and discharge, corneal clouding, keratic precipitates, anterior chamber cell and flare, cell deposits on the corneal endothelium and lens capsule, fibrin strands, iris hyperemia and edema. Laser flare and clinical ocular evaluations demonstrated a robust and significant anti-inflammatory effect of Dex when compared to vehicle-treated eyes, which validated the applied scoring methodology for the evaluation of anterior chamber inflammation in ocular safety studies.

The Porcine Corneal Opacity and Reversibility Assay (PorCORA) and Assessment of the Drivers of Classification with Regard to Ocular Damage

The Draize rabbit eye test assesses damage to a number of different eye structures, which are scored and weighted based on their anatomic and physiologic importance. The structures are: Cornea (CO), Conjunctiva (Conj), and Iris (IR). Corneal irritation is assessed by opacities on the cornea, Conj irritation is assessed by increased vascularization, and IR damage by function of the iris (ability to constrict or dilate pupil) and deepening of the pupil. The heaviest weighting is on corneal damage, which is 20 points, and finally IR is only 10 points. Since the CO scores have the heaviest weight, and most often are the drivers of eye irritation, we developed an ex vivo corneal model to assess these effects. The PorCORA is an ex vivo corneal assay, which can distinguish between a material's potential to cause severe (reversible) versus
corrosive (irreversible) damage. We tested a total of 56 chemicals and dilutions of chemicals ranging from corrosive (GS category 1) to non-irritating (GS not categorized). Using Cooper Statistics, we arrived at an accuracy of 89% with a positive and negative predictivity of 85% (cat. 1) and 93% (not cat. 1), respectively. To determine if these Cooper Statistics could be improved, we used the drivers of classification concept based on Barros et al., 2016. Upon re-examination of our data based on this published database and methodology, we found that four chemicals (1,2,4-Triazole, N-Butanol, 2,5-Dimethyl-2,5-Hexanediol, and Potassium Cyanate) had invalid tests (animals euthanized prior to day 21) or produced irritation not driven by corneal opacities. These chemicals were removed from our dataset. Without these four chemicals the accuracy improved to 92%. Moreover, the major change was in our positive predictivity, which increased to 91%. The negative predictivity for this subset of chemicals remained the same. Lastly, PorCORA’s predictivity was assessed based on CO persistency; i.e., materials that produced low CO scores (from Draize Rabbit Eye Tests). Of the 56 chemicals tested, 40 had low severity (i.e., CO mean scores < 3). The accuracy for persistence of low CO scores was 88% with positive and negative predictivity of 79%, and 92%, respectively. Based on these data, the PorCORA was proven to be a valid test to assess a material’s potential to distinguish reversible versus irreversible eye damage.

**1496 Sex- and Age-Related Differences in Cadmium-Induced Global Transcriptomic Profiles in Adult Zebrafish Eye Tissues**

M. J. Jenny1, K. Srinivasan2, B. O’Shields1, and A. G. McArthur2.
1University of Alabama, Tuscaloosa, AL; and 2McMaster University, Hamilton, ON, Canada.

Although cataracts and macular degeneration are disease pathologies related to aging, environmental factors, such as heavy metal exposure, may also increase the risk of disease. Cigarette smoking contributes to the development of these pathologies, with the toxic metal cadmium (Cd) considered to be a major contributor to cigarette-related eye pathologies. Using the zebrafish model, we exposed 6- and 10-month adults to 50 μM Cd for four hours prior to assessing changes in global gene expression by RNA sequencing (RNA-seq) in whole eye tissue. To determine sex-specific changes in gene expression, transcriptomic profiles between 10-month male and female zebrafish were compared. A total of 431 genes (174 up-regulated and 257 down-regulated) were differentially expressed in 10-month males, while 461 genes were differentially expressed in 10-month females (105 up-regulated and 362 down-regulated) in response to Cd treatment. For further characterization of differences in the response to Cd exposure, age-dependent comparisons were performed between 6- and 10-month males. A total of 311 genes (183 up-regulated and 128 down-regulated) were differentially expressed in 6-month males, while 375 genes were differentially expressed in 10-month males (195 up-regulated and 180 down-regulated) in response to Cd treatment. Only 38% of differentially expressed genes in 10-month old zebrafish were shared between males and females, while 32% of differentially expressed genes in male zebrafish were shared between 6- and 10-month old fish. Based on gene ontology (GO) enrichment analysis, the 10-month male Cd exposure (up-regulated genes) was the only treatment with any eye-specific enriched terms (eye development, eye morphogenesis and camera-type eye morphogenesis), while terms related to cellular defense and inflammation were enriched in most treatments. Overall the 6- and 10-month male zebrafish only shared 24% of the enriched GO terms, while 10-month males and females only shared 14% of the enriched terms. These results highlight significant differences in sex and age-dependent differential gene expression in response to Cd exposure, providing greater insight into mechanisms of metal-induced stress which may contribute to the development of eye pathologies (1821ES0263910).

**1497 Cosmetics Europe Analysis: Towards Development of an Ocular Toxicity-Defined Approach Using In Vitro Test Methods and Physicochemical Properties as Components within an IATA**

B. Desprez1, N. Alépée3, E. Adriaens3, D. Bagley2, J. Hmistallah1, K. Mewes2, U. Pfannenbecker1, and P. McNamee2.
1Cosmetics Europe, Brussels, Belgium; 2L’Oréal, Aulnay Sous Bois, France; 3Adriaens Consulting, Aalter, Belgium; 4Colgate-Palmolive, Piscataway, NJ; 5Chanel Parfums Beauté, Neuilly sur Seine, France; 6Henkel AG & Co. KGaA, Düsseldorf, Germany; 7Beiersdorf AG, Hamburg, Germany; and 8The Procter & Gamble Company, Egham, United Kingdom.

In 2017, OECD published a guidance document on an Integrated Approach on Testing and Assessment (IATA) for serious eye damage and eye irritation. This provides guidance on how to integrate existing and / or newly generated information for decision making, including those on further testing or on classification & labelling for potential eye hazard of chemicals. In this context, physico-chemical properties may be used to identify chemicals not likely to cause serious eye damage / eye irritation and to help orient towards a Top-Down or Bottom-Up approach. Overall aim of Cosmetics Europe (CE) eye program is to gain better recognition by regulators / scientific organizations of safety assessments using strategies based on alternative approaches. A core focus area is data integration / evaluation of testing strategies (TS) / approaches. CE has created a comprehensive database of chemicals for which in vitro data are available with corresponding historical in vivo data. Physico-chemical properties are also being integrated. We used ~130 chemicals from this database and built on initial TS developed from the CEFIC CON4EI project, to evaluate robustness of such TS and identify areas for refinement. A key outcome is that combining in vitro test in combination would improve correct identification of Cat. 1 and Cat. 2 but not the specificity beyond that of a single test method. Preliminary analysis of physico-chemical properties using PCA identifies that the specificity of a TS is improved by integrating selected physico-chemical properties without majorly affecting the sensitivity. For example, for liquid chemicals (n=62) combining 2 in vitro test methods (RhCE and BCOP) in a Bottom-Up approach correctly predicts 81.3% Cat. 1, 71.4% Cat. 2 and 75.0% No Cat. Incorporating the physico-chemical properties LogP and vapour pressure increased correct identification of No Cat to 96.8% without major impact on correct identification of Cat. 1 and Cat. 2.

**1498 ROS Generation and JNK Activation Contribute to 4-Methoxy-TEMPO-Induced DNA Damage in HepG2 Cells**

4-Methoxy-TEMPO, a derivative of 2,2,6,6-tetramethylpiperidine-1-oxyl (TEMPO), is a stable nitroxide radical and is generally used in organic and pharmaceutical syntheses for the oxidation of alcohols. Previously, we reported the involvement of reactive oxygen species (ROS) and c-Jun N-terminal kinases (JNK) in TEMPO-induced apoptosis in mouse LS174Y cells. In this study, we investigated 4-methoxy-TEMPO induced toxicity in human HepG2 hepatoma cells and its underlying mechanisms. Treatments with 4-methoxy-TEMPO (0.5-5 mM for 2-6 hours) caused oxidative stress as demonstrated by increased intensity of the ROS indicator H2DCF-DA, decreased levels of glutathione. 4-Methoxy-TEMPO treatment also induced DNA damage as characterized by increased levels of DNA tail intensity is the Comet assay, increased phosphorylation of related proteins including γ-H2AX, p-Chk1, and p-Chk2, and activation of MAPK signaling pathways. In addition, 4-methoxy-TEMPO also induced autophagy as demonstrated by the conversion of LC3B-I to II, decreased level of p62, and the appearance of GFP-LC3B punctae. To investigate the crosstalk between different signaling pathways, pretreatment of HepG2 with N-acetylcystein (NAC), an ROS scavenger, attenuated 4-methoxy-TEMPO-induced DNA damage, suppressed JNK activation, and diminished autophagy induction. Furthermore, inhibiting JNK activation by a JNK-specific inhibitor, SP600125, decreased DNA damage levels induced by 4-methoxy-TEMPO. These results suggest that multiple mechanisms including ROS generation, DNA damage, and MAPK activation contribute to 4-methoxy-TEMPO-induced toxicity.
Genotoxicity assessment of pharmaceuticals or active ingredients used in cosmetology is mandatory for registration. In addition to the standard in vitro/in vivo test battery, other assays can be of interest because of their high throughput in the drug discovery stage. Among them, the γH2AX assay is suggested for detecting genotoxic properties of chemicals. The phosphorylation of γH2AX has been demonstrated to be a sensitive marker for DNA double strand breaks (DSB). Likewise, p53-binding protein 1 (53BP1) is an important regulator of the cellular response, promoting the end-joining of distal DNA ends. Keratinocytes are routinely used for skin toxicity studies. Large-scale cultures of primary keratinocytes demanded by high throughput approaches face obstacles such as a limited lifetime and in vitro differentiation, often compromising reproducibility. Here, we describe the expansion of primary keratinocytes after lentiviral transduction (upcyte® keratinocytes) for large-scale production and their subsequent use in γH2AX/53BP1 genotoxicity screenings. Resulting cells revealed typical keratinocyte morphology and were characterized by high expression of the basal marker CK5/14 while lacking expression of CK1/10. To further evaluate their suitability for genotoxicity studies, we challenged upcyte® keratinocytes and neonatal human epidermal keratinocytes (NHEK) with 16 model compounds including non-genotoxic controls (e.g. ampicillin trihydrate, D-threose, etoposide) and genotoxic compounds (e.g. paclitaxel, colchicine). Intranuclear γH2AX and 53BP1 spots were analyzed using an automated imaging approach. When looking at the γH2AX spot count, upcyte® keratinocytes were comparable to NHEK and allowed accurate identification of clastogenic compounds. In conclusion, we observed that γH2AX was not observed with non-genotoxic compounds. Interestingly, intranuclear 53BP1 spot counts revealed a base level 2 to 4.8 fold higher in upcyte® keratinocytes when compared to NHEK. This may explain that the fold induction of intranuclear 53BP1 spots after exposure to genotoxic compounds tended to be smaller in upcyte® keratinocytes when compared to NHEK. Direct sequencing of endogenous genes using error-corrected Next Generation Sequencing (NGS) has the potential to more accurately characterize mutagenesis, dose response, and ultimately cancer risk. In order to test the hypothesis that chemically-induced mutations in endogenous genes are comparable to the already validated cl t transgene, we directly examined the cl t gene and 4 endogenous genes in genomic DNA from the liver and bone marrow of BB mice treated with vehicle, N-ethyl-N-nitrosourea (ENU) and benzaldehyde (BpA) according to OECD guidelines. Using Duplex Sequencing (DS), the most accurate form of error-corrected NGS currently available (error rate <1/10^9), we compared the mutational frequencies (MF) and spectrum in the cl t transgene with a set of endogenous genes of varying expression level and chromosomal location: Polr1c, rhodopsin, haptoglobin and beta-cat- enin. As expected based on conventional BB plaque assay data, DS demonstrated that the cl t MF increased in response to chemical treatment to a degree that varied by tissue type. The endogenous genes also exhibited a clear increase in MF in response to mutagen treatment, similar to that seen in cl t, albeit with a reproducible 2-3 fold variation in magnitude between loci. The mutation spectrum in both the cl t gene and endogenous genes was also similar, and characteristic of ENU (T>A) and BpA (C>A) based on previous reports. The truncleotide spectral analysis demonstrated that adjacent nucleotide context strongly mod- ules mutagenic potential. For example, the number of base-pair substitutions was highly dependent on context, and additional active mutations in conventional BB, this could not be fully recognized with sequencing of individual plaques. These results support the con-
Measurement of DNA damage is an important factor in predicting human cancer risk of toxicants. In vitro mutagenic effects can be detected using reporter genes in bacteria and cells. However, in vivo mutagenesis was difficult to measure until development of transgenic rodent mutation assays. Assays, such as Big Blue® (BB), rely on recoverable bacteriophage shuttle vectors and loss of cII gene function measured using a bacterial-based plaque assay. Direct measurement of de novo mutations in DNA using standard next-generation sequencing is impossible due to an error rate (~10^{-3} mutants/base) well above the background mutation frequency of ~10^{-10} to 10^{-8}. Duplex Sequencing (DS) is a tag-based error correction method using both DNA strands that improves sequencing accuracy permitting detection of one mutant in ~10^{8} bases. The cII gene in BB animals is a qualified biomarker for in vivo mutation and the temperature selective plaque assay (PA) is a validated method to measure cII mutants (OECD TG 488). Here, we evaluated DS as an alternative method to measure cII mutant frequency (MF). We examined MF from liver (L5178Y) and BB mice treated with vehicle, N-ethyl-N-nitrosourea (ENU) or benzo[a]pyrene (BaP). The two methods gave similar fold increases in MF even though BB PA measures phenotypic mutants/gene and DS measures mutants/sequenced base. ENU gave increases in LV MF of 4.2-fold for PA and 4.3-fold for DS, and in BM MF of 10.6-fold (PA) and 7.1-fold (DS). BaP gave fold increases in LV MF of 4.9 (PA) and 3.6 (DS) and in BM MF of 17.7 (PA) and 9.5 (DS). Hierarchical clustering of cII mutants showed that ENU mutants from LV and BM and BaP in BM gave group specific signatures. Mutant spectra from vehicle animals overlapped somewhat with BaP spectra in LV. Spectra matched those classic for ENU (T→A) and signatures. Mutant spectra from vehicle animals overlapped somewhat with BaP spectra in LV. Spectra matched those classic for ENU (T→A) and BaP, consistent with literature. Mutant plaques were isolated and sequenced from duodenum and BM from similarly treated animals. Comparing cII mutant sequence from DS measurement of genomic DNA and cII mutant plaques showed the expected loss of function mutations in both while DS revealed additional synonymous mutations missed by PA. This work demonstrates that DS is capable of detecting background and induced cII mutants comparable to traditional plaque methods.

**1505 Comparison of In Vitro Toxicity of E-Vapor Condensates to Literature Data for Cigarette Smoke Condensates**

M. M. Moore1, B. G. Coffa2, and M. Lee2, 1Ramboll Environ US Corporation, Little Rock, AR; and 2Altira Client Services, LLC, Richmond, VA.

The Food and Drug Administration Draft Guidance (2016) “Premarket Tobacco Product Applications for Electronic Nicotine Delivery Systems” recommends toxicological evaluations, including assessing in vitro genotoxicity and cytotoxicity, for new electronic nicotine delivery systems (ENDS) or e-vapor products. The Draft Guidance also recommends that the toxicity of ENDS be compared to the toxicity of traditional tobacco products such as combustible cigarettes. In the current analysis, we compared the genotoxic/cytotoxic potency (biological response per mass quantity) of condensates from selected e-vapor ENDS products marketed as MarkTen® with the condensates from combustible cigarettes. For the e-vapor products, the aerosol condensates were collected from MarkTen® products with a total of 7 formulations (a carrier (propylene glycol, glycerine, plus 5% nicotine) and 6 e-liquids (carrier plus flavor mixtures)). The e-vapor condensates were tested in two genotoxicity assays ( Ames Test and in vitro micronucleus assay (MN) using TK6 cells) and MN assays of cigarette condensates were genotoxic in the Ames and MN assays and cytotoxic in the NRU assay. The e-vapor condensates were not cytotoxic (NRU assay viability >80%) and not genotoxic in the Ames Test or the MN assay at any of the tested concentrations.

**1506 Absence of In Vitro Mutagenic and Genotoxic Properties of Two Supercritical Tobacco Extracts**

Super-critical carbon dioxide was used to extract tobacco constituents, especially aroma compounds from tobacco. The same method is used to extract natural substances for food, flavour, fragrance and pharmaceutical applications. The extracts were developed for use in a next generation tobacco product, where consumable ingredients are heated but not burned. Studies conducted on this next generation tobacco product indicated reduced exposure to toxicants in the aerosol generated, when compared to reference cigarette smoke. Part of the extracts’ stewardship was a series of in vitro mutagenicity and genotoxicity tests. Two liquid extracts were tested, derived from Virginia, Burley and Oriental tobaccos. The tests were for bacterial mutagenicity ( Ames test), mammalian mutagenicity (mouse lymphoma assay, MLA) and mammalian genotoxicity (the in vitro micronucleus test, IVMNT). All tests were conducted according to OECD guidelines, in an independent laboratory complying with GLP. The Ames test included bacterial strains TA98, TA100, TA102, TA1535 and TA1537. The MLA and IVMNT used LS178Y cells and V79 cells, respectively. All tests were with and without metabolic activation (rat liver S9). The vehicle control was dimethyl sulphoxide. Appropriate positive controls were used for each bacterial strain or cell line and level of metabolic activation. Test results were valid in terms of concurrent vehicle and positive control responses and historical ranges. All positive controls gave clear, statistically significant and reproducible responses, within their historical ranges. The extracts were tested up to 5mg/plate (Ames test) or 5mg/ml (MLA and IVMNT) which is the maximum recommended concentration for substances of unknown, variable or complex composition. Mutagenicity or genotoxicity were not observed in any of the tests. The conclusion was that these specific extracts were not mutagenic or genotoxic in vitro.
The exacerbatuse of animals in scientific research and industry has encouraged some researchers to create the 3Rs idea in 50th decade. These principles started the development and validation of alternative methods to the use of animals. In this context, we can highlight the use of three- dimensional cell culture for toxicological proposes, especially in the field of nutrition. Our model used in vitro hepatocyte culture itself as an integrated system. This combines metabolism and endpoint measurement in a hepatocyte culture, will increase confidence in results and could be used for chemical toxicity evaluation with results of concept, we determined genotoxic potential of octadiene (OCTA) and could be used for chemical toxicity evaluation with results more significant for human health when compared to monolayer cell culture.

Hepatocytes as a Metabolic-Activating System for Genotoxicity Testing: A Case Study with Octadiene

Use of the induced rat S9 as metabolic activating system in in vitro genotoxicity testing raises several issues including the high false positive rates seen with in vitro-based screening and therefore, questionable human relevance of in vitro results. The goal of this study was to demonstrate the importance of addressing both metabolic activation and detoxification to increase the predictivity of in vitro genotoxicity testing. As a proof of concept, we determined genotoxic potential of octadiene (OCTA) using a metabolically competent human primary hepatocyte suspension. OCTA requires cytochrome P450-mediated bioactivation to elicit genotoxicity. However, in vivo, OCTA’s active metabolites are detoxified by epoxide hydrolase and glutathione S-transferase, which cannot be fully captured by adding induced rat S9 to in vitro toxicity assays. As conventional genotoxic endpoints are not compatible with suspension culture, we measured DNA damage in HT1080 cells, a widely used in vitro genotoxicity testing model, by transferring media from primary hepatocytes to the suspension culture, we measured DNA damage in HT1080 cells, and the DNA adducts were identified in bronchial epithelial BEAS-2B cells. BEAS-2B cells were treated with 4-(methylhydroxynitrosamino)-(3-pyridyl)-1-butanone with Human Bronchial Epithelial Beas-2b Cells

F. Xie, K. Hu, G. Zhao, and X. Li, Zhengzhou Tobacco Research Institute of CNTC, Zhengzhou, China. Sponsor: R. Meng

4-(methylhydroxynitrosamino)-(3-pyridyl)-1-butanone (NNK) is among the most important carcinogenic tobacco-specific nitrosamines (TSNAs) in tobacco products, which is powerful cancer-causing agents in animal models targeting mainly the lung in rats, mice, hamsters, and ferrets. Metabolic activation of the carcinogenic NNK results in the formation of 4-(3-pyridyl)-4-oxobutylation (POB)-DNA adducts, which have been previously identified in tissues of laboratory animals treated with NNK, but its carcinogenic potential in humans is not known. To obtain a better understanding of the genotoxicity of NNK in humans, we have investigated its metabolism and its ability to form DNA adducts in bronchial epithelial BEAS-2B cells. BEAS-2B cells were treated with NNK at doses ranging from 0.1–100 μM, and the DNA adducts were identified and characterized by UHPLC–Q-TOF/MS/MS and UHPLC–MS/MS. Six major methylation DNA adducts were identified, including three methylation DNA adducts, methyl-2’-deoxyguanosine, methyl-2’-deoxycytidine, methylyl-2’-deoxyadenosine and methyl-2’-deoxymethylguanine. In addition, four minor DNA adducts, including O6-[4-(3-pyridyl)-4-oxobutyl-1-yl]-2’-deoxyguanosine (O6-POB-dG), O6-[4-(3-pyridyl)-4-oxobutyl-1-yl]cytidine (O6-POB-C), O6-[4-(3-pyridyl)-4-oxobutyl-1-yl]thymidine (O6-POB-dT), 8-hydroxy-2’-deoxyguanosine (8-OH-dG), and 8-methoxy-2’-deoxyguanosine (8-MOP), were identified. Preincubation of BEAS-2B cells with 8-methoxypsoralen (8-MOP), a selective mechanism-based inhibitor of CYP2B6, resulted in a strong decrease in the formation of NNK metabolites and a concomitant decrease in DNA adduct formation. With the addition of S9 mixture solution, the concentration of NNK metabolites and DNA 8-OH-dG were identified, which were identified with 8-MOP. Therefore, under the tested conditions, these e-liquids were negative for genotoxicity, implying no biological relevance of very weak in vitro genotoxicity signals.
Among short-term tests developed to assess genotoxicity of chemical compounds, the micronucleus (MN) assay is largely used for detecting chromosome damage. MN test allows classifying clastogenic and aneugenic events, with easy measurement in both in vitro and in vivo experimental systems. The assay represents a tool in risk evaluation and developments for automation scoring. However, MN assay does not provide a dynamic assessment of the genotoxic event and also lacks a relevant human metabolically competent cell model. Our goal was to develop an in vitro MN test coupled with a metabolically well-equipped RGIHep

In April 2017, the China FDA (CFDA) released a draft guidance on Genotoxicity Testing and Data Interpretation for Pharmaceuticals Intended for Human Use for public comments. The guidance has yet to be finalized. To better understand these changes, the genotoxic guidelines from different agencies (e.g., CFDA, ICH Testing Guideline (TG), and OECD TGs) were compared. The current draft CFDA version was changed mainly based on ICH and OECD TGs. Compared to the current CFDA guidance, the main changes are listed as follows: 1) Genotoxicity battery option 2 is accepted; 2) in vitro micronucleus assay is considered equally suitable, besides in vitro chromosomal aberration assay (CAA) and mouse lymphoma assay (MLA); comet assay is recommended as a second in vivo assay; 3) genotoxicity endpoints can be incorporated into repeated dose toxicity studies; 4) Ames assay should still be carried out for compounds that are toxic to bacteria (e.g., some antibiotics); 5) the maximum top concentration recommended for in vitro cytogenetic assays and MLA is reduced to 1 mM or 0.5 mg/ml, whichever is lower; 6) relative population doubling (RPD) and relative increase in cell count (RCC) are the recommended cytotoxicity parameters for in vitro cytogenetic assays, and the cytotoxicity should not exceed a reduction of about 50% in cell growth; 7) when solubility is limiting, the maximum concentration, if not limited by cytotoxicity, should be the lowest concentration at which minimal precipitate is visible in cultures for in vitro cytogenetic assays and MLA; 8) automated analysis and rat blood are formally accepted for in vivo micronucleus assay if appropriately validated; 9) the scored number of cells to improve the statistical power is increased; and 10) more emphasis is placed on the evaluation of test results and follow-up test strategies. Although the draft version mainly refers to ICH TG, there are still several differences based on China’s actual condition. The main differences are listed as follows: 1) Ames experiment needs to be repeated even if the result is clearly positive or negative; 2) positive control should be included in every in vivo study; 3) genotoxicity battery should be fully investigated prior to clinical trials; and 4) special recommendations on traditional Chinese medicine should be included. Based on the above analysis, the draft version of CFDA TG is very similar to ICH TG, but there are still some special requests.
Acrylic bone cement is self-curing cement comprising of liquid and powder components of methyl metacrylate (MMA). It has been used extensively in orthopedics; however, adverse effects including exothermic reaction and bone cement implantation syndrome were associated with its use. In this case study, we investigated the genotoxic potential of two types of bone cement implant devices, bone cement loaded with and without antibiotic, which are both comprised of 97% MMA. The samples were fully cured and stored at -80°C prior to extraction. In Salmonella/E. coli Mutagenicity Test (Ames test), 0.316% and 3.16% of neat polar extract of antibiotic-loaded bone cement induced a statistically significant increase in the number of revertant colonies in TA100 strain in the presence of metabolic activation. However, the number of revertants was less than twofold of the number in the corresponding negative control. These data indicated that the extracts were not mutagenic.

We found that 25% of the neat polar extracts from bone cement with and without antibiotic induced 17% and 8% metaphases with aberrations, respectively, in the presence of metabolic activation. Interestingly, the increase of chromosome aberration was not observed in cured samples that were stored at room temperature. These data suggest that the clastogenic effect could be the result of a direct effect of MMA. In conclusion, our results provide initial evidence about the biocompatibility of the MMA bone cement.

The 3D Reconstructed Human Skin Comet and Micronucleus (MN) assays have been developed and validated to follow-up on positive results from the current in vitro genotoxicity test battery using cultured cells as they represent the exposure more realistically for dermally-applied chemicals such as cosmetic ingredients. Validation of these assays includes testing chemicals that are not genotoxic themselves, but can be converted into mutagenic metabolites. For example, 2-acetylaminofluorene (2-AAF) is a carcinogen when administered dermally, orally, or by intraperitoneal injection in rodents and shows positive effects in vitro primarily after metabolic activation. N-hydroxy-2-acetylaminofluorene (N-OH-2-AAF) and N-hydroxy-2-aminofluorene (N-OH-2-AF) are genotoxic metabolites of 2-AAF that form DNA adducts. In this study, 3D reconstructed human skin models were topically treated with 2-AAF and these metabolites. 2-AAF did not increase DNA damage in keratinocytes in the MN assay when administered in multiple (2-3) applications at 24 hr intervals but could be detected in the Comet assay in the presence of the DNA polymerase inhibitor aphidicolin. No increase in DNA damage was observed in N-OH-2-AAF in the MN assay after multiple treatments while a single 3h exposure to N-OH-2-AAF caused a large dose-related increase in the Comet assay. A significant increase in the MN assay was only obtained with the highly reactive N-OH-2-AF metabolite after multiple treatments over 72h, but N-OH-2-AAF caused a strong increase in DNA damage after a single 3h exposure in the Comet assay. In support of these results, DNA adduct formation, as measured by the 32P-postlabeling assay, was examined in parallel samples and adduct levels after 2-AAF treatment for 3h were minimal but increased >10-fold after multiple exposures over 48h. These results suggest that enzyme(s) involved in 2-AAF metabolism can be induced in the skin models. As expected, a single 3h exposure to N-OH-2-AAF and N-OH-2-AF resulted in DNA adduct levels that were at least 10-fold greater than that observed with 2-AAF after multiple exposures. Our results demonstrate that the type of DNA damage caused by the 2-AAF metabolites is more efficiently detected in the 3D skin Comet assay than the MN assay and that after enzyme induction, 2-AAF can be detected in the modified Comet assay.
Obesity is an increasing global concern with studies reporting a significantly elevated risk of and a poor prognosis for a variety of cancers in people with a high body mass index. Obesity stimulates oxidative stress that can cause DNA double-strand breaks (DSBs) and reduced DNA repair capacity. DSBs can result in gene translocations that can disrupt oncogenes in cancers like Burkitt lymphoma (BL) and Chronic Myeloid Leukemia. The c-MYC oncogene in BL harbors vulnerable breakpoint “hotspots” enriched in repetitive DNA sequences. Such sequences can adopt alternate DNA structures (i.e. non-B DNA; e.g. H-DNA) and differ from the canonical B-form DNA double helix. We have found that H-DNA structures are intrinsically mutagenic in human cells and mice. We speculate that the formation of non-B DNA structures can increase the accessibility of DNA double-strand breaks and damage and impact DNA repair efficiency and accuracy, leading to more cancer-associated genetic instability.

Thus, we hypothesize that obesity increases DNA structure-induced genetic instability in vivo, contributing to mutation “hotspots” in cancer. To determine the extent to which obesity stimulates the mutagenic potential of H-DNA, groups of transgenic mice harboring a mutation-reporter vector with H-DNA-forming sequence (mapping to a breakpoint hotspot in BL) were put on control, 30% calorie-restricted (CR) diet and diet-inducing obesity (DIO) for 13 weeks. Subsequently, the mutation-reporter vector was recovered from the spleen tissues (n=3 mice/group) and subjected to mutagenesis assay. The mutation frequencies in genomic (g) DNA from control, CR, or DIO mice were determined between 2.3, 2.4 and 9.6 respectively. The mutation spectra showed large deletions (300-900 bp), small deletions (50-200 bp), point mutations and transversion events. To determine the impact of DIO on DNA damage and expression of any of the “hotspots” in the same groups, we performed a limited inter-laboratory validation study. In total 27 compounds (24 test compounds and 3 assay controls) were tested at least three times by two independent laboratories. The within-laboratory (WLR) and between-laboratory reproducibility (BLR) of the assay as well as the concordance of classification (genotoxic versus non-genotoxic) for the tested compounds was determined. The WLR for the six different ToxTracker reporters was assessed per category of reporters (DNA damage, oxidative stress, protein damage) and for all reporters together. The overall WLR was on average 94% for both laboratories. For laboratory 1, the average WLR ranged from 92.2% (oxidative stress) to 95.1% (protein damage). For laboratory 2, the average WLR ranged from 90.6% (protein damage) to 94.9% (genotoxicity). Also the BLR was evaluated for the different reporters with the highest concordance for the genotoxicity reporters (96.3%), followed by the reporters for p53 activation (92.6%), oxidative stress (88.0%) and protein damage (85.2%). This resulted in an overall BLR of 90.5%. Predictive capacity for genotoxicity was calculated for each laboratory and for the cumulative results of the two laboratories. The sensitivity for identification of genotoxic compounds was 77.8% (7 out of 9 genotoxic compounds tested positive in ToxTracker). The specificity was 94.1% (16 out of 17 non-genotoxic compounds tested negative in ToxTracker for both laboratories. In this study, the overall concordance between ToxTracker and the standard battery of in vitro and in vivo genotoxicity tests was 85%. Overall, the interlaboratory validation indicates an excellent transferability and predictive capacity of the ToxTracker assay. Furthermore, the combination of the six GFP reporter cell lines can be applied to gain insight into the mechanisms of genotoxicity.
The replacement of animal testing for safety assessment of chemicals is the concern of many researchers. In this context, in vitro genotoxicity safety assessment tests are needed. Reconstructed skin models are particularly interesting test systems, especially for compounds with a dermal route of entry since they entail the barrier function of the skin. The FADU assay, (Fluorimetric Detection of Alkaline DNA Unwinding) has recently been introduced as a rapid and reliable method to detect DNA strand breaks in vitro. In an effort to set up genotoxicity testing of chemicals to be applied to the skin, the automated FADU assay and human reconstructed skin models were combined. In a first step, the principios suitability of skin models (e.g., cell systems) for the FADU assay was tested. Secondly we attempted to reduce the tissue processing time after treatment in order to minimize manual processing steps and to more rigidly control the DNA repair period. epoCS were treated for 3 h with two genotoxic agents (methyl methanesulfonate (MMS), 4-nitroquinoline 1-oxide (4NQO): 16 µM/cm²). Subsequently, cells were separated enzymatically and DNA strand breaks were measured.

In order to avoid time consuming enzymatic cell separation a second approach utilized biopsy punches (1 mm), to withdraw small samples of the treated skin models. The samples were analyzed on behalf of the automated FADU assay (AUREA qTOX-analyzer, 3T analytik). In short the tissue samples obtained were lyzed chemically and were analyzed for DNA strand break frequency. The DNA damage detection is based on progressive DNA unwinding under highly controlled conditions of alkaline pH, time and temperature. A fluorescent dye is used as a marker for double stranded DNA. Controls are run in parallel with the treated cells. Importantly, the MMS and 4 NQO resulted in a clear increase in DNA double strand breaks detected after 3h incubation time as expected from literature data. By combination of the reconstructed skin model epiCS and the FADU genotoxicity assay, it is demonstrated that that this double strand breaks in genotoxic chemicals are sensitively detected. Our results clearly show that the FADU assay with reconstructed skin models is a promising tool for safety assessment of compounds with a dermal route of entry while taking into account the influence of the skin barrier function.

There is still a lot of discussion on the genotoxicity of antimony compounds. Both trivalent and pentavalent compounds are generally negative in mammalian genotoxicity assays, but in mammalian cell lines, trivalent compounds have generated some positive results, while pentavalent compounds remained negative. Therefore, we investigated the genotoxic potential of a group of nine antimony compounds (5b-metal, four trivalent and four pentavalent) in the ToxTracker assay. ToxTracker is a panel of mammalian stem cells that contain different fluorescent reporters for induction of DNA damage, oxidative stress, and protein damage. The differential induction of the GFP reporters, as well as cytotoxicity of the tested compounds, is determined by flow cytometry. Selected compounds were analyzed in the absence and presence of an S9 rat liver extract-based metabolizing system. Quantitative data analysis is done using ToxPlot software. The validity of the ToxTracker assay results was confirmed by exposure to various reference compounds and assessing the specificity of the different reporter cell lines. None of the nine antimony compounds did induce the BscI2-GFP genotoxicity reporter that is associated with generation of pro-mutagenic DNA lesions or the Rtkn-GFP genotoxicity reporter for DNA strand breaks. Antimony, sodium antimonate, diantimony trioxide, antimony-3-sulfide, antimony glycolate, antimony-3-chloride, and antimony-5-chloride all induced the Srxn1-GFP and Blvrb-GFP oxidative stress markers significantly. None of the breaks induced were alanized by diantimony trioxide, antimony-3-sulfide, antimony glycolate, antimony-3-chloride, and antimony-5-chloride at cytotoxicity levels <75%. There was no indication in ToxTracker for metabolic activation of any of the antimony compounds. None of the tested antimony compounds showed genotoxicity in the ToxTracker assay even at the absence of or presence of a metabolizing system. Seven compounds induced significant levels of oxidative stress in the absence of a metabolizing system. Six of those compounds also showed a significant induction of oxidative stress in the presence of a metabolizing system.
DNA damage response proteins are stained and require vigilant analysis by the investigator, the proximity assay only positively stains foci at sites where DNA response proteins are physically binding during the DSB signaling cascade, thereby facilitating less biased and more time efficient analysis of DNA damage foci.

1527 The ToxTracker Reporter Assay Detects Indirect Genotoxicity by High-Lever of Oxidative Stress

ToxTracker is a mammalian stem cell-based reporter assay that detects activation of specific cellular signaling pathways upon exposure to unknown compounds (Hendriks et al, Tox Sci 2016). ToxTracker contains six different GFP-tagged reporters that allows discrimination between induction of DNA oxidative stress and protein damage in a single test. We first performed an extensive validation using 62 compounds from the recently updated ECVAM compound library. ToxTracker classified the genotoxic carcinogens as genotoxic with cytotoxicity of 94%. The non-genotoxic carcinogens and non-carcinogens were classified as non-genotoxic by ToxTracker with a specificity of 95%. Interestingly, various compounds that give misleading positive results in the conventional in vitro genotoxicity assays did not activate the DNA damage. However, it did induce high levels of oxidative stress or protein damage in ToxTracker. To further investigate indirect genotoxic effects of compounds that induce high levels of oxidative stress, a selection of 10 different metals, quinones, benzene compounds, and food additives were tested in ToxTracker in the presence of the ROS scavengers NAC (N-acetyl cysteine) or BHT (butylated hydroxytoluene). For each compound, three concentrations that induce 10-25/30% cytotoxicity in the reporter cell lines were tested in combination with increasing concentrations of NAC or BHT. In the absence of the ROS scavengers, all tested compounds activated the Snx1-GFP reporter for oxidative stress but often also activated the Rtkn-GFP genotoxicity reporter that is associated with induction of DNA strand breaks. Addition of NAC/BHT significantly reduced activation of the Snx1-GFP oxidative stress reporter. Interestingly, for many compounds also activation of the Rtkn-GFP DNA damage reporter was strongly reduced in the presence of the ROS scavengers, suggesting that the weak induction of DNA strand breaks by these compounds is likely a result of high levels of oxidative stress. The complete absence of induction of the Bsc12-GFP DNA damage marker, that is activation by DNA replication stress and induction of bulky, promutagenic DNA lesions, indicates that the tested compounds did not react directly with the DNA. Also cytotoxicity of the compounds was reduced by simultaneous incubation with a ROS scavenger, indicating that induction of oxidative stress is an important cytotoxic effect that can indirectly contribute to the genotoxic properties of compounds.

1528 Profiling the Budding Yeast Genome for Resistance to Heterocyclic Aromatic Amines

M. T. Fasullo, N. St. John, and F. Doyle. SUNY Polytechnic Institute, Albany, NY.

The incidence of colon cancer is correlated with a diet containing red meat. Charred red meat contains heterocyclic aromatic amines (HAAs) that are carcinogenic. Since HAAs are also genotoxins, we hypothesize that there are genetic factors that confer a higher incidence of colon cancer in individuals exposed to HAAs, such as 2-amino-3-methylimidazo[4,5-f]quinoline (IQ) and 2-amino-3, 8-dimethylimidazo[4,5-f]quinoline (MeIQx). These genetic factors may include polymorphic phase I and phase II genes that metabolically activate HAAs and genes that confer toxicity and DNA damage resistance. Because many Saccharomyces cerevisiae (budding yeast) genes are orthologous to human genes, budding yeast has been a useful model organism to identify basic housekeeping genes that confer resistance to toxicants, such as HAAs. We used the budding yeast diploid deletion library, which is a collection of ~5,000 strains each deleted for a single non-essential gene, to profile the yeast genome for HAA resistance. Budding yeast does not contain P450s that activate these compounds, so expression vectors that contain specific human P450s were introduced into the budding yeast genome for resistance to heterocyclic amines. The top five Genomic Ontology (GO) biological processes include transcription from RNA polymerase promoter, lipid metabolic process, responses to chemical, protein complex biogenesis, and regulation of organelle organization. Other GO biological processes include chromatin organization, response to chemical, and DNA repair. Among the DNA repair genes, genes involved in DNA damage tolerance and base excision repair (NTG1) were identified. NTG1 polymorphisms have previously been identified as genetic risk factors for colon cancer, and the yeast studies suggest that this risk may be aggravated when an individual’s diet contains HAAs. The yeast screens thus provide a novel methodology to identify genetic variants that confer resistance to HAA toxics. Support: National Institutes of Health, 1R15ES023685-01.

1529 Applicability of HepaRG Cell Line for Automated Assessment of DNA Strand Breaks

D. Dressler1, J. Pfitzer2, G. Daniel1, K. Engelhart-Jentzsch1, F. K. Gehring2, and C. Chesné1. 1BioTeSys GmbH, Esslingen, Germany; 2T Analytik GmbH, Tuttlingen, Germany; and 3Biopredic International, Saint Grégoire, France.

In the context of testing genotoxic potential of chemicals the automated FADU (Fluorimetric Assay for Detection of Alkaline DNA Unwinding) assay provides a critical role in the assessment of the genotoxic potential of various noxes due to the requirement of bioactivation. The HepaRG cell line with the expression of a broad range of Phase I and II enzymes, transporters, and nuclear factors is one of the best candidates mapping the response expected from human hepatocytes. The aim of the presented study was the assessment of the principle applicability of the HepaRG cells in the FADU assay. Two common genotoxic agents without the need of bioactivation (methyl methanesulfonate (MMS) and etoposide) as well as D-mannitol as negative control were investigated. Furthermore, applicability of HepaRG was tested for aflatoxin, a genotoxic agent with the need of bioactivation. HepaRG cells were supplemented with well-known genotoxic substances with different modes of action etoposide, MMS, and aflatoxin. The maximum concentration of aflatoxin was not cytotoxic tested with a common cytotoxicity assay. The DNA damage detection is based on progressive DNA unwinding under highly controlled conditions of alkaline pH, time and temperature. A fluorescent dye is used as marker for double stranded DNA. Controls are run in parallel with the treated cells in the conventional in vitro genotoxicity assay. The DNA damage detection was reproducibly and reliably for well-known genotoxic noxes with and without need of bioactivation. Our data indicate that this combination is a promising rapid method for safety assessment of chemicals.

1531 Integration of Liver Micronuclei, Blood Micronuclei, and Blood Pig-a Assays into a 28-Day Rat Study as a 3Rs Friendly Approach for Evaluating Chemicals’ In Vivo Genotoxic Potential—Proof-of-Concept with Diethylnitrosamine

Regulatory guidance documents note the value of assessing multiple tissues and the most appropriate endpoints when evaluating chemicals for in vivo genotoxic potential. However, conducting several studies to consider multiple endpoints and tissue compartments is time-consuming and resource-intensive. Furthermore, conventional approaches for scoring genotoxicity endpoints are slow, tedious, and less objective than the ideal. We are striving to address these deficiencies with the current state-of-the-art by i) employing flow cytometry-based methods for scoring liver micronuclei, blood micronuclei, and blood Pig-a mutation, and ii) integrating the assessments into a common general toxicology study design, the rat 28-day repeat dose study. As proof-of-concept, an experiment was performed with 6-week-old male Sprague Dawley rats exposed to diethylnitrosamine (DEN) for 28 consecutive days at 0, 5, 10 or 15 mg/kg/day. Blood was collected for the micronucleus reticulocyte (MN-RET) assay on Days 4 and 29. A aliquot of each Day 29 blood sample was also evaluated for the frequency of Pig-a mutant cells. Day 29 left lateral lobe liver sections were collected from exanguinated rats and processed for liver micronucleus scoring (MNHEP). Whereas MN-RET frequencies were not affected by DEN exposure, MNHEP exhibited dose-related increases (9.1-fold for the high dose group). Furthermore, the MNHEP values were highly cor-
related with parallel assessments accomplished via microscopy (R2 = 0.89). Concurrent with MNHEP analyses, assessments of Ki-67-positive events and the proportion of 2n, 4n, and 8n nuclei provided evidence for treatment-related changes to hepatocyte proliferation. Pig-a mutant cell frequencies were slightly elevated, suggesting DEN can induce gene mutation to hematopoietic cells in the bone marrow, despite the low level of genotoxic metabolites that reach this compartment. Collectively, these results suggest augmented genotoxicity assays can be successfully integrated into repeat-dose studies for higher efficiencies, and better utilization of animals.

**1532 Double Strand Break Repair by Capture of Unintentional Sequences, an Emerging New Possible Risk for the Leading-Edge Technology**

R. Ono 1, Y. Yasuhiko 1, K. Aisaki 1, S. Kitajima 1, J. Kanno 2, and Y. Hirabayashi 1, 1National Institute of Health Sciences, Kawasaki, Japan; and 2Japan Bioassay Research Center, Hadano, Japan.

Among DNA damages, double strand breaks (DSBs) are one of the most toxic to a cell. Failure in DSB repair could lead to genomic instability and cancer. DSBs can be caused by various assaults by both exogenous environmental factors (e.g. chemical agents, ionizing radiation, ultraviolet light) and endogenous cellular events (e.g. transposition, meiotic double strand break formation). The CRISPR/Cas system allows the introduction of DSBs at particular loci in the genome, therefore, it is possible to investigate the DSBs and DSB repair events accurately by using the CRISPR/Cas system. As a result, DSBs introduced into the mouse zygote by the CRISPR/Cas system are occasionally repaired by the capture of retrotransposons and/or mRNA sequences. This DSB repair mechanism with reverse transcription (RT)-mediated DNA repair of retrotransposon-mediated DSB repair (RMDR), was observed at least 2% of the DSB-induced yzogotes irrespective genome loci., because among the captured sequences, some were apparently derived from RT-mediated spliced mRNAs (Ono et al. 2015). In this study, lengths of the indels introduced by the CRISPR/Cas system in vivo and in vitro were determined by deep sequencing of PCR products amplified with two primers across the target DSB site. One of the novel findings of our high-throughput sequencing analyses is that they generate novel long-range fusion proteins between DSB-introduced gene and truncated retrotransposons and/or mRNA sequences. Both of which can contribute both to genome instability and cancer. A DSB repair by capture of unintentional sequences have a potential to lead to genomic instability. The findings of this study highlight an emerging new possible risk for this leading-edge technology. Double strand break repair by capture of retrotransposon sequences and reverse-transcribed spliced mRNA sequences in mouse zygotes. Scientific reports 5: 12281.

**1533 Evaluation of Germline Mutations Induced by Ethyl Methanesulfonate in Different Reproductive Development Stages of Caenorhabditis elegans Using Whole Genome Sequencing**

T. Chen 1, B. Pan 1, J. Yan 1, Y. Chen 1, T. W. Robison 2, M. Powley 3, R. H. Hefflich 3, and H. Dul 1, 1US FDA/NCTR, Jefferson, AR; 2US FDA, Silver Spring, MD; and 3University of California Riverside, Riverside, CA.

Germline mutation is a heritable change in the DNA that occurred in a germ cell and can be passed on to their descendants. Germline mutation is a test result for more than 30 known inherited disorders. A practical assay for detecting germline mutations is desired for regulatory purpose. Caenorhabditis elegans (C.elegans) has a short hermaphroditic life cycle, a relatively small genome, and a large number of offspring, making it an ideal model for assaying germline mutagenicity of chemicals. In this study, a panel of transgenic strains of different germline development stages of the worm to mutagenic insults to assess whether the model can appropriately detect chemical-induced mutations in male and female germs. Parent worms were treated with 25 mM ethyl methanesulfonate (EMS), a model germline mutagen, for 4 hours in L3 larval stage. After the germl line undergo robust proliferation, L4 larval stage when the hermaphrodite develops spermatogenesis, and young adult stage when the hermaphrodite ceases spermatogenesis and switches to oogenesis. The whole genome of F1 offspring from each individual worm treated with EMS or the vehicle was sequenced and the sequencing data were analyzed with a bioinformatics pipeline including VarScan, a variant calling program. The mutation frequencies (MFs) were 185-fold, 130-fold and 175-fold higher in the L3, L4 and young adult treatment groups, respectively, than the control group (MF is 2 ×10–6). More than 90% of the induced mutations are G:C >A:T transitions, a signature mutation type induced by EMS. The MFs induced in sperm germs were slightly lower than those in early germ cell proliferation stage and in egg germs. The results suggest that C. elegans can sensitively detect exposure of germline mutagens in both male and female germ cells, as well as in early germline proliferation stage.

**1534 Validation of the ToxTracker Reporter Assay for the Genetic Toxicology Assessment of Petroleum Products**

Certain poorly refined petroleum streams that contain relatively high levels of 3-7 ring polycyclic aromatic hydrocarbons (PAHs) are known to have mutagenic properties and cause skin tumors in mice. Since the guideline carcinogenicity test has obvious time, cost and animal-welfare constraints, screening assays were developed such as the IP346 assay and Modified Ames test. To further underpin these assays and increase their predictivity by including a mechanistic component, 8 petroleum substances (PS; highly refined, with various levels of 3-7 ring PAHs) were tested in the ToxTracker reporter assay. ToxTracker is a panel of six validated mammalian stem cell lines each containing a GFP reporter to detect induction of DNA damage, oxidative stress and protein damage in a single test. DMSO extracts, containing the “biologically active” fraction (i.e. mostly 3-7 ring PAHs) of the petroleum substances were prepared following standard procedures. These DMSO extracts were tested in the ToxTracker assay at 3 different levels of cytotoxicity (10, 25 and 50%), along with 4 positive control samples. The DMSO abstracts were analyzed in the absence and presence of 59 liver extracts to include a mutagenic mixture. PAHs are known to be autofluorescent, which could interfere with analysis of the GFP reporters. Therefore, activation of the six ToxTracker biomaker genes was also confirmed by quantitative RT-PCR. In parallel, aliquots of these DMSO extracts were tested in the standard Modified Ames test for validation purposes and PAH levels were analyzed by ring class. The ToxTracker protocol was modified to allow analysis of autofluorescent test substances. ToxTracker showed that poorly refined petroleum streams containing high levels of 3-7 ring PAH are genotoxic as observed by induction of the Bsc12-GFP and Rtkn-GFP genotoxicity reporters. Activation of the Bsc12-GFP reporter is associated with induction of bulky, promutagenic DNA lesions and the Rtkn-GFP reporter with induction of DNA strand breaks. The poorly refined petroleum extracts also induced high levels of oxidative stress and protein damage, in line with the toxicity profile of these extracts. Highly refined products, containing virtually no (3-7 ring) PAHs, did not induce any cytotoxicity or activation of the ToxTracker reporters. These observations were confirmed by the results of the Modified Ames assay.

**1534a Mycoplasma Infection Induces Oxidative Stress and Affects Cellular Base Excision Repair**

Y. Ji, M. Karbaschi, and M. S. Cook, Florida International University, Miami, FL.

Mycoplasma contamination is a major concern for in vitro cell culture models. Mycoplasma is resistant to antibiotics, so the most difficult challenges are the prevention and treatment of mycoplasma contamination. Numerous studies show that mycoplasma infection generates a variety of cellular responses, in a variety of cell lines. However, there is a lack of information about the effects of mycoplasma infection on genomic instability. In this study, a dopaminergic neuronal cell line (BE-M17), which is popular in vitro model of Parkinson’s disease, was used to evaluate genomic instability and base excision repair (BER), during mycoplasma infection using the hOGG1-modified comet assay. The results showed that mycoplasma infection resulted in significantly elevated levels of DNA damage, in the form of strand breaks, alkaline-sensitive sites (SB/ALS) and oxidized purines, compared to uninfected cells (P < 0.0001). Uninfected cells repaired SB/ALS more rapidly than infected cells over first 1 h (P < 0.001). However, SB/ALS were fully repaired in both uninfected and infected cells 2 h after H2O2 challenge. Uninfected cells showed complete repair of oxidized purines after 24 h, but in infected cells, these were not fully repaired until 30 h (P < 0.0001). In conclusion, the study showed that not only does mycoplasma infection induce oxidative stress and DNA damage, but it also affects the main pathway responsible for the repair of oxidatively damaged DNA (BER). In this in vitro model, there is no mechanism for infection-induced inflammation, a source of reactive oxygen species. Therefore, further studies are needed to evaluate how mycoplasma infection causes oxidatively damaged DNA, and how it modulates the cellular DNA repair ability.
Chemosensitivity is an area of concern that has arisen due to the implementation of cancer chemotherapy. Several platinum compounds, including cisplatin, are currently used as anticancer drugs; however, some cancer types, such as ovarian cancer, tend to become resistant to cisplatin chemotherapy and this limits its usefulness, and results in increased mortality. Therefore, there is a significant need to discover an effective treatment for cancer, which reactivates chemosensitive tumors. This study aims to understand how ovarian cancer cell lines become resistant to cisplatin chemotherapy, which will help in identifying factors which may confer sensitivity in resistant tumors. Modified comet assays were used to measure interstrand cross-link (ICL) formation and repair, together with base excision repair (BER) in chemosensitive (SKOV-3) and chemosensitive (OCI-P5x and A2780) ovarian cancer cell lines. This method analyzes DNA damage formation and repair at the level of a single cell. The data revealed considerable differences among the ovarian cancer cell lines in response to cisplatin treatment. Although we discovered that the peak of crosslink formation for all three cell lines was at 12 h; we noted a significant attenuation of DNA crosslink formation in the chemoresistant cell line SKOV-3, compared to the chemosensitive lines, which was attributed to increased nucleotide excision repair over the first 12 h. In contrast, no differences in BER were noted between the cell lines. The ICL comet assay was also used to study the role of nuclear organization on DNA damage formation, through comparison of response in nuclear bodies and intact cells. The results demonstrated the same rank order of dose-response in nuclear bodies as in intact cells, but with chemoresistant cells being considerably more resistant to damage formation, at all doses cisplatin. These data provide interesting insights into differences in the DNA damage response between chemoresistant and chemosensitive cells, and future experiments will explore the molecular basis of these differences.

Toxicity of Cigarillos Versus Cigarettes: Smoke Chemistry, Cytotoxicity, and Genotoxicity

L. M. Crosby1, B. Yucesoy1, C. Leggett1, Z. Tu1, S. A. Belinsky2, J. McDonald1, S. Long1, G. Wu1, H. Irshad1, L. G. Valero1, and H. Rosenfeldt1.

There has been limited toxicity testing of cigarillos, including comparison to cigarettes. The present study compared smoke chemistry and cytotoxic/genotoxic potential of ten conventional cigarettes and cigarillos selected based on largest market share. Aerosolized whole smoke and total particulate matter (TPM) were generated using the Health Canada Intense (CI) and the International Organization for Standardization (ISO) puffing protocols. Smoke chemistry was examined for select tobacco-specific nitrosamines, polycyclic aromatic hydrocarbons (PAH) and formaldehyde using liquid/gas chromatographic-mass spectrometric methods. Cytotoxicity was assessed using the neutral red uptake assay. The genotoxic potential of the products was assessed using the Ames test with TA98 and TA100 strains and the thymidine kinase (TK) gene mutation assay. TPM from cigarillos were more potent than cigarettes in inducing cell death. Micronuclei formation at the highest dose of TPM showed significantly greater genotoxicity for cigarillos compared to cigarettes in the presence and absence of rat liver S9 fraction. In Ames test, both tobacco products exhibited significant dose-dependent increases in mutation frequency with TA98 and TA100, in the presence of S9. Enhanced mutation frequency was also observed for both tobacco products in the TK assay; however, effects were significantly greater with cigarillos in the presence of S9. The levels of all measured PAHs and carbonyls (except acrolein), N-nitrosonornicotine and 4-(methylnitrosamino)-1-(3-pyridyl)-1-butane were significantly greater in cigarillos than cigarettes. Benzo[a]anthracene and chrysene were the most abundant PAHs in all products. The CI puffing protocol led to increased aerosol constituent levels compared to the ISO protocol. As the gas/vapor phase was not studied, the results represent only a subset of the potential toxicity related to whole smoke of tested products. Under conditions of this study, these data showed that cigarillos have significantly more toxic potential than cigarettes.
Mitochondrial Toxicity has been shown to contribute to a variety of organ toxicities, such as liver, cardiac and kidney. In the past decade, two high throughput applicable screening platforms (isolated rat liver mitochondria: glucose-galactose grown HepG2 cells) to assess mitochondrial toxicity have been deployed in many pharmaceutical companies. However, only two publications have demonstrated the utility of these screens as a predictor of human drug induced liver injury. In the present study, we screened 73 hepatotoxicants, 49 cardiotoxicants, 46 nephrotoxicants and 60 compounds not known to cause human organ toxicity for their effects on mitochondrial functions in the assays mentioned above. Predictive performance was evaluated using specificity and sensitivity of the assays for predicting particular organ toxicity. Our results show that the highest sensitivity for all the drug classes was when compounds were tested at 100 µM (drug concentration in human plasma). The sensitivity was 63%, 33% and 28% for hepatotoxicants, cardiotoxicants and nephrotoxicants, respectively, and the overall specificity was 93% and above. We were not able to detect compounds that induced toxicity via mechanism such as induction of mitochondrial membrane permeability transition pore, or mitochondrial membrane swelling and depolarization, or inhibition of fatty acid oxidation, or exhibit toxicity at higher doses (outside our testing range). The sensitivity was increased to 78%, 39% and 38% for hepatotoxicants, cardiotoxicants and nephrotoxicants, respectively when additional mechanisms were included in the predictive analysis. Furthermore, we examined the physicochemical space associated with such liability and found that compounds which tested positive in the mitochondrial toxicity assays had higher median clogP (Calculated Log Partition Coefficient) values and lower median TPSA (Topological Polar Surface Area) values than compounds that were negative in the mitochondrial assay. There were no differences between the different organ toxicity test sets, which prevents the assays to be used to predict particular organ toxicity.

In Vivo Toxicological Outcomes Assessment by Physicochemical Properties and In Vitro Screening Data

Limiting toxicity-driven attrition of drug candidates is a key challenge for the pharmaceutical industry. To address this issue, guiding medicinal chemists to safer, more productive chemical space would clearly be an effective strategy. An analysis of exploratory toxicity studies of 245 Pfizer internal compounds, suggests that drug candidates in the chemical space low-clogP and high-TPSA, are considerably less likely to be cause toxicological effects at total plasma concentrations below 10 µM. Following this report, an internal Eli Lilly analysis showed partial support to the rule, whereas AstraZeneca’s assessment concluded the opposite. This difference is likely due to the different chemical space within each company, but the influence of the toxicological endpoint measured (e.g., preclinical vs. Phase 1 survival) cannot be excluded. According to a patent analysis, Takeda’s compound library has a different chemical space, as defined by clogP, MW, HBD, HBA, RotB, chiral C, sp3, Ar and ArHet, when compared to those of Pfizer, Eli Lilly and AstraZeneca. This situation motivated us to analyze our internal compounds to help identify our own safer chemical space. Interestingly, assessment of 193 internal Takeda compounds suggested that both low-clogP and high-TPSA are well-correlated with toxicity occurrence at 10 µM total concentrations, similarly to Pfizer’s analysis. If ATP-competitive kinase inhibitor project compounds were removed from the analysis, the odds are dramatically enhanced. Despite the difference in chemical space between Pfizer and Takeda, our results provide support to the 2750 nM useful guideline for medicinal chemists. In addition to physicochemical properties, high-throughput in vitro ADME screening data were also investigated to understand if any of these contributed towards the prediction of toxicity at 10 µM. Among them, decreased microsomal metabolism and high-Toxscore were correlated with toxicity occurrence yet interestingly, there was no correlation with lipophilicity. A combination of these orthogonal features (clogP, TPSA, and microsomal metabolic stability) significantly improves the prediction of toxicity occurrence.

Detection of Pre- and Post-Metabolism Compound Toxicity Using Co-Cultured Autobioluminescent Human Cells

T. Xu1, A. Frank2, M. Conway2, S. Ripp1,2, and D. Close2. 1University of Tennessee, Knoxville, TN; and 2490 BioTech, Knoxville, TN.

In vitro cell-based assays are critical components of the drug discovery workflow to serve as early-stage screening tools to identify potential therapeutic compounds as well as eliminate compounds with undesired toxicity. It is critical that new in vitro assay system be developed that can perform these screens at lower costs, with higher throughput, and with improved prediction of in vivo outcomes. However, this need is currently limited by the lack of cost-effective in vitro assays capable of replicating the complex interactions of multiple tissues types. In this study, we evaluated the use of autobioluminescent human cells to support higher-throughput and more data intensive co-culture assay formats as a promising solution to this problem by co-culturing in 3D of one type Ewing’s sarcoma (EFT) cell line (A-673, TC-32, and TTC-446) in two primary EFT cell lines (TC-32 and CHLA-10) as well as an unrelated HEK293 renal epithelial cell line. The average PMO efficacy (EC50) in TC-32 cells was 670 ± 130 nM with a range from 420 to 890 nM; in CHLA-10 cells the average EC50 was 250 ± 130 nM with range from 110 to 560 nM. In contrast, the average EC50 in HEK293 cells was 3,070 nM with range from 460 to 16,700 nM. Synergy was observed for a cocktail of all PMOs at low doses, but the cocktail was less effective than single agents at oligomer doses above 1 µM. Synergy was also observed for both EFT cell lines when single agent targeting PHGDH was combined with XAGE1 or CYP4F22. Antagonism was observed for both EFT cell lines when CCND1 was combined with XAGE1 or CYP4F22, and when IGFBP2 was combined with CCND1 or RBM11. The k-mer based transcriptomic approach to antisense drug target identification is effective, as it consistently identified gene targets with dose dependent effects on EC50 and FC. The in vivo assay setup resulted in two synergies and antagonism, which are as yet not predictable. Synergistic combinations of effective targets hold significant potential to identify highly effective anticancer therapy (HEAT), however, care must be exercised in selecting optimal combinations.
Genetically engineered rodent models (i.e. gene knockout (KO)) have been critical tools in early safety de-risking of drug development. Temporally controlled conditional KOs (cKOs), where the loxP-flanked gene of interest is deleted at a given time point by use of a tamoxifen (TAM)- or tetracycline-driven Cre recombinaise (Cre), can bypass developmental phenotypic influence and be beneficial to understand target safety in the intended patient population. However, there are often not available cKOs or phenotypic analysis for novel targets, and the appropriate model needs to be developed. For target safety assessment of gene X, we recently generated a cKO mouse using a CAG-Cre strain (loxP/loxP; CAG-Cre). Cre negative mice with the loxP-flanked gene X (loxP/loxP; CAG-Cre) served as control animals. Both cKO and control mice (12-14 week-old) were dosed with TAM at 400 mg/kg food for 3 weeks. Following a 2-week wash out period, there were no differences in clinical observations, hematology, and chemical between cKO and controls. However, the cKO had minimal to marked pancreatic acinar atrophy. To understand whether pancreatic findings in the cKO were due to the deletion of gene X or Cre activity, we repeated the study by having additional control animals, which are Cre positive mice without loxP-flanked gene X (wt/wt; CAG-Cre). Pancratic lesions were found in TAM-treated Cre positive mice with or without loxP-flanked gene X. However, control Cre positive mice without loxP-flanked gene X or TAM-treated Cre negative mice with loxP-flanked gene X had no pancreatic findings. These results suggested that pancreatic lesions were related to Cre activity but not the deletion of gene X. Additionally, our historical data revealed that pancreatic acinar atrophy is likely to be a Cre strain specific since these findings were not noted in TAM-treated Rosa26-Cre mice without knocking out the target gene. Our results highlight the importance of including proper control groups for phenotypic analysis when using cKO models to differentiate effects of non-specific background lesions (i.e. Cre activity) from the effects of knocking out the target gene.

Thrombocytopenia in Cynomolgus Monkeys Induced by a Therapeutic Human Monoclonal Antibody

In pre-clinical cynomolgus monkey studies, decreases in circulating platelets were observed within 24 h following a single intravenous administration of mAb X, mAb Y, or mAb Z (monoclonal IgG1 antibodies with a modified IgG1 tail lacking effector function) at several doses tested (0.5, 1.5 and 10 mg/kg). In some animals the decrease in circulating platelets continued over several days/weeks and some animals developed thrombocytopenia. The effect was not dose-dependent, but platelet numbers recovered immediately once the antibody was cleared. All three antibodies bind to the same target, with mAb Y binding to a different overlapping epitope compared to mAb X and mAb Z. The target of these antibodies was known to be expressed on both human and cynomolgus monkey platelets. Treatment with the IgG1 wildtype isotype of these antibodies resulted in activation of platelets in vitro, as determined by upregulation of CD62P and activation of GPIb/IIa receptors. It was demonstrated that addition of Fc block or engineering the isotype of these antibodies resulted in activation of platelets. It was demonstrated that addition of Fc block or engineering the isotype of these antibodies resulted in activation of platelets. It was demonstrated that addition of Fc block or engineering the isotype of these antibodies resulted in activation of platelets.

Drug-induced mitochondrial toxicity (DIMT) has gained growing interest during the early stage of drug discovery and development. Accumulating evidence implicates drug-induced mitochondrial dysfunctions as a leading cause of undesired side effects and/or off-target toxicities. Hence early-stage identification of compounds that cause mitochondrial dysfunction is informative during lead optimization and ultimately candidate selection. Glycolysis/Galactose Assay (GGA) has been traditionally employed to assess DIMT, but suffers from technical feasibility issues: low sensitivity and specificity to identify clinically relevant toxicants. Pharmaceutical companies recently employ assay systems to provide more feasible information of DIMT using a cell-based Seahorse XF96 Analyzer (Seahorse assay) and an isolated mitochondrial assay system for mitochondrial toxicity (iMitox). In this study we compared performance across assay systems using a selected set of 30 commercially available compounds with suspected mitochondrial toxicity and clinical adverse events, with the objectives to increase sensitivity and specificity in detecting DIMT and thus to facilitate risk categorization of each compound. A quantitative analysis with defined thresholds was applied for each assay and the results were compared across all Seahorse assay, iMitox and the existing GGA. While 11 out of 30 compounds showed the same risk category (6 low, 5 mito-tox) in all 3 assays, 4 out of 30 that displayed cytotoxic effects in GGA were categorized in low risk in both Seahorse assay and iMitox. Fifteen out of 30 were identified as responders based on oxygen consumption rate (OCR) compared to DMSO vehicle control by both (5), or either Seahorse assay (7)/ iMitox (3), respectively. These results demonstrate that iMitox and Seahorse assay replicate each other, as each screening system provides higher sensitivity, specificity and confidence in identifying potential
Drug-induced irregular heart beat (pro arrhythmia) and/or changes in contractility (inotropic liability) can limit the utility of potential novel therapeutics. Since abnormal ventricular repolarization can cause not only electrical disorders, but also affect the heart’s contractile function, the main motivation of this study was to develop a new model based on adult human primary cardiomyocytes to provide a preclinical tool for the simultaneous assessment of drug-induced pro-arrhythmogenic and pro-inotropic effects. To facilitate the scalability of the model to high throughput methodologies, we recorded fractional sarcosome shortening (SS) using a digital, cell geometry measurement system (IonOptix®) and then record changes in the contractility transients to infer both isotropic (SS) as well as pro-arhythmogenic risk (aftercontraction (AC), contractility escape and time to 90% relaxation). To address the clinical relevance of this approach, we performed a validation study in which we assessed the effects of a set of reference drugs with known clinical outcomes. Both positive and negative controls were selected, including 23 torsadogenic and 10 non-torsadogenic drugs. The approach provided very reliable prediction of pro-arhythmogenic and isotropic risks. For example, we found that AC incidence with doxetilide, a torsadogenic drug, was seen starting at 10x the free Effective Therapeutic Plasma Concentration (fETPC), while verapamil, a non-torsadogenic drug, did not induce ACs up to the highest possible of fETPCs tested in our study (222x). When the assessment of drug risk was based on effects observed at 10x the fETPC, human cardiomyocyte-based model differentiates between torsadogenic and non-torsadogenic drugs with excellent assay sensitivity and specificity values: 96% and 100%, respectively. Our data also demonstrate that human cardiomyocytes also identify drugs associated with inotropic effects. hERG channel blockers, like dofetilide, have no effects on SS, while multi-channel blockers, like verapamil, inhibited SS. Thus, adult human primary cardiomyocytes can simultaneously predict risks associated with pro-arrhythmogenic and inotropic activity. This approach enables the generation of reliable and predictive data for human cardiac safety assessment in early drug discovery, and appears to be more predictive than the stem cell-derived cardiomyocyte models.
gate the link between off-targets and toxicological effects. With the off-target module, potential off-targets can be predicted for any of the 20,000 reviewed, human proteins in UniProt. The predicted off-targets combined with a TargetTissueSA are an useful approach to elucidate toxicities that might not be target-related.

1549 An Unanticipated Toxicity Profile of Anti-Fucosyl-GM1 Antibody Conjugated to a Tubulysin Payload after a Single-Dose Intravenous Administration to Cynomolgus Monkeys

Y. Callejas1, P. Ponath2, P. Cardarelli3, B. Gemzik4, and R. Westhouse1. 1Bristol-Myers Squibb Co, Lawrenceville, NJ; and 2Bristol-Myers Squibb Co, Redwood City, CA.

Fucosyl-GM1, a sphingolipid monosialoganglioside and tumor-associated antigen (TAA), has been detected in about 72% of small cell lung cancer (SCLC), 24% of adenocarcinomas, and 14% of squamous cell carcinomas, while its expression in normal tissues is almost non-existent. Potential new treatments for SCLC include the use of conjugated monoclonal antibodies. Here we describe the toxicity of a novel antibody-drug conjugate ADC consisting of a fully human IgG1 antibody linked to a small molecule microtubule polymerization inhibitor via a site-specific conjugation (bacterial transglutaminase) with drug-antibody ratio of 4. The objective of this study was to evaluate the toxicity of BMT-125961 when given as a single dose to cynomolgus monkeys and to determine changes in peripheral nerve conduction velocity. This ADC was administered as a single intravenous injection at doses of 1, 4, and 8 mg/kg to 3 groups (mixed females and males) of monkeys. Parameters evaluated included clinical observations, body weight, food consumption, peripheral nerve conduction, clinical pathology, gross and microscopic pathology, and serum toxicokinetics. Serum exposure (AUC (0-infinity)) was approximately dose proportional with a profile consistent with ADC experience. Observed clinical effects included redness at injection site progressing to other areas with posterior black blotching. Persistent cough was observed at 8 mg/kg beginning on Day 38. Reduced food consumption and sustained body weight loss, particularly at 8 mg/kg (~10%). There was a progressive increase in serum AST (max @8.7X) and ALT (max @2x) on Days 4 and 15 with partial recovery on Day 21, at 4 and 8 mg/kg. Hematologic indicated an inflammatory process beginning Day 9 or 21 at the same doses, with vacuolated monocytes evident in peripheral blood smear. Unexpected pulmonary effects presented grossly as consolidation and reddening of ventral (gravity-dependent) lung lobes with a very clear delineation between normal and abnormal lungs. Histologically, the consolidated areas of lung were characterized by fluid expansion of alveoli (exudative alveolitis) and granulomatous foci with vacuolated macrophages and fibrosis. There were no effects on peripheral nerve conduction velocity.

1550 New iPSC-Based Neural In Vitro Approach for Seizure Liability Testing

Standard animal models have shown insufficiencies in predicting adverse effects of therapeutic compounds particularly on the CNS, mostly because of limited concordance with human neurotoxicity. The high attrition rate of new drugs in clinical studies is largely attributed to CNS-related safety failures unidentified in pre-clinical testing. One of the most common issues encountered during safety assessment over the past 5 years is the induction of seizures at relevant therapeutic concentrations. Moreover, GABA	extsubscript{A} receptors as primary mediators of inhibitory neurotransmission, represent a vulnerable target for neurotoxic environmental chemicals, many of which lead to seizures in humans. Therefore, new human in vitro assays are urgently needed for de-risking of new drugs and higher throughput testing of multitude of chemicals with daily human exposure. Based on direct reprogramming of induced pluripotent stem cells (iPSCs) into highly functional neurons of defined subtypes, we developed a pure human neuronal/glial co-culture platform for comprehensive electrophysiological measurements using multi-electrode arrays (MEAs). When combining defined ratios of glutamatergic to GABAergic neurons together with astroglial cells, robust neuronal activity, including synaptically driven spontaneous synchronized network bursting can be recorded at 3-4 weeks post seeding. Due to parallel acquisition of multiple parameters, our platform allows detailed characterization of neurotoxicity effects of test compounds. Here, we optimized our platform to specifically and quantitatively assess chemically-induced seizure-like activity in a semi high-throughput setting. As part of the HESI NeuTox Group, we tested a set of 8 compounds with clinically reported seizurogenic effects in patients, which parameters remained detected in iPS-based testing.

Importantly, our human system was able to identify specific alterations in neuronal activity of all test compounds in a dose-dependent manner, and determine seizure-like firing patterns in the most potent subset. We also used our platform to test a set of environmental neurotoxicants with well-established effects on human GABA	extsubscript{A}Rs, and successfully identified changes in activity indicative of seizurogenic effects over a large range of concentrations. Hence, we report the development and proof of concept of a novel iPSC-based neuronal/glial in vitro approach for the assessment of seizure liabilities of chemical compounds in a human-relevant cell context.

1551 Improved Prediction of Arrhythmia Potential in Drug Discovery and Development

Predicting the potential to be associated with the arrhythmia Torsades de Pointes (TdP) is a key activity in early drug discovery. Classically, a 30-fold margin between therapeutic concentrations and the inhibitory potency at the hERG potassium channel is used to predict arrhythmic potential. Kramer et al (2013) showed a mixed ion channel inhibition approach improved the prediction. The best model described was the ratio between the IC50 values at the hERG channel and the L-type calcium channel. This was “Model 5” and had a sensitivity of 97%, specificity of 83%, and an overall accuracy of 91%. “Model 5” does not take to account therapeutic concentrations, target potency, or the non-linear relationship between concentration and effect. We illustrate two techniques that perform as well or better than “Model 5” but take in to account relative potency and channel balance. Using the “Model 5” data set, we calculate the changing balance across concentrations, as a net inhibition. Net inhibition at 25-fold, the therapeutic concentrations as a predictor of TdP had an accuracy of 93%, a sensitivity of 94%, and specificity of 91%. The two false positive and false negative calls had very close net degrees and would be susceptible to errors in the estimates of ion channel potency or the contribution of metabolites. Net inhibition is more predictive than “Model 5” and other recent predictors and is analogous to the net current metric recently suggested as a measure by others using an in silico cardiac model. “Model 5” could have an advantage early in drug discovery, as it does not require knowledge of the therapeutic concentrations. We applied another intuitive triaging process, Fast Frugal Trees. This requires information on hERG and calcium channel potency along with an in vitro measure of target potency. All such data are available early in discovery. It has an accuracy of 91%, with sensitivity and specificity of 91%. This is better than previously published predictors of TdP, as good as “Model 5,” and is compatible with the discovery process. In summary, the net inhibition metric takes in to account the therapeutic levels and nonlinear relationship between response and concentration, and is an effective predictor of TdP potential and does not require the use of an in silico model. Early in discovery, Fast Frugal Trees can also be used to make quick decisions on compound progression.

1552 Transcriptomic Biomarkers to Assess the Liver and Metabolic Responses Associated with Bioactivation Mechanisms of Drug-Induced Liver Injury

Drug induced liver injury (DILI) is a major reason for attrition, denied commercialization, marketplace withdrawal and restricted prescribing in the marketing of new pharmaceuticals. Metabolic bioactivation is thought to contribute to a significant number of liver associated adverse drug reactions (ADR) in humans that fail to be detected in standard preclinical animal studies. A challenge for pharmaceutical drug safety is to identify which drug candidates form chemically reactive metabolites (CRM) that pose a high risk in the clinic and projected therapeutic doses. We developed a rat liver transcriptional biomarker and an in vitro cellular model, to discern doses of drugs with bioactivation mediated hepatotoxic potential, by measuring transcriptional pathways activated by electrophilic CRMs. Here we describe establishment of this system using benchmarked CRM forming test compounds and systems using a curated list of commercial drugs and internal Merck compounds anchored in clinical experience with respect to ADRs and hepatotoxicity. Based on 130 compounds run in short-term rodent studies and consideration of the clinical dose administered, the approach yielded 33% sensitivity and 95% specificity for discriminating safe from hepatotoxic
Bioengineered let-7c is Effective at Reducing Orthotopic Hepatocellular Carcinoma Tumor Burden and is Well Tolerated in Mouse Models

Given pleiotropic molecular targeting mechanisms, restoration or inhibition of endogenous microRNAs (miRNA) is a promising pharmacological strategy. Recently, our group has bioengineered a collection of miRNA agents in live cells using a non-coding carrier RNA (nCAR) based technology. In vitro screening identified nCAR/let-7c as the most potent at inhibiting hepatocellular carcinoma (HCC) viability; this was found to be processed to the mature let-7c molecule and suppressed target gene expression. As such, in vivo efficacy and safety of this agent was characterized in the present study using polyethyleneimine (PEI) and liposomal-polyplex (LPP) RNA formulations. Huh7 cells stably expressing luciferase and green fluorescent protein were orthotopically engrafted into immunocompromised mice. To evaluate efficacy, 40 μg of nCAR/let-7c or a truncated control agent was administered systemically every other day for two weeks, followed immediately by necropsy. Live animal bioluminescent and ex vivo fluorescent imaging suggested that LPP-formulated nCAR/let-7c reduced tumor burden to a greater degree than all controls and PEI-formulated nCAR/let-7c. Additionally, both nCAR/let-7c and truncated control agents were well-tolerated compared to untreated mice, as evidenced by gross evaluation and similar body-weights throughout the study; however, further studies are warranted in immunocompetent animal models to elucidate the complete toxicological profile and immunogenic potential of nCAR/let-7c. These data are the first to demonstrate that let-7c restoration using a biologically-derived agent can serve as a potent antineoplastic agent, presenting a new, clinically-relevant strategy for HCC therapy.

Seizure Liability Assessment in Human IPS-Neurons Using Microelectrode Array and High-Throughput Screening via Calcium-Flux

G. Luerman, D. Hess, C. Fleming, and R. Kettenhofen. NCardia, Cologne, Germany.

New, higher throughput predictive models are always required to address the evolving needs of preclinical R&D and safety assessment. Human neurons derived from induced pluripotent stem cells present a predictive, flexible and potent tool due to their unlimited availability, physiological relevance and lack of interspecies translatability issues. iP5-derived neurons express a plethora of neurotransmitters at physiologically-relevant levels. This can help to accelerate the assessment of clinically relevant issues such as psychological disorders, drug-induced seizure liability, peripheral neuropathy, and other CNS-related issues. Here we present two models that take advantage of instrumentation featuring 96 (or 384) well plates with automated compound handling/robotics and measurements for a cost-effective and animal-free neurological phenotypic assessment. 1. 96/384 well optical readout: calcium transient flux induced by neurotransmitters using the Hamamatsu μCell. Here we show that multiple monoamine neurotransmitters, glutamate, NMDA, acetylcholine, etc. induce increases a fluorescent calcium reporter in a concentration-dependent manner. 2. 96 well electrical (extracellular field potential) recordings: three separate neuronal populations were co-cultured with isogenic IPS astrocytes until mature, synchronous burst firing was achieved. The effects of 9 seizure-related compounds (as part of the HESI Neutox MEA consortium) on the neuronal activity using the Axion Maestro MEA technology were assessed and results were correlated to established primary rodent models.

Qualification and Deployment of an In Vitro Liver Model (HepatoPac) Used Early in Pharmaceutical Development to Help De-Risk for Drug-Induced Liver Injury

Drug-induced liver injury (DILI) remains a major safety concern for pharmaceutical development despite significant efforts across academia and industry to detect DILI early in development. Merck has deployed a set of rat liver transcriptional biomarkers in a short-term in vivo rat study to inform on the potential of drug candidates to generate high liver burden of chemically reactive metabolites (CRM) and to help predict risk for clinical hepatotoxicity. Here we describe a 9-day in vitro assay using micropatterned human and rat hepatocyte co-culture systems (HepatoPac®) as a compound, animal and time-sparing approach to de-risk compound series shown to have high CRM burden in vivo. We established a transcriptional biomarker signature in vitro, and qualified the use of the signature in the HepatoPac models using 90+ commercial drugs and Merck internal compounds, including liver safe and unsafe analogs. The assay showed a high concordance (80%) with results obtained in vivo with the same compounds. Taking into the consideration calculated human liver in vitro clinical exposures, the in vitro rat model provides ~80% sensitivity and ~90% specificity for distinguishing liver safe from hepatotoxic drugs. While overall performance between the in vitro human and rat models was similar, appreciable differences were observed for several compounds, suggesting species differences in drug-metabolic pathways, turnover rates, and/or xenobiotic responses that could drive discrepant biomarker responses. In conclusion, we show that the HepatoPac micropatterned co-culture liver model is a resource sparing approach to improve DILI risk assessment from CRM early in preclinical development.

In Vivo-In Vitro (IVIV) Correlation of the Response to Prototypical Rat Liver CYP-Inducers—Assessment of Between-Strain, Gender, and Species Variability

M. Untrau1, M. Nappaye2, C. Demougeot2, A. Bonet3, J. Decorde4, M. Fonsi5, and L. Richard1,2. 1iCaly-Cell, Plobsheim, France; 2Université de Bourgogne Franche Comté, Besançon, France; and 3CitoxLAB, Evreux, France.

Since the potential risk of liver cytochrome P450 (CYPs) induction to cause drug-drug interactions and adverse effects needs to be considered during the development of any new medication, regulatory studies using primary human hepatocytes are included as part of the regulatory package requested during drug development. Toxicology studies performed in preclinical species often suggest a species-dependent response of liver CYPs, it is thus appropriate to assess which test species is closest to humans (if any) and should be chosen for pivotal toxicological studies. The between-species variability, including human, can be assessed in vitro using primary hepatocyte cultures, as long as IVIV correlation in preclinical species has been confirmed. In the present investigation the induction potential of prototypical CYP1A (β-naphthoflavone), 2B (phenobarbital), 2C (3a-demethasone) and 4A (bezafibrate) inducers was revealed by the increases in mRNA expression and isozyme-specific activities, both after in vivo treatment of male Sprague Dawley (SD) rats and after in vitro treatment of primary male SD rat hepatocytes cultures. Strain, gender and species differences (mRNA induction) were effectively evaluated in vitro primary cell cultures: for example the response of SD rat hepatocytes was higher to both phenobarbital (10-fold higher CYP2B2 induction) and bezafibrate (2-fold higher CYP4A induction) compared to Wistar rat hepatocytes; the response of males was higher than females (Wistar) to phenobarbital and demethasone (3-fold higher induction of respectively, CYP2B and CYP3A); the response of rodents was higher than non-rodent species to bezafibrate (4- to 100-fold higher CYP4A induction). CYP3A response to rifampicin compared to demethasone was higher only in human hepatocytes, with large inter-donor variability in the response. In conclusion, this approach allows not only in vitro-in-vivo extrapolation (IVIVE), but it also offers a potential significant reduction in the number of laboratory animals needed for drug research, in accordance with the 3Rs (Refinement, Reduction, Replacement).
The disposition and clearance of drugs by the kidney relies largely on a well-characterized subset of membrane transport pumps collectively known as solute carrier or SCL proteins. Among the SLC family proteins, OAT1, OCT2 and OAT3 are the most important transporters in kidney tissue, and are recommended by the FDA, ITC and the EMA as targets for drug-drug interaction studies. Therefore, there is a large demand for kidney toxicity models, especially in-vitro models, that have a normal human kidney origin, functioning transporters, accurate clinical predictability, and consistent data output for initial drug interaction studies. Unfortunately, primary renal epithelial cells lose OAT1 and OCT2 transporter expression over time in culture. Transiently expressing these transporters in primary renal epithelial cells yields large variations between experimental models making data hard to interpret. Current cell line-based models are available using MDCK, CHO, U2OS, or other lines which either do not have human kidney tissue origin or are themselves cancer lines, significantly compromising clinical predictability. In our study, we have generated kidney transporter cell models using well-characterized hTERT-immortalized primary Renal Proximal Tubule Epithelial Cells that stably overexpress either the OAT1, OCT2 or OAT3 gene. After confirming the SLC mRNA expression for each gene by RT-PCR, we performed immunostaining that showed OAT1, OCT2 and OAT3 were only trafficked to the plasma membrane. Notably, these clones show typical epithelial morphology, functionality, and expression of the appropriate epithelial and kidney tissue specific markers. Most importantly, we verified that the overexpressed transporters have normal transport activities using 5-CF, 6-CF, ASP+, and EAM5+ assays. Furthermore, uptake of these compounds are blocked in a dose-dependent manner by well-known SLC inhibitors, indicating that the overexpressed kidney transporters are functioning as expected. Overall, our data demonstrates that these modified renal epithelial cell lines maintain kidney transporter expression over time, are useful tools, and can provide physiological and human kidney function, and are more consistent and reliable than comparable in-vitro models currently used to determine the effect of exogenous compounds on renal membrane function. 

The availability of human primary cell-based 3D small intestinal (SMI) microtissues that recapitulate the structure and function of the in vivo counterpart is critical to predict the safety and bioavailability of drugs intended for oral administration. Here we present drug permeability of a newly developed in vitro 3D-human small intestinal (SMI) microtissue model. The SMI microtissues are cultured using primary human intestinal fibroblasts and enterocytes and their 3-dimensional polarity and morphology mimics that of native in vivo tissues. Characterization of the microtissues included evaluation of structural features, barrier properties, and expression of drug transporters and drug metabolizing enzymes. To evaluate the suitability of the microtissues for drug absorption, the apparent permeability coefficients (Papp) for a panel of 18 benchmark drugs with known human absorption values were determined. Drug-drug interactions were examined using compounds known to be substrates or inhibitors of efflux transporters. Results showed that the microtissues are highly reproducible with physiological TEER values averaging 146±20.8 Ω*cm² (% CV: 14.2%) and 142±13.8 Ω*cm² (CV:9.7%) in the US (N=128 lots) and Slovakia (N=9 lots) facilities. The microtissues expressed drug transporters and metabolizing enzymes known to be present in vivo. Drug permeation results showed that the microtissues could discriminate between low and high permeability drugs with 94% accuracy. The in vitro Papp values correlated well with human absorption data (r² = 0.85). SMI microtissues exposed to drug efflux transporter substrates and inhibitors reduced the drug efflux ratio while increasing the bioavailability of the test drug, providing evidence of drug efflux transporter activity. In conclusion, the SMI microtissues appear to be a useful pre-clinical tool for predicting drug activity and bioavailability of orally administered drugs. 

Lineozid (LZD) is an oxazolidinone with potent activity against drug-resistant M.tuberculosis; however, prolonged courses and high doses of LZD therapy are associated with adverse effects resulting from LZD-induced mitochondrial toxicity (MT). We have previously developed a panel of in vitro assays that encompass three major adverse events resulting from MT namely (1) energy metabolism disruption, (2) increased oxidative stress, and (3) altered apoptosis. We utilized the same panel to test LZD-associated MT in K562 (chronic myelogenous leukemia) cells treated with 0, 2.5, 5, 10 and 20 mg/L of LZD for two weeks in culture. Cells were harvested on Days 2, 4, 7,9,11 and 14 following LZD exposure, lyed and evaluated using assays detecting oxidative phosphorylation (OXPHOS) complex 1-5 levels, ATP, total glutathione, ROS/RNS and caspase 3 content. LZD treatment resulted in a panel of 1 in vitro assays that encompass three major adverse events resulting from MT namely (1) energy metabolism disruption, (2) increased oxidative stress, and (3) altered apoptosis. We utilized the same panel to test LZD-associated MT in K562 (chronic myelogenous leukemia) cells treated with 0, 2.5, 5, 10 and 20 mg/L of LZD for two weeks in culture. Cells were harvested on Days 2, 4, 7,9,11 and 14 following LZD exposure, lysed and evaluated using assays detecting oxidative phosphorylation (OXPHOS) complex 1-5 levels, ATP, total glutathione, ROS/RNS and caspase 3 content. LZD treatment resulted in a 40-90% decrease in OXPHOS Complex 1, 3, and 4 and levels in K562 cells over controls. While ATP and caspase 3 levels were marginally elevated post LZD treatment, the oxidative stress biomarkers were similar to those reported in controls. We also characterized the LZD induced MT in K562 cells cultured in either glucose- or galactose-based medium for two weeks. This was done to ensure that the MT biomarkers determined were not misinterpreted, as cancer cells have the ability to bypass OXPHOS cycle to generate ATP through glycolysis in glucose rich conditions. Similar results were obtained for toxicity evaluations conducted in both media regardless of the energy source. In addition, we evaluated whether secondary substrates of MT such as OAT1 and OAT3 were affected. Both substrates were conserved in K562 cells over the duration of the treatment. K562 cells were cultured for 14 days with 20 mg/L of LZD. On Day 14, treatment drug was removed in one subset of K562 cells and these cells were allowed to propagate in LZD-free culture medium for an additional two weeks. LZD treatment was continued for a second subset of cells until the end of study. All MT effects were resolved in K562 after discontinuation of LZD treatment, two weeks after therapy cessation. Overall, our panel of in vitro assays
characterized the LZD-induced MT profile in K562 cells and this information can be used as a benchmark for MT screening for future generation oxazolidinones. 1561 H/R Stress and Circumventing the Crabtree Effect Enhance Susceptibility of HepG2 to MPT-Inducer (troglitazone)

Troglitazone (TRO), developed as an antidiabetic agent that improves insulin resistance, withdrew from the market because of its rare but severe liver injury. In our line of study, it was found that 1) TRO induced mitochondrial permeability transition (MPT), a trigger of apoptosis, in isolated rat liver mitochondria (1), 2) activation of Ca2+-independent phospholipase A2 was involved in TRO-induced MPT (2), 3) Hypoxic reperfusion (H/R) stress sensitized rats to diclofenac (MPT inducer)-induced liver injury. However, it has yet been elucidated whether TRO-induced MPT leads to apoptotic cell death and that is exacerbated under H/R condition. In this study, we tried to verify these hypotheses using HepG2 cells. To increase detection of drug-induced mitochondrial effects, HepG2 cells were forced to rely on mitochondrial oxidative phosphorylation rather than glycolysis by substituting galactose for glucose in the growth media. To reproduce H/R stress in vitro, HepG2 cells were exposed with 1% O2 condition (hypoxia for 4 h) and then substituted with 20% O2 condition (re-oxygenation). Generation of reactive oxygen species (ROS) was assessed by dichlorodihydrofluorescein diacetate (DCFDA). Cellular MPT induction was detected by mitochondrial Ca2+ retention assay. Cell death was assessed by release of LDH and by co-staining of Annexin V/Zombie dye. In galactose-substituted medium, generation of ROS was promoted by H/R condition. Because oxygen concentration is raised drastically under H/R condition, mitochondria might accordingly induce ROS through its activated respiratory chain. Moreover, under H/R condition, TRO-induced-MPT was further enhanced compared with that under normoxic condition. Furthermore, TRO-induced increase of Annexin V positive cells was enhanced by H/R condition. These observations are suggested that H/R condition-induced ROS production enhances susceptibility to MPT induction by TRO and therefore exacerbates apoptosis cell death in HepG2 cells. Substitution of sugar source with galactose and simulating H/R condition increase sensitivity of hepatocytes to TRO-induced MPT and apoptosis in vitro likely as a result of increased mitochondrial oxidative stress. 1562 Exploration of Biomarkers for Predicting Drug-Induced Liver Injury in Co-Culture Systems of Human Peripheral Blood Mononuclear Cells with Hepatocellular Carcinoma-Derived Cells

S. Oda1, Y. Uchida1, M. D. Aleo2, M. Hizue3, L. D. Marroquin2, P. H. Koza-Taylor1, J. Whittenour1, and T. Yokoi1. 1 Nagoya University Graduate School of Medicine, Nagoya, Japan; 2Pfizer, Inc., Groton, CT; and 3Pfizer, Inc., Tokyo, Japan.

Prediction of drug-induced liver injury (DILI) risk remains a major challenge because of its multifactorial mechanisms. Immune and inflammatory reactions are considered one of the mechanisms for DILI; however, biomarkers in vitro systems using immune cells have not been comprehensively studied yet. In this study, we aimed to find potential biomarkers for predicting DILI in in vitro co-culture systems of peripheral blood mononuclear cells (PBMCs) with human liver cell lines. HepG2 or differentiated HepaRG cells were seeded onto the lower compartment of the Transwell® insert system and, after 24 h, freshly isolated human PBMCs were added onto the upper compartment. Immediately after the PBMC seeding, the co-cultured cells were treated with DILI-positive drugs (amiodarone, ketoconazole, tiotBABIC acid, diclofenac, and trovafloxacin) or DILI-negative drug (chloroquine, mebendazole, ethacrinic acid, lactulose) for 24 h. Then, total RNA was isolated from PBMCs and analyzed using the Agilent SurePrint G3 human gene expression microarray. Overall, 160 and 50 genes were upregulated more than 2-fold in PBMCs/HepG2 cells and PBMCs/HepaRG cells, respectively, by the treatment with 5 DILI-positive drugs. By excluding genes that were upregulated by the treatment with 5 DILI-negative drugs, 113 and 42 genes were extracted. Among them, five genes were commonly upregulated between PBMCs/HepG2 cells and PBMCs/HepaRG cells, however, quantitative PCR could not validate the microarray data probably due to their low expression in PBMCs. Next, we extracted upregulated 476 genes from PBMCs/HepaRG cells by the treatment with 3 or more out of 5 DILI-positive drugs. By considering expression levels in intact PBMCs with reference to a database, 9 genes were selected and 6 genes were correctly validated. These included IL-1α, IL-1β, and IL-8. Taken together, we establish co-culture systems of PBMCs with liver cell lines and suggested that selected biomarkers might correctly predict DILI risk in the in vitro assay. Ongoing investigations to understand differences in responses between fresh and frozen PBMCs also will be described.

1563 Profiling of Liver Toxicity Protein Biomarkers in Rat Plasma by Mass Spectrometry

A. Licollari, and R. Bagshaw. Nucro-Technics, Scarborough, ON, Canada.

Pre-clinical assessment of pharmaceutical compounds for regulatory submission is performed using classical toxicological analyses. However, ‘omics technologies may offer a quick readout of a compound’s potential for liver toxicity. We have previously demonstrated a proteomic signature for prediction of DILI biomarker assays from rat plasma in which >90% of 83 biomarkers measured such as apolipoproteins and fumarylacetoacetase predicted Acetaminophen (APAP)-induced hepatotoxicity. The objective of the current study was to examine the performance of this assay using compounds with varying hepatotoxicity mechanisms while considering other contextual factors such as the fed-state of the rats. Rats were treated orally with dose vehicles or a single high dose of different hepatotoxic or nephrotoxic compounds. Groups were included to compare fed-state of the animals prior to and during treatment. Protein biomarker data from rat plasma as measured by LC-MS/MS was assessed using multivariate statistical analysis to categorize the treatments. We found the changes in major secretory proteins were highly-associated with APAP toxicity. We also found that changes in biomarkers for APAP toxicity did not overlap substantially with biomarker profiles for other drugs used in the study - including Buspirone, Finasteride, Fluamamide, and Nefazodone. While biomarker profiles differed from the treatment group, we noted overlap between compounds with varying hepatotoxicity mechanisms. We found that changes in biomarkers for APAP toxicity did not overlap substantially with biomarker profiles for other drugs used in the study - including Buspirone, Finasteride, Fluamamide, and Nefazodone. While biomarker profiles differed from the treatment group, we noted overlap between compounds with varying hepatotoxicity mechanisms. We found that changes in biomarkers for APAP toxicity did not overlap substantially with biomarker profiles for other drugs used in the study - including Buspirone, Finasteride, Fluamamide, and Nefazodone.
recruitments in our case were predominately comprised of M1 macrophages. Pro-inflammatory condition of monocytes was likely to be associated with thrombus formations. Although there remain additional investigations to be done, characterization of whether pro-inflammatory- or tissue repair-types of macrophages provided clue for further elucidation of mechanisms of action.

Institutes for Biomedical Research, Basel, Switzerland.

Bacterial mutagenicity, absorption, thereby increasing efficacy and reducing systemic toxicity. Breast cancer drugs may increase local delivery and reduce systemic dose levels with the aim to identify NOAELs and/or LOAELs. Knowledge of the pharmacokinetic profile in the selected animal species is key to decide suitable in vitro photo-safety testing.

41 systemic photo-LLNA studies (7 reference compounds, 34 drug candidates) demonstrated the utility of this approach. Phototoxicity in vivo is clearly a dose-dependent effect. The applied level of simulated sunlight (normalized to 10 J/cm² UVA) is sufficient to elicit phototoxic responses using reference compounds and corresponds well to typical sunlight exposure (Bau50). Therefore, NOAEL-derived safety margins versus therapeutically relevant drug levels based on Cmax are an appropriate method to support human risk assessment and are regulatory accepted (ICH S10, 2013). In some cases, e.g. for drugs with very limited systemic exposure, even the IC50 value obtained under irradiation in the in vitro 3T3 NRU Phototoxicity Test (OECD TG 432) can be used to estimate the margin versus therapeutically relevant drug levels and to support risk assessment in a weight-of-evidence approach.

In comparison to oral or iv administration, direct topical application of breast cancer drugs may increase local delivery and reduce systemic absorption, thereby increasing efficacy and reducing toxicity. Bacterial mutagenicity, in vitro clastogenicity, in vitro phototoxicity, and in vivo dermal sensitization studies were performed to evaluate the safety of a gel formulation of endoxifen being developed for breast cancer prevention. E2/EE2-endoxifen was not mutagenic in four strains of S. typhimurium or in E. coli WP2 uvrA, either with or without metabolic activation; positive control articles were mutagenic in all tested strains. E2/EE2-endoxifen did not induce structural chromosomal aberrations in Chinese Hamster Ovary cells, either with or without metabolic activation; two positive control articles did demonstrate significant clastogenicity. E2/EE2-endoxifen was not phototoxic in the neutral red uptake assay in BALB/c 3T3 fibroblasts; the positive control article did induce significant phototoxicity. Dermal sensitization was evaluated in female Hartley guinea pigs (modified Buehler method) using four study groups (vehicle control gel: 0.5% (E/Z)-endoxifen gel; 1.0% (E/Z)-endoxifen gel; and 5% (E/Z)-4-dinitrochlorobenzene; DNCB); DNCB caused erythema well-defined to severe erythema in all animals. Possible evidence of dermal sensitization in endoxifen-treated groups was seen at 24 h after the first challenge very slight to well-defined erythema in 5/10 and 4/10 animals in low and high dose groups versus very slight edema in 1/10 vehicle controls). After rechallenge, very slight edema was seen at 24 h in 4/10 vehicle control animals and in 4/10 animals in groups receiving low or high doses of (E/Z)-endoxifen gel. These data demonstrate that (1) (E/Z)-endoxifen is not mutagenic in a bacterial (Ames test) battery that is used widely for mutagenicity evaluations; (2) (E/Z)-endoxifen does not induce chromosome aberrations in a mammalian cell system that is commonly used to identify clastogenic agents; and (3) (E/Z)-endoxifen is not phototoxic in a standard in vitro assay. The possibility of weak sensitizing activity of (E/Z)-endoxifen gel appears to be caused by the component of the gel vehicle rather than by (E/Z)-endoxifen itself. [HHSN2612015000241]

The recent change by European authorities in legislation regarding the minimum housing requirements for large animals on safety assessment studies has highlighted the need to refine certain practices. Historically, for infusion studies using a surgically implanted catheter, single housing was accepted since few alternative products were available. In order to better comply with European requirements as well as to ensure the highest standard in terms of animal welfare, our laboratory developed an ambulatory model for infusion studies in large animals. Four cynomolgus monkeys were surgically implanted in the femoral vein as per standard procedures, with the exception that the catheter length was shortened as the animals were not tethered. The catheter was exteriorized into a jacket backpack, which also held the pump and the infusion bag.

Animals were group housed and recovered from surgery for 12-14 days with a saline intravenous infusion maintenance rate of 2 mL/hr. The rate was then increased to 2.5 mL/kg/hour, a rate commonly used for continuous infusion toxicology studies, and animals were administered saline continuously (24 hrs/day) for 28 days. The infusion was then stopped and animals underwent 4 weeks of once weekly intermittent infusion at 20 mL/kg/hr for 1 hr, and then 4 weeks of once weekly intermittent infusion at 0.2 mL/kg/hr for 4 hrs. Clinical condition was monitored daily and body weight once weekly. To evaluate any effect of the additional weight carried by the animals, heart rate, blood pressure, body temperature and activity level were monitored by telemetry for 24 hrs with incremental weights (corresponding to different sizes of infusion bags) placed into the jacket backpack. Accuracy of the monitoring equipment was tested at each occasion of dosing. There was no abnormal clinical sign noted, and no significant changes in body weights. Weights between 330 and 730 g in the backpack had no impact on any of the physiological parameters measured. Group housing of the animals was successful for the duration of the project, and no damage to the jackets or pumps was observed. Less repair surgeries were required than with the tethered approach, which suggests this model is more stable. Overall, these results show that the ambulatory system can be successfully used for both continuous or intermittent intravenous infusion studies for a duration of up to 4 weeks in the monkey while improving the welfare of the animals.

Phototoxic properties of systemically applied pharmaceuticals may be the cause of serious adverse drug reactions. Despite being clinically manageable in principle, they can limit clinical use of a drug depending on the indication. Protective measures against sunlight can be applied very reasonably during a few days but may not be practicable for chronic treatments. Thus, both patients and health authorities are unlikely to accept a relevant photosensitization risk, including skin tumors, in such situations. Although definitive clinical testing is an option it is rarely considered as it can only be done late during clinical development and it is significantly more expensive than any preclinical testing (Bauer, Photochem Photobiol Sci, 2016). Thus, a reliable preclinical photosafety assessment strategy combining in vitro and in vivo approaches is usually applied early on. For most drug candidates, photosafety evaluation can be based purely on spectroscopic measurements (Bauer, Regul Toxicol Pharmacol, 2014) and in vitro results (Schümann, Toxicol Sci, 2014). However, a few compounds will need confirmation in vivo, for instance those with oral or nasal presentation. Therefore, NOAEL-derived safety margins versus therapeutically relevant drug levels based on Cmax are an appropriate method to support human risk assessment and are regulatory accepted (ICH S10, 2013). In some cases, e.g. for drugs with very limited systemic exposure, even the IC50 value obtained under irradiation in the in vitro 3T3 NRU Phototoxicity Test (OECD TG 432) can be used to estimate the margin versus therapeutically relevant drug levels and to support risk assessment in a weight-of-evidence approach.
lack of off-target interactions. TK revealed dose proportional increases in AUC and C_{max} over the dose range of 50 to 500 mg/kg and accumulation of mAb114 from the first to last dose interval. The mean terminal half-life for mAb114 ranged from approximately 7 to 15 days. Ex vivo binding to recombinant Ebola glycoprotein was demonstrated in serum and cerebrospinal fluid (CSF), suggesting that mAb114 was pharmacologically active and distributed through the central nervous system via CSF. Based on these data the NOAEL was considered to be 500 mg/kg/week and associated with a mean C_{max} of 24,206 μg/mL and mean AUC of 237,090 day·μg/mL. Simulation of human PK indicated that for the proposed clinical high dose of 50 mg/kg, the safety margins based on the cerebrospinal and AUC were 19-fold and 20-fold, respectively. In summary these data indicate that mAb114 is safe and has a broad therapeutic window.

**1569 Repeat-Dose Toxicity and Metabolism of Topical (E/Z)-Endoxifen Gel in Minipigs**

W. D. Johnson1, M. Muzzio1, C. J. Dretsac1, R. E. Glaze1, and D. L. McCormick1. IIT Research Institute, Chicago, IL; 1CRL-Pathology Associates, Chicago, IL; and 1National Cancer Institute, Bethesda, MD.

When compared to oral or iv administration, direct topical application of breast cancer drugs to the breast may increase local delivery and reduce systemic absorption, thereby increasing efficacy and reducing toxicity. A 28-day repeat-dose study was performed in female minipigs to characterize the toxicity and metabolism of an (E/Z)-endoxifen gel being developed for breast cancer prevention. Groups of 8 Göttingen minipigs received topical (dermal) exposure to E/Z-endoxifen gel (E/Z-endoxifen doses of 2 or 4 mg/day) or vehicle gel only for 28 consecutive days. Gels were applied daily to the same nipple of each minipig; the high dose was applied daily over a dermally doseable to the nipple. In addition, a pharmacology comparator group of 4 minipigs received daily gavage exposure to Z-endoxifen for 28 days. Endpoints included mortality; body weights; clinical observations; local tolerability; clinical pathology; drug and metabolite levels in plasma and liver; and histopathology. Topical application of E/Z-endoxifen gel was well-tolerated by female minipigs: no mortality, clinical evidence of toxicity, local toxicity, body weight effects, changes in clinical pathology parameters, or gross or microscopic findings were observed. Dose-related decreases in absolute and relative ovary weights were seen in both groups receiving topical (E/Z)-endoxifen gel, reflecting the pharmacologic action of this drug. Endoxifen is rapidly glucuronidated in minipigs; with few exceptions, plasma levels of endoxifen were below the limit of quantitation, regardless of route of exposure. Endoxifen glucuronide was measurable in the mammary gland (but not plasma or liver) of minipigs receiving topical (E/Z)-endoxifen gel. By contrast, high levels of endoxifen glucuronide were present in the plasma of minipigs receiving oral exposure to Z-endoxifen. Both endoxifen and endoxifen glucuronide were measurable in the liver of minipigs receiving oral exposure; endoxifen glucuronide was also present in the mammary glands from the oral exposure group. Repeat-dose topical administration of E/Z-endoxifen gel for 28 days was well-tolerated in female minipigs, and resulted in mammary gland levels of endoxifen glucuronide that were comparable to those seen following administration of a much higher oral dose of Z-endoxifen (HHSN2612015000241).

**1570 Preclinical Safety Evaluation of KBP-5074, a Novel Non-Steroidal Mineralocorticoid Receptor Antagonist for the Treatment of Cardiorenal Diseases**

Mineralocorticoid receptor antagonists have been demonstrated to reduce the risk of mortality in patients with heart failure and to decrease proteinuria in patients with cardiorenal diseases. KBP-5075 binds selectively to mineralocorticoid receptors with excellent in vitro antagonistic activity (IC50 2.7 nM). The primary objective of this study was to evaluate the preclinical safety of KBP-5074 in CD-1 mice. Safety pharmacology studies included in vitro and in vivo proarrhythmia assays. The NOAEL was 15 mg/kg. Genotoxicity studies of KBP-5074 included in vitro mutagenesis and chromosomal aberration studies as well as in vivo micronucleus test in CD-1 mice. KBP-5074 demonstrated no genotoxicity potential. A pilot study of KBP-5074 in SD rats was performed to select the dose levels for the IND-enabling one-month oral toxicity study. Once daily dosing of KBP-5074 at 50 mg/kg/day or higher for 14 days was not tolerated. Based on these results, the one-month oral rat toxicity study was performed using 0 (Vehicle control) 2, 6 and 20 mg/kg/day. No apparent drug-related toxicity was observed rats treated with 2, 6, or 20 mg/kg/day. The NOAEL was determined to be 6 mg/kg/day for both male and female rats. A pilot study of KBP-5074 was also performed to select the dose levels for the one-month oral toxicity in Beagle dogs. Once daily dosing of KBP-5074 at 100 mg/kg for 7 days showed significant toxicity findings. Based on these data, the GLP oral dog toxicity study was performed using 0, 2, 6 and 20 mg/kg/day. The NOAEL of KBP-5074 was determined to be 6 and 2 mg/kg/day in male and female dogs, respectively. Based on the above studies, it was concluded that the preclinical safety profile of KBP-5074 would support the initiation of clinical trials in man.

**1571 Calculation of a Permitted Daily Exposure Value for the Solvent 2-Methyltetrahydrofuran**

T. Parris1, N. Duncan2, and W. P. Beieruschmitt3. 1AstraZeneca, Cambridge, United Kingdom; and 2Pfizer, Inc., Groton, CT.

In response to increasing concerns around the potential environmental impact of industrial chemicals, the pharmaceutical industry is seeking alternatives for traditional solvents used during the manufacturing process. Taking into consideration the principles of green chemistry, 2-methyltetrahydrofuran (2-MeTHF) is proposed as a suitable replacement for the structurally similar solvent tetrahydrofuran (THF). 2-MeTHF is derived from renewable sources and is more easily recovered thereby facilitating its reuse. However, 2-MeTHF is currently not included in the International Conference on Harmonisation (ICH) Q3C residual solvent guidelines and their Pre-Registered Daily Exposure (PDE) limit was proposed below which there would be negligible safety concerns for patients exposed to it as a residual impurity in a drug product. To enable the calculation of a PDE, a GLP compliant 3-month repeat-dose oral toxicity study in rats with a 1-month recovery period was conducted with weights of 80, 250, 500, and 1000 mg/kg of 2-MeTHF. Administration of doses of up to 1000 mg/kg/day was tolerated. Based on minimal observed effects on the liver at ≥500 mg/kg/day, the NOAEL in this study was considered to be 250 mg/kg/day. Following the ICH methodology including this NOAEL and a safety factor of 250, a PDE of 50 mg/day was derived to support the safe use of 2-MeTHF in the pharmaceutical industry.

**1572 Optogenetic Pacing for Assessment of Proarrhythmic Potential of Drugs in Induced Pluripotent Stem Cell-Derived Cardiomyocytes**

Induced pluripotent stem cell-derived cardiomyocytes (iPSC-CMs) have been proposed to be used as a part of the Comprehensive in vitro Proarrhythmia Assay (CIPA). Currently available iPSC-CMs contract spontaneously with various frequencies. Dependence of CMs action potential duration on the beating rate is most often corrected using empirical formulas derived for clinical QT interval dependence on heart rate that may not be appropriate for iPSC-CMs, especially with wide beating rate ranges. Using a viral vector (rAAV9-CAG-CHR2-GFP, University of North Carolina) we expressed channelrhodopsin2 (Chr2) in iPSC-CMs (iCell2, ProPrep study) and used a 48-well light delivery device (Lumos, AstraZeneca) to simultaneously pace cell cultures at various frequencies (0.1, 1, 10, 50, and 150 Hz) while recording drug-induced field potential duration (FPD) prolongation and arrhythmias using a microelectrode-array system (Maestro, Axion). After optimizing the intensity and duration of the stimulating light pulses, we recorded iPSC-CMs responses to three drugs: dofetilide (0.3-10 nM, a sodium channel blocker); ranolazine (0.1-100 μM, a calcium blocker) and ranolazine (0.1-100 μM, a balanced hERG and late sodium current blocker) with and without pacing. Dofetilide-induced dose-dependent FPD prolongation in all experiments with clinical observations; local tolerability; clinical pathology; drug and metabolite levels in plasma and liver; and histopathology. Topical application of E/Z-endoxifen gel was well-tolerated by female minipigs: no mortality, clinical evidence of toxicity, local toxicity, body weight effects, changes in clinical pathology parameters, or gross or microscopic findings were observed. Dose-related decreases in absolute and relative ovary weights were seen in both groups receiving topical (E/Z)-endoxifen gel, reflecting the pharmacologic action of this drug. Endoxifen is rapidly glucuronidated in minipigs; with few exceptions, plasma levels of endoxifen were below the limit of quantitation, regardless of route of exposure. Endoxifen glucuronide was measurable in the mammary gland (but not plasma or liver) of minipigs receiving topical (E/Z)-endoxifen gel. By contrast, high levels of endoxifen glucuronide were present in the plasma of minipigs receiving oral exposure to Z-endoxifen. Both endoxifen and endoxifen glucuronide were measurable in the liver of minipigs receiving oral exposure; endoxifen glucuronide was also present in the mammary glands from the oral exposure group. Repeat-dose topical administration of E/Z-endoxifen gel for 28 days was well-tolerated in female minipigs, and resulted in mammary gland levels of endoxifen glucuronide that were comparable to those seen following administration of a much higher oral dose of Z-endoxifen (HHSN2612015000241).
The daily oral administration to rats of an investigational drug in neurodegenerative disease at a dose of 300 mg/kg/day resulted in body weight loss leading to early termination. Diffuse villous atrophy, epithelial erosion and variable hyperplasia were observed in the duodenum. At 100 mg/kg/day, the test item was well tolerated for 14 days and histopathology of the duodenum was limited to multinucleated giant cells with/without clefts in the mucosa. Examination of snap-frozen unstained sections of the duodenum by polarized microscopy revealed the presence of minute birefringent material in the duodenal mucosa and triggered further investigations by Mass Spectrometry Imaging. The slides of snap-frozen unstained duodenum were analyzed by MALDI-FTICR-MSI in positive polarity mode and identified the test item as the polarizing material in multinucleated giant cells of the duodenum. We interpreted that the absorption of the test item led to pH-dependent precipitation out of a supersaturated solution of the test item in the duodenum mucosa and formation of multinucleate giant cells scavenging this poorly soluble material. At higher doses, the scavenging phenomenon was overwhelmed by the amount of precipitate, leading to mucosal epithelial damage (villous atrophy, epithelial erosion) and physical consequences on animal health status (decreased nutrient absorption and body weight loss). When unaccompanied by structural damage, the mucosal APP precipitation was considered a local dose-dependent reversible effect. Advancements in Mass Spectrometry Imaging allowed fast resolution of the issue with minimal additional experiments.

**Plethysmography Versus Blood-Gas Parameters: Overlap and Considerations in Nonclinical Safety Assessment Studies**

Evaluation of blood gas parameters is a suggested method for assessing test article effects on respiratory function in nonclinical safety pharmacology and toxicology studies. The sensitivity of the ABL80 FLEX CO-OX instrument to measure arterial blood gas measurements has not been thoroughly investigated in rats. This study evaluated intra-precision, inter-precision, stability, intra-individual variability, and type of collection apparatus for blood gas collections. Additionally, this study compared blood gas values to head-out plethysmography data in Sprague Dawley rats administered a respiratory stimulant; 20 mg/kg theophylline-line via oral gavage. Blood was collected from the femoral arterial catheter and analyzed with the ABL80 FLEX CO-OX blood gas analyzer using Radiometer assays. Intra-precision and inter-precision variability was acceptable for all endpoints, with the exception of standard base excess, actual base excess, and anion gap (K⁺). The following endpoints exhibited acceptable nook parameter stability through 30 minutes post-collection: bicarbonate, concentrations of hemoglobin, sodium ions and chloride ions, fractions of methemoglobin and carboxyhemoglobin. Although results from Pico syringes, Westmed (Pico 3100-25) syringes, and capillary samples were generally similar, it is recommended that one type of collection device be used within a study, rather than using these devices interchangeably. In head-out plethysmography evaluation, theophylline significantly increased tidal volume, respiration rate, and minute volume within 2 hours postdose. However, fractions of carboxyhemoglobin and methemoglobin and concentrations of bicarbonate, calcium ions and hemoglobin were minimally decreased by the theophylline; other blood gas parameters were not significantly altered during this same postdose time span. These data suggest that blood gas measurements are less sensitive than plethysmography for nonclinical safety evaluation of respiratory safety pharmacology, but blood gas parameters can be valuable supplemental data.

**Drug-Induced Toxicity in Rats Due to API Precipitation in the Intestinal Mucosa**

Histone deacetylases (HDACs) are crucial players of epigenetic regulation, largely through their influence on gene transcription, and therefore have important roles in numerous biological processes. Levels of these proteins are implicated in different disease states such as cancer, cardiovascular, neuronal and musculoskeletal diseases, which makes them promising therapeutic targets. The goal of this study was to generate a comprehensive knowledge base to account for epigenetic targets and their safety assessment. We made computable all publically available data about molecular functions, biological processes as well as the data supporting involvement in pathologies/diseases. We explored mechanisms that underlie target effect of candidate drug or perturbed biological pathway. In order to test our system, we focused on the histone deacetylases HDAC1 and HDAC3 and their characterization as valid and safe therapeutic targets in colon cancer. Here we confirmed that developed HDAC1 and HDAC3 functional and several HDAC1/3 associated pathologies and diseases that are related to cancer. In addition the system associated HDAC1 and HDAC3 to some other diseases on cellular, organ and organ system level related to cardiovascular system (congestive heart failure, cardiac hypertrophy), smoking, obesity, diabetes, musculoskeletal system and formation and Brain function. We identify proteins related to colon carcinoma and HDAC1/3, including those involved in cell cycle regulation, proliferation, angiogenesis, apoptosis and growth factor receptor signaling. In order to confirm the therapeutic potential of HDAC1/3 inhibitors, we used a gene expression data from human colorectal carcinoma cells treated with Largazole, an HDAC1/3 inhibitor. Bioinformatics analysis provides the molecular mechanism of how Largazole induces downstream transcriptional changes in cell cycle inhibitors p21, p15 and CDK6, proapoptotic BCL2 protein and growth factor receptors EGFR, HER-2 and RS-1, all triggered by HDAC1/3 inhibition and other partnering proteins within the colon carcinoma model. Here we confirmed that developed database and software can contribute to a better understanding of therapeutic potential of HDAC1/3 inhibition in colon cancer and other disease indications and can increase the coverage of traditional safety reports.

**Intravenous Toxicity of Fentanyl, Remifentanil, and Carfentanil in the New Zealand White Rabbit**

L. K. Wright¹, J. S. Forster¹, R. W. Moret², J. A. Renner², B. I. Gaviola¹, T. S. Moran¹, R. J. Lawrence¹, B. J. Benton¹, M. W. Busch², and M. G. Feasey.¹ US Army Edgewood Chemical Biological Center (ECBC), Aberdeen Proving Ground, MD; and ²Excet, Inc., Springfield, VA.

Fentanyl is a narcotic estimated to be 100x more potent than morphine. It acts primarily through interaction with mu-opioid receptors located in brain, spinal cord and smooth muscle. Fentanyl is prescribed to patients who have developed tolerance to less potent analgesic drugs. In extreme potential of overdose and death, Fentanyl elicits respiratory depression by slowing signal transduction in the respiratory centers of the brain and causing rigidity in skeletal and thoracic respiratory muscles. Fentanyl also been shown to depress the respiratory brainstem center’s ventilator response to rising levels of CO2. Remifentanil is an opioid, agonist and antagonist with an extremely short duration of action. It was approved for use in heptically compromised patients, as it is metabolized by circulating esterases within the liver. Carfentanil is estimated to be 100x more potent than fentanyl in regards to its analgesic potency, which may or may not correlate to toxicity. While not used in human medicine, carfentanil was...
used as a large animal sedative. It is hepatically metabolized and has been shown to exert its effects longer than that of both fentanyl and remifentanil. This study was conducted to investigate the biological effects of commercially available opioid analgesics, specifically fentanyl, remifentanil and carfentanil, administered by the intravenous route to New Zealand White rabbits. The effects of interest were the median lethal dose and the median effective dose. As the endpoint of incapacitation. Additionally, the progression of signs related to drug response and toxicity were monitored to characterize the symptomology of these compounds; this includes cardiac damage biomarkers, saturated oxygen, as well as opioid-targeted toxic signs. Carfentanil was observed to be approximately 10x more lethal than fentanyl and 500x more lethal than remifentanil. Generally, symptomology was the same among these compounds with the greatest difference being time to recovery. Rabbits exposed to remifentanil recovered more quickly than those exposed to fentanyl or carfentanil, which demonstrates the ability of remifentanil to be rapidly cleared, limiting its propensity to accumulate in tissues and prolong the exposure.

**1578 Examining the Impact of Eliminating the Concomitant Satellite Cohort in Toxicology Studies**

M. Hackett. Battelle Memorial Institute, West Jefferson, OH. Sponsor: S. Anand

The ICH is considering a revision to guidance S3A to allow blood microsampling of the main study cohorts of a general toxicology study for toxicokinetic (TK) analysis. Published data shows only minor hematological effects when 32-200 μL of blood is collected up to 6 times/day in healthy animals (Kerris-Glover, 2014; Caruso, 2015). The purpose of this study was to show the bleed effects from microsampling would also be negligible in animals treated with a toxic dose of an approved drug and confirm the bleeds would not impact the interpretation of study results. Female and male Sprague Dawley rats were dosed with either 500 mg/kg ascorbic acid or normal saline via IP injection daily for 7 days. Animals in both groups were 1) not bled, 2) serial bled 6 times/day via the tail vein at 100 μL/bled on Days 1 and 7 or 3) bled twice/day via the retro-orbital venous plexus at 600 μL/bled on Days 1 and 7 (composte). Endpoints included clinical signs of toxicity, body weight measurements, and clinical and anatomic pathology. VPA induced ataxia, lethargy and temporary coma consistent with previously published results (Zieve, 1989). VPA-treated animals also exhibited a body weight loss of 3-11% over the week of treatment, testicular atrophy, immuno-suppression, and minor liver impairment. Minor effects of the blood collection were observed in the hematology of the VPA-treated, microsampled animals consistent with the corresponding saline controls; however, no parameter reached statistical significance when compared to their respective unbled controls. Further, the changes measured in the microsampled groups at the end of the dosing period all successfully reverted to baseline following a 14-day recovery period, though the microsampled group at the end of the dosing period all success-

**1579 Assessment of the Efficacy and Safety of Synergistic Florfenicol and Thiamphenicol Combination as a New Drug against Actinobacillus pleuropneumoniae and Pasteurella multocida**

P. Rattanapanadda1, T. Rairat1, H. Kuo2, Y. Hsu1, and C. Chou1

1National Chung Hsing University, Taichung, Taiwan; and 2National Chiayi University, Chiayi, Taiwan.

Florfenicol (FF) and thiamphenicol (TAP) have been reported to exhibit both in vitro and in vivo synergism against clinical isolates of Staphylococcus aureus from pigs and Pasteurella multocida from chickens. Synergistic combination of existing antibiotics is a desirable practice because it could provide a broader antibacterial spectrum and minimize toxicity as well as the emergence of resistant bacteria. The current study aims to investigate if FF and TAP synergism also occurred for Actinobacillus pleuropneumoniae and Pasteurella multocida, the two important upper respiratory pathogens in pigs. Clinical toxicological assessment of FF-TAP including acute oral toxicity, Ames mutagenicity as well as resistance induction by P. multocida under sub-inhibitory concentrations were evaluated. Potential synergistic effect was observed on 58% of A. pleuropneumoniae (n=50) and 45% of P. multocida (n=79) isolates. Fractional inhibitory concentration index indicated that 38% of A. pleuropneumoniae and 50% of P. multocida had values ≤ 0.5. Overall, the MIC of FF could be reduced to less than ½ and ¼ of its original strength (1 MIC) against A. pleuropneumoniae and P. multocida respectively, when combined with 1/2 MIC of TAP. The in vitro and in vivo toxicity results suggested no significant toxic effects of FF-TAP combination. In addition, the MIC of FF/TAP combination on P. multocida was not changed after 12 passages. Therefore, this combinational antibiotic synergism may offer an attractive alternative for effective therapy against infections of these two pathogens in susceptible pigs. Furthermore, since the dosages are significantly reduced compared to the labeled recommendation dose, it is reasonable to also expect reduced residue time and improved safety as indicated in this study.

**1580 An Integrated Strategy for Leveraging Novel Tissue Transcriptional Biomarkers, Translational Safety Biomarkers, and Advanced In Vitro Models to Reduce Drug Attrition and Improve Pharmaceutical Safety in Drug Discovery and Development**

Historically ~13% of drug candidates fail due to findings seen in first GLP animal toxicology studies, and ~40% of all candidate attritions are due to safety concerns seen in animal toxicology studies (Waring, M.J. et al. (2015) Nat Rev Drug Disc). To combat this, Merck investigators introduced several changes that have brought attrition rates down to less than 5% through first GLP studies, and the contribution of animal toxicities to overall attrition to less than 10%. Here we describe some of the components contributing to this improvement. Transcriptional biomarker signatures focused primarily on adverse drug-induced alterations in liver, heart, kidney and skeletal muscle were designed into a 5-day rat study conducted at 2 dose levels to identify sources of high dose intolerability, and safety issues that could be expected near the desired safety margin. Drug safety has been assessed in this candidate selection (CS) safety lead optimization “stage gate” study before making decisions to enter regulated stages of drug development. Complex in vitro 3-D liver models have also been deployed in parallel, to accelerate timelines and reduce resources for identifying improved molecules when flagged by certain findings in such CS studies. Many but not all of the endpoints, either in vivo or in vitro, are focused on sensitive detection of predominant mechanisms and key events associated with organ toxicities, including, for example, excessive chemically reactive metabolite burden, activation of certain nuclear-receptor transcriptional pathway signatures, severe systemic inflammatory responses, mitochondrial injury, and perturbation of bile acid homeostasis. For certain drugs that enter regulated stages of drug development and still present with significant animal toxicities, attrition reductions have been achieved on a strategic case-by-case basis, using in some cases new translational safety biomarkers, including imaging, to establish safe clinical monitorability or customized investigative approaches to inform mechanism and human relevance. Experience supporting the value of the approach and examples describing integration of these approaches are presented.

**1581 Intra-Arterial Administration of Alprostadil in Peripheral Arterial Obstructive Disease: A Toxicological Comparison of Alcoholic Solutions with Lyophilised Powder Containing α-Cyclodextrin**

A. Woolley1, E. Hesse2, and B. Hansbauer1. 1ForthTox, Linlithgow, United Kingdom; and 2Gebro Pharma, Fieberbrunn, Austria. Sponsor: A. Woolley

This was a comparison of local tolerance of intra-arterial (IA) infusions of prostaglandin E1 (PGEl, Alprostadil) prepared from ethanolic (ETHO) concentrates of PGE1 (Pridorx) with PGE1 lyophilized with cyclodextrin (Prostavasin). PGE1 is used in PAOD in single doses up to 60 μg, up to 80 μg/day IV, and up to 20 μg/day IA. IA infusion is not yet approved for ETQH concentrates. Aqueous solutions of PGE1 have poor stability, unless prepared from lyophilized formulations with α-cyclodextrin.
no macroscopic findings at day 8. Animals dosed with Pridax® and the treatment site on day 3; pale kidneys were noted in one; there were no macroscopic findings at day 8. On day 3, rabbits treated with Pridax® had a marked red area (2-5 mm) at the injection site that were interpreted as typical effects of IM or ID dosing as changes were no longer present after the 28-day recovery period. No increased spleen weights in several groups; these effects were reversible, regardless of route of exposure, as all rabbits developed neutralizing antibodies against the target virus. Both vaccines were well tolerated by rabbits curious whether clinical IA use of an ETOH formulation of Pridax® would be safe, compared with formulations lypolysiphied with α-cyclodextrin.

### Bone Marrow Immunophenotyping Reference Data—Integrated Biopsies in a Study with Cynomolgus Monkeys

In the non-clinical safety assessment of biological medicinal products, often cynomolgus monkeys (Macaca fascicularis) are the only relevant species. We have established a method for immunophenotyping (IPT) of bone marrow cells from cynomolgus monkeys that can be used to study pharmacology and immunotoxicity in this animal model. Bone marrow cells were harvested from cynomolgus monkeys in the scope of an intravenous infusion study. Bone marrow cells were harvested proximal from the left humerus of 7 male (up to 6.5 kg) and 14 female monkeys (up to 4.8 kg) that were anaesthetized for implantation of the port catheter system. After repeated dosing with a test article, animals were anaesthetized before necropsy, and bone marrow cells were then harvested proximal from the right humerus. The bone marrow was sampled using a veterinary bone marrow biopsy needle and a syringe filled with EDTA fluid. Following the pre-dose sampling, skin wounds were sutured. All animals were treated with the analgesic meloxicam (0.1 mg/kg, subcutaneously) and the antibiotic sulfadiazine/trimetprim (24 mg/kg intramuscularly). Following lysis of erythrocytes, cells were stained with specific antibodies against CD8, CD14, CD20, CD25, CD38, CD69, and CD138. Following the reference formulation showed arterial thrombosis on Day 3 (marked in all 3 animals treated with the reference and mild in 1/3 animals treated with Pridax) and Day 8 (1/ group). IA injection of Pridax® or Prostavasin® was irritant to the arterial wall resulting in thrombosis. The effect was less marked after Pridax® showing that Pridax® was better tolerated. These results show that IA injection of Pridax® was well tolerated and that its effects were less than those with Prostavasin® with no renal change. It is considered that these studies show that clinical IA use of an ETOH formulation of Pridax® would be safe, compared with formulations lypolysiphied with α-cyclodextrin.

### Altered Bile Acid Homeostasis and Mitochondrial Function: Potential Mechanisms for BMS-986020-Induced Human Hepatobiliary Toxicity

M. Gill1, L. Sivaraman1, K. Chadwick1, J. Woodhead2, K. Yang2, B. Howell2, M. Graziano3, and L. Lehman-McKeeman1. 1 Bristol-Myers Squibb, Princeton, NJ; and 2DILysm Services, Inc., Research Triangle Park, NC.

In a Phase 2 clinical trial, BMS-986020, a lysophosphatidic acid 1 (LPA1) receptor antagonist under development for idiopathic pulmonary fibrosis, produced hepatobiliary (HB) toxicity (1 ALT, AST, and ALP; cholecytisitis). In the absence of liver toxicity in rat and dog, additional non-clinical assessments were undertaken retrospectively to identify a potential mechanism(s) of toxicity. BMS-986020 inhibited the canicular bile acid (BA) efflux transporter BSEP (4.8 µM IC50) and MRP2 (37 µM), but did not increase oxidative stress. HB toxicity was not predicted in rats (6 months; 100x human AUC) or dogs (9 months, 7x), but, in a retrospective rat study (7 days, 100x), a prototypical response to rat Bsep inhibition was observed (↑ plasma BA [≤ 14x], ↑ expression of MRP3 [9x], MRP4 [2.4x], and Bsep [1.9x], and L expression of the BA uptake transporter, NTCP [0.8x]). In a retrospective monkey study (8 days, 2x human AUC), BMS-986020 increased ALT (2x) and GLDH (4.9x) and bile ductule hyperplasia, cholangitis, and cholestasis, demonstrating that the monkey was the only nonclinical species sensitive to BMS-986020-induced HB toxicity. DILysm simulations predicted 17.5% compared with 20.8% incidence of patients with ALT > 3x ULN in the clinic when a combination of BA transporter and mitochondrial ETC inhibition was represented. These results are consistent with reports that combinations of altered BSEP, MRP, MDR3, and mitochondrial function in the clinic when a combination of BA transporter and mitochondrial ETC inhibition was represented. These results are consistent with reports that combinations of altered BSEP, MRP, MDR3, and mitochondrial function studies show that clinical IA use of an ETOH formulation of Pridax® would be safe, compared with formulations lypolysiphied with α-cyclodextrin.

### Human Hepatobiliary Toxicity

Funding provided by The Geneva Foundation through NIAID contract HFN52201200019C.
β-catenin, a core component of Wnt/β-catenin signaling is a key molecule in the pathogenesis of Wnt-dependent familial and sporadic colorectal cancer (CRC). CEQ508 is an oligonucleotide therapeutic using live-attenuated *Escherichia coli* genetically engineered to deliver β-catenin short-hairpin RNA to mediate RNA interference (RNAi) in the gastrointestinal (GI) epithelium of patients with CRC. The long-term safety of daily oral administration of CEQ508 was evaluated in Cynomolgus monkeys. CEQ508 contained the plasmid pMBV43-H3 encoding the sequence for a shRNA against the mRNA of β-catenin, as well as the ability to enter the host cells and release the expressed shRNA through the use of two unrelated proteins, invasin and listeriolysin. CEQ626 was used as nonspecific shRNA control. Groups of three Cynomolgus monkeys/sex/group (n = 18) received the highest dose anticipated in the dose-escalating clinical trial of CEQ508 (10^11 colony forming units [CFU]/day) or CEQ626 and control vehicle via nasogastric gavage once daily for 280 days with a 7-day recovery period. Serum collected pretreatment and monthly throughout the study was analyzed for Th1 cytokine induction. Colon tissue was collected pretreatment and after 1, 3, 4, 5 and 6 months and local cytokine response was monitored using gene expression arrays of 84 different cytokines, chemokines and related receptors, and compared to serum collected from LPS-treated monkeys and corresponding controls. CEQ508 did not induce serum and local cytokine response in the panel of proinflammatory markers analyzed. In 280 days of daily oral dosing, no test article-related adverse effects were observed. In 280 days of daily oral dosing, no test article-related adverse responses were identified in a variety of parameters, including clinical observations, body weights and temperatures, serum chemistry, coagulation, hematology, and anatomical pathology assessments. Evaluation of fecal material confirmed the presence of CEQ508 or CEQ626 in the GI tract. Monkeys were evaluated up to Bup doses of 80 mg/kg in a full-thickness skin incision. Pigs were euthanized on Days 3, 14, or 28. LIQ865A was well-tolerated, at all doses with no evidence of systemic toxicity. Local incision site responses were the same as those described in the rat. Particles were noted in the injection sites of all LIQ865A groups on Day 3. By Day 14, the inflammatory response had resolved, all incisions appeared healed and particles, noted in only a few LIQ865A animals, showed significant degradation. On Day 28, no microparticles were observed in incisional tissues. LIQ865A was well-tolerated, both locally and systemically, up to Bup doses of 80 mg/kg in the rat and 36 mg/kg in the minipig. The local changes associated with LIQ865A were consistent with a degradable foreign body and what is reported for Bup. No novel findings or safety concerns were identified. These studies provided adequate safety data/multiples to support Phase 1 LIQ865A clinical trials.

ANX005 is a humanized IgG4 recombinant antibody against C1q that inhibits its function as the initiating molecule of the classical complement cascade. The safety and tolerability of ANX005 is currently being evaluated in a phase I trial in healthy volunteers (www.ClinicalTrials.gov Identifier:NCT03010046). Inhibition of C1q can be applied therapeutically in a broad spectrum of diseases, including acute antibody-mediated autoimmune disease, such as Guillain-Barré syndrome (GBS), and in chronic diseases of the central nervous system involving complement-mediated neurodegeneration (CMND), such as Alzheimer’s disease (AD). To support the clinical development of ANX005, several nonclinical studies were conducted to assess the pharmacology, pharmacokinetics, and potential toxicity of ANX005. The rat and the Cynomolgus monkey were determined to be pharmacologically relevant and the most appropriate nonclinical species for toxicity studies with ANX005. Results from the toxicology studies showed that intravenous administration of ANX005 once weekly for 4 weeks was well tolerated in rats and monkeys, with no ANX005-related adverse findings. Serum levels of ANX005 in monkeys correlated with a reduction of free C1q levels, both in the serum and in the cerebrospinal fluid. In summary, ANX005 showed proof-of-concept in the *in vitro* and *in vivo* nonclinical pharmacology models, with no toxicity in 4-week repeat-dose toxicology studies in rats and monkeys. The non-observed-adverse-effect level (NOAEL) was 200 mg/kg/dose, which is 200-fold higher than the first-in-human (FIH) starting dose of 1 mg/kg in healthy volunteers.

ANX005 is a mixture of Curcumin (C)and Doxorubicin (D). This mixture is designed to have a more targeted effect on cancer cells. IMX-110 administered by single IV slow bolus at 12.0 C/3.0 D mg/kg to Crl:CD (SD) rats induced changes in hematology on Day 6 after dosing (all dose groups). The single dose of IMX-110 at the level of 21.1 C/5.3 D mg/kg was considered the maximum tolerated dose (MTD). IMX-110 administered by IV slow bolus for 5 consecutive days to rats at 6.0 C/1.5 D and 12.0 C/3.0 D mg/kg/day resulted in mortality in the high dose group, clinical signs of toxicity and induced decreases in body weights, changes in hematology (both dose groups but much more pronounced in the high dose group), clinical chemistry and coagulation. The dose of IMX-110 at the level of 6.0 C/1.5 D mg/kg/day was considered the MTD after dosing for 5 consecutive days. The dose of IMX-110 at the level of 12.0 C/3.0 D mg/kg/day was considered the severely toxic dose (STD) after dosing for 5 consecutive days. The dose of IMX-110 at the level of 6.0 C/1.5 D mg/kg/day was considered non-toxic. IMX-110 administered by IV slow bolus for 5 consecutive days to dogs at 0.9 C/0.225 D and 1.8 C/0.45 D mg/kg/day resulted in moribund sacrifice of both animals in the high dose group, clinical signs of toxicity, decreases in body weights, decreases in food consumption, changes in hematology and clinical chemistry (both dose groups but much more evident in the high dose group), and coagulation. The dose of IMX-110 at the level of 0.9 C/0.225 D mg/kg/day was considered the STD after dosing for 5 consecutive days. Based on these results, pivotal murine and canine studies are being performed. The study was sponsored by Immix Biopharma Australia Pty Ltd.
of proarrhythmia risk assessment but experimental methods and factors that influence variability of these ECG parameters in non-clinical species need to be further evaluated. In addition, evaluation of a broader range of positive and negative control drugs may help establish their translational and discriminative value.

**1591 A Flow-Cytometry Assay to Assess B-Cell Maturation Antigen Expression in Peripheral Whole Blood of Cynomolgus Monkeys**

S. Dutta, J. Mundra, G. Bannish, and Y. Xiao, ENVIGO, East Millstone, NJ.

Multiple myeloma (MM) is the second most common hematologic malignancy. MM is characterized by abnormal proliferation of monoclonal plasma cells (PC) resulting in monoclonal immunoglobulin, osteolytic bone disease and immunosuppression. Among new immunotherapeutic targets for MM, the cell surface transmembrane protein B-cell maturation antigen (BCMA/TNFRSF17/CD269) is most promising target for immunotherapy due to its key role in PC survival, high expression on PC, malignant PCs but not on naive and memory B cells, CD34+ hematopoietic cells, or any other normal tissue cells. BCMA modulates optimal PC survival by inducing signal cascades upon binding to proliferation-inducing ligand (APRIL) and/or B-cell activating factor (BAFF). Several high affinity anti-BCMA therapeutics such as BCMA-T cell bispecific antibody (EM801), bispecific T cell (BiTE) targeting BCMA and CD3e (Bi 836909) and anti-BCMA antibody drug conjugate (GSK2857916) are currently in various stages of preclinical/clinical assessment. Preclinical toxicology testing of anti-BCMA therapeutics requires a suitable non-human primate model. Cynomolgus monkeys are pharmacologically relevant species for non-clinical safety assessment, pharmacokinetics and pharmacodynamics studies of anti-BCMA therapeutics due to BCMA expression on their peripheral blood B cells and PCs. We report here, development of a flow cytomtery assay to assess BCMA expression in peripheral blood of various species of non-human primates and B cell subset immunophenotyping and BCMA detection was performed using commercial CD269, CD20, CD27, CD40, CD38 and CD138 antibodies. Natural killer (NK) and T cells were excluded based on CD159a and CD2 expression and B cells were assessed in the CD45+/SSCINT CD159a+CD159a+CD2+leukocyte population. BCMA expression on different B subsets (CD27+/CD10-, CD27-/CD10+) and CD138+ PCs in peripheral blood as well as species and sex-specific variations in BCMA expression were studied. In summary, this is the first report of detection of BCMA expression on B cells in peripheral blood of cynomolgus monkeys and its species-specific variations. This study also highlights the use of flow cytomtery to detect/screen BCMA expression for toxicity and PK/PD assessment of anti-BCMA therapeutics.
Impairment of mitochondria by drugs and chemicals could lead to organ toxicity, or even mortality. A number of in vitro platforms and assays have been developed in recent years to identify and de-risk this liability during early drug development. Currently established in vitro models rely largely on the use of cancer/immortalized cell lines with limited metabolic activity, or isolated mitochondria, with mitochondrial dysfunction measured by cellular respiration or ATP production and cell viability under selected nutrient conditions. It has been suggested that some compounds known to cause drug-induced liver injury (DILI) by damaging mitochondria may require drug metabolism capability and/or a longer-term treatment for the toxicity to manifest. Complex micropatterned co-culture model (HepatoPac™) may therefore offer an advantage in detecting certain drug-induced mitochondrial liabilities. In the present work, we first evaluated metabolic responses of rat and human HepatoPac to a set of paradigm mitochondrial toxicants with various known modes of action. In addition, selected DILI drugs and Merck internal compounds demonstrated a high degree of concordance between results obtained in this model and those with other detection methods. Media metabolite changes were profiled and we found that baseline biochemical metabolite profiles and the responses to mitochondrial insults in HepatoPac differed significantly from those of hepato- toma cell lines, and also sometimes between rat and human HepatoPac. In HepatoPac, concentration-dependent media urea decreases follow-owing drug exposures in the absence of cytotoxicity provide a sensi-tive indicator of mitochondrial dysfunction. In addition, metabolic "fingerprints" indicate disturbances in metabolic pathways associated with established mechanisms of mitochondrial toxicity. For example, increases in glucose consumption and lactate production track well with chemicals known to disrupt the electron transport chain, while distinct metabolomics patterns are seen with other mechanisms of mitochondrion toxicity. Overall, our data suggest that drug-induced mitochondrial toxicity can be monitored using changes of certain culture media metabolites of HepatoPac, and this approach could provide an additional risk assessment tool to mechanism-based in vitro toxicity testing.

We conducted a 6-month GLP safety study in rats with sutezolid (STZ; PNU- 100480), an oxazolidinone for the treatment of tuberculosis. STZ was given twice daily (BID; ~6-hr interval) by gavage for 180 days to adult male, female and ovariecto-mized (OVX) female rats followed by a 30-day recovery. Male and female rats were given STZ at 7.5, 15, 30, 60 or 120 mg/kg/day BID. Starting Week 4, all STZ-treated animals showed decreased gain and/or loss of body weight relative to controls. We decreased the high-dose from 120 to 100 mg/kg/day, the mid-dose from 60 to 50 mg/kg/day, and from BID to single daily dose. Intermittent convulsions were observed during handling in the non- OVX females starting on Day 80 and continuing through Day 210. A total of 31 convulsions were observed in 5 rats, in the 15, 30 and 100 mg/kg non-OVX female groups; no convulsions were seen in the control or low-dose, or in any males or OVX females. Other STZ-related clinical observations were considered related to the body weight decreases. STZ and its active metabolites (M1: PNU-101603; M2: PNU-101244) had a Tmax of ~1 hr after the second dose. Major dose dependent sex differences were noted in the plasma exposure of STZ, with females, including OVX females, having significantly higher (up to 12- or 16-fold) plasma levels of STZ than males, which may be due to differences in the metabolism of STZ between males and females. Males had significantly higher plasma levels of the metabolites M1 (30- to 40-fold) and M2 (2- to 3-fold) than STZ. Non-OVX females and OVX females also had a higher (17- to 48-fold) plasma exposure of M2 than that of STZ. Third microscopic findings in all STZ-treated groups included oval cell hyperplasia and numbers of portal macrophages containing gold pigment were present in the livers of non-OVX females at ≥7.5 mg/kg (a finding reported in a previous 13-week study). Oval cell hyperplasia reversed after recovery, while increased pigment was still observed in portal macrophages in all STZ-treated groups. STZ was well tolerated by males and ovariectomized females, but sporadic convul-sions were seen in several hormonally normal females. The maximum tolerated dose (MTD) is considered to be ~100 mg/kg/day. A no observed adverse effect level (NOAEL) could not be determined, but is considered to be ≥7.5 mg/kg/day. Work supported by NIAID Contract HHSN272201400006E.

Extracellular Field Potential (FP) and impedance recordings of SC-CMs are currently used to detect drug induced cardiac arrhythmia liabilities. Major endpoints include the field potential duration (FPD), the duration of the impedance twitch, and the presence of proarrhythmic markers including early and delayed afterdepolarizations and fibrillations. We used the cardioECR instrument (ACEA Biosciences) and cellCM™ cardiomyo-cyte (cardiac Dynamics) assay to 1) identify the FP parameter (that best captures the intrinsic frequency-dependence of repolarization and 2) assess the extent the system can detect the mitigating effect of drugs with multiple ion channels effects (MICE) on proarrhythmic activity. Cardiac repolarization in FP recordings is encapsulated by one positive (T1) and two negative (T2) peaks. We plotted a linear relation with comparable slopes of 0.133 and 0.129 respectively (n=2) between T2 and T3 durations and beat period in the spontaneous frequency range. T1 shows a shallower slope (0.031) suggesting that the parameter does not follow closely the repolarization process and consistent with its limited response to drugs that affect the FPD. MICE effects were investigated by assessing the effect of different combinations of pure hERG (E-4031) and hCav1.2 (nifedipine) channel blockers designed to simulate distinct IC50 hERG/hCav1.2 ratios (HCR). The functional relationship between the number of wells showing proar-rhythmic markers and log HCR was fitted to a logistic function with an inflection point at -0.148 and a HCR of 0.71. Thus, compounds with HCR values ≤0.71 are predicted to induce proarhythmic activity in SC-CMs as we here show for dofetilide (0.001), sotalol (0.58), cisapride (0.002), quinidine (0.11), moflaxacin (0.50) and ibutilide (0.003). As expected for hERG (3667) showed a proarhythmic activity. Notably, the 0.71 ratio observed in SC-CMs is comparable to the 0.89 cutoff for drug-in-duced torsadogenic activity observed in the clinic (Kramer, Obejero-Paz et al., 2013). The evidence indicates that 1) T2 and T3 durations are reli-able endpoints to assess the effect of drugs on cardiac repolarization and 2) SC-CMs are useful tools to detect MICE with HCR cutoff values for proarrhythmic activity comparable to the clinic.
The infectious bursal disease virus (IBDV) is an immunosuppressive virus of chickens causing the infectious bursal disease. One promising strategy for preventing this highly contagious disease is using recombinant subunit vaccine, employing viral protein 2 (VP2) as epitopic antigen. Traditionally, the quality of vaccine was mostly evaluated by the host response or herd immunity against the pathogen that was immunized with, which normally happened after the vaccine was given. In the present study, an affinity capillary electrophoresis (ACE) method for VP2 detection and quantification was successfully developed in an attempt to evaluate the vaccine quality before and after its use, including the degree of adjutant-VP2 complex and the existence of specific antibody against VP2. Fixed concentration (100 μg/ml) of anti-IBDV VP2 IgG monoclonal antibody (mAb) was mixed with varying concentrations (10-100 μg/ml) of VP2 subunit viral particle (SVP) and analyzed by ACE using in a 60-cm fused-silica capillary (75 μm-inner diameter) with 20 kV voltage and 50 mM boric acid buffer (pH9) containing 1 mM sodium dodecyl sulfate as running buffer. Samples were diluted with boric acid buffer and injected by pressure of 0.5 psi for 3 sec. The detection wavelength (UV) was 214 nm. The migration times of mAb and SVP were 4.69 and 5.65 min, respectively, while those of mAb-SVP complex was in the range of 4.80-5.34 min which prolonged with increasing SVP level.

Linear relationship between the remaining mAb and SVP concentration was established with binding saturation at the ratio of 0.42. Potential applications of this method include quantifying VP2 concentration in the vaccine product as quality control measure of vaccine product and its stability. Specifically, the degree of association/dissociation between VP2 and adjutant could be evaluated by this technique. In addition, the ACE-UV analysis can also be applied for measuring anti-IBDV antibody in chicken serum for evaluating host immunity response against the virus.
Colorectal cancer (CRC) is the second leading cause of cancer-related death in the US and risk is on the rise in both middle aged and young adults. Despite 70-90% of all CRC incidence being attributed directly to diet, Americans routinely consume highly processed foods that are energetically-poor. The overall objective of this study was to determine the impact of trans-generational or multi-generational consumption of the total Western diet (TWD), a Western-style diet formulated for rodents using human US nutrient intake data, in a murine model of inflammation-associated colorectal carcinogenesis. The hypotheses tested were that 1) ancillary feeding TWD would promote colitis-associated caecal colorectal cancer (CAC) in F1 offspring, and 2) inter-generational feeding TWD would further exacerbate disease development. C57BL/6J mice were bred for three generations, during which they were fed either a standard diet (AIN93G) or TWD during the F0 generation only, for the duration of F1 or F2 generations, or the F3 generation only. The azoxymethane and dextran sodium sulfate model of CAC was employed in F3 offspring, subsequently necropsied at 24 weeks of age. Notably, tumor incidence was increased by indirect exposure to TWD (92%) when compared to consecutive AIN93G exposure only (56%). Moreover, successive exposure to TWD markedly increased tumor burden (3-fold increase) when compared to direct TWD exposure. Neither ancestral nor cumulative TWD exposure increased body weight or fat mass. In summary, trans-generational TWD exposure increased CAC incidence and disease severity in third generation offspring that were not directly fed this diet, and continuously feeding TWD for three generations distinctly exacerbated disease outcome in third generation offspring. Ongoing analysis will include gene expression profiling of colonic mucosal cells, followed by promoter methylation analysis that is expected to reveal an epigenetic mechanism of action.

Development of a Consensus Approach for Botanical Safety Evaluations

J.C. Griffiths1, J. Edwards2, S. Fitzpatrick3, C.L. Galli4, A.W. Hayes5, C. Mahony5, D.S. Marsman6, N.H. Oberlies7, L. O’Keefe8, A.L. Roe9, N.J. Walker10, and C.L. Wilson11. 1Council for Responsible Nutrition, Washington, DC; 2DSM Nutritional Products, Kaiseraugst, Switzerland; 3US FDA/CFSAN, College Park, MD; 4Università Degli Studi Di Milano, Milan, Italy; 5Michigan State University, East Lansing, MI; 6Procter & Gamble Co., Egham, United Kingdom; 7Procter & Gamble, Cincinnati, OH; 8University of North Carolina at Greensboro, Greensboro, NC; 9The Procter & Gamble Co., Cincinnati, OH; 10NIHES, Research Triangle Park, NC; and 11The Coca-Cola Company, Atlanta, GA.

Interest in botanicals (in consumer care products; most notably in foods, over-the-counter medicines and supplements) coupled with a desire to minimize animal testing, presents unique challenges for this category of ingredient. For both food botanical ingredients there are various safety assessment approaches from heavy reliance on post market surveillance of adverse events, to tiered strategies built on existing data and new data generated to meet specific safety needs (e.g., including but not limited to chemical characterization, genotoxicity/carcinogenicity testing, developmental/ reproductive testing, ADME considerations). A multi-stakeholder roundtable was held at the 2017 EUROTOX meeting in Bratislava, Slovakia to review a decision tree methodology for botanical safety evaluation. The presentations covered an overview of the European Food Safety Agency’s 2009 report on data needs for food supplements and a proposed holistic approach; evaluation of the safety of botanical dietary supplements; natural product characterization methods; and challenges in assessing disposition of these complex mixtures. The participants developed a series of statements in order to: discuss and provide their perspective on the proposed decision tree methodology; and identify key elements needed to build a robust botanical safety evaluation; highlight and debate vulnerabilities in these tactics; and share additional perspective to ensure this end-to-end safety approach is sufficient, actionable and timely. Critical areas and data gaps were identified as opportunities for future focus, and elements include better context on systematic assessment of weight of evidence, use of in silico approaches, inclusion of threshold of toxicological concern considerations, assessing natural product-drug interactions, and adoption of in vitro and in vivo physiologically-based pharmacokinetic modeling.

1602 Development of a Consensus Approach for Botanical Safety Evaluations

Safety Evaluation of Daily Oral Administration of Egg Shell Membrane Via Soft Chew to Male and Female Beagles

R.G. Henderson1, J. Miller2, and J. G. Lopez3. 1ToxStrategies, Inc., Wilmington, NC; 2ToxStrategies, Inc., Brookville, OH; and 3Virbac Corporation, Fort Worth, TX.

Eggshell membrane has been evaluated in several clinical trials demonstrating beneficial effects for joint and skin health in companion animals in recent years. However, no data demonstrating the safe use of eggshell membrane in targets species are available in the public domain. The protocol for the present study was based on the EPA Health Effects Test Guideline for Companion Animal Safety. Eight beagle dogs (4 per sex; mean 8.7 kg) received one soft chew orally per day on Days 0–83, followed by 5 soft chews/day on Days 84–110. Each 2 g soft chew contained eggshell membrane (66 mg), hyaluronic acid (8 mg), Boswellia serrata extract (5 mg; 65% boswellic acids), astaxanthin (250 mg; algae), and vitamin D3 (50 IU). Body weights were recorded on Day 0 and weekly thereafter. Blood was collected for hematology and clinical chemistry evaluations on Days 0, 83, and 111. On average, the majority of animals consumed the test article wholly with a dose acceptance score of 1. Physical examinations on Day 1 revealed abnormalities in bilateral otitis externa in two male dogs and one female dog and right ear otitis externa in one female dog. On Days 83 and 111, all dogs were observed to have dental tartar ranging from light to moderate, which was determined not to be treatment related. There were no observed abnormalities during the clinical observations for the duration of the study. Body weights were statistically higher after treatment with the soft chew on Days 84 and 111, relative to pre-treatment body weights; the average weight gain was 1.2 kg. Significant increases in creatine kinase values were observed on Day 111 (combined mean 157.9 U/L), relative to Days 0 and 83 (99.0 and 103.6 U/L, respectively). In addition, aspartate aminotransferase levels were significantly increased on Day 111 (32.1 U/L) compared to Day 20 (23.8 U/L) and Day 83 (25.1 U/L). While some significant differences in pre- and post-treatment serum chemistry results were observed, they remained within the normal reference ranges, and therefore were determined not to be clinically significant. Only bicarbonate on Day 83 was outside the normal range, with a combined mean value of 26.4 mmol/L slightly above the reference range of 15-25 mmol/L. In conclusion, the eggshell membrane product was found to be safe when administered to dogs orally for 111 days up to the targeted margin of safety of 5x the recommended dose.

Safety Evaluation of Daily Oral Administration of Egg Shell Membrane Via Soft Chew to Male and Female Beagles

1604 Dietary Early Glycation Products Protect Type 1 Diabetic Mice against Hyperglycemia through Altering Immune Homeostasis

Y. Chen, and T.L. Guo. University of Georgia, Athens, GA.

Early glycation products (EGPs) are proteins modified with reducing sugar moieties (e.g., glucose). They are generated in the first step of Maillard reaction/glycation, and are present in pre-processed/processed food and food-based products. These compounds have been shown to affect the bioactivity of food-delivered end-products (AGEs). This modification enhances the physiochemical properties of proteins (e.g., solubility), and has been proposed as a strategy to improve food protein qualities. However, the health effects of EGPs are rarely known. Our previous studies suggested that EGPs are anti-inflammatory. In contrast, AGEs, which are pro-inflammatory, are tightly associated with aging and hyperglycemia and are proved to be detrimental to almost all the organs and systems. We hypothesized that EGPs was protective for type 1 diabetes (T1D) through modulating the Th1/Th2 balance. Food-borne EGPs were produced from a whey protein isolate-glucose model system, with non-reacted samples (NR) and AGEs as controls. Two T1D models were used: streptozotocin (STZ)-induced T1D in female C57BL/6J mice, and non-obese diabetic (NOD) mice (non-diabetic females and males, and diabetic females). The C57BL/6J mice were dosed with water, glucose solution, NR, EGPs and AGES (600 mg/kg body weight, 8 wk) and then intraperitoneally develop T1D with 4 consecutive i.p. injection of STZ (50 mg/kg Bw), and they were continuously dosed for another 4 wks. NOD mice were dosed with NR and EGPs for 8 wks. Bw and blood glucose levels were measured weekly; diabetic incidence (blood glucose > 200 mg/dL) was recorded; glucose tolerance test (GTT); and insulin challenge test. Sera were separated, and spleen and thymus were harvested for flow cytometry analysis of the immune cell populations. The results showed that EGP-treated NOD mice showed significant lower blood glucose levels, delayed diabetes onset, less responsive to glucose challenge, and reduced insulin challenge test. EGP-treated T1D mice showed normal fasting glucose levels, normal glucose tolerance test (GTT), and reduced insulin challenge test. In addition, the diabetic females displayed lower or even normal blood glucose levels after EGP-treatment. The flow cytometric data showed that EGP-treated mice had a significantly higher CD4/CD8 ratio (an

147 2018 SOT Annual Meeting
for a Langmuir type equation to be compared. Sample C-5 showed a pattern compatible with Langmuir (I-2) equation (R² = 0.99), while C-12 showed a linear trend more compatible with the Freundlich model (R² = 0.96). Currently we are working with CEC determinations among other complementary analysis in order to find the best characteristics for aflatoxin binders. Funded by Industry Award by Minerals Technologies.

**1607 Low/No-Calorie Sweeteners and Effects on the Gut-Microbiota: Assessing the Nonclinical and Clinical Data and Implications for Food Safety**

A. R. Lobach, and A. Roberts. InterTek Scientific & Regulatory Consultancy, Mississauga, ON, Canada.

Low/no-calorie sweeteners (LNCS) are repeatedly under the spotlight with regards to their benefits and safety in foods. A study published in 2014 concluded that LNCS as a group of compounds induce glucose intolerance, which is mediated by alterations in the composition of the gut microbiota. This study captured widespread media attention; however, several other studies published prior to this did not report such alterations in the gut microbiota and LNCS. In response, we set out to undertake an in-depth analysis of the nonclinical and clinical data existing in the public domain relevant to LNCS and gut microbiota function and health. To investigate whether an association exists between LNCS exposure and modulation of the gut microbiota, a comprehensive review of the scientific literature was conducted. The search generated 115 hits, of which 13 were identified as relevant primary research articles investigating LNCS (including aspartame, saccharin, sucralose, and rebaudioside A) in vivo and measuring changes in microbial populations in the gut. The design of each study was critically reviewed and reported outcomes were evaluated. Several common critical issues were identified in study design including the lack of proper control groups, particularly isocaloric controls, as dietary factors are key determinants in gut microbial composition. Furthermore, LNCS doses administered in the majority of nonclinical studies were greater than the currently established acceptable daily intakes (ADI), greatly limiting the relevance to humans in a dietary context. In all, 3 nonclinical studies that employed LNCS doses at or below the ADI reported a change in gut microbiota, all of which were conducted in mice, a species with a gut microbiome that is significantly different than humans. No clinical studies reported changes in gut microbiota that could be definitively linked to LNCS exposure. The sum of the data establishes no clear evidence of any adverse effect of LNCS on the gut microbiota at doses relevant to human use. The safety databases that have been developed over decades for several structurally unrelated LNCS indicate that these compounds as a group, or individually, pose no safety concerns at their currently approved levels, a viewpoint that is supported by all the major international food safety and health regulatory authorities.

**1608 A Safety Analysis of an Energy Drink**

Concern has centered around possible health effects from drinking energy drinks. Yet Americans consume hundreds of millions of bottles of energy drinks every year. Is it safe? We addressed this question first by evaluating the safety of caffeine in an energy drink in a manner consistent with Generally Recognized as Safe (GRAS). We also researched current caffeine consumption, quantified added consumption from energy drinks, reviewed key toxicity and epidemiology studies, and conducted a quantitative analysis. Next, we evaluated whether caffeine consumption in an energy drink, combined with caffeine intake from other sources, would fall within safe limits of total caffeine intake. Finally, we convened a panel similar to a GRAS panel, which conducted an in-depth evaluation of caffeine safety under the conditions of its intended use in an energy drink. The GRAS panel panel found little evidence of an association between cardiovascular disease (CVD) or other adverse health effects and caffeine (coffee) intake. Major studies found either an inverse association or no significant association between chronic coffee consumption and CVD, heart failure, stroke, myocardial infarction, and atrial fibrillation. Some individuals, especially individuals who are not regular coffee drinkers, and thus not habituated to caffeine, may be at increased risk of a coronary event or stroke, but it is unclear if caffeine or other risk factors are responsible for these outcomes. We also evaluated the correlation between caffeine consumption and other health endpoints including bone mineral density (BMD), intraocular pressure (IOP) and glaucoma, diabetes and blood glucose, reproductive health (male and female), and cancer. In addition, we evaluated other constituents in energy drinks such as vitamins, amino acids, and nutrients. For the product evaluated, we concluded that these ingredients are safe if the energy drink is consumed in accordance with the product-label direc-
tions. Based on our safety assessment, the calculated margins of safety (MOSs) for all vitamins, amino acids, and nutrients for a 70 kg adult are slightly greater than or less than 1, indicating that no adverse effects would be expected. We concluded that consumption of the energy drink in a manner consistent with the product-label is safe.

### 1609 Microbiological Quality and Aflatoxin Contamination of Roasted Cashew Nuts Sold in Lagos, Nigeria

M. C. Ogunrin1, O. P. Alika2, N. Lubanza1, O. Atanda2, and M. Mwanza1. 1North West University Mafikeng Campus, Mafikeng, South Africa; and 2McPherson University, Mafikeng, Nigeria.

This study aimed at assessing the microbiological quality of roasted cashew nuts sold in Lagos State, Nigeria. Moisture content, Total Viable Count, Aflatoxigenic potential of aspergillus isolates and Total aflatoxins concentration of the cashew nuts were determined using standard methods and ELISA method respectively. The Moisture content, total plate count and fungi count ranged from 5.00 - 86.0% (Mean; 9.3%), 5.5 - 64.5 x 10^5 cfu/g (Mean; 35 x 10^5 cfu/g) and 1.0 - 4.5 x 10^5 cfu/g (mean ; 27.5 x 10^5 cfu/g) respectively. Nine different fungi species belonging to 5 major genera were isolated with Aspergillus flavus, Rhizopus oryzae and Fusarium oxysporum having the highest percentage occurrence (50% each) across the state. In addition, E. coli was present in all the samples but one (1-12x10^5 cfu/g), while Staphylococcus aureus was detected in 25% of the samples. Furthermore, aflatoxin concentration ranged from 0.1 - 6.8 µg/kg (80% above EU limit of 4µg/kg). Cashew nut consumers in Lagos State are at risk of exposure to aflatoxins and food borne diseases. This calls for mitigation measures from appropriate governmental organizations.

### 1610 Beyond the History of Safe Use of Botanicals and Their Extracts in Foods: A Proposed Standardized Framework for Their Safety Assessment

F. de Mooij1, L. Meunier1, J. Garthoff1, and A. W. Hayes1. 1Danone, Utrecht, Netherlands; and 2Michigan State University, East Lansing, MI.

In recent years, an industry wide trend, driven by consumer preference for more ‘natural’ foods and food ingredients, is occurring. This preference is often fed by the consumer's belief that everything coming from nature is safe or at least, safer than manufactured or processed food ingredients. This has led to a prominent trend in which more botanically derived functional and technological useful ingredients are added to food, often replacing their traditional and historically proven safe synthetic counterparts. For product developers and risk assessors, this trend presents many challenges. Although botanicals (and their extracts) often make the claim that they have been safely consumed in some form for many years, there is most often a general lack of robust safety and toxicological data to support such claims. As the first tier in a newly proposed decision tree approach for the risk analysis for botanicals, the literature (preferably published by a regulatory body (ESFA, FDA, EMA) is searched for the available safety data on the botanical and its primary constituents. Although additional data are becoming available on many botanicals, there is still a large data gap for most, in particular dealing with repeated exposure and vulnerable subpopulations (e.g., children, pregnant women, elderly). This lack of data drives on to a second tier in which the plant’s compounds are assessed individually. Important to consider in the second tier is the various extracts of the botanical. The essential oils containing flavors, scents and other functional chemicals are often concentrated in ethanolic extracts, which may contain up to 90 chemicals. These extracts are extremely complex and the chemicals in the extracts need to be identified and evaluated for their toxicity. Tools are constantly being developed that identify what often are called ‘compounds of concern’ or compounds with known biological activity. Additionally, harvesting methods and seasons, plant parts, and extraction methods all lead to different extracts which in turn may lead to different chemicals of concern. These tools together with better chemical characterization of the extract by suppliers should allow for more precise identification of these compounds. In the third step, these identified compounds undergo individual and specific risk assessment approaches (e.g. TTC).

### 1611 Occurrence of Selected Mycotoxins in Maize Destined for Human Consumption in South Africa

T. Ekowomadu. Northwest University Mafikeng, South Africa, Mafikeng, South Africa.

Contamination of foods by mycotoxins has been linked to various health and economic implications to both man and animals. This study was carried out to evaluate the occurrence of mycotoxins contaminating commercial and small scale maize grains and to evaluate potential health risks for consumers based on South African and international regulations. A total of 100 maize samples were randomly collected from commercial farmers and small-scale farmers across the North-west province of South Africa. Mycotoxin analysis was done using Immuno-affinity column (IAC), Thin Layer Chromatography (TLC), High Performance Liquid Chromatography (HPLC) and Enzyme Linked Immunosorbent Assay (ELISA). Results obtained revealed that Fumonisin B1 (FB1) was the most contaminant mycotoxin in the small-scale and commercial samples with incident rate of 100% and 98.6% respectively. Aflatoxins contamination in samples occurred at incidences of 26.7% in small-scale samples and 25.0% in commercial samples. The levels of AFs were varied between 0.080-9.34 µg/kg and 0.32-8.60 µg/kg in small scale and commercial samples respectively, though still within the EU acceptable limits of 10 µg/kg (Total aflatoxin). Furthermore, ochratoxin A (OTA) has a high incident rate of 97.8% and 93.0% and ranged from 3.60-19.44 µg/kg and 1.60-9.89 µg/kg respectively in small-scale and commercial maize samples while zearealenone (ZON) occurred in 50% and 55% of small-scale and commercial samples respectively. These results demonstrate that maize especially those from small-scale farmers may contribute to dietary exposure to mycotoxins. Farmers and consumers should be alerted to the dangers of mycotoxins contamination in maize with resultant health risks.

### 1612 Assessment of Aflatoxin B1-Induced Adverse Impacts on Nutritional Compositions of Gut-Microbial Metabolome in F344 Male Rats

J. Zhou, L. Tang, and J. Wang. University of Georgia, Athens, GA.

Gut-microbial metabolome, a collection of thousands of micronutrients and functional metabolites, was previously found to be severely affected by oral exposure to Aflatoxin B1 (AFB1) in F344 male rats. In this study, we assessed the changes of nutritional composition in this metabolome through HRLC-LTQ-Orbitrap Elite MS and GC-EI-Q MS based metabolomics analysis. The rats were orally exposed with AFB1 at doses of 0, 5, 25 and 75 µg AFB1/kg body weight (B.W.) for 5 weeks, and a total of 120 samplings were conducted for GC/MS based metabolomics analysis in the pooled feces samples collected in each dose group. There were 1490 features aligned from the dataset. Among the top 100 significant features, 61 metabolites were identified by searching NIST database, OPLS-DA and Random Forests together extracted 10 distinct metabolites, including D-lactic acid, 3-hydroxybutyric acid, erucic acid, cholesterol, 20α, 22R-dihydroxycholesterol, N-acetyl-L-alanine, α-trehalose, L-arabinose, galactitol, and turanose. The MS based metabolomics analysis was further conducted. Data was collected via the CID-MS/MS mode. Raw files were processed through both on-line XCMS and off-line MZmine modules. The two modules provided 2498 and 3925 MS1 features, respectively. A total of 86 metabolites were identified from the 140 remarkable features (adjusted-p < 0.05) by searching HMDB and METLIN databases with precursor ions or MS/MS spectra. In order to search for the correlated biochemical pathways and diseases, the integrated dataset was undergone enrichment analysis using KEGG and HMDB. We found that oral exposure to AFB1 in rats reduced total content of carbohydrates and amino acids, gut lactic acid bacteria, production of short chain fatty acids and related secondary aliphatic acids. AFB1-exposure also disrupted the production of amino acids and neurotransmitters e.g. melatonin and 5-HT, the absorption of food-contained long chain fatty acids, as well as bile acid secretion and metabolism. The correlated diseases included seizures, liver damage, diabetes, autism and multiple sclerosis, etc. The affected pathways mainly included glucose metabolism, glycolysis, metabolism of amino acids and neurotransmitters. These results provide us an insight into the impact of oral exposure to AFB1 on the nutritional composition of the gut-microbial metabolome, as well as the affected biochemical pathways and diseases.
### 1613 Evaluating the Applicability of Read-Across Tools and High-Throughput Screening Data for Food Relevant Chemicals

J. Wynder, J. Ovesen, A. Maier, R. Judson, N. Kleinstreuer, and M. Krishan.

Alternative toxicity methods to characterize the hazards of chemical substances have been proposed to reduce animal testing and efficiently screen thousands of chemicals. Relevant resources include large in vitro datasets from efforts such as the high-throughput screening (HTS) ToxCast/Tox21 programs and read-across tools such as the Organization for Economic and Cooperation Development (OECD) QSAR toolbox.

The goal of this work is to compare the results from traditional toxicity studies with predictions from these alternative testing methods for food relevant chemicals in ToxCast. Computational models developed using ToxCast HTS data were used to predict the activity of food relevant chemicals against the estrogen receptor (ER) and androgen receptor (AR) pathways. We identified 94 putatively estrogen- or androgen-active food relevant chemicals in ToxCast. To reduce possible confounding from cytotoxicity and cell stress, the ER and AR model results were filtered based on observed in vitro cytotoxicity, which resulted in 89 putatively active, non-cytotoxic food chemicals. As a proof of concept, we further shortlisted these 89 chemicals based on the availability of in vivo data related to developmental and reproductive toxicity (DART).

This resulted in 10 putatively active, non-cytotoxic, endocrine disrupting chemicals. Structural similarity and similar mode of action were used to identify potential analogues for the 10 chemicals. We used read-across approaches to compare the pattern and potency of DART for the analogues to that of the target chemical. These methods identified 3 target chemicals for which the analogue approach and computational models successfully predicted the DART potential of the food relevant chemicals. This study demonstrates that ToxCast/Tox21 HTS assay data can be used for prioritization along with weight of evidence from read-across tools to evaluate food relevant chemicals, although the limitations in the approaches are evident. This abstract does not necessarily reflect US EPA policy.

### 1614 Evidence on the Intake of Intense Sweeteners, Appetite Regulation, and Body Weight Development: A Scoping Review of Reviews

Observed associations between consumption of diet foods and prevalence of overweight have sparked controversy over whether intense sweeteners, despite contributing negligibly to energy intake, may promote weight gain. In this scoping review, we assessed reviews published from 2006 to May 2017 to obtain an overview of hypotheses, research approaches and features of the evidence on intense sweeteners’ potential relationships to appetite regulation and weight development. The 40 included reviews present hypotheses both on how intense sweeteners can reduce or maintain body weight and on how these can promote weight gain. We classified only five publications as systematic reviews; another nine presented some systematic procedures, while 26 reviews did not describe criteria for selecting or assessing the primary studies. Evidence was often presented for intense sweeteners as a group or unspecified, and against several comparators (i.e. sugar, water, placebo, intake levels) with limited discussion on the interpretation of different combinations. Apart from the observational studies, the presented primary evidence in humans is dominated by small studies with short follow up - considered insufficient to assess weight development. Systematic reviews of animal studies are lacking in this topic area. The systematic evidence only partly explore forward hypotheses. Primary studies seem to be available for systematic exploration of some hypotheses, but longer-term experimental studies in humans are sparse.

### 1615 Polyphenol Oxidase/Caffeic Acid Reduces the Allergenicity of Ovalbumin in a Balb/c Mouse Model

P. Tong, S. Chen, J. Wang, J. Gao, and H. Chen.

Food allergy has been recognized as a common public health problem and affects an estimated 6-8% of children and 2-5% of adults. Egg is one of the “top 8” most allergenic foods in children and infants, with an estimated annual incidence of 1.6-3.2%. To mitigate the allergic adverse effects and develop hypoallergenic food products are still a challenging task for the research field and food industry. In this study, we tried to modify the food allergen, ovalbumin (OVA), with caffeic acid-assisted cross-linking technique catalyzed by polyphenol oxidase (PPO). OVA is the most abundant egg white protein and is also a well-known food allergen. The modulation effects were evaluated in a Balb/c mouse model. 8 female mice per group were orally sensitized with OVA or cross-linked OVA using cholera toxin as adjuvant. Clinical signs of allergy, specific antibody levels, serum histamine levels, mast cell protease-1 (mMCP-1) concentrations, morphological structure of duodenum, and cytokines were further determined. Both OVA and cross-linked OVA induced allergic diarrhea in Balb/c mice, however, the histological symptoms of the small intestines were much milder in mice fed with cross-linked OVA than in those fed with OVA alone. A tendency toward decreased allergen-specific IgE, IgG, IgG1 and IgG2a levels, as well as serum histamine and mMCP-1 concentration were observed in cross-linked OVA group (p<0.05), accompanied by an inhibition of IL-4, IL-5, IL-13, and IFN-γ production in the stimulated splenocyte cell (p<0.001).

Results of this study demonstrate that caffeic acid-assisted PPO-catalyzed cross-linking technique was an effective method to significantly reduce the potential allergenicity of OVA, but may not completely eliminate it.

### 1617 An Occurrence of Aflatoxigenic Fungi and Aflatoxin Contamination in Raw Groundnut from Selected Markets in Obafemi Owode Local Government, Ogun State, Nigeria

T. A. Dada, M. Adetunji, N. Awa, O. Atanda, and M. Mwanza.

Groundnut is one of the most nutritious oil-seed used in Africa, and it is valued for its protein and oil content. This study aimed at investigating the microbiological quality and level of aflatoxin contamination in raw groundnut sold in Obafemi Owode local government. A total of 15 different composite groundnut samples were collected from five major markets in the zone; and the Moisture content, total microbial count, frequency ratio of isolates and aflatoxins level in the samples were determined using standard methods and ELISA method. The mean moisture content of the groundnut ranged from 5.10 - 7.21%, while Total Viable bacteria count ranged from 58-89 x10^3 cfu/g and Total Fungi Count ranged from 4 - 24 x10^3 cfu/g. The most frequent organisms isolated from the samples included Penicillium spp (87.5%), Aspergillus flavus (83.3%), Aspergillus niger (42.85%), Fusarium spp (12.5%) among others. The total aflatoxin concentration ranged from 29 ppb - 33.8 ppb. The aflatoxins level in all the samples were far higher than the recommended EU permissible limit of 4 ppb and the US FDA recommendation of 20 ppb. Groundnuts consumers at Obafemi Owode are at risk of exposure to aflatoxins especially the young and infant. Appropriate intervention by concerned agencies is recommended.
California Proposition 65 requires businesses to provide a warning if a product sold in California contains a carcinogen at levels that would result in exposures above its Safe Harbor Level (SHL) or No Significant Risk Level (NSRL). Furfuryl alcohol (FFA), a flavoring ingredient and by-product of thermal processing of foods, was added to the Proposition 65 list via the authoritative bodies mechanism after US EPA’s conclusion that FFA is likely to be carcinogenic to humans based on results from 2-year NTP inhalation bioassays in rats and mice. Like acrylamide, also on the list, FFA is formed in baked and roasted foods, including coffee. As OECDHA has not derived an SHL/NSRL for FFA, the current work was undertaken to (i) derive an NSRL and to (ii) determine if FFA in different types of coffee is likely to exceed the NSRL. Derivation of the NSRL was based on OECDHA methodology. Modelling of the incidence data from the rat for nasal tumors, using a linear dose-response model, yielded the most conservative (lowest) NSRL for FFA of 16 micrograms/day. From data from NHANES 2013-14 were used to identify the mean daily consumption of coffee products (brewed/fILTERED, specialty, and instant), which may contain up to 408 ppm (mg FFA/kg dry coffee). Based on this concentration estimate, FFA exposures from consumption of brewed/fILTERED coffees were up to 1,100,000 micrograms/day. FFA levels in specialty coffees and instant coffees, estimated at 2,300 and 1,600 micrograms/day, respectively. For exposures to be below the NSRL, the concentrations of FFA on a dry weight basis would need to be below approximately 0.57, 2.8, and 4.1 ppm for brewed, specialty, and instant coffees, respectively. While coffee products may require a warning for FFA, such products might already have the warning due to acrylamide content in which case one label could address both substances. As coffee is consumed in significant amounts and is known to contain amongst the highest amounts of FFA, other foods would need to be evaluated independently to determine whether a warning label is warranted under California Proposition 65 legislation. If such foods are consumed in lower amounts and have lower FFA concentrations than coffee, a warning might not be required.
Cyclodextrin is a unique compound produced by cyanobacteria, and it is increasingly perceived as a global water-quality issue growing in scope and persistence. It has hepatotoxic, general cytotoxicity, and neurotoxic effects, affecting plants, several aquatic organisms, and mammals with different degrees of damage. The present work studies the genotoxicity of pure CYN by the in vitro micronucleus (MN) assay (OCDE 487) in LS178T TE-21 cell line and the comet assay in Caco-2 cells, including in this case also the study of the indirect oxidative damage of DNA using restriction enzymes. The results obtained showed that the potential genotoxicity of the cyanotoxin could be related with CYN metabolites. The cyanobacterial toxin cylindrospermopsin (CYN) is recognized as one of the most globally important of the freshwater algal toxins due to the expanding distribution of CYN producers into different regions, representing serious human and environmental health risks across many countries. Its ability for bioaccumulation in tissues of different organisms intended for human consumption may have implications in food safety. In this sense, edible tissues of plants and vegetables could represent a possible route of human intoxication if they are irrigated or in direct contact with CYN-contaminated waters. A method for determination of CYN, ergoalkaloid (EA)-producing endophyte that results in numerous the first time. The procedure is based on solid phase extraction with graphitized carbon cartridges, and quantification by Ultra-performance liquid chromatography tandem mass spectrometry (UPLC-MS/MS). The method exhibits good linearity (r² = 0.9999) with linear range from 5-500 ng CYN/g fresh weight (f.w.), and sensitivity, with limits of detection and quantification of 0.22 and 0.42 ng CYN/g f.w., respectively. Mean recoveries ranged 85-104% and intermediate precision values from 12.7 to 14.7 %, acceptable according to the tabulated values. The validated method demonstrated to be robust for three different variables tested. Moreover, it has been successfully applied for the extraction and quan-
tification of CYN in real vegetables samples such as lettuce and spinach, previously exposed to 10 and 50 µg CYN/L in the laboratory. Results reveal that CYN uptake in both lettuce and spinach leaves was greater when the exposure concentration was lower. This work emphasizes the need to develop validated methods to monitor the occurrence of CYN in crop products irrigated with waters affected by cyanobacterial blooms. This method will improve the real human exposure evaluation required in risk assessment. Acknowledgments: Ministerio de Economía y Competitividad of Spain (AGL2015-64558-R, MINECO/FEDER, UE) for financial support. Leticia Díez-Quijada also acknowledges for the grant BES-2016-07873 associated with this project (MINECO/FEDER).

Toxic Endophyte-infected Tall-Fescue Dysregulates the Fecal Microbiota of Grazing Beef

R. S. Mote1, G. Suen2, N. S. Hill3, Z. B. Turner1, Z. P. Sanders1, D. P. Jones3, J. H. Skarlupka3, and N. M. Filipov1. 1Emory University, Athens, GA; 2University of Wisconsin, Madison, WI; and 3Emary University, Atlanta, GA.

Microbiome homeostasis and dyshomeostasis are understudied in food-producing animals, such as beef cattle, especially under condi-
tions of various environmental stressors. Tall fescue, the predominant southeastern United States forage grass, can become infected with a toxic, ergoalkaloid (EA)-producing endophyte that results in numerous physiological deterrents, ultimately decreasing weight gains. This eco-
nomically costly condition is known as fescue toxicosis (FT). The impact of toxic fescue on grazing beef microbiota (MB) and the role it might play in FT etiology, has yet to be investigated. So, we used 16S rRNA sequencing and a metatranscriptome from Angus steer grazing toxic (E+; n = 6) or non-toxic (Max-Q; n = 6) tall fescue over a 28 day grazing trial. Firmicutes and Bacteroidetes phyla comprised 90% of both Max-Q and E+ steer MB. Significant early decreases of Erysipelotrichaceae and delayed increases of Ruminococcaceae and Lachnospiraceae families were the main effects of E+ grazing. The genera Oscillibacter increased after 14 days of E+ grazing. Many operational taxonomic units within the Ruminococcaceae and Lachnospiraceae families negatively correlated with weight gains (decreased by E+) and positively correlated with respiration rates (increased by E+). Thus, E+ grazing induces MB dysbiosis in a way that could contribute to the altered lipid metabolism and enteric nervous and immune system dysfunction associated with FT. Moreover, E+ grazing-induced MB shifts could influence MB metabolism, potentially modulating FT-related feeding behaviors through enteroendocrine activities. Detection of decreased Prevotellaceae and increased Clostridiaceae likely reflect MB selection pressure from degra-
diation of EA and other plant/endophyte-derived metabolites. Overall, our data characterize the grazing Angus steer fecal MB and indicate that E+ grazing results in MB shifts that either associate with, or, contribute to, FT pathophysiology. Support: USDA, NIFA, Grant Number 67030-25004.

Cherry Intake Potential to Improve Intestinal Health

C. A. Hobbs1, M. Koyanagi2, C. Swartz1, J. Davis1, S. Kasamoto1, R. Maronpot2, L. Recio1, and S. Hayashi2. 1Integrated Laboratory Systems, Research Triangle Park, NC; 2San-Ei Gen F.F.I., Inc., Osaka, Japan; 3Public Interest Incorporated Foundation Biosafety Research Center, Shizuoka, Japan; and 4Maronpot Consulting LLC, Raleigh, NC.

Quercetin and its glycosides have been shown to possess potential ben-
efits to human health. Several flavonoids are available to consumers as dietary supplements, promoted as anti-oxidants; however, incorporation of natural quercetin glycosides into food and beverage products has been limited by poor miscibility in water. Enzymatic conjugation of multiple glucose moieties to isoorientin to produce alpha-gly-
cosyl isoorientin (AGIQ) has been shown to enhance solubility and bioavailability. AGIQ is used in Japan as a food additive and has been granted generally recognized as safe (GRAS) status. However, although substantial genotoxicity data exist for quercetin, there is very little avail-
able data for AGIQ and isoorientin. To support expanded global mar-
eting of food products containing AGIQ, comprehensive good labora-
tory practice-compliant testing of the genotoxic potential of AGIQ and isoorientin was conducted in accordance with current regulatory test guidelines. Both chemicals tested positive in reverse mutation assays in several bacterial strains with and without metabolic activation, and 4-hour, but not 24-hour, exposure to isoorientin resulted in chromo-
osomal aberrations in CHO-WBL cells in the presence and absence of metabolic activation. All other in vitro mammalian micronucleus and chromosomal aberration assays, micronucleus and comet assays in male and female B6C3F1 mice and female Sprague Dawley rats, and mutation assays evaluating multiple potential target tissues in transgenic mice (Muta™ mouse) were negative for both chemical. These results supplement existing toxicity data to further support the safe use of AGIQ in food and beverage products.
An OECD 408 dietary 90-day toxicity study was conducted on test material (10-undecenal, a widely used flavor and fragrance ingredient). Sprague Dawley rats (10 rats/sex/dose) were fed diets containing 0, 200, 2000, 6000 or 20000 ppm (equivalent to a mean achieved dosage of 0.143, 138.6, 382.3 and 1135.9 mg/kg/day, respectively) of 10-undecenal for 90 days. Estrous cycling, sperm analyses and reproductive organs were also evaluated. A dose-related reduction in body weights was observed among males of the 2000, 6000 and 20000 ppm dose groups and females of the 6000 and 20000 ppm dose groups. Body weight gains were significantly decreased among high dose males throughout the study and among 6000 ppm males and 20000 ppm females only during the first few weeks of the study. Overall food consumption was reduced in animals of both sex treated at 2000, 6000 and 20000 ppm. Food efficiency was also reduced among the high dose group animals during the first week of the study. Centrilobular hepatocellular hyper trophy was reported in males of the 2000, 6000 or 20000 ppm dose groups during microscopic examination, which did not exceed minimal severity limits. There were no corresponding degenerative or inflammatory changes observed, and was therefore considered to be an adaptive response. Microscopic examinations revealed epithelial acanthosis of the limiting ridge of the stomach among males and females of the 2000 and 20000 ppm dose groups and also in females of the 6000 ppm dose group. This finding was considered to be indicative of a local irritation potential associated with the route of administration, and not related to the systemic toxicity of 10-undecenal. Thus, the NOAEL for systemic toxicity was considered to be 2000 ppm or 138.6 mg/kg/day, based on reductions in food consumption and body weights among the higher dose groups. There were no treatment-related effects on the reproductive organs up to the highest dose tested. Thus, the NOAEL for reproductive toxicity was considered to be 20000 ppm or 1135.9 mg/kg/day, the highest dose tested.

The introduction of GM plants modified for nutritional purposes into the food supply requires a comprehensive evaluation of the potential influence of GM food on nutrient intake. Codex guidelines have been established which state that this assessment should be undertaken by simulating the replacement of consumption of the unmodified food (“conventional counterpart”) with the modified food. If the nutrient profile is modified such that it is more comparable to another food, Codex indicates this is also appropriate to conduct an assessment for that food (“appropriate comparator”). However, the guidelines are general and accommodating to different methodological approaches. We therefore set out to develop a decision matrix that incorporates key methodological considerations related to such a nutrient intake assessment. The dietary assessment at intake is baseline and after substitution of foods from the original plant, and requires two basic inputs: food consumption data and the concentration of the nutrient(s) of interest in the original and GM food. In terms of the former, a food consumption database which allows a comprehensive assessment, and manipulation of intake is essential. Intakes should be examined in the context of the total diet for the entire population, while also taking consideration of potentially vulnerable population groups, and individuals with extremes of intake. The selection of the nutrient(s) to be examined may consider factors such as compositional differences between the original and modified food(s), nutrient intake recommendations, and the availability of reliable nutrient data. Sources of concentration data include standard recipes, market and supply data, and technological considerations. These data are also used to determine whether the assessment should be conducted only for the conventional counterpart, or also for the appropriate comparator. Finally, the extent of the replacement must be decided; in the first instance, it may be appropriate to assume a 100% replacement, however, this may be refined to consider more realistic scenarios considering production volume and market share data. This decision matrix serves to assist in identifying the specific information to be incorporated into a GM nutrient assessment using considerations that are unique to each situation and dependent on the nature of the modification.

Ready to eat manufactured baby foods, are natural puree that contain more than one food, usually a mixed fruits, veggies and grains. Due to their physico-chemical characteristics, these components are able to be contaminated by fungi such as Alternaria, Fusarium, Penicillium, and Aspergillus in turn lead to the occurrence in these foods of mycotoxins that are secondary metabolites produced by fungi, presenting varied chemical structures that have the common characteristic of toxicity against humans and animals. The Rapid Alert System for Food and Feed of the European Union reports mycotoxins on the third positions according to the total number of hazard notifications (RASFF, 2015). The objective of the study was to evaluate the presence of 15 mycotoxins (DON, 2AcDON, 15-AcDON, NEO, DAS, NIV, ZON, α-ZOL, β-ZOL, α-ZAL, β-ZAL, FUS X, T2, HT2 and PAT) in ready-to-eat baby foods samples (n=80) by QuEChERS extraction and determination gas chromatography-tandem mass spectrometry determination (GC-MS/MS).

The methods accuracy was evaluated by recovery assays at four concentration levels, and precision, expressed as the intra- and inter-day relative standard deviations (RSD%) were calculated. Good validation results in terms of recoveries (63-117%), reproducibility (RSDs <15%) and repeatability (RSDs<20%) were reached. Moreover, limits of detection (0.5-2.5µg/kg) and quantitation (1-10µg/kg) achieved were lower than the legislated limits. Matrix effect was evaluated and matrix-matched calibrations were used for quantitation. Results showed presence of at least one mycotoxin in 21% of analyzed samples. The mean contamination level of NIV, DON, HT2 and PAT were 2.5, 3.75, 6.2 and 15 µg/kg respectively. The obtained results indicated that mycotoxins are present in different baby food samples which point out the need to perform continuous surveys to insure babies’ health. The dietary exposure of the child population was estimated using the deterministic approach, through the evaluation of the consumption and data of ready-to-eat baby foods mycotoxin contamination to assess the estimated daily intake (EDI) and values obtained resulted below the tolerable daily intake for the selected mycotoxins. Acknowledgements: The Spanish Ministry of Economy and Competitiveness (AGL2016-77610-R) and Government Scholarship program Carlos Antonio López, Paraguay.

**1634a** A Survey of Mycotoxins in Infant/Toddler Foods and Breakfast Cereals in the US Retail Market

B. Flannery, K. Zhang, C. Oles, and A. Adeuya. US FDA, College Park, MD.

Mycotoxins are ubiquitous secondary metabolites produced by fungi, and they are commonly found in foods. Mycotoxin consumption is associated with adverse human and animal health outcomes making it important to understand their concentration and distribution among food. The goal of this study was to conduct a mycotoxin survey of commercial infant/toddler cereals and teething biscuits, as well as breakfast cereals in the United States. We collected 215 retail samples from 3 geographic locations and used stable isotope dilution liquid chromatography tandem mass spectrometry to analyze aflatoxins, fumonisins, deoxynivalenol, HT-2 toxin, ochratoxin A, T-2 toxin and zearalenone. Results showed the concentrations of detected mycotoxins were below the FDA action and guidance levels. One or more mycotoxins were found in 69% (101/147) of the infant/toddler foods and 50% (34/68) of breakfast cereals with deoxynivalenol being the most frequently detected. Mycotoxin co-occurrence was observed in 12% of infant/toddler foods and 32% of breakfast cereals with co-occurrence most often occurring in oat-based cereals. Rice-based cereals contained mycotoxins less frequently than other cereal types. Taken together, mycotoxins were frequently detected among food samples; however, concentrations were low.

**1634b** A Limited Survey of Corn Meal and Alkaline Cooked Products for Aflatoxin-Fumonisin Co-Contamination in the Southeastern US, 2015-2016

K. Xue, A. Showker, T. Mitchell, R. Riley, and K. Voss. University of Georgia, Athens, GA; and United States Department of Agriculture, Athens, GA.

Aflatoxins are mycotoxins found in corn. They exert adverse health effects in humans including liver cancer and stunted growth in young children. Fumonisins (FB) are also common mycotoxin contaminants of corn and their co-occurrence with aflatoxins has been reported. FB cause species-specific toxicities in animals, however their human health effects are until uncertain. Experimental and epidemiological evidence nonetheless suggests that FB are a risk factor for growth inhibition in children, birth (neural tube) defects, and cancer if contaminated corn is consumed in large amounts on a regular basis. Aflatoxins and FB exert their toxic and carcinogenic effects in animals through different but complementary mechanisms and co-exposure is a growing concern for human health. Corn-based food products acquired from local markets in the southeastern US were surveyed in 2015 (Survey 1) and 2016 (Survey 2) to determine the extent of co-contamination. Survey 1 included 18 alkaline cooked (nixtamalized) corn flours and 23 corn meal samples. Survey 2 included the alkaline cooked products (n=7) and grits (n=10). Aflatoxin B1 (13.4 µg/kg) was found in only one sample, an alkaline cooked corn flour from Survey 1. In contrast, FB were found in all samples surveyed. Mean total FB (FB1-24) concentrations in Survey 1 alkaline cooked corn flours and corn meals were 0.72 (±0.62 SD) mg/kg and 0.18 (±0.07 mg/kg, respectively. Total FB in Survey 2 averaged 0.23 (±0.30) mg/kg in grits and 0.43 (±0.32) mg/kg in polenta. The results of this limited survey indicate that aflatoxin-FB co-contamination of corn products purchased in the southeastern US during 2015-2016 was uncommon.

**1634c** Considerations for a Noni Juice Standard: Scopoletin Concentration

Morinda citrifolia L. (noni) fruit has been used as a food or traditional medicine in Polynesia for over 2000 years. In many parts of the world, noni juice is available as a dietary supplement or “functional food”. The FAO/WHO Coordinating Committee for North America and the Southwest Pacific is considering development of a regional commodity standard for fermented noni juice that would define essential composition and quality factors. Noni juice preparations contain varying levels of phytochemical constituents, including scopoletin (a coumarin derivative), due to variations in growth or post-growth processes. Coumarin and its derivatives are known anticlotgulants and may increase risk of bleeding in humans. A literature search was conducted to identify information about exposure, toxicity and pharmacokinetics of scopoletin to inform a specification for scopoletin in noni juice. Clinical study and adverse event information about noni juice were also examined for evidence of adverse effects related to scopoletin. Adverse effects noted in animals treated orally with scopoletin include toxicity to the brain and prolonged bleeding time. Although some people have experienced adverse events after consuming noni juice, none can be directly attributed to scopoletin exposure. A no observable adverse effect level (NOAEL) for scopoletin could not be identified from available literature. More research is needed to establish the hazard potential of scopoletin in noni juice. A 13-week, guideline, three dose toxicity study of scopoletin in rats (which includes a behavioral toxicity battery) should be conducted (at a minimum) to more fully investigate the potential for scopoletin to cause toxicity. An updated survey of scopoletin concentrations in noni juice would help inform estimated exposure levels. Studies also need to be performed to: a) identify growth and post-growth conditions which result in low concentrations of scopoletin in noni juice, and b) determine whether scopoletin peroxidase (or some other enzyme) can be employed to selectively reduce concentrations of scopoletin in noni juice.

**1634d** Scientific Analysis of Adverse Effects Associated with Kava

K. Middleton, and D. Smegal. US FDA, College Park, MD.

Kava, derived from the roots of the plant Piper methysticum, has been traditionally used for centuries in the Pacific Islands as a recreational and ceremonial drink. It has become increasingly popular in other regions and can be found as beverages or dietary supplements marketed for relaxation and stress relief. We conducted a scientific analysis of adverse health effects associated with consumption of kava and its...
components. Kava use has been associated with adverse effects, most notably hepatotoxicity, which has been attributed to the kava cultivar, use of certain plant parts, kava constituents, extraction method, and contaminants. Considering literature highlighting the liver as a target organ for kava, we examined FDA’s CSFAN Adverse Event Reporting System (CAERS) for adverse events related to kava and kava containing products (2004-2017). CAERS identified more than 30 reported cases of adverse events from kava exposure. Of the cases reported, roughly half were associated with adverse events involving the liver. Adverse events were confounded due to poor reporting, concomitant use of other substances, and preexisting conditions. Therefore, it is difficult to determine if contamination of the reported products is directly associated with adverse liver effects. FDA will continue to monitor the literature for kava, as well as adverse events from kava exposure. In addition, we continue to provide scientific support to the development of the Codex Alimentarius Commission’s proposed regional standard for kava.

1636 The Air Pollutant Watch List as a Tool to Decrease Hazardous Air Pollutants in Texas

J. Myers, Texas Commission on Environmental Quality, Austin, TX.

The Texas Commission on Environmental Quality (TCEQ) uses air permitting, air monitoring, and the air pollutant watch list (APWL) to address areas in Texas where air monitoring data show persistent, elevated concentrations of air toxics. The APWL program allows the agency to focus its resources, notify the public, engage stakeholders, and develop strategies to reduce emissions in areas that show persistently elevated levels of toxic products. The APWL program includes a list of chemicals targeted for regulation, a list of thresholds and concentrations at which the agency will take action, and a list of areas where the concentration of a listed chemical is too high to be acceptable. The agency collects on a regular basis.

1637 Cytotoxic Flavor Chemicals in Top-Selling Electronic Cigarette Refill Fluids

E. Omaiyi1, M. Hua2, W. Luo2, K. McWhirter2, J. F. Pankow2, and P. Talbot1. 1 University of California Riverside, Riverside, CA; and 2 Portland State University, Portland, OR.

Thousands of electronic cigarettes (EC) refill fluids are sold worldwide with little understanding of their toxicology. Our purpose was to identify the top-selling EC refill fluids, quantify the presence of these products, evaluate their cytotoxicity, and identify flavor chemicals that contribute to cytotoxicity. EC users’ flavor preferences and top-selling products were evaluated in an Internet survey, by contacting local EC shops in Southern California, and by visiting online EC stores. Regulatory EC refill fluids were purchased from local shops, their flavor chemicals were identified and quantified by gas chromatography-mass spectrometry, and their cytotoxicity was evaluated using the MTT assay. Authentic standards of flavor chemicals present in the highest concentrations were screened to identify those that were the most cytotoxic.

1638 Using Systematic Review to Support the “Regulatory Intelligence” Strategy in Industry

X. Yang, and M. Mueller. Nalco Water, Naperville, IL.

The rising role of systematic review on chemical risk assessment has been reshaping regulatory decisions to provide stakeholders with more precise and certain regulatory decisions. Industry continues to use systematic review methodology in risk assessment and be proactive in the agency’s decision making processes.

1639 Reduce Animal Testing for Acute Toxicity in US EPA Pesticide Programs

J. Tao, T. Keigwin, and A. Lowit. US EPA, Washington, DC.

Historically, pesticide regulations rely heavily on mammalian toxicity data derived from animal testing. US EPA’s Office of Pesticide Programs (OPP) is evaluating and adopting alternative approaches to more traditional methods of toxicity testing. OPP generally receives 200-300 6-packs per year and has set goals around significantly reducing the use of animals in acute toxicity “6-pack” studies. The current oral, acute dermal, and acute inhalation toxicity, primary eye and skin irritation, and skin sensitization. In this presentation, we are reporting on the number of alternative studies submitted to OPP for pesticide product registrations from 2010 to 2017. The Agency encourages the Up-and-Down (UAD) method for acute oral toxicity and the Local Lymph Node Assay (LLNA) for skin sensitization. As a result, the UAD method is pre-
dominate among acute oral toxicity studies submitted. The LLNA has become a preferred study over the traditional Buehler Test. The Agency has received a large number of the UADL and LLNA studies in recent years. Additionally, under the Agency’s initiative to develop non-animal alternatives for acute toxicity testing, OPP has developed the guidance document, *Updated Guidance for Testing Antimicrobial Cleaning Products (ADCPs) for Their Potential to Cause Eye Irritation*, which accepts Bovine Corneal Opacity and Permeability assay (BCOP), EpiOcular assay (EO), and Cytosensor Microphysiometer (CM) assay eye irritation testing for registration of ADCPs. We have received a limited number of in vitro alternative studies for eye irritation under this guidance but the number of submissions is slowly increasing. In 2016, OPP finalized the *Guidance for Waiving Acute Dermal Toxicity Tests for Pesticide Formulations & Supporting Retrospective Analysis*. We are beginning to see waivers submitted under this guidance.

### 1640 Evidence Supporting a Quantitative Dermal Sensitization Assessment for Methylisothiazolinone

Under 40 CFR 152.25(a), a treated article is defined as “an article or substance treated with, or containing, a pesticide to protect the article or substance itself.” Pesticides may be registered for such use, but do not bear a pesticide label or effectively use other communication methods to inform and protect people against potential hazards. Dermal sensitization is a potential hazard from exposure to treated articles. In an effort to better assess risk from such exposures, the agency has been evaluating approaches to quantitative assessment of dermal sensitization. Methylisothiazolinone (MI) is presented as a case study for quantitative assessment, since robust data from multiple lines of evidence exist. Specifically, MI is shown to be a positive dermal sensitizer in laboratory animal tests (guinea pig and local lymph node assays), from studies in human volunteers (repeat open application tests) and recently, from results of in silico assays with MI (Direct Peptide Reactivity Activation assay (DPPRA), KeratinoSens, and Human Cell Line Activation Test (h-CLAT)). Each line of evidence has strengths and uncertainties for a quantitative approach. Guinea pig assays can identify positive sensitizers but do not provide potency or dose-response information. The local lymph node assay can identify potency of a sensitizer for induction but does not provide information on elicitation thresholds. Human tests can characterize dose-response relationships for induction and elicitation and identify thresholds, but do not have large study populations and can show wide individual variation in concentrations that elicit sensitization responses. In vitro/in silico assays for identification of dermal sensitizers address animal welfare concerns and can provide information on sensitization potency as well as information on induction thresholds, but need further development for characterization of dose-response relationships and/or identification of quantitative thresholds for induction and elicitation. This abstract does not represent official US EPA policy.

### 1641 A Harmonized Global Paradigm for Crop Protection Chemical Assessment

**T. L. Serek1, J. Mehta2, and D. C. Wolf3. DuPont Haskell Laboratory, Newark, DE; 2Dow AgroSciences, Abingdon, United Kingdom; and 3Syngenta Crop Protection, Greensboro, NC.**

The collective vision and realization of Exposure-Driven Assessment of Crop Protection Chemicals requires a paradigm shift in support of globally harmonized, risk assessment-based regulatory decision-making. This requires the application of best available science, via integration of new and traditional data streams, to create tailored exposure-driven risk assessments. The International Conference of Harmonization (ICH) for pharmaceuticals can be used as a starting point for this approach. Risk assessment should be the basic operating principle for all decision-making and is essential to scientifically-defensible chemical product stewardship. To be successful this new Crop Protection Road Map for Regulatory Outcome Pathway requires appropriate communication between the regulatory community and the regulated industry. This communication is critical to enable the rapid incorporation of new technologies and advancing science. The outcome would increase the speed, efficiency and accuracy of regulatory decision-making for human health and environmental protection. Global participation and utilization are necessary in order to reap the benefits of smarter, “fit-for-concern”, integrated, and tiered testing strategies. This approach has been successful for drug development and can be successful for the development of innovative solutions for crop protection.

### 1642 Improving Scientific Peer Review by Expert Panels: Case Study of a Large, Two-Tiered Peer Review

**S. Hays, and C. R. Kirman. SciPinion, Bozeman, MT.**

A large, two-tiered peer review was conducted to assess the quality of the safety data collected for a consumer product as part of Tier 1. 5 peer review panels were convened to review various components of the data package, which consisted of 15 publications/reports covering 9 studies, with access to all underlying raw data (including histopathology slides). Tier 1 included efforts from 50 scientists from all over the world, with more than 950 combined years of experience across multiple disciplines. The Tier 1 peer reviews were robust and included a large amount of material to be reviewed by each Tier 1 panel, with unprecedented access to underlying raw data via links to an external web portal. As part of Tier 2, duplicate expert panels were convened to review the results obtained from the Tier 1 panels. Tier 2 involved 17 scientists with greater than 610 combined years in risk/safety assessment. The Tier 2 panels were intended as oversight panels, given optional access to Tier 1 data packages, for the purpose of address over-arching product safety issues. The data collected from this large peer review yielded a robust data set for additional analyses. With respect to reproducibility, the responses from the Tier 2 panels indicate that the results are highly reproducible, with similar metrics for means for codified responses (1.08 vs. 1.02) and consensus metrics (0.73 vs 0.74). With respect to employment sector bias no statistically significant differences (p>0.05) were found across employment sectors (academia, former government, industry) for science questions. Additional findings with respect to the identification of outlier reviewers, and the roles of anonymity, independence, and compensation are discussed.

### 1643 Important Differences between Summary Values Used in Scientific Studies and the Design Value of National Ambient Air Quality Standards

**S. S. Lange. Texas Commission on Environmental Quality, Austin, TX.**

Ozone and particulate matter less than 2.5 µm (PM$_{2.5}$) are 2 of the air pollutants regulated in the US Environmental Protection Agency (EPA) National Ambient Air Quality Standards (NAAQS) program. While there is a lot of focus on the level (concentration) for a NAAQS pollutant, several other factors are also crucial for setting a NAAQS, including the indicator, form, and averaging time of the pollutant, and using the highest monitor in an area. The purpose of this work was to determine how ozone or PM$_{2.5}$ summary metrics used in key epidemiology studies compare to the regulatory design value. Studies used for quantitative risk assessment in the 2015 ozone NAAQS review were evaluated. Whereas the ozone NAAQS is set at 70 ppb for the annual 4th highest 8-hour maximum daily average, averaged over three years at the highest monitor in an area, many alternative metrics were used in these studies. Most common were 1-hr maximum or 24-hr average concentrations; multi-day averages from 2 - 30 days; no consideration of the form; and averaging across all monitors in an area. Like the findings with ozone, while there is both a 12 µg/m$^3$ annual average (averaged over 3 years at the highest monitor in an area) and a 24-hour 35 µg/m$^3$ (99th percentile, averaged over 3 years at the highest monitor in an area) PM$_{2.5}$ NAAQS, many metrics have been used in epidemiology studies. Differences included the indicator itself: imputing PM$_{2.5}$ data from PM$_{10}$ data, light scattering data, clearing index, or airport visibility data; or using PM$_{10}$ or PM$_{2.5}$ data as a direct substitute for PM$_{2.5}$. Other discrepancies include using multi-day averages of 2 to 8 days; no consideration of the 24-hour form; and averaging across all monitors in an area. Therefore, many of the concentration metrics used in epidemiology studies cannot be used to directly inform regulatory metrics, and in some cases are not good representations of concentration changes over time. These summary metrics must be reconciled to the regulatory design value before any judgments are made as to the protectiveness of current and alternative NAAQS.
China has recently joined the International Conference on Harmonization (ICH) which has its set of guidelines (“Safety-ICH S” and “Multidisciplinary-ICH M”) covering nonclinical development of new drugs which are accepted by the US FDA, EMA and Japanese regulatory agencies. Chinese regulatory agency (China Food and Drug Administration, CFDA), until currently, still follows its own guidelines. These guidelines are generally similar to those of ICH but some differences exist in testing requirements. In addition, CFDA just issued a new version of GLP on Sept 2017 which is in many ways similar to international standards while some specific details need further clarifications. A drug developer needs to be aware of these different specific requirements to avoid a delay or rejection (i.e., “clinical hold”) following regulatory submission to initiate clinical trials in China. This poster will highlight similarities and differences between nonclinical requirements for both small (chemically synthetized) and biopharmaceutical molecules in terms of high level requirements and detailed study designs. Some special compounds like antibody-drug conjugate (ADC) and bio-similar drugs are good representatives of these differences and compared in this poster. Setting up a winning drug development strategy and selecting a competent lab to conduct the nonclinical studies should be considered at the initial stage to assure successful and cost-effective drug development process to win the regulatory approvals globally.

The Preclinical Innovation and Patient Safety Initiative: Recommendations for Advancing Preclinical Pharmaceutical Testing

E. Baker, Physicians Committee for Responsible Medicine, Washington, DC.

Preclinical drug testing is critical to understanding the toxicity, pharmacology and pharmacokinetics of candidate drugs. The Preclinical Innovation and Patient Safety (PIPS) Initiative fosters collaboration among drug development stakeholders - including federal agencies, patient, research and health organizations, academia, technology companies and the pharmaceutical industry - to implement modern human-focused preclinical approaches. Participants recognize that more predictive approaches are fundamental to the timelier delivery of safe and effective medicines. This presentation highlights the scientific, regulatory, policy, training and educational recommendations made by a group of stakeholders during the kick-off roundtable in January 2017, and explores three projects identified by PIPS participants as likely to provide high impact on the field of toxicology. First, modern approaches to validation should incorporate human data. This is the only way to overcome the challenge of comparing human in vitro approaches to currently available animal safety data. The legislation 21st Century Cures and the Prescription Drug User Fee Act mandate that FDA make real world human data/evidence more accessible. PIPS identified that implementation of the mandates should include making real world evidence available to method developers for validation purposes in order to better understand a method’s predictive ability. Second, researchers must have access to human cells and high-quality tissues in order to use human-focused approaches. Currently, there are no guidelines for collection and care of human cells and tissues intended to be used for research. PIPS is coordinating efforts to develop guidelines to ensure the collection and care of human cells and tissues intended to be used for human-focused approaches. Currently, there are no guidelines for the overall hazard characterization. This can facilitate characterization of biological events between MIE and effects at the cell, organ and organism level obtained from traditional ecological toxicity tests (i.e., apical effects), and enhances characterization of hazard. An example using two thiocarbamate substances (CAS RN 137-76-8 and CAS RN 120-54-7) illustrates how this approach is being used, and the potency differences within the thiocarbamate ecological hazard profiles attributable to toxicokinetics and hypothesized covalent interactions.

Cyanobacteria: Understanding the Toxicology to Communicate Risks and Support Decision Making

R. Chung, A. Leung, and R. Copes, Public Health Ontario, Toronto, ON, Canada.

Cyanobacterial blooms in recreational waters are often considered a concern for swimmers due to the potential for skin rash and gastrointestinal illness. In the summer of 2016, a conservation authority in Ontario reported a cyanobacterial bloom in a local lake. The conservation authority also reported a total microcystins concentration in exceedance of the Canadian Recreational Water Guideline of 20 µg/L.
expressed as microcystin-LR). In response, the local health unit applied the precautionary principle and posted a ‘do not enter’ warning to lake users until more samples could be taken. However, due to the number of water bodies in the area that required monitoring, a follow up visual inspection and water sample could not be taken in a short turnaround time. As a result, the health unit had to balance adequately communicating risks to public users of the lake while minimizing the decision of when to retract the warning. This common response to cyanobacterial blooms poses a challenge to public health management of recreational water activity. To assist public health’s interpretation of results and risk communication, Public Health Ontario (PHO) is undertaking a jurisdictional scan of cyanobacterial guidelines and standards. The jurisdictional scan will compare the derivations of recreational water guidelines and standards between jurisdictions to determine the interpretation and application of cyanobacterial toxicity data. Specifically, the consideration of cyanobacterial toxins such as microcystins, anatoxins, and saxitoxins and the derivation of guidelines and standards may provide public health with a better understanding of the risks posed by cyanobacterial blooms. The overall objective of this comparison is to provide an interpretation of toxicity data to inform public health action in the management of recreational waters.

1649 Margin of Exposure Approach for Interpreting Concentrations of Perfluoroalkylated Substances in Drinking Water
T. Lalvani, R. Chung, and R. Copes. Public Health Ontario, Toronto, ON, Canada.

Perfluoroalkylated substances (PFAS) were used historically in firefighting foam in Canada. While import and production of PFAS in North America has now ceased, existing stocks are still in use and international manufacturing has increased. For most Canadians, exposure to PFAS occurs largely through diet and consumer products, followed by indoor dust, and drinking water. PFAS were detected in surface water and groundwater of a Northern Ontario community, where these compounds were used during firefighting training and testing of firefighting equipment. Specifically, perfluorooctane sulfonate (PFOS) and perfluorooctanoic acid (PFOA) were identified in private drinking water wells in the community, as well as the source water for the municipal system. Communicating how risks from chemical exposures is challenging, and may be further complicated when there is emerging scientific evidence. Currently, there are no established Canadian drinking water guidelines or standards for PFOS and PFOA. Health Canada has proposed drinking water guidelines for PFOS and PFOA that differ from other jurisdictions. Without an established drinking water guideline or standard, a margin of exposure (MOE) approach was undertaken to interpret concentrations of PFOS and PFOA. The MOE for a given health effect describes how close human levels of exposure are to the lowest level reported in animals for a particular health effect. It differs from a hazard quotient assessment used in setting drinking water and other standards by regulators where the hazard quotient compares a toxicological reference value (TRV) with an estimated intake. This work showcases an example of how the MOE was used to manage risk communication without selecting a particular drinking water guideline or TRV. The use of the MOE approach allowed public health officials to communicate a relative indication of health concern about the concentrations of PFAS found in the drinking water to the community. This approach also ensures that the ongoing regulatory process for establishing a drinking water guideline or standard is not overstepped, and that public health’s management of risks remains relevant even after the regulatory framework for deriving a drinking water guideline or standard has been finalized.

In June 2016 Congress passed the Frank R. Launtenberg Chemical Safety for the 21st Century Act (or the Lautenberg Act). This action amended the Toxic Substances Control Act (TSCA), which over forty years ago gave the U.S. Environmental Protection Agency (EPA) the authority to restrict the manufacture, release, use, import, and disposal of chemical substances. Among the changes included in the amendment is an express mandate that the EPA consider “potentially exposed or susceptible subpopulations” such as infants, children, pregnant women, workers, or the elderly when conducting a risk evaluation of chemical substances under TSCA. Although the susceptible subpopulation language included in several of the updated sections is new to TSCA, EPA has experience in identifying and assessing the possibility of increased risk posed by chemicals to the most susceptible groups among the public, particularly children. Amended TSCA provides an opportunity to advance this experience in the use of susceptibility concepts during the risk evaluation process. Initial steps in the effort to implement the consideration of susceptible groups under the Lautenberg Act have been undertaken. More than 20 current EPA policy and guidance documents that include discussion of susceptibility were compiled and reviewed with regard to their usefulness and potential impact under amended TSCA. This effort has resulted in the definition and scope of susceptible subpopulations found in these documents includes a wide range of considerations, with substantial information focusing on concerns for pregnant women, infants and children. Based on this review of current policy and guidance, case studies focusing on children identified were identified in an effort to illustrate how some of these key concepts may be applied to the risk evaluation process under amended TSCA. The review and case studies presented here may be helpful in implementing the potentially exposed and susceptible subpopulations provisions of amended TSCA. The findings and conclusions of this presentation do not necessarily represent the official views of US EPA or the Association of Schools and Programs of Public Health (ASPPH).
may be demonstrated by a number of means including a demonstration that the predicted ground level concentrations for the permitted emissions, evaluated on a case-by-case and chemical-by-chemical basis, do not cause or contribute to a LOC. The TCEQ’s ambient air monitoring program is extensive and provides data to help assess the potential for adverse effects from all sources (point, mobile, etc.) in an area. If air toxics are persistently monitored at a LOC, a localized APWL area is established. The purpose of the APWL is to help reduce ambient air toxic concentrations below LOCs by collaborating with stakeholders and focusing TCEQ resources in a particular area. The TCEQ Toxicology Division (TD) uses the most up-to-date methods to derive health-protection levels for chemicals in air. These methods are included in the TCEQ Guidelines to Develop Toxicity Factors, which were externally peer-reviewed by a panel of experts in inhalation toxicology and risk assessment. The Guidelines describe how the TD conducts scientifically sound toxicity assessments to establish levels of chemicals in air below which adverse health and welfare effects would not be expected (i.e., LOCs). Since the health effects review for air permitting differs from the evaluation of measured ambient air monitoring data, different risk management objectives and terminology for levels are used for the two programs. The use of different values and terminology is appropriate because the air permitting and air monitoring programs perform different functions in the protection of human health and welfare. This poster will highlight examples of decreases in air toxic levels in localized areas of Texas, resulting from the interactive nature of these programs and will illustrate the role of TD in these programs.

1653 Changes to the Common Rule Regulations and Implications for Human Research
M. Madden, US EPA, Chapel Hill, NC.

The regulations that govern research involving human subjects are known as the “Common Rule” because they are shared in common by 18 federal departments and agencies that conduct and support such research (The US Food and Drug Administration is not a signatory to the Common Rule). These regulations have not changed substantively since 1981. During that time, the research they cover has evolved considerably, with new scientific techniques and new ethical challenges that do not always fit well under the established structure. These include an evolving concept of what constitutes identifiable information and biostatistical techniques, such as whole genome sequencing, and concerns over commercialization and informed consent. A six-year rulemaking process began in 2011, with a preliminary draft notice release and more than 3,000 public comments received. This process culminated in the publication of a revised final rule on January 19, 2017. The majority of changes will take effect in January 2018, bringing sweeping changes for scientists and their institutions, funding agencies, and the Institutional Review Boards (IRBs) that oversee this work. This informational session will review the reasons for change, the rulemaking process, and the major changes in the revised regulations with a presentation by the US Environmental Protection Agency representative on the Interagency Working Group that drafted the new Common Rule. The daily experiences of implementing the Common Rule changes in a timely manner into human subject research at an academic institution and areas where the new rule is not clear will be shared by a presenter with the Office of Clinical Research at the University of Texas Health Science Center at San Antonio (UT Health San Antonio). UT Health San Antonio has several IRB authorization agreements with nearby institutions, such as Brooke Army Medical Center and the Southwest Research Institute, to serve as the single IRB of record for collaborative research. Potential issues with implementation of the new rule with studies at collaborative sites will be presented. A third speaker from the National Institute of Environmental Health Sciences IRB will discuss the potential impact of the new Common Rule on the submission and implementation of grant applications and also will provide insights on possible upcoming changes in the National Institutes of Health processes for human studies. This session will present extremely important ethics information for those who perform research with human subjects, including industry, government, and academia, and will facilitate discussions about applicability of the changes to current research and potential research designs and submissions. Disclaimer: The views expressed are those of the authors and do not necessarily represent the views or policies of the US EPA.

1654 Management of Toxic Wastes in Africa: Challenges and Opportunities
A. Kadry, US EPA, Washington, DC.

Africa is the world’s second-largest and second-most-populous continent, with a population of 1.2 billion people. In spite of its vast natural resources, Africa faces endemic poverty, food insecurity, and pervasive underdevelopment, with almost all countries lacking the human, economic, and institutional capacities to effectively and sustainably develop and manage their resources. In Africa, use of chemicals has taken a central stage in improving health, agriculture, mining, education, and many industrial processes. While African countries are heavy users of industrial chemicals, there is an absence of effective chemical waste management systems, as well as chemical safety education and rigorous enforcement of safety regulations. This absence has the potential to contribute to the exposure of a large portion of the population to toxic chemicals. Users and non-users of chemicals risk exposure to toxic chemicals as a result of ignorance of the risks, failure to employ protective measures, and ineffective implementation and enforcement of safety regulations of these chemicals. It was, thus, not surprising when the World Health Organization published alarming of the results of a survey of residents on chemicals of public health risk concern and their management. Many chemicals of public health concern that are banned, controlled, or withdrawn in the developed countries are still in use or shipped for disposal to Africa. These hazardous and toxic wastes pose risks to nearby water, soil, and air and have the potential to cause serious environmental and human health impacts. In addition, there are thousands of tons of industrial waste, containing hazardous chemicals, that are improperly discharged or emitted into the ambient. In many African countries, industrial waste in liquid form is usually discharged into sewer systems or rivers as effluent, while solid waste is either dumped in landfills or pits within workplace premises or close to residential areas. In addition, international illegal dumping remains a prevalent issue in chemicals management in Africa. Many African countries lack appropriate, cost-effective, and economically viable technology for chemical waste recovery and disposal. The purpose of this session will be to highlight examples of decreases in air toxic levels in localized areas of Texas, resulting from the interactive nature of these programs and will illustrate the role of TD in these programs.

1655 Moving Beyond Theory to the Use of Systematic Review and Evidence-Based Risk Assessment
D. Wikoff, ToxStrategies, Asheville, NC.

The use of systematic review and evidence-based methodologies in toxicology and risk assessment have evolved from theory to practice. This informational session seeks to provide an overview of the landscape of the use of systematic review in regulatory decision making. Recognizing that there are many efforts to advance the science in this arena, this session will focus on efforts specifically associated with risk-based practices, such as development of health-based benchmarks (e.g., acceptable daily intakes, reference doses, etc.) rather than characterization of potential hazard (e.g., likelihood to be a hazard to humans for a given health outcome). Tools and frameworks initially developed for the field of medicine have been adapted for applying research questions, and in many cases, new tools have been developed. The presentations will describe how the regulatory practitioners have
The obesity epidemic and associated co-morbidities are becoming an increasing concern to public health. Obesity can be generally defined by excess storage of lipids in adipose tissue. Central adipose tissue content directly correlates with the development of metabolic syndrome and cardiovascular complications that alter adipose tissue metabolism. Adipose tissue is not only a storage depot for triglycerides, but it is a metabolic active tissue that is responsible for the release of adipokines, such as liver and skeletal muscle, by hormonal-signaling pathways. In addition to lipid metabolism and mobilization, adipose tissue is intricately involved in glucose homeostasis and, therefore, contributes overall to the maintenance of systemic energy balance. It is suggested that adipose tissue plays an important role in the development of obesity-related diseases, thus requiring greater knowledge and understanding of adipose tissue development, signaling pathways, and identification of roles in systemic diseases. Current toxicological findings implicate a role for multiple persistent environmental chemicals, such as phthalates, tributyltin (TBT), and Di-(2-ethylhexyl) phthalate (DEHP) in promoting adiposity. Increases in adiposity are attributed to dysregulation of various metabolic pathways via genetic/epigenetic alterations, as well as contributing environmental factors. Recent studies have demonstrated accumulation of persistent environment toxicants due to their lipophilicity in adipose tissue, making adipocytes and preadipocytes targets of toxicity. Many of these studies have established the diverse mechanisms by which “obeses” promote adiposity. Overall, toxicants appear to have direct and indirect effects on adipose tissue homeostasis and adipose tissue dysfunction, a key characteristic of obesity with implications of metabolic disease. Many compounds have been identified via high-throughput screening programs focusing on target-specific binding. These programs include ToxCast, Tox21, and, more recently, the Endocrine Disruption Screening Program. Prioritizing these chemicals for further in vivo research is essential due to the number of identified chemicals by these programs. Discerning the cellular and molecular basis for endocrine and physiological outcomes of these chemicals is paramount in toxicological research. The objective of this symposium is to present an overview of the effect of obesogens or endocrine-disrupting chemicals on adiposity. Future research is warranted to contribute to the understanding of the contributions of other metabolically important tissues (liver, skeletal muscle, intestine) and the overall contribution to a growing obesity epidemic in both adults and children worldwide. In vitro exposure outcomes to TBT pertaining to the development of a “thrifty genotype” and phthalate exposure effects on adipocyte differentiation and maturation will be discussed, demonstrating the importance of adipocyte as a potential target of DEHP and other plasticizers. The adipocyte regulator PPARγ can be induced by environmental ligands favoring white adipocyte development, while dichlorodiphenyltrichloroethane exerts its effects on brown adipose tissue and the inhibition of thermogenesis, demonstrating the diversity of adipocyte function. Adipose tissue is responsive to endocrine disruptors; therefore, it is important to also understand the sex-dependent differences in human adipocyte function and distribution. Lastly, the implications of adipocyte research in regards to regulatory standards and the testing of compounds for adipogenic properties must be optimized and standardized utilizing specific assays that are most closely related to/adipocytes. Medium-throughput assays with greater relevance to downstream cellular outcomes in context to PPARγ and glucocorticoid signaling could be the future of prioritizing adipogenic compounds for risk assessment. The speakers will introduce the overall importance of adipose tissue homeostasis for human health and the contribution of environmental toxicants to its dysregulation.
Metabolic homeostasis is controlled, in part, by a family of proteins called nuclear receptors, which are the mechanism by which lipophilic hormones and hormone-like molecules regulate gene expression. One such nuclear receptor is peroxisome proliferator activated receptor γ (PPARγ). Its activation is essential for white, brite (brown-in-white) and brown adipogenesis, mature adipocyte maintenance, and insulin sensitivity. PPARγ activation regulates energy homeostasis by both stimulating fat mass and metabolic health, the goal of this presentation is to review current knowledge of mechanisms that determine where fat is deposited and sex differences in body fat distribution but remain poorly understood. Our data and others in the current literature provide evidence that suggests the following:

- Fat distribution in males vs. females. The world Health Organization (WHO) still recommends dichlorodiphenyldichloroethylene (DDE) for malaria control, and high body burdens of DDE, as well as other metabolites, are found in people across the world, and these levels continue to increase. The National Toxicology Program (NTP) recently used DDT. Human migration, semi-volatility, persistence, and bioaccumulation continue to globalize exposures to DDT and its more persistent metabolite dichlorodiphenyldichloroethylene (DDE) through the food supply. Further, most adults born in the US prior to the DDT ban were highly exposed to DDT during their developmental window that programs lifetime metabolic function and are now of age for heightened metabolic disease risk. Quantitative meta-analyses of seven prospective studies consistently indicate that humans exposed to elevated levels of DDE have an increased risk of obesity (beta = 0.13 BMI z-score (95% confidence interval: 0.01, 0.25) per log increase of p,p'-DDE). We exposed pregnant and nursing mice to a technical mixture of 1.7 mg DDT/kg body weight from gestational day 11.5 to postnatal day 5 and confirmed their circulating DDT and DDE levels (means: 2.2 ng p,p'-DDE/mL serum, 51.1 ng p,p'-DDT/mL serum) were within the range reported in people. Maternal DDT and DDE exposure increased the adiposity and insulin resistance of the adult mouse offspring. This long term metabolic toxicity resulted from reduced energy expenditure due to underlying impaired brown adipose thermogenesis in mice. Indeed, impaired thermogenesis was evident in mouse offspring on the last day of maternal dosing through nine months of age, when extensive transcripts involved in thermogenesis were down regulated in brown adipose. Cultured brown adipocytes also had decreased basal and uncoupled respiration in response to exposure to 1 through 1000 nM p,p'-DDE during adipogenic differentiation. These in vitro effects also coincided with increased expression of genes regulating thermogenesis, such as Ucp1. Our evidence indicates that the consistent association of DDE with human obesity can be explained by impaired brown adipose thermogenesis.

Evidence That the Pesticide DDT and Its Metabolite DDE Are Obesogens
M. A. La Merrill. University of California Davis, Davis, CA.

The developmental origins of obesity hypothesis posits a multifaceted contribution of environmental and genetic factors to the fetal origins of obesity and metabolic disease. Adipocyte hyperplasia during gestation and early childhood may result in predisposition for obesity as an adverse event later in life. The PPARG and NR3C1 (glucocorticoid nuclear receptor) pathways have a well-defined role in programming adipose-derived stem cell differentiation. For the PPARG screen, a set of 60 chemical compounds identified in ToxCast as PPARG active (49) or inactive (11) were initially evaluated for effects on adipogenesis and cytotoxicity. Appropriate hits were further tested in a series of 4 orthogonal assays representing 7 different events in PPARG-dependent adipogenesis, including gene transcription, protein expression, and adipokine secretion. Collectively, a total of 14/49 (29%) prioritized chemicals were identified with moderate-to-strong activity for human adipogenesis. A similar approach was taken to assess activity of 2 prioritized compounds identified as having NR3C1-dependent bioactivity. The universal concentration-response, multi-endpoint design of these assays provides a weight-of-evidence determination of chemical-biological activity based on hit frequency, efficacy, and potency. The approach demonstrates a process of prioritizing compounds from high-throughput screens and moving them into a mechanistic in vitro model to identify mode-of-action in context with a physiological outcome. This enables filtering of hit data to further prioritize the number of compounds deemed relevant for additional testing or risk assessment.

Screening ToxCast and Tox21-Prioritized Chemicals for Mechanistic Function in a Human Adipose-Derived Stem Cell Model of Adipogenesis
C. Deisenroth. US EPA, Durham, NC.

The developmental origins of obesity hypothesis posits a multifaceted contribution of environmental and genetic factors to the fetal origins of obesity and metabolic disease. Adipocyte hyperplasia during gestation and early childhood may result in predisposition for obesity as an adverse event later in life. The PPARG and NR3C1 signaling in context with multiple phenotypic outcomes related to adipocyte differentiation. For the PPARG screen, a set of 60 chemical compounds identified in ToxCast as PPARG active (49) or inactive (11) were initially evaluated for effects on adipogenesis and cytotoxicity. Appropriate hits were further tested in a series of 4 orthogonal assays representing 7 different events in PPARG-dependent adipogenesis, including gene transcription, protein expression, and adipokine secretion. Collectively, a total of 14/49 (29%) prioritized chemicals were identified with moderate-to-strong activity for human adipogenesis. A similar approach was taken to assess activity of 2 prioritized compounds identified as having NR3C1-dependent bioactivity. The universal concentration-response, multi-endpoint design of these assays provides a weight-of-evidence determination of chemical-biological activity based on hit frequency, efficacy, and potency. The approach demonstrates a process of prioritizing compounds from high-throughput screens and moving them into a mechanistic in vitro model to identify mode-of-action in context with a physiological outcome. This enables filtering of hit data to further prioritize the number of compounds deemed relevant for additional testing or risk assessment.

Sex and Depot Differences in Adipocyte Biology
S. K. Fried. Icahn School of Medicine at Mount Sinai, New York, NY. Sponsor: L. Armstrong

Increasing evidence suggests that chemicals present in the environment and food additives can increase risk for obesity. These so-called obesogens can act directly on adipocyte metabolism and growth, or indirectly via effects on other organ systems. As many of these compounds and their metabolic products may be conjugated within the adipocyte. For the long term goal of understanding how obesogens influence fat mass and metabolic health, the goal of this presentation is to review current knowledge of mechanisms that regulate adipocyte tissue growth and function, how these differ among different anatomical fat depots, and sex differences in adipocyte biology. Body fat is stored in highly specialized cells (adipocytes or fat cells) and organized within distinct anatomical depots. Women, compared to men, have a greater percentage of body fat, and it is distributed differently. In ~50% of women, more fat is deposited in gluteal-femoral subcutaneous depots, resulting in a pear shape. Intriguingly, the ability of these fat depots to expand is associated with metabolic health. In addition, on average, men, compared to women have more fat in the trunk, in both visceral, i.e. that associated with digestive organs, and abdominal subcutaneous depots. In both sexes, however, the size of the waist reflecting upper body or truncal fat is associated with higher risk of type 2 diabetes and cardio-metabolic diseases, and the amount of visceral fat highly correlated with metabolic dysfunction including insulin resistance and dyslipidemia. The mechanisms that determine where fat is deposited and sex differences in fat distribution but remain poorly understood. Our data and others in the literature indicate that differences in function of among adipose depots reflect distinct development origins and are in part cell-autonomous. Collectively, these observations indicate that understanding of mechanisms that by which some depots to expand or remodel is a critical to maintaining metabolic health in males vs. females.
Inhalation represents the primary route of exposure to aerosolized nanomaterials (NMs) and ultrafine particles in humans. This increasing use of NMs in consumer-based products warrants a thorough evaluation of their biological impacts and a need to test a large number of different types of NMs. Due to the substantive time, cost, and animals required to conduct traditional in vivo toxicity tests, there is much interest in developing human-relevant strategies that are less reliant on the use of animals to assess the toxicity of these materials for various risk assessment applications. This session will include presentations on in vitro systems that are currently being used to assess the inhalation toxicity of nanomaterials and ultrafine particles. Additionally, presenters will discuss the parameters that are critical to consider when designing in vitro systems and which facilitate their interpretation and application in risk assessment, including the following: dosimetry, aerosol generation, and exposure, appropriate cell types, and identification of relevant endpoints. Contribution of adverse outcome pathways (AOPs) to experimental and regulatory toxicology of NMs and strategies for the development of AOP-based computational tools and databases will also be discussed. By discussing the aforementioned parameters, this session will provide an insight into the factors that should be considered to increase the ability of in vitro models to predict human outcomes eventually leading to their use in regulatory decision making.

Integrated In Vitro-in Vivo Models for Nanomaterial and Ultrafine Particle Toxicity Testing: Moving from a Screening Hazard Tool to Predictive Models for In Vivo Adverse Effects

T. A. Stueckle1, D. C. Davidson1, V. Kodali1, T. Kornberg1, Y. Rojanasakul2, and L. W. Rojanasakul1. 1NIOSH, Morgantown, WV; and 2West Virginia University, Morgantown, WV.

Engineered nanomaterial and ultrafine materials (ENMs) are revolutionizing a diverse spectrum of commercial and industrial sectors with improved or novel technologies. Animal inhalation studies report ENM deposition in the deep lung with distinct disease risks; however, they are time- and resource-consuming and cannot be used to assess each ENM. With the advent of AOPs, and computational and computational models of ENMs, there is no consensus on how to rapidly screen associated hazards and define risks for occupational and public exposures. Several regulatory bodies have urged researchers to develop alternative approaches and integrated in vitro-in vivo effect models to press the question: Can in vitro models predict in vivo effects? Here, we examine several in vitro models that show evidence for predictability of in vivo damage, fibrosis, and tumorigenesis responses using scaled, realistic pulmonary exposure doses for several ENMs. Single- and multi-walled carbon nanotubes (CNT), and cerium oxide are known to penetrate into lung interstitium and induce interstitial fibrosis. Using scaled models of ultrasensitive per alveolar surface area, these ENMs stimulate fibroblast proliferation, collagen production, and a fibroblast stem cell-like phenotype that correlate with in vivo effects. Furthermore, the use of co-culture models has improved the understanding of how the inflammatory response mediates fibrosis development. Since some CNTs possess properties similar to known carcinogens, long-term, continuous exposures were tested in vitro and resulted in neoplastic or malignant transformation that correlated well with in vivo effects. CNT-transformed human lung bronchial epithelial cells exhibited elevated cancer hallmarks, proto-oncogene signaling, and evidence of cancer stem-like cells, consistent with known lung cancer signaling and established clinical biomarkers. Recent expansion of this approach to nano-sized metal oxides suggested that in vitro human cell models have potential as a useful tumorigenesis screening tool. In summary, development of integrated in vitro-in vivo approaches to assess ENM and ultrafine particle toxicity will fill key knowledge gaps and allow development of predictive in vitro models.

1665 Predictive 3D Lung Models to Assess the Toxicity of Inhaled Nanoparticles

B. Rothen-Rutishauser. University of Fribourg, Fribourg, Switzerland.

The lung is considered by far the most important portal of entry into the human body for aerosolized nanoparticles (NPs) released into the environment from combustion-derived processes, or, in an occupational setting via the use of NPs-containing consumer products, such as aerosol sprays. Although animal testing is still the most prevalent model used for risk assessment of inhaled nanoparticles, intensified efforts have been made during the last years towards a systematic development and evaluation of innovative and more reliable in vitro (human) lung cell models. Such models provide standardized and reproducible tools for high-throughput screening but also allow investigating mechanistic studies of inhaled nanoparticles at the single cell level. There are numerous in vitro lung models described to evaluate the human pulmonary epithelial tissue barrier but the choice of the model and the mode of exposure depends on the relevant scenario to be studied. These models range from simple mono-cultures to highly sophisticated 3D models, involving a combination of relevant cell types. Furthermore, air-liquid interface (ALI) exposure is more realistic towards mimicking in vivo conditions in the lung than the suspension exposure. A dose-controlled deposition of various nanomaterials at the ALI of cultured lung cells is therefore preferred. The advantage of such an approach is that the material characteristics can be fully controlled by monitoring the mass deposition on the lung cell surface on-line, allowing to produce a dose-effect correlation. Current research is ongoing to optimize such in vitro tests combining 3D lung models with ALI systems to predict the development of pulmonary diseases such as fibrosis following long-term exposures to aerosolized carbon nanotubes. Such an approach will help to address the regulatory safety testing requirements for inhaled nanomaterials while reducing the use of animals for this purpose.

1666 Contemporary Considerations in Engineered Nanomaterial Characterization, Aerosol Generation, and Exposure

C. S. Sayes. Baylor University, Waco, TX.

Traditional hazard testing models using animal inhalation chambers are time and financially expensive. Cell culture models have shown promise as surrogates in screening assays when multiple substances require preliminary information on toxicity. There is also a growing need for development of representative aerosol exposure systems that use a cell-based lung model to simulate inhalation exposure and assess potential hazards associated with aerosolized materials in a rapid and cost-effective manner. This talk presents two aerosol exposure apparatus: a settling chamber and a gentle impactor. Both have been demonstrated as a system capable of exposing cells in culture at the air-liquid interface using gravimetric settling and impaction as aerosol delivery mechanisms. These aerosol exposure apparatus are composed of two critical parts: (1) an aerosol concentrating chamber that delivers liquid and/or solid aerosols in the size range of 1–3 μm in mass median diameter and (2) an exposure chamber where co-cultured cells are maintained at the air-liquid interface during exposure. The aerosol used in the development of this system was mineral oil mixed with sodium fluorescein that served as a surrogate for known occupational respiratory toxicants. The settling chamber was constructed with simple design specifications but exhibits a low deposition efficiency (8%). It has also proved to be a challenge when increasing dosages of same-sized aerosols by altering aerosol input to the system; this occurred due to aggregation at high aerosol concentration in the chamber. Due to the limitations of the settling chamber an alternate system, the gentle impactor, was developed. The gentle impactor requires a more sophisticated design based on aerosol dynamics of target size for the droplets to be delivered. The delivery is more efficient which leads to a shorter exposure duration for the same dosage as compared with the settling chamber. It also enables consistent exposure to the same sized aerosols. From these results, depending on the needs of the experiment, either the settling chamber or the gentle impactor show promise as a high-throughput exposure tool that could be used in conjunction with other current cell-based biological test models.
An Integrated Methodology across the Dispersion Preparation-Colloidal Characterization-Cellular Dosimetry Continuum for Engineered Nanomaterials

P. Demokritou. Harvard School of Public Health, Boston, MA. Sponsor: M. Sharma

Due to the potential public health risk arising from exposure to engineered nanomaterials (ENMs) through consumer applications, a thorough evaluation of their safety is essential. Owing to the fast pace of ENM generation, high-throughput in vitro methods for safety assessments are sorely needed, but to date have proven unreliable with limited predictive capabilities extending to in vivo models. One major contributor to the discrepancies that exist between these models is a failure to reconcile in vitro and in vivo dosages. Despite growing evidence of the importance of ENM dosimetry for accurate hazard assessments, few toxicological studies take it into consideration. This oversight is likely due to a lack of standardization of exposure protocols, the need for additional extended preparations, characterization, and in vitro dosimetry estimation. This presentation will highlight recent advancements that strengthen our understanding on integrated approaches for calculating and predicting relevant dosages for in vitro cellular nanotoxicological studies. It will also highlight several mature, sophisticated computational tools and experimental methods for obtaining dosimetry information in vivo and extrapolating those findings to in vitro cellular systems, with specific examples related to “real world” ENM exposures. In addition to discussing the current state of the field regarding ENM dosimetry, discussions will center on the need and means for future development of this area.

Dosimetry Modeling to Aid In Vitro to In Vivo Extrapolation (IVIVE) of Inhaled Nanomaterials for Risk Assessment Applications

A. M. Jarabe, US EPA, Research Triangle Park, NC.

Accurate in vitro to in vivo extrapolation (IVIVE) of inhalation exposures for applications in support of risk assessment requires consideration of the physicochemical properties of the inhaled agent, characterization of the major mechanisms of its disposition in the respiratory tract, description of key anatomical and physiological properties in humans or other test species for which data may exist, and an adequate understanding of the target exposure scenario in humans or assumptions relevant to regulatory decision making. Dosimetry models have been developed to capture these key features and thereby afford the flexibility and versatility to support the requisite steps ranging from aiding in vitro experimental design, through translation of dose across various test species, to facilitating inferences regarding the probability of pathogenesis processes typically represented by endpoints or key events in an adverse outcome pathway (AOP) which may span a scale from genomic profiling to identifying in vivo dosimetry estimation. This presentation will describe critical concepts and key parameters of inhalation dosimetry for nanomaterials and then illustrate available model structures with key steps of IVIVE to advance the accuracy and regulatory acceptance of new testing and data streams. The impact of dosimetric adjustment on resultant assessment derivations is demonstrated. Opportunities for refining current default inhalation dosimetry algorithms used in dose-response analysis will be highlighted to show how risk assessment applications can continue to evolve as more sophisticated computational structures emerge, including a brief discussion of how ultimately computational models of inhalation dosimetry will serve as the bridge from AOP to virtual tissues and systems biology descriptions of the cardiopulmonary system is provided. Disclaimer: The views expressed in this abstract are those of the author and do not necessarily represent the views or policies of the US EPA.

Advances in Developing Adverse Outcome Pathways to Assess Inhalation Toxicity of Nanomaterials

S. V. Brule. Louvain Centre for Toxicology and Applied Pharmacology (LTAP), Brussels, Belgium. Sponsor: M. Sharma

An adverse outcome pathway (AOP) is a conceptual structure that portrays a simplified linear/sequential diagram of pathways from the molecular initiating event (MIE) induced by a chemical to the adverse outcome (AO), via a series of key events (KE). Due to the large number and types of nanomaterials (NM) with varying physico-chemical properties, there is an urgent need for strategies to predict their toxicity for regulatory purposes. By identifying causative NM characteristics and relevant intermediate toxicity pathways/endpoints, AOPs can highlight knowledge gaps and research priorities to improve predictive approaches. AOPs can help identify predictive endpoints, their respective contribution to the AO, and relevant test assays. AOPs are derived from existing knowledge based on in vitro, in vivo, or computational systems, and KE should ideally represent routinely measurable/quantifiable endpoints. In the in vivo world, AOPs are being developed to strengthen the lung fibrotic hazard of carbon nanotubes (CNTs). We will review and critically comment on these different efforts. Vietti and colleagues based their AOP on in vitro and in vivo data, emphasizing on pathways/endpoints for which correlation between in vitro and in vivo data exist. Labib et al. derived their AOP from general knowledge in lung fibrosis, including other experimental models such as bleomycin-induced lung fibrosis, and on genomics data. Both methods led to similar AOP, with most KE in common. By comparing genomics data obtained from the lung response to different types of NM, Labib et al. showed that regulations of gene expression and toxicity pathways are highly variable regardless of the NM studied, suggesting a possible common AOP for all NM. The magnitude of the effects however varies, possibly reflecting the fact that the lung responses to other NM are weaker than to CNT. By comparing different carbonaceous NM, various authors also identified common pathways (e.g., inflammation and release of growth factors) that could predict their potential to induce lung fibrosis, supporting the possibility to draw a common AOP at least for all CNT. Contribution of AOP to experimental and regulatory toxicity of NM, strategies for the development of AOP, as well as associated issues and limitations will be discussed.

Chemical Grouping for 21st-Century Toxicology, Risk Assessment, and Decision Making

J. Simmons. US EPA, Research Triangle Park, NC.

“Grouping” is a generic term describing placing chemicals in groups based on characteristics or factors that the assembled chemicals have in common to enable consideration of more than one chemical at the same time. Developing chemical groups is necessary for a variety of useful purposes, including something as seemingly simple, but as critically important, as safe chemical storage. Key uses of grouping in toxicology decision-making include grouping of co-occurring chemicals in the environment, the body, or the exposome; creating and prioritizing groups for chemical mixtures toxicology and mixtures risk assessment; and identifying chemicals that are toxicologically similar (i.e., that share the same adverse outcome pathway (AOP) or have the same molecular interaction but converge later in the pathway) or are toxicologically independent. Another important use is developing groups that facilitate the filling of data gaps by techniques such as read-across, trend analysis, extrapolation, interpolation, and QSAR; this use of grouping results in reduced experiment effort, saving time, resources, and experimental animals. Grouping also benefits green chemistry and enables the use of molecular design for reducing unwanted toxicity. Traditionally, groups have been based on exposure alone or toxicity alone. Strategies laid out in Toxicology Testing in the 21st Century: A Vision and a Strategy (National Research Council (NRC), 2010) and corresponding advances in exposure science, high-throughput toxicology, ‘omics sciences, and computational technologies have resulted in a wide array of next-generation methods and tools. The purpose of this session is to highlight how these advances are being translated and used in group decision-making approaches. In this session, experts from industry, academia, and government will present state-of-the-art insights into new methods currently being developed and employed that have current or future application to chemical groups. The importance of accurate grouping in the future development and translation of risk assessment will be illustrated. The full presentation will showcase a novel, fully-integrated text mining-based tool capable of automatically analyzing relevant literature and classifying a given chemical according to its carcinogenic mode of action based on a structured taxonomy. The second talk will focus on using a mechanistic understanding of the interaction between a chemical and the MIE within an AOP, coupled with 2D chemical structure information, group chemicals and how inclusion of chemical bioactivity profiles may then be used to refine the initial groupings. The third presentation will present the application of the concept of connectivity mapping in a predictive toxicology paradigm, where gene-expression profiles and pattern-matching software algorithms are used to find connections between chemicals, adverse events, and genes to group chemicals with similar mechanisms of action. The fourth talk will illustrate how chemical categories associated with specific MIEs can be utilized to guide higher level QSAR methods, such as comparative molecular field analysis, that enable quantitative predictions to be made regarding chemical binding affinity and/or downstream bioactivity without needing to fully elucidate the shape of the binding pocket of the biological target. The final presentation of the session will explore the influence of grouping decisions and misclassification errors that might occur on risk prediction when using
the relative potency factors method to assess mixtures risk, focusing on variability introduced if the same (or different) dose-response curve shape is assumed for all chemicals in the group when the shapes truly differ (or are the same) or when independence is assumed for convergent AOPs and the resulting uncertainty of the estimated mixture response. Disclaimer: The views expressed are those of the authors and do not necessarily represent the views or policies of the US EPA.

1671 Why Do We Need 21st-Century Grouping Methods?

J. E. Simmons. US EPA, Research Triangle Park, NC.

Historically, the lack of methods, models, and tools for grouping chemicals has limited exposure-based grouping to the chemicals or the mixture from a specific process, product, source, or chemical class. Similarly, toxicity-based groupings of chemicals, while ideally based on chemicals sharing the same mechanism/mode of action or adverse outcome pathway, have most often defaulted to the same target organ. Only recently have the advances in exposure science, high-throughput toxicology, omics sciences, and computational technologies resulting from application of the strategies laid out in in Toxicology Testing in the 21st Century (NRC, 2007) and Exposure Science in the 21st Century (NRC, 2012) begun to be applied to grouping. The importance of establishing appropriate and scientifically defensible groups and the impact of grouping choices is illustrated with an example based on grouping chemicals for chemical mixtures toxicity, risk assessment, and decision making. The views expressed in this abstract are those of the author and do not necessarily represent the views or policies of the US EPA.

1672 CRAB 2.0: A Text Mining-Based Approach for Grouping Chemicals According to Carcinogenic Modes of Action

1Karolinska Institutet, Stockholm, Sweden; and 2University of Cambridge, Cambridge, United Kingdom. Sponsor: J. Simmons

Searching and structuring scientific literature manually for risk assessment is a heavy time-demanding task. The number of articles of potential interest is growing exponentially, and detailed information on mechanisms and/or modes of action (MOA) is needed for characterizing the risk. An automated literature review process that could identify mechanistic information in scientific reports should have the potential to effectively support and speed up the process of chemical risk assessment. Text mining (TM), a growing field of computer science, has emerged as a potential solution for bridging the gap between free-text and structured representation of information in the scientific literature. Together with computer linguistics at University of Cambridge, we have developed a novel fully integrated TM-based tool CRAB 2.0, which automatically analyzes relevant literature and efficiently classifies a given chemical according to its carcinogenic MOA based on a structured taxonomy. The taxonomy specifies scientific data types of relevance and captures current understanding of the processes leading to cancer development. It covers both genotoxic and non-genotoxic MOA categories and sub-categories. In an effort to further facilitate risk assessment, we used the tool in order to define the groups of chemicals with homogenous or similar MOAs, for example to identify and separate dioxin-like PCBs from non-dioxin-like PCBs by automatically searching and utilizing information from the relevant text. This should be the first step toward more efficient risk assessment of such a complex group of chemicals, where the toxicity has been described in several articles of chemical groups data gap filling methods such as read-across can be used to predict provide predictions for chemicals within a chemical group that currently lack relevant toxicological data. This presentation will cover how 2D chemical structure information and bioactivity profiles can be utilized to group chemicals, and how the inclusion of bioactivity profiles may help in the refinement of these chemical groupings for chemical prioritization and/or hazard/risk assessment. Additionally, this presentation will discuss how chemical categories can be used in conjunction with AOP networks to guide various aspects of mixtures risk assessment. This is an abstract or a proposed presentation and does not necessarily reflect US EPA policy. Mention of trade names or commercial products does not constitute endorsement or recommendation for use.

1674 Use of Connectivity Mapping (CMap) as a Tool to Group Chemicals Based on Mode of Action

Perturbation of a biological system via an external insult results in a characteristic gene expression profile. This expression profile is unique to the biological system and insult under consideration. Querying a representative signature of this profile against other such profiles using pattern matching methods provides an opportunity to identify both known and unknown connections between perturbed biological systems. This concept named “Connectivity Mapping (CMap)” was first described by Lamb et al. (2006) as a means to find connections between small molecules, diseases, and drugs. The concept can be applied to a predictive toxicology paradigm to find connections between chemicals, adverse events, and genes. In regulatory risk assessment, predictive toxicology often includes read-across as the most widely used alternative to animal testing (ECHA 2014, OECD 2014). Ideally, read-across would include demonstration of biological similarity in addition to the structural similarity between the source and target chemicals. CMap can be used to probe toxicodynamic similarity between source and target chemicals. The gene profile data can be used to provide evidence of biological similarity and the potential for structurally related chemicals that are biological outliers and thus reduce the uncertainty associated with a read-across based safety assessment. This presentation will provide an overview of the CMap concept and how it can be adapted to a predictive toxicology paradigm. Data from a proof of concept study using 34 chemicals and its expansion to a further 108 chemicals will be shared. The practical applicability of the method in grouping chemicals with similar modes of action will be demonstrated. Important watchouts such as the importance of using relevant dose and its impact will be discussed. Areas for further improvement of the tool/concept will also be discussed.
Using Chemical Categories to Inform Quantitative Risk Assessment

T.E. Allen, J.M. Goodman, M.N. Grayson, S. Gutsell, and P.J. Russell. 1University of Cambridge, Cambridge, United Kingdom; and 2Unilever, Sharnbrook, United Kingdom.

Chemical categories allow us to group molecules with other similar molecules quickly and efficiently for purposes such as read-across. These chemical categories can also be used to guide higher level QSAR approaches to inform quantitative risk assessment. The aim of this research is to move such QSAR models away from a global perspective and closer to a desired target. Molecular initiating events (MIEs) provide the platform for this. MIEs are initial chemical interactions between chemicals and biological systems that can lead to a toxic outcome via an adverse outcome pathway (AOP). In one instance, chemical informatics approaches have been used to develop categories based on the chemical characteristics of molecules that interact with a wide variety of human targets. Higher level QSARs are then applied to these well-defined chemical categories to allow the prediction of the activity of some binders to human targets well within one log unit. This has been achieved using comparative molecular field analysis (CoMFA), providing both a predictive model for activity and a visual representation of the fields the test molecules sit in without any understanding of the biology of the target. CoMFA can guide molecular development, by showing the hydrogen bonds and steric interactions that cause molecules to be more or less active, allowing chemical concerns to be systematically designed out of molecules. In another instance existing chemical categories for Ames mutagens have been used to guide higher level calculations. Density functional theory transition state modelling has been used to calculate activation energies for the reactions of chemicals with a model DNA base. Chemicals with high activation energies have been found to be inactive via this MIE, while similar chemicals with lower activation energies covalently bind to DNA and are mutagenic. This model directly models the chemistry of the MIE and opens a gateway for the modelling of other similar MIEs. Predictions made at the MIE level can subsequently be used in other dose-response models, through an AOP, to understand higher level toxicological outcomes. By further developing and refining these approaches we hope to learn more about the chemical characteristics that cause MIEs to happen, and hence better understand these important molecular interactions.

Estimating the Impact of Grouping Misclassification on Risk Prediction When Using the Relative Potency Factors Method to Assess Mixtures Risk

J. Swatout,1 and R.C. Hertzberg.1 US EPA, Cincinnati, OH; and 2Biomathematics Consulting, Atlanta, GA. Sponsor: J. Simmons

Environmental health risk assessments of chemical mixtures that rely on component approaches often begin by grouping the chemicals of concern according to toxicological similarity. Approaches that assume dose addition typically are used for groups of similarly-acting chemicals and those that assume response addition are used for groups of indepen- dently acting chemicals. Grouping criteria for similarity can include a common adverse outcome pathway (AOP) and similarly shaped dose-response curves, with the latter used in the relative potency factor (RPF) method for estimating mixture response. Independence of toxic action is generally assumed if there is evidence that the chemicals act by different mechanisms. Partial independence is a special case, in which the chemicals act initially by different mechanisms, but their toxicodynamic pathways eventually converge to produce or affect a common product that leads directly to the adverse outcome. Misclassification can occur when the grouping is measured if errors are made in the assignment of AOP dose-response shape, or independence. Several questions arise about the potential for misclassification error in the mixture risk prediction. If a common AOP has been established, how much error could there be if the same dose-response curve shape is assumed for all chemicals, when the shapes truly differ and, conversely, what is the error potential if different shapes are assumed when they are not? In particular, how do those concerns impact the choice of index chemical and uncertainty of the RPF-estimated mixture response? What is the quantitative impact if dose additivity is assumed when complete or partial independence is in fact the case? What is the impact if a chemical is assigned to the wrong AOP group? These concepts and implications will be presented with numerical examples in the context of uncertainty of the RPF-estimated mixture response, both regarding endpoint and numerical accuracy when representing the group. The views expressed in this abstract are those of the author and do not necessarily represent the views or policies of the US EPA.

Role for NF-κB p50 in the Regulation of Chronic Neuroinflammation by Free Radicals

M.L. Block, Indiana University School of Medicine, Indianapolis, IN.

Redox-signaling is implicated in deleterious microglial activation under- lying central nervous system (CNS) diseases, but how NF-κB, a dysoxidant microglial function is poorly understood. Here, the oxidation of NF-κB p50 to a free radical intermediate is identified as a marker of dysfunctional (exaggerated and persistent) pro-inflammatory activation of microglia. Microglia exposed to steady fluxes of H2O2 showed altered NF-κB p50 protein-protein interactions, decreased NF-κB p50 DNA binding, and augmented late-stage TNFa expression indicating that H2O2 impairs NF-κB p50 function and prolongs amplified M1 activation. NF-κB p50 (+/−) mice and cultures demonstrated that loss of NF-κB p50 function disrupted M2 (alternative) response and impaired resolution of the M1 response. Treatment with the spin-trap DMPO mildly reduced LPS-induced TNFa in the brain in NF-κB p50 (+/+) mice. Interestingly, DMPO failed to reduce and strongly augmented brain TNFa production in vivo.
in NF-κB p50(-/-) mice, implicating a fundamental role for NF-κB p50 in the regulation of chronic neuroinflammation by free radicals. These data identify NF-κB p50 as a key redox-signaling mechanism regulating CNS-specific chronic inflammation. New findings demonstrating the role of environmental toxicants (for example, paraquat) and aging in this process will also be discussed.

**1679 Overcoming Bias in F2-Isoprostane Oxidative Stress Measurement: Quantifying the Contribution of Inflammation**

T. J. van’t Erve. NIEHS/NIH, Research Triangle Park, NC.

Oxidative stress is recognized to play a role in the etiology of numerous diseases as well as environmental exposures. Increases in oxidative stress are measured through biomarkers; the best recognized biomarker is the lipid oxidation product 8-isoprostaglandin F2α (8-iso-PGF2α). However, 8-iso-PGF2α is also simultaneously produced enzymatically by the prostaglandin-endoperoxide syntheses (PGHS) in vivo. This alternative pathway has been mostly ignored in the interpretation of many published studies, leading to potentially incorrect conclusions. It has now become necessary to distinguish the two sources of 8-iso-PGF2α to avoid bias in data interpretation and conclusions. We established a novel method using the 8-iso-PGF2α to prostaglandin F2α ratio. We used this approach to simultaneously assess inflammation and oxidative stress in two animal models (CCI4 and LPS) and in humans (smokers and non-smokers). Measurements from these studies show that generation of 8-iso-PGF2α involves both pathways in vivo and the predominant source changes significantly depending on the model. In conclusion, we have validated the 8-iso-PGF2α / PGF2α ratio as a method to distinguish the sources of biomarker generation in vivo. Our work necessitates re-examination and re-interpretation of previous studies claiming induction of oxidative stress. This can alter the etiology of classic oxidative stress diseases and exposures such as smoking to ones more focused on the stimulated inflammatory response.

**1680 Inflammation Differentiated from Oxidative Stress in Reproductive Epidemiology: Understanding the Environmental Impact on Birth Outcomes**

K. K. Ferguson. NIEHS/NIH, Research Triangle Park, NC. Sponsor: M. Kadiiska

Chronic exposure to elevated levels of environmental contaminants (e.g., phthalates) has been repeatedly shown to be associated with adverse pregnancy outcomes. Endocrine disruption is posited as the primary mechanism of action for these contaminants, but oxidative stress and inflammation pathways may also play a significant role. To date, little research has been performed to distinguish between these two mechanisms to adverse outcomes and complications in pregnancy such as preterm birth and fetal growth. In this analysis, we examined data from a cohort of 761 pregnant women to investigate the associations between urinary 8-isoprostane concentrations, separated into chemical and enzymatic fractions based on the novel 8-iso-PGF2α / PGF2α ratio, in relation to adverse birth outcomes. We additionally examined preliminary data on associations between urinary phthalate metabolites and these fractions. Participants were recruited early in pregnancy and provided urine samples at three study visits. Phthalate metabolites and oxidative stress measures were quantified in urine from the third visit. In preliminary analyses, the chemical fraction of 8-iso showed an inverse association with gestational age at delivery. This may be particularly important in toxicology, since some environmental contaminants are associated with an increase in this chemical fraction as well.

**1681 Emerging Indications of Biomarkers for Use in Humans within a Cluster of Redox-Related Diseases: Relevance of Biomarkers of Oxidative Stress, Inflammation, Antioxidants, and Redox Signaling**

H. H. Schmidt. Maastricht University, Maastricht, Netherlands. Sponsor: M. Kadiiska

Successful biomarker policies of both inflammation and oxidative stress are vital to the advancement of directed therapies across a variety of toxicities, exposures and diseases that can influence clinical decision and provide optimal treatment. As of today, no biomarker of oxidative stress measured in circulation provides information on the cellular source, tissue or organ involved. In addition, many markers are confounded by generation through inflammatory processes. These facts might explain why the translational shortcut of this theory, antioxidant therapy, has failed so often and has never shown enough evidence to be incorporated in guidelines, approved by regulatory agencies, or recommended and reimbursed by health insurance systems. Since ROS have a complex metabolism and are generated by different enzymes at diverse sites and at different times, it is proposed that aggregating this plurality of systems into a single theory of disease may not be the best way to develop new drugs. Future research may need to focus on specific pathways of oxidation rather than on non-specific ROS scavengers.

**1682 Estrogen Receptor Signaling as a Mechanism of Developmental Toxicity**

D. Gorelick. University of Alabama at Birmingham, Birmingham, AL.

Estrogens are steroid hormones that influence the development and function of nearly every major organ system in the body—from the gonads to the central nervous system. Xenobiotic agents that mimic estrogens or influence estrogen production or metabolism can exert profound effects on organismal development. Aberrant estrogen receptor signaling is classically associated with reproductive toxicity. However, in the last decade, it has become apparent that abnormal estrogen receptor signaling during development can cause widespread changes in cardiovascular, immune, and metabolic functions. With the development of new molecular tools, improved understanding of developmental biology, and the use of new model organisms, tremendous advances have been made in understanding how estrogen receptors regulate development at the molecular, cellular, and physiological levels. This session will explore cutting-edge research in developmental toxicology, revealing the mechanisms by which estrogen receptors influence organismal development. Using an Adverse Outcome Pathway (AOP) framework, the speakers will explore estrogen receptor-mediated toxicity from the molecular initiating event (receptor activation) through adverse outcomes, such as organ malformation and dysfunction, thus linking early signaling events to organismal toxicity. The first speaker will discuss novel in vitro and in silico screening approaches to predict and model estrogen receptor toxicity and how these approaches are being used for hazard assessment and testing prioritization and are leading to compound development under the new Toxic Substances Control Act guidelines. To evaluate high-throughput estrogen receptor toxicity predictions, novel in vivo models are required. The second speaker will present on a novel zebrafish model being used to explore why some embryonic tissues are more sensitive to estrogen exposure than others. The third presentation will outline the similarities and differences by which estrogens and related sex hormones influence gonad development at the molecular and cellular levels and how these mechanisms can be hijacked by exposure to xenoestrogens during critical periods of development. The final two speakers will focus on adverse outcomes and discuss how estrogen receptors influence developmental toxicity in a sexually dimorphic manner with a focus on energy homeostasis and social, sexual, or anxiety-like behaviors in offspring of exposed mothers. These five speakers, using diverse approaches and model systems, will demonstrate how understanding the detailed mechanisms by which estrogen receptors influence developmental toxicology will improve the ability to identify potentially deleterious xenoestrogens and pharmaceutical estrogens with less side effects on patients and their offspring.
Endocrine disrupting chemicals (EDCs) likely influence human and aquatic organisms by mimicking endogenous hormones and disrupting the natural balance of hormone exposure. Estrogens, steroid hormones whose signaling pathways are commonly disrupted by EDC exposures, invoke a wide range of molecular and cellular effects, where the activation or inhibition of signaling pathways depends on the types of estrogens, their levels, and the developmental stages at which exposure occurs. To study how concentration and timing of xenoestrogen exposure influence gonad development, we used the zebrafish model system. Zebrafish embryos are transparent and genetically tractable, providing a unique opportunity to study how xenoestrogens influence gonad development.

In contrast to mammals, ultrasonic vocalizations and investigation of opposite-sex and sociosexual and anxiety-like behaviors are changed by EDCs; among these, reproductive neuroendocrine systems, sex differences in gonadal hormones, especially during critical periods of life, especially in the developing fetus and infant, are particularly problematic. In the case of the brain's neuroendocrine systems, sex differences in gonadal hormones, especially estrogenic endocrine disrupting compounds (EDCs) have most recently been linked to the development of obesity and type-2 diabetes in adults. The studies have focused attention on three groups of estrogenic EDCs: Phyoestrogens/mycotoxins (zearealenone, a-zearealenol), alkylphenols (nonylphenol and flame retardant diethyl diphenyl ethers (PBDE) and organophosphate flame retardants (OPFR)). The effects of maternal exposure to zearealenone and OPFRs on adult energy homeostasis is largely unknown. In two separate studies, we characterized the effects of maternal exposures to these compounds on adult energy homeostasis and glucose homeostasis in mice. In Experiment 1, oral maternal exposures to a-zearealenol from gestational day 7 (GD7) to postnatal day (PND) 14 altered glucose tolerance and insulin sensitivity in a sex-specific manner. Female mice were more glucose tolerant and insulin sensitive. Male mice were less glucose tolerant and more insulin resistant. There was no consistent pattern of findings across parameters of energy and glucose homeostasis for nonylphenol. In Experiment 2, we exposed dams to flame retardants: The PBDE congener 2,2',4,4'-tetrabromodiphenyl ether (BDE-47, 1 mg/kg/day) and a mixture of common OPFR (triphenyl phosphate (TPP), trimethyl phosphate (TCP), tris (1,3-dichloro-2-propyl) phosphate (TDOP), 1 mg/kg/day) from gestational day 7 (GD7) to postnatal day (PND) 14. Males from OPFR-treated dams had shorter ano-genital distance indicating feminization. In adulthood, FR treatment in males fed a low-fat diet (LFD) exhibited less adiposity and activity while increasing energy expenditure. Males from OPFR-treated dams exhibited elevated heat production and lower fat diet (HFD) and increased glucose intolerance. Indeed, these males did not have a typical response to a glucose challenge when fed a HFD. Collectively, these data suggest that exposure to these estrogen EDC can alter energy homeostasis in adulthood in sex-dependent manner.

Environmental chemicals with estrogenic activity can disrupt development and programming leading to adverse physiological effects in adults. These estrogenic endocrine disrupting compounds (EDCs) have most recently been linked to the development of obesity and type-2 diabetes in adults. The studies have focused attention on three groups of estrogenic EDCs: Phyoestrogens/mycotoxins (zearealenone, a-zearealenol), alkylphenols (nonylphenol and flame retardant diethyl diphenyl ethers (PBDE) and organophosphate flame retardants (OPFR)). The effects of maternal exposure to zearealenone and OPFRs on adult energy homeostasis is largely unknown. In two separate studies, we characterized the effects of maternal exposures to these compounds on adult energy homeostasis and glucose homeostasis in mice. In Experiment 1, oral maternal exposures to a-zearealenol from gestational day 7 (GD7) to postnatal day (PND) 14 altered glucose tolerance and insulin sensitivity in a sex-specific manner. Female mice were more glucose tolerant and insulin sensitive. Male mice were less glucose tolerant and more insulin resistant. There was no consistent pattern of findings across parameters of energy and glucose homeostasis for nonylphenol. In Experiment 2, we exposed dams to flame retardants: The PBDE congener 2,2',4,4'-tetrabromodiphenyl ether (BDE-47, 1 mg/kg/day) and a mixture of common OPFR (triphenyl phosphate (TPP), trimethyl phosphate (TCP), tris (1,3-dichloro-2-propyl) phosphate (TDOP), 1 mg/kg/day) from gestational day 7 (GD7) to postnatal day (PND) 14. Males from OPFR-treated dams had shorter ano-genital distance indicating feminization. In adulthood, FR treatment in males fed a low-fat diet (LFD) exhibited less adiposity and activity while increasing energy expenditure. Males from OPFR-treated dams exhibited elevated heat production and lower fat diet (HFD) and increased glucose intolerance. Indeed, these males did not have a typical response to a glucose challenge when fed a HFD. Collectively, these data suggest that exposure to these estrogen EDC can alter energy homeostasis in adulthood in sex-dependent manner.

Environmental endocrine-disrupting chemicals (EDCs) are exogenous chemicals that perturb hormones and their actions. Exposures to EDCs during life, especially in the fetal and infant, are particularly problematic. In the case of the brain's neuroendocrine systems, sex differences in gonadal hormones, especially estrogenic endocrine disruptors, are determined by developmental EDC exposures causing the brain in a sexually dimorphic manner, manifesting later in life as a disease or dysfunction. We treated pregnant rats with low dosages of a weakly estrogenic commercial polychlorinated biphenyl (PCB) mixture, Aroclor 1221 (A1212, 0.5 or 1 mg/kg) or estradiol benzoate (EB, positive control at 50 μg/kg). Adult offspring were assessed using a battery of behavioral tests to assess functional neurobehavioral changes. The brains of these rats were subsequently used for protein and gene expression assays, and hormones were assayed. Results of behavioral testing show that social, sociosexual and anxiety-like behaviors are changed by EDCs; among these, ultrasonic vocalization and investigation of opposite-sex responses are specifically affected. Gene expression profiling of brains from these animals has identified suites of genes differ
entially affected by PCBs compared to vehicle rats, with sex-, age-, and brain-region specific differences. Interestingly, while some of the actions of PCBs are similar to those of EB, others are different, indicating both estrogenic and non-estrogenic actions. This body of work indicates that gestational exposure to PCBs has life-long effects on the developing brain, neuroendocrine systems, and reproductive and social behaviors.

1688 High-Throughput Transcript Profiling and Functional Assessment: From Screening to Systems Biology Strategies for Personal Chemical Safety Predictions

C. Corton. US EPA, Durham, NC.

High-throughput screening (HTS) assays are an important component of chemical safety evaluation programs carried out by a number of organizations. However, it is recognized that the assays do not sufficiently cover all potentially important pathways. In the last few years, adaptation of gene expression profiling to high-throughput formats has been increasingly considered an attractive alternative to individual assays due to lower costs and the ability to simultaneously measure them. While microarrays have been used extensively in more focused lower-throughput studies and comprise the bulk of large publicly-available databases, technologies that can measure the targeted expression of the entire genome are emerging as attractive alternatives. Novel computational approaches are increasingly being used to move the field from using transcript profiles as hypothesis-generation tools to accurately predicting effects. Functional genomics strategies that identify gene-chemical interactions in gene-knockdown screens have proven valuable to validate predictions from transcript profiling and to determine species-specific effects. These integrated high-throughput genomics approaches will allow identification of relevant key events that are quantifiable in high-throughput (HT) transcriptomic settings and predict cell and biological changes, as well as human-translational, implications. This session highlights major advances in the field of using transcript profiling and functional genomics in a number of areas important in risk assessment. The first presentation will highlight recent results of a large-scale HT screen of 1,000 chemicals in a human cell line, allowing dose-response modeling of biological pathways on a massive scale. The second and third presentations will describe novel computational approaches which utilize both private and publicly-available data to make predictions of molecular targets and of chemical perturbations in gene networks that lead to toxicity. The last two talks will discuss exciting work which identifies genetic modifiers of responses to chemicals, allowing assessment of individual susceptibility to chemical injury. This session will be of wide interest, including to scientists interested in the application of gene expression profiling and in vitro assays to regulatory decision making.

1689 High-Throughput Transcriptionomics: From Screening to Pathways

I. Shah. US EPA, Durham, NC.

The US EPA ToxCast effort has screened thousands of chemicals across hundreds of high-throughput in vitro screening assays. The project is now leveraging high-throughput transcriptomic (HTTr) technologies to substantially expand its coverage of biological pathways. The first HTTr screen has measured the expression of 19,290 genes in MCF7 cells for more than 1,000 chemicals in a concentration response format. We have developed a computational strategy to interpret the HTTr data in terms of pathway perturbations, the specificity of pathway perturbations and associated points of departure. A strategy for integrating these new transcriptomic technologies into high throughput toxicity testing will be presented and the challenges discussed. We believe HTTr technologies can be deployed in a tiered fashion to complement the existing suite of high-throughput in vitro screening assays to realize the vision of toxicity testing in the 21st century.

1690 Identification of Potential Chemical Carcinogens in Compendia of Gene Expression Profiles

C. Corton. US EPA, Durham, NC.

Chemicals induce cancer through partially characterized adverse outcome pathways (AOPs) that include molecular initiating events (MIEs) and downstream key events (KEs). Microarray profiling of chemical-induced effects is being increasingly used in medium- and high-throughput formats. We developed computational strategies to identify chemicals in large microarray compendia that activate MIEs/KEs. Predictive biomarkers were built from profiles of knockdown or overexpression of the transcription factor (TF) and through selection of genes consistently regulated by chemicals known to modulate the TF. Gene expression profiles were compared to biomarkers using a correlation-based method which determines the significance of the overlapping gene expression allowing for prediction of modulation of that MIE/KE. The predictive biomarkers accurately identify chemicals that modulate a number of MIEs (genotoxicity assessed using p53-dependent genes, the endocrine disruptor targets estrogen receptor (ER) and androgen receptor (AR), as well as xenobiotic receptors aryl hydrocarbon receptor (AhR), constitutive activated/androstane receptor (CAR), peroxisome proliferator-activated receptor a (PPARa)) or downstream KEs (cell proliferation and oxidative stress (assessed indirectly through Nrf2 activation)). A number of examples will be given of applications of this approach including screening in 1) ER positive breast MCF-7 cells, 2) AR positive prostate LAPC-4 cells, and 3) human primary hepatocytes. Our screen identified many unique chemicals previously unknown to affect these pathways. In the MCF-7 compendium of 1,153 unique compounds, 75 compounds were found to activate ERs and 39 suppressed ERs. ERs activators included those that are known ERs agonists as well as previously unrecognized activators. Chemicals were identified that increased cell proliferation in MCF-7 cells either dependent or independent of ER activation. Our approach highlights the value of using transcript profiling to identify chemicals that have the potential to cause cancer. This does not represent US EPA policy.

1691 Reducing Noise and Boosting Biological Signal Detection in Large Transcriptomic Datasets

I. Stevens. Lilly Research Laboratories, APex, NC.

High throughput transcriptomic data present significant challenges computationally due to the dimensionality of the data and in assigning biological interpretations necessary to construct mechanism-based risk assessments. Classification techniques, e.g. signature response profiling, were developed to allow read across from training sets of compounds to test compounds for risk characterization. Other methods focus on elucidating underlying biological response pathways that are activated or repressed by exposure to xenobiotics. Among the latter methods, unsupervised approaches that organize large datasets into a modular format based on coalescent properties of biological systems have advantages both computationally, by reducing the dimensionality of, e.g. from 104 genes to 102 modules, and for data interpretation since they reveal the underlying modular structure of the biological systems of interest. We have used one such method, weighted gene co-expression network analysis (WGCNA), to create a modular representation of gene expression for liver and kidney transcriptomic data using DrugMatrix and TG-GATES data. In this presentation, we illustrate how detailed time series of changes in modules of co-expressed genes reveal important compound-specific as well as more general organ-based adaptive responses to a drug-induced toxicity. The ability to separate compound-specific from organ-based adaptive responses provide novel insights for risk assessment.

1692 High-Throughput Identification of Genotype-Specific Vulnerabilities to Drug Treatment

Patient response to therapeutics, especially newer targeted therapies, is increasingly linked to genetic dependencies. In order to better identify clinical populations that will respond to a given therapy, we must develop robust in vitro assays using clinically relevant cellular models to study genotype-specific vulnerabilities and biomarkers of drug response. Scaling high throughput screening assays to hundreds or thousands of cell lines is critical to better cover the clinical diversity of disease and to power correlation analyses to understand specific vulnerabilities. Groups and efforts such as NC1-60, Sanger/MGH, the Cancer Cell Line Encyclopedia (CCLE) and The Broad Institute’s CTD profiler have demonstrated the utility of screening compounds against a larger axis of cell lines. However, these efforts require very large investments of both time and resources to complete, making routine screening at this scale still a challenge. To overcome this technical hurdle, we have established a high throughput cell viability screening method, PRISM, to multiplex the screening process by utilizing uniquely DNA barcoded cancer cell lines to perform drug screening in pooled cell lines. This presentation will discuss the development of a robust screening platform that allows routine and rapid screening of thousands of compounds against hundreds of genomically characterized cell lines to generate response signatures. We will show examples of how response signatures can be correlated to a variety of complementary orthogonal

1693 High-Throughput Identification of Genotype-Specific Vulnerabilities to Drug Treatment

Patient response to therapeutics, especially newer targeted therapies, is increasingly linked to genetic dependencies. In order to better identify clinical populations that will respond to a given therapy, we must develop robust in vitro assays using clinically relevant cellular models to study genotype-specific vulnerabilities and biomarkers of drug response. 1694 High-Throughput Identification of Genotype-Specific Vulnerabilities to Drug Treatment

Patient response to therapeutics, especially newer targeted therapies, is increasingly linked to genetic dependencies. In order to better identify clinical populations that will respond to a given therapy, we must develop robust in vitro assays using clinically relevant cellular models to study genotype-specific vulnerabilities and biomarkers of drug response. Scaling high throughput screening assays to hundreds or thousands of cell lines is critical to better cover the clinical diversity of disease and to power correlation analyses to understand specific vulnerabilities. Groups and efforts such as NC1-60, Sanger/MGH, the Cancer Cell Line Encyclopedia (CCLE) and The Broad Institute’s CTD profiler have demonstrated the utility of screening compounds against a larger axis of cell lines. However, these efforts require very large investments of both time and resources to complete, making routine screening at this scale still a challenge. To overcome this technical hurdle, we have established a high throughput cell viability screening method, PRISM, to multiplex the screening process by utilizing uniquely DNA barcoded cancer cell lines to perform drug screening in pooled cell lines. This presentation will discuss the development of a robust screening platform that allows routine and rapid screening of thousands of compounds against hundreds of genomically characterized cell lines to generate response signatures. We will show examples of how response signatures can be correlated to a variety of complementary orthogonal
data sets including baseline genomic features (CCLE), and both chemical and genetic (genome-wide shRNA and CRISPR) perturbational profiles. In particular, we will highlight our effort to assemble, annotate and screen a 5,000 compound Broad Drug Repurposing library across 500+ cell lines to provide a foundational dataset for expanded signature correlations to known and well annotated chemical entities. We will share examples of how this integrated signature based screening and analysis approach yields identification of novel genetic vulnerabilities of specific cancer cell lines. This approach can lead to rapid hypothesis generation toward mechanistic understanding of specific genetic traits to drug treatment outcome.

**Functional Genomics of Cellular Stress Pathways: Towards a Personalized Chemical Safety Assessment**

B. van de Water, Universiteit Leiden, Leiden, Netherlands.

The activation of adaptive stress response pathways is a key event in chemical-induced tissue injury. Toxicogenomics has established the variety of stress pathways and their downstream components that define cell repair and defence of different target tissues, including liver, kidney, and heart. These involve the oxidative stress response pathway, the unfolded protein response pathway, DNA damage response, and immune signalling response pathways. While the critical core regulators and transcription factors that drive these pathways have been well described, the components that control these networks and, likewise, adaptation to chemical insults, are largely unknown. We have integrated imaging-based quantitative phenotyping of adaptive stress pathway activation with large scale RNAi-based functional genomics to identify individual signalling molecules, kinases, phosphatases, ubiquitinas, and transcription factors, that define the amplitude of oxidative stress response, unfolded protein response, and cytokine immune signalling response. We have further assessed the role of these individual signalling components in the onset of cytotoxicity. Human whole genome sequencing identifies the assessment pathway number variants in P70S6k or genetic polymorphisms in these individual signalling components. This will drive our understanding of individual susceptibility to chemical injury and move the field towards personalized chemical safety assessment.

**Revisiting Biology: Using Genomic and Epigenomic Editing to Gain Novel Insight into the Molecular Mechanisms of Toxic Exposure Effects and Susceptibility**

S. McCullough, US EPA, Chapel Hill, NC.

The genome and epigenome work hand-in-hand as central regulators of cell fate and function and therefore of susceptibility and toxic exposure effects. The use of traditional molecular methods has established a foundation with respect to the molecular mechanisms underlying the adverse effects of many toxic exposures; however, their efficacy in defining causative relationships between gene products, genetic polymorphisms, and epigenetic modification states with toxic exposure effects and susceptibility has been limited. The recent development of practical applications for clustered, regularly interspaced, short palindromic repeat (CRISPR) technology permits the selective revision of both the genome and epigenome in basic science research. In our lab we have used CRISPR-Cas9 to the target DNA locus using a sequence-specific guide RNA (gRNA), which provides increased specificity and ease of design compared to previous approaches using zinc finger nucleases (ZFNs) and transcription activator-like effector nucleases (TALENs). CRISPR can also be specifically modified the genome through either the targeted disruption of CpG sites that are subject to DNA methylation, or through the expression of epigenetic modifying enzymes/domains that are fused to “deactivated” Cas9 (dCas9), such that it can be targeted to specific genomic loci by synthetic guide RNA (sgRNA) but lacks nuclease activity. This permitted the targeting of transcription factors or epigenetic modifying enzymes to specific genomic loci, thus providing the technical framework to interrogate the relationships between changes in specific epigenomic modifications and expression-associated phenotypes. Separately, a novel class of small RNAAs, known as piRNAs, has recently been shown to orchestrate the targeted methylation of DNA within the mammalian genome. In a manner similar to the capacity of sgRNA to target dCas9, synthetic designer piRNAs can recruit DNA methyltransferases to hypermethylate specific genomic loci, thus silencing associated genes. This presentation will set the stage for the session by describing the similarities and differences between the molecular mechanisms utilized by these transformative tools, discussing their potential within the field of toxicology, and demonstrating their applications in revising biology.

**Use of CRISPR-Cas9 to Elucidate the Role of Nrf2 in the Response of T Cells to Electrophilic and Oxidative Stress**

C. Rockwell, Michigan State University, East Lansing, MI.

The introduction of CRISPR-Cas9 technology for gene editing has transformed basic science research. In our lab we have used CRISPR-Cas9 gene editing to elucidate the role of nuclear factor erythroid 2-related factor 2 (Nrf2) in T cell functional and genetic immunomodulation. Nrf2 in T cell functions can be targeted to alter both DNA methylation and histone modifications at specific loci to directly link changes in epigenetic modification states to exposure outcomes and susceptibility. The application of these technologies will open the door to the next generation of precision therapeutic and revolutionary in the field of toxification by providing novel opportunities to understand and modulate exposure-related disease and susceptibility at the genetic and epigenetic level. The goal of this session is to examine the range of applications of genome and epigenome engineering from their use in molecular and mechanistic toxicology studies to their potential as therapeutic strategies and to review the inherent safety considerations that their use entails. To achieve this, the session will bring experts together to discuss the development of these technologies and their current use in toxicity studies covering cultured human cells, mouse models, and human clinical trials. The session will answer questions such as how do CRISPR-Cas9 and piRNAs work, and what are the benefits and challenges facing their integration into the field of toxicology? Can CRISPR-Cas9 genomic editing be used to explore the role of key toxicity-associated pathways, such as NF-κB and NRF2, in the response to oxidative stress? How can the targeted modification of epigenetic states with dCas9 and piRNAs be used to provide causative relationships between specific epigenetic loci and disease/exposure outcomes? What is the current state of CRISPR-based therapies, and how does the toxicity and efficacy testing of these next-generation pharmaceuticals differ from that used for traditional therapeutic agents? The session will reveal a better understanding for the benefits, challenges, and applications of genome- and epigenome-engineering approaches in toxicology studies and will provide perspective on the unique considerations required during the development and testing of these technologies as next-generation therapeutic agents.
novel methodology represents a relatively easy and inexpensive option for reliably modulating gene expression and dissecting the role of transcription factors such as Nrf2, or other genes involved in the response to toxic stimuli. Overall, our studies demonstrate an important role for Nrf2 in modulating T cell function, suggesting activation of Nrf2 could be a useful marker for predicting immunomodulatory potential of chemicals. CRISPR-Cas9 was an important tool for these studies that also has broad applicability for a variety of different mechanistic studies in toxicology.

**1697 Applications of CRISPR-Cas9-Based Epigenetic Editing Technologies in Modeling and Treating Human Disease**

I. Hilton. Rice University, Houston, TX. Sponsor: S. McCullough

The ability to define the relationships between endogenous genetic and epigenetic variation and human disease is lacking. This limitation is especially pressing for diseases that are linked to dynamic environmental and/or inflammatory signals, and therefore have multiple potential pathological drivers. The repurposing of prokaryotic CRISPR-Cas9 adaptive immune systems has revolutionized the capacity to engineer the human genome and created tools to meet these critical needs. The nuclease activity of Cas9 can be abolished to produce a “deactivated” genomic targeting platform called dCas9. The dCas9 scaffold can be combined with transcriptional or epigenetic effector domains to finely tune the expression of endogenous genes and artificially deposit epigenetic signatures. We have developed a novel epigene editing tool by fusing the catalytic core of the human EP300 acetyltransferase to dCas9 (dCas9-p300). We have used this programmable acetyltransferase to demonstrate the causal linkage between endogenous chromatin acetylation and subsequent gene expression. Moreover, we have shown that dCas9-p300 robustly activates gene expression from endogenous enhancers and promoters, thus expanding the targeting capacity of epigene editing tools. Additionally, we have developed a high-throughput epigene editing platform to functionally interrogate the noncoding human genome. Importantly, these epigene editing strategies can be used to assign the function of epigenetic signatures and to activate or suppress the transcription of genes putatively involved in disease phenotype, and have the potential to modulate exposure effects and susceptibility at the epigenetic level. For instance, our group has used these approaches to activate and suppress loci involved in human disease and inflammation, including the human globin genes, TNFR1, and IL1R1. Cutting-edge CRISPR-Cas9-based genome and epigenome engineering technologies will continue to impact basic and translational research into the foreseeable future. This talk will provide an overview of the principles that govern the use of these tools in establishing molecular mechanisms underlying human disease and in exploring cellular responses to toxic exposures and inflammation. In addition, the potential therapeutic applications of these technologies in clinical settings will be discussed.

**1698 Development of piRNAs for Target-Specific DNA Methylation**

D. C. Dolinoy. University of Michigan, Ann Arbor, MI.

Epigenetic changes to DNA are associated with age, disease, and environmental influences. Precision modification of the epigenome holds great promise for our ability to modify environmentally induced changes in gene expression, yet it is currently out of reach using common techniques (drugs, transgenics, etc.). Through a NIH Director’s Transformative Award we are developing a suite of tools, based on the Piwi-interacting RNA (piRNA) system, to advance precision epigenetic editing, while avoiding off-target effects and immunogenicity, and immunotoxicity caused by the bacterial Cas9 protein will be described and discussed in the context of US and EU authority expectations. In addition, typical gene-medicine related challenges like the definition of a safe human starting dose or identification of a useful marker for predicting immunomodulatory potential of chemicals. The 2016 Workshop Session “Cannabis in the Courtroom” explored topical areas for scientific testimony and briefly touched on the public health and safety impacts of legalized marijuana products. This session expanded upon topics raised during the 2016 session which relate to the lack of federal oversight of the cannabis industry. With the growing acceptance of marijuana use and its legalization in some form (medical, recreational) by 28 states and the District of Columbia, including new medical marijuana legislation passed in Texas in 2017, marijuana has become a booming business that essentially is unregulated at the federal level because of the conflict imposed through listing of marijuana as a Schedule I drug by the Drug Enforcement Administration (DEA). Texas has just passed medical marijuana laws in limited cases, opening up a new market for entrepreneurs in the state. Currently, the US government has relinquished authority to the states with respect to the growing, distributing, and selling of marijuana where it is legal to do so under state laws. This session will explore the impact of the current absence of federal oversight on public health and safety by presenting a number of scenarios and outcomes stemming from the widespread and legal uses of cannabis in more than half of the states and the stark differences in individual state regulations. Topics will include: 1) safety concerns for edible marijuana products; 2) regulatory status of marijuana and its implications for academic research; 3) policy implications for federal authorities in light of public perceptions of marijuana’s benefits and risks; and 4) patient safety concerns with use of non-approved drug products and access to such products. The session will include a discussion from the legal perspective on the problems encountered with the “hands-off” approach currently taken by the federal government and will conclude with a panel discussion.
1703 Ensuring the Safety of “Edibles” in West Virginia: Lessons Learned for New Medical Marijuana Legislation in Texas

E. Janus. Compassion West Virginia, Huntington, WV.

Cannabis as a medicine, as dispensed by state-authorized programs, is now available to over half the population of the United States and growing. Edible products are a rapidly growing segment of the medical and recreational cannabis programs, and the safety of these products is a concern addressed in different ways by different state regulators. A review of the regulation and safety of edible cannabis products will be provided along with what is known about exposure trends. Colorado legalized the retail sale of recreational marijuana in late 2012, and the first retail stores opened for business on January 1, 2014. Since that time, calls to the Rocky Mountain Poison Center (RMPC) for marijuana exposures have increased and subsequently plateaued. With the rising delta-9-tetrahydrocannabinol (THC) concentrations in products, much national attention has been paid to the state of Colorado for observations of epidemiologic and medical outcome following recreational marijuana use. The purpose of this presentation is to investigate and discuss the various effects of the legalization of recreational cannabis from the RMPC perspective. All calls to our poison center involving marijuana exposures from January 1, 2015 to December 31, 2016 were identified and analyzed. Data collected included age, gender, product type, referring facility, clinical outcome, signs, and symptoms. The total number of reports of exposures called to the RMPC to marijuana products increased from 225 in 2015, to 231 in 2015, and 237 in 2016. As observed in both 2014 and 2015, the most common age group involved was 13 to 19 years (N=170; 75.5%). The pediatric cases were defined as under 12 years (N=19; 9.1%). Of the pediatric cases, 6-0 years of age were responsible for 9 of the 19 pediatric cases (47.4%). Of the total pediatric cases, 107 (51.1%) were children under 5 years old, many of which were accidental child ingestions. Of the total pediatric cases, 51.1% were children under 5 years old, many of which were accidental child ingestions. Of the total pediatric cases, 51.1% were children under 5 years old, many of which were accidental child ingestions. Of the total pediatric cases, 51.1% were children under 5 years old, many of which were accidental child ingestions. Of the total pediatric cases, 51.1% were children under 5 years old, many of which were accidental child ingestions. Of the total pediatric cases, 51.1% were children under 5 years old, many of which were accidental child ingestions. Of the total pediatric cases, 51.1% were children under 5 years old, many of which were accidental child ingestions. Of the total pediatric cases, 51.1% were children under 5 years old, many of which were accidental child ingestions. 1705 Mechanism-Driven Computational Modeling of Hepatotoxicity Based on Chemical Information, Biological Data, and Toxicity Pathways

L. Zhao1, W. Wang1, D. P. Russo1, L. M. Aleksunes2, and H. Zhu1.
1 Rutgers, The State University of New Jersey, Camden, NJ; and 2 Rutgers, The State University of New Jersey, Piscataway, NJ.

Hepatotoxicity is a leading cause of attrition in drug development and has resulted in a considerable number of drug withdrawals from the market. Traditional preclinical and clinical studies to evaluate drug hepatotoxicity are expensive and time-consuming. With the advent of critical advancements in in vitro testing approaches, in particular High Throughput Screening (HTS), there has been a rapid accumulation of chemical toxicity data and a critical need to combine this data with available biological datasets. Together, big data offer a novel alternative approach to evaluate hepatotoxicity potential for new and existing chemicals. To this end, we curated and merged all available in vivo hepatotoxicity data obtained from the literature and public database resources, which yielded a comprehensive dataset of ~4,000 unique compounds that could be categorized as hepatotoxic or non-hepatotoxic in human. For compounds in this datasets, ToxPrint Chemotypes from ChemoTyper® were used to generate potential structural toxicophores. Next, biological responses were profiled using in-house automatic data mining tool to search against the PubChem BioAssay database. Then, the chemical-biological data were clustered based on chemical-in vitro relationships. Using the clustered bioprofiles of the training set containing over 2,500 compounds, multiple read-across models were developed that showed acceptable predictivity in the cross validation procedure (positive predictive values: 0.87 to 1.00). By integrating toxicophore information into top chemical-in vitro-in vivo relationships, the predictivity was further improved by 12.8% to 68.0% for 14 models (positive predictive values: 0.72 to 0.96). These selected models could be used to predict the hepatotoxic potential of over 1,200 external new compounds and achieved similar performance (positive predictive values: 0.64 to 1.00). The chemical-in vitro-in vivo relationships obtained from these top ranked models can
be integrated into several adverse outcome pathways (AOPs). This study developed new computational read-across models based on substantial publicly available data that can be used to predict the hepatotoxicity of new compounds and elucidate novel mechanisms of injury by integrating chemical and biological data into toxicity pathways.

### 1706 Development of an Animal Model of Abacavir-Induced HLA-Mediated Liver Injury

B. Song, S. Aoki, and K. Ito. Chiba University, Chiba, Japan. Sponsor: T. Satoh

Genome-wide association studies have indicated that adverse drug reactions are highly associated with specific Human Leukocyte Antigens (HLA) alleles. For instance, abacavir induced hypersensitivity syndrome and fluclouxacinil induced liver injury are associated with HLA-B*57:01 allele. Carbamazepine induced Stevens-Johnson syndrome/toxic epidermal necrosis is associated with HLA-B*15:02 allele. However, the mechanism of pathogenesis is still unclear due to the lack of desirable animal models. Abacavir, a human immunodeficiency virus reverse transcriptase inhibitor, can induce multi-organ toxicity exclusively in patients carrying the HLA-B*57:01 allele. Previously, we have originally developed HLA-B*57:01 transgenic mice, and found that topical application of abacavir on mice ears could provoke proliferation of CDB+ lymphocytes in the local lymph nodes. Here we challenged to reproduce abacavir-induced liver injury in these mice. However, oral administration of abacavir alone to HLA-B*57:01 transgenic mice did not elevate alanine aminotransferase (ALT, a liver injury marker). Considering the importance of innate immune activation, HLA-B*57:01 transgenic mice, their littermates and HLA-B*57:03 transgenic mice (as negative control mice) were co-treated with abacavir and CpG-oligodeoxynucleotide (a toll-like receptor 9 agonist). By the co-treatment, significant elevation of ALT, pathological change in liver, increase of activated CD8+ T cells, and tissue infiltration of immune cells were observed exclusively in HLA-B*57:01 transgenic mice. These results indicated that CpG-oligodeoxynucleotide induced inflammatory reactions or innate immune activations are indispensable for abacavir-induced HLA-mediated liver injury. In addition, abacavir-induced liver injury was mainly resulted from CD8+ T cells. Collectively, we developed for the first time HLA-mediated drug-induced idiopathic liver injury mouse model by treating HLA-B*57:01 transgenic mice with abacavir and CpG-oligodeoxynucleotide. This model has a potential use in unmasking the mechanism of HLA-mediated idiopathic adverse drug reactions, promoting drug development, and contributing to personalized medicine.

### 1707 PCBs Alter the Hepatic Phosphoproteome in TASH

Nonalcoholic fatty liver disease (NAFLD) can be caused by hyperal- loric diets in combination with environmental exposures to pollutants such as polychlorinated biphenyls (PCBs). PCBs may act as a second hit driving disease progression from steatosis to steatohepatitis. Nuclear receptor and kinase function is regulated by phosphorylation and both have been implicated in the pathogenesis of steatohepatitis. Limited data exist on the phosphoproteome alterations in NAFLD animal models. Polychlorinated biphenyl (PCB) exposure has been shown to promote liver disease in a residential human population and in diet induced obesity animal models. Identifying kinase phosphorylation alterations in the pathogenesis of toxicant-mediated NASH will elucidate therapeutic interventions to prevent steatohepatitis. C57BL/6 mice were fed either a control diet or high fat diet and treated with either corn oil or Aroclor 1260 (20mg/kg) by gavage. In this study, we used titanium dioxide phosphopeptide enrichment from mouse liver tissue and conducted LC/MS/MS analysis to measure phosphorylated proteins in each sample. Peptides sequences identified from the spectra were matched to the Mouse Protein database to identify the proteins. PEAKS Studio 8 software was used to quantitate the normalized abundance of select phosphopeptides. A total of 1765 phospho-peptides were identified in this study. Within the dietary-PCB interaction group 23.8% of the total phosphosites detected were significantly decreased. CDKS, CDC2, AKT, CK1, and ERK were among the most affected pathways. This work demonstrates that kinases are modulated in the pathogenesis of NASH. This global loss of protein phosphorylation in the liver may be due in part to multiple signalling pathways being diminished in the pathogenesis of NAFLD.

### 1708 Combined Inhibition of MET and EGFR Signaling Abolishes Hepatocyte Proliferation and Fibrosis Induced by TCPOBOP (1,4-bis [2-(3,5-Dichloropyridylxyloxy)] Benzene) in Mice

B. Bhushan, and G. K. Michalopoulos. University of Pittsburgh School of Medicine, Pittsburgh, PA.

TCPOBOP (1,4-Bis [2-(3,5-Dichloropyridylxyloxy)] benzene) is a constitutive androstane receptor (CAR) agonist that induces robust hepatocyte proliferation and hepatomegaly without any liver injury or tissue loss. A recent study demonstrated that TCPOBOP-induced regeneration can protect liver from failure even in massive tissue loss (91% hepatec- tomy), indicating great clinical potential. However, mechanisms of TCPOBOP-induced hyperplasia are highly underexplored. TCPOBOP-induced hyperplasia is known to be CAR-dependent with no evidence of involvement of cytokines and growth factors signaling. Receptor tyrosine kinases MET and epidermal growth factor receptor (EGFR) are known to play a critical role in liver regeneration after partial hepa- toctomy, but their role in TCPOBOP-induced direct hyperplasia is not yet explored, which was investigated in the current study. Since these receptor tyrosine kinases are known to compensate for each other, MET KO mice were treated with Carcaptinib, an EGFR inhibitor (EGFRI), for combined inhibition of MET and EGFR signaling. Combined inhibition of MET and EGFR signaling (MET KO + EGFRI) dramatically reduced TCPOBOP- induced hepatomegaly and remarkably attenuated hepatocyte proliferation. Effects were not significant by elimination of individual receptor tyrosine kinase signaling (MET KO or EGFRI). Effect of combined elimi- nation on hepatocyte proliferation was found to be more pronounced in females compared to males. Interestingly, nuclear translocation of CAR and expression of CAR target genes were not altered in MET KO + EGFRI mice, indicating CAR activation is not affected. However, induc- tion of Cyclin D1, a key regulator of cell cycle entry, was almost com- pletely abolished in MET KO + EGFRI mice. A similar pattern was also observed for other cyclins (Cyclin A and B) that govern cell cycle pro- gression. FOXM1 is a key transcription factor that governs transcription of genes important for DNA replication/mitosis and regulates TCPOBOP- mediated hepatocyte proliferation. TCPOBOP-driven induction of FOXM1 and its target genes was remarkably diminished in MET KO + EGFRI mice. In conclusion, our study revealed a novel role of signaling via MET and EGFR receptors in hepatomegaly and hepatocyte prolifera- tion induced by TCPOBOP.

### 1709 Comparative Analysis of Toxicokinetics and Toxicodynamics of Perclorehylene in Cytochrome P450 2E1 Knockout and Humanized Transgenic Mice

Y. Luo1, S. Furuya1, H. Yoo2, and I. Rusyn1. 1. Texas A&M University, College Station, TX; and 2. University of North Carolina at Chapel Hill, Chapel Hill, NC.

Perclorehylene (PCE), a commonly used dry-cleaning solvent, is a probable human carcinogen. Toxicity of PCE is associated with generation of oxidative and glutathione conjugation metabolites. Upon absorption, PCE can be metabolically activated by cytochrome P450s (CYPs) to trichloroacetic acid (TCA), or conjugated with glutathione to metabolites with nephrotoxic potential, S-(1, 2, 2-trichlorovinyl) glutathione (NAcTCVC). These pathways are qualitatively similar, but quantitatively different across species. It is thought that CYP2E1 is crucial to PCE oxidation, and may play a role in bio-activation of nephrotoxic metabolites; however, inter-species differ- ences in the contribution of CYP2E1 to PCE metabolism and toxicity are not well understood. Therefore, the role of CYP2E1 in metabolism and toxic effects of PCE was investigated using male and female wild-type [Sv129], Cyp2e1-null [Cyp2e1(-/-)], and humanized Cyp2e1 [hCyp2e1] mice. It was hypothesized that CYP2E1 status would determine the extent of oxidative metabolism of PCE which would be pronounced impact on the toxicity of PCE. Mice were dosed with PCE (500 mg/kg, p.o.) or vehicle (5% alkamuls EL-620 in saline) for 5 consecutive days. Liver, kidney, and serum were collected 2 hours after the last treat- ment. The amounts of TCA formed in liver of PCE-treated animals in both sexes were significantly lower in Cyp2e1(-/-) and humanized Cyp2e1 (hCyp2e1) mice. It was hypothesized that CYP2E1 status would determine the extent of oxidative metabolism via TCA pathway. PCE metabolism was significantly higher in female mice. However, PCE-induced lipid accumulation was found in livers of Sv129 mice. PCE-induced proximal tubule injury in both sexes was Cyp2e1 mouse. In conclusion, our results indicate that PCE toxicity is determined by CYP2E1 activity and that sex differences in CYP2E1 function lead to species differences in the metabolism and toxicity of PCE.
demonstrate that CYP2E1 is an important, but not exclusive player in the oxidative metabolism of PCE, as well as PCE-induced toxicity in mouse liver and kidney. Therefore, inter-species and inter-individual differences in CYP2E1 function may contribute not only to the differences in PCE metabolism, but also to differences in PCE-induced toxicity.

**1710 A High-Throughput Screen Identifies Novel Targets for Kidney Tubular Regeneration**

M. B. Monteiro, S. Ramm, V. Chandrasekaran, and V. Vaidya

Harvard Medical School, Boston, MA; and Brigham and Women’s Hospital, Boston, MA.

Acute kidney injury (AKI) is associated with substantial morbidity and mortality, and often serves as the precursor to chronic kidney disease, which can only be managed supportively, with no curative therapy. Kidney proximal tubular epithelial cells (PTECs) contribute the most towards tubule repair, playing a key role in regeneration after injury. To uncover new molecules that can promote tubular regeneration, we performed a high-throughput phenotypic screening of 1902 compounds at 11 µM, measuring increases in proliferation of primary human PTECs. After 48h of treatment, 129 compounds promoted an average increase in Normalized Cell Count (NCC) >1.1 compared to the initial count (0h). Clear separation of positive, negative and toxic controls showed sensitivity (Z-factor >0.3) and a correlation coefficient of 0.86 amongst duplicates to define a dose response (DRC) and a 2-fold increase in positive hits at 1µM, 3µM, 10µM and 30µM confirmed eight compounds as pro-proliferative based on an increase in NCC >1.1 and an increase in actively cycling Edu-positive cells >6.5%. Furthermore, we determined the impact of these compounds on tubular cell proliferation under basal conditions and after the different types of injury: hypoxia (1% O2; for 24h); drug-induced toxicity (Cyclosporin A, 7.5µM or CdCl2, 15µM) and in vitro. We have identified potential first-in-class compounds that stimulate kidney tubular epithelial cell proliferation after acute kidney injury in vitro.

**1711 2,3,7,8-Tetrachlorodibenzo-p-dioxin-Elicted Dysregulation of Bone Remodeling Produces an Osteopetrosis-Like Phenotype in Male and Female C57BL/6 Mice**

K. A. Fader, R. Nault, S. Raehlt, L. McCabe, and T. Zacharewski

Michigan State University, East Lansing, MI.

Aryl hydrocarbon receptor (AhR) activation alters bone morphology and remodeling in a species, ligand, and regal specific manner; however, the underlying mechanisms remain poorly understood. We examined the dose-dependent effects of 2,3,7,8-tetrachlorodibenzo-p-dioxin (TCDD; 0.01-30 µg/kg) on femoral microarchitecture and gene expression in male and female mice following oral gavage every 4 days for 28 days. Micro-computed tomography revealed a dose-dependent 2.5-fold increase in trabecular bone area density (BMD) and a 2.9-fold increase in bone volume fraction (BVF) in male femurs, with similar increases in females. Bone marrow adiposity in the distal trabecular region of the femur was reduced 4.1-fold in both sexes. Decreased serum levels of bone turnover markers including tartrate-resistant acid phosphatase (TRAP), amino-terminal propeptide of type 1 collagen (P1NP), and osteocalcin, combined with femoral repression of proteases required for degradation of organic bone matrix (cathepsin K, matrix metalloproteinase 13), suggest both bone resorption and formation were affected by TCDD. Differential gene expression in the male femur was associated with bone development and regulation of mineral and structural biosynthesis, and chemotaxis. Notably, femoral expression of transmembrane glycoprotein NMB (Gpnmb), which plays a crucial role in osteoclast and osteoblast differentiation and function, was dose-dependently induced 18.8-fold. Moreover, increased serum 1,25-dihydroxyvitamin D3 levels were consistent with TCDD-elicited renal induction of 1α-hydroxylase Cyp27b1 and may contribute to impaired bone resorption. In summary, AhR activation by TCDD alters the bone resorption – formation balance, resulting in an osteopetrosis-like phenotype with increased BMD.

**1712 Role of AhR in the Susceptibility to Type 1 Diabetes**

A. K. Ehrlich, J. Pennington, N. Shulzenko, A. Morgun, and N. L. Kerkvliet

Oregon State University, Corvallis, OR.

In recent years, there has been a steady rise in the incidence of type 1 diabetes (T1D), a childhood disease characterized by insulin-dependent hyperglycemia due to immune-mediated destruction of insulin-producing beta cells. Genetic factors only partially account for T1D risk; therefore, environmental factors must play a critical role in the disease process. Two environmental factors that have been linked to T1D susceptibility include diet and an alteration in the intestinal microbiome. Furthermore, metabolites derived from the diet and microbiome have been shown to activate the aryl hydrocarbon receptor (AhR), a ligand-activated transcription factor that regulates the immune response. In our studies, we hypothesized that these diet- and microbial-derived endogenous AhR ligands influence the development of T1D. To test this hypothesis, we generated NOD.AhR+/+ mice and compared the incidence of diabetes (BGL > 250 mg/dL) in wild-type NOD mice to their AhR-deficient littermates at 30 weeks of age. Unexpectedly, female NOD.AhR-/- mice had a decreased incidence and onset of diabetes in comparison to the NOD. AhR+/+ mice. A similar trend was observed between knockout and wild type male mice. While immune cell composition was unchanged in relation to AhR status in the pancreatic lymph nodes, the percentage of F4/80+ macrophages and CD25+Foxp3+ T cells was higher in the mesenteric LN of NOD.AhR-/- mice in comparison to NOD.AhR+/+ mice. The expression of genes that have been associated with AhR activation in the intestines was compared between NOD.AhR+/+ and NOD.AhR-/- mice. In the ileum, NOD.AhR-/- mice had a reduced expression of genes encoding the antimicrobial peptides Gzmb and Lcn2 in comparison to NOD.AhR+/+ mice, consistent with prior findings. In addition, preliminary data show that NOD.AhR-/- mice have increased Bacteroidales family bacteria (S24-7) and decreased Ruminococcus gnavus in comparison to NOD.AhR-/- mice. Interestingly, previous studies have shown that S24-7 bacteria are associated with T1D protection while Ruminococcus bacteria are associated with T1D promotion, consistent with the reduced incidence of diabetes in NOD.AhR-/- mice compared to NOD.AhR+/+ mice. Current studies are focused on determining if AhR-dependent shifts in the microbiome directly impact diabetes incidence with the goal of identifying dietary and/or bacterial interventions that could reduce susceptibility to T1D.

**1713 Live Animal Molecular Imaging Techniques Demonstrate that Anti-Tumor Necrosis Factor-α Antibody Mitigates Lung Injury Induced by Nitrogen Mustard**

A. Murray, A. Venosa, R. Malaviya, D. Adler, E. Yurkow, A. J. Gow, J. D. Laskin, and D. L. Laskin, Rutgers, The State University of New Jersey, Piscataway, NJ.

Nitrogen mustard (NM) is a cytotoxic alkylating agent that causes acute lung injury which progresses to fibrosis. This is associated with upregulation of the proinflammatory/profibrotic cytokine, tumor necrosis factor alpha (TNFα). Previously we demonstrated that anti-TNFα antibody was effective in mitigating NM-induced lung injury. In the present studies, we used high definition magnetic resonance imaging (MRI) and computed tomography (CT) to follow the progression of NM-induced injury and the effects of anti-TNFα antibody. Anti-TNFα antibody was administered i.v. to male Wistar rats (15 mg/kg, every 8 days) beginning 30 min after i.t. instillation of PBS or NM (0.125 mg/kg). CT and gradient (GRE) and fast spin echo (FSE) MRI scans were performed 1, 3, 7, 14, 21, and 28 d post exposure. CT scans showed that in control animals, total lung volume increased with time. Treatment of rats with NM resulted in a significant loss of lung volume, which was most prominent at 1 and 3 d post NM; this was ameliorated by anti-TNFα antibody. MRI imaging showed low-density shadows at 1 and 3 d post NM, indicative of fluid buildup, a response also reduced by anti-TNFα. CT scans were also used to assess the functional respiratory area of the lung (by comparing signal intensity). At 28 d, the relative respiratory area of the lung of NM treated animals was reduced when compared to control animals (0.377 - 0.532 vs. 0.965-1.027). This loss of respiratory volume was confirmed by MRI and histology. Anti-TNFα antibody treatment of the animals partially restored the decrease in respiratory volume (0.729-0.827). These data show that MRI and CT imaging efficiently track the progression of NM-induced lung injury in live animals and can be used to monitor potential therapeutics, such as anti-TNFα antibody. NIH ES04738, AR055073, ES050522, and HL086621.
Triclosan (TCS) is an antimicrobial used at high concentrations in hospitals and consumer products. Mast cells, which share signal transduction elements with numerous other cell types (such as T cells and neurons), are found throughout the body and play key roles in various physiological processes. When activated, mast cells secrete cytoplasmic granules (degranulation). Simultaneously, actin causes cellular movements (ruffling). We previously showed that TCS inhibits mast cell degranulation and membrane ruffling in antigen (Ag)-stimulated rat mast cells (RBL-2H3). We found that these effects are due, at least in part, to triclosan’s inhibition of Ag-stimulated Ca2+ influx. This result led us to hypothesize that signaling enzymes downstream of Ca2+ rise, such as phospholipase D (PLD) and protein kinase C (PKC), would be affected by TCS. We found that TCS inhibits the activity of PLD in Ag-stimulated mast cells. TCS has no effect on the activity of PKC, as measured by an ELISA which simultaneously detects activity of 8 isoforms (α, β, γ, δ, ε, η, ι, ζ). Thus, for greater specificity in assessing triclosan’s effects on PKC, we further investigated the individual PKC isoforms, in particular PKCβII and δ, which are important in mast cell degranulation and ruffling. Using PKCβII-EYFP constructs, we found rapid (within ~2 min of Ag addition) translocation of PKCβII from cytosol to plasma membrane. Surprisingly, neither translocation (%) nor time to translocation of this Ca2+-dependent PKC isoform was affected by TCS, even under experimental conditions in which TCS inhibited degranulation and ruffling. A similar lack of TCS effect on PKC translocation was found in additional experiments with 15 and 45 min antigen exposures. Overall, these ELISA and confocal results suggest that PKC activity is not a major target of TCS and that triclosan’s disruption of mast cell function is likely not mediated through PKC. We are now investigating TCS effects on PKC δ translocation. These data deepen the understanding of TCS inhibition of signal transduction in mast and related cells.
**1719 From Bedside to Bench: What Only Our Patients Can Teach Us**

S. Bradberry, National Poisons Information Service (Birmingham Unit) and West Midlands Poisons Unit, Birmingham, United Kingdom.

One of the greatest challenges faced in recent years by clinical toxicologists practising in an acute hospital setting is the diagnosis and management of individuals intoxicated with new psychoactive substances. Global legislative bodies have struggled to implement effective and workable strategies to reduce the harm caused by these agents, not least because as fast as one drug is controlled an analogue is developed to circumvent the law. The resulting rate of change of chemical structures encountered has led to a multiplicity of pharmacological and toxicological effects including an increasing number of deaths. The challenge for the clinician is increased by a paucity of toxicodynamic and toxicokinetic data linked fundamentally to the fact that even the chemicals involved may not be known. In the emergency department, physicians learn their most valuable lessons directly from their patients, building diagnostic and management expertise largely by direct experience. Rapid access to comprehensive sophisticated analytical methods (such as ultra performance liquid chromatography with exact mass time of flight/TOF) has become increasingly important in establishing an accurate diagnosis, literally clarifying what is happening at the bedside only by returning to the bench. TOF analysis typically screens qualitatively for over 1,000 drugs and metabolites and it is the norm for there to be an extremely poor correlation between what patients state or believe they have taken and what is identified in their bodily fluids. In addition, “unknown” compounds are frequently detected weeks or months before that compound is formally named and recognized as a psychoactive substance. Chemical standards or markers for these new agents are obtained only when patients are prepared to provide samples of their purchases or direct toxicologists to an appropriate website. These markers can then be used to retrospectively clarify agents taken by individuals for whom no formal diagnosis had previously been possible. Two important classes of novel psychoactive substances, the amphetamine-like cathinones and the synthetic cannabinoids admirably demonstrate the importance of this concept of bedside to bench translational toxicology.

**1720 Importance of Translation from In Vitro Testing to Approved Products and Treatments**

D. Mendrick, US FDA, Silver Spring, MD.

It is critical to be able to translate findings from the in vitro environment to the clinic and back again to make progress in developing new treatments and enabling patient care. We need more human relevant data in regulatory decision making although that can be very difficult as 1) humans do not always predict humans reliably since many drugs show toxicity issues after they are marketed and, 2) poisons and new drugs of abuse cannot ethically be tested on humans. One way to proceed is to identify biomarkers of disease and toxicity to enable translation from cell culture to animals to humans. Biomarkers of population response and individual reactions (i.e., precision medicine) are needed although, in some cases, implementation may prove to be too expensive for routine use. To accomplish this broad mission, there is a critical need for involvement of experts in all areas from the bench to the bedside to ensure public health.

**1721 Mitochondria Biogenesis and Dysfunction in Cellular Senescence in Cardiopulmonary System**

I. Rahman, University of Rochester, Rochester, NY.

Emerging evidence sheds light on new mitochondrial functions that are not related to cellular energy production, which involve mitophagy (removal of damaged mitochondria from a cell prior to cell death) and mitochondrial protein quality control. Mitochondrial function is associated with aging, cell death, and disease. Mitochondrial proteins, such as Pink1, Parkin, and Drp1, along with sub-organellar signaling by oxidant stress and redox changes, are involved in mitochondrial dysfunction. This is associated with inflammation and cellular senescence via DNA damage and alterations in telomere shortening complex (a complex which protects telomeres from DNA damage). Toxicological perspectives on mitochondrial or mitochondria toxicity (MitoTox) research include a multidisciplinary approach in different target organs in the pathogenesis of cardiopulmonary and vascular diseases. The goal of this session is to highlight the recent advances of mitochondria research in toxicology, particularly in mitochondrial biogenesis, dysfunctional mitophagy, redox changes, cell signaling, and DNA damage/repair or rejuvenation of the damaged mitochondria upon toxic chemical or environmental insults in epithelial cells, fibroblasts, and myocytes in cellular senescence (premature aging) of the cardiopulmonary system. The information in the session will share the change in paradigm of involvement of mitochondrial stress signaling that would improve the gap in understanding the mechanisms of mitochondrial dysfunction in cellular senescence in the cardiopulmonary system.

**1722 Mitochondria-Nuclear Signaling and Mitophagy by Toxicants in DNA Damage and Lung Cellular Senescence**

I. Rahman, University of Rochester, Rochester, NY.

The presentation will focus on the involvement of mitophagy in stress-induced cellular senescence in the pathogenesis of chronic inflammatory diseases in response to toxicants. Environmental tobacco smoke and toxicants/oxidants-mediated alterations of mitophagy (Pink1, Parkin) are known to occur in stress-induced DNA damage and cellular senescence. Impaired mitophagy and perinuclear accumulation of damaged mitochondria are described by redox stress during cellular senescence, and this phenomenon is due to suborganellar signaling. Current knowledge on mitophagy field in relation to stress-induced cellular senescence will be discussed.

**1723 Impairment of Mitochondrial Function by Particulate Matter and Nanomaterials in Cardiovascular and Pulmonary Diseases**

J. M. Hollander, West Virginia University School of Medicine, Morgantown, WV. Sponsor: I. Rahman.

Detrimental effects on mitochondria have been proposed to play important roles in cardiovascular disease pathogenesis. Strong evidence from a multitude of studies suggest that impairment of the mitochondrion may contribute to cardiac contractile dysfunction and atherosclerosis, both of which may be the result of disruption to critical mitochondrial processes involving various proteins and miRNA. Increasing evidence suggests that reactive oxygen species (ROS) and oxidative stress are involved in airborne particulate matter (PM), diesel exhaust, and nanoparticles-mediated lung and cardiovascular injury (endothelium, myocytes and microvascularitites). The physical characteristics and the chemical composition of PM and nanoparticles play a key role in ROS generation in vitro and in vivo. The mitochondria are major subcellular targets for PM and nanoparticles as well as a source of ROS production. Another mechanism is direct physical targeting by ambient ultrafine particles that affect redox status of the cells and mitochondrial structure. Further, nanoparticles, including nanomaterials or ambient particles, cause mitochondrial aberrations and cellular senescence. An understanding of the mitochondrial effects of these particles is key in understanding the mechanisms of particle-induced adverse health effects and exacerbations via impaired mitophagy.

**1724 Cardiovascular Mitochondrial Dynamics and Dysfunction by Exposure to Ultralite or Nano Particulate Matter**

C. J. Wingard, Bellarmine University, Louisville, KY.

Increasing evidence suggests that reactive oxygen species (ROS) and oxidative stress are involved in airborne or engineered particulate matter (PM)-mediated lung and cardiovascular injury. The mitochondria are novel subcellular targets for nanoparticles as well as a source of ROS production. Excessive ROS production with alteration of mitochondrial electron transfer and permeability transition (PT) pore opening is associated cardiovascular dysfunction. In this presentation, we will discuss evidence for a hypothesis that nanoparticles can mediate mitochondrial aberrations in driving cardiopulmonary diseases (e.g. ischemia-reperfusion, fusion, and mitotanding of the mitochondrial effects (e.g. redox changes, bioenergetics, and PT) of these particles can be critical in understanding the mechanisms of particle-induced adverse health effects and exacerbations in cardiopulmonary system.
1725 Mitochondrial DNA Damage and Dysfunction in Vascular Disease by Environmental Toxicants
J. L. Fetterman, Boston University School of Medicine, Boston, MA. Sponsor: I. Rahman

Cardiovascular risk factors increase oxidative stress within the vasculature resulting in the loss of nitric oxide bioavailability and chronic inflammation. Mitochondria are an important source of oxidants, and are particularly sensitive to oxidative damage. Evidence suggests that mitochondrial damage and abnormalities are a significant contributor to vascular dysfunction and may even precede the development of atherosclerotic plaques. We found that elevated mitochondrial DNA damage was associated with type 2 diabetes and clinical atherosclerosis even after adjustment for age and sex. Endothelial cells from type 2 diabetic patients had higher mitochondrial oxidant production compared to cells from non-diabetic patients. Endothelial cells from type 2 diabetes had lower levels of proteins involved in the regulation of mitochondrial turnover through autophagy (p62, LC3B, Fis1) and proteins involved in mitochondrial displacement through biogenesis (TFAM, NRF-1). Up-regulation of autophagy restored mitochondrial networks and lowered mitochondrial oxidant production in commercially available endothelial cells under high glucose. Additionally, autophagy up-regulation improved insulin-induced nitric oxide production and eNOS activation in both high glucose treated endothelial cells and endothelial cells from diabetic patients, suggesting improving mitochondrial turnover may be a potential therapeutic target for improving diabetic vascular disease. Further, mitochondria are highly sensitive to environmental toxicants and may serve as biomarkers of injury. Endothelial cells from traditional cigarette smokers or electronic cigarette users were associated with increased mitochondrial oxidant production and vascular dysfunction (increased inflammation and decreased nitric oxide bioavailability). This presentation by a junior/emerging toxicologist/investigator will provide recent research findings on mitochondrial DNA damage and vascular function in vascular disease by environmental toxicants.

1726 Redox Regulation of Mitochondrial Dysfunction and Cellular Senescence in Atherosclerosis
R. Asmis, University of Texas Health Science Center at San Antonio, San Antonio, TX. Sponsor: I. Rahman

This presentation will be by a local talented researcher interested in redox regulation of mitochondrial function in cardiovascular disease. Mitochondrial dysfunction leads to increased ROS production, which is a critical aspect of heart failure. Regulation by ROS and protein S-glutathionylation is an important process in mitochondrial respiration. Alteration in protein S-glutathionylation via thioltransferase glutaredoxin 2a can disrupts mitochondrial respiration and ATP production in macrophages in proatherogenic responses. The mitochondria changes in heart failure and the downstream effects of these changes will be presented.

1727 Advancing the Adverse Outcome Pathway Framework: An International Horizon-Scanning Approach
R. Conolly, US EPA, Research Triangle Park, NC.

In 2007, the US National Research Council laid out a vision and strategy for toxicity testing in the 21st century, which aspired to transform current testing approaches by making greater use of recent scientific advances in cell-based and computational methods. The adverse outcome pathway (AOP) framework, which emerged to address this vision, has since gained international traction as a systematic approach for capturing existing knowledge to transparently link mechanistic data to apical toxicity endpoints as a means to inform research and risk assessment. While the framework has evolved significantly since its introduction in 2010, it was recognized that a survey of the broader scientific community would be useful in identifying challenges and in guiding future initiatives. To that end, a horizon-scanning exercise was conducted to solicit questions from the global scientific and regulatory communities, including the SOT community, regarding the perceived challenges and/or limitations that must be addressed to realize the full potential of the AOP framework. Following this exercise, a Society of Environmental Toxicology and Chemistry (SETAC) Pellston Workshop, comprised of international participants representing industry, government, academia, and non-governmental organizations (NGOs), was held in Cornwall, Ontario, Canada, in April 2017 to begin exploring these themes and answering associated key questions. This session will serve as a podium to present the outcomes of the horizon-scanning exercise and of the Pellston Workshop and to foster discussion with attendees in order to continue advancing the AOP framework. Specifically, presentations will cover topics such as the development and application of AOP networks, qualitative AOPs and associated modeling approaches, and the status of and future needs for application of the framework in regulatory decision making. Furthermore, talks will explore a roadmap to enhance awareness of, involvement in, and acceptance of the AOP framework by regulatory agencies, scientists, and other stakeholder groups. In all, presentations will serve frequently asked questions identified during the horizon scanning and address common misunderstandings pertaining to the AOP framework. Finally, the audience will be asked to participate in a panel discussion following the presentations to build upon ideas and outcomes derived from the Pellston Workshop.

1728 Adverse Outcome Pathways: Moving from a Scientific Concept to a Globally-Accepted Framework

In 2016, we reached out to the membership of SOT, as well as other national and international scientific and regulatory communities, to collect questions and provide an opportunity to discuss key outstanding challenges that must be addressed in order to realize the full potential of the AOP framework. During this Horizon Scanning effort, a total of 340 valid questions were received and ranked by an international expert group from academia, government, industry, and NGOs. This ranking was utilized to identify the four distinct but connected core topics that were addressed during the workshop, and each of which is summarized in the subsequent presentations: 1) AOP networks and their applications (Presentation #2); 2) quantitative AOPs and their applications (Presentation #3); 3) regulatory use of the AOP framework (Presentation #4); and 4) roadmap to expand awareness of, involvement in, and application of the AOP framework and AOP knowledgebase in the broader scientific and regulatory/environmental policy communities (Presentation #5). Furthermore, this exercise provided the opportunity to identify and clarify common misperceptions, as well as bring forward new thinking to advance the science and discuss the path forward. This introductory presentation will provide an overview of the Horizon Scanning exercise, and the overall outcomes and common themes that emerged during this exercise and the subsequent Pellston Workshop during which these themes were addressed. It will set the stage for the subsequent presentations that each address one of the four main topics listed above. Common themes that spanned across these main topics included the need to simplify, translate, and better communicate the AOP framework to the broader international stakeholder community, and a consensus that the AOP framework does not represent a rigid tool but rather a knowledge repository for diverse stakeholders ranging from epidemiologists to mainstream experimental toxicologist to risk assessors and managers. Furthermore, when considering the AOP framework and its applications, the field of environmental toxicology and human health naturally merged into a continuum that is at the nexus of Toxicology in the 21st century.
The use of adverse outcome pathways (AOPs) and related concepts has increased in scientific and regulatory sectors over the past decade, coinciding with pressures to find innovative solutions for evaluating chemical safety in a more efficient and effective manner. In this context, a series of recent workshops and publications have investigated how AOPs may be applied to regulatory decision-making, concluding that in each case, the AOP must be fit-for-purpose. To enhance opportunities to utilize AOPs, there is a need to provide guidance on how to evaluate and define fit-for-purpose given a particular regulatory scenario. This presentation will provide examples for applying AOP concepts to a variety of scenarios over the life stages of chemical development (i.e., from product development/discovery, registration, to environmental regulations and stewardship activities). It is recognized that the utility of an AOP within a regulatory context is influenced by both the level of development of the construct itself in combination with the tools available to measure key events (KEs) (e.g., assays or models) and key event relationships (KERs) within the AOP. Criteria to consider when determining if the tools for measuring endpoints within the AOP of interest are sufficiently predictive (i.e., fit-for-purpose) for regulatory applications will be proposed. Considerations for evaluating the suitability of AOPs will be discussed, recognizing that the accepted level of uncertainty varies based on the nature of the decision and the context in which the AOP is being applied. Additional input from the audience will be sought to further advance the use of the concept.
to enter the skin. One of the challenges for prioritization can be potentially addressed by identifying chemicals that penetrate quickly by using the lag time parameter. This talk presents an overview for approaches taken to examine diffusion estimates based on chemical properties. This abstract does not reflect US EPA policy.

**1735 Skin Absorption of Metal Worker Fluids and Complexities Inherent in Additional Components**

R. E. Raynes. North Carolina State University, Raleigh, NC.

Occupational settings can lead to dermal exposure of workers to metalworking fluids (MWFs), which may be toxic. The fluids are mixtures of vehicles (water or oil), minerals from metal work, and additives such as corrosion inhibitors. A systematic study of dermal permeability is needed due to differing ratios of components in these metal fluids. A lack of information is especially apparent with the addition of biocides to these mixtures. The porcine skin flow-through cell system provides concentration-time profiles needed for the estimation of permeability. A large dataset is available for porcine penetration for pesticides in aqueous solution. By combining this information with the mixture data available from MWFs, computational predictions can be then used to prioritize in vivo studies. This talk will summarize our systematic effort to quantify dermal penetration for complex mixtures generated in occupational settings.

**1736 Impact of Natural Compounds on Dermal Absorption for Consumer Products and Their Computational Prediction**

J. E. Riviere. North Carolina State University, Raleigh, NC.

Natural compounds are present in increasing numbers within consumer products. This includes increased use in vehicles, adding to the complexity of the mixture used dermally. Although purported to be benign, these compounds may have the potential to affect dermal absorption of applied chemicals. In vitro experiments using porcine skin allowed for the collection of concentration-time datasets used in the calculation of permeability and flux. These dermal descriptors were then incorporated into a quantitative permeation relationships (QSPR) for different topical preparations to quantitatively assess mixture-induced interactions. Some of these natural compounds acted as permeation enhancers, leading to increased dermal penetration when used as a mixture. The study of natural compounds used in topical mixtures needs further characterization. This talk will address the need to study natural compounds and their impact on dermal penetration.

**1737 The Skin Is a Non-Homogenous Physiological Organ: What Should We Consider for Computational Predictions?**

G. B. Kasting. University of Cincinnati, Cincinnati, OH.

Although diffusion is considered the main determinant for dermal penetration, there are physiological conditions that can affect permeability. One major consideration is skin hydration, since in vitro experiments may change the normal hydration present in skin. Another physiological condition such as inflammation and swelling may affect permeability. Then there is the question about different skin components, such as nails and hair follicles. How do these skin subtypes affect absorption for a given chemical? Should computational predictions include this diverse skin landscape with different sub-types and components? Can skin condition or disease alter the normal diffusion process? This presentation will focus on the diverse skin landscape needed when considering computational predictions for dermal penetration.

**1738 In Silico-In Vitro Extrapolation for Dermal Exposure**

J. Spires. Simulations Plus, Lancaster, CA. Sponsor: M. Evans

In vitro measurements of skin penetration are often used to predict in vivo dermal exposure for a compound. However, correlations between in vitro and in vivo exposure, or correlations between different types of in vitro experiments, are often poor, and the reasons for this are often unclear. In silico modeling of transport into and between skin layers can be used to separate and quantify the mechanisms leading to different dermal exposure of diverse compounds, and may also improve extrapolations between various in vitro experiments and in vivo delivery. The GastroPlus TCAT module was developed to mechanistically model in vivo transport of compounds into and within the skin. This talk will discuss the process of adapting GastroPlus to simulate in vitro dermal experiments and explore how well it can predict in vitro dermal delivery mechanisms.

**1739 Defining Domains of Applicability for Zebrasfish within Toxicology: A Retrospective and Prospective Workshop**

J. Freeman. Purdue University, West Lafayette, IN.

Over the past 20 years, adoption and integration of the application of zebrafish as a toxicological model system has magnified in most areas of toxicology-based research. As a well-recognized biomedical research model, zebrafish presents numerous strengths that have been leveraged in many toxicity studies. Rapid ex vivo development of a small, near-transparent singular embryo permits ease for assessing chemical perturbations at all stages of early development, as well as use in high-throughput screening and automated phenotyping. In addition, a complete genome sequence, array of tools for manipulating gene function, and availability of several thousand mutant and transgenic lines provides, similarly to mouse models, readily available resources for comprehensive mechanistic studies of toxicity. Furthermore, maturation at three months of age and a shorter lifespan allow for multi- and transgenerational studies and efficient identification and evaluation of developmental origins of health and disease. As researchers continue to expand the use of the zebrafish in toxicology, limitations of this animal model also are being identified. In this session, the first presentation will highlight what has been learned from more than two decades of using zebrafish in toxicity research, which has spanned developmental mechanistic studies to current applications in high-throughput screening of chemicals and chemical mixtures. The second talk will discuss zebrafish as a comparative model to rodent neurobehavioral testing, including analysis of larval behavior outcomes with long-term neurobehavioral dysfunction in adults. The third speaker will focus on the advantages and challenges of using zebrafish to define mechanisms of immediate (larval), later in life (adult), and transgenerational consequences of a developmental toxicant exposure linking single-cell transcriptomic, epigenomic, and phenotypic outcomes. The fourth presentation will highlight the strengths and constraints for using transgenic zebrafish in drug development and therapeutics for epilepsy. The final speaker will address the benefits of using zebrafish as a replacement for mammalian toxicity testing and the importance of accounting for toxicokinetic processes and dosimetry. Overall, the session will bring together several leading research laboratories that have extensive experience with the zebrafish model in various toxicological disciplines to provide a reflection of the knowledge that has been gained over the past 20 years relative to the strengths and constraints of the model system in toxicological experiments. In addition, this session will explore a comparison of zebrafish to other animal models, best practices, current questions, and future research needs.

**1740 Utilizing the Power of High-Throughput Zebrafish Screening to Identify Hazardous Chemicals and to Help Design Safer Chemicals**

R. Tanguay. Oregon State University, Corvallis, OR.

We started over two decades ago using zebrafish as a new model system to better understand the mechanisms of TCDD developmental toxicity and these initial studies convinced us that this system could be used more broadly and across chemical space and for many applications. Since those studies in the 1990s, the field has matured into many exciting areas across the molecular and systems biology continuum. The studies utilized our rapid multi-dimensional embryonic zebrafish assay as a platform for collecting and comparing the bioactivity of hundreds of chemicals and chemical mixtures. This system has proven effective for defining chemical activity profiles and for providing the initial clues to understand the mechanisms that underlie toxic responses. Chemicals from many commercial and governmental sources for testing in our high throughput zebrafish testing facility were obtained. The identity of the compounds are coded and initially blinded to the laboratory. All chemicals were applied for developmental toxicity in zebrafish across broad concentration ranges. All exposures were initiated at 6 hours post fertilization (hpf) and were continuous until 120 hpf. At 24 hpf embryos were assessed for changes in an embryonic photomotor response (PMR) behavior, which is a sensitive early measure of neuromuscular activity. At 120 hpf the morphological endpoints were recorded. Utilizing the PMR together with the numerous visible endpoints increases the sensitivity to discern
Zebras (Danio rerio) embryos and larvae have been suggested as a vertebrate model not only to improve understanding of fish development and toxicology, but also to complement or even replace mammals for rapidly assessing chemical impact. Hundreds to thousands of chemicals can today be rapidly screened while obtaining high content information on morphological and/or physiological changes in the early life stages of this fish. Yet, the toxicokinetics—i.e., how chemicals are absorbed by the fish, distributed, metabolized, and eliminated—is far less explored. In order to shed light on the role of toxicokinetics in the response of fish to chemicals and in the comparability of the response to mammals, we characterize chemical distribution using combinations of mass spectrometry-based quantitative and imaging methods along with kinetic modeling, in addition to analyzing toxic and behavioral outcomes. Focusing, for example, on the well-known psychoactive drug cocaine, and on the new psychoactive substance, meta-chlorophenylpiperazine (mCPP), we found highest accumulation of these chemicals in the larval fish eye, while they reached much lower but comparable levels in brain and trunk. Using hypo-pigmented fish, accumulation of the drugs in the eye was confirmed to be due to melanin and can be explained by the basic chemical nature of these drugs. Though cocaine brain levels covered those known to cause hyperactivity in mammals, only mCPP (decreased locomotion) was recorded in zebrafish larvae. Results therefore point to cocaine’s anesthetic properties as the dominant mechanism of interaction in the fish: Upon entry through the fish skin and gills, it first acts on peripheral nerves, rapidly overriding any potential stimulatory response in the brain. Despite differences in effective tissue levels in zebrafish larvae and rodents with respect to mCPP, we observed similar behavioral responses—e.g., hypolocomotion—suggesting that zebrafish larvae are a useful model to study serotonin-targeting drugs. Based on these and other examples of our research, we highlight the importance of taking toxicokinetic processes into account when using zebrafish embryos and larvae in chemical risk assessment.
Get the Lead Out: The Persistent Problem of Lead Exposure from Soil, Dust, and Water

M. Hughes, US EPA, Research Triangle Park, NC.

The heavy metal lead, a known neurotoxicant, has been used for centuries in a variety of industries and household and consumer products. The choice to use lead is a reflection of its physical/chemical properties, including softness, ductility, poor conductivity, and resistance to corrosion. While a natural component of Earth’s crust, high concentrations of lead in the environment, particularly soil, have resulted from human activity and its resistance to natural degradation. From the decades-long use of lead as a fuel additive, soils in urban areas with high traffic volume have been found to have highly elevated levels of lead. In residences that pre-date 1978, when lead-based paint was banned in the United States, dust from deteriorating paint contains elevated levels of lead. The soils found on and near several industrial smelting sites, such as in East Chicago, IN, also have high levels of lead. Finally, lead is found in drinking water in homes that have water pipes containing lead, with leaching a complex function of pH, alkalinity, and source water characteristics. It is well noted that homes typically located in older urban centers have drinking water with a high risk of elevated lead levels, particularly if the water is corrosive. Elevated blood levels have been found in people, particularly children, who were exposed to soils, dust, and water containing high levels of lead. The main public health issue with lead is that it is neurotoxic, especially to children. Elevated levels of lead in children can result in behavioral disorders and impairment of intelligence and learning. There is no known biological requirement for lead, although it is absorbed fairly well following ingestion or inhalation. Lead accumulates in bone, as it has similar properties as calcium, taking its place in this organ. Lead in bone can be a long-term source of internal exposure, as it can be released from bone into the systemic circulation and reach other organs. This session will bring together experts on lead with regard to its exposure, neurotoxicological effects, and the use of models to predict blood lead levels in individuals exposed to lead in soil, dusts, and water. The first presenter will discuss the positive association between lead in soil or bioaccessible (an in vitro method simulating gastrointestinal tract) lead and blood lead levels in children in an urban area. This presentation will show the feasibility of using in vitro methods to improve child lead risk assessments in the place of total soil lead content. The second presentation will share how soil lead levels and children’s blood levels have changed pre- and 10 years post-Hurricane Katrina in New Orleans, Louisiana. It was observed that when lead soil levels decreased, the blood lead levels in the children also decreased. The third presentation will focus on the potential mechanisms of lead that result in adverse health outcomes following maternal lead exposure with the potential development of neurotoxicity in the offspring. This includes studies from both human and laboratory animal exposures. The fourth presentation will evaluate the impact of varying regional screening levels on blood lead predictions in the Integrated Exposure Uptake Biokinetic (IEUBK) model to aid in reducing uncertainty in human health risk assessments. The final presentation will describe the development of the US Environmental Protection Agency’s (EPA) SHEDS-Multimedia and IEUBK models to determine the level of lead in drinking water that should result in children’s blood lead levels that are less than specified values. The analysis reveals the importance of the soil and dust ingestion exposure pathway. The session will share information on the associations between exposure to lead in soil, dust, and water to blood lead levels, neurotoxic mechanisms of lead exposure, and modeling efforts to predict children’s blood lead levels following exposure. **Disclaimer:** The views expressed are those of the authors and do not necessarily represent the views or policies of the US EPA.

The Astonishingly Holistic Role of Soil in Lead Exposure of Children

H. Mielke, C. R. Gonzales, and E. T. Powell. Tulane University School of Medicine, New Orleans, LA.

The long-term resilience and sustainability of community welfare is linked with its environmental quality. One impediment to community welfare is children’s chronic lead exposure and its clinical consequences including health, learning, and behavioral disorders. There is no safe level of lead exposure, and this revelation is confounded by the fact that after exposure takes place, there is no known effective intervention. In August, 2005, Hurricane Katrina flooded 80% of New Orleans. This presentation explores the natural experiment of soil and children’s blood lead changes in New Orleans before and ten years after the flood. Pre- and post-Katrina soil lead and children’s blood lead results were matched and stratified by 172 communities in New Orleans. SHEDS-Multimedia methods were used to organize, describe, and map the pre- and post-Katrina data. Comparing pre- and post-Katrina results, simultaneous decreases occurred in soil lead that also saw exaggerated declines in children’s blood lead. Health and welfare disparities continue to exist between soil lead and children’s exposure within inner-city areas and outer communities of the city. At the scale of a city this investigation demonstrates that lessening soil lead effectively reduces children’s blood lead. The lead dust deposition reservoir of soil relates to its astonishingly holistic role as both a source of ingestible and inhalable lead dust. Transporting low lead soil lead into urban communities can result in a more hopeful and economical as an effective method for primary lead prevention.

Lead-Induced Neurotoxicities From Maternal Exposure to Neurodegenerative Alzheimer’s Disease

W. Zhend, N. Li, P. Territo, and Y. Du. 1Purdue University, West Lafayette, IN; 2Henan Agriculture University, Henan, China; and 3Indiana University, Indianapolis, IN.

Lead (Pb)-induced neurotoxicities have been well documented. Children exposed to Pb have been associated with cognitive deficits and neurobehavioral alterations. This presentation will start with a recent human study conducted in China, where the researchers report that maternal exposure to Pb impairs the neurobehavioral development such as the Apgar (appearance, pulse, grimace, activity, and respiration) score in newborn babies. Recent findings from animal studies by this group on effects of Pb exposure on amyloid plaque formation, which is the initial feature of Alzheimer’s Disease (AD) pathogenesis, and the expression of calciytensin (Clstn), a protein family regulating axonal transport of amyloid precursor protein (APP), will then be discussed. In Tg-SwDI mice that carry the human APP gene, subchronic oral Pb exposure was found to increase amyloid beta (peptides found in amyloid plaques) levels in cerebrospinal fluid, brain cortex and hippocampus; there was also a significant increase of amyloid plaques in animals. Noticeably, Pb-exposed mice showed an impaired spatial learning ability. Real-time imaging of the blood-brain barrier (BBB) permeability by using a dynamic contrast-enhanced computed tomography technique further revealed reduced brain regional blood flow and increased barrier permeability following Pb exposure in the mice. Studies of offspring of pregnant rats exposed to Pb in drinking water from gestation to weaning further showed that the expression of Clstn2 in offspring brain had a Pb dose-related decrease in hippocampus and cerebral cortex at PND21. These observations suggest that Pb exposure not only disrupts the BBB function, but also disrupts the system that regulates APP axonal transport. Consolidation of these observations in the context of maternal Pb exposure and offspring neurotoxicity will be extensively discussed.
In 2012, the CDC recommended that blood lead levels (BLLs) should be benchmarked to a reference value (RV), equal to the 97.5th percentile BLL from the National Health and Nutrition Examination Survey, rather than the 10 µg/dL “level of concern.” The RV was 5 µg/dL in 2012. US EPA has not yet updated its Regional Screening Level (RSL) for soil lead to reflect the 2012 reference value, nor has it finalized revisions to other IEUBK models although it has indicated that it will do both. Use of the target BLL has important implications for managing exposures of children to lead. In this analysis, we evaluated the impact of different exposure assumptions for the soil lead RSL, assuming a target BLL of 5 µg/dL and a probability of an elevated BLL of 1 or 2%. We chose assumptions which may plausibly differ across sites, or, with the BLL geometric standard deviation (GSD), may differ at lower BLL distributions. Specifically, we varied the population BLL GSD, soil lead bioavailability, soil-dust transfer rate, and water lead concentrations. Depending upon the chosen assumptions, calculated soil lead RSLs varied several-fold, in some cases yielding median RSLs below background soil lead levels for certain urban areas. We also evaluated uncertainty in quantifying the contribution of soil lead to BLL in the IEUBK model by comparing IEUBK model estimates to those based on statistical modeling from soil lead: blood lead epidemiology studies. This comparison indicated higher blood lead concentrations with the IEUBK model than with the selected reference probabilistically-based models. While this analysis identified important challenges for remedial decisions with use of the RV target, it also identified approaches for priority setting and areas for reducing uncertainty with additional information.

**W 1750 Probabilistic Modeling of Childhood Multimedia Lead Exposures: Examining the Soil Ingestion Pathway**

R. Tomero-Velez¹ and V. Zartarian². ¹US EPA, Research Triangle Park, NC; and ²US EPA, Boston, MA. Sponsor: M. Hughes

This talk describes a multimedia probabilistic exposure modeling approach to guide public health decisions related to lead, achieved by coupling US EPA’s SHEDS-Multimedia and IEUBK models. The goal of this effort was to advance a national-scale understanding of the relationship between lead concentrations in environmental media and blood lead levels (BLL) of infants and young children, with the purpose of determining what drinking water levels can keep children’s blood lead levels below specified levels. Many factors play a role in lead exposure, including media concentrations, age-dependent media intake rates, lead bioavailability, and biological variability in lead uptake. Our probabilistic modeling approach incorporated distributional assumptions for each of these factors, with the exception of bioavailability for which point estimates were applied. We observed good agreement in predicted childhood BLL (0-23% relative error) with nationally representative children’s BLL, yet somewhat decreased agreement for a regional assessment (35-43% relative error). Pathway contribution analysis (national scale) revealed soil/dust ingestion was the dominant pathway for BLL above the 80% percentile among children 2 to 7 years of age, and suggests a high value of information for determinants of this pathway (lead soil and dust concentrations, soil/dust ingestion rates, and lead soil/dust bioavailability). While considerable work has been done to assess lead bioavailability (e.g., lead species, nutritional status), making use of this data in exposure modeling is constrained by the availability of pertinent exposure information. Herein we discuss these data needs with emphasis on identifying populations most at risk from lead exposure. This abstract does not represent US EPA policy.

**W 1751 Nanotoxicology: State of the Science and the Path Forward**

The US National Nanotechnology Initiative (NNI) was established in 2001 to support the responsible development of the emerging science of nanotechnology and bring together stakeholders from the federal government, industry, and academia. The goal was to thoroughly address the potential health and safety implications of nanomaterials. Stakeholders emphasized the complexity of nanotoxicology, the importance of understanding the novel physicochemical properties of nanomaterials, and how traditional toxicity testing strategies should be modified to address these unique properties. The toxicology community has responded to this call-to-action through the emergence of nanotoxicology as a subspecialty, including the 2008 launch of the SOT Nanotoxicology Specialty Section. Over the past 10 years, thousands of peer-reviewed studies have been published in journals, including those developed specifically for nanotoxicology, in addition to numerous meetings and symposia. Currently, the nanotoxicology community is at a critical juncture where stakeholders have begun to pose serious questions regarding the achievements of this new science. Concerns include the presentation and robustness of the data in published studies and whether standardized and validated methods were used. General questions surround whether available data meet critical data gaps, whether nanotoxicology should continue to exist as a subspecialty of toxicology, and whether consolidating the toxicology community should work in tandem with other disciplines that play a critical role in understanding the relative risks associated with nanomaterials. This session will bring together researchers and scientists from the federal government, industry, and academia to provide an overview of the lessons learned and the support provided to industry for commercializing nano-enabled products. The session will present carbon nanotube toxicity as a case study of the efforts to understand whether toxicity of engineered nanomaterial exposure is adequately understood. Other topics include the state of the science in terms of human health effects, the potential for the NNI in advancing research in nanotoxicology, and the future directions of industries for incorporating nanotechnology. Lastly, the path forward for nanotoxicology, highlighting knowledge gaps and emerging research needs, will be presented, followed by an open discussion with the panel of speakers.

**W 1752 State of the Science: Nanotoxicology of Carbon Nanotubes (CNTs)**

V. Castranova. West Virginia University, Morgantown, WV.

Carbon nanotube applications in structural materials, electronics, and medicine are expanding rapidly, leading to potential occupational exposures. Fifteen years ago, concern was raised that high aspect ratio CNTs may act as asbestos-like fibers to cause disease. Numerous studies have since shown that CNTs cause lung inflammation/damage, granulomas (due to CNT agglomerates), and fibrosis (due to deposition of smaller CNT structures in the distal lung). Although the pulmonary response, including asbestos-like, CNT pathogenesis differs from asbestos; i.e., 1) CNTs are not a single class and pose toxicity in varying ways; 2) CNTs are not single-walled; 3) CNTs are not radially rigid; and 3) lung gene expression pathways differ for MWCNTs vs. asbestos. Indeed, the fibrogenic potency of CNTs appears driven by their ability to enter the alveolar interstitium and directly activate fibroblast proliferation and collagen production. Pulmonary fibrogenic potential is single-walled CNTs > multi-walled (MWCNTs) > carbon nanofibers = asbestos. Carboxylation of MWCNTs decreases fibrotic potency, while amination enhances bioactivity. These pulmonary responses to CNTs are qualitatively similar in mice vs. rats and quantitatively similar in male vs. females. Recent results also indicate that MWCNTs can both initiate and promote lung cancer, with male rats being more susceptible to MWCNT-induced lung tumors than female rats. MWCNTs can migrate to the interpleural space, and after two years of inhalation exposure MWCNT-induced mesothelial hyperplasia was reported. However, to date, no mesotheliosis has been demonstrated following pulmonary exposure to MWCNTs. Pulmonary exposure to MWCNTs has also been reported to adversely affect cardiac performance and microvascular function. Lung sensory neurons in the lung are involved in this response. Therefore, recent expansion of nanotoxicology data allows for risk analysis for CNTs.

**W 1753 State of the Science: Human Health Effects of Engineered Nanomaterials**

M. Schubauer-Berigan. NIOSH, Cincinnati, OH. Sponsor: T. Thomas

Human (epidemiologic) studies of the health effects of engineered nanomaterials (ENM) have been few and generally confined to the materials expected to be most hazardous (e.g., carbon nanotubes (CNT) or nanofibers (CNF)) or in most common use (e.g., titanium dioxide). The occupational setting is currently the most appropriate for conducting health studies of ENM, given the low exposures and study feasibility challenges in the general population. General studies are provided to demonstrate that the small workforce sizes involved in ENM manufacturing and use, difficulty for researchers in accessing the populations, and problematic exposure assessment for most ENM; an emblematic example of the latter is uncertainty about which aspects of ENM exposure are most relevant to health. A recent review of epidemiologic studies of ENM identified 13 studies in progress (three-quarters of which were cross-sectional) of 9 unique populations of ENM workers. In addition, a relatively large cross-sectional study of US CNT and CNF workers has been completed and full publications of studies of other CNT workers have appeared in the literature. Relatively few overt health effects have been found to be
associated with CNT or CNF exposure in these epidemiologic studies. The exposures in the human studies are generally lower than those used in most toxicology studies, which hampers their comparability. Most published studies have reported some inflammatory or other biomarkers to be associated with measured exposures to ENM, although specific findings tend to be inconsistent across populations. These and other challenges in conducting epidemiologic research of ENM point to the need to pool data across studies and populations. This will require study coordination to ensure comparability of exposure and outcome measurement.

W 1754 Ensuring Responsible Development of Nanotechnology
L. Friedersdorf. National Nanotechnology Coordination Office (NNCO), Arlington, VA.

From the very inception of the US National Nanotechnology Initiative (NNI), responsible development of nanotechnology has been one of its primary goals. Responsible development encompasses support for the development of knowledge for the evaluation of the potential risks and benefits of nanotechnology to the environment and human health and safety; timely dissemination, evaluation, and incorporation of this knowledge; consideration of ethical, legal, and societal implications; and incorporation of sustainability principles. This presentation will provide an overview of the role the NNI has played in addressing this goal. Mechanisms employed to promote active discussion about nanotechnology-related environmental, health, and safety research and to leverage knowledge and resources internationally will also be discussed.

W 1755 An Industry Perspective on the Federal Role in Nanotoxicology
S. Clancy. Evonik, Parsippany, NJ.

Industry has been an active participant in the field of nanotechnology for many years. In fact, industry’s involvement precedes the use of the term “nanotechnology,” through the production and use of materials described by terms such as “ultrafine,” that we may describe as nanomaterials today. Along the way, the industry community has also taken steps to ensure the responsible development and use of nanomaterials, which has often included considering important matters such as characterization and toxicology. The US Federal government has played an important role in helping to establish more common approaches to these issues including more common terminology, metrology, and EHS practices. These improvements have facilitated the development of new materials and increased the confidence in the safe use of legacy nanomaterials. This presentation will feature examples of how the contributions from the Federal government have supported these activities and suggest opportunities for additional contributions.

W 1756 Nanotoxicology and the Path Forward
A. Elder. University of Rochester, Rochester, NY.

As the field of nanotoxicology is growing into maturity, there is a need to conduct research on the health effects of nanomaterials today. Along the way, the industry community has also taken steps to ensure the responsible development and use of nanomaterials, which has often included considering important matters such as characterization and toxicology. The US Federal government has played an important role in helping to establish more common approaches to these issues including more common terminology, metrology, and EHS practices. These improvements have facilitated the development of new materials and increased the confidence in the safe use of legacy nanomaterials. This presentation will feature examples of how the contributions from the Federal government have supported these activities and suggest opportunities for additional contributions.

P 1757 An In Vivo Model for the Simultaneous Assessment of Cardiovascular, Neuromuscular, and/or Central Liabilities of Oximes: Establishing 2PAM Liabilities and Mode-of-Death
S. Roof, R. Hamlin, and C. del Rio. QTest Labs, Columbus, OH. Sponsor: R. Hamlin

Pralidoxime (2PAM) is a clinical-stage field-ready oxime utilized as a cholinesterase reactivator. Due to its multiple on/off target actions, as well as to the tight interactions between cardiovascular, neuro-muscular, and respiratory centers, establishing its specific liabilities in vivo remains difficult. In this study, the simultaneous dose-response(s) of 2PAM on neuro-muscular and cardiovascular end-points were evaluated in vivo, in an effort to establish specific in vivo liabilities. Ten anesthetized (2.5% isoflurane) and mechanically-ventilated male Sprague Dawley rats were instrumented to simultaneously assess systemic/left ventricular hemodynamics as well as skeletal and diaphragmatic function in order to differentiate between central and direct junctional effects, diaphragmatic function was studied in both intact (n = 5, centrally driven) as well as de-centralized preparations (n = 5) where the phrenic nerve was transected cranially and electrically stimulated (4V for 10 ms at 0.2 Hz). In all cases, data were collected before and during 2PAM Administration (2.5 mg/kg/min IV) for 2 hours. 2PAM treatment dose dependently depressed skeletal and diaphragmatic muscle function. Both stimulated (femoral nerve) skeletal muscle and intact (centrally-driven) diaphragmatic twitch matched comparable time-courses, declining 50% (IC50) and 90% from baseline (IC90) at cumulative 2PAM doses of ~80 and ~160 mg/kg, respectively. Alternatively, stimulated (de-centralized) dia-phragmatic function was more resistant to inhibition (IC50:180 mg/kg, IC90: 250 mg/kg), suggesting both a direct and a central action of 2PAM. In all cases, administration of 2PAM resulted in slight vasopression (+14 ± 3 mmHg) and in an early positive chronotropic effect (+11-20 ± 3 bpm). Taken together, these data support diaphragmatic/respiratory depression as the primary liability of 2PAM in vivo (likely resulting in death via hypoventilation/asphyxia), as 2PAM lacked detrimental cardiovascular effects at the exposures studied. In addition, the results also suggest both that 1) 2PAM may directly alter central/afferent respiratory pathways and 2) skeletal muscle function may provide premonitory insights into the diaphragmatic function of oropharmacology, this study demonstrates that the potential neuro-muscular, cardiovascular, and respiratory in vivo liabilities of oximes can be simultaneously assessed pre-clinically.

P 1758 Evaluation of Agonists for the A1 Adenosine Receptor as Novel Anticonvulsant Medical Countermeasures to Soman (GD) Nerve Agent Intoxication
T. Thomas1, and T. Shih2. Army Research Laboratory, Aberdeen Proving Ground, MD; and *US Army Medical Research Institute of Chemical Defense, Aberdeen Proving Ground, MD. Sponsor: J. Dillman

Current medical countermeasures often have limited efficacy in suppressing seizure activity after organophosphorus nerve agent (NA) intoxication. Toward developing a more effective anticonvulsant treat-ment, we have shown that stimulation of the A1 adenosine (ADO) receptor (A1AR) with the agonist N6-cyclopentyladenosine (CPA) effec-tively prevents NA seizure. CPA at the effective dose (60 mg/kg) produces unwanted side effects e.g., prolonged sedation. This study aimed to determine if efficacy could be achieved at lower CPA doses, and to also determine if other agonists could potentially prevent seizure with fewer side effects. To do so, Sprague Dawley rats were surgically prepared for recording brain electroencephalographic (EEG) activity. One week later, rats received HI-6 (125 mg/kg, IP) and atropine methyl nitate (2 mg/kg, IM) to prevent peripheral cholinergic symptoms and, thus, promote survival without affecting central activity. Rats were exposed to GD (1.6 x LD50, SC) or control vehicle 30 min later. One minute after GD, rats were injected IP with one of the following A1AR agonists at increasing dose levels until anti-seize efficacy was achieved: CPA, 2-Chloro-N6-cyclopentyladenosine (CCPA), and (±)-5’-Chloro-5’-deoxy-ENBA (ENBA). Rats were prepared for neurohistopathological scoring 24 hrs later (0=no damage, 16=most severe). All A1AR agonists were effective in preventing seizure and promoting as a novel discriminative dose for the A1AR agonists were 60 mg/kg CPA, 36 mg/kg CCPA, and 62 mg/kg ENBA. Whereas saline-treated rats experienced 100% seizure and 21% survival (N=28), ADO treatments reduced seizure occurrence and improved survival rates: 8% seizure and 83% survival with CPA (60 mg/kg, N=12), 17% seizure and 75% survival with CCPA (36 mg/kg, N=12), and 8% seizure, 83% survival with ENBA (62 mg/kg, N=12). ADO also suppressed neuropathology: saline-treated rats had severe brain
damage: average score of 14.8±1.8. ADO rats appeared normal: 0.2±0.6 for CPA, 0±0.0 for CCPA, and 1.4±0.4 for ENBA. Other ADO induced physiologic effects (sedation, Bradycardia, and hypothermia) were minimized with CCPA and ENBA vs. CPA: 89% of CCPA, 100% of ENBA, and 0% of CPA rats were ambulatory at 24 hr. The data from this study suggest that CCPA and ENBA are superior candidate ADO agonists for countering NA seizure.

**1759 Temporally Altered Fecal Microbiota and Urine Metabolome following Soman Poisoning**

D. Getnet1, A. Gautam1, A. V. Hoke1, R. Kuma1, A. K. Cheema2, F. Rossetti2, C. R. Schultz2, R. Hammamieh1, L. A. Lumley3, and M. Jett1. 1US Army Center for Environmental Health Research, Ft. Detrick, MD; 2Georgetown University Medical Center, Washington, DC, 3WRAIR, Silver Spring, MD; and 4US Army Medical Research Institute of Chemical Defense, Aberdeen Proving Ground, MD.

The experimental pathophysiology of organophosphorus (OP) chemical exposure has been extensively reported. Here, we describe for the first time an altered fecal microbiota and urine metabolome that follows intoxication with soman, a lipophilic G class chemical warfare nerve agent. Non-anaesthetized Sprague Dawley male rats were subcutaneous-ly administered soman at 0.8 - 1.0 of the median lethal dose (LD50) and evaluated for signs of toxicity. Animals were stratified based on seizing activity to evaluate effects of soman exposure on fecal bacterial biota and urinary protein and metabolome. Soman was resuspended in the fecal biota by preferentially expanding Facklamia, Agrobacterium, Bilophila, Enterobacter, and Morganella genera of the Firmicutes and Proteobacteria phyla, some of which are known to hydrolyze OPs. However, analogous changes were not observed in the bacterial biota of the ileum, which remained the same irrespective of dose or seizing status of animals after exposure. Interestingly, when considering just the seizing status of animals, we found that the urine metabolome was markedly altered. Leukotriene C4, kynurenic acid, 5-hydroxyindoleacetic acid, norepinephrine, and aldosterone were excreted at much higher rates at 72 hrs in seizing animals, consistent with multi-organ involvement during soman poisoning. However, at 75 days post soman exposure, bacterial biota stabilized and no differences were observed. These findings demonstrate the feasibility of using the dysbiosis of fecal bacterial biota in combination with urine metabolome alterations as biosensors for OP exposure to enhance current triage standards and estimation of affected radius on existing clinical laboratory workflows. This approach will be effective at a much earlier time point that remains to be defined.

**1760 Bromine-Induced Myocardial Damage and Dysfunction**

S. Ahmad1, A. Ahmad1, A. Zaky1, J. X. Masjano Juncos1, W. Chih-Chang1, W. E. Bradley2, I. Zafar3, P. Powell4, N. Mariappan5, W. E. Louch1, D. A. Ford1, S. Matalon1, and L. J. Dell’Italia1. 1University of Alabama at Birmingham, Birmingham, AL; 2Oslo University Hospital and University of Oslo, Oslo, Norway; and 3St. Louis University, St. Louis, MO.

Inhaled halogen gases produce reactive species on the pulmonary epithelial cell surface that circulate and cause extensive cardiac injury. However, the mechanisms of such myocardial damage are not well understood. This gap in knowledge limits the potential for development of effective therapies. We sought to determine the role of bromine and brominated lipid derivatives in causing cardiac dysfunction. Bromine inhalation (600 ppm) in rats caused acute increases in circulating troponin 1, fatty acid binding protein and NT-proBNP, and ECG ST-segment elevation. Echocardiography revealed a hypercontractile left ventricle (LV), decreased heart rate, decreased mean arterial pressure (MAP), and decreased plasma and LV norepinephrine levels. LV SERCA was extensively brominated and activity was decreased by 70 percent and an increase in cytosolic calcium sensitive calpain activity. Transmission electron microscopy (TEM) demonstrated contraction band necrosis, disruption of the z-disc, and mitochondrial swelling and disorganization. Administration of MDL28170 within one hour of exposure decreased calpain activity and significantly decreased acute mortality. However, LV spherical dilatation and interstitial fibrosis remained at 7 days in survivors. That bromine reactants cause the myocardial damage was confirmed by direct injection of the brominated fatty aldehyde, 2-bromo-hexadecanal (Br-HDA) into the LV cavity of a rat. Br-HDA caused acute LV enlargement and dysfunction with extensive disruption of the mitochondrial/sarcromeric architecture and extensive myocardial damage as in the in vivo bromine inhalation. Increased trends of calpain activity and extensive neutrophil accumulation occurred in the myocardium of Br-HDA treated rats. Cardiopulmonary calpain activation mediated by both adrenergic discharge and SERCA2 inactivation may together underpin halogen (bromine)-induced myocardial damage and dysfunction.

**1761 Manipulation of Macrophage Function for Treatment of Chlorine-Induced Airway Fibrosis**

Chlorine is a highly toxic gas used in a variety of industrial processes and is considered a chemical threat agent. We showed previously that the development of airway fibrosis in mice after chlorine inhalation was associated with inflammation and inefficient epithelial repair. To assess the role of macrophage populations in chlorine-induced airway fibrosis, we treated chlorine-exposed mice with agents affecting macrophage function. FVB/NJ mice were exposed to 240 ppm-hr chlorine, and gene expression was analyzed in developing fibrotic airway lesions. To analyze myeloid cells that may be involved in the development of fibrosis, flow cytometry was performed using digested whole lungs. Macrophage ablation in chlorine-exposed mice was performed using macrophage Fas-induced apoptosis (MAFIA) transgenic mice treated with the dimerizer compound AP20187, which induces apoptosis in macrophages. To assess the contribution of the M2 macrophage marker arginase 1 (Arg1) which has been implicated as a mediator in the development of fibrosis, Arg1 conditional knockout (Arg1 flox x Tek-Cre) mice were used. Arg1 expression was examined by immunofluorescence staining. Picrosirius red staining was performed to determine collagen deposition in major airways. Quantification of collagen content was analyzed by ImageJ. Chlorine exposure resulted in upregulation of genes associated with macrophage function and increased Arg1-expressing cells in developing fibrotic lesions. Neutrophil and eosinophil macrophages increased with chlorine exposure. Corticosteroid treatment decreased Arg1-expressing cells and inhibited the development of airway fibrosis. Ablation of macrophages in MAFIA mice inhibited the development of airway fibrosis. Conditional knock out of Arg1 in Arg1 flox x Tek-Cre mice ablated Arg1 expression but did not affect chlorine-induced airway fibrosis. Taken together, these results implicate macrophages in the development of airway fibrosis and provide avenues that could prove useful for inhibiting fibrosis development after airway injury.

**1762 Nucleic Acid Scavenging Mitigates Inflammation in Rats Exposed to 2-Chloroethyl Ethyl Sulfide (CEES)**

N. Mariappan, M. Husain, I. Zafar, V. Singh, S. Ahmad, and A. Ahmad. University of Alabama at Birmingham, Birmingham, AL. Sponsor: A. Ahmad

Sulfur mustard (SM) or its analog 2-chloroethyl-ethyl sulfide (CEES) are strong alkylating agents. Its acute/chronic inhalation causes airway injury with enhanced vascular permeability and inflammation. Rats exposed to CEES showed increased levels of circulating cell free nucleic acids in the bronchoalveolar lavage fluid (BALF) and plasma. Previous studies have shown increased levels of extracellular nucleic acids (exNA) in a number of diseases. Studies have also shown that exNA can promote inflammation. Rats were exposed to 10% CEES using a nose-only aerosol inhalation system. At the end of the study (12hrs) lungs were lavaged and BALF and plasma were collected for nucleic acid measurements. An acute exposure of rats to CEES resulted in significant increase in protein and IgM in the BALF supernatant, indicating disruption of the alveolar-capillary membrane. There was also an increased neutrophil influx. Western blot analysis of BALF supernatant showed increased HMGB1 protein, a mediator of inflammation. CEES exposure also caused increase in the proinflammatory cytokines and chemokines, IL-6, IL-1α, CXCL1 and CCL2. In order to understand the role exNA in CEES induced lung injury, total NA was isolated from BALF supernatant and added exogenously to airway epithelial cells (16HBE). Addition of exNA caused increases in proinflammatory cytokines IL-6, CXCL1 and CCL2 mRNA levels. As increased circulating exNA are associated with lung injury induced by CEES, we postulated that inhibiting nucleic acids in vivo in rats could protect against CEES induced lung injury. Therefore, we used heparin/methenamine bromide (HMB) as a nucleic acid scavenging polymer or as a mitigating agent in CEES exposed rats. Two hours after CEES exposure, HMBBr (10mg/kg/bw) was administered intraperitoneally. HMBBr
Skin exposure to sulfur mustard (SM) is characterized by severe blister formation and a prolonged inflammatory response. The damage may be further exacerbated by overexpression of matrix metalloproteinases (MMPs) which involve degradation and remodeling of the extracellular matrix and basement membrane proteins. The type IV collagenase (MMP9 and MMP2) may mediate the disruption of type IV collagen (ColIV), a major component of the basement membrane zone (BMZ) in skin wounds post SM exposure. N-hydroxy-3-phenyl-2-(4-phenylbenzenesulfonamido) propanamide (BiPS) was tested as a highly selective MMP2/MMP9 inhibitor. The study aimed to evaluate the therapeutic effectiveness of topically delivered BiPS to protect against SM induced skin injury. We performed a time course study (24, 72, and 168 hr) and a single pretreatment BiPS using in vivo mouse ear skin to determine improvement using histopathologic changes, MMP9 gene expression, and BM protein expression as markers. SM induced characteristic skin structural damage including edema, inflammation, and a disrupted BMZ. The study showed significant reduction in edema and improvement in overall tissue structure by 72 hr post SM exposure. mRNA expression of MMP9 was significantly downregulated in the BiPS treated group by 168 hr post exposure. Immunofluorescent studies showed that significant reduction of MMP9 expression in the skin sections for all time points; the basement membrane (BMZ) expression appeared continuous without disruption and was similar to the unexposed control skin. These results suggest that BiPS may modulate MMP9 expression which may in turn improve base ment membrane integrity after skin exposure to SM. BiPS, the MMP2/ MMP9 inhibitor BiP may hold promise as a potential therapeutic countermeasure against SM induced skin injury. Grant funding supported by ES05022, T32ES007148, and NIAMS U54AR050573.

**1763 BiPS, a Type IV Collagenase Inhibitor Modulates Matrix Metalloproteinase 9 in Sulfur Mustard-Exposed Mouse Skin**

Y. Chang1, R. A. Hahn1, B. P. Casillas2, M. K. Gordon1, J. D. Laskin1, and D. R. Gerecke1. 1 Rutgers, The State University of New Jersey, Piscataway, NJ; and 2MRIGlobal, Kansas City, MO.

Skin exposure to sulfur mustard (SM) is characterized by severe blister formation and a prolonged inflammatory response. The damage may be further exacerbated by overexpression of matrix metalloproteinases (MMPs) which involve degradation and remodeling of the extracellular matrix and basement membrane proteins. The type IV collagenase (MMP9 and MMP2) may mediate the disruption of type IV collagen (ColIV), a major component of the basement membrane zone (BMZ) in skin wounds post SM exposure. N-hydroxy-3-phenyl-2-(4-phenylbenzenesulfonamido) propanamide (BiPS) was tested as a highly selective MMP2/MMP9 inhibitor. The study aimed to evaluate the therapeutic effectiveness of topically delivered BiPS to protect against SM induced skin injury. We performed a time course study (24, 72, and 168 hr) and a single pretreatment BiPS using in vivo mouse ear skin to determine improvement using histopathologic changes, MMP9 gene expression, and BM protein expression as markers. SM induced characteristic skin structural damage including edema, inflammation, and a disrupted BMZ. The study showed significant reduction in edema and improvement in overall tissue structure by 72 hr post SM exposure. mRNA expression of MMP9 was significantly downregulated in the BiPS treated group by 168 hr post exposure. Immunofluorescent studies showed that significant reduction of MMP9 expression in the skin sections for all time points; the basement membrane (ColIV) expression appeared continuous without disruption and was similar to the unexposed control skin. These results suggest that BiPS may modulate MMP9 expression which may in turn improve basement membrane integrity after skin exposure to SM. BiPS, the MMP2/ MMP9 inhibitor BiP may hold promise as a potential therapeutic countermeasure against SM induced skin injury. Grant funding supported by ES05022, T32ES007148, and NIAMS U54AR050573.

**1764 Developmental Exposure to TCDD Has Distinct Transgenerational Effects on CD8+ T Cell Responses during Influenza Virus Infection in the Male and Female F3 Generation**

C. M. Post, C. G. Burke, C. T. O’Dell, and B. P. Lawrence. University of Rochester School of Medicine and Dentistry, Rochester, NY.

Developmental and early life exposures can cause lasting effects on an offspring’s health and contribute to disease. The effects of some developmental exposures have even been demonstrated to persist across generations. SM exerts transgenerational effects on the immune system which have not been broadly explored. Exposure of pregnant mice to the prototype aryl hydrocarbon receptor (AhR) ligand 2,3,7,8-tetrachlorodibenzo-p-dioxin (TCDD) leads to a suppressed CD8+ T cell response to influenza A virus (IAV) infection in both male and female adult F1 offspring. The reduced response is characterized by fewer cytotoxic CD8+ T cells capable of producing the antiviral cytokine interferon gamma (IFNγ). The goal of this study was to determine whether the reduced CD8+ T cell response to IAV observed in male and female offspring was transmitted to the unexposed male and female generation F2. Developmentally exposed F1 offspring were generated by treating dams (F0) with 4 μg/kg body weight doses of TCDD or peanut oil vehicle control. Within each treatment group, F1 offspring were paired with non-sibling F1 offspring to create the F2 generation. The F3 generation was created by pairing F2 offspring with non-sibling, non-cousin F2 offspring from the same treatment group. Mature, 8-week-old F3 male and female vehicle and TCDD lineage offspring were infected with IAV and the CD8+ T cell response was measured using flow cytometry. The CD8+ T cell response to IAV remained suppressed in female TCDD lineage F3 offspring compared to vehicle F3 lineage offspring. In contrast, the CD8+ T cell response to IAV in male vehicle and TCDD lineage did not differ, indicating that the male lineage was no longer affected by F0 exposure to TCDD. Thus, although F0 exposure to TCDD altered the CD8+ T cell response to IAV in both male and female mice in the F1 generation, the durability of the changes across generations varied between sexes. The results of this study indicate that developmental exposures are capable of affecting the immune system across generations. This study across multiple generations also highlights the importance of including both males and females in assessments of the effects of developmental exposures on the immune system across multiple generations.

**1765 Developmental Activation of the Aryl Hydrocarbon Receptor Durably Alters the Responsive Capacity of CD4+ T Cells**

Early life environmental exposures have lasting effects on health and can contribute to disease. For example, exposure to contaminants that contain ligands of the aryl hydrocarbon receptor (AhR), including some organochlorine pesticides, has been linked to decreased immune function later in life. However, the cellular mechanisms that drive these durable changes remain poorly defined. Recently, we showed that developmental activation of the AhR using its prototype ligand 2,3,7,8-tetrachlorodibenzo-p-dioxin (TCDD) impairs conventional CD4+ T cell responses to influenza A virus (IAV) infection in adult offspring. Adoptive transfers revealed this defect is due to a direct effect in the CD4+ T cell lineage. This study demonstrates that the diminished response to an immune challenge, naive animals do not have detectable changes in lymphoid organ cellularity or the distribution of T cell subpopulations. This suggests that developmental exposure causes cryptic changes in CD4+ T cell function, which can contribute to disease. To identify the signaling pathways associated with altered CD4+ T cell functional capacity, we used RNA sequencing. Specifically, we compared gene expression profiles in naïve (CD44lo) and activated (CD44hi) CD4+ T cells from TCDD exposed and vehicle control offspring developmentally exposed to TCDD or vehicle control. Differentially expressed genes were identified in pathways critical for CD4+ T cell activation, proliferation, differentiation, and metabolism. Using functional bioassays, we observed that IAV infected offspring developmentally exposed to TCDD exhibit reduced CD4+ T cell proliferation and T helper differentiation. These findings suggest that AhR activation during development shapes T cell response capacity later in life by affecting numerous cellular pathways, including mitochondrial metabolism. Given that coordinated shifts in T cell metabolism are essential for T cell responses to numerous challenges, and that humans are regularly exposed to many different types of AhR ligands, this has broad reaching implications for how exposure shape T cell mediated immune responses.

**1766 Prenatal Exposure to Perfluoroalkyl Substances (PFASs) and Associations with Childhood Asthma and Allergy Related Outcomes and Infectious Diseases**

Prenatal exposure to perfluoroalkyl substances (PFASs) has been reported to be immunosuppressive in that PFAS levels have been positively associated with rates of infectious diseases in childhood. With respect to asthma- and allergy-related outcomes, reports have been inconsistent. The aim of the study was to investigate associations between prenatal PFAS exposure and asthma- and allergy-related outcomes, and infectious diseases, up to 7 years in a subcohort of the Norwegian Mother and Child Cohort Study. Nineteen PFASs were measured in plasma from a sample of 1,977 pregnant women. Health outcomes were collected from questionnaires and included doctor-diagnosed asthma, atopic eczema, food allergy, and inhaled allergy at 7 years of age and childhood infections at 3 and 7 years of age. Logistic and Poisson regression with Bonferroni corrections were applied. Most abundant PFASs were perfluorooctane sulfonic acid (PFOS), perfluorooctanoic acid (PFOA), perfluorohexane sulfonic acid (PFHxS), perfluorononanoic acid (PFNA), perfluoroundecanoic acid (PFUnDA), and perfluorohexamete sulfonic acid (PFHpS). After corrections, only a negative association between PFUnDA and atopic eczema [OR(95%CI): 0.69(0.55, 0.86)] were found between the six PFASs and the doctor-diagnosed out-
comes at age 7 years. With regard to infections, positive associations were found between PFOA and PFNA and bronchitis/pneumonia at age 3 (p<0.05): 0.22 (0.09, 0.34) and 0.17 (0.08, 0.25), respectively and gastric flu at age 7 years (0.390, 0.27, 0.51) and 0.24 (0.16, 0.32), respectively, and between PFHxS and throat infection at age 3 years (0.260, 0.11, 0.41)). Whereas, negative associations were found between PFOS and PFOA and urinary tract infection -0.24 (0.36, 0.13) and -0.25 (0.38, 0.12), respectively, and PFOS and ear infection at age 3 years (-0.13 (-0.21, -0.06)). The results show a weak support for an association between maternal PFAS levels and allergy-related outcomes. The observed associations between maternal PFAS levels and infections, support immunosuppressive effects for some, but not all, childhood infections.

1769 Difference in Immunological Characteristics between Patients with Malignant Mesothelioma and Diffuse Pleural Thickening

Our previous study has reported the immunological differences between malignant mesothelioma (MM) and pleural plaque (PL) with no tumor, malignant disease and just sign caused by inhalation exposure to asbestos respectively, in which MM showed increases in Treg markers on T helper (Th) cells and blood inflammatory cytokines, whereas PL showed increases in granulocytes with expression in cytotoxic T lymphocytes (CTL) and blood IFN-γ. The present study compared immunological characteristics between MM and diffuse pleural thickening (DP), a benign disease caused by asbestos exposure. Peripheral blood mononuclear cells (PBMCs) and plasma were prepared and assayed for cell surface markers of CD4+ (Th), CD8+ (CTL), CD56+ (NK) and monocytes by lumineux and flow cytometry respectively (FCM). The part of the four population of cells were sorted by FCM and stored in fresh or after 1-day-stimulation with PMA and ionomycin except for monocytes, followed by analysis for mRNA levels of the genes which have a role in development and functions of each population of cells. The surface expressions of GITR and CD69 on Th cells and those of CXCR3 and CD66 on CTL were high in MM compared with DP. The mRNA levels of RORC in Th and of c-Rel were high in MM, whereas the mRNAs of GATA-3 in Th and PRF1 in CTL were high in DP. There were no differences in plasma cytokine concentrations between MM and DP. Those 8 parameters showing the significant differences were statistically examined by linear regression analysis, which resulted in estimation of the two factors. The high factor loading in the first factor was shown by GITR and CD69 on Th, CXCR3 and CD66 on CTL and mRNAs of RORC in Th and c-Rel in NK, whereas mRNAs of GATA-3 and PRF1 in CTL showed high factor loading in the second factor. The 2D plot with these two factors clearly distinguished the two groups of MM and DP. These results indicate that there are obvious differences in immunological characteristics including suppressive function and target-lytic activity executed by Th and CTL between MM and DP.

During primary influenza A virus (IAV) infection, activation of the aryl hydrocarbon receptor (AHR) diminishes host responses by negatively regulating the ability of dendritic cells (DC) to prime naïve CD8 T cells, leading to reduced expansion and differentiation of CD8+ cytotoxic T lymphocytes (CTL). However, the mechanism by which AHR regulates DC function in vivo is unknown. Unbiased gene expression profiling in vivo A. M. Franchini, J. R. Myers, G. Jin, and P. Lawrence. University of Rochester, Rochester, NY.

The prevalence of autism spectrum disorders (ASD) has increased from 1/500 in 1995 to 1/68 in 2010. While the etiology of autism is not entirely understood, it is suggested that multiple factors such as environmental, immunological, and genetic influences are involved. Anti-brain antibodies have been implicated as a possible mechanism for autism pathogenesis. Exposure to diesel exhaust particles (DEP) during pregnancy has been suggested to perturb the maternal-fetal immunologic environment. We propose that DEP exposure during pregnancy can increase the likelihood of anti-brain antibody production, resulting in an increased risk of developing ASD in the child. In vitro DEP exposure reduced neuronal viability and connectivity and the damage is suggested to be due to generation of inflammation and anti-brain antibodies. Sera of individuals with autism and with lupus display antibodies to different brain antigens as delineated by Western analysis. An organotypic culture system demonstrated that DEP inhibits development of dopamine neuron innervation from the substantia nigra into the striatum and cortex.

During primary influenza A virus (IAV) infection, activation of the aryl hydrocarbon receptor (AHR) diminishes host responses by negatively regulating the ability of dendritic cells (DC) to prime naïve CD8 T cells, leading to reduced expansion and differentiation of CD8+ cytotoxic T lymphocytes (CTL). However, the mechanism by which AHR regulates DC function in vivo is unknown. Unbiased gene expression profiling was used to identify gene and signaling pathways in DCs modulated by AHR activation in vivo. Exposure of mice to the prototypical AHR ligand 2,3,7,8-tetrachlorodibenzo- p-dioxin (TCDD) revealed 631 differentially expressed genes (DEGs) in purified lung DCs as compared to DCs from unexposed animals. This region mapped to a β-strand located at the interface between the monomer and the receptor, which recognizes a patch of overlapping peptides, compared with monomer. Antibodies from mice immunized with aggregated scFv preferentially recognize a patch of overlapping peptides, compared with monomer. This region mapped to a β-strand located at the interface between the Vh andVk domains. Further, molecular dynamics simulations indicated that the Vh domain is less stable than the Vk domain, suggesting the interface region between the two domains becomes exposed during partial unfolding of the scFv during aggregate formation. The data are consistent with the hypothesis that epitopes from partially unfolded states become revealed or more exposed in the aggregated state, and that this can augment the IgG antibody response. This observation offers the theoretical possibility that epitopes preferentially associated with aggregates can be identified from the anti-drug antibody serum IgG response which may lead to better methods for detection of anti-drug responses and informed design of therapeutic proteins to control immunogenicity.

1770 Characterization of Immunogenic Responses to Protein Aggregates by Peptide Array
R. J. Dearman1, T. Eyes1, J. Kimber1, N. Smith2, and J. P. Derrick1.
1University of Manchester, Manchester, United Kingdom; and 2Lonza, Cambridge, United Kingdom.

The use of therapeutic protein products or biologics has revolutionized the treatment of inflammatory conditions such as rheumatoid arthritis. Biologics are generally associated with lower onset of toxicity than low molecular weight drugs. However, a major issue is the development of immunogenicity, particularly the development of neutralizing antibodies that compromise efficacy. It has been demonstrated that aggregation of biologics is an important factor driving undesirable immunogenicity but the mechanisms are unclear. There is currently little information as to how aggregates interact with B-cell receptors or cognate antibodies at the protein sequence level and whether aggregate specific epitopes dominate these interactions. Using an antibody fragment (single chain antibody variable fragment; scFv) that forms aggregates following incubation at 40°C for 25min, anti-scFv IgG responses have been induced by intraperitoneal injection of BALB/c mice with monomer or aggregates. Aggregate specific immunogenic signatures have been identified by oligo-peptide micro array, using a series of overlapping 15mer peptides based on the linear sequence of scFv and printed onto glass slides. IgG antibodies from mice immunized with aggregated scFv preferentially recognize a patch of overlapping peptides, compared with monomer. This region mapped to a β-strand located at the interface between the Vh and Vk domains. Further, molecular dynamics simulations indicated that the Vh domain is less stable than the Vk domain, suggesting the interface region between the two domains becomes exposed during partial unfolding of the scFv during aggregate formation. The data are consistent with the hypothesis that epitopes from partially unfolded states become revealed or more exposed in the aggregated state, and that this can augment the IgG antibody response. This observation offers the theoretical possibility that epitopes preferentially associated with aggregates can be identified from the anti-drug antibody serum IgG response which may lead to better methods for detection of anti-drug responses and informed design of therapeutic proteins to control immunogenicity.
Biotherapeutics are finding increasing clinical application, particularly for the treatment of inflammatory diseases such as psoriasis. However, despite humanization, immunogenicity can limit their use due to reduced efficacy and/or associated adverse health effects. Many factors can impact on immunogenicity, and we here characterized the influence of oxidation on protein aggregation and immunogenic potential. The effects of protein oxidation on structure and folding and the quality and vigor of the in vivo immune response following immunization of BALB/c strain mice have been investigated. A model recombinant protein, HEL4, a human V δ domain, was produced in E. coli and purified using Protein A affinity chromatography. The protein was oxidized using hydrogen peroxide and heat treatment (42°C) for one hour, and then stir-stressed to achieve aggregation. Mass spectrometry, NMR, dynamic light scattering and circular dichroism were employed to characterize structural changes in the protein associated with oxidation and aggregation. Groups of BALB/c mice were injected intraperitoneally with unmodified (monomeric), oxidized or oxidized stir-stressed (aggregated) HEL4 weekly for 3 weeks, and serum antibodies were measured by ELISA. Oxidation of HEL4 resulted in loss of tertiary structure, although the protein remained monomeric, and dramatically increased the propensity of the oxidized HEL4 to aggregate. Monomeric HEL4 induced low level antibody production, whereas increased serum IgM, IgG and IgG1 antibodies were detected in mice immunized with the stir-stressed oxidized HEL4, and to a lesser extent, the oxidized HEL4. IgG2a was detected only after immunization with the aggregated protein, suggesting that aggregation triggered preferential activation of Th1 (Th1) cells. Both the Th1 skewing and the persistence of IgM antibody responses may be caused by antigen repetitiveness on the surface of antibody binding to HEL4, as it is a mutant, bovine IgG. The formation of aggregates caused IgM, IgG and IgG1 antibodies to be detected in mice immunized with the oxidized HEL4, and to a lesser extent, the oxidized HEL4. IgG2a was detected only after immunization with the aggregated protein. These data demonstrate that the loss of structure resulting from oxidation caused enhanced protein aggregation and increased immunogenicity, despite humanization, immunogenicity can limit their use due to reduced efficacy and/or associated adverse health effects. Many factors can impact on immunogenicity, and we here characterized the influence of oxidation on protein aggregation and immunogenic potential.
or MEHP supplemented cultures, showing that the neonatal ovaries are not metabolizing DEHP or MEHP. Thus, it is likely that folliculogenensis is not accelerated in neonatal ovaries exposed to DEHP because they do not metabolize it to the more toxic metabolite, MEHP. 1775 Assessment of Oxybenzone, Octylmethoxycinnamate, Octylsalate, and Octocrylene in Endocrine Disruptor Screening Panel Studies

B. McIntyre1, L. Zorrilla2, S. Borghoff, and P. Foster.1.1 NIEHS, Research Triangle Park, NC, and 2IJS, Research Triangle Park, NC.

Oxybenzone (OXY), octylmethoxycinnamate (OCM), octylsalate (OCY), and octocrylene (OCT) are UV absorbing agents in sunscreens. Their potential estrogenic and androgenic effects were evaluated in vitro; estrogen receptor (ER) and androgen receptor (AR) binding and transcriptional activation, and in vivo; rat urotrophic and Hershberger biosassays, respectively. OXY displayed weak ERα-mediated luciferase activity with a LogEC50 of 5.5 LogMl. Using ERs isolated from rat uteri, OXY, OCT, and OCM were classified as “non-interacting” at exposure levels 10-10 to 10-4M. OXY was classified as “equivocal”. Administration of OXY, OCM, OCT, and OCY for 3 days did not alter uterine weights when assessed up to a limit dose of 1g/kg. OCM, OCT and OCY did not exhibit AR agonist or antagonist transcriptional activity. OXY did not demonstrate AR agonism, however there was an exposure-dependent increase in serum inflammatory cytokines (e.g., IFNγ, IL13, and IL6) compared to air controls. In summary, serum collected from dams after peri-implantation O2 exposure was bioactive in naïve trophoblasts and contained an altered metabolic and inflammatory profile. These findings suggest a role for O2-induced systemic factors in the impairment of placental health and vascular remodeling that can lead to IUGR. Abstract does not reflect US EPA policy.

1777 Bisphenol-Specific Effects on Gap Junction Intercellular Communication in Ovarian Theca Cells

J. Gingrich, Y. Pu, B. Upham, and A. Veiga-Lopez. Michigan State University, East Lansing, MI.

Ovarian theca cells provide structural, vascular, and endocrine support to the growing follicle. Gap junctional intercellular communication (GJIC) is essential for cell layer stability, growth, and ovulation. Bisphenols (BPs) are endocrine disrupting chemicals (EDCs) used in the production of polycarbonate plastics and epoxy resins. In particular, bisphenol A (BPA) can impair ovarian development and inhibit GJIC in mammalian epithelial cells. However, much remains unknown on the effects of BPs in ovarian cells, and if this could be a contributing factor towards impaired ovarian development reported in BPA-exposed females. We investigated if BPA, and/or its analogs bisphenol S (BPS) and bisphenol F (BPF), would inhibit GJIC in theca cells at an environmentally relevant dose. A preclinical and monovalent animal, the sheep, was used as an animal model. Primary theca cells were isolated from the ovaries of healthy sheep (n=3) and cell purity confirmed by vimentin and fibrin-5 immunostains. Passage 2 cells were grown to ~80% confluence and exposed to BPA, BPS, or BPF (1, 10, 50, 100, 200, 500, and 1,000 ng/ml) for 24h to establish a maximal response dose. This dose was then used in a time-response experiment (0, 3, 6, 12, and 24h) to determine the form fetal GJIC effect. Finally, inhibitors of the phospholipase C and MAPK pathways were used in conjunction with bisphenol exposure to elucidate a mechanism of action. GJIC was assessed using a scrape loading and dye transfer assay. BPS, but not BPA or BPF, enhanced GJIC starting at 100 ng/ml, peaked at 200 ng/ml, and began to decline at 500 ng/ml. At 200 ng/ml, BPS started to affect GJIC within 3h, but peaked and plateaued after 12h. Additionally, we demonstrate that this effect can be blocked by a PKC-dependent MAPK inhibitor (12-o-tetradecanoylphorbol-13-acetate, TPA), and rescued through pre-treatment with a panPKC-inhibitor (GF109203X). This study is the first to report that BPS can modulate GJIC. Further studies are necessary to elucidate how BPS modulates GJIC through the MAPK signaling pathway, the specificity of this effect to female reproductive tissues, and the in vivo impact enhanced GJIC in the ovary has on female fertility parameters such as steroidogenesis, folliculogenensis, and ovulation. Supported by NIEHS (1K22ES026208 to A.V-L.).
were utilized. Micro-CT imaging of juvenile animals showed that there were no differences in skeletal growth of long bones between the three groups indicating no effects of isoflurane and/or x-ray exposure on the juvenile skeletal growth. In conclusion, micro-CT can be utilized as a valuable tool for skeletal assessments in rat fetuses and for longitudinal long bone measurement in rats from birth to weaning in juvenile toxicity studies.

The Trichloroethylene (TCE) Metabolite S-(1,2-dichlorovinyl)-L-cysteine (DCVC) Alters Oxidative Stress and Apoptotic Responses During Syncytialization in a Human Placental Cell Model (BeWo)

A. L. Su, S. M. Harris, and R. Loch-Caruso. University of Michigan, Ann Arbor, MI.

Syncytialization is a cellular differentiation process in which cytotrophoblasts in the placenta fuse and form multinucleated syncytiotrophoblasts. Syncytiotrophoblasts are the cells at the outermost layer of the fetal side of the placenta, exchanging waste, nutrient, and gas between the mother and fetus. They are also in direct contact with maternal blood and blood-borne toxicants. Despite the importance of syncytialization, literature is scarce about how toxicants may influence the process. This study investigated how the trichloroethylene (TCE) metabolite S-(1,2-dichlorovinyl)-L-cysteine (DCVC) impacts syncytialization and biological responses during syncytialization. DCVC is involved with antioxidant response, these results show that DCVC alters apoptotic and oxidative stress responses during syncytialization. Garcin and associates showed that regulators of cholesterol transport (e.g. STAR) that regulates cholesterol transfer from the endoplasmic reticulum to the plasma membrane were significantly upregulated in placental cells exposed to TBT. These results were replicated in all three species studied. In conclusion, TBT disrupted the ABCA1 expression in a dose-dependent manner. TBT also induced ABCA1 expression in a dose-dependent manner and increased the upregulation of ABCA1 mRNA expression relative to control. These results suggest that TBT disrupts the ABCA1 expression in a dose-dependent manner and increased the upregulation of ABCA1 mRNA expression relative to control.

Low Lead Concentrations Decrease the Sperm Function by Altering the Acrosome Reaction in Mice

The acrosome reaction (AR) is the process necessary to penetrate the oocyte zona pellucida, allowing the fertilization; it consists in the fusion of the outer acrosomal and plasma membrane to release the hydrolytic enzymes of the sperm acrosome. Before the AR occurs, the spermatozoon suffers a series of changes called sperm capacitation that include a rearrangement of the cytoskeleton, which involves the polymerization of actin that is necessary to the RA. Lead (Pb) exposure has been associated with adverse effects on the male reproductive system, including low fertilization and alterations in the acrosome in experimental models at high concentrations similar to occupational exposures. The aim of this study was to evaluate the sperm quality, the AR (initial, spontaneous and induced-ARo, sAR and iAR, respectively) using the labelling with peanut agglutinin (PNA-FITC) and fluorescence microscopy and the sperm capacitation (by Tyr phosphorylation (P-Tyr) and actin polymization) by immunodetection. Sperm cells incubated with capasitizing medium (Witten’s with 6 mg/mL BSA) of CD1-mice exposed to 0.01 % Pb2+/45 days in drinking water (a spermatogenic cycle). Blood Pb (PbB) concentration at the end of the treatment was 9.4 ± 1.6 μg/dL. The sperm quality parameters were not affected, whereas an increase in the ARo was observed compared to the controls (38.4 ± 3.7 vs 57.4 ± 2.4 %, p = 0.0038) and the iAR after the challenge with a calcium ionophore (A23187, functional AR) was decreased (29.4 ± 1.7 vs 15.1 ± 2.0 %, p = 0.001), the sAR was not affected. P-Tyr showed the same level (0.94 ± 0.2 vs 1.0 relative units) in capacitated spermatozoa compared to the controls. Finally, a significant decrease of 67 and 52 % (p<0.001) in actin polymerization was observed in Pb-treated mice in capacitating conditions, in the sperm head and tail, respectively, suggesting a molecular mechanism of Pb toxicity in sperm function. Our data suggest that exposure to environmental concentrations of Pb (PbB <10 μg/dL) decrease the acrosome function (decreased iAR), which can affect the ability of the spermatozoon to fertilize the oocyte, contributing to the male fertility problems.

Multispecies Study: Environmentally Relevant Dose of Tributyltin Impairs Theca Cell Cholesterol Homeostasis Through the Retinoid X Receptor in Pigs, Sheep, and Cows

Y. Pu, J. Gingrich, and A. Veiga-Lopez. Michigan State University, East Lansing, MI.

Tributyltin (TBT) is an organotin chemical used as a chemical catalyst and biocide with human exposure ranging between ~0.1 and 85 ng/ml in blood. TBT can stimulate cholesterol efflux in non-steroidogenic cells, suppressing steroidogenesis. Since cholesterol is the precursor for sex hormone production, we hypothesized that TBT disrupts intracellular cholesterol transport balance and impairs steroidogenesis in ovarian theca cells. We studied TBT’s effect on cholesterol trafficking, luteinization, and steroidogenesis in theca cells in three species (pig, sheep, and cow). Theca cells were isolated and purified from ovaries from all three species with collagenase and cell density gradient. Cell viability and cell death were assessed by trypan blue dye. Immunocytochemistry for impacting syncytialization because previous studies showed DCVC as bioactive in placental cells and have associated TCE exposure with adverse pregnancy outcomes. The BeWo cell line, cultured initially as cytotrophoblasts and induced to differentiate in vitro into syncytiotrophoblasts via forskolin treatment, was used to assess how DCVC affects syncytialization and biological responses during syncytialization. DCVC is involved with antioxidant response, these results show that DCVC alters apoptotic and oxidative stress responses during syncytialization. Garcin and associates showed that regulators of cholesterol transport (e.g. STAR) that regulates cholesterol transfer from the endoplasmic reticulum to the plasma membrane were significantly upregulated in placental cells exposed to TBT. These results were replicated in all three species studied. In conclusion, TBT at an environmentally relevant dose, stimulates theca cell cholesterol transport, but decreases ACAT expression, which reduces the ability of the theca cell to uptake cholesterol from the circulation, impairing the ability of the theca cells to provide cholesterol to the growing oocytes. The challenge of the ARo was observed compared to the controls (38.4 ± 3.7 vs 57.4 ± 2.4 %, p = 0.0038). Finally, a significant decrease of 67 and 52 % (p< 0.001) in actin polymerization was observed in Pb-treated mice in capacitating conditions, in the sperm head and tail, respectively, suggesting a molecular mechanism of Pb toxicity in sperm function. Our data suggest that exposure to environmental concentrations of Pb (PbB <10 μg/dL) decrease the acrosome function (decreased iAR), which can affect the ability of the spermatozoon to fertilize the oocyte, contributing to the male fertility problems.
tests. Testis T production was significantly reduced by DPeP but not by WY or clofibrate. Taken together, these results support the hypothesis that activation of the PP-α pathway is not the MIE in phthalate-mediated male reproductive toxicity in the fetal rat testis. Disclaimer: This abstract does not necessarily reflect US EPA policy.

### 1783 Biological Relevance of Key Events (KE) In Utero in the Androgen Adverse Outcome Pathway Network (AOPn) to Adverse Effects in F1 Male Rats

L. E. Gray1, J. Conley1, C. Lambright1, N. Evans1, V. Wilson1, and P. Foster1. 1.US EPA, Durham, NC, and 2.NIEHS, Durham, NC.

We are conducting studies to evaluate the biological relevance of changes in KEs and molecular initiating events (MIEs) in AOPs to determine if these changes are predictive of the dose levels of chemicals that disrupt the androgen signaling pathway in utero. Herein, we focus on chemicals that disrupt fetal testis endocrine function or act as androgen receptor (AR) antagonists. Our objective is to determine if KE EDS or MIE EC50 can be used to predict the doses that produce adverse effects after exposure during sexual differentiation. While several MIEs for the phthalate AOP have been proposed, the data indicate that PP-α agonists (pinirinic acid, clofibrate and FRD-903, GenX), and a COX inhibitor (Paracetamol) do not reduce fetal testis testosterone production (TROD) or gene expression profiles, in contrast with the phthalate esters (PE). Because the MIE is unknown, we have developed a statistical model of the relationships between the KEs and the adverse effects of PE. This model uses data from several different PE studies and compares reductions in fetal TROD and testis gene expression with the doses that produce reproductive malformations. For AR antagonists, statistical analysis of gene data for >50 chemicals indicate that the in vitro EC50 values for AR antagonism are poorly correlated the ED50 values for effects on male rat reproductive development (R<10%). For example, potency rankings of the in vitro EC50 are negatively correlated with the in vivo EDS for BPC, BPA, vinclozolin and pynfluquinazon. In contrast, the ED50 values for the inhibition of androgen-dependent tissue growth in short-term in vivo assays are highly correlated (R>85%) with the ability of the chemical to disrupt androgen-dependent reproductive tract development in utero. At present, we are unable to entirely replace animals to interrogate the in utero effects of chemicals using the MIEs for PE or AR antagonists, these models do enable us to significantly reduce animal use by using two short term assays to identify points of departure for hazard identification. However, these KEs would not predict the adverse effects of chemicals that disrupt this AOPn through different AOPs. Research is needed to identify as yet unquantified AOPs in the AOPn to improve the predictive ability across all MIEs and to integrate these into a predictive statistical model. This abstract does not reflect Agency Policy.

### 1784 Difference in MiRNA Expression by Several Testicular Toxicants

Testicular toxicity is induced by several chemicals, such as drug or fertilizer, and the toxicity is a one of the cause of withdrawal for drug development. Recently, it was reported non-coding RNA has a role for spermatogenesis. In the present study, we investigated changes in microRNA expression by several testicular toxicants, ethylene glycol monomethyl ether (EGME, spermatocyes target compound), dimethoxybenzene (DB, Sertoli cells), 2.5-hexahexide (HD, Sertoli cell) and cyclophosphamide (CP, spermatogonia). As a first study, EGME administered to the male rats at 2000 mg/kg single orally and after 6 and 24 hr of dosing, testes were applied to histopathological examination and gene expression analysis using mRNA microarray and real-time RT-PCR. At 6hr, slight decrease of phacypetere spermatocytes with cell shrinkage and nucleus pyknosis and, at 24 hr, remarkable decrease or cell death of phacypetere spermatocytes with Sertoli cell vacuolation were observed. Gene expression analyses revealed increases in mir-700-5p expression at 6 hr and mir-134, mir-320 and mir-188-5p at 24 hr, and decreases in mir-449a and mir-92a at 24 hr. As a second study, different testicular toxicants, DB, HD or CP were given to male rats and after 24 hr, histopathological changes and above the microRNA expression were investigated. Histopathologically, decrease or cell death of spermatocytes and vacuolation of Sertoli cell was observed in DB treatment, and cell death of spermatocytes was seen in CP, but there was no change in HD. DB and HD, induced decreases in mir-134 and mir-320 expression, and there were no changes by CP, there were different changes by EGME. Taken together, the different reaction of microRNA expression may be reflected on the difference of target cells, and these data indicated these microRNAs might work as the biomarker of testicular injury.

### 1785 Evaluation of 2,3,4,5-Tetrabromo-Ethylhexylbenzoate (EHTBB)-Treated Fischer Rats in a Reproduction Screening Study

EHTBB, a common environmental contaminant in found in household dust, is a component of the flame retardant mixture Firemaster550 (FM550). FM550 replaces PBDEs and is used in the production of foam for baby chairs and mattresses and is an exposure concern for children. Routes of exposure for humans to EHTBB are unclear, although ingestion and inhalation of flame retardants has been well documented. EHTBB-related changes were monitored using apical indicators of health status in Fischer rats following oral exposure via a rodent reproductive screening study (OECD TG421). Rats were exposed in feed, ranging in dose from 0mg to 7500mg/EHTBB/kg feed. Male and female rats were on dose for 14 days prior to breeding. Male rats were 56±1 days on dose (DOD) prior to necropsy. Dams were 40-52 DOD when necropsied at postnatal day 4 (PND4). Pups were also necropsied at PND4. Body weights (BW) of rats on the 7500mg EHTBB/kg diet were significantly decreased in females compared to controls beginning on DOD3 and in males on DOD7, and remained so for the duration of the study. Animals dosed at 1875mg EHTBB/kg diet had significant decreases in BW by DOD7 in females and DOD35 in males. Food palatability was not the reason for weight loss in the high dose. Water consumption was significantly increased by DOD10 and remained so in both sexes at 7500mg EHTBB/kg diet. Excessive urination was also observed in the high dose group. Organ weight/BW ratios at necropsy were significantly changed in thymus, spleen, thyroid, kidneys and brains for females and males at 7500mg EHTBB/kg diet. Organ weights were also significantly affected for testes, heart, liver and adrenals in males, and for ovaries and uterus in females. Reproductively, no live births were observed in females at 7500mg EHTBB/kg diet and significantly reduced litter weights were found at PND4 for 1875mg EHTBB/kg diet group. Male sperm kinetic parameters at time of necropsy showed severely affected sperm motility in the highest dose group. These reproductive changes, combined with clinical chemistry and haematology endpoints, indicate that EHTBB has a number of potential target organs resulting in multiple health effects.

### 1786 The Effects of Electronic Cigarette Vapor on Placental Trophoblast Cell Function

Despite evidence that maternal smoking is associated with numerous adverse outcomes, 10-35% of women still smoke during pregnancy. Recently, electronic cigarettes (e-cigarettes) and other electronic nicotine delivery systems have become available, and are being marketed as effective smoking cessation tools. However, there is considerable uncertainty regarding their safety for use during pregnancy. The goal of this study was to examine the effects of e-cigarette vapor (EVOD KangerTech*) to vaporize 3ml of unflavored e-liquids containing 0 or 12 mg/ml nicotine (Blacklisted®) into 30ml of cell culture media. Htr-8/SVneo cells, a model of first trimester trophoblast cells, were exposed to up to 1% of the vapor conditioned media to assess cell viability (LDH release), proliferation (BrdU incorporation), migration (wound healing assay), invasion (Matrigel Transwell assay), and tube formation (a surrogate for angiogenesis). Exposure to e-cigarette conditioned media with or without nicotine did not significantly affect cell viability, proliferation or migration (all p>0.05) at any dose tested. Treatment with e-cigarette conditioned media with or without nicotine reduced trophoblast invasion by 35-40% versus control (p<0.05). E-cigarette conditioned media also had no effects on tube formation with significant reductions in total tube length, total segment length, and number of junctions (p<0.05). Exposure to e-cigarette vapor conditioned media had profound effects on normal placental trophoblast function; an effect which could not be solely attributed to the presence of nicotine. These results suggest that an evaluation of the safety of e-cigarette use during pregnancy is urgently required.
Indianapolis, IN; and decreases in induction. Dose dependent maternal and fetal endpoints were examined on GD20. TCDD tissue concentration was followed by GD9-20 daily maintenance doses to examine the potency of 2,3,7,8-tetrachlorodibenzofuran (TCDF) relative to TCDD or TCDF Effects on Pituitary and Testicular Steroidogenic Pathways

R. Budinsky, J. Passage, S. Sriman, L. Aylward, and K. Johnson. Dow Chemical Company, Midland, MI; Dow AgroSciences, Indianapolis, IN; and Summit Toxicology, Falls Church, VA.

In utero exposure to TCDD can reduce epididymal sperm counts in adult rats. A mode-of-action (MOA) involving AhR-induced suppression of fetal Leydig cell production has been proposed. Experiments were performed to evaluate fetal and in vitro activation on pituitary and testis steroidogenic genes expression and to examine the potency of 2,3,7,8-tetrachlorodibenzo-p-dioxin (TCDD) relative to TCDD. Pregnant Sprague Dawley rats (n = 5/group) were gavaged with 30, 50, 100, 1500, 2000, 6000, or 10,000 ng/kg of TCDD or TCDF on GD8. The GD8 loading dose was followed by GD9-20 daily maintenance doses of 0, 3, 30, 220, 220, 660, 1230, and 2200 ng/kg/day for TCDD. We also examined the response to a single GD15 dose of 10,000 ng/kg for both congers. In both study designs, maternal and fetal endpoints were examined on GD20. TCDD tissue concentrations in dam liver and adipose and the whole fetus were higher than TCDF (e.g., up to approximately 4- and 6-fold, respectively). One to two orders of magnitude higher maternal TCDD and TCDF concentrations were observed in maternal tissue relative to the whole fetus. AhR activation was observed in all tissues examined (including fetal pituitary and testis) as evidenced by Cyp11a induction. Dose dependent increases in Lhb and Fshb gene expression were observed in fetal pituitary after TCDD but not with TCDF. TCDD, but not TCDF, produced a dose-dependent decrease in fetal testis steroidogenic genes (Star, Cyp11a1, Cyp17a1, and Scarb1). While the evidence suggests a potential mode-of-action for reduced epididymal sperm counts, relatively high doses of TCDD or TCDF was required. The lack of a significant effect of TCDD on fetal pituitary gonadotropin and testis steroidogenic gene expression could be secondary to limited tissue concentration accumulation caused by its self-induced metabolic clearance. TCDF’s absent response and unique kinetics should be uncertainty considerations in the development of its relative potency and toxic equivalency factor.
D(2-ethylhexyl) phthalate (DEHP) is a plasticizer used in numerous consumer products. Studies have shown that DEHP acts as an endocrine disrupting chemical and adversely affects reproductive outcomes in males. However, little is known about the effects of prenatal DEHP exposure on female reproductive outcomes and whether these effects occur in subsequent generations. Therefore, this study tested the hypothesis that prenatal exposure to DEHP accelerates the onset of puberty, disrupts birth outcomes, reduces fertility-related indices, and accelerates the onset of reproductive senescence in the F1, F2, and F3 generations of female mice. To test this hypothesis, pregnant CD-1 mice were orally dosed with corn oil (vehicle control) or DEHP (20 and 200 µg/kg/day, and 500, and 730 mg/kg/day) daily from gestation day 10.5 until birth. To produce the subsequent generations, F1 females were mated with untreated males to obtain the F2 generation and F2 females were mated with untreated males to produce the F3 generation. In the F1 generation, prenatal exposure to DEHP accelerated the onset of puberty and disrupted fertility-related indices. In the F2 generation, exposure to DEHP accelerated the onset of puberty, increased the female sex ratio, and disrupted fertility-related indices. In the F3 generation, DEHP exposure accelerated the onset of puberty, increased the female sex ratio, decreased female pup anogenital index, and reduced fertility-related indices. Collectively, these data indicate that prenatal DEHP exposure at environmentally relevant doses accelerates the onset of puberty, disrupts birth outcomes, and disrupts fertility-related indices in a multigenerational and transgenerational manner in female mice. These data also indicate that prenatal exposure to DEHP accelerates reproductive aging in a multigenerational and transgenerational manner. Supported by NIH P01 ES028484, EPA RD-83459301, T32 ES057326, and the Billie A. Field Fellowship.

**Prenatal Exposure to Di(2-ethylhexyl) Phthalate Promotes Adverse Transgenerational Effects on the Reproductive Capacity of Female Mice**

**High-Quality Sperm RNA Isolation for Preclinical and Clinical Reproductive Toxicogenomic Studies**

E. Bianchi1,2, A. Stermer1, K. Boekelheide1, M. Sigman1,2, S. J. Hall1, and K. Hwang1,2. Brown University, Providence, RI; and Rhode Island Hospital, Providence, RI.

Gene expression profiling of mammalian sperm has been proposed as a novel non-invasive tool to evaluate male fertility and testicular toxicity. However, isolation of sperm RNA is a challenging procedure due to the unique biology of sperm and the heterogeneous population of cells present in the ejaculate, indicating the need for high quality control checks to ensure reproducibility of data generated from sperm RNA. Semen contains somatic cells, such as leucocytes and epithelial cells, along with spermatooza that contain a very low abundance of RNAs compared to somatic cells. Therefore, somatic cell removal is essential to avoid contamination of sperm transcripts. The present study was designed to develop a reliable and effective protocol for RNA isolation from rat and human sperm that delivers highly purified and intact RNA, verified using RNA-specific electrophoresis and molecular biology approaches such as RT-PCR and western blot analysis. To develop a standardized sperm RNA protocol, we evaluated quality and purity of rat sperm RNAs isolated using different sperm collection, purification and RNA extraction approaches. For rat, a high-quality sperm RNA extraction methodology consists of collection of epididymal fluid with repeated needle punctures of the epididymis, somatic cell elimination using detergent-based somatic cell lysis buffer (SCLB), and the use of a RNA isolation Kit. This sperm RNA isolation technique was then adapted to human sperm. The method we have optimized is suitable for comparative sperm transcriptomic analysis, such as sequencing and directed PCR. In conclusion, this RNA isolation protocol across species adaptations improves reproducibility of functional genomics studies of pharmacetical, chemical, and environmental exposures and infertility in pre-clinical and clinical setting.

**Utilizing In Vitro Developmental Models to Predict Teratogenic Exposures**

J. Panzica-Kelly, and K. Augustine-Rauch, Bristol-Myers Squibb, Pennington, NJ.

In vitro developmental toxicity assays have been evaluated extensively for hazard identification of compounds for potential teratogenic liability. However less is understood regarding how these assays may predict in vivo teratogenic exposures. Our laboratory combined cytotoxicity and dysmorphology in a 2 assay paradigm for predicting a range of concentrations that may correlate with teratogenic Cmax concentration in vivo. Twenty-one compounds with characterized teratogenic Cmax were used to treat mouse embryonic stem (ES) cells in a concentration range designed to identify an IC50 value over a 3-day culture period. The IC50 was used to establish a possible adverse effect exposure range in vivo (1:25 ratio of the IC50 to the IC50 value). The positive in vitro exposure concentration was captured in the predicted range in 13 out of 15 compounds (87%). The remaining 6 compounds exhibited solubility limitations with undetermined IC50 values. These compounds were assessed in rat whole embryo culture (WEC) by treating gestation day 9 embryos for 48 hours at the positive in vivo concentration of each compound. Percent effect was calculated by morphological assessment of each embryo and a 30% increase of malformations predicted in vivo teratogenic exposure. Three of 6 compounds presented teratogenicity in WEC at their reported teratogenic Cmax concentration. An expanded concentration range is under exploration to determine whether it could increase sensitivity and be applied in this paradigm. Using the ES-WEC strategy with the current methodology, predicted teratogenic Cmax concentration range was correct for 16 out of 21 compounds (76%).

**Elucidation of the Mechanism of Nitinol Toxicity in Human Fallopian Tube Cells**

Nitinol, the nickel-titanium alloy, is the major constituent of multiple medical devices including cardiovascular and reproductive stents. The cardiovascular devices have been used routinely with minimal adverse clinical effects; however, the nitinol-based devices inserted in female reproductive tracts (i.e., fallopian tubes) cause severe inflammatory and hypersensitivity responses. The reason why the reproductive tissue
Other studies have detected TiO\textsubscript{2}-NP in the ovary, demonstrating that as well. More studies are needed. Antral follicles toxicity for each NP. These effects may be related to steroidogenic follicular internalization followed by cell death. The internalization of nickel is a function of exposure time and concentration with significant uptake observed at even the lowest concentration (0.25 mM) and the shortest exposure time (5 hours). This is linearly correlated to programmed cell death because the membrane flipping, studied with Annexin V antibody and flow cytometry, increased with nickel internalization. Expression of follicular lineage specific genes was unchanged during 5h exposures; however, majority of genes including PAX8, WDFD2, CP, CLDN3, KRT7, and MSLN were significantly down regulated (75-90%) with increasing concentrations in 24-hour exposure. Thus, the data indicate that nickel toxicity in fallopian tube cells is dependent on nickel release and that CP and PAX8 expression might serve as diagnostic biomarkers for hypersensitivity reactions.

### 1796 Effects of TiO\textsubscript{2} and ZnO Nanoparticles on Ovarian Antral Follicle Morphology and Growth

Nanoparticles (NP) are widely used because of their novel properties. NP properties and biological effects can be modified by characteristics such as the core material, size, charge, among others. Zinc oxide nanoparticles (ZnO-NP) and titanium dioxide nanoparticles (TiO\textsubscript{2}-NP) are used in several personal care products. Some studies have found that ZnO-NP and TiO\textsubscript{2}-NP exposure decrease hormone levels and pregnancy rate. Other studies have detected TiO\textsubscript{2}-NP in the ovary, demonstrating that this NP is able to circulate in the bloodstream and reach the female gonad. However, knowledge on the toxic effects or the mechanisms in the female reproductive function is limited. Follicle microenvironment closely relates to alterations on the oocyte quality. Ovarian follicles are responsible for steroidogenic hormone production and growing, housing and promoting competence of the oocyte to release a competent oocyte into the oviduct. This work aimed to evaluate ovarian follicle growth and morphology alterations after TiO\textsubscript{2} and ZnO NP exposure. Agglomeration can modify some NP properties, which can determine their transport to the ovary. Thus, we established a dispersion of the nanoparticles in water (stock suspension) and characterized their hydrodynamic diameter (D\textsubscript{h}) and zeta potential (ζ) in culture medium for both NP. Antral follicles from fresh C57BL/6J mouse ovaries were cultured for 7 days in groups: 1) control (culture medium), 2) low NP concentration (5 μg/mL), and 3) high NP concentration (50 μg/mL). Follicle growth was recorded during 7 days of culture by measuring follicle size in two perpendicular axes, and using an inverted microscope with a calibrated ocular micrometer. Follicular morphology was assessed on images captured on days 0, 3, and 7 of culture. Our results suggest that NP form agglomerates in culture medium with sizes ranging from 118 to 538 nm for TiO\textsubscript{2}-NP and 25 to 311 nm for ZnO-NP, having potential zeta values in the -14.6 to -10.0 mV range. Follicular growth was delayed by the high ZnO-NP concentration, whereas the follicular morphology was altered by the high TiO\textsubscript{2}-NP concentration, suggesting different mechanisms of toxicity for each NP. These effects may be related to steroidopgenic follicular activity and oocyte development quality alterations. Antral follicles can be affected by NP exposure, and normal functions can be damaged as well. More studies are needed.

### 1797 Environmentally Relevant Doses of Di(2-Ethylhexyl) Phthalate (DEHP) Increases the Rate of Arrest in Cell Divisions of the Zygote

L. Y. Parra-Forero\textsuperscript{1}, M. A. Mojica-Villegas\textsuperscript{2}, E. Alfaro-Pedraza\textsuperscript{1}, and J. Hernández-Ochoa\textsuperscript{1,3}, \textsuperscript{1}CINVESTAV-IPN, Mexico City, Mexico; and \textsuperscript{2}National Polytechnic Institute, Mexico City, Mexico.

Di (2-ethylhexyl) phthalate (DEHP) is an endocrine disrupting chemical used as a plasticizer that has been related to numerous pathologies, including a negative influence in the high percentage of infertility. High doses of DEHP have been associated with detrimental effects on oocyte maturation, zygote development and implantation failures; however, the relevant doses of environmental chemicals are unknown. This study was aimed to determine the effect of environmentally relevant DEHP doses on zygote development using a murine model. Female CD1 mice older than 3 to 4 weeks with vaginal opening were administered orally with 0, 20, 200, or 2000 μg DEHP/kg of body weight (bw)/day using tocopherol-free gel as vehicle. Treatment was extended with four estrous cycles (15-20 days), from estrus to estrus. The highest dose is equivalent to an occupational exposure, whereas the intermediate and lower doses are equivalent to an environmental exposure. After the dosing period, females were induced to superovulate by injecting ip 5 IU pregnant mare serum gonadotropin (PMSG), followed by 5 IU human chorionic gonadotropin (hCG) 48 h later. After hCG injection, females were mated with a non-exposed male of proven fertility, and then sacrificed at different times to obtain zygotes in specific cell divisions, such as 1-, 2-, 4- cells, morula and blastocyst. The data showed no significant differences in estrous cycle length, however, the number of zygotes was significantly decreased by DEHP treatment at each stage of development (zygote from 1 cell to blastocyst), whereas the dose of 200 μg/kg bw/day increased cellular division arrest at the late stages of zygotic development (Morula and blastocysts). Taken together, these data suggest that an environmental dose of DEHP (200 μg/kg bw/day) may impair zygote development, but higher doses may also impair earlier events such as ovulation and fertilization.

### 1798 Mono-(2-ethylhexyl) Phthalate (MEHP) Reversely Perturbs Blood Testis Barrier (BTB) in Pre-Pubertal Rats

R. Tiwary, University of Texas at Austin, Austin, TX. Sponsor: J. Richburg

The blood testis barrier (BTB) constituted by tight junctions between Sertoli cells creates an unique microenvironment for developing spermatocytes, is a well-studied target of numerous environmental toxicants. MEHP is the active metabolite of a widely used plasticizer (DEHP) in commercial products and has been recognized as a reproductive toxicant. Here, the influence of MEHP on BTB integrity is described as well as the signal transduction pathways that underlie this effect. Treatment of Post Natal Day (PND) 27 rats with 700 mg/kg MEHP for 24 hours perturbed the BTB integrity as indicated by a biotin tracer assay. Additionally, MEHP treatment induced transient surge of p44/42 Mitogen Activated Protein Kinase (MAPK)-JNK1/2, p38 and ERK protein kinases, possibly instigated via the observed enhanced expression levels of pro-inflammatory cytokines-IL-6 and TNFα as indicated by qPCR analysis. We further investigated that MEHP treatment of PND 27 rats with 700 mg/kg MEHP followed by a recovery period of 5 weeks could reverse the BTB disruption. Taken together, these findings indicate a role for the MAPK pathway in instigating the disruption of the BTB disruption after MEHP exposure; although this effect on the BTB was reversible.

### 1799 Effects of Developmental Exposure to Bisphenol AF on Sprague Dawley Rats

M. Bharadwaj, J. Warmack, and S. E. Fenton, NIEHS, Research Triangle Park, NC.

Bisphenol AF (BPAF) is a fluorinated analogue of Bisphenol A (BPA). It is used in the manufacturing of common consumer products. The estrogenic activity of BPA has been well characterized but little is known regarding the effects of its analogues in use, such as BPAF. This study determined endocrine-related health outcomes in Sprague Dawley rats offspring following early-life exposure to BPAF. Timed-pregnant dams were randomly assigned to 6 groups (Vehicle control (VC): n = 16, 2 groups; BPAF: n = 8 or 9, 4 dose groups). Dams were gavaged, twice daily starting on gestation day (GD) 6 through postnatal day (PND) 21 in

#### References

groups that were blindly allocated: 0, 0.25, 1.0, 2.5, or 25.0 mg BPA/kg body weight (BW). Dams were weighed and dosing was adjusted daily. The VC was 5 mL refined sesame oil/kg BW. Litter size, pup BW, and live/ dead count were recorded on PND 1. Litter sizes were equalized on PND 4 (n = 8; −4 M:4 F) and BW was recorded until PND 21. On PND 4 and 21, one pup/sex and their respective dams (PND 21) were euthanized and biological samples were collected for analysis of metabolic and internal BPA dose. All remaining offspring were evaluated for pubertal timing. The dam’s percent BW gain during gestation was significantly lower in the highest dose group (p < 0.01) compared to controls. The gestational length was not significantly different from VC. There was no significant loss of fetuses during gestation (gestation loss = total implantation sites − total pups born). The loss of pups from birth until PND 4 (partition loss) was elevated in the highest dose group (18.9 ± 7.7 vs 45.8 ± 14.6%; p = 0.14). Regardless of sex, the pup BW at birth and PND 4 in the highest dose group were significantly lower than those from VC dams (p = 0.02 and 0.01; respectively). However, the pup BW at PND 21 did not show significant changes at any of the dose levels, compared to VC. The age of vaginal opening (VO) for exposed females was not significantly different from the pups born from VC dams but the BW at VO in the highest dose group was significantly lower (p < 0.01) than VC pups. Genotype effects on VO were not observed. The overall significant effects on body weight and elevated pup loss may be related to the potential disruption of normal hormonal activities. Further studies are warranted to pinpoint the exact timing and alterations of specific gene signaling pathways that may be associated with these phenotypes.

1800 A Mouse Population-Guided Approach to Identify Genetic Loci That Potentially Modulate TCDD-Mediated Gene Dysregulation in the Uterus

K. Bayes1, D. Nava1, P. Dombos1, M. Warren2, D. Threadgill2, E. Crockett3, and J. LaPres3. 1Michigan State University, East Lansing, MI; and 2Texas A&M University, College Station, TX.

2,3,7,8-tetrachlorodibenzo-p-dioxin (TCDD) is a ubiquitous environmental contaminant that causes a number of disease states, such as metabolic syndrome, cancer, and embryo toxicity. Most, if not all, of these toxicities are mediated through activation of a PAS-superfamily transcription factor called the aryl hydrocarbon receptor (AHR). Little is known how multiple exposures ultimately lead to TCDD-induced pathologies. Here, we used a population-based approach to identify potential genetic modifiers that may affect susceptibility to TCDD-mediated gene expression in the uterus of pregnant mice. In specific crosses (males x females), 54 genetically diverse strains of mice were dosed with 0, 1, or 100 ng/kg/day of TCDD for the first 10 days of pregnancy. Following exposure, total mRNA was extracted from the uterus and the expression of 9 AHR-target genes was assessed. Interestingly, though the 14 strains of mice varied in the AHR allele they carried, the expression of several AHR-target genes, such as cytochrome P450 1A1, did not follow the predicted pattern how such strains differ. The gene expression results were used to scan the genome for quantitative trait loci (QTL) to identify genetic modifiers that drive strain-specific expression patterns. Statistically significant QTL peaks (p<0.05) were found to overlap across multiple AHR-target genes on three chromosomes (1, 9, and 13). The overlap in significant peaks may indicate novel genetic modulators involved in driving inter-strain differences in AHR-mediated gene transcription in the uterus. Furthermore, these results may help identify genetic variants within the human population that may be at higher risk for TCDD-mediated toxicity.

1801 Chemical-Induced Facial Dismorphogenesis: A Modeling Approach to Help Understanding of the Mode-of-Action

F. Metrucci1, A. Moretto2, F. Di Renzo2, and E. Menegola2. 1ASST Fatebenefratelli Sacco, Milano, Italy; and 2University of Milano, Milano, Italy.

Oral clefts are multifactorial in origin, involving both genetic and environmental risk factors during the first trimester of pregnancy, but specific causes of mostly are unknown. The identification of the target of the different chemicals contributing to cranio-facial morphogenesis is a key step to identify the altered morphogenetic pathways and to evaluate the contribution of multiple exposures to the development of such defects. The post-implantation rat whole embryo culture (WEC) is a validated toxicological method proposed also for modelling approaches. The aim is to fit the experimental data from WEC exposed to facial morphogens, by using PROAST software, in order to model the experimental data and ascertain whether the different molecules could act via the same pathogenic pathway. The chemicals selected were: retinoic acid (RA), ethanol (EtOH), and azole antifungals (the human drug fluconazole, FLUCO and the antiprotozoal dihydrofuran, FON) and anti-epileptics (valproic acid, VPA). All selected molecules induce branchial arch defects in WEC. RA was chosen as index compound considering that all the other selected molecules are suspected to interfere with RA signaling cascade. A syndrome similar to the one described after RA, EtOH and furosemide (an anti-diuretic response exposure) was selected: the affected districts were the encephalon, the facial primordia and the auricles (branchial apparatus) and the tail. By contrast, the exposure to azoles affected only the branchial arches. The PROAST analysis was applied only on branchial outcomes, the common target for all the tested substances. Data were modelled in order to obtain the different dose-response curves (Hill model) and to evaluate the steepness confidence intervals. As the parallelism hypothesis was not rejected, data were analysed by using the exponential model normalizing the potency of each compound to that of RA. Dosages were then transformed in RA-equivalents and data was analysed dataset by dataset the data passed the goodness-of-fit test and, therefore, the assumption of a similar mode of action for the different molecules cannot be rejected. The results of the present work are consistent with the hypothesis that a common morphogenetic pathway is affected by the exposure to the tested chemicals triggering the observed craniofacial defects. Supported by H2020 Euromix.

1802 MEHP-Induced Germ Cell Apoptosis

J. J. Voss, A. R. Stermer, R. Ghaifari, R. Tiwary, and J. H. Richburg. University of Texas at Austin, Austin, TX.

The testis is an immune-privileged organ that maintains an immune suppressive environment with few leucocytes in the testicular interstitium. We have previously shown that exposure of peripubertal (postnatal day) (PND) 28 Fischer rats to an acute dose of mono(2-ethylhexyl) phthalate (MEHP), a well-described Sertoli cell toxicant, leads to an accumulation of CD11b+ cells in the interstitial space of the testis that closely correlates with a robust incidence of germ cell (GC) apoptosis. CD11b is expressed on the outer membrane of many leucocytes of the innate immune system, including monocytes, macrophages, and granulocytes. Here we test the hypothesis that the infiltrating immune cells contribute to GC cell death. PND 28 Fischer rats that received 100 mg/kg MEHP showed a significant CD11b+ immune cell infiltrate consisting of both CD68+ cells, a monocyte and macrophage marker, and neutrophils, identified by morphology and the expression of myeloperoxidase. The numbers of both cell types peaked at 12 hours, but by 48 hours, the numbers of infiltrating GCs had returned to baseline. An immunofluorescence analysis of the testicular macrophages of MEHP-treated rats showed significantly upregulated expression of Tnfα and iNOS, and the Arg1/Nos2 ratio was reduced compared to macrophages from the interstitium of control-treated tests, although small increases in Il10 and Tgfβ1 were observed too. Depletion of circulating monocytes with Gd2+ liposome phosphate prior to MEHP-treatment did reduce the macrophage influx into the testis, but did not lower germ cell apoptosis. Additionally, depletion of neutrophils using an anti-polymorphonuclear cells antibody prevented both macrophage and neutrophil infiltration into the testis, but also did not affect germ cell apoptosis. These results show that exposure to MEHP leads to a rapid and temporary influx of pro-inflammatory monocytes and neutrophils in the interstitium of the testis. However, with this dosing paradigm, they do not appear to exacerbate phthalate-induced injury to the testis and their functional significance remains unknown.

1803 Dog Testis Toxicity of Glucagon Receptor Antagonist Monitored Using Monthly Sperm Assessment, Followed by Recovery

C. J. Bowman1, A. Papanikolaou2, F. J. Geoly1, L. W. Udyke1, S. R. Dalton2, and G. D. Cappon1. 1Pfizer, Inc., Groton, CT; and 2Covance, Madison, WI.

Microscopic effects on spermatogenesis were observed in the testis and epididymis with 3 months of dosing dogs at ≥150 mg/kg/day with PF-06291874, a glucagon receptor antagonist. No effects were observed in shorter duration dog studies or in any rat studies at similar doses. To better characterize the onset and reversibility of this toxicity in dogs, sperm from normospermic dogs were euthanized, and rats were sacrificed at multiple time points. Sperm were monitored monthly during a 9-month study with a 5-month recovery period. In the 9-month study, male beagle dogs were dosed once daily by oral gavage with 0, 10, 50, 100, or 500 mg/kg with 8, 5, 5, 8, and 11 male dogs per group (female dogs were also part of the study but are not described here). Five males per group were necropsied after 9 months...
and 3 males in the control, 100 and 500 mg/kg groups were necropsied after a 5-month recovery. Post-mortem evaluation included weights and microscopic evaluation of the reproductive organs. Semen from all animals was collected approximately monthly for automated evaluation of sperm motility, density, and total counts using a Hamilton Thorne IVOS sperm analyzer. The microscopic findings in the tests at the end of the dosing phase as recorded in the group exposed to CrVI were reduced sperm count, incidence and severity of multinucleated spermatocytes at ≥100 mg/kg and degeneration of spermatocytes at 500 mg/kg. Considered secondary to the testis damage, hyposperma and cellular debris were noted in the epididymis at ≥100 mg/kg. The monthly sperm analysis resulted in test article induced reductions in sperm density and no significant differences in sperm counts during the dosing phase at ≥100 mg/kg. These effects on sperm generally started during month 3 of the dosing phase and generally correlated with the microscopic findings in the testis and epididymis. Although 2 out of 3 recovery animals at 500 mg/kg indicated lower sperm counts and motility at the end of dosing, there were no male reproductive effects observed at the end of the recovery period, including recovery of sperm endpoints. In conclusion, serial sperm evaluation provided time-course information complementary to the terminal testicular toxicity observed, as well as a potential predictive biomarker of recovery in the testis and epididymis.

1804 Temephos Impairs Ovulation, Oocyte Fertilization, and Zygote Quality in an In Vivo Model
E. Alfaro-Pedraza1, L. Y. Parra-Forero1, M. A. Mojica-Villegas2, J. F. Herrera-Moreno2, A. E. Rojas-García2, and I. Hernandez-Ochoa1. 1CINVESTAV-IPN, Mexico City, Mexico; and 2Universidad Autónoma de Nayarit, Tepic, Nayarit, Mexico.

Temephos is an organophosphate pesticide approved by the World Health Organization (WHO) to combat vectors (Aedes aegypti) that transmit diseases, such as dengue virus and zika, and it is classified as a pesticide of low toxicity. In recent years, the toxic effects of temephos have been observed as a result of studies showing cytotoxic effects on human lymphocytes when using similar concentrations to those found in the environment. However, the potential reproductive toxicity of temephos is scarcely studied. The aim of this study was to evaluate the effect of temephos on oocyte fertilization and zygote quality. CD1 female mice received orally 15, 150 and 1500 μg/kg/day of temephos during 4 estrous cycles. To evaluate temephos toxicity, the enzymatic activity of acetylcholinesterase (AChE) and butyrylcholinesterase (BuChE) was assessed in blood and serum, respectively, by the Ellman method. At the end of exposure, females were mated with no-exposed males and 48 h later the 2-cell zygotes were collected. Our results showed that there were no significant differences in body weight gain of the treated females remained at each stage of the cycle were similar to those spent by the control group. The total number of released zygotes and the number of 2-cell zygotes were decreased in the 150 and 1500 μg/kg/day- treated groups compared to control. Furthermore, zygotes from the 150 and 1500 μg/kg/day doses had high rates of fragmented blastomeres compared to control. In conclusion, in vivo exposure to organophosphorous pesticide temephos impairs ovulation, fertilization and the zygote quality without altering AChE and BuChE activities. Supported by the Pesticide Toxicology Network-Conacyt No. 280945. [RESCM1]QUITA UNO.

1805 Vitamin C and Moringa oleifera Leaves Ameliorate Carbamazepine-Induced Reproductive Toxicity in Male Wistar Rats
J. G. Akorede1, A. Basiru1, H. G. Mikail2, F. S. Ambali1, and T. K. Biobaku1. 1University of Ilorin, Ilorin, Nigeria; and 2University of Abuya, Abuja, Nigeria.

The use of antiepileptic drugs for chemotherapy has been popular for practices in decades. However, long time use of certain antiepileptic drugs such as carbamazepine (CBZ) may reduce sperm motility, induce sperm abnormalities and decrease testicular volume. The present study was aimed at evaluating the effect of vitamin C and Moringa oleifera (MO) in ameliorating adverse reproductive effect, induced by chronic CBZ administration in Wistar rats. Forty adult male wistar rats (150-250g) were randomly divided into 5 groups (8= each). Group I received distilled water (DW) at 2 ml/kg; Group II was administered vitamin C (100 mg/kg); Group III was administered Moringa oleifera (250 mg/kg), Group IV was administered CBZ only (20 mg/kg) while Group V was pretreated with vitamin C (100 μg/kg), MO (250 mg/kg) and exposed to CBZ (20 mg/kg) after 30 minutes. The regimens were administered orally once daily for 15 weeks. At the end of the treatment period, the rats were sacrificed and the pituitary glands and testicular tissues were assayed for Malondialdehyde (MDA) concentrations and Superoxide dismutase (SOD) and Catalase (CAT) activities. The serum was assayed for follicle stimulating hormone (FSH), luteinizing hormone (LH) and testosterone, epididymal sperm count and sperm motility was also determined. Data obtained were expressed as mean ± SEM and analyzed using ANOVA. The result showed that the significant increase in concentrations of pituitary and testicular MDA and a decrease in the activities of SOD and CAT exposed to CBZ were ameliorated by pretreatment with vitamin C and MO. There was significant increase in concentrations of testosterone level, while FSH and LH recorded no significant difference in the group pretreated with vitamin C and MO before exposed to CBZ. There was significant increase in epididymal sperm motility (P < 0.01) and no significant difference in the group pretreated with vitamin C and MO before exposed to CBZ. Our result indicates that vitamin C and MO ameliorate reproductive toxicity induced by chronic CBZ exposure due to their synergistic protective antioxidant activity as well as boosting the antioxidant enzyme production of the pituitary glands and the testes.

1806 Toxicity of Waltheria Indica Root
A. Basiru1, J. G. Akorede1, K. O. Soetan2, and F. O. Olayemi3.
1University of Ilorin, Ilorin, Nigeria; and 2University of Ibadan, Ibadan, Nigeria.

The decreasing efficacy of anti-trypanosomal drugs and the narrow prospects of anti-trypanosome vaccine development in the nearest future have occasioned the search for plants with anti-trypanosomal potentials. Waltheria indica (Sterculiaceae) has been reported to have anti-trypanosomal, antimarial, antibacterial and antifungal effects. Most plants with antibacterial and anti-protozoan (including anti-trypanosomal) effects have been reported to adversely affect male fertility. However, there is dearth of information on the toxicological evaluation of this plant on the reproductive system. Hence, this work investigated the reproductive toxicity of Waltheria indica root extract in Wistar rats. Ethanolic extract of Waltheria indica root (200, 400 and 800 mg/kg) and distilled water (3 ml/Kg) were administered by gavage to 28 days to adult male rats (180-200 g, n=5), and thereafter sacrificed. Sperm motility, viability, count and morphology were examined microscopically. Serum from each rat was analyzed for Follicle Stimulating Hormone (FSH), Luteinizing Hormone (LH), Testosterone and prolactin by enzyme immunoassay technique. Alanine Aminotransferase (ALT), Aspartate Aminotransferase (AST) and Alkaline Phosphatase (ALP) were measured spectrophotometrically. Data were analyzed using one way analysis of variance (ANOVA) at 95% confidence interval. The result showed that Waltheria indica significantly decreased sperm motility and count and increased the percentage abnormal sperm cells. Serum FSH, LH and testosterone were also decreased. While the serum prolactin increased at the highest dose. Serum ALT, AST, LDL, HDL and total protein levels were not affected by Waltheria indica. While the cholesterol, triglyceride, urea and ALP were significantly increased at the highest dose. In conclusion, Waltheria indica root extract adversely affect the reproductive system in Wistar rats. Further investigation is ongoing to isolate the bioactive compound responsible for the reproductive toxicity and its effect on fertility specific genes such as CatSper and HongrES1 genes.

1807 Disorganization of Uterine Artery Remodeling during Pregnancy Due to Gestational Exposure to Chromium: Mediated through Matrix Distruption
J. A. Stanley, X. Yu, J. C. Behlen, K. K. Sivakumar, J. A. Arosh, G. Han, and S. K. Banu. Texas A&M University, College Station, TX.

Hexavalent chromium (Cr VI) is a heavy metal environmental endocrine disruptor, used in a wide range of applications in the chemical industry, electroplating, steel alloys and stainless steels, as well as many other uses. Increased use and improper disposal of Cr in the developing countries and in the U.S. have increased Cr levels in the air, soil and drinking water. According to Environmental Working Group, Cr has been found in high levels in the drinking water sources from more than 34 states in US Women working in Cr industries and the Cr-contaminated area experience infertility problems and preterm abortions, and still birth. CrVI is rapidly transported inside the cell by anion transport mechanisms, and it leads to multiple cellular dysfunctions that include DNA adduct formation, deregulated cell cycle, apoptosis and carcinogenesis. The preterm delivery rates are 12-13% in the US, 5-9% in UK, and 11.9% in Africa. A variety of risk factors has been linked to preterm birth including medical conditions of the mothers/fetus, genetic influences, behavioral and socioeconomic factors and iatrogenic prematurity. Maternal exposure to environmental contaminations has been considered as an important contributor to preterm birth. We hypothesize that pre-natal exposure to chromium disorganized uterine artery remodeling by altering collagen, elastin, MMPs and TIMPs, as well as
Vinpocetine (VIN) is an antiandrogenic fungicide and endocrine disrupting compound reported to cause multigenerational phenotypic and epigenetic changes. However, mechanisms of perturbation and mediators of heritability remain unclear. Here, we assessed the influence of antiandrogenic activity by comparing in utero VIN exposure to the strongest antiandrogenic VIN metabolite, M2. We also assessed roles of CoA-dependent enzymes in vivo in primary rat, rabbit, human and mouse hepatocytes showed that conjugation of 4-alkyl benzoic acid to Coenzyme A (CoA) and subsequent inhibition of CoA dependent enzymes is the putative pathway leading to the reproductive effects seen in rats. Accumulation of CoA-conjugates for 4-isopropylbenzoic acid and related p-alkyl benzoic acids in plated rat hepatocytes correlates to male rat reproductive toxicity (n > 15). Studies on human plated hepatocytes provide evidence that this pathway is not relevant to humans where the accumulation of these CoA-conjugates is not seen for this class of compounds, indicating a strong species difference in metabolic fate. Additional investigation into the formation of 4-alkyl benzoic acid CoA conjugates in vivo in both rat liver and tests will provide further evidence as to this mechanistic action as well as additional studies to elucidate the direct pathway to interference with spermatogenesis. Consideration of the oral NOAEL in rats, evidence for low relevance of the rat metabolism to humans and topical exposure only from fragrance application provides for a high margin of safety in use. 

1809 Maternal Genetic Lineage and Crossing Scheme Determines Intergenerational Response to the Endocrine Disruptor Vinpocetine

Vinpocetine (VIN) is an antiandrogenic fungicide and endocrine disrupting compound reported to cause multigenerational phenotypic and epigenetic changes. However, mechanisms of perturbation and mediators of heritability remain unclear. Here, we assessed the influence of antiandrogenic activity by comparing in utero VIN exposure to the strongest antiandrogenic VIN metabolite, M2. We also assessed roles of CoA-dependent enzymes in vivo in primary rat, rabbit, human and mouse hepatocytes showed that conjugation of 4-alkyl benzoic acid to Coenzyme A (CoA) and subsequent inhibition of CoA dependent enzymes is the putative pathway leading to the reproductive effects seen in rats. Accumulation of CoA-conjugates for 4-isopropylbenzoic acid and related p-alkyl benzoic acids in plated rat hepatocytes correlates to male rat reproductive toxicity (n > 15). Studies on human plated hepatocytes provide evidence that this pathway is not relevant to humans where the accumulation of these CoA-conjugates is not seen for this class of compounds, indicating a strong species difference in metabolic fate. Additional investigation into the formation of 4-alkyl benzoic acid CoA conjugates in vivo in both rat liver and tests will provide further evidence as to this mechanistic action as well as additional studies to elucidate the direct pathway to interference with spermatogenesis. Consideration of the oral NOAEL in rats, evidence for low relevance of the rat metabolism to humans and topical exposure only from fragrance application provides for a high margin of safety in use. 

1808 Explaining the Low Relevance of the Rat Reproductive Toxicity Data on 3-(4-Isopropylphenyl)-2-Methylpropaln to Human Metabolism and Exposure

G. Adamson, Givaudan, East Hanover, NJ.

3-(4-Isopropylphenyl)-2-methylpropanol (Cyclamen Aldehyde) is a substance used widely in fragrances for a broad range of consumer products. An extended 1-generation reproductive toxicity study in rats (OECD 415) via oral gavage was conducted at 0, 25, 75 and 150mg/kg bw/day. This study showed an increase in epididymal weights at 150 mg/kg/day, a decrease in sperm motility at 275 mg/kg/day, decreased sperm count and density at 75 mg/kg/day and moderate to marked sperm granulomas at 150 mg/kg/day in F generation males. The NOAEL for reproductive toxicity was 25 mg/kg/day. Similar effects were also seen in a short-term (14 day) oral gavage study in male rats. Further investigation has revealed that 3,4-isopropylbenzaldehyde, responsible in vitro for the reproductive effects seen, is consistent with data on other structurally similar substances, notably 4-tert-butyl benzaldehyde. An in vitro metabolism study comparing the ability to produce this metabolite in primary rat, rabbit, human and mouse hepatocytes showed that 4-alkylbenzoic acid was only detectable in rat hepatocytes which indicates that this toxic metabolite is specific to rats. Human liver metabolism in vitro was found to be closest to rabbits and a confirmatory study was conducted. A 14-day study in rabbits via oral gavage at 0, 30, 100, 300mg/kg/day showed no effects either on male reproductive organs or on sperm parameters. Mechanistic work shows that conjugation of 4-alkyl benzoic acid to Coenzyme A (CoA) and subsequent inhibition of CoA dependent enzymes is the putative pathway leading to the reproductive effects seen in rats. Accumulation of CoA-conjugates for 4-isopropylbenzoic acid and related p-alkyl benzoic acids in plated rat hepatocytes correlates to male rat reproductive toxicity (n > 15). Studies on human plated hepatocytes provide evidence that this pathway is not relevant to humans where the accumulation of these CoA-conjugates is not seen for this class of compounds, indicating a strong species difference in metabolic fate. Additional investigation into the formation of 4-alkyl benzoic acid CoA conjugates in vivo in both rat liver and tests will provide further evidence as to this mechanistic action as well as additional studies to elucidate the direct pathway to interference with spermatogenesis. Consideration of the oral NOAEL in rats, evidence for low relevance of the rat metabolism to humans and topical exposure only from fragrance application provides for a high margin of safety in use.
1812 The Role of Aryl Hydrocarbon Receptor (AHR) Signaling in Hemochorial Placentation
K. Iqbal1, P. Dhakal1, K. F. Roby1, S. Pierce1, and M. J. Soares1,2.
1University of Kansas Medical Center, Kansas City, KS; and 2Children’s Research Institute, Children’s Mercy, Kansas City, MO. Sponsor: U. Apte

AHR is a cytoplasmic ligand-dependent transcription factor controlling the biological responses to environmental pollutants. Upon binding, pollutants such as 2,3,7,8-tetrachlorodibenzo-p-dioxin (TCDD), AHR translocates into nucleus and activates transcription of AHR target genes such as Cyp1a1. The hemochorial placenta serves an essential role in fetal health and is potentially susceptible to environmental pollutants. The purpose of this study was to explore how exposure to TCDD acting through AHR shapes placental development and to determine site(s) of TCDD action. Pregnant rats were exposed to TCDD at gestational day (gd) 6.5 and placentaation sites were collected at gd 13.5. TCDD exposure resulted in a delay in upregulation of Cyp1a1 expression. Our data suggest a potential role of CYP1A1 in gd 13.5 placentaation sites revealed activation of AHR signaling in decidua/maternal gland and in mesenchymal components of the labyrinth zone but not the junctional zone of the chorioallantoic placenta. Compared to oil treated controls, TCDD treated gd 13.5 placentaation sites exhibited deep intrauterine trophoblast invasion characterized by cytokeratin positive endovascular trophoblast. We next generated an Ahr null rat model that failed to express AHR and to induce CYP1A1 enzyme expression following TCDD exposure. As a first step in determining the site(s) of TCDD actions, we evaluated the effects of TCDD administration during pregnancy in wild type females mated with wild type males, Ahr null females mated with Ahr null males, and Ahr null females mated with wild type males. Mating schemes that resulted in disruption of AHR activity in maternal tissues interfered with TCDD-activated placental site adaptations. Additionally, to explore the role of CYP1A1 in TCDD-activated placental adaptations we generated Cyp1a1 null rats using CRISPR-Cas9 genome editing. Collectively, these findings indicate that at least some of the TCDD effects on placental development are mediated through its actions on the mother. In summary, we have identified a developmental window of sensitivity to environmental pollutants affecting hemochorial placentaation, the potential of impacting fetal and postnatal health. Supported by NIH grants HD020676, HD079363; Sosland Foundation.

1813 Estrogenic Activity of Polycyclic Aromatic Hydrocarbon Ortho-Quinones in Human Endometrial Cells

Polycyclic aromatic hydrocarbons (PAHs) are pervasive byproducts of incomplete combustion of organic materials, including fossil fuels, food, and tobacco. Cigarette smoking is associated with reproductive abnormalities in women and some PAHs are endocrine disruptors. Moreover, PAHs or their metabolites can activate estrogen receptors (ER), resulting in endocrine disruption. In one pathway of PAH activation, aldo-keto reductases (AKRs) convert PAH trans-dihydrodiols into PAH ortho (o)-quinones, which are then shuttled into the nucleus by the aryl hydrocarbon receptor to modulate gene expression. Given the similarity between planar PAH o-quinones and estrogen (ER), we hypothesize that PAH o-quinones can bind and activate ERs in estrogen target tissues e.g. endometrium. This activation may modulate ER-target genes leading to cell proliferation. We tested the estrogenicity of 3 PAH o-quinones (benzo[a] pyrene-7,8-dione (BPQ), benz[a]anthracene-3,4-dione and 5-methyl-chrysene-1,2-dione) in endometrial cells. We used the inducible alkaline phosphatase activity in Ishikawa cells, a human endometrial adenocarcinoma cell-line, as the read-out for ER activation. We demonstrated that these compounds induce ER activity, and that this activation is inhibited by Fulvestrant, an ER antagonist. Western blots showed that both 17α-ethynyl estradiol (E2) and BPQ induce the translocation of ERα into the nucleus to modulate gene expression. We also found that benzo[a]pyrene (BaP), upregulates AKR1C1 and 1C3 at the mRNA, protein and functional level which would be responsible for PAH metabolism, using high performance liquid chromatography and APCI mass spectrometry in the selected reaction monitoring mode, we find that BaP and benzo[a]pyrene-7,8-dihydrodiol are metabolized to the estrogenic BPQ in Ishikawa cells. Low micromolar concentrations of BPQ increase Ishikawa cell proliferation to the same level observed with the highest concentrations of E2. Our data indicates that o-quinones may play a role in the disruption of ER signaling in the endometrium most likely through ERα. Supported by P30-ES013508 and T32-ES019851.

1814 Machine Learning-Based High-Content Analysis to Characterize Phenotypes Associated with the Reproductive Toxicity of Bisphenol A, Bisphenol S, Bisphenol AF, and Tetrabromobisphenol A in a Testicular Cell Co-Culture Model
J. S. Siracusa1, L. Yin2, and X. Yu1. 1University of Georgia, Athens, GA; and 2ReproTox Biotech LLC, Athens, GA.

High-content analysis (HCA), an image-based quantitative cellular analysis, has emerged as a powerful tool for the assessment of chemical toxicity. We previously developed a multi-parametric HCA to examine the testicular toxicities of Bisphenol A (BPA) and its analogs, bisphenol S (BPS), bisphenol AF (BPAF), and tetrabromobisphenol A (TBBPA). Due to the complexity and the richness of high-dimensional HCA data, there are increasing demands for effective computational strategies to characterize and quantify phenotypic effects at a single-cell level. Our previous study established the testicular co-culture model, comprising spermatogonial cell, Leydig cell, and Sertoli cell lines, has been shown informative for assessing cellular phenotypes across the various timescales and treatment doses at single-cell based level. Our machine learning based HCA pipeline to explore complex phenotypic changes, and characterize the toxicity of BPA and its analogs in this co-culture model. Utilizing machine learning-based phenotypic analysis, we observed the treatments of BPA or its analogs resulted in the loss of spatial arrangement in the three-dimensional structure of the cytoskeleton, and induction of G2/M phase arrest in a dose- and time- dependent manner. Specifically, BPAF significantly induced multinucleated cells, which was associated with an increase of DNA damage response and impaired actin filament structure. In combination, BPA and its analogs induced different toxicities on multiple endpoints in the co-culture model, and BPAF exhibited the highest toxicity compared to TBBPA, BPA and BPS. In summary, this finding suggests that the HCA integrated machine learning algorithm powers the traditional HCA approach, and quantitatively examined the differences of cellular phenotypes across the various timescales and treatment doses at single cell-based level. Our machine learning based HCA approach provides a deeper insight into the cellular dynamics and molecular complex within an in vitro testicular co-culture model. Supported by R43 ES027374-01 funding.

1815 The Endocannabinoid Anandamide Inhibits the Fetoprotective Activity of the Placental Efflux Transporter BCRP/ABC2

The breast cancer resistance protein (BCRP/ABC2), an efflux transporter highly expressed in placental syncytiotrophoblasts that protects the fetus from exposure to a wide range of potential developmental toxins including zearalenone, zeranol, bisphenol A, and perfluorooctanoic acid. Anandamide (AEA), a lipid signaling molecule and an endogenous cannabinoid, has been shown to play a critical role in placental development and embryo development. Dysregulation of the endocannabinoid system has been implicated in gestational disorders such as spontaneous miscarriage, preeclampsia, and intrauterine growth restriction. While excess AEA has been shown to inhibit syncytialization of trophoblasts, its influence on placental transporter function has not yet been investigated. Here, we sought to identify novel mechanisms underlying placental BCRP regulation by AEA. To test this, human trophoblast BeWo B30 cells were treated with AEA and analyzed for biomarkers indicative of syncytialization and BCRP expression and activity. Treatment with AEA (0–10 μM, 3–24 h) reduced the basal syncytialization of BeWo cells, as evidenced by a 40-50% decrease in HCGβ and synectin-2 mRNAs. AEA (10 μM, 24 h) also reduced BCRP mRNA and protein expression between 35 and 50%. Down-regulation of BCRP mRNA was blocked by forskolin, an activator of adenylate cyclase, and 8-Br-CAMP, a cAMP analogue, as well as AM630, an inhibitor of the CB2 receptor. AEA (10 μM, 24 h) also reduced efflux of BCRP substrates mitoxantrone and Hoechst 33342. AEA (10 μM, 24 h) also inhibited adenylate cyclase activity as evidenced by a 75% reduction in intracellular cAMP levels and a complete inhibition of forskolin-induced phosphorylation of the cAMP response element binding protein (CREB). Syncytialization of placental trophoblasts and placental transporter function is critical in protecting the embryo from toxic insults. Our data indicate that the endocannabinoid AEA plays a mechanistic role in down-regulating placental transporter expression and activity via CB2-CAMP signaling, which may be responsible for disrupting placental barrier function during gestational disorders. Supported by R01ES20522, T22ES007148, and P30ES005022.

2018 SOT Annual Meeting
Epilepsy afflicts an estimated 65 million people worldwide and roughly 30% of patients have drug-resistant epilepsy, such as Dravet syndrome (DS), wherein seizures are not adequately controlled with existing antiepileptic drugs. DS occurs in roughly 1:16,000 individuals in the United States, most of which are diagnosed as infants. Patients often are desperate for treatment due to DS's drug-resistant characteristics; therefore, many turn to alternative medicines, such as cannabidiol (CBD). The most abundant Cannabis constituent, Δ9-tetrahydrocannabinol (THC), has been studied widely in the realm of developmental and reproductive toxicology; however, few studies have focused on CBD's toxicity. The goals of this project are to assess gene expression patterns, behavior phenotypes, and reproductive fitness of a subsequent F1 generation following an F0 developmental exposure to concentrations of THC or CBD below the lowest observed adverse effect level (0.024, 0.12, 0.6 mg/L (0.08, 0.4, 2 μM) THC, 0.006, 0.03, 0.15 mg/L (0.02, 0.1, 0.5 μM) CBD, or 0.005% DMSO control in zebrafish. During key developmental stages, THC and CBD caused differential expression of c-fos, bdnf, and dazl in the F0 generation, while only CBD differentially expressed dazl in F1 larvae at 48 and 96 hours post fertilization (hpf). In undosed F1 larvae, THC reduced F0 ovarian activity of 96 hpf larvae during light/dark cycles. Lastly, THC (0.024 and 0.12 mg/L) and CBD (0.15 mg/L) significantly reduced the number of F0 offspring, but no effect was observed on fertilization or hatching rate in the F1 generation. Behavioral assessment of F0 and F1 adults for cognitive impairment following developmental exposure to THC or CBD are underway. This research highlights the need for further understanding of the possible ramifications from early-life cannabinoid exposure.

Cannabinoid Multigenerational Developmental and Reproductive Toxicity in Zebrafish

D. R. Carty, C. Thornton, and K. L. Willet, University of Mississippi, Oxford, MS.

Mycoxin Zearalenone (ZEA) Induces Toxicity and Alters miRNA Expression in C57Bl/6 Mouse Placenta

C. Andersen1, R. Li1, L. Hu2, A. E. El Zowalaty1, Z. Wang1, and X. Ye1, University of Georgia, Athens, GA; and 2South China Agriculture University, Guangzhou, China.

Found on grain crops and grasses all over the world, zearalenone (ZEA) is a major mycoxin derived from Fusarium fungi. With potential chronic exposure, ZEA poses a great risk to the general health of both animals and humans. ZEA in feed causes reproductive disorders in domestic animals such as swine. Previously we demonstrated that ZEA (20-40 ppm) impaired female fertility in mice. Since the placenta plays an essential role in female fertility and ZEA can be metabolically activated by placental enzymes, ZEA may have adverse effects on placental development leading to impaired female fertility. To determine the effects of ZEA on placental development, young virgin female mice were mated with CD-1 males and checked for a vaginal plug the next morning. On D5.5 (post-implantation), the placenta was randomly assigned into five groups and fed with 0, 0.8, 4, 10, and 40 ppm ZEA diets. Body weight was recorded daily. Mice were dissected on D13.5. There was an increased rate of implantation site resorption in 40 ppm group, placental hemorrhage in 10 and 40 ppm groups, reduced weight of live fetus in 40 ppm group, and reduced weight of placentas with live fetus in 40 ppm group. Placental histology indicates dose-dependent changes in the labyrinth layer, most dramatically in the 40 ppm group, such as dilated fetal capillaries filled with nucleated fetal blood cells and dilated maternal blood spaces filled with enucleated maternal blood cells. These data indicate disorganized placental labyrinth upon ZEA treatment resulting in insufficient fetal-maternal interface for efficient nutrient and gas exchange, which may count for the reduced fetus weight in the 40 ppm ZEA-treated group. ZEA treatment also led to lipid accumulation in the labyrinth layer of D13.5 placentas. Placental cells have unique regular epigenetic profiles that plaque placental functions. Disrupted epigenetic profiles may lead to defective placental development. Our microRNA (miRNA) array analysis on the above D13.5 placentas in the 0, 4, and 40 ppm groups (N=4/group) reveals a unique placental miRNA profile and a set of ZEA-targeted placental miRNAs. Interestingly, several of the differentially expressed miRNAs were dysregulated in the placentas from patients with preeclampsia. We continue investigating cellular and molecular mechanisms of ZEA-induced placental toxicity.

Mycoxin Zearalenone (ZEA) Induces Toxicity and Alters miRNA Expression in C57Bl/6 Mouse Placenta

Pollutant-Induced Changes in the Ryanodine Receptor and the L-Type Voltage Gated Ca2+ Channel Alter DREAM-Mediated Gene Transcription

N. D. Schuko, J. Alfaro, J. Lepe, D. Bhandari, and E. B. Holland, California State University, Long Beach, Long Beach, CA.

Environmental pollutants, including non-co-planar polychlorinated biphenyl (ncPCB) congeners and triclosan, cause cellular Ca2+ signal disruptions (GDT) by altering the expression of the ryanodine receptor (RyR) or the L-type voltage gated Ca2+ channels (CaV1). These channels are important to numerous Ca2+ signaling pathways within the cell, but the extent to which CSD through RyR and CaV1 contribute to altered cellular function is unclear. We investigated whether CSD can alter gene transcription normally regulated by the Ca2+-sensitive transcriptional repressor downstream regulator element antagonist modulator (DREAM). This research utilized GTI-7 hypothalamic neuronal cells, TaT1 thyrocytic cells, and GH3 anterior pituitary cells to assess whether CSD alters transcription of gonadotropin releasing hormone (GnRH), thyroid-stimulating hormone (TSH), or prolactin (PRL), respectively, all of which are regulated by DREAM. Cells were exposed to varying concentrations of pollutants for multiple time-periods, and GnRH, TSH or PRL levels assessed using qPCR. GTI-7 cells exposed to the potent RyR activator PC-9B5 did not alter GnRH mRNA expression, which was supported by low RyR basal gene expression. In contrast, GnRH expression in GH3 cells tended to increase with increasing PC-9B5 concentrations at three hours. It is predicted that cellular exposure of TaT1 cells to PC-9B5 will increase TSH transcription in a dose-dependent manner. GTI-7 cells exposed to triclosan, a CaV1 inhibitor, decreased GnRH transcription in a dose-dependent manner and after just three hours. When CaV1 levels are inhibited or when intracellular Ca2+ concentrations are decreased, DREAM remains bound to DNA, repressing transcription, which is consistent with reduced GnRH transcription in the presence of triclosan. This work helps address whether CSD is contributing to alterations in DREAM-mediated transcription, which has been implicated in the function of the digestive system, central nervous system, and tied to pain reception, learning and memory and thyroid-gland health.
Traditional in vitro breast cancer models evaluate estrogenic compounds on breast cancer cells cultured on a flat plastic surface, and exclude the matrix proteins, tissue structure, and supportive cell types of the mammary microenvironment. Our objective was to develop a physiologically relevant in vitro breast model, characterize how the tumor microenvironment influences model sensitivity, and validate the model for chemical testing. Our base platform consists of a MCF7-derived duct surrounded by a collagen I matrix. As previous studies found that fibroblasts regulate the expression of epithelial estrogen receptor α (ER), we integrated human mammary fibroblasts (HMFs) into the matrix surrounding the duct and evaluated sensitivity to 17β-estradiol (E2). Consistent with previous studies, fibroblasts increased ER transactivation and reduced ER protein. Histological examination revealed that E2-induced hyperplasia occurred 7 days earlier when fibroblasts were included in the matrix. We found this was due to a reduction in MCF7 apoptosis, as there was reduced expression of cleaved caspase-7 protein as well as caspase-7 mRNA in our co-culture model. Next, we evaluated the sensitivity of our co-culture platform by exposing the model to 100 nM of 5 chemicals with varying levels of estrogenic activity: E2, estrone, genistein, bisphenol-A and fenamilo. Exposure to test chemicals significantly upregulated ER transactivation and increased expression of proliferation marker Ki67. Exposure to ER antagonist fulvestrant inhibited these effects. In summary, this study provides insight into how the tumor microenvironment regulates estrogenic response, and introduces a novel platform for testing estrogenic compounds in vitro.

1821 Adipogenic Activity of House Dust Extracts
C. D. Kassotis, K. Hoffman, and H. M. Stapleton. Duke University, Durham, NC.

Obesity contributes to >$200 billion in annual US health care costs, and also promotes increased risks of other common health problems, chemicals, termed “obesogens”, can increase weight gain in animal models and/or triglyceride accumulation in vitro. House dust contains a wide diversity of chemicals, and we’ve previously demonstrated that dust extracts can disrupt nuclear receptors known to regulate adipogenesis (proliferation and growth of fat cells). As such, we sought to assess the extent that dust extracts could promote triglyceride accumulation and/or cell proliferation in cell culture. House dust samples (n=137) were collected from central NC households. Briefly, the main living area was vacuumed and dust was extracted with organic solvents and evaporated/reconstituted in DM50. 3T3-L1 cells were induced to differentiate and dosed with extracts over ten days, and assayed for triglyceride accumulation (normalized to max rosiglitazone (RSG)-induced response), DNA content, and cell viability. Eighty-five of the 137 dust extracts tested (62%) exhibited significant triglyceride accumulation, with 43 exhibiting >40% relative to the positive control, RSG. Twenty elicited effects at <10 μg dust/well, and 17 exhibited >100% of the maximal RSG response. Ninety-eight (72%) of the dust extracts elicited significant cell proliferation, with 12 exhibiting increases of >40% relative to vehicle controls. Sixty-three elicited effects at concentrations <1.0 μg/well, and two exhibited >80% proliferation. These data highlight the ability of house dust extracts to induce both triglyceride accumulation and pre-adipocyte proliferation at environmentally relevant levels, below the 50 mg of dust that a child is estimated to consume daily (EPA Exposure Handbook). Concentrations of several halogenated and organophosphate flame-retardants were measured in these samples and most were correlated with triglyceride accumulation, though few were independently active, suggesting that mixtures or co-occurring compounds were promoting the majority of the activity. In addition, adipogenic activity was positively correlated with serum thyroid stimulating hormone concentrations and negatively correlated with free triiodothyronine (T3) and thyroxine (T4) in matched adult household residents. This suggests that mixtures of contaminants in the house dust extracts may be disrupting molecular mechanisms that promote fat cell development and disrupt thyroid hormone homeostasis in residents.

1822 In Vitro Bioactivity of Source and Treated Water from Seven Drinking Water Treatment Plants along a Swedish River

Surface waters are contaminated with chemicals from multiple sources, including industry, agriculture, wastewater effluents, and natural toxicants. In Sweden 50% of the drinking water supply comes from surface water, which implies high demands on inlet water quality and drinking water treatment plant (DWTP) efficiency. Chemical analysis is not always sufficient to detect hazardous compounds and in vitro bioassays are useful tools to monitor potential toxic activities of the total mixture of chemicals in a water sample. The objective of this study was to compare the bioactivity of source and treated water from seven DWTPs along Göta Älv, a river in southwest Sweden. Samples were collected at the inlet and outlet of the DWTPs and concentrated by Solid Phase Extraction using Oasis HLB. Using reporter gene assays we measured the in vitro estrogen (ER), androgen (AR), aryl hydrocarbon (AhR), and peroxisome proliferator-activated alpha (PPARα) receptor activities, as well as Nrf2 and NFκB activities at non-cytotoxic concentrations of water samples concentrated 50 fold. Most of the DWTP samples exhibited AhR and PPARα activities and in a few samples ER and AR antagonistic activities were observed, with lower activities in the outlet compared to inlet samples. One DWTP exhibited a markedly different profile with higher ER, AR antagonistic and Nrf2 activities in the outlet than the inlet samples, suggesting an inefficient treatment at this specific DWTP. No samples showed any PPARα or NFκB activities. The study demonstrated that the bioactive components of the surface water was generally reduced in the DWTPs and that bioassays are useful screening tools in toxicological assessment of drinking water.
Tetrabromobisphenol A (TBBPA) is a commonly used high production volume brominated flame retardant. This study evaluated a oral TBBPA dose response exposure for endocrine disrupting activity. Timed-pregnant Wistar Han rats were exposed to TBBPA from gestation day (GD) 6 to postnatal day (PND) 21 and the resulting offspring were orally exposed from PND 22 through approximately PND 90 at concentrations of 0, 0.1, 0.5, and 200 mg/kg/day, with the same type oil vehicle control and blind dose allocation. Pups were culled to 4 per sex litter on PND 4. Serum and thyroids were collected from dams on GD20 (n=3) and PND21 (n=12), fetuses on GD20 (fetal blood pooled by sex n=3), male offspring on PND 21, 42,90 and 1 year (n=12-15), and female offspring on PND 21, 33, 90 and 1 year. Pubertal timing was assessed and vaginal smears were used to select females in estrus for necropsy at PND 90 and 1 year. Sera were evaluated for hormone concentrations of thyroid stimulating hormone (TSH), T3, T4, and free T4. Preliminary immunoassay data demonstrated the following: There were no significant changes in groups dosed with <250 mg/kg/day TBBPA at any time point or in dams at any dose. In the 250 mg/kg/day group, the females at PND 33 and the males at PND 42 had significantly lower serum T4 than controls and both males and females at PND 90 had significantly lower serum levels of T4 and free T4 compared to the controls. A recovery period was observed starting at 100 µM, where the effect peaked. This xenobiotic in the mutant strains were almost flat for most concentrations, until the treatment reached 100 µM, where the effect peaked. In contrast, NPEO9 induced a concentration-dependent response for sod-4 mutants, with greater fluorescence induction than NP at similar examined levels. In short, the toxic effects of NPEO9 and NP can be observed at low concentrations with particular responses along the concentration-effect curves. Colciencias-UniCartagena, 727-2015.
1828 Selective Biological Action of Bisphenol A, AF, and S Involves Differential Coregulator Interactions

Y. Li1, L. Perera1, L. Coons1, K. Burns1, J. Ramsey1, K. Pelch1, R. Houtman2, R. Beuning2, C. Teng2, C. Teng1, and K. Korach3.

Bisphenol A (BPA) is an endocrine-disrupting chemical (EDC) found to be harmful to human health. Recently, widespread usage of bisphenol chemicals (BPs) such as BPAF and BPS are used as replacements for BPA. However, the potential biological action of these chemicals is poorly understood. Our objective was to examine the estrogenic effects of BPA, BPAF, and BPS and the molecular mechanisms of action in the estrogen receptor alpha (ERα) and ERβ. In this study, we performed an in vitro cell culture study, which was used to assess estrogenic effects of BPA, BPS, and BPS to estrogen. Microarray assay for real-time coregulator-Nuclear receptor interaction analysis was used to identify coregulators of BPA, BPAF, and BPS and molecular dynamic (MD) simulations were used to determine the bindings in the ERα-complex. We demonstrated that BPA and BPAF have agonistic activity for both ERα and ERβ, but BPS has ERα selective specificity. We concluded that coregulators were differentially recruited in the presence of BPA, BPAF, or BPS. Interestingly, BPS recruited more corepressors when compared to BPA and BPAF. From a series of MD analysis, we predicted concentration-addition model dose-response curve, the effect of BPA, BPAF, and BPS complexes. These findings provide an important basis for the understanding of the molecular mechanisms of EDCs, such as BPS, in ER-mediated transcriptional activation, biological activity, and their effects on physiological functions in human health.

1830 Exposure to CrVI during Early Pregnancy Increases Oxidative Stress and Disrupts the Expression of Antioxidant Proteins in Placental Compartments

J. C. Behlen, J. A. Stanley, K. S. Sivakumar, R. J. Taylor, J. A. Aronsh, R. C. Burghardt, and S. K. Banu, Texas A&M University, College Station, TX.

Hexavalent chromium (CrVI) is a heavy metal that is widely used in more than 50 industries such as leather and tannery, textile, metallurgical, chemical and automobile. Environmental contamination with CrVI is a growing problem both in the United States and in developing countries. Due to increased use and improper disposal of CrVI levels in the water, soil, and air continue to increase predisposing humans to several illnesses. The approved safety limit for chromium drinking levels is 0.1 ppm while levels as high as 5.28 ppm have been documented. In utero exposure to chemicals, drugs and heavy metals is well-documented to adversely affect development and biological activity and toxicological studies have demonstrated relationships between CrVI exposure and increased risk of abnormal menses, spontaneous abortion, stillbirth, preterm birth, developmental defects and neonatal death in pregnant women. These adverse outcomes in the offspring are caused as type two diabetes, stroke, heart disease and hypertension. This study was designed to understand the mechanism of CrVI toxicity on placental oxidative stress and antioxidant (AOX) machinery. Pregnant mother rats were treated with or without CrVI (50 ppm K2Cr2O7) through drinking water from gestational day (GD) 9.5-14.5, and placentas were analyzed on GD 18.5. Results indicated that maximum accumulation of Cr was measured in the merial gland compared to laryngoid and basal (junc- tional) zones of the placenta. CrVI reduced the trophoblast cell population. CrVI increased reactive oxygen species (ROS) and decreased the expression of AOX proteins. CrVI disrupts the trophoblast proliferation of the placenta. This study provides insight into the critical role of AOXs in placental function. This work was supported by National Institute of Environmental Health Sciences grants ES025234-01A1 (S.K.B.)

1831 Validation of a Glucocorticoid Receptor Effects-Based Environmental Sample Screening Tool

E. Medlock Kakaley, M. Cardon, L. Gray, P. Hartig, and V. Wilson, US EPA, Research Triangle Park, NC.

Glucocorticoid receptor (GR) agonists have been detected in waste and surface waters domestically and around the world using both analytical chemistry and cell-based bioassay methods. Although a variety of GR agonists have been detected, the way in which a mixture of chemicals may contribute to a single biological endpoint e.g. additive, synergistic or antagonistic, remains unknown. Therefore, we characterized 18 known GR agonists, as well as one antagonist (mifepristone) using a transcriptional activation bioassay. CV1 cells, devoid of endoge nous GR, were virally transduced with human GR and MMTV-luciferase genes. Cells were treated with individual ligands, a fixed ratio mixture, or using a two-chemical matrix design. Agonist efficacy (maximum response relative to dexamethasone reference) varied and potency (EC50) ranged over several orders of magnitude, 48.09 to 102.5% and 1.278e-10 M to 3.93e-8 M, respectively. The IC50s for the antagonist, mifepristone, was 8.355x10^-10 M in competition with 1pM dexamethasone. Concentrations for an equipotent mixture of the twelve full agonists were determined using relative potency values (EC50/Dexam/EC50/Reference) and mean slope. Although the observed response (DexEq50) of the twelve chemical mixture fell within the 95% confidence interval of the predicted concentration-addition model dose-response curve, the response observed with two partial agonists (21-hydroxyprogesterone and corticosterone) in equipotent mixtures with dexamethasone did not. The twelve agonist mixture suggests that GR ligands activate the ability all bisphenols tested at 10 nM compared to control at early stage of differentiation, while the opposite was noted for C/EBP-α, a marker of late stage of adipogenesis. Increased PPARα caused by bisphenol correlated well with perilipin (present at the surface of lipid droplets) and lipoprotein lipase (involved in fatty acids uptake by adipocytes), both genes are regulated by PPARα. Interestingly, higher concentration of bisphenols induced downregulation of both transcription factors PPARα and C/EBP-α during the early and late stage of differentiation, which was in agreement with Red Oil R staining, suggesting inhibition of adipo genesis. Our results show that the effect of bisphenols on differentiation of adipocytes is dose-dependent and the strategy of substituting other bisphenols for BPA does not abrogate potentially dangerous health effects. This work was funded by R01 ES022759.
of the receptor to initiate gene transcription additively, however partial GR agonists may interfere with full agonist activity. This evaluation of GR-specific pharmaceuticals will enable the differentiation of GR ligands in environmental mixtures samples from future surface and waste water studies. Abstract does not necessarily reflect US EPA views or policy.

**1832 Review of Triazoles Toxicology: Mode-of-Action and Effects on the Endocrine System**

G. Jupe, and J. O’Connor. Envigo, Huntington, United Kingdom.

Sponsor: L. Coney

The toxicology of triazoles was investigated in relation to potential to affect aspects of the endocrine system, from the molecular initiating event to the organism response with the aim of developing an adverse outcome pathway (AOP). Triazole compounds play a key role as antifungals in agriculture and in human mycoses and as non-steroidal anti-oestrogens in the treatment of oestrogen-responsive breast tumours in postmenopausal women. At high doses, these compounds affect the liver, the thyroid, and reproductive organs fertility, and development in several species. There is increasing evidence for adverse effects of high doses of triazole fungicides on the mammalian steroid metabolism. In the EU, specific triazoles are included in a candidate list of substances for further evaluation of their role in endocrine disruption. This review looks at the link between triazole toxicity in the female mammalian endocrine system, the CYP19 inhibition and summarizes how the available data may fit into adverse outcome pathways. Based on animal studies and human case studies, inhibition or deficiency of CYP19 causes the estrogen levels to decrease. This is the first key event of adverse outcome pathways in the female reproductive system. The estrogen profile of antifungal triazoles appears similar to the effects of CYP19 inhibitor drugs in rats and monkeys and the phenotype of CYP19 knockout mice, suggesting that the mode of action of triazoles in the female reproduction could be linked to inhibition or deficiency of CYP19 and the subsequent decrease in estrogen levels. The key events are impaired folliculogenesis and placental degeneration. The adverse outcome is reduction or loss in fertility of mammals.

**1833 Pharmacological Estrogen-17α-Ethyl Estradiol (EE)-Responsive NRF1 Gene Networks in Human Breast Cancer Cells: Its Involvement in the Carcinogenic Effect of EE**

J. D. Ramos, J. Das, and D. Roy. Florida International University, Miami, FL.

Lifetime exposure to elevated levels of estrogen is a risk of breast cancer. Birth-control pills containing 17α-ethinyl estradiol (EE) also increase breast cancer risk. Recently, we have shown that NRF1 (Nuclear Respiratory Factor 1) expression is upregulated in pregnancy and that this hormonally regulated gene is essential for breast tissue development. NRF1 is also involved in the development of breast cancer. In this study, we investigated the role of NRF1 in breast cancer cells. To validate findings from CTD curated data, we used Bayesian network analysis to identify molecular gene networks. NRF1 protein expression was significantly higher in clinical samples of breast cancer. Analysis of ChIP-seq data revealed ~10,000 possible NRF1 target genes (TGs) in breast cancer cells. The list of enriched pathways showed EE responsive E2 and NRF1 common TGs associated with breast cancer. Several 17β-estadiol (E2) interacting genes in breast cancer under the enrichment of the KEGG breast cancer pathway. In breast cancer, there are many E2-responsive genes that are NRF1 TGs. These genes are also responsive to EE. To validate findings from CTD curated data, we used Bayesian network (BN) analysis on RNA-seq data of breast tumor samples. We observed that both EE and NRF1 gene networks were associated with breast cancer. The breast cancer NRF1 network in human breast cancer patients was completely different from normal breast tissue samples. Breast cancer associated NRF1 regulatable genes were also regulated by both E2 and EE. Our results revealed the probabilistic graphical networks of NRF1 TG’s affected by the interaction with EE in breast cancer. These NRF1 regulatable genes alone, or in concert with others, may contribute to the breast cancer-dependent differences in the EE responsive gene networks and breast carcinogenicity in response to exposure to EE.

**1834 Tributyltin Protects against Ovariectomy-Induced Bone Loss Only in Mice on a Low Fat Diet**

R. Freid1, S. Kim1, A. Hussein Ali2, and J. Schlezinger1. 1Boston University School of Public Health, Boston, MA; and 2Boston University School of Medicine, Boston, MA.

Bone quality is determined by both genetic and environmental factors. Risk factors for poor bone quality are estrogen loss at menopause, a high fat diet and exposures to drugs/chemicals that activate proinflammatory/proliferator activated receptor gamma (PPARγ). We unexpectedly observed that the environmental PPARγ/retinoid X receptor ligand, tributyltin (TBT), represses periosteal bone formation but increases trabecular bone mass in mice. This is in contrast to TBT’s known ability to suppress osteogenesis in vitro. Here, we examined the interaction of estrogen loss, diet and TBT exposure in female, C57BL/6j mice. Mice underwent sham surgery or ovariectomy (OVX) at 10 weeks of age. At 12 weeks of age, they were placed on a low (10% kcal) or high (45% kcal) fat, sucrose-matched (17% kcal) diet. Mice were treated by oral gavage 3 times per week with Vh (sesame oil, 5 µl/g) or TBT (1 or 5 mg/kg) for 14 weeks. OVX increased body weight gain in mice on either diet. TBT enhanced body weight gain in intact mice but decreased weight gain in OVX mice on a high fat diet. Bone tiss concentration increased in a dose-dependent manner; TBT resulted in a reduction of cortical thickness and bone area without a reduction in total area, regardless of diet. A significant increase in marrow area suggests that bone resorption increased on the endosteal surface. In high fat fed mice, TBT further reduced the cortical thickness, bone area and total area, without affecting marrow area, suggesting that TBT suppressed osteogenesis on the periosteal surface. OVX only decreased trabecular bone volume fraction in mice fed a high fat diet; however, trabecular number and connective density were decreased regardless of diet. Surprisingly, TBT protected against OVX-induced trabecular bone loss in low fat fed mice. TBT’s protective effect was nullified by the high fat diet. Serum CTX was reduced in TBT- treated, OVX mice, on either diet. However, serum PINP and osteocalcin were reduced by TBT only in OVX mice on the high fat diet. Gene expression analyses on cortical bone and bone marrow were being conducted and will provide information on TBT’s disparate effect between the cortical and trabecular compartments and search protective effects of TBT and why the protective effect is nullified by a high fat diet. Our novel observations will provide new information on basic bone biology, potential therapeutic targets and toxicological pathways.
Thyroid hormone (TH) homeostasis is dependent on multiple proteins for TH synthesis, transport, and peripheral metabolism and elimination. Deiodinase enzymes play an essential role in converting THs between active and inactive forms by converting the pro-hormone thyroxine (T4) to the active hormone triiodothyronine (T3) or converting both T4 and T3 to inactive forms. Chemical inhibition of deiodinase activity has been identified as an important endpoint to include in screening chemicals for thyroid hormone disruption. To address the lack of data regarding the potential of chemicals to inhibit the deiodinase enzymes, we established robust in vitro assays and screened over 1800 unique chemicals for inhibition of human deiodinase type 1, 2, and 3. The activity of the deiodinase enzymes was determined utilizing the Sandell-Kolthoff reaction for non-radioactive determination of iodide in a 96-well plate format. The majority of the chemicals did not inhibit deiodinase activity in the initial screen with a single high concentration (target concentration of 200 µM). Across the three enzymes, only 12-17% of the chemicals produced enzyme inhibition of 20% or greater. The EPA’s ToxCast phase 1, v2, phase 2, and e1k chemical libraries each included multiple chemicals that produced enzyme inhibition of 50% or greater in the three deiodinase assays; these chemicals were further tested in concentration-response mode to determine relative potency. Comparison across the three deiodinase isoforms shows similar results for over 90% of the tested chemicals; however, there are over 50 chemicals that show greater than 50% inhibition of only one of the three deiodinases. This set of three deiodinase inhibition assays is a significant contribution to the field for expanding the scope of exposure chemistry used to identify chemicals having the potential to interfere with thyroid hormone homeostasis. Further work to determine whether this in vitro activity translates to effects in vivo is needed. Additionally, this study sets the groundwork for development and evaluation of structure-activity relationships for deiodinase inhibition in the context of deiodinase chemicals for further testing to identify adverse outcomes of deiodinase inhibition. This abstract does not necessarily reflect US EPA policy.

Benign prostate hyperplasia (BPH) affects 40% of men over the age of 50 and is characterized by enlargement of the prostate gland. BPH is a multifactorial disease and several mechanisms such as aging, proliferation, hormones, and fibrosis have been proposed. While the etiology of BPH is still poorly understood, estrogens have been implicated in the development and maintenance of BPH. Estrogens primarily signal via classical estrogen receptors ERα and ERβ through ligand activated nuclear development and maintenance of BPH. Estrogens can bind to ERs to facilitate genomic and nongenomic responses. A proposed mechanism is that when estrogens mediate their effects through GPER, this can cause transactivation of EGFR. Activation of EGFR can stimulate signaling cascades that regulate cell functions such as proliferation, meaning this mechanism could be a contributing cause of BPH. BPA’s transactivation of EGFR is of concern as it is used to harden plastics in household products, and repeated exposure can be considered a public health concern for consumers.

In vitro based assays are increasingly being used to identify potential endocrine disrupting chemicals. Thyroperoxidase (TPO), an enzyme essential for thyroid hormone (TH) synthesis, is a target site for disruption of the thyroid axis for which a high-throughput screening (HTS) assay has been developed. Physiologically-based pharmacokinetic/pharmacodynamic (PBPK/PD) models can aid in translating findings from in vitro assays to in vivo effects. This study used known TPO inhibitors, methimazole (MMI) and 6-propylthiouracil (PTU), to provide in vivo data for PBPK/PD modeling. Adult male LE rats were exposed to 0, 1, 3, and 10 ppm PTU or 0, 3, 30 or 200 ppm MMI in drinking water for 4, 7, and 14 days. Serum and thyroid glands were collected to assess PTU, MMI, and TH levels. Serum and gland PTU and MMI levels increased in a dose-dependent manner. Serum T3 and T4 were reduced by PTU in a dose- and time-dependent manner, with larger decrements seen at all time-points with exposure to 3 and 10 ppm. TSH was elevated after 7 days of exposure, largest increases observed with 14-day exposure to 10 ppm PTU. However, the low dose group did not differ from controls, despite declines in serum T3 and T4. Serum T3 and T4 decreased with 4-day exposure to MMI. TSH increased with 7 and 14-day exposure to 30 and 200 ppm MMI. T3, T4, rT3, and mono- and di-iodothyronines (MIT, DIT) were also measured in the glands of rats exposed to PTU for 4 days. TH levels decreased in a dose-dependent manner with greater decreases observed in D1 (53%, 73%) and T4 (40%, 80%) following exposure to 1 and 10 ppm PTU, respectively. Glandular TH and PTU measured permitted the estimation of in vivo TPO inhibition using a PBPK/PD model. The in vivo derived concentration constant (IC50) was 1.55 µM which was slightly higher than the in vitro IC50 value of 1.24 µM. Moreover, measured serum PTU and TH concentrations were adequately simulated by PBPK/PD modeling. Analyses of additional time-points are underway for gland concentrations of chemical and TH as input for TPO inhibition in the context of exposed animals. These data provide a framework to translate the magnitude of TPO inhibition obtained from HTS assay relative to the degree of TH perturbation in vivo. This abstract does not necessarily reflect US EPA policy.

Benign prostate hyperplasia (BPH) affects 40% of men over the age of 50 and is characterized by enlargement of the prostate gland. BPH is a multifactorial disease and several mechanisms such as aging, proliferation, hormones, and fibrosis have been proposed. While the etiology of BPH is still poorly understood, estrogens have been implicated in the development and maintenance of BPH. Estrogens primarily signal via classical estrogen receptors ERα and ERβ through ligand activated nuclear development and maintenance of BPH. Estrogens can bind to ERs to facilitate genomic and nongenomic responses. A proposed mechanism is that when estrogens mediate their effects through GPER, this can cause transactivation of EGFR. Activation of EGFR can stimulate signaling cascades that regulate cell functions such as proliferation, meaning this mechanism could be a contributing cause of BPH. BPA’s transactivation of EGFR is of concern as it is used to harden plastics in household products, and repeated exposure can be considered a public health concern for consumers.

In vitro based assays are increasingly being used to identify potential endocrine disrupting chemicals. Physiologically-based pharmacokinetic/pharmacodynamic (PBPK/PD) models can aid in translating findings from in vitro assays to in vivo effects. This study used known TPO inhibitors, methimazole (MMI) and 6-propylthiouracil (PTU), to provide in vivo data for PBPK/PD modeling. Adult male LE rats were exposed to 0, 1, 3, and 10 ppm PTU or 0, 3, 30 or 200 ppm MMI in drinking water for 4, 7, and 14 days. Serum and thyroid glands were collected to assess PTU, MMI, and TH levels. Serum and gland PTU and MMI levels increased in a dose-dependent manner. Serum T3 and T4 were reduced by PTU in a dose- and time-dependent manner, with larger decrements seen at all time-points with exposure to 3 and 10 ppm. TSH was elevated after 7 days of exposure, largest increases observed with 14-day exposure to 10 ppm PTU. However, the low dose group did not differ from controls, despite declines in serum T3 and T4. Serum T3 and T4 decreased with 4-day exposure to MMI. TSH increased with 7 and 14-day exposure to 30 and 200 ppm MMI. T3, T4, rT3, and mono- and di-iodothyronines (MIT, DIT) were also measured in the glands of rats exposed to PTU for 4 days. TH levels decreased in a dose-dependent manner with greater decreases observed in D1 (53%, 73%) and T4 (40%, 80%) following exposure to 1 and 10 ppm PTU, respectively. Glandular TH and PTU measured permitted the estimation of in vivo TPO inhibition using a PBPK/PD model. The in vivo derived concentration constant (IC50) was 1.55 µM which was slightly higher than the in vitro IC50 value of 1.24 µM. Moreover, measured serum PTU and TH concentrations were adequately simulated by PBPK/PD modeling. Analyses of additional time-points are underway for gland concentrations of chemical and TH as input for TPO inhibition in the context of exposed animals. These data provide a framework to translate the magnitude of TPO inhibition obtained from HTS assay relative to the degree of TH perturbation in vivo. This abstract does not necessarily reflect US EPA policy.
The hypothalamus regulates many important biological functions such as reproduction, thermoregulation, and energy balance. Orexigenic NPY neurons located in the arcuate nucleus (ARC) of the hypothalamus play an essential role in energy homeostasis. Disruption of this balance can cause metabolic disease states such as obesity and anorexia. EDGs such as organophosphate flame retardants (OPFR) are a potential cause of hypothalamic dysfunction as they accumulate in human tissues and impinge on endogenous nuclear receptors such as ERα and PPARy. Previously, we demonstrated that OPFR oral treatment in adult mice decreased ARC expression of neuropeptide Y and increased growth hormone secretagogue receptor (GHSR) and KCNQ channel subunit expression in a sex-dependent manner. We hypothesized that these effects would augment the activity of the M-current in NPY neurons leading to a suppression of NPY excitability and a reduction in food intake. We will use voltage clamp, whole-cell patch-clamp to record the M-current in NPY neurons utilizing selective KCNQ channel blocker XE991 with standard activation and deactivation protocols from male and females after OPFR treatment. In males, OPFR treatment increased the peak current (84±15) in NPY neurons at -35 mV compared to control (59±10). These data correlated with an increase in expression of KCNQ-3 in male NPY neurons (1.63±0.16 compared to 0.97±0.14, p < 0.05). Our data suggest that serial exposures to EDC, especially flame-retardants may impact the hypothalamic melanocortin neurocircuitry leading to dysregulation of energy homeostasis.
Few ligands for thyroid hormone receptor (TR) have been identified beyond endogenous ligands and pharmaceuticals, suggesting TR is a very selective nuclear receptor (NR). However, diverse chemical libraries, particularly of environmental chemicals, have not been tested for TR activity. We evaluated the hypothesis that TR is highly selective and that modulation of TR activity is unlikely to be a key mechanism for thyroid hormone disruption by developed environmental chemicals. A TR luciferase reporter gene assay in the rat pituitary-derived GH3 cell line was used for quantitative high-throughput screening in agonist and antagonist format against the 10K Tox21 chemical library. In agonist mode, 28 active compounds were identified with potencies from 0.01-91 µM. To confirm these as TR agonists, a series of additional assays were performed: 1) the GH3 cell line; 2) a second TR reporter gene assay—human TRβ in a mammalian one-hybrid format; and 3) a mammalian one-hybrid assay for the retinoid X receptor (RXRα), a potential activator of this receptor through a permissive heterodimer effect; and, 4) a TR:coactivator recruitment assay using the human TRβ ligand-binding domain and SRC-2 peptide. Results showed all 28 compounds repeated as actives in the GH3 assay, with 22 direct TR ligands and 6 via RXR activity. The antagonist assay mode identified 2352 actives of which 1488 had an AC50 for cytotoxicity within 3-fold or less of the corresponding reporter gene AC50, and 868 were considered false positives. We confirmed activity in the 2 reporter gene assays; however, the coactivator recruitment assay failed in antagonist mode. As an alternative, we tested 285 available putative antagonists in a NR translocation assay using GFP-tagged chimeric molecules of glucocorticoid receptor and the TRβ ligand-binding domain known to be responsive to a known TR antagonist, 1-850. Of these, 43 exhibited significantly increased NR translocation activity at the highest concentration tested, 100 µM, but only 17 demonstrated activity at lower concentrations. Fourteen of these were pharmaceutical compounds not previously shown to have TR activity. Overall, this work supports the hypothesis that thyroid hormone disruption via TR perturbation by environmental chemicals is a rare event, and that other modes of action are likely of higher importance for screening this chemical space. This abstract does not necessarily represent the views of the US EPA.
Incidence and prevalence of reproductive disorders have significantly increased over the past three decades. This fact has led to the study of endocrine disruptors (ED), ubiquitous chemical compounds present in the environment and in the human diet, able to interact with hormones, disrupting among others, reproductive function. ED act at very low doses, exert different mechanisms of action and comprehend a great number of substances. Genistein is a phytoestrogen classified as so-called endocrine disruptor (EED) and its human exposure occurs primarily through the consumption of soy-based food and beverages products, which are becoming more popular as nutritional supplements and are frequently used in baby’s formulas, juices and milk substitutes. At certain age periods, like development and early childhood, there is a window in which certain substances exert higher susceptibility to toxic effects. This study aimed to use as a biological model the nematode Caenorhabditis elegans to assess the effect of genistein as an endocrine disruptor using reproduction related endpoints such as brood size and egg production. As lethal concentration was determined at 1000 μM of Genistein previously dissolved in Dimethyl sulfoxide (DMSO), exposures were carried out at sub-lethal concentrations of 0.1, 1, 10, and 100 μM. DMSO 1% was used as control. About ten nematodes were exposed to genistein solutions for 24 h, and both the number of eggs and the number of worms born per nematode exposed were counted. This procedure was carried out three times. It was concluded that genistein increases the reproduction behavior on C. elegans augmenting brood size and raising egg production at low concentrations, but this effect is inverse at high concentrations, evidencing its endocrine disruption capability. GRANT 155-2017 Investigation Vice-rectory of the University of Cartagena.

Bisphenol A (BPA) is used in the production of polycarbonate plastics, epoxy resins and thermal paper, among others. Its exposure to humans through food, drinks and dermal contact makes BPA an ubiquitous molecule. BPA binds to several proteins associated with the endocrine system, and some reports suggest it increases the risk of obesity, among other metabolic diseases in humans. The objective of this work was to determine the obesogenic action of BPA on human adipoblasts. A sample of peripheral white adipose tissue was taken from a female volunteer. Adipocyte derived stem cells (ADSCs) were isolated, exposed to vehicle control or different BPA concentrations, and assayed their proliferative activity. Viable cells were counted by trypan blue staining exclusion method. To determine adipogenic differentiation, confluent cultures were incubated for four weeks with DMSO or BPA, and stained with Oil Red O. Pigment was extracted with isopropanol and its absorbance quantified by spectrophotometry. The proliferation of adipoblasts increased with BPA concentration, a process that was also observed for lipid accumulation. This study demonstrated the obesogenic action of BPA and the need to regulate the use of this xenobiotic to eliminate human exposure.
1852a Exposure to Low Levels of Triclosan Reduces Estrogen Sulfotransferase Activity in Fetal Liver and Placenta of Pregnant Ewes

M. O. James, E. N. Jackson, L. Rowland-Faux, and C. E. Wood. University of Florida, Gainesville, FL.

Sulfonation is an important reaction in the biotransformation and homeostasis of estrogens. Previous in vitro studies found that triclosan is an especially potent inhibitor of ovine placental estrogen sulfotransferase, with $K_c$ of less than 0.1 nM. As the placenta is the main organ responsible for estrogen synthesis in pregnancy in sheep as well as women, and the liver is another site of estrogen biotransformation, this study examined the effects of triclosan exposure of pregnant ewes on fetal placental and hepatic sulfotransferase activity. Triclosan, 0.1 mg/kg/day, or saline vehicle were administered to late gestation fetal sheep for two days either by direct infusion into the fetal circulation or infusion into maternal blood. On the third day, fetal liver and placenta were harvested and analyzed for triclosan and for cytosolic estradiol sulfotransferase activity. Placenta contained higher concentrations of triclosan than liver in each individual sheep in both treatment groups. In both placenta and liver there was a negative correlation between triclosan tissue concentration (pmol/g tissue) and cytosolic sulfotransferase activity (pmol/min/mg protein) towards estradiol. These findings demonstrated that in the sheep exposed to very low concentrations of triclosan, this substance is taken up into placenta and inhibits estrogen sulfonation. 1853 Exposure to PCB126 during the Nursing Period Significantly Impairs Early-Life Glucose Tolerance

B. Rice1, J. D. Preston1, K. W. Sammons1, S. Y. Ngu Tenlep1, L. J. Reynolds2, H. L. Swanson1, and K. J. Pearson1. 1University of Kentucky, Lexington, KY; and 2Old Dominion University, Norfolk, VA.

Polychlorinated Biphenyls (PCBs) are persistent environmental organic pollutants that are known to have detrimental health effects. In a mouse model in our laboratory, PCB126 exposure during pregnancy and nursing alters offspring body composition and glucose tolerance. This purpose of this study was to expose dams to PCB126 during the nursing period only. Female ICR mice were bred and half of the dams were exposed to either vehicle (safflower oil) or 1 mol% PCB126 per kg of body weight via oral gavage on postnatal days 3, 10, and 17 (n = 9/group). Offspring body weight, lean and fat mass, and glucose tolerance were measured. Both male and female offspring displayed normal body weight as well as body composition (p > 0.05). However, both male and female offspring that were exposed to PCBs during the nursing period had significantly impaired glucose tolerance at 3 weeks of age (p < 0.05). This persisted until 9 weeks of age in the male offspring (p < 0.05), but the difference disappeared as the male offspring aged (p > 0.05). Our earlier work suggests that in utero and postnatal PCB126 exposure predisposes offspring to having lower lean mass and impaired glucose tolerance later in life. However, our current study shows that exposure to PCB126 through the mother's milk impairs glucose tolerance in the short-term and is likely caused by impairments in insulin receptor signaling in the periphery as others have shown with direct PCB exposures in adult mice. Future experiments will investigate the mechanisms of dysfunction caused by in utero PCB126 exposure, which may be driving the increased risk of obesity and insulin resistance in adult offspring.

1854 In Utero and Lactational TCDD Exposure Causes Lower Urinary Dysfunction in Adult Male C57BL/6J Mice

Benign prostatic hyperplasia (BPH) and other lower urinary tract factors such as increased prostatic collagen content have been associated with voiding dysfunction (increased frequency, urgency, and incomplete bladder emptying) in aging men. The causes of BPH and mechanisms for voiding dysfunction are not fully known. IUL TCDD exposure exacerbates urinary dysfunction in Tg(CMV-cre);Nkx3-1(+/-);Pten(fl/+). The purpose of this study was to test the hypothesis that IUL TCDD exposure alone or in conjunction with adult T+E exposure also causes urinary dysfunction in wild type (C57BL/6J) male mice. Mice received sham surgery or were subcutaneously implanted with T (25mg) and E2 (2.5mg) slow-release implants to drive voiding dysfunction and were evaluated 8 weeks later. Anesthetized cystometry was used to measure non-voiding contractions and intervoid interval (IVI). Prostatic collagen content was assessed by quantitative analysis of picrosirius red staining. IUL TCDD alone, T+E alone, and IUL TCDD combined with T+E, all significantly increased non-voiding contractions compared to control, T+E alone increased IIVI compared to untreated control mice, and combining IUL TCDD exposure with T+E appeared to protect against this increase. Prostate collagen density was unchanged by IUL TCDD alone, evidence that it is not sufficient to drive prostate fibrosis. This study is the first to demonstrate that IUL TCDD exposure changes lower urinary tract function in adult male wild type (C57BL/6J) mice. Supported by NIH Grants U54 DK099328, R01 ES001332 and T32 ES007015.

1855 Metabolic Impacts of Developmental Exposures to Phthalates and Phthalate Mixtures: Early Evidence for Persistent PPAR Activation

K. Neier1, B. E. Gregg2, C. Harris3, and D. C. Dolinoy1. 1University of Michigan School of Public Health, Ann Arbor, MI; and 2University of Michigan, Ann Arbor, MI.

Exposures to phthalates, ubiquitous plasticizing chemicals, have been associated with an increased risk for metabolic syndrome and obesity. Phthalates' impacts on metabolism are thought to be due to peroxisome proliferator-activated receptor (PPAR) activation; however, this mechanism has not yet been investigated with respect to developmental exposures. Furthermore, little is known with respect to phthalate mixtures and PPAR activation. To test the hypothesis that developmental exposures to phthalates and phthalate mixtures result in PPAR activation that persists through adulthood, we used an ovine genetic mouse model. Two weeks prior to mating, dams were fed 1 of 6 experimental diets: 1) 7% corn oil control, 2) 25 mg DEHP/kg chow, 3) 25 mg DBP/kg chow, 4) 75 mg DINP/kg chow, 5) 25 mg DEHP + 75 mg DINP/kg chow, and 6) 25 mg DBP + 25 mg TEBP + 75 mg DINP/kg chow. At weaning, approximately 1 male and 1 female were sacrificed for tissue collection, and 1 male and 1 female were followed until 10 months of age, with metabolic phenotyping occurring across the life course. Sex-specific differences in metabolic parameters were observed in phthalate-exposed offspring. Males exposed to DEHP or DINP only had increased body weight compared to controls (p=0.06 & 0.04, respectively), but did not exhibit significant alterations in body composition. Females exposed to DEHP or DINP only had increased body fat (p=0.04 & 0.08, respectively), decreased lean mass (p=0.02 & 0.04, respectively), and decreased glucose oxidation (p=0.04 & 0.10, respectively) compared to controls; females exposed to DEHP also exhibited increased fat oxidation (p=0.04). Females exposed to a mixture of all three phthalates had increased water weight at 8 months (p=0.07), and had increased plasminogen activator inhibitor 1 (PAI-1) (p=0.09) and improved insulin sensitivity (p=0.08) at 10 months relative to controls. Obese metabolic effects were not evident in offspring fully exposed to phthalates are consistent with PPAR activation, suggesting PPARs may be persistently activated. Interestingly, mice exposed to phthalate mixtures showed protection against obesity and insulin resistance. Ongoing analyses will further characterize PPAR activation in liver and adipose using RNA-seq, DNA methylation, and oxidative stress analyses.

1856 Developmental Exposure to Brominated Flame Retardant 2,2',4,4'-Tetrabromodiphenyl Ether (BDE-47) Permanently Alters Liver Lipid Metabolism in Mice

A. Suvorov. University of Massachusetts, Amherst, MA.

Tight regulation of fatty acids uptake by the liver is the major process that contributes to a healthy balance of lipids between blood and the liver. Abnormal shifts in this balance in either direction result in increased morbidity and mortality risks. An increased uptake of fatty acids results in accumulation of triglycerides in hepatocytes and is referred to as hepatic steatosis or nonalcoholic fatty liver disease (NAFLD). The most common form of chronic liver disease, NAFLD increases the risk of type 2 diabetes, dyslipidemia, hypertension, cardiovascular and kidney disease, liver cirrhosis, hepatocellular carcinoma, and mortality. On the other hand, a decreased uptake of fatty acids by the liver may result in hyperlipidemia and atherosclerosis, the primary risk factors for heart attack. Thus, improving our understanding of preventable causes of lipid imbalance may have significant consequences for public health. Polybrominated diphenyl ethers (PBDEs) were used as flame-retardant additives in a wide range of polymers and were recently withdrawn from commerce in North America and Europe. Generations that were born
when environmental concentrations of PBDE reached their maximum have now reached 0-15 years of age and in the US account for 1/5 of the total population. Our experimental data demonstrate that exposure to 2.2',4,4'-tetrabromodiphenyl ether (BDE-47), the most prevalent PBDE congenor in human samples, during sensitive developmental windows may result in permanent changes in liver lipid metabolism. Developmental exposure to 0.2 mg/kg body weight of BM-A77 in CD-1 mice results in a permanent 2.5-fold suppression of the fatty acid influx pump CD36 in the liver, which is associated with significant increases in circulating triglycerides in blood. Exposure of CD-1 mice to 1 mg/kg BDE-47 produces an opposite effect on CD36 expression and triglyceride balance, and results in more than a 5-fold increase in expression of CD36 and an associated increase in lipid deposition in the liver. Many other lipid metabolism genes undergo similar changes in expression in liver in response to low and moderate doses of BDE-47. Similarly, low and moderate/high doses of PBDE have opposite effects on mTOR regulated processes. Our evidence suggests that developmental exposure to PBDE may be an important environmental factor of lipid imbalance programming and that this programming may be mTOR dependent.

This study tests the hypothesis that embryonic exposure to ATZ results in age and sex-specific changes in behavior, the adult brain transcriptome, and adult body and brain size, according to the Developmental Origins of Health and Disease (DOHaD) hypothesis. Zebrafish (Danio rerio) embryos were treated with 0, 0.3, 3, or 30 ppb (ppb; μg/L) ATZ immediately after fertilization and exposed through 72 hours post-fertilization (hpf). At 120 hpf, a visual motor response (VMR) test examined larval behavior. Larvae were also grown to 9 months post fertilization (mpf) or 14 mpf. At 9 mpf, a novel tank test, a light-dark box, and an open field test evaluated adult behavior. Microarray analysis investigated ATZ related differences in gene expression. At 14 mpf, the body length, weight, and brain weight was measured to evaluate effects of ATZ on mature body and brain size. For the larval VMR, only the 30 ppb treated larvae were hypactive. However, the 9 mpf adult behavioral tests found non-monotonic, sex-specific behavior changes, with male zebrafish having decreased activity and female zebrafish having increased signs of anxiety. Microarray analysis identified sex-specific transcriptomic alterations, with females having altered expression of genes in pathways related to sexual injury, neurodevelopment, and system disorders and males having altered gene expression in endocrine and reproductive system disorder and nervous system development and function pathways. Adult zebrafish also had non-monotonic, sex-specific alterations in body length, body weight, and brain weight. This study suggests that developmental exposure to ATZ does cause sex-specific alterations in adult neural function.

Trans-Generational Consequences of Lead Exposure, Prenatal Stress, and the Combination

Fixed interval schedule of food reward in F3 offspring. Subsequently, changes in anxiety-like behavior were examined using an elevated plus maze (EPM), as were striatal protein levels of tyrosine hydroxylase (TH), glucocorticoid receptor (GR) and brain derived neurotrophic factor (BDNF) and serum corticosterone levels in F3 offspring. EPM behavior was significantly altered by Pb and P5 in a lineage specific fashion: Pb increased center and closed arm entries and times of F3 MMM females, Pb increased center arm duration of F3 MMM females, and Pb reduced center and closed arm entries/duration of F3 MMM males. Serum corticosterone was altered only in F3 females, with Pb-related reductions in FMF females, and P5-related reductions in MFF females. Changes in striatal protein levels early in F3 were consistent across both sexes and included Pb- and P5-based increases in striatal BDNF protein in FFF females, Pb and P5-induced alterations in TH, GR and BDNF in MFF females, and altered TH protein levels in MMM, MFM and MFF males. These studies further confirm transgenerational effects of Pb/P5 in mice and show that they can exhibit lineage-dependency; they also underscore the need for human studies of Pb-based transgenerational effects. Supported by P30 ES00247.
female C57BL/6J mice on defined, low-fat diets were exposed to control Cd for >2 weeks before being established into breeding pairs (F0). Pregnant dams and offspring were continuously exposed to the same toxicant as their parents after weaning. At weaning, offspring (F1) were collected and portions of the livers were fixed in 10% formalin for histology or processed for metals analysis. Liver to body weight ratios were calculated and liver damage was assessed by pathology (ALT, AST) and histology (HE). Metal exposure did not significantly change any variable in the F1 group. Hepatomegaly and histology; females appeared to be less responsive to HFD than males. All toxicant exposures exacerbated the effect of HFD on variables of liver damage; the effect became more severe the longer the animals were exposed and was more pronounced in males than females. The initial results suggest that these toxicants enhanced liver injury caused by obesity. Future work will build on these findings and examine other target organs of metabolic syndrome.

**1863 In Utero Exposure to Ultralow Particles Induces Placenta Stress in Mice**

R. Morales-Rubio, M. Uribe-Ramirez, and A. De Vizcaya-Ruiz
CINVESTAV-IPN, Distrito Federal, Mexico.

Recent studies have shown that the exposure to ambient airborne matter (PM) with an aerodynamic diameter of ≤100 nm, also called incidental ultrafine particles (UFP), during sensitive developmental stages may predispose to disease later in life. In addition, epidemiological studies suggest that exposure to airborne particulate matter is associated with adverse gestational outcomes, such as premature birth, reduced birth number, and small size for gestational age. Furthermore, placenta stress may influence these adverse outcomes. We tested if the hypothesis of in utero exposure to UFP affects stresses in the pregnant mouse and if the placenta affects gestational outcomes.

Our results show that the collected UFP exhibited nanometric diameters (60% < 100 nm) and irregular morphology, measured by DLS and SEM. Organic carbon, elemental carbon, metals (Ti, Cr, Fe, Ni, Cu, and Zn) and PAHs (naphthalene, phenanthrene, and benzo[a]pyrene) were detected in the lungs of exposed dams to UFP. After pregnancy, plasma BPA was measured from newborns post waning. First, we evaluated the indirect or direct contact of UFP on fetuses by the increase of pigmented cells (eye-sprouts) on the RPE (unpigmented retinal pigment epithelium) in the exposure group. In the lungs of exposed dams to UFP, we observed an increase in pro-inflammatory cytokine (IL-6, IL-10, and TNF-α), expression of MCP-1, and MIP-2 as a pulmonary response to UFP. On the other hand, the placental stress by in utero UFP exposure was shown by an increase of 8-hydroxy-2-deoxyguanosine (8-OHdG) as well as an increase in IL-6, KC, and MCP-1. Also, an increase of 8-OHdG, IL-6, KC, MCP-1 and a decrease of the fetus. Our results support that the in utero exposure to UFP of Mexico City promotes adverse gestational outcomes involving placental stress.
Multidrug resistance protein 4 (Mrp4; encoded by Abcc4) is a basolateral efflux pump that transports several xenobiotics and endogenous molecules such as prostaglandins and cyclic nucleotides. Mrp4 is highly expressed in kidney and bladder, with minimal expression in liver. Recently, our laboratory determined that mice lacking Mrp4 develop hepatic steatosis during compensatory tissue regeneration following partial hepatectomy. These studies indicate that Mrp4 may play a significant role in lipid homeostasis. Recent studies have also showed that Mrp4 is expressed in adipose tissue, yet the role of Mrp4 in adipose tissue physiology and lipid metabolism is unknown. To begin addressing this, WT and Mrp4 knockout (Mrp4-/−) mice were subjected to 24-hour fasting. The mouse embryonic fibroblast cell line 3T3-L1 was also used to investigate the role of Mrp4 in adipogenesis. The results showed that both male and female Mrp4-/− mice have increased adipose tissue to body weight ratio and adipocyte cell size in both fed and fasted conditions. Additionally, the lack of Mrp4 is associated with increased serum glucose levels and impaired glucose tolerance in mice challenged with the glucose tolerance test. In parallel to increased adipose tissue weights, Mrp4-/− mice also showed increased leptin gene expression. In vitro studies using 3T3-L1 cells showed that pharmacological inhibition of Mrp4 function using either MK571 or C1 increases adipogenesis and expression of adipose tissue markers such as fatty acid binding protein 4 (Fabp4), lipoprotein lipase (Lpl), glucose transporter type 4 (Glut4) and peroxisome proliferator-activated receptor gamma (Ppar-γ). In conclusion, our studies show that the absence of Mrp4 or chemical inhibition of Mrp4 function using either MK571 or C1 increases adipogenesis and the total sum of metabolism. The findings suggest that exposure to VOCs could disrupt cardiometabolic functions. While VOC exposures have been linked to several outcomes of cardiometabolic dysfunctions, the impact of VOCs on pediatric obesity remains unclear. Exposure to VOCs may contribute to the development of obesity in children and adolescents. The association of urinary PAH with obesity and overweight in children and adolescents is particularly high within 200 m of homes. Further studies are needed to determine the mechanisms underlying this association and to develop strategies to attenuate the perturbed gene expression patterns in response to VOC exposure in both mother and offspring.

Polycyclic aromatic hydrocarbons (PAHs) are known carcinogens and suspected endocrine disruptors. Exposure to PAHs has been associated with obesity in children and adolescents. The association of urinary PAH metabolites with adiposity outcomes (BMI z-score and rate of obesity) in children and adolescents, the last National Health and Nutrition Examination Survey (NHANES). 2009-2014 cycles were analyzed. Multivariate linear and logistic regression to analyze the association of BMI z-score, and obesity with concentrations of the molar sum of total PAHs metabolites, and the sum of the metabolites based on their family structure were performed in 2241 individuals 6-19 years of age who participated in the 2009-2014 NHANES. Furthermore, the analyses were stratified by developmental stage (e.g. children 6-11 and adolescents 12-19). BMI z-score, and obesity were positively associated with the molar mass sum of the PAHs and the total sum of PAHs metabolites with increasing quartiles of exposure among children 6-11 years of age and adolescents (12-19 years of age) with evidence of a dose-response. The sum of polycyclic aromatic hydrocarbons were associated with obesity and increased BMI z-score in children, but not in adolescents. Total urinary PAH metabolites and naphthalene metabolites were associated with higher leptin gene expression in children, but not in adolescents if NHANES 2009-2014. Furthermore, this is the first report of an association of the sum of polycyclic aromatic hydrocarbons with obesity in children and of an association of the molar mass sum of PAH with obesity in adolescents in a nationally representative cross-sectional survey.

Disclaimer: The findings and conclusion in this report are those of the author and do not necessarily represent the views of CDC/ATSDR.

The general public is frequently exposed to high levels of volatile organic compounds (VOCs) derived from a variety of sources. VOC exposures have been linked to acute myocardial infarction, heart rate variability, hospital admissions and the prevalence of type 2 diabetes (T2D). This finding suggests that exposure to VOCs could disrupt cardiac processes and induce or exacerbate obesity, T2D and their resultant cardio-vascular complications. While VOC exposures have been linked to several outcomes of cardiometabolic dysfunctions, the impact of VOCs on cardiometabolic risk factors such as serum lipids has not been examined, and which VOCs exert specific health effects have not been identified. This study will use the 2011/2012 National Health and Nutrition Examination Survey (NHANES) to cross-sectionally examine the associations between urinary metabolites of VOC (U-VOC) exposures and serum lipid levels using survey weighted regression models. The findings suggest that exposure to VOCs showed more negative associations with high-density lipoproteins (HDL) and more positive associations with circulating triglycerides. Of the 26 UM-VOCs examined, 13 were negatively associated with HDL and positively associated with triglycerides in smokers, while none showed such a pattern of association in non-smokers. In smokers; negative associations with HDL ranged from -0.3 to -3.6 percent change per VOC inter-quartile range (IQR) and positive associations with triglycerides ranged from 0.5 to 8.3 percent. In smokers, MHBMA1, a metabolite of 1,3-butadiene, was associated with a 1.4% decrease in HDL and a 5.7% increase in triglycerides per 0.2 ng/mg increase. Both metabolites of trichloroethylene showed negative associations with HDL and xylene, and xylene (-15.4%) change. Associations between peak greenness and overall VOC exposure, based on primary PCA classification, were significant at 25m, 50m, 100m, 200m, and 300m radii. This association was observed to be highest within 200m radii, with an increase of 22% with a 0.1 unit change in NDVI. The interquartile range of NDVI standard deviation within a 200m radius was significantly associated with urinary metabolites of acrylamide, benzene, 1,3-butadiene, styrene, and xylene (10.7 to 48.3% change). Associations between NDVI standard deviation and principal component analysis of VOC compounds were observed to be highest within a 200m radii, with a significant increase of 40%. Results suggest that residential vegetation, particularly within 200m of homes, is associated with lower exposure to anthropogenic VOCs.

The association of urinary PAH metabolites with adiposity outcomes (BMI z-score and rate of obesity) in children and adolescents, the last National Health and Nutrition Examination Survey (NHANES). 2009-2014 cycles were analyzed. Multivariate linear and logistic regression to analyze the association of BMI z-score, and obesity with concentrations of the molar sum of total PAHs metabolites, and the sum of the metabolites based on their family structure were performed in 2241 individuals 6-19 years of age who participated in the 2009-2014 NHANES. Furthermore, the analyses were stratified by developmental stage (i.e. children 6-11 and adolescents 12-19). BMI z-score, and obesity were positively associated with the molar mass sum of the PAHs and the total sum of PAHs metabolites with increasing quartiles of exposure among children 6-11 years of age and adolescents (12-19 years of age) with evidence of a dose-response. The sum of polycyclic aromatic hydrocarbons were associated with obesity and increased BMI z-score in children, but not in adolescents. Total urinary PAH metabolites and naphthalene metabolites were associated with higher leptin gene expression in children, but not in adolescents if NHANES 2009-2014. Furthermore, this is the first report of an association of the sum of polycyclic aromatic hydrocarbons with obesity in children and of an association of the molar mass sum of PAH with obesity in adolescents in a nationally representative cross-sectional survey.

This finding suggests that exposure to VOCs could disrupt cardiac processes and induce or exacerbate obesity, T2D and their resultant cardio-vascular complications. While VOC exposures have been linked to several outcomes of cardiometabolic dysfunctions, the impact of VOCs on cardiometabolic risk factors such as serum lipids has not been examined, and which VOCs exert specific health effects have not been identified. This study will use the 2011/2012 National Health and Nutrition Examination Survey (NHANES) to cross-sectionally examine the associations between urinary metabolites of VOC (U-VOC) exposures and serum lipid levels using survey weighted regression models. The findings suggest that exposure to VOCs showed more negative associations with high-density lipoproteins (HDL) and more positive associations with circulating triglycerides. Of the 26 UM-VOCs examined, 13 were negatively associated with HDL and positively associated with triglycerides in smokers, while none showed such a pattern of association in non-smokers. In smokers; negative associations with HDL ranged from -0.3 to -3.6 percent change per VOC inter-quartile range (IQR) and positive associations with triglycerides ranged from 0.5 to 8.3 percent. In smokers, MHBMA1, a metabolite of 1,3-butadiene, was associated with a 1.4% decrease in HDL and a 5.7% increase in triglycerides per 0.2 ng/mg increase. Both metabolites of trichloroethylene showed negative associations with HDL and xylene, and xylene (-15.4%) change. Associations between peak greenness and overall VOC exposure, based on primary PCA classification, were significant at 25m, 50m, 100m, 200m, and 300m radii. This association was observed to be highest within 200m radii, with an increase of 22% with a 0.1 unit change in NDVI. The interquartile range of NDVI standard deviation within a 200m radius was significantly associated with urinary metabolites of acrylamide, benzene, 1,3-butadiene, styrene, and xylene (10.7 to 48.3% change). Associations between NDVI standard deviation and principal component analysis of VOC compounds were observed to be highest within a 200m radii, with a significant increase of 40%. Results suggest that residential vegetation, particularly within 200m of homes, is associated with lower exposure to anthropogenic VOCs.
and positive associations with triglycerides with increasing UM-VOCs in smokers. In non-smokers increased odds of dyslipidemia was associated with increasing levels of two 1,3-butanediol metabolites (DHMBMA OR: 1.003, MHMBMA OR: 1.25) and two xylene metabolites (2MHA OR: 1.007, 3MHA, 4MHA OR: 1.001). Collectively VOCS, particularly 1,3-butanediol and trichloroethylene, at concentrations found in conventional tobacco smoking exposures, as well as 1,3-butanediol and xylene at concentrations found at general environmental levels, are associated with cardiovascular disease risk by inducing dyslipidemia.

**1869 Phthalate Exposure and Pediatric Asthma Exacerbation: Reviewing Evidence of an Association and Future Directions**

R. S. Babadi1, S. Sathyanarayana2-3, and C. J. Karr1,3, 1University of Washington, Seattle, WA; 2Seattle Children’s Research Institute, Seattle, WA; and 3Northwest Pediatric Environmental Health Specialty Unit, Seattle, WA.

Phthalates are a class of high-production volume chemicals with applications in consumer products, building materials, and medical devices. Phthalates migrate from polymers and are present in the US in indoor dust at higher concentrations than any other consumer product chemical. Their prevalence in home, daycare, and school environments poses a high risk of exposure for children, and over 90% of children in the US have detectable concentrations of phthalate metabolites in their urine. Emerging evidence suggests these exposures may promote complex pathological mechanisms in the lung which ultimately lead to common pathways of cellular inflammation, enhanced bronchial responsiveness, and greater obstruction of airflow - the hallmarks of asthma. Most investigations of the association between phthalate exposure and pediatric asthma focus on developmental effects by examining gestational exposure, early-life exposure, or both, and the attendant health effects are becoming major public health concerns. In order to investigate the ameliorative effects of ascorbic acid as an antioxidant and intervention therapy in cases of occupational exposure especially when the subjects cannot be removed from the source of exposure.

**1871 Plasma Fluoride and Renal Function in Adolescents (12-19 Years): An Analysis of NHANES 2013-2016**

F. Scinicariello, and M. Buser. CDC/ATSDR, Atlanta, GA. Sponsor: M. Mumtaz

Fluoride has an important role in bone mineralization and the formation of dental enamels; it is frequently added to drinking water, toothpaste, and mouth rinse to prevent dental decay. The major route for excretion of fluoride is the kidney, and fluoride nephrotoxicity has been reported in animal studies and in humans undergoing administration of halothane anesthetics. To investigate whether there is an association between plasma fluoride (PF) and markers of renal function—estimated glomerular filtration rate (eGFR), serum uric acid (SUA), and hyperuricemia—in US adolescents (12-19 years of age) of the National Health and Nutrition Examination Survey (NHANES) 2013-2016 (n=2096) who are exposed to low levels of fluoride. Multivariate linear regression was used to analyze the association of PF with eGFR (both the original and Schwartz formula – eGFRschwartz) and the updated eGFR(urea) and SUA. Both eGFR and SUA were natural log-transformed in the analyses; the results were re-transformed and presented as percent differences. Multivariate logistic regression was used to analyze the association of PF with hyperuricemia (defined as SUA ≥6 mg/dL). PF was analyzed via weighted quartile and as natural log-transformed. Participants in the 3rd and 4th PF quartiles had decreased eGFR - using either formula. These decreases remained when analyses excluded individuals with eGFR ≤60 mL/minute/1.73 m2. Furthermore, individuals in the 4th PF quartile had significantly increased SUA (% difference [95% CI]: 5.74 [2.54, 9.04] compared to the referent PF quartile, with evidence of dose-response trend (p-trend =0.008). Compared to the referent PF quartile, participants in the 2nd 3rd, and 4th PF quartiles had higher odds to have hyperuricemia (OR [95% CI]: 1.78 [1.22, 2.60]; 1.59 [1.03, 2.45]; and 2.25 [1.47, 3.34], respectively). Sensitivity analyses using natural log-transformed PF confirmed the associations with eGFR, SUA, and hyperuricemia. This exploratory study is the first to look at markers of renal function associated with PF following low-level exposure in an adolescent population. Reverse causation, where decreased eGFR may lead to increased PF, may not be excluded. However, analyses restricted to individuals with normal eGFR (>60 mL/minute/1.73 m2) suggests that PF may affect renal function, as indicated by decreased eGFR and increased SUA. Further studies, especially a prospective cohort study, are necessary to evaluate the association between PF and renal function, considering the public health implications of renal dysfunction in adolescents.

**1872 Toxicological Effects of Lead in Children from a Fishing Community on the Atlantic Coast of Colombia**

Lead (Pb) is a multifaceted and complex environmental pollutant that affects childhood health. In Colombia Pb is a threat for vulnerable children. The aim of this research was to evaluate possible relationships between blood lead levels (BLL) and IQ, hematological and biochemical parameters, and gene expression in children from Tasajera, a fishing town at the Colombian Caribbean. A total of 133 blood samples were collected from children 5-16 years old. This research was approved by the ethics committee of the University of Cartagena and each study participant’s parent provided written informed consent. BLL were measured by atomic absorption; the Kaufman Brief Intelligence Test (K-BIT) was administered to measure the IQ; whole blood was used for hematology; plasma was utilized to analyze hepatic toxicity markers (ALT, AST, ALP); and gene expression was quantified from blood RNA using RT-PCR. The ALAD rs 1800435 polymorphism was characterized in children who had BLL ≥20 μg/dL, employing RFLP. The mean BLL was 20.6±9.4 μg/dL. BLL >10 μg/dL were found in 29% of children. The mean BLL of 10 μg/dL was used as the cut-off to separate children with Pb exposure from those without. The mean BLL of the group with BLL ≥10 μg/dL was 20.6±9.4 μg/dL, while the other group had a mean BLL of 4.6±2.8 μg/dL. The BLL ≥10 μg/dL group had significantly lower IQ scores compared to the BLL <10 μg/dL group. Regarding ALAD
variants, ALAD 1-1 was predominant, whereas ALAD 1-2 had little prev-
ance. In short, children who live in fishing areas present a high risk of exposure to Pb that affects their physical and neurological develop-

1873 Behaviors, Motivations, Health Effects, and Biomarkers among Smoking and Non-Smoking E-Cigarette Users

T. Sussan1, M. Patatanian2, G. Roy2, J. Meinent2, F. Shahzad2, E. Tabassum2, J. Cohen2, R. Wise3, M. Blaha3, C. Fraser4, J. Holbrook2, Atlanta, GA; Colciencias-UniCartagena, Grants of exposure to Pb that affects their physical and neurological develop-
ment, as well as hematological status. Colciencias-UniCartagena, Grants

The use of electronic cigarettes (EC) has risen exponentially, and ECs are now the most popular tobacco product among teenagers in the US. EC manufacturers utilize marketing strategies to target both smokers and non-smokers, but it is unclear how perceptions, behaviors, and health effects differ between these groups. We conducted a survey of 320 adult EC users to determine demographics, behaviors, perceptions, and moti-
vations underlying use. Based on these results, a longitudinal trial of non-smoking EC users and non-users is currently being conducted to
determine oral, respiratory, and cardiovascular health effects and oral and
urinary biomarkers of use. Our survey respondents were predominantly
young adults, 74% were identified to be former smokers, while 20% identified themselves as current smokers and 6% were never smokers. Former smokers reported a longer history of EC use and higher nicotine concentrations than current smokers. For former and
current smokers, the primary motivation for EC use was to quit smoking, and nearly half indicated in the plan to reduce their nicotine concen-
tration and quit using ECs. Among former smokers, self-reports on use
and measures of dependence were consistent with nicotine replacement
as their primary motivation. The majority of former and current smokers also reported that their respiratory health had improved as a result of EC use, although this effect was stronger for former smokers. Never smokers reported less frequent EC use and dependence compar-
ted to former and current smokers. Their primary motivations for use were enjoyment and popularity, and they displayed a reduced desire to eventually quit using ECs. As of October 2017, 20 EC users and 20 non-
users were recruited in the VAPing Observational Research Study (VAPORS), and analysis of oral microbiome and urinary biomarkers is ongoing. These responses provide insight into the underlying behav-
iors of smoking and non-smoking EC users. Ongoing analysis of health effects and biomarkers among non-smoking EC users will improve our understanding of the physiological effects of chronic EC use.

1874 Dioxin-Like Compounds, Cytokines, and Hypertension in the Anniston Community Health Survey Follow-Up

M. Pavuk1, E. Yang1, L. Birnbaum2, and M. Cave3. 1CDC/ATSDR, Atlanta, GA; 2NIHS, Research Triangle Park, NC; and 3University of Louisville, Louisville, KY.

In 2014, we conducted the follow-up study (ACHS II) of the Anniston Community Health Survey (ACHS in 2005-7) where residents’ polychlo-
rinated biphenyls (PCBs) concentrations were 2-3 times higher than in the general US population. Results from ACHS showed significant associations between PCBs and hypertension/blood pressure. When endothelial cells are exposed to PCBs or other dioxin-like compounds in animal studies, inflammatory pathways may be activated and lead to increased expression of cytokines, which can result in the develop-
ment of atherosclerosis and hypertension. ACHS II included measure-
ments of dioxins in addition to PCBs as well as measurements of serum cytokine in order to further study the connection between these chem-
icals and hypertension. Serum samples and covariate information were available for 338 participants. Hypertension status was defined as being on antihypertensive medication or having a systolic/diastolic blood pressure greater than 140/90 mmHg; 262 (77.5%) participants were hypertensive. Cytokines measured included interleukin IL-1β, IL-2, IL-
4, IL-5, IL-12, IL-13, plasminogen activator inhibitor-1 (PAI-1), and tumor necrosis factor alpha (TNFα) using two separate multiplex bead arrays (HADK2MAG-61K and HADK1MAG-61K; EMD Millipore, Billerica, MA). The polychlorinated dibenzo-p-dioxins (PCDD), dibenzofurans (PCDF), and non-ortho PCBs were measured using high-resolution gas chroma-
tography/high-resolution mass spectrometry and expressed as dioxin
equivalent toxins (TEQs, pg/g lipid). To analyze the connection between cytokines and the various chemicals among hypertensive individuals we used multivariate linear regression, adjusting for age, sex, BMI, family history of high blood pressure, and smoking status. Among hyper-
tensive individuals, we found significant associations between PCDD TEQ and TNFα and PAI-1 (β=0.14, p=0.010). These relationships were not observed among non-hypertensive individuals. The associations observed here among the hypertensive participants support the findings that the chemicals may contribute to endothe-

1875 Perfluoroalkyl Substances in the Fernald Community Cohort: Exposure Distributions and Associations with Thyroid and Kidney Function

B. E. Blake1, S. M. Pinney2, E. P. Hines1, S. E. Fenton1, and K. K. Ferguson1. 1NIHS, Durham, NC; 2University of Cincinnati, Cincinnati, OH; and 3US EPA, Durham, NC.

Perfluoroalkyl substances (PFAS) are a diverse class of chemicals used in industry and consumer products to make materials resistant to friction, water, and oil. Exposure is ubiquitous in industrialized populations and those whose drinking water comes from contaminated groundwater, and previous human studies suggest exposure to PFAS is associated with adverse health effects. Associations between eight PFAS and in-
dicators of thyroid disruption and kidney function were examined using repeated measures of both PFAS and outcomes. Participants were selected from the Fernald Community Cohort based on household water supply from a PFAS-contaminated water source. Subjects had up to 3 repeated measures of serum PFAS (N=210 participants, N=517 total measurements) and several health exams. Kidney function (estimated glomerular filtration rate, eGFR) and thyroid stimulating hormone (TSH) were the focus endpoints. Linear mixed effects models were implemented to examine each association, adjusting for participant age, sex, and year of sample collection among other confounders. An interquartile (IQR) increase in serum perfluorononanoate (PFNA), per-
fluorohexane sulfonate (PFHxS), and perfluorodecanoate (PFDeA) was associated with a -1.66% (95% CI= -0.32, -0.23), -1.95% (95% CI= -3.41, -0.49), and -2.47% (95% CI= -4.48, -0.45) decrease in eGFR relative to the population mean, respectively. On the other hand, an IQR increase in serum 2-(N-methyl-perfluorooctane sulfonamido) acetate (Me-PFOSA-AcOH) and 2-(N-ethyl-perfluorooctane sulfonamido) acetate (Et-PFOSA-AcOH) was associated with a 1.66% (95% CI= 0.40, 2.93) and 1.27% (95% CI= 0.09, 2.46) increase in eGFR relative to the median. An IQR increase in serum perfluorooctanesulfonate (PFOS) was associated with a 10.21% increase in serum TSH (95% CI: 2.29, 18.74). In sex stratified models, an IQR increase in PFHxS was associated with a 24.1% (95% CI= 5.01, 46.66) increase in serum TSH in males; this association was not signifi-
cant in females however the interaction between PFHxS, sex, and TSH was significant (p<0.05). Our findings suggest an association between PFAS exposure and altered thyroid and kidney function in exposed communities.

1876 Systematic Review and Meta-Analysis of Diazepam and Labor Duration

X. Liu, K. Zu, T. Lam, and J. E. Goodman, Gradient, Cambridge, MA.

The therapeutic agents of the benzodiazepine (BZD) class, such as diaz-
epam (7-chloro-1,3-dihydro-1-methyl-5-phenyl-2H-1,4,benzodiazepin-
ium), exhibit the characteristic properties of the gamma-aminobutyric acid (GABA)-A receptors, a family of ligand-gated ion channels essential for the regulation of the central nervous system (CNS). In addition, GABA-A receptors are also located in the spinal cord and motor neurons, which mediate myorelaxant effects. Their potential role in labor is as yet unexplored. Therefore, we conducted a systematic review and meta-analysis to determine whether diazepam, a ligand of GABA-A receptors, impacts labor duration. We conducted literature searches in PubMed and Scopus and reviewed reference lists of review articles and original studies. We systematically and critically reviewed all the identified studies; for those with sufficient data, we used random-effects models to calculate summary mean differences between labor dura-
tion in women treated with diazepam and women in control groups. We conducted subgroup and sensitivity analyses when possible and assessed the presence of publication bias. We identified 12 studies for systematic review, none of which were of overall high quality, primarily due to co-administration of other analesic drugs during labor. Of the 12 studies, 9 had sufficient quantitative information to be included
a primary meta-analysis. We found that women treated with diazepam had a similar labor duration as placebo-treated controls (summary mean difference of labor duration: -0.41 hours; 95% CI: -0.97 to 0.16; I² = 63.2%; p-heterogeneity = 0.001), and this result was generally robust to several subgroup and sensitivity analyses. The funnel plot suggests that the presence of publication bias towards small studies favoring a shorter labor duration with diazepam treatment; however, Egger’s test for small study effects was not statistically significant (p = 0.07). Collectively, the clinical evidence indicates that diazepam does not prolong labor duration. This suggests that drugs currently being developed that target α2-containing GABA-A receptors are not likely to prolong labor via this mechanism.

1877 Endocrine-Disrupting Metals in Ambient Air May Be Associated with Increased Breast Cancer Incidence in the US

V. Vu, and Y. Wei. Mercer University School of Medicine, Macon, GA.

Heavy metals are ubiquitous environmental pollutants. Recent studies have suggested that certain heavy metals could act as endocrine disruptors that mimic the actions of hormones, such as estrogens, and contribute to the development and progression of breast cancer. In this study, we examined the association between ambient air emissions of several endocrine-disrupting heavy metals and the incidence of female breast cancer in the United States by analyzing the county-level data from the Surveillance, Epidemiology, and End Results (SEER) Program and the National Emissions Inventory of the US Environmental Protection Agency. Linear regression analysis was conducted using SPSS 22.0 for Windows to examine the association in unadjusted and adjusted models. The adjusted annual age-adjusted incidence rates of female breast cancer were observed in the urban and more industrialized regions among the 9 SEER regions of the US over the time period of 1973-2014. Of the metals analyzed, air emissions of arsenic (β=5.21; p=0.004), cadmium (β=16.23; p=0.033), lead (β=375.66; p=0.001), and mercury (β=27.07; p<0.001), but not chromium VI (β=2.54; p=0.069), were found to be significantly associated with the incidence of female breast cancer after adjusting for race, poverty level, education, smoking prevalence, and obesity rate. Among these metals, emissions of lead showed the strongest association with breast cancer incidence. Our results demonstrated that exposure to heavy metals in ambient air may be associated with increased incidence of breast cancer. Further studies are needed to explore these interactions and to elucidate the mechanisms of action.

1878 Longitudinal Assessment of Liver and Kidney Functions among Adolescent Pesticide Applicators

A. Ismaii1, O. Hendy2, G. Abdel Rasoul2, K. Wang3, J. Olson3, M. Bonner4, and D. Rohman1. 1University of Iowa, Iowa City, IA; 2Menoufia University, Shebin Elkom, Egypt; and 3State University of New York, Buffalo, NY.

Egyptian adolescents work seasonally for the Ministry of Agriculture applying pesticides to cotton fields throughout the country. Organophosphorus (OP) pesticides are primarily applied to control cotton boll weevils. Liver and kidney impairments are major concerns among workers exposed to OP pesticides. The aim of the current study is to assess the effect of repeated exposure to OP pesticides on the liver and kidney functions among adolescent pesticide applicators. A total of 221 applicators were recruited from four field stations in Menoufia Governorate, Egypt, and they were followed for three consecutive years: 2014, 2015, and 2016. A non-applicator group was included during 2015 and 2016. Participants were examined three times each year: during the application season, immediately following the end of the season, and two months after the season ended. Blood samples and baseline medical information were collected at each test session and analyzed for cholinesterase activity, and liver and kidney functions. Functions included alanine aminotransferase (ALT), aspartate aminotransferase (AST), alkaline phosphatase, (ALP), gamma glutamyl transpeptidase (GGT), total bilirubin (TB), direct bilirubin (DB), total protein (TP), albumin, urea, and creatinine. While both acetyl cholinesterase (ACHE) and butyryl cholinesterase (BChE) activity showed changes over time, inhibition during exposure, and recovery after the end of exposure, only BChE exhibited differences between applicators and non-applicators over the three years of the study. The majority of serum measures of liver and kidney functions (ALT, AST, ALP, GGT, TB, urea, and creatinine) showed deterioration immediately after the end of the application season compared to during the application season, and then recovery two months after application had ended. Across the three years, serum GGT and TB did not return to baseline levels, suggesting a long-term impact on these measures of liver function. Exposure to OP pesticides significantly influenced several serum measures of liver and kidney functions, particularly immediately following application. Study outcomes demonstrate the sensitivity of liver and kidney function to exposure to OP pesticides and reflect that repeated exposure to pesticides may lead to progressive deterioration of these functions.

1879 Spatial Patterns of Childhood Leukemia Incidence and Air Toxics in Pennsylvania

Previous studies have examined childhood leukemia incidence with exposure to traffic- and industrial-related air toxics. While many of these studies used surrogates for these exposures, such as proximity to major roadways and traffic density, only a few have estimated rates of ambient concentrations of carcinogenic air toxics. Our goal was to examine potential associations for estimated concentrations of outdoor air toxics with childhood leukemia incidence. We obtained modeled, census tract-level concentrations of air toxics from the 2005 National-Scale Air Toxics Assessment (NATA). Incident leukemia cases (n = 1,245) in children and teens under 20 years of age in 2007-2014 were obtained from the Pennsylvania Cancer Registry. We calculated age-, sex-, and race-adjusted standardized incidence ratios (SIRs) for the study population at the census tract level using the expected number of leukemia cases based on the national average of leukemia incidence rates from the Surveillance, Epidemiology, and End Results Program. Exploratory spatial data analysis was used to assess spatial patterns of leukemia SIRs across Pennsylvania over the study period. We conducted spatial and temporal analyses to examine associations between air toxics and leukemia SIRs, adjusting for sociodemographic covariates derived from the US Census Bureau. The present analysis revealed that higher concentrations of formaldehyde and tetrachloroethylene were significantly associated with higher leukemia SIRs with coefficients of 0.22 (S.E.=0.11, p=0.042) and 0.83 (S.E.=0.42, p=0.048), respectively, after adjustment for sociodemographic factors. Benzene and 1,3-butadiene, which previous studies found were associated with increased childhood leukemia incidence, were positively but not significantly associated with leukemia SIRs in our analysis. In this analysis, air toxics such as formaldehyde and tetrachloroethylene are associated with higher incidence of childhood leukemia. Primary prevention strategies for childhood leukemia could incorporate the identification and elimination of sources of these air toxics.
Some investigators have suggested that personal cosmetic talc use is a risk factor for mesothelioma and ovarian cancer, while others maintain that the weight of evidence clearly establishes that cosmetic talc does not increase the risk of either disease. In this evaluation, we assessed the temporal association between U.S. cosmetic talc consumption and the incidence of mesothelioma and ovarian cancer in females. A similar investigation comparing peak asbestos consumption rates in the US demonstrated a corresponding peak in incidence of mesothelioma in males after an appropriate latency period. In this analysis, we evaluated cancer incidence in women because (1) many talc-containing products are marketed specifically for use by women, and (2) women are less likely to have experienced significant (confounding) workplace exposures to asbestos. Cosmetic talc usage rates by year (metric tons per year from 1975 to 2003), which were compiled by the United States Geological Survey (USGS), indicate that product use peaked in 1977 at approximately 70,000 metric tons per year and was never less than 16,000 metric tons per year during that time frame. Throughout the post-1975 time frame, several studies have reported that the rates of pleural and peritoneal mesothelioma in women has remained constant. Our evaluation of the Surveillance, Epidemiology, and End Results (SEER) 9 cancer registry database (1973-2014) is consistent with these findings and shows an age-adjusted incidence rate of mesothelioma for women in the range of approximately 2.5 to 4.9 per million. Similarly, age-adjusted incidence rates in the SEER registry for ovarian cancer remained stable over the last several decades, and have actually declined somewhat from approximately 16 annual cases per 100,000 in 1975 to 11 annual cases per 100,000 in 2014. We suggest that if cosmetic talc use was truly a significant risk factor for either disease, then given the decades of documented extensive use, an observable increase in these diseases would have been observed at some point in the last 10 to 20 years. These findings are consistent with the National Occupational Mortality Surveillance (NOMS) database, which has consistently reported no increased incidence of female pleural or peritoneal mesothelioma in occupations that are expected to routinely use cosmetic talc, such as hairdressers, barbers, and cosmetologists.
Textbooks of epidemiology on the use of the Bradford-Hill criteria (or considerations) have consistently devalued if not eliminated the analogy criterion for causal inference. As part of a broader inquiry into the practice of causal inference, I conducted a systematic review of the literature to examine whether the practice of causal inference reflects this methodological development. PubMed and TOXLINE were searched for English-language publications that refer to Bradford-Hill (i.e. methods papers) and/or employ the criteria (i.e. application papers) and were published between 1990 and the present. Of 247 publications identified, 46 met inclusion criteria. Of these 10 methods papers accurately reflect the idea promulgated in the textbooks that analogy can be achieved by simple similarity arguments (subject to the imagination of the authors), that it is a weak association, that it “doesn’t work”, and may be detrimental, that it is equivalent to coherence or biological plausibility, or that it should be abandoned altogether. Of the 36 practice papers where criteria were applied (with specific reference to Bradford-Hill), 7 authors ignored analogy and the remainder employed the simplistic notion that if A causes a disease B then “by analogy” a similar exposure A’ is likely to be a cause of B or any other disease. Analogy in theory and in practice has been effectively eliminated from causal inference in epidemiology. Even in situations in which the simplistic “similarity” argument is employed, the remaining criteria—e.g. strength, dose-response, consistency, and biological plausibility—reign.

Multiple epidemiological studies have consistently demonstrated that high levels (100-1,000 µg/L) of arsenic in the drinking water is associated with a marked increase in lung cancer risk. The same has not been consistently demonstrated at low levels. We have conducted an analysis of lung cancer incidence and arsenic levels in groundwater used as drinking water supply for US counties to examine the relationship at low (<50 µg/L) arsenic levels, the historical limit for both EPA and WHO. The exposure data are from the USGS ground water arsenic database which have been used in multiple studies and the outcome data (lung cancers, 2009-2013) are from the NCI. Co-variables are from the US Census Bureau and the CDC. The exposure metric was the median drinking water well arsenic level. Poisson analyses were conducted at low (<50 µg/L) arsenic levels, the historical limit for both EPA and WHO.

Chronic, low-dose exposure to inorganic arsenic (iAs) is connected to high incidences of cancer in the United States and worldwide. iAs has been attributed, in part, to changes in the epigenome, although studies of trans-generational effects on gene expression. Recent data has emerged on the adverse effects of MeHg and the nutritional intake (TWI) in 2012 for MeHg. However, new epidemiology data has emerged on the adverse effects of MeHg and the nutritional benefits from fish consumption. We reviewed the current literature and developed a graphical data compendium to visually present the data from epidemiology studies on neurodevelopmental effects of MeHg. We identified over 50 studies in the literature published since 2000 on prenatal exposure to MeHg and subsequent neurodevelopmental outcomes in children. Because these studies relied mostly on regression or correlation analyses, we compiled central tendency values to describe exposure. The reported values were graphically presented in a series of data-array figures and organized by biomarker, child age, cohort location, and neurodevelopmental outcome. By inspecting the visual array of data, a few key observations emerge. Adverse effects in childhood persisted into adulthood in some cohorts but not in others. While the majority of studies found detrimental effects of MeHg exposure on neurodevelopment, some studies did not find adverse effects of MeHg, despite adjusting for multiple confounders. Effects were observed at different levels of MeHg exposure, including estimated doses comparable to the EPA RfD, JECFA PTWI, and EFSA TWI. We conclude that the graphical analysis of this complex body of research is helpful in highlighting possible trends and uncertainties for further investigation.

Epigenetic (EG) changes induced by therapeutic agents and environmental xenobiotics have trans-generational effects on gene expression. EG alterations are inheritable and have significant potential to trigger pathological conditions. The addictive potential of opioids during fetal development can induce EG modifications, resulting in altered physiological states. To determine the mechanism whereby EG changes from opioids influence developmental progression, mouse embryonic stem (mES) cells were exposed to 1 to 1000 µm morphine sulfate (MS) for 24 hrs. Cell viability, global DNA methylation, and gene expression of DNA methyltransferases (i.e. DNMT1, DNMT3a, DNMT3b) were measured at the 24 hrs with RT-PCR and ELISA using corresponding anti-S-methylcytosine antibody. Cell viability of mES cells significantly decreased at 1000 µm MS only (P<0.001, N=3) but was unaffected at lower concentrations. Global DNA methylation levels were increased at 1 µm MS (apparent hormesis effect; P<0.001, N=3) yet decreased at 10 µm and 100 µm MS (P<0.01 and P<0.001, respectively, N=3). While no net changes were detected in DNA methylation levels following MS exposure up to 1000 µm, the cells exhibited concentration-dependent down regulation (1.0 to 2.5-fold) of all MT’s, with DNMT3a demonstrating the most sensitive response. The results suggest that opioids, at concentrations less than those needed to suspend viability, alter EG modifying enzymes during stem cell differentiation. DNMT1 is usually referred to the “maintenance methyltransferase” since it has a higher preference for hemi-methylated DNA. DNMT1 targets the DNA replication fork, by factors such as HHR1, that recognizes hemi-methylated DNA. HHR1 and UHR2 are members of the SRA family of MT’s (SET and B-box domains) that recognize (P<0.001) ubiquitous-like, domain-containing proteins that recognize and join with hemi-methylated DNA, and are essential for maintenance methylation. DNMT3a and -3b are the predominant de novo MT’s, while the latter is also involved with methylation of satellite DNA and pericentromeric regions. In particular, these MT’s are crucial for normal embryonic progression, expansion, and differentiation, thus supporting the understanding that opioids have high potential to cause a fetal addiction syndrome through the alteration of EG pathways.

Chronic, low-dose exposure to inorganic arsenic (iAs) is connected to high incidences of cancer in the United States and worldwide. iAs has been associated with the epithelial-to-mesenchymal transition (EMT) in which cancer cells lose their adhesion properties and increase in motility, allowing them to travel to other parts of the body and metastasize. The mechanism behind iAs-mediated carcinogenesis and EMT has been attributed, in part, to changes in the epigenome, although studies on this are limited. These changes can include histone post-translational modifications, incorporation of histone variants, or DNA methylation reprogramming. Our use of high resolution studies has identified...
changes in DNA methylation patterns and histone H2B variant regulation as key players in IA-mediated carcinogenesis and EMT. Using Methyl-seq, we show genome-wide and gene-specific changes in DNA methylation patterns that correlated to changes in gene expression in response to IA exposure. After removal of IA exposure, we observe moderate reversal of DNA methylation changes, gene expression patterns, and EMT. We also identified ten histone H2B variants that are dysregulated during IA-mediated carcinogenesis using top-down mass spectrometry. These variants are possibly modulating DNA compaction around the nucleosome, thereby altering gene expression patterns in chronically IA-treated cells. Our studies indicate that inorganic arsenic-mediated carcinogenesis is instigated, in part, by changes to the epigenome including DNA methylation and histone H2B variants.

**1890 Regulation of Chromatin Assembly and Cell Transformation by Exposure to a Physiologically-Relevant Concentration of Formaldehyde**

D. Chen1, C. Liu2, S. Meij3, L. Fang3-4, X. Liu3, K. Lu3, and C. Jin1. 1New York University School of Medicine, Tuxedo Park, NY; 2University of North Carolina at Chapel Hill, Chapel Hill, NC; 3Tongji University, Shanghai, China; 4Nanjing University, Nanjing, China; and Dana-Farber Cancer Institute and Harvard T.H. Chan School of Public Health, Boston, MA.

Formaldehyde (FA) is an environmental and occupational chemical carcinogen. Most studies of FA-induced carcinogenicity have focused on DNA damage and mutagenesis induced by DNA adducts and DNA-protein crosslinks, however, little is known about the molecular mechanisms responsible for FA-induced epigenetic dysregulation. Previously we demonstrated that exposure to 0.5 mM of FA dramatically decreases lysine acetylation of the N-terminal tails of cytotoxic histones H3 and H4, thereby inhibiting chromatin assembly. Endogenous FA concentration in human blood ranges between 20 μM and 100 μM. Thus, to test whether similar outcomes can be seen at a more relevant FA dose, we treated human BEAS-2B cells with 100 μM FA and studied its effect on histone modification, chromatin assembly, transcription, and cell transformation. Continuous exposure of cells to the physiologically relevant concentration of FA significantly reduced the levels of cytotoxic H3K9&K14Ac and H4K12Ac. The reduction was likely due to the formation of FA-histone lysine adducts that give lysine formylation and Schiff base were detected by mass spectrometry in cells. Cellular fractionation and Western blot analysis show the amount of histone H3 in chromatin fraction decreases by about 20%; chromatin immunoprecipitation assays show the level of histone H3, an H3 variant, is significantly reduced at the majority of loci tested, suggesting that FA compromises chromatin assembly at a physiologically relevant concentration. Moreover, knockdown of the H3.3 gene, which mimics inhibition of chromatin assembly, altered expression of a number of cancer-related genes deregulated by FA and facilitated FA-mediated anchorage-independent cell growth. These results suggest that defective chromatin assembly may play important roles in FA-induced transcriptional deregulation and cell transformation. This work was supported by NIH grants R01ES026138-01, 3P30ES00260, R03ES024147, and R01GM099409 as well as National Natural Science Foundation of China Grant 31329003.

**1891 Characterization of Functional and Molecular Endpoints of Potential Adverse Health Effects Associated with Age, Diet, and Occupational Exposure in an Animal Model**

The exposome is the measure of all exposures of an individual in a lifetime from conception to death and how those exposures affect health. An individual’s exposome is highly variable and dynamic throughout their lifetime. The goal was to design an exposure paradigm that would address multiple exposome components, including lifestyle (e.g., diet), age, and occupational exposure (welding fume; WF) in a controlled animal model. Functional and molecular endpoints predictive of adverse health effects were identified by biological fluids of exposed animals that are translatable to human populations were examined. Male Fischer 344 rats were maintained on a high fat western (HF) or regular (REG) diet for 24 wk. At wk 7 during diet maintenance, groups of rats were exposed by inhalation of stainless steel WF (20 mg/m³ x 3 hr/d x 4 d/wk x 5 wk) or filtered air (control) until wk 12 at which time some animals were euthanized. A separate set of rats were allowed to recover from WF exposure until the end of the 24 wk period. Whole blood and bronchoalveolar lavage fluid were collected at wk 7 (baseline before WF exposure), 12, and 24 wk to assess blood cell differential and to recover serum, peripheral blood mononuclear cells (PBMCs), and lung phagocytes for epigenetic analysis and immune response. Significantly elevated % change in body weight and serum triglycerides were observed in groups maintained on the HF diet. At all time points, plasma triglycerides were higher by recovered phagocytes and PBMC telomere length were significantly decreased in the REG+WF, HF+air, and HF+WF groups compared to the REG+air group. A significant decrease also was observed in telomere length over the 24 wk regimen in all groups. In summary, age, diet, and occupational exposure (WF inhalation), important exposome components, altered immune response and epigenetic endpoints in rats. An animal model may be advantageous for studying the exposome because of the ability to control all external exposures and to measure potential adverse health outcomes of each animal over its entire lifespan and to link a specific internal biological response/endpoint with a specific exposure.

**1892 Combinatorial Effect of Butyl Benzyl Phthalate and a High-Fat Diet on Epigenetic Regulation of Adipogenesis and Obesity**

C. A. Powell, K. Bhakta, S. Meruvu, J. Zhang, and M. Choudhury. Texas A&M University, College Station, TX.

Obesity has reached epidemic proportions worldwide. Exposure to endocrine disrupting chemicals (EDCs) such as those found in plastics may influence the development of obesity. Our studies investigate the effect of the EDC butyl benzyl phthalate (BBP) in combination with a high-fat environment on epigenetic regulation of obesity. We hypothesize that BBP and a high-fat diet (HFD) act synergetically to enhance obesity via epigenetic regulation of microRNA (miR) promoter methylation. C57Bl/6 male (8 weeks old) mice were fed chow diet (CD) (4% kcal from fat) or HFD (60% kcal from fat) with or without BBP (3 mg/kg/day) for 12 weeks. Mice were assessed for body weight and food intake and adipose tissue weights were measured. 3T3-L1 preadipocytes were treated with BBP, palmitic acid (PA), or a combination of both to induce adipogenesis. Adipogenic characteristics and epigenetic regulatory mechanisms were analyzed in mature adipocytes. Mice fed HFD+BBP had significantly increased body weights compared to HFD alone, and CD and CD+BBP fed mice (P<0.01 for HFD and P<0.001 for CD groups). Mice fed HFD+BBP also had significantly larger WAT weights compared to HFD (P<0.01) or CD groups (P<0.001). BBP (1 μM, 10 μM, 50 μM) exposure in 3T3-L1 cells induced adipogenesis in a dose-dependent manner, and BBP+PA increased adipogenesis over individual treatments with a significant upregulation of adipogenic gene expressions compared to PA alone (P<0.001). BBP significantly upregulated miRs-34a, 103, 107, and 125a expression in mature adipocytes (P<0.01). BBP+PA further significantly upregulated miR-34a, 103, 107, and 125a expressions compared to control or PA (P<0.001). DNA-methyltransferase (DANMT) expression in mature adipocytes were significantly decreased with BBP treatment (P<0.01) and further decreased in combination with PA (P<0.001). Concurrently, global DNA methylation was significantly reduced with BBP treatment (P<0.05) and further decreased with BBP+PA treatment (P<0.001 compared to control; P<0.05 compared to PA alone). Thus, BBP and a high-fat environment increased obesity in mice and increased adipogenesis in vitro. BBP and PA increased adipogenic miR expression while decreasing DNA methylation and DNMT expression. We are currently investigating miR promoter methylation in adipogenesis. This suggests that an HFD and EDC exposure can worsen an individual’s metabolic health by altering the epigenome program.

**1893 N-Ethyl-2-Pyridoline and DNA Methylation: Identification and Verification of Target Genes by Next-Generation Sequencing and Mass Spectrometry**

H. U. Käferle1, C. U. Köhler1, J. Besken1, F. Marquet1, A. Saillenfait2, and T. Brüning1. 1Institute for Prevention and Occupational Medicine, Ruhr University, Bochum, Germany; 2Institut National de Recherche et de Sécurité, INRS, Vauxdovre, France.

N-ethyl-2-pyridoline (NEP) is frequently used as an industrial solvent and classified as a reproductive toxicant. However, no studies are available on the mode-of-action of NEP. Therefore, we orally exposed rats (n=5 per dose group) to 0, 5, 50, and 250 mg NEP/kg/d up to 28 days and studied the influence of NEP on DNA methylation, an early epigenetic event, in tissue samples of the liver, kidney, adrenal gland,
thymus, testis, epididymis and ovary. When directly comparing the 0 and 250 mg/kg/d dose groups, next generation sequencing (NGS) of enriched methylated DNA regions showed methylation changes predominantly in the liver, kidney, thymus and the adrenal gland of females but not in the ovaries, whereas the testes, kidney and liver was predominantly affected in males. In general, methylation differences were (up to 10-fold) more pronounced in the lab samples that were more affected by NEP rather than females. Strongly affected genes in both males and females were Map3k5, Vomr272, and Phka2. In addition, prominent methylation differences in Zbtb7a, Ehm2, and Man1a1 were observed in males and Golt1b and Mageb4 in females. All changes were found when studied both, the median and maximum observed differences of the enriched methylated DNA regions sequenced by NGS. By using MALDI-TOF MS as an independent technique we verified the NGS data. Wherever a full coverage by specific amplicons of the methylated DNA regions was possible in the MS-based approach, the NGS data could be confirmed by MS. In particular, Map3k5 showed prominent methylation differences (all hypermethylation) in almost all tissue samples, in both sexes, in all exposed dose groups, and both by NGS and MS. In addition, methylation differences of Phka2 and Vomr272 could be confirmed by MS in selected tissues of males and are also most likely due to sex NEP. Overall, our studies suggest that NEP might cause alterations in the MAPK and JNK-pathways and in carbohydrate and glycogen metabolism of rats. Ongoing studies investigate whether the observed effects on DNA methylation influence the downstream regulation of the respective genes.

1894 Exposure to Pesticides Alters the Sperm DNA Methylation in Sprayers from Nayarit, Mexico
L. G. Gil-Mendoza1, M. J. Solís-Heredia1, L. Hernández-Cadenas1, A. E. Rojas-García2, and B. Quintanilla-Vega1. 1CINVESTAV-IPN, Mexico City, Mexico; 2InSP, Mexico City, Mexico; and 3Universidad Autónoma de Nayarit, Nayarit, Mexico.

Pesticides are contaminants that represent a health problem worldwide. Their excessive use causes reproductive problems, including damage to sperm DNA and these alterations have been related to epigenetic modifications. DNA methylation is the most studied epigenetic mechanism, which involves the transfer of a methyl group to DNA in CpG sites catalyzed by DNA-methyltransferases. DNA methylation is crucial in spermatogenesis and it is known that methylation profiles in somatic cells. Our objective was to evaluate the DNA methylation in spermatoozoa of men exposed to pesticides and its relationship with the semen quality and DNA damage. A cross-sectional pilot study was conducted in urban sprayers and in a non-exposed group (n=60) from Nayarit, Mexico (Pacific coast). We evaluated the semen quality (WHO guidelines), the genetic damage by CSPA (Sperm chromatin structure assay, %DFI-DNA fragmentation index), and the global sperm DNA methylation (%5mC) using LINE1 by ELISA (Active motif methylation assay, %DFI-DNA fragmentation index), and the global sperm DNA methylation (%5mC) using LINE1 by ELISA (Active motif methylation assay). DNA methylation and gene expression were measured in CD14+ monocytes isolated from neonatal blood cell subtypes is uncharacterized. AHRR DNA methylation and gene expression were measured in CD14+ monocytes isolated from cord blood collected from nonsmoking (n=15) and smoking mothers (n=29). Cytotline levels were analyzed in cord blood serum. Bisulfite-treated DNA was pyrosequenced across 6 AHRR CpG sites. Gene expression of AHRR, and 3 additional candidate genes (CYP1B1, TMEM176A, and TMEM176B) was measured using RT-PCR. Across the 6 AHRR CpG sites we found a 9-15% methylation decrease in smoking mothers relative to nonsmoking mothers, with the most significant decrease at the CpG located at chr5:373490 (-15%, p=4.77E-06). In cord blood monocytes, no significant smoking-associated changes in gene expression of AHRR, CYP1B1, TMEM176A, or TMEM176B were observed. The CpG site at chr5:373378 (cg05575921) is widely accepted as a biomarker of smoking in neonatal and adult blood, consistent with our results in monocytes (-10.6%, p=2.60E-06). However, previous work in adults has revealed that several nearby CpGs in AHRR show similar or greater changes. This was less of an AHRR methylation decrease in cord blood monocytes relative to our previous findings in adult blood monocytes (-10% in cord blood vs -25% in adults). This effect size difference may be due to lower levels of tobacco use in pregnant women and, fetal blood may receive a lower dose of the active compounds in tobacco smoke due to maternal metabolism and the placental barrier. In adult monocytes, AHRR methylation level and gene expression are strongly correlated, however we found no significant relationship in cord blood monocytes. AHRR expression in adult monocytes is a transient response requiring recent smoking, thus time variation since the last cigarette smoked by mothers may introduce variation in gene expression. In this study, highly significant smoking-associated changes in AHRR methylation levels in cord blood monocytes were observed. However, relative to adults, we found more variability in cotinine, AHRR demethylation, and AHRR gene expression among subjects thus limiting statistical power to observe associations.

1895 Resveratrol Attenuates Allergic Asthma and Associated Inflammation in the Lungs through miRNA Regulation
E. Alharris, H. Alghetaa, M. Nagarkattti, and P. Nagarkattti.
University of South Carolina, Columbia, SC.

Asthma is an allergic condition characterized by airway hyper-responsiveness and increased bronchial spasm, inflammation and mucous secretion. More than 25 million Americans suffer from asthma, with children constituting around 7 million. The inflammation in asthma is mediated by Th2 cell activation with increased levels of IL-4, -5, and -13. Resveratrol (3,4,5-trihydroxystilbene)- a polyphenolic stilbene, has been shown to mediate anti-inflammatory properties. In the current study, we investigated if resveratrol could suppress allergic asthma. To that end, we induced asthma in BALB/c mice by injecting ovalbumin (OVA) with aluminum hydroxide intraperitoneally followed by 7 days treatment with resveratrol (100mg/kg) by oral gavage. Intranasal ovalbumin inhalation was given on day 0 and days 7 and 14. We found that resveratrol significantly attenuated the asthmatic lung (induced by ovalbumin) and caused reduction in CD3+CD4+ and CD3+CD8+ cell numbers in pulmonary tissue of sensitized mice when compared to vehicle controls. There was significant reduction in T-helper cells both in pulmonary tissue and BALF in resveratrol treated group with reduced levels of IL-5, IL-13, GM-CSF and TNF-a in BALF. Interestingly, miRNA-34a was downregulated in cells from the lungs of asthmatic mice treated with resveratrol. Ingenuity pathway analysis (IPA) demonstrated that miRNA-34a was targeting FOXP3, the transcription factor for Tregs that are highly immunosuppressive. Moreover, our PCR results showed that resveratrol-treated OVA mice expressed higher levels of FOXP3 in lung-infiltrating mononuclear cells. Immunofluorescent staining of pulmonary tissue also showed higher expression levels of FOXP3-expressing mononuclear cells in resveratrol treated mice compared to control group. Overall, our studies suggest that resveratrol treatment may be a potential therapeutic agent for asthma.

1896 Maternal Smoking, AhRR Methylation, and Gene Expression in Umbilical Cord Blood CD14+ Monocytes

Tobacco use during pregnancy is a major risk factor for adverse outcomes in children. While smoking is strongly associated with epigenetic modifications in whole blood DNA in both adults and neonates, the relationship between epigenetic modification and gene expression in cord cell subtypes is uncharacterized. AHRR DNA methylation and gene expression was measured in CD14+ monocytes isolated from neonatal cord blood collected from nonsmoking (n=15) and smoking mothers (n=29). Cotinine levels were analyzed in cord blood serum. Bisulfite-treated DNA was pyrosequenced across 6 AHRR CpG sites. Gene expression of AHRR, and 3 additional candidate genes (CYP1B1, TMEM176A, and TMEM176B) was measured using RT-PCR. Across the 6 AHRR CpG sites we found a 9-15% methylation decrease in smoking mothers relative to nonsmoking mothers, with the most significant decrease at the CpG located at chr5:373490 (-15%, p=4.77E-06). In cord blood monocytes, no significant smoking-associated changes in gene expression of AHRR, CYP1B1, TMEM176A, or TMEM176B were observed. The CpG site at chr5:373378 (cg05575921) is widely accepted as a biomarker of smoking in neonatal and adult blood, consistent with our results in monocytes (-10.6%, p=2.60E-06). However, previous work in adults has revealed that several nearby CpGs in AHRR show similar or greater changes. There was less of an AHRR methylation decrease in cord blood monocytes relative to our previous findings in adult blood monocytes (-10% in cord blood vs -25% in adults). This effect size difference may be due to lower levels of tobacco use in pregnant women and, fetal blood may receive a lower dose of the active compounds in tobacco smoke due to maternal metabolism and the placental barrier. In adult monocytes, AHRR methylation level and gene expression are strongly correlated, however we found no significant relationship in cord blood monocytes. AHRR expression in adult monocytes is a transient response requiring recent smoking, thus time variation since the last cigarette smoked by mothers may introduce variation in gene expression. In this study, highly significant smoking-associated changes in AHRR methylation levels in cord blood monocytes were observed. However, relative to adults, we found more variability in cotinine, AHRR demethylation, and AHRR gene expression among subjects thus limiting statistical power to observe associations.
DNA methylation status changes as a function of age in humans and animal models, a process that may play a role in chronic disease development. Recent reports have shown toxicant-mediated shifts away from the baseline rate of age-related DNA methylation, a concept termed “environmental deflection.” We tested the hypothesis that developmental exposure to bisphenol A (BPA) results in environmental deflection of the epigenome, as manifest via longitudinal epigenome-wide DNA modifications in matched mouse blood (2, 4, and 10 months of age). To characterize whether the aging epigenome is driven by changes in 5-methylcytosine (5-mC) or 5-hydroxymethylcytosine (5-hmC), DNA modifications were measured in longitudinal blood samples from isogenic mice developmentally exposed to Control (n=18) or Control+50 µg/kg diet BPA (n=18) diets. Genome-wide 5-mC and 5-hmC levels were measured using two genome-wide sequencing methods -- enhanced reduced representation bisulfite sequencing (eRRBS) and hydroxymethylated DNA immunoprecipitation sequencing (HMeDIP-seq). Examining the epigenome by age, we identified 38,300 uniquely differentially methylated CpGs (DMCs) and 8,613 differentially hydroxymethylated regions (DHMRs). Comparing age-related DMCs and DHMRs, 1,854 annotated genes showed both differential 5-mC and 5-hmC by developmentally exposed to BPA exposure. When testing for environmental deflection by BPA exposure using an age:exposure interaction term, we identified 54,693 significant DMCs, but zero significant DHMRs. Using ChIP-enrich, we tested DMCs and DHMRs for enriched gene ontology pathways. Combined, our genome-wide results show age- and BPA-related differential 5-mC and 5-hmC, including one gene - Nfic - at the exact same chromosomal region. At this shared region, 5-mC and 5-hmC levels both decreased with age. Reflecting these age-related epigenetic changes, Nf1c RNA expression from blood samples also decreased with age. In separate analyses by BPA exposure, we identified 64,284 unique DMCs and 9,950 DHMRs. One annotated gene - the imprinted locus Gnas - showed both significant age-related 5-mC and 5-hmC by developmentally exposed to BPA exposure. When testing for environmental deflection by BPA exposure using an age:exposure interaction term, we identified 54,693 significant DMCs, but zero significant DHMRs. Using ChIP-enrich, we tested DMCs and DHMRs for enriched gene ontology pathways. Combined, our genome-wide results show age- and BPA-related differential 5-mC and 5-hmC, but only minimal evidence for environmental deflection of age-related methylation by developmental exposure.

Phthalates have been linked to adverse pregnancy complications. Placental hypoxia plays an important role in the pathogenesis of the hypertensive disorder of pregnancy preeclampsia. MiR-210-3p (hypo-ami) has been shown to be upregulated in the placenta and plasma of patients with preeclampsia. A recent epidemiological study showed an association also resulted in differential methylation of genes in BAT. A subset of differentially methylated DNA loci in BAT were also detected in blood, demonstrating a treatment-specific consistency across tissues. These data suggest a role for the epigenome in mediating DDT-impaired thermogenesis.

Epigenetic regulation is considered as the mediator between gene and environment interaction. Previously, we have demonstrated that the methylation of tripartite motif containing 36 gene (TRIM36) enhanced in the course of cell malignant transformed induced by PAHs in a dose-dependent manner. The dynamic changes in methylation of tripartite motif containing 36 gene (TRIM36) CpG site 4, 5, 6, 8 was demonstrated that the methylation of TRIM36 hot spots methylated in the peripheral blood lymphocytes (PBLCs) of the subjects. The difference and correlation between the exposure, TRIM36 methylation, and DNA damage were analyzed to characterize the changes of TRIM36 hot spots methylation. We revealed that specific CpG site 4, 6, 8 of TRIM36 promoter is specifically hypermethylated in COEs-, and As-exposed population but hypomethylated in the DE- and benzene- exposure workers. The methylation of TRIM36 responds to different environmental exposure in a dose-dependent manner. Moreover, the status of TRIM36 methylation was negatively correlated with the gene expression in the COEs- and benzene-exposed workers, demonstrating that TRIM36 gene expression is regulated by DNA methylation. The mediation analysis indicated that genetic damage might be mediating the aberrant TRIM36 methylation. Combined analysis from COEs- and DE-exposed population demonstrated that the methylation of TRIM36 CpG site 4, 5, 6, 8 was correlated with levels of PAHs exposure and extent of genetic damage in a dose-dependent manner. The dynamic changes in methylation of TRIM36 suggest that CpG site-specific alterations might be attributable to mediate the adverse health effects and be the candidate biomarker for monitoring PAHs exposure.
1901 Placental Methylation at Metastable Epialleles Is Predictive of Childhood BMI at Ten Years of Age

J. S. Clark1, E. M. Martin1,2, T. O’Shea2, and B. Fry1,2. 1 Gillings School of Global Public Health, Chapel Hill, NC; and 2University of North Carolina at Chapel Hill, Chapel Hill, NC.

The placenta is a critical organ for understanding both fetal and later life disease. Metastable epialleles (MeS) represent time and tissue stable sites of methylation. Additionally, these sites can be influenced via cytosine methylation (CpG) by detrimental conditions surrounding conception. Thus, placental CpG methylation patterning at metastable epialleles could provide mechanistic understanding into the developmental origins of health and disease (DOHaD) hypothesis. Here we set out to assess placental CpG methylation at predicted metastable epialleles to understand their influence on later life body mass index (BMI). Placental methylation was measured using the Illumina 450k and 850k arrays in 202 placental samples. A total of 21 probes were identified across arrays representing candidate metastable epialleles. Infants in the study were subsequently followed up for height and weight measurements at 1, 2 and 10 years of age. Placental methylation at the metastable epialleles was tested for association to BMI at each of the follow up time points. A total of six sites, namely cg12004671, cg22757362, cg27225663, cg4878745, cg12949927, and cg13786083 displayed association with BMI at age, 2 or 10 years of age after adjustment for race, sex, socio-economic status, and gestational age. For these sites, cg048788745, cg12949927, and cg27225633 increasing methylation was associated with decreased BMI, while cg12004671, cg12949927, and cg22757362 increasing methylation was associated with increases in childhood BMI. These data represent sites in the epigenome associated with later life health outcomes, suggesting that placental methylation could provide predictive capacity for children’s health.

1902 Benzyl Butyl Phthalate (BBP) Regulates IncRNA H19 during Adipogenesis in C3H10T1/2 Stem Cell Line

J. Zhang, and M. Choudhury. Texas A&M University, College Station, TX. Sponsor: S. Meruvu

Over the last decade, there has been a dramatic and rapid deterioration in metabolic health primarily due to the emergence of the obesity epidemic and the rise in diabetes rates. Our studies show that BBP, a widespread endocrine disruptor, induces epigenetic stress during adipogenesis in C3H10T1/2 stem cell and 3T3-L1 preadipocyte, which may be one of the contributions to recent metabolic disorder crisis. In the present study, we hypothesized that BBP may deregulate long non-coding RNA (lncRNA) H19 to induce adipogenesis in mesenchymal stem cells (C3H10T1/2). After confluence, C3H10T1/2 cells were treated with or without BBP (0.01 µM, or 50 µM) for 8 days. Cells were then harvested and RNA was extracted on day 2, 4, 6, and 8. Our results showed that gene expression of H19 was significantly decreased from day 2 to day 4 under 50 µM BBP exposure (P<0.05). However, there was no significant change observed at day 6 and day 8. Consistently, RNA expression of miR-103/107, one target of H19 and implicated in adipogenesis, was also significantly increased from day 2 to day 4 (P<0.05 or P<0.01), except for let-7e. On day 6 though, only let-7b was significantly increased. Interestingly, insulin receptor substrate 1, one of the key insulin signal transduction regulators, was significantly downregulated from day 2 to day 8 under 50 µM BBP exposure (P<0.01). However, gene expression of insulin receptor and insulin receptor substrate 2 was not altered by BBP exposure. Our study suggests that IncRNA H19 may regulate adipogenesis at an early time point and BBP can lead to increased adipogenesis and metabolic dysregulation by impairing vital epigenetic regulators such as IncRNA H19 and its miRNA targets.

1903 MicroRNAs Influence Inter-Individual Variability in the Expression of Drug Metabolizing Enzymes and Transporters

Among humans, individuals exhibit a significant disparity in drug sensitivity, efficacy and toxicity which is largely due to inter-individual variability in the expression of genes encoding drug metabolizing enzymes and transporters (DMETs). MicroRNAs (miRNAs) belong to a group of non-coding RNAs that control gene regulation epigenetically. During the last decade there has been growing interest in the role of epigenetic factors, including the role of miRNAs, in the regulation of DMET expression. Many studies have reported correlations between the expression of specific miRNAs and the expression of DMETs; however, only a small number of studies have demonstrated the mechanisms underlying the correlations. To investigate the mechanisms by which miRNAs regulate DMET expression in human liver, we systematically analyzed expression files for 370 DMET genes and approximately 1200 miRNAs, selected candidate miRNAs that could target mRNA transcripts for key DMETs, and then applied a series of biochemical and biological assays to elucidate the molecular basis for miRNA-dependent DMET gene regulation. Reporter gene assays, electrophoretic mobility shift assays, enzymatic assays, proteomic assays, and bioinformatics analyses provided in vitro, in vivo, and in silico evidence establishing the specificity and potency of miRNA-dependent molecular mechanisms suppressing the expression of CYP1A2, CYP2B6, CYP2C9, CYP2C19, CYP2D6, CYP2E1, CYP3A4, ALDH5A1, SULT1A1, SULT1A2, and SULT2A1 at an inhibition level of 15-35%. Furthermore, we applied integrative approaches to show that interactions between miRNAs and drugs can influence drug-drug interactions. Notably, these results provide molecular and biochemical insights into how miRNAs modulate DMET gene expression and contribute to variations in drug metabolism and toxicity in humans.

1904 Mechanism of Trans-Generational Inheritance of Reproductive Dysfunction Stemming from Environmental Bisphenol A Exposure in C. elegans

Our work aims to characterize the molecular mechanisms of memory of environmental exposures, using Bisphenol A (BPA) as a model chemical. Utilizing a transgenic repetitive array assay, carried out on the model organism C. elegans, we identified a germline desilencing response that lasted at least five generations, with and without initial ancestral exposure. The desilencing response was coupled with changes in gene expression and sterility at the F2 generation, with some F3 and later generations losing the original BPA response. The desilencing effect was coupled with several reproducible effects at the F3 generation, including a significant increase in both germline apoptosis and embryonic lethality. Importantly, the germline condition also showed a reduction in the repressive marks H3K9me3 and H3K27me3. The reduction of these repressive marks could be reversed with both chemical and genetic intervention targeting Junmonji demethylases jmjd-2 and jmjd-3/utx-1, required for reduction of H3K9me3 and H3K27me3 marks, respectively. The genetic and chemical intervention also reduced germline apoptosis and embryonic lethality at the F3 generations, rescuing the initial BPA response. Additional analyses showed us that the germline desilencing effect is not exclusive to the array as a profound alteration of the F3 germline transcriptome as well as a moderate upregulation of X-linked transcripts are also identified using RNAseq. Consistent with these transcriptional changes, we observe a 25% to 50% decrease of in H3K9me3 and H3K27me3 expression. These results suggest that environmental exposure to BPA can alter the transcriptome and protein expression of the germline, epigenome, and how to prevent transmission of these effects across generations.

1905 PCB Exposure and Altered DNA Methylation in the Anniston Community Health Survey

G. S. Pittman, X. Wang, M. R. Campbell, S. J. Coulter, J. R. Olson, M. Pavuk, L. S. Binnbaum, and D. A. Bell. 1 NIEHS, Research Triangle Park, NC; 2 University of Buffalo, Buffalo, NY; and 3 CDC/ATSDR, Atlanta, GA.

The Anniston Community Health Survey I and II (ACHS I, II) cross-sectional studies, were conducted from 2005-2007 and 2014 to explore the extent of PCB and other persistent organic pollutant (POP) exposures in Anniston’s population and to assess potential adverse health outcomes. DNA methylation profiles in blood cells have been associated with aging, environmental exposures and disease. We hypothesized that exposure to POPs may alter DNA methylation levels in the immune cells of Anniston residents. In ACHS-I, Anniston residents were selected using stratified random sampling, and ACHS-II participants were recruited from the ACHS-I cohort. 35 PCB congeners were measured in serum. Methylation was measured in whole blood DNA with Illumina arrays (ACHS-I, n=537, EPIC 850K; ACHS-II, n=332, 450K). Wet weight concentrations for the 35 PCBs were summed and log10-transformed. We modeled associations between methylation at each individual CpG and sum35PCB using multivariable linear regression adjusted for age, race, sex, current smoking (yes/no), total serum lipids, and estimated percentages of 6 white blood cell types. In ACHS-I we identified 16 CpGs sites at which methylation was associated with sum35PCB exposure (p<10^{-6}). Of these sites, 9 CpGs were unique to the 850K array. We observed 4 CpGs with greater than 2% differential methylation between the highest and lowest PCB exposure level (based on quartiles). Most statistically significant CpG (p = 6.38x10^{-6}) was a CpG in the serine phosphorylation enzyme AURKB was lowest at Days 3 and 7. Most other differentially regulated epigenetic modifiers (44 of 92 examined) gradually increased during differentiation. Modeling the basal expression of epigenetic modifiers has revealed critical time windows for epigenetic regulation of DPGs and laid the foundation for investigating the effect of xenobiotics that may influence the expression of DPGs through epigenetic mechanisms.

1906 Modeling the Expression of Epigenetic Enzymes and Drug-Processing Genes in Differentiating HepaRG Cells Revealed Critical Time Windows for Human Liver Development

During liver development drug-metabolizing enzymes (DME) and transporters (together called “drug-processing genes” (DPGs)) are regulated by epigenetic modifiers such as DNA methylation and histone modifications. Regulation of expression of DPGs may lead to adverse drug reactions by altering the expression of DPGs in newborns and children. In vivo regulation of human liver development is limited due to the scarcity of samples and ethical concerns. The goal of this study was to establish an in vitro model of human liver development for epigenetic regulation of DMEs; HepaRG cells are a line of human hepatocytes used to determine the regulation of DPGs at a fully differentiated stage. Modeling the basal expression of DPGs in mouse and human hepatocytes showed at most 2-fold higher expression of DPGs in mouse and human hepatocytes than in liver. In the present study, we examined changes in 63 genes that are DMEs and 35 genes that are enriched for histone modification marks H3K9me3 and H3K27me3 in the germline which can lead to the increased risk of liver disease. In a similar manner, we identified effects due to c-Jun and C/EBP delta levels in HepaRG cells. The results of this study demonstrated that regulation of DPGs in HepaRG cells is different from that in liver. The findings of this study will be useful for elucidating the mechanisms of human liver development.

1907 Examining the Effects of Ethanol on the Epigenome in C. elegans

L. Truong, J. Camacho, and P. Allard. University of California Los Angeles, Los Angeles, CA.

In sexually reproducing organisms, the development of germ cells is vital for the faithful transmission of the genome and its associated epigenetic marks across generations. Recent findings have suggested that DNA methylation alterations in mammalian germ cells in response to environmental exposures can be inherited across multiple generations. However, embryonic germ cells undergo two waves of epigenetic reprogramming that decreases DNA methylation and establishes a blanket slate. Thus, we believe that histone marks may be the mediators of epigenetic memory since germ cells rely heavily on repressive chromatin marks, H3K9me2/3 and H3K27me3 during reprogramming. In previous work using a Caenorhabditis elegans strain containing a highly repetitive GFP transgene that is silenced in the germline, we had discovered that BPA presents a desilencing effect in directly exposed worms as well as in their progeny in a transgenerational manner. In the current study, we performed RNAi to target the same known chromatin modifying enzymes in C. elegans in order to identify the genetic pathways that are involved in ethanol's transgenerational effects. This project therefore will identify potential mechanisms for the transgenerational effects of ethanol exposure and carry important implications for human reproductive health in the context of environmental exposures.

1908 Global Methylation and Hydroxymethylation Analysis in Livers of Mice Treated with Non-Genotoxic Carcinogens with and without Methyl Supplemented Diet

Many non-genotoxic carcinogens (NGCs) are known to cause perturbation in DNA methylation which can be an early event leading to changes in gene expression and onset of carcinogenicity. Phenobarbital (PB) has been shown to induce changes in liver DNA methylation (5-mC) and hydroxymethylation (5-hmC) patterns in mice in time dependent manner. The goal of this study was to assess if clofibrate, another well-studied rodent NGC, would produce epigenetic perturbations in mice and 2) if feeding mice Methyl Supplemented (MS) diet would alter/reverse changes induced by PB. CByB6F1 mice were treated with PB and MS diet for each time point were fed a methionine/choline enriched diet. Global liver 5-mC and 5-hmc levels were assessed by Liquid Chromatography- Ionization Mass Spectrometry (LC-MS). Gene expression analysis was conducted using microarrays (Affymetrix). Exposure to phenobarbital produced a significant decrease in global 5-hmc levels in mouse livers after both 7 and 28 days whereas clofibrate treatment resulted in 5-hmc level decrease after 28, but not after 7 days of dosing. A slight increase in 5-hmc levels was observed in MS diet subgroup compared to phenobarbital alone after 7, but not after 28 treatment days. None of the treatments produced a significant change in global 5-mC levels compared to controls. After 28 day exposure, the total number of expression changes in the liver was lower in MS diet group than in PB alone. Many PB induced genes essential to cell proliferation, growth and invasion showed at least 2 fold lower number of change in MS group compared to PB alone. These genes include S100A8, MCM5/6, Esco2, S0X10, BIRC5, RRM2, Gstm3, RAD51, Atrx as well as Cyp2b10; many of them are reported to be regulated by DNA methylation. Both increases in the global 5-hmc
level and decreased numbers of gene expression changes in MS diet fed mice after 7 days suggests possible early protective effect of methyl-rich diet. Although further work is needed to assess differential methylation in relation to gene expression and mechanisms of toxicity, LC/MS can be the first tier indicating global epigenetic changes induced by NGCs.

1909 Inter-Individual Variability in Epigenetic and Genotoxic Responses to 1,3-Butadiene in a Population-Based Collaborative Cross-Mouse Model

L. A. Lewis1, B. Borowa-Mazgaj2, A. de Conti2, G. Chappell1, W. Bodnar3, I. P. Pogribny2, and I. Rusyn1. 1College Station, TX; 2Texas A&M University, College Station, TX; 3US FDA/NCTR, Jefferson, AR; and 1University of North Carolina at Chapel Hill, Chapel Hill, NC.

1,3-Butadiene (BD) is a known human carcinogen that is both an occupational and environmental health hazard. Although it is well-established that genotoxicity is the key mechanism of BD carcinogenesis, epigenetic events have also been observed. Previous studies in a multi-strain mouse model revealed that inter-strain (e.g. inter-individual) differences exist in both BD-induced DNA damage and epigenetic effects. These studies indicated that variation in epigenetic alterations could drive the inter-individual susceptibility to BD genotoxicity. In the present study, we investigated whether or not there is population variability in epigenetic alterations and genotoxic effects in response to BD exposure by using the Collaborative Cross (CC) mouse model. We tested the hypothesis that there is variation in BD-induced epigenetic events and DNA damage. Male mice from 50 CC strains were exposed to 0 or 625 ppm of BD by inhalation (6 hr/day, 5 days/week) for 2 weeks. We evaluated genotoxic and epigenetic effects of BD in tissues that are a target (lung and liver) and non-target (kidney) of BD-induced carcinogenesis. Genotoxicity was assessed by measuring THB-Gua adduct levels. We observed that exposure to BD resulted in variable levels of THB-Gua adducts between strains and tissues. In order to investigate the epigenetic effects, we evaluated the levels of histones H4K20me3, H3K27me3, H3K9me3, H3K9ac, and H3K27ac in the livers. We observed variable response to BD as a strain-specific manner for all histone modifications as a result of BD exposure. Additionally, we analyzed the status of these histone modifications in the livers of unexposed mice and found that the strains with low levels of THB-Gua adducts after exposure to BD were characterized by a markedly high histone H3K27ac/H3K27me3 ratio, a mark of transcriptionally active chromatin. In contrast, this ratio was substantially lower in strains with high levels of THB-Gua adducts. This indicates that strain-dependent variability of BD-induced DNA damage and potentially greater tissue susceptibility to carcinogenesis may be predetermined by the pre-exposure epigenome status of a target organ.

1910Arsenic-Induced CPG Methylation Patterning in Placental JEG-3 Trophoblast Cells Via the Glucocorticoid Receptor: Support for the Transcription Factor Occupancy Theory

C. J. Meakin, O. A. Adebambo, E. M. Martin, and R. C. Fry. University of North Carolina at Chapel Hill, Chapel Hill, NC.

Exposure to inorganic arsenic (iAs) is a major public health problem as millions of individuals worldwide are exposed above the WHO limit of 10 ppb in drinking water. Arsenic exposure is associated with altered epigenetic profiles such as DNA methylation that have been associated with detrimental health effects, including cancer, adverse cognitive development and pregnancy outcomes. One hypothesis explaining iAs’s ability to alter DNA methylation is the transcription factor occupancy (TFO) hypothesis. This posits that DNA methyltransferase cannot gain access to DNA when transcription factors have bound to and occupied response elements of selected genes, thereby influencing Cpg methylation patterning. Given that iAs can act on the Glucocorticoid Receptor (GR), we set out to examine whether iAs exposure affects GR and GR target gene Cpg methylation and expression. In support of the TFO, we hypothesized that sites of decreased methylation would be associated with increased expression and increased methylation would be associated with decreased expression. To test this, placental JEG-3 cells were exposed to 1 μM iAs for 24 hours. Following exposure, methylation levels were assessed with the EPIC Illumina platform and gene expression was assessed using the Qiagen GR PCR array. A total of 450 GR-associated Cpg sites representing 253 genes displayed significantly altered Cpg methylation levels in relation to iAs exposure. An integrated analysis of methylated GR genes and gene expression data revealed 130 Cpg probes representing 54 genes with overlap. Of these genes, a total of 25 displayed changes representative of the transcription factor occupancy theory, demonstrating either hypermethylation in association with decreased gene expression or hypomethylation in association with increased gene expression. These genes included FK506 Binding Protein 5 (FKBP5), AFA/FMR2 Family Member (AFF1), Protein Activator 3 (RAS3), and Damage Inducible Transcript 4 (DDIT4), which are all associated with the development of adverse cognitive outcomes or cancer endpoints. Taken together, these results demonstrate the ability of iAs to modulate GR gene methylation and subsequent gene expression, and the potential epigenetic reprogramming resultant from transcription factor occupancy.

1911 DNA Methylation Epigenetically Regulates NF-κB Pathway Genes during COPD Exacerbations

G. Kaur, and S. Batra. Southern University and A&M College, Baton Rouge, LA.

Chronic Obstructive Pulmonary Disease (COPD) is a global health problem with ineffective current therapies and lack of knowledge about the pathobiology of the disease. Cigarette smoking is the leading cause of COPD, however, not all the smokers develop COPD. Exacerbations of COPD are caused by microbes and dust common to the environment with about 20-50% of exacerbations caused due to bacterial colonization in the lower airways of the patient. It is generally accepted that epigenetic mechanisms especially DNA methylation play important role during the disease prognosis in COPD. We thus hypothesized that DNA methylation patterns vary significantly in case of bacterial pathogen in COPD. To test this we used in vitro study model which mimics COPD exacerbations and performed methylation specific-PCR (MS-PCR) for NF-κB and STAT3 pathway genes. In brief, we challenged human alveolar type II epithelial cells (A549) with cigarette smoke extract (CSE) or DMSO (control) for 24 hr which included 3h challenge with bacterial lipopolysaccharide (LPS from Pseudomonas aeruginosa) before harvesting the cells. Samples were processed to determine the production of cytokines/chemokines, regulation of transcription factors and DNA methylation of specific genes. Our findings demonstrate significant increase in the transcriptional and translational profile of inflammatory mediators in CSE-exposed A549 cells challenged with LPS as compared to control group. We also observed significant decrease in the Cpg methylation at NF-κB and IKK promoter regions, however, the regulation at NIK and STAT3 promoter was insignificant. We also investigated the expression levels of Dnmts at protein level in various study groups. We observed increase in the expression of Dnmt2 and Dnmt3a in the CSE-treated cells challenged with LPS. Results from whole-exome bisulphite sequencing also shows downregulation of DNA methylation at CpG islands of NF-κB pathway genes. Overall our results indicate that activation of NF-κB mediated inflammatory pathway is regulated by alterations in DNA methylation at the CpG sites of these genes. Further studies are in progress to understand the mechanism of epigenetic regulation of NF-κB pathway in detail during COPD exacerbations which will help in the development of better and more effective therapeutic intervention strategies.

1912 Epigenetics and Genotoxicity: Potentially Interrelated Roles in Chemical Carcinogenesis

G. Chappell, and J. E. Rager. TaxStrategies, Inc, Austin, TX.

The relationship between genotoxicity-induced mutagenesis and cancer has been extensively demonstrated and is well accepted, while the roles of epigenetic regulators that are involved in inter-individual differences in carcinogenic potential and carcinogenic processes is not as clear. We aimed to assess the state-of-the science on the interplay between epigenetic alterations, DNA damage and carcinogenesis, and to gain an understanding of the availability of epigenetics data for DNA-damaging agents that have been classified as carcinogens. We first investigated the molecular mechanisms by which epigenetic alterations can render cells more vulnerable to genetic damage, and contrasted these with epigenetic mechanisms necessary for proper damage response and repair. The following connections between epigenetics and DNA damage and repair were identified: (i) preferential binding of reactive chemicals or metabolites to methylated cytosines at mutational “hotspots”, (ii) histone modifications that affect chromatin structure, resulting in altered accessibility of DNA to damaging agents and/or DNA repair machinery and/or recruitment of DNA repair machinery to sites of damage, and (iii) changes in abundance and activity of miRNAs that regulate the expression of genes involved in DNA damage response. These relationships are supported by data for three chemicals: benzo[a]pyrene, 1,3-butanediol, and formaldehyde. For example, significant enrichment for the functional category ‘DNA replication, recombination, and repair’ was observed among the mRNA targets of two miRNAs altered by exposure to benzo[a]pyrene and 1,3-butanediol. Despite the importance of epigenetics in chemical carcinogenesis, there is a general lack of infor-
mation on epigenetic responses among DNA damage agents. Among the 48 chemicals/metals (not including pharmaceuticals) and related occupations classified as “carcinogenic to humans” by the International Agency for Research on Cancer, we identified through a review of literature and cancer monographs that genotoxicity was reported for 36, and published information on epigenetics exists for just over half of these substances. Understanding of genotoxic responses and chemical-induced cancer. This evaluation identified epigenetic mechanisms that are important in the carcinogenic potential of DNA-damaging chemicals, and may be considered as candidates for further research and inclusion in cancer hazard evaluation.

### 1913 Screening and Evaluation of Endocrine Disrupting Chemicals on Sirtuin Regulation and Inflammatory Response in Macrophages

M. Park1, A. K. Garcia2, and M. Choudhury1. 1Texas A&M University, College Station, TX and 2San Luis Potosi Institute of Scientific Research and Technology, San Luis, Mexico. Sponsor: S. Meruven.

There has been an epidemiologic rise in the prevalence of metabolic disorders with emerging evidence linking low grade inflammation as an underlying mechanism. Macrophages have been implicated in promoting inflammation in diabetes and obesity. Our published evidence reported endocrine-disrupting chemicals (EDCs) induced sirtuin dysregulation in pre-adipocytes, placental cells, and liver cells. Sirtuins, a novel epigenetic histone deacetylase class regulator, have also been shown to play a role in inflammation. In this study, we screened six EDCs hypothesizing that EDC exposure leads to an inflammatory response in the macrophage via sirtuin regulation. RAW 264.7 cells were treated with 0.5, 5, and 50 μM of EDCs (Bisphenol A (BPA), Bisphenol F (BPF), Diethylene glycol diethyl ether (DEG), Mono (2-ethylhexyl) phthalate (MEHP), Perfluorooctane sulfonate (PFOS), BBP) and showed higher exposures than native communities fishing on tributaries that feed into the MDD River (Queros (median 0.9 ppm, range 0.05-44.8 ppm)). To evaluate the possible impacts of hazardous environmental stresses on epigenetic modifications mediated through virtual screening of 1154 pesticides on human DNMTs (DNMT1, PDB code: 35WR) and (DNMT3, PDB code: 2QVR). Molecular docking calculations for DNMTs-pesticide complexes were performed using AutoDock Vina. Binding-affinity values, contact patterns and molecular diversity were employed as selection criteria of consensus pesticides as virtual hits of DNMTs. The best DNMTs-pesticide complexes selected according to their high absolute affinity values (kcal/mol) for both DNMT1 and DNMT3 were Bromadiolone (11.0; 9.1), Flocoumafen (9.9; 9.0), Difenacoum (9.7; 9.1), and Difenacoum (11.4; 10.2). These chemicals were molecularly clustered and all belong to second generation rodenticides. The most frequent interacting residues for DNMT1-pesticide complexes were Trp1170A, Phe1170A, Met 696A, Glu698A; whereas for DNMT3 those were Glu303B, Pro739A, Lys740A and Glu303B. These results suggest that rodenticides used for pests control are potential DNMT ligands and therefore may modulate DNA methylations, finding with important environmental and clinical implications. This discovery may be useful to identify new epigenetic biochemical pathways activated by these xenobiotics, using this information as a starting point for future validations with in vitro and in vivo assays.

### 1914 Mitochondrial-Epigenetic Crosstalk Endpoints in PBMCs from Genetically Diverse Individuals with High Methyl Mercury Exposure Living Near ASGM in the Peruvian Amazon

The Madre de Dios (MDD) region of the Peruvian Amazon has experienced rapid artisanal small-scale gold mining (ASGM) expansion. Communities near ASGM have high methylmercury (MeHg) exposure via contaminated fish consumption. We evaluated MeHg exposure using total hair mercury (Hg) in n=2308 individuals across 23 MDD communities Diamante (median 5.2 ppm, range 0.4-21.4 ppm), Isla de los Valles (median 7.1 ppm, range 1.2-16.7 ppm), and Puerto Azul (median 5.2 ppm, range 2.2-14.1 ppm) fish directly on the MDD River, and showed higher exposures than native communities fishing on tributaries that feed into the MDD River (Queros (median 0.9 ppm, range 0.4-2.1 ppm), and Palotafo-Teparo (median 2.7 ppm, range 1.4-6.4 ppm)); or mining towns (Hupepetuca (median 0.9 ppm, range 0.003-20.3 ppm), and Quebrada Nueva (median 0.8 ppm, range 0.05-44.8 ppm)). To evaluate potential biological impacts of MeHg exposure in a genetically diverse study population, we measured mitochondrial and epigenetic endpoints in whole blood from a subset of baseline participants (n=32; n=16 “HIGH” >10 ppm total hair Hg, n=16 “LOW” <1ppm total hair Hg, matched on age and sex). Emerging evidence strongly supports cross-talk between these two systems. We measured mitochondrial DNA (mtDNA) damage and copy number (CN). We evaluated cell type proportions and DNA methylomes using Illumina 850K epic microarrays. Although neither mtDNA damage nor CN were associated with Hg, both DNA methylomes (β=0.65, p=0.009) and cell type proportions were significant predictors of mtDNA damage, but these relationships were attenuated on inclusion of Hg in the model. These results suggest that T cells are preferential targets for mtDNA damage. We are currently analyzing methylation data as potential mediators or consequences of mitochondrial responses. This work highlights the importance of a “systems biology” approach to biologically related toxicity endpoints.

### 1915 Alterations in Epigenetic Control: In Silico Evaluation of Pesticides as Potential Modulators of Human DNA Methyltransferases

DNA methylations are part of epigenetic changes that modulate gene expression, processes carried out by DNA methyltransferases (DNMTs). A wide range of chemicals can promote changes in the epigenome, including pesticides, making them attractive candidates of association with chronic diseases. In this study, human DNMTs were evaluated as potential targets for pesticides through virtual screening of 1154 pesticides on human DNMTs (DNMT1, PDB code: 35WR) and (DNMT3, PDB code: 2QVR). Molecular docking calculations for DNMTs-pesticide complexes were performed using AutoDock Vina. Binding-affinity values, contact patterns and molecular diversity were employed as selection criteria of consensus pesticides as virtual hits of DNMTs. The best DNMTs-pesticide complexes selected according to their high absolute affinity values (kcal/mol) for both DNMT1 and DNMT3 were Bromadiolone (11.0; 9.1), Flocoumafen (9.9; 9.0), Difenacoum (9.7; 9.1), and Difenacoum (11.4; 10.2). These chemicals were molecularly clustered and all belong to second generation rodenticides. The most frequent predicted interacting residues for DNMT1-pesticide complexes were Trp1170A, Phe1170A, Met 696A, Glu698A; whereas for DNMT3 those were Glu303B, Pro739A, Lys740A and Glu303B. These results suggest that rodenticides used for pests control are potential DNMT ligands and therefore may modulate DNA methylations, finding with important environmental and clinical implications. This discovery may be useful to identify new epigenetic biochemical pathways activated by these xenobiotics, using this information as a starting point for future validations with in vitro and in vivo assays.

### 1916 Identification of Smoking-Induced Changes in DNA Methylation in an Epigenome-Wide Scan

S. Ichihara1, M. Nakatochi2, T. Matsubara3, M. Yokota3, and K. Yamamoto4. 1Jichi Medical University, Shimotsuke, Japan; 2Nagoya University, Nagoya, Japan; 3Aichi Gakuin University, Nagoya, Japan; and 4Kurume Medical University, Kurume, Japan.

Gene expression in eukaryotes is regulated in part by epigenetic modifications mediated through DNA methylation and stable histone modifications, an exquisite biological system that maintains cellular homeostasis. There is significant evidence that the dysregulation of epigenomic functional complexes disrupts information processing of the study of the possible impacts of hazardous environmental stresses on epigenetic modifications has attracted interest because it allows a better understanding of disease pathogenesis. To identify the genes involved in smoking-induced epigenetic alteration, we assessed the DNA methylation levels of 473,864 autosomal CpG sites in a total of 384 subjects from Japanese general population-based cohorts. Genomic DNA obtained from peripheral blood was bisulfite treated and genome-wide methylation profiles were obtained using the Illumina Human Methylation 450K BeadChip. After removing an outlier sample and low call rate sites, we detected 11 sites with 6 loci, including NFE2L2, ALPL2, DPR15, AHR9, IRAK3, and F2RL3, which had adjusted P values of less than 0.01 in comparisons between current and non-current smokers for the DNA methylation levels. To address whether the smoking-induced DNA demethylation is reversible, the difference in the DNA methylation levels among never, former, and current smokers was examined. In former smokers, the sites in ALPL2, AHR9, IRAK3 and F2RL3, which had P values of less than 0.01 in comparisons between current and non-current smokers, whereas the sites in DPR15 and NFE2L2 showed the
nearly the same DNA methylation levels observed in never smokers. The smoking-induced change in the DNA methylation levels is not dependent on smoking dose or years, but its restoration is dependent on the time since smoking cessation, suggesting that the epigenome adapts dynamically to smoking stress.

**1917 Anaemic Induction Disrupts Lipid Profile and Alters Lipoprotein Metabolism Gene Expression in a Rat Model**

O. O. Ogunrinola, S. N. Olaitan, O. O. Fajana, O. A. Ogunrinola, O. A. Rotimi, and S. O. Rotimi, 1 Lagos State University, Ojo, Lagos, Nigeria; 2 Babcock University, Ilishan Remo, Nigeria; and 3 Covenant University, Ota, Nigeria.

Iron metabolism in animals is altered by haemolytic anaemia induced by phycocyanin (Phyco) treatment. However, its effects on lipid metabolism remain elusive. The aim of this study was to examine the impact of anaemia on lipid profiles and lipoprotein metabolism gene expression in rats. Fourteen adult male Wistar rats were randomly classified into normal control and anaemia-induced groups (n = 7) respectively. Anaemia was induced by daily administration of Phyz at 10 mg/kg for eight consecutive days; after which blood was collected and liver excised. Lipid profiles of plasma and liver were determined spectrophotometrically while the expression of genes associated with lipid and lipoprotein metabolism was assayed by reverse transcriptase polymerase chain reaction (RTPCR). Anaemia resulted in a significant (p < 0.05) decrease in plasma HDL-C and triglycerides, and an increase in plasma VLDL-C, LDL-C and total cholesterol. We conclude that anaemia induces alterations in the expression of genes associated with lipid and lipoprotein metabolism. This is the first study to investigate the impact of anaemia on lipid profiles and lipoprotein metabolism gene expression in rats.

**1918 A Cellular Game of Telephone: Trans-Cellular Reprogramming in Responses to Toxic Stimuli**

E. C. Vitucci, G. Budziszewski, and S. D. McCullough, 1 University of North Carolina at Chapel Hill, Chapel Hill, NC, and 2 US EPA, Research Triangle Park, NC.

Exposure to air pollution is a leading cause of cardiopulmonary morbidity and mortality; however, while these effects outside the lungs have been associated with aberrant oxidative stress and inflammation, the underlying molecular mechanisms are poorly understood. We hypothesized that air pollutant exposure of human bronchial epithelial cells (HBEC) could alter the expression of pro-inflammatory and pro-oxidant stress genes in adjacent, but physically separated, human bronchial epithelial cells (HBECS) through alterations to the epigenome. To test this hypothesis, we exposed confluent monolayers of HBEC, grown on the apical surface of Transwell permeable membranes, to diesel exhaust particles (DEP) or polycyclic aromatic hydrocarbons (PAH). We analyzed the expression of two sets of genes, one associated with HBEC and the other with the basolateral compartment. A variety of pro-inflammatory and oxidative stress genes were induced in HBEC-1 cells cultured in the presence of DEP-exposed HBEC. Using IL-8 and HMOX1 as representative genes in the pro-inflammatory and oxidative stress responses, respectively, we then determined whether these changes in gene expression were associated with alterations to the epigenome. We assessed the abundance of four histone modifications with established roles as key regulators of gene expression, whether these changes in gene expression were associated with alterations to the epigenome. We assessed the abundance of four histone modifications with established roles as key regulators of gene expression, including di/trimethyl histone H3 lysine 4 (H3K4me3) and lysine 27 (H3K27me3). We observed that DEP-exposed HBECs resulted in a significant (p < 0.05) increase in the abundance of H3K4me3 and H3K27me2/3 and unmodified histone H3. The abundance of H3K27me3 increased within the promoters of both IL-8 and HMOX1 in HBEC-1 cells cultured in the presence of DEP-exposed HBEC. These indirectly exposed HBECs were associated with an increase in the expression of IL-8 and HMOX1 in HBEC-1 cells cultured in the presence of DEP-exposed HBEC. These indirectly exposed HBEC-1 cells also exhibited increased H4ac within IL-8 and HMOX1 enhancer regions. In addition, a reduction in H3 occupancy accompanied these histone modifications. This trans-cellular epigenetic reprogramming within the HBEC-1 cells suggests a more open chromatin conformation and was associated with an enhanced pro-inflammatory and oxidative stress response to a secondary challenge with lipopolysaccharide. Our findings demonstrate that pollutant-exposed epithelial cells reprogram the expression of pro-inflammatory and oxidative stress genes in adjacent cells. These findings ultimately provide a mechanistic mechanism by which exposure to air pollution can cause adverse health effects in tissues that are not directly exposed, and further heighten the importance of understanding the effects of air pollution on tissues beyond the airway.

**1919 Phthalates Contamination in Commercial Alcohol: Effects on Sirtuin Regulation**

A. K. Gutierrez Garcia, H. I. Ali, S. Meruvu, C. A. Powell, L. F. Schultz, A. De Leon Rodriguez, and M. Choudhury, 1 San Luis Potosi Institute of Scientific Research and Technology, San Luis Potosi, Mexico; and 2 Texas A&M University, College Station, TX.

Phthalates have attracted public regulatory attention due to their possible adverse environmental and human health effects. Our group demonstrated the presence of endocrine disruptor phthalate in vegetable cans, baby bottles and microwaveable containers from the Mexican market. In a screening assay (GC/MS technique) of various samples of tequila and mezcal, we discovered that these beverages were contaminated with phthalates specifically DEHP and in many cases were above the permitted limits. Furthermore, computational molecular docking analysis showed that DEHP binds to sirtuin 3, a member of the Class III histone deacetylases family involved in regulation of metabolism. Therefore, we hypothesize that phthalate contamination in alcoholic beverages may synergistically dysregulate sirtuins during metabolic processes. HepG2 cells were exposed to different concentrations of DEHP (0, 100 nM, 1 μM, 5 μM, 10 μM, 25 μM, and 50 μM) with or without ethanol (0, 1 nM, 100 nM, 1 μM, 10 μM, and 25 μM) for 48 h. Sirtuin regulation and lysine acetylation were analyzed. Treatment with DEHP and ethanol alone or in combination for 48 h did not affect cell viability. DEHP alone significantly decreased gene expression of sirtuin 3 and 5 in a dose-dependent manner (P < 0.001) whereas sirtuin 1, 2, 6, and 7 showed nonmonotonic changes. Sirtuin 4 gene expression showed no changes in response to DEHP. Ethanol alone significantly decreased all sirtuins in a dose-dependent manner (P < 0.001). In comparison to ethanol or DEHP alone, the combination of DEHP and ethanol significantly downregulated the expression of sirtuin 7 while no significant effects were observed for any of the other sirtuins. Finally, after 72 h, 1 nM and 10 μM ethanol significantly increased protein acetylation while decreasing sirtuins 1 and 3 protein expression, with no effects detected on sirtuins 5, 6, and 7 protein expression. We are currently investigating the sirtuin regulation in human hepatocytes. In conclusion, a combination of DEHP and ethanol may change sirtuin regulation which may affect liver pathology.

**1920 N-Acetylcysteine Protects Endogenous High Glucose/Fatty Acid Toxicity and Streptozotocin-Induced Cytotoxicity in Pancreatic Beta Cells**

H. Razza, A. M. Al Nahdi, and A. John, CMHS, UAE University, Al Ain, United Arab Emirates.

Prevalence of diabetes is on the rise globally and causing extraordinary burden on the health systems, both in developed and developing countries. Pancreatic beta-cell mass destruction/neogenesis/proliferation (e.g. in type1) and/or malfunction (type2) have been implicated in diabetes etiology, pathology, progression as well as in responses towards disease managements. Oxidative stress and alterations in mitochondrial energy metabolism play important roles in diabetes-induced cellular complications. Several studies, including our own, have suggested that sirtuins are the basal-salient component. A variety of pro-inflammatory and oxidative stress genes were induced in THP-1 cells cultured in the presence of DEP-exposed HBEC. Using IL-8 and HMOX1 as representative genes in the pro-inflammatory and oxidative stress responses, respectively, we then determined whether these changes in gene expression were associated with alterations to the epigenome. We assessed the abundance of four histone modifications with established roles as key regulators of gene expression, including di/trimethyl histone H3 lysine 4 (H3K4me3), pan-acetyl histone H4 (H4ac), di/tri-methyl histone H3K27 (H3K27me2/3), and unmodified histone H3 (H3). The abundance of H3K27me3 is increased within the promoters of both IL-8 and HMOX1 in THP-1 cells cultured in the presence of DEP-exposed HBEC. These indirectly exposed THP-1 cells also exhibited increased H4ac within IL-8 and HMOX1 enhancer regions. In addition, a reduction in H3 occupancy accompanied these histone modifications. This trans-cellular epigenetic reprogramming within the THP-1 cells suggests a more open chromatin conformation and was associated with an enhanced pro-inflammatory and oxidative stress response to a secondary challenge with lipopolysaccharide. Our findings demonstrate that pollutant-exposed epithelial cells reprogram the expression of pro-inflammatory and oxidative stress genes in adjacent cells. These findings ultimately provide a mechanistic mechanism by which exposure to air pollution can cause adverse health effects in tissues that are not directly exposed, and further heighten the importance of understanding the effects of air pollution on tissues beyond the airway.
221 Comparative Effects of High Glucose and High Palmitic Acid Treatment on Cell Survival, Oxidative Stress, and Mitochondrial Bioenergetics in RIN-SF and HepG2 Cells

A. M. Al Nahdi, A. John, and H. Raza, CMHS, UAE University, Al Ain, United Arab Emirates.

According to WHO, over 400 million cases of diabetes were reported in 2014 and is estimated to be the 7th leading cause of death by 2030. As obesity is considered as one of the most important risk factors, this disease is also referred to as “diabesity”. Glucotoxicity and lipotoxicity, due to persistent hyperglycemia and dyslipidemia, and increased inflammation are the main causative factors affecting the progression and pathology of diabetes. Using both in vivo and in vitro models, we have previously reported increased oxidative stress and mitochondrial dysfunction in diabetes. Here, we have compared the effects of high glucose (up to 30 mM) and high saturated fatty acid, palmitic acid (0.3 mM), on cell survival, inflammatory responses, oxidative stress, mitochondrial function and apoptosis using rat pancreatic Rin-SF insulin secreting cells as well as human hepatoma derived HepG2 cells. Our results show that high glucose and high palmitic acid alone or in combination inhibits cell survival, as measured by MTT assay, and induces apoptosis by altering cell signaling and mitochondrial functions, in a dose-dependent manner. The gluco- and lipotoxicity in these cellular systems were also observed at the metabolic level as seen by alterations in energy metabolism in the mitochondrial and cytosolic compartments. Furthermore, we also observed that these cells were under severe oxidized and inflammatory stress as shown by increased reactive oxygen species (ROS) production and alterations in glutathione (GSH) dependent antioxidant homeostasis. Our results also show that treatment with N-acetylcysteine, a ROS scavenger, attenuated the effects of gluco-/lipotoxicity observed in these cells. These results may have implications in better understanding the etiology and pathophysiology of diabetes and associated complications.

222 Endoplasmic Reticulum Stress and MAPK Signaling Pathway Activation Underlie Leflunomide-Induced Toxicity in HepG2 Cells

Z. Ren1, S. Chen1, T. Qing2, J. Xuan1, L. Couch1, B. Ning1, L. Shi1, and L. Guo1. 1US FDA/NCTR, Jefferson, AR; and 2Fudan University, Shanghai, China.

Leflunomide, used for the treatment of rheumatoid arthritis, has been reported to cause severe liver problems and liver failure; however, the underlying mechanisms are not clear. In this study, we used multiple approaches including genomic analysis to investigate and characterize the possible mechanisms of the cytotoxicity of leflunomide in hepatic cells. We found that leflunomide caused endoplasmic reticulum (ER) stress and activated an unfolded protein response, as evidenced by increased expression of related genes including CHOP and GADD34; and elevated protein levels of typical ER stress markers including CHOP, ATF-4, p-eIF2β, and spliced XBP1. The secretion of Gaussia luciferase showed increased cell survival against UVB-induced apoptosis in cell treated with leflunomide in an ER stress reporter assay. Inhibition of ER stress with an ER stress inhibitor 4-phenylbutyrate, and knockdown of ATF-4 and CHOP genes partially protected cells upon leflunomide exposure. In addition, both genomic and biochemical analyses revealed that JNK and ERK1/2 of MAPK signaling pathways were activated, and both contributed to the leflunomide-induced cytotoxicity. Inhibiting JNK activation using a JNK inhibitor attenuated the ER stress and cytotoxicity of leflunomide, whereas inhibiting ERK1/2 using an ERK1/2 inhibitor or ERK1/2 siRNA increased the adverse effect caused by leflunomide, suggesting opposite roles for the two pathways. In summary, our data indicate that both ER stress and the activation of JNK and ERK1/2 contribute to leflunomide-induced cytotoxicity.

223 Electronic Liquids Induce Osteotoxicity in Which Flavoring Is a Key Factor

C. E. Otero, and S. Hegland. The College of Idaho, Caldwell, ID.

Electronic cigarettes (e-cigs) are a relatively new method of nicotine delivery advertised as a healthier alternative to traditional tobacco products. While early studies support this claim, the health effects of e-cig use are still widely unknown. As the popularity of e-cigs increases, especially among middle- and high-school age kids, so does need to determine the health consequences associated with e-cig use. Another significant health concern is that children have become seriously ill after ingesting the electronic liquids (e-liquids) used in e-cigs. Since smoking traditional tobacco products is a risk factor for osteoporosis, our lab hypothesizes that exposure to e-liquids can also impair bone function. For this research, the human osteoblast-like cell line MG-63 was used as a model. Cells were treated for 48 hours with dilutions of commercially available un-vaped e-liquids of various flavors, without or with (0.1 mg/mL) nicotine, for analysis of cell viability through MTT assays and immunofluorescence for collagen type I. Cell viability results showed a dose dependent decrease in all the e-liquids tested, but the effect was most pronounced in cinnamon flavored e-liquids and least pronounced in flavorless e-liquids consistently in all the brands tested. There were no consistent differences between treatments with or without nicotine. Immunofluorescence for collagen type I showed decreased protein expression after exposure to a non-cytotoxic dose of un-vaped e-liquid with or without nicotine. We conclude that exposure to e-liquids alters osteoblast function, and further investigation is warranted to determine the cellular mechanisms involved.

224 Insights into the Effect of Subtle Chemical Modification of Aryl Chloroethyurea (CEU) as Small Molecules Targeting Either β-Tubulin or Prohibitin and Thioredoxin-1

J. S. Fortin1, A. Patenaude2, B. Bouchon3, and R. C.-Gaudreault4. 1University of Missouri, Columbia, MO; 2Axis of Neuroscience, Quebec, QC, Canada; 3Unité Mixte de Recherche 484, Clermont-Ferrand, France; and 4CR CHU de Québec, Axxe Oncologie, Quebec, QC, Canada. 3Sponsor: C. Alden, McGill University.

Chloroethyureas (CEU) are protein alkylating agents displaying potent antineoplastic properties that covalently bind to β-tubulin and affect microtubule polymerization dynamics. A different CEU subset has been shown to induce cell growth inhibition without alkylating β-tubulin. Our research focus is to understand the mechanisms underlying the antiproliferative activity of that new class of compounds. From B16 and MDA-MB-231 cells incubated with [(14)C-urea]-CEU-25 and [(125)I]-CEU-98 were separated using 2D-electrophoresis followed by MALDI-TOF identification of modified proteins. Protein expression and distribution were investigated by Western blot analyses and immunocytochemistry. Cell cycle arrest was obtained by treating the cell line B16 with CEU-22 and its bioisosteric derivative CEU-98 are original CEU prototypes that covalently bind to β-tubulin via an ester linker on Glu198. The alkylation leads to microtubule depolymerization phenotype, cell cycle arrest in G2/M and inhibition of cell proliferation in vitro. A newly isolated subset of CEUs exemplified by the prototypical CEU-25, alkylates prohibitin (PHB) on Asp40 and thioredoxin isoform-1 (TRX1). CEU-25 arrests cells predominantly in G1 phase and inhibits Trx-1 and PHB nuclear translocation. The intracellular proteins alkylated by the new CEU subset were identified as the PHB and TRX1. Different protein targets profiles explain the G1 cell cycle arrest. Our research emphasizes that a subtle chemical modification might lead to drastic change of protein target. Our finding might help to design new potent anticancer drugs that will target specific and lethal biological pathway essential to tumor growth.

225 Epidermal-Specific Deletion of TC-PTP Promotes UVB-Induced Keratinocyte Cell Survival through the Regulation of VEGFR2/JNK Signaling

M. Kim1, J. Lim2, M. Baek3, L. D. Morales1, J. Jang2, A. T. Tsin1, and D. J. Kim1. 1University of Texas Rio Grande Valley, Edinburg, TX; and 2Korea Basic Science Institute, Daejeon, Korea, Republic of.

UVB can contribute to the development of skin cancer by modulating PTK signaling. It has been suggested that UVB increases the ligand-dependent activation of PTKs and induces PTP inactivation. Our recent studies have shown that T cell protein tyrosine phosphatase (TC-PTP) deficiency predisposes mice to skin carcinogenesis induced by two-stage chemical regimens, which indicates its critical role in the prevention of chemically-induced skin cancer. In the current work, we report that activation of TC-PTP leads to increased keratinocyte susceptibility to UVB-induced apoptosis via the downregulation of VEGFR2/JNK signaling. TC-PTP-deficient (TC-PTP KO) mice showed significant resistance to UVB-induced apoptosis in epidermis. To assess the role of TC-PTP in UVB-induced apoptosis, we generated immortalized TC-PTP KO keratinocytes from the epidermis of TC-PTP KO mice. Immortalized TC-PTP KO keratinocytes showed increased cell survival against UVB-induced apop-
DNA Damage-Induced Apoptosis and MAPK Pathway Contribute to the Toxicity of Dronedarone in Hepatic Cells

Dronedarone, an antiarrhythmic drug, has been marketed as an alternative to amiodarone. The use of dronedarone has been associated with severe liver injury; however, the mechanisms remain unclear. In this study, the possible mechanisms of dronedarone-induced liver toxicity were characterized in HepG2 cells. Dronedarone decreased cells viability and induced apoptosis and DNA damage in a concentration- and time-dependent manner. Pretreatment of the HepG2 cells with apoptosis inhibitors (caspase-3, -8, or -9) or the necrosis inhibitor (Necrox-5), partially, but significantly, reduced the release of lactate dehydrogenase. Dronedarone caused the release of cytochrome c from mitochondria to cytosol, a prominent feature of apoptosis. In addition, the activation of caspase-2 involved in dronedarone induced DNA damage, and dronedarone exposure activated JNK and p38 signaling pathways. Inhibition of JNK and p38 by specific inhibitors attenuated dronedarone-induced cell death, apoptosis, and DNA damage. Additionally, suppression of caspase-2 decreased the activities of JNK and p38. Dronedarone triggered DNA damage was regulated by down-regulation of topoisomerase IIa at both transcriptional and post-transcriptional levels. Taken together, our data show that DNA damage, apoptosis, and the activation of JNK and p38 contribute to dronedarone-induced cytotoxicity.

Characterization of Whole Smoke and Smokeless Tobacco Exposure to a 3D Human Oral Tissue Model

B. Keyser1, M. Bachelor2, A. Malone3, and W. Fields1. 1R4F Services Company, Winston-Salem, NC; and 2MatTek Inc., Ashland, MA.

Oral disease is frequently associated with viral and environmental exposures as well as oral hygiene. The use of tobacco is an additional risk factor in the development of oral disease. The goals of this study were to evaluate cytotoxicity, inflammatory response and oxidative stress in response to extracts of CORESTA smokeless tobacco reference products (CRPs) exposed to a 3D human oral buccal model, EpiOral™, as well as to determine the potential cytotoxicity of whole smoke in this model. CRPs for snus (CRP1), moist snuff (CRP2) and dry snuff (CRP3) were each extracted in complete artificial saliva (CAS) with a ratio of 300 mg of CRP to 1 mL of CAS. CRP extracts were sterile-filtered and stored at 80°C until the time of exposure. CRP extracts (15 - 300 mg/ml) were added topically to the apical side of EpiOral™ tissues for 24 or 48 hours continuously. Cytotoxicity (3-(4,5-dimethylthiazol-2-yl)-2,5-diphenyltetrazolium bromide; MTT), oxidative stress (8-isoprostanate) and inflammatory response (cytokine release; IP10, IL-1α, IL-8) were measured after each time point. Whole smoke exposure were conducted by exposing the EpiOral™ tissues to whole smoke with depths of 8-isoprostane at 48 hours of exposure. Collectively, the data suggest that the EpiOral™ three-dimensional human cell culture model may be useful in differentiating smokeless tobacco products and evaluating between tobacco product categories.
Ethanol-induced apoptosis in neural crest cells (NCCs), a multipotent progenitor cell population, are implicated in the Fetal Alcohol Spectrum Disorders (FASD). Previous studies from our laboratory have demonstrated that sulforaphane (SFN), a vegetable-derived isothiocyanate, can prevent ethanol-induced apoptosis in NCCs. Epithelial-mesenchymal transition (EMT) is a process by which cells lose their epithelial phenotype and acquire mesenchymal phenotype, which is essential for NCC migration. The induction of EMT has also been shown to confer resistance to apoptosis in cancer cells. The objective of this study is to investigate whether ethanol exposure can induce apoptosis in NCCs by inhibiting EMT and whether SFN can prevent ethanol-induced apoptosis by epigenetically modulating the expression of EMT transcriptional factor Snail1. We found that exposure to ethanol resulted in a significant increase in apoptosis in NCCs. Co-treatment with SFN significantly reduced ethanol-induced apoptosis. Ethanol treatment also inhibited EMT, as indicated by an increased expression of E-cadherin, an EMT-suppressing marker, and a reduced expression of vimentin, an EMT-promoting maker. Treatment with SFN significantly reversed ethanol-induced changes in the expression of E-cadherin and vimentin, and restored EMT. We also found that ethanol exposure significantly decreased the mRNA expression of Snail1, which can be reversed by co-treatment with SFN. To determine whether ethanol and SFN regulate the expression of Snail1 by histone modification, the expression of kdm5a, a lysine-specific demethylase, and the levels of trimethylation of histone H3 lysine 4 (H3K4me3) at the promoters of Snail1 were determined. We found that ethanol exposure increased the expression of kdm5a which was reversed by SFN. The ChIP-qPCR analysis revealed that ethanol exposure significantly reduced the levels of H3K4me3 at the promoters of Snail1 and that SFN treatment reversed the ethanol-induced reduction of H3K4me3. Additionally, knock-down of kdm5a restored EMT and significantly decreased apoptosis. Taken together, these results demonstrate that ethanol exposure can induce apoptosis in NCCs by inhibiting EMT and that SFN can protect against ethanol-induced apoptosis by reverting ethanol-induced reduction in the levels of H3K4me3 at the promoters of Snail1, restoring the expression of Snail1 and EMT in ethanol-exposed NCCs.

1930 Sulforaphane Protects against Ethanol-Induced Apoptosis in Neural Crest Cells through Epigenetically Modulating the Expression of Snail1 and Restoring EMT

Y. Li, F. Yuan, T. Wu, L. Lu, J. Liu, and S. Chen. University of Louisville, Louisville, KY.

Prostate cancer is one of the most frequently diagnosed malignancies and the second leading cause of cancer related death in men in the developed countries. The androgen deprivation therapy (ADT) is a classical treatment strategy, but development of resistance to ADT is a major obstacle for the management of advanced prostate cancer. Therefore, search for the novel therapeutic approaches are urgently needed. Fenofibrate, a fibrate, is now being used to treat hypercholesterolemia and hyperlipidemia. Recent reports have indicated that fenofibrate exerts anti-proliferative and pro-apoptotic properties in a few types of cancers. However, report on fenofibrate-induced effects on prostate cancer cells remains lacking. Here we aimed at testing whether fenofibrate can be repurposed for the suppression of human prostate cancer with its cell lines in a vitro model, and underlying mechanism. Methods: We used include cell viability, measured by MTT assays, apoptotic cell death, analyzed by flow cytometry, and Western blots and real-time PCR for the signaling pathway-related targets at both protein and mRNA expression levels, respectively. Results showed that fenofibrate inhibited the growth of androgen-independent prostate cancer cell lines DU145 and PC-3 in dose- and time-dependent manners. Then we chose 50 µM of fenofibrate as the optimal dose in the future studies and demonstrated that fenofibrate-induced cell death is predominately apoptotic death that is mediated by the activation of caspase-3- and AIF-dependent signaling pathways in both cell lines. Thereafter, the underlying mechanism was explored with DU145 cell line alone. We showed that fenofibrate increased the expression of Bad and decreased the expression of Bcl-xl and Survivin. Furthermore, fenofibrate induced a significant increase in apoptosis as measured by Annexin V/PI staining, with or without the addition of nicotine. Conclusions: These results suggest that fenofibrate indeed significantly inhibited human prostate cancer cell proliferation via apoptotic action, which will provide a great potential to be applied into clinics for the treatment of ADT resistance prostate cancer. Therefore, further study in mechanistic details by which fenofibrate suppress prostate cancer proliferation is mediated by its inhibition of the Jak2/Stat3-dependent cell survival pathway.

1932 Fenofibrate Induces Human Prostate Cancer Cell Apoptosis Likely Via Jak2-Stat3 Pathway

Electronic cigarettes (e-cigs) continue to gain worldwide popularity as a healthier alternative to traditional tobacco products. The potential risks that e-cigs impose on human health are currently under investigation. The unidentified health risks associated with e-cigs use combined with newly implemented federal regulations on production standardization point to the need for e-cig research. Since tobacco use is a well-known risk factor for bone-related diseases, we are interested in the effect of e-cigs on bone-forming osteoblasts. We hypothesize that exposure to e-liquid can impair osteoblast function. Human osteoblast-like Saos-2 cells were exposed to different concentrations of unvaped commercially available e-liquids with either 0 mg/ml, 0.01 mg/ml, 0.1 mg/ml or 1 mg/ml of nicotine for 48 hours. Cell viability was assessed using an MTT assay. Alkaline phosphatase (ALP) activity, a widely used marker for osteoblast activity, was also measured. Unvaped e-liquids were found to significantly reduce cell viability in a dose-dependent manner. This reduction was exacerbated with flavorings agents and varied between different flavors, with fruity flavors having the most cytotoxic effects and no flavorings having the least effect. Furthermore, the cytotoxic effects of the e-liquids were similar in treatments with or without the presence of nicotine. There were no detectable changes in ALP activity in response to any of the e-liquid exposures with or without nicotine. These studies indicate that the degree of osteotoxicity depends on the flavorings. Ongoing studies are investigating mRNA expression of genes involved in osteoblast function including COL1A1, RUNX2, and ALP. This study provides insight into the potential impact of e-cig use on bone health. This research is supported by an Institutional Development Award (IDeA) from the National Institute of General Medical Sciences of the National Institutes of Health under Grant #P20GM103408.

1933 The Effect of Electronic Cigarette Liquids (E-Liquids) on the Human Osteoblast-Like Cell Line Saos-2

J. A. Noeker, and S. J. Heggland. The College of Idaho, Caldwell, ID.
We evaluated the use of bioluminescent real-time viability and LDH release assays for toxicity studies of 3D cultures. The sensitivity (limit of detection <10 cells/well) and nondestructive nature of both assays address the need for monitoring drug toxicities in a time-dependent manner using a small number of cells. We used a novel bioluminescent LDH toxicity assay to monitor the time-dependent effect of panobinostat and doxorubicin on HCT116 spheroids formed in 384 ultra low adherence plates using 2,500 cells/well. Drug toxicity was measured at 24, 48 and 72 hours by removing 5μl of medium for each time point, diluting, freezing and analyzing the samples at the end of the experiment. Both drugs showed time and concentration dependent increases in toxicity with EC50 values decreasing from 1.8 μM to 3.8 μM for doxorubicin and from 17.1 μM to 2.3 μM for panobinostat between 24 and 72 hours of treatment. In both cases the toxicity was measured with >15 fold increase in signal at maximum drug concentration as compared to untreated control. The assay was further validated using 3D human liver microtissues. Treatment of microtissues with staurosporine and aflatoxin resulted in LDH release with calculated EC50 values of 2.9 μM and 3.5 μM, respectively. A bioluminescent real-time viability assay was also validated using induced pluripotent stem cell derived hepatocytes plated in 384-well ULA plates to form spheroids from 2,000 cells/well. The spheroids were dosed every 2 days with hepatotoxic compounds, amiodarone and tolcapone, and viability was determined after 2, 4, 7 and 11 days. For both compounds prolonged exposure increased toxicity and reduced EC50 between 2 days and 11 days of treatment (by up to 8 fold for amiodarone and more than 1,000 fold for tolcapone). These data indicate that both bioluminescent real-time viability and LDH toxicity assays provide convenient tools for measuring drug induced toxicity. The assays are compatible with small numbers of cells, allow monitoring of changes in toxicity over extended periods of time and preserve the viable cells for further analysis or use with other end-point assays.

Heavy Metals in C. elegans

A major route of exposure to various heavy metals is through contaminated soil and water. Research has shown that these substances play roles in the induction of various diseases such as cancer, neurodegeneration and birth defects. In the cell, proteins such as metallothioneins respond to heavy metal exposure and chelate the metal to prevent cellular damage. However, little is known about the cellular response in regards to DNA damage after heavy metal exposure. To provide a better understanding of this cellular response, the induction of both cell cycle arrest and apoptosis were investigated after exposure to copper, cadmium, iron, lead, nickel and silver in the nematode C. elegans. Growth assays were conducted to determine EC10 and EC50 concentrations, which were utilized to determine the DNA damage response pathway. Apoptosis and cell cycle arrest induction upon exposure to a given heavy metal was analyzed in the germline of adult animals after 24h exposure. Apoptosis in the germline was significantly induced in response to all the heavy metals in a dose dependent manner. Nickel, iron and cadmium had the greatest induction at their EC50 concentrations. Additionally, cell cycle arrest was induced in a dose dependent manner for all six metals. Nickel and silver resulted in the greatest induction of cell cycle arrest at their EC50 concentrations. Copper, cadmium, iron, lead, nickel and silver all induce apoptosis and cell cycle arrest in response to exposure suggesting cellular damage and possibly DNA damage from low dose exposures. Investigating the mechanism behind these inductions can help us to better understand the underlying causes to effects of exposure.
Development of a functional blood-brain barrier (BBB) is a complex process regulated by multiple cell types. BBB development consists of several key events during heterotypic cellularization of the embryonic neuroepithelium: vascular invasion and patterning from the perineural vascular plexus; neuroprogenitor proliferation, migration and differentiation in the subventricular zone; and cytokine/growth factor signaling co-opted from microglia, resident macrophages originating in the yolk sac. Disruption of these key events could lead to BBB developmental toxicity. For example, microglia disruption during development is hypothesized to disrupt BBB formation via decreased vessel branching and compromised vessel stabilization. To examine the effects of chemical exposure on the developing BBB, a cell agent-based model was built to recapitulate key events during development of the neurovascular unit. This computer model enables stochastic interactions between microglia and endothelial cells via a complex signaling network (Notch/dIl4, CSF1, VEGF, VEGFR). Molecular elements in these pathways were linked to available receptor targets through EPA’s ToxCast high throughput screening (HTS) dataset in order to translate bioactivity results from the HTS dataset into quantitative predictions of BBB dysmorphogenesis. A simulated dose-escalation study was conducted with Mancozeb, which showed a concentration-dependent response on ToxCast assays of three critical signals mediating microglial-endothelial interplay: CSF1 at low concentrations, VEGFC at an intermediate concentration range, and VEGFA at the upper bound. The predicted no-effect-level (pNEL) on the system transitioned into a predicted lowest effect level (pLEL) at 30% inhibition of CSF1R. The model outcome was decreased surface abundance and reduced branching of the invading vascular network. The pLEL (0.3 μm) from this computational NVU (cNVU) model agreed with the Mancozeb-specific tubulogenesis point-of-departure (0.6 μm) reported from in vitro culture system investigating tubulogenesis in human progenitor cells vs. embryonic (ECV304) from the VAL interface platform. Taken together, development and validation the cNVU model could help predict chemical perturbations to the complex biology of the developing BBB. This abstract may not reflect US EPA policy.

Quantitative Imaging-Based Phenotypic Screening of Adaptive Stress Response Pathways and Computational Methods to Predict Drug-Induced Liver Injury

Early phase drug safety assessment for hepatotoxicity remains a major concern. Improved understanding of mechanisms of action of toxicity is essential to guide the drug development process. Although prediction models can be trained using biological fingerprints of drugs, we present an innovative in vitro toxicity testing platform that addresses both these approaches. Based on transcriptomics data mining we developed a panel of reporter cell lines using BAC technology allowing endogenous regulation of the GFP tagged protein. With high-content live cell imaging and informatics tools we can quantify the temporal and concentration dependent dynamics of key proteins functioning as a hub in specific cellular signaling pathways. Here we focus on five key adaptive stress response signaling programs: 1) the oxidative stress pathway; 2) the UPR in the ER; 3) the heatshock response in the cytoplasm; 4) the DNA damage response; and 5) inflammatory NFκB-signaling. In addition, features of cytotoxicity were captured, including cell count, and stains for necrosis and apoptosis. Together these data allow a compound specific benchmarking of cellular adaptation versus progression to adverse cell outcome. Due to the temporal information relative transcription factor translocation rates and relative protein net production rates are obtained. This allows a physiologically relevant quantification of stress response activation as compared to setting a threshold which results in binary type of on/off switch data. Together these data allow us to define two important features of a tested compound: 1) a biological fingerprint representing all the identified signaling pathways from the pathways and 2) an in vitro therapeutic window which we define as the concentration space between adaptive stress pathway activation to onset of cell death. We present the application of above approach for the assessment of drug-induced liver injury liability using a stress response reporter screen with 118 DILI compounds with different levels of DILI severity. We identified significantly reduced concentrations for onset of adaptive stress response activation for severe DILI compounds and show how the biological fingerprints can be applied to obtain a 70% accuracy of DILI severity using support vector machines and deep neural networks.

1940 Systems Toxicology Assessment of Exposure to Different Snus Extracts and the Total Particulate Matter Fraction of Cigarette Smoke on Human Gingival Organotypic Cultures

Swedish snus, a type of moist snuff, is a smokeless tobacco product (STP) commercialized in the Nordic countries. Published studies indicate a possible association of Swedish snus use with oral pathological conditions, although many of them lack to account for the variability of product chemistry and use patterns. During the last years organotypic cultures have been successfully used as in vitro models for examining the short-term response to environmental exposures and thereby assessing the induced biological effects. The present study aimed at determining the biological impact of a repeated 72-h exposure of human gingival organotypic cultures to snus, extracted from a commercially available product, in comparison with extracts from a reference snus product (CRP1.1, Coresta) and the total particulate matter (TPM) smoke fraction from 3R4F cigarettes. The snus extracts and TPM were tested in two nicotine-matched dilutions - with the TPM dilutions selected to represent a toxic and a sub-toxic stimulus. In addition, a higher concentration of the snus extracts was included, reflecting nicotine levels observed in the saliva of snus users. To assess the exposure effects, we employed a Systems Toxicology approach that complements measurements of cytotoxicity, histopathology, and pro-inflammatory mediator secretion with computational network biology analysis of transcriptome changes. While TPM induced substantial morphological changes, cultures treated with both snus extracts, even at a twenty-five fold higher concentration than TPM, did not exert any obvious histopathological modification. Perturbations of toxicity-relevant networks, such as those related to cell stress and inflammation, and the secretion of pro-inflammatory mediators will be analyzed. This study is of importance to indicate whether Swedish snus products could potentially exert a reduced harm to the oral mucosa in comparison with cigarette smoke.

1941 Biological Test Procedure for Fresh Generated Smoke and Aerosols under Air Liquid Interface Exposure in 24 and 96 Multiwell Plates

R. Wieczorek1, E. Trelles Sticken1, L. Simms2, and T. Walele3.
1Reemtsma Cigarettenfabriken GmbH, an Imperial Brands PLC, Hamburg, Germany; 2Imperial Tobacco Limited, Bristol, United Kingdom; and 3Fontem Ventures, Amsterdam, Netherlands. Sponsor: F. Ayala-Fierro

Smoke and aerosol contain particulate matter as well as volatile substances. Both fractions are of potential toxicological relevance and should be considered when assessing biological activity of smoke / aerosol mixtures. Rapid ageing of the mixtures lead to problems regarding trapping and effective delivery of both fractions to the cells. Therefore, dedicated exposure systems have been developed allowing the exposure of biological in vitro systems to freshly generated smoke / aerosols. Imperial Brands’ Smoke Aerosol Exposure In Vitro System (SAEIVS) is designed to expose cells in multiwell plates (MWP) at the Air Liquid Interface (ALI) conditions. The system allows direct contact of both aerosol particles and gas phase components with the apical humid cell surface, recreating exposure at the lung surface as it occurs in vivo. SAEIVS enables in vitro testing of aerosols generated from different product categories encompassing tobacco products and e-cigarette devices. Up to 5 tobacco products or e-cigarette devices can be puffed simultaneously and deliver the smoke/aerosol in undiluted or diluted form. Treated rows of wells are exposed to the generated smoke / aerosol whereby guaranteeing stable exposure conditions over an extended time period sufficient for testing of several hundred puffs. The genotoxicity testing is performed with hamster lung cells V79 exposed grown on inserts and placed in 24 MWPs. Mutagenicity testing is realised by bubbling background suspension directly with freshly generated smoke / aerosol thereby guaranteeing stable exposure conditions and close contact of bacteria cells with the test atmosphere. Salmonella typhimurium Strain TA100 is used in this case because it is highly sensitive to mutagenic substances in both the gas phase and in the particulate matter of smoke / aerosol.
impact neurogenesis through BBB disruption. Taken together, this model integrates new in vitro cell-based tests with existing ToxCast data to translate cell-cell interactions within the NVU into a predictive toxicology framework of BBB disruption. This abstract does not reflect US EPA policy.

1944 Systems Toxicology Assessment of Flavors Compounds Present in E-Vapor Products Using Human Primary Bronchial Epithelial Cells

Philip Morris International, Neuchatel, Switzerland.

Assessing the toxicity of e-cigarettes is challenging considering the large variety of flavored e-liquid mixtures and devices commercially available and the lack of standardized testing methods. While most flavors used in e-liquids are usually considered as safe when ingested or applied topically, there is limited data about their toxicity when they are inhaled. We recently developed a high-throughput approach to assess the biological impact of e-liquid ingredients on primary human lung epithelial cells in vitro. Submerged cells were exposed to serial dilutions of various single flavor compounds in a solution composed of propylene glycol (41%), vegetable glycerin (38%), and nicotine (0.6%). First, real-time cell viability was assessed over a 24h exposure period by impedance-based diagnostic, prognostic, or exposure surveillance utilities. Disclaimers: Research was conducted in compliance with the Animal Welfare Act, and all other Federal requirements. The views expressed are those of the authors and do not constitute endorsement by the US Army.

1943 An Integrative Systems Toxicology Model for Neurovascular Developmental Toxicity

K. S. Salti1, T. J. Zurlinden1, N. C. Baker2, and T. B. Knudsen1. 

1US EPA, Research Triangle Park, NC; and 2Leidos, Research Triangle Park, NC.

The blood-brain barrier (BBB) limits passage of toxicants into brain tissue and may be an important tissue interface for developmental neurotoxicity, although the extent to which drugs and chemicals interact with BBB anatomical development is not well known. We utilized a computational systems model of the neurovascular unit (cNVU) in concert with in vitro ToxCast chemical effects data on neurogenesis and angiogenesis assays to build a predictive model of BBB developmental disruption. A subset of 38 ToxCast chemicals was tested for effects on endothelial cell (HUVEC) and neuroprogenitor cell (hNPC, hNC, hNN) behaviors at a range of concentrations. ToxPi potency scores were derived for each chemical across a range of 8 neurogenesis and 9 angiogenesis cellular behaviors. We identified 3 major clusters of cellular effects (neurogenic, neuro-endothelial, and negligible). There were 311 ToxCast assays associated with the positive effects groups, 32 of which could be mapped to one of 21 critical nodes in a nascent systems model of NVU development. ToxPi scoring was used to predict putative BBB disruptors from among the compounds tested, in addition to the complete ToxCast chemical library. PFOs for example, a perfluorinated compound of human health concern, had one of the highest NVU-relevant ToxPi scores suggesting a potential effect on BBB development. PFOs also affected network formation in the neurogenic, but not angiogenic systems. It also tested positive in several inflammatory assays in ToxCast (e.g., TGFβ1, VCAM1, MCF5, IL8, CSF1R, TIE2) suggesting an integrative model would reveal an impact on cytokine signaling. Moreover, at least one study found that PFOs exposure increased BBB permeability. Both PFOs and the synthetic thalidomide analogues, SNPR-33, tested positive for angiogenic effects as detected by ToxCast hits on VEGF signaling (e.g., VEGFR1, VEGFR2, VEGFR3). Both of these compounds also impacted neurogenic endpoints in vitro and suppressed TGFβ1, one of three ToxCast assays directly implicated in progenitor development in the cNVU model. These results highlight potential molecular initiating events that may lead to BBB disruption.

1942 Gene Expression Profiling in Multiple Brain Regions and Peripheral Tissues of Soman Exposed Rats

1US Army Center for Environmental Health Research, Frederick, MD; 2OakRidge Institute for Science and Education, Frederick, MD; 3US Army Center for Environmental Health Research, Ft. Detrick, MD; 4US Army Center for Environmental Health Research, Frederick, MD; 5The Genesis Foundation, Frederick, MD; 6Clinical Research Management, Silver Spring, MD; 7Edmond Scientific Company, Aberdeen Proving Ground, MD; and 8US Army Medical Research Institute of Chemical Defense, Aberdeen Proving Ground, MD. Sponsor: M. Madejczyk

Soman (GD) is a potent acetylcholinesterase inhibitor that results in increased levels of acetylcholine leading to a cholinergic crisis upon exposure. This crisis induces convulsions and causes seizures and death if left untreated. Understanding the effects of GD is vital to developing a method of detection and treatment for exposure. We studied gene expression changes associated with GD exposure and resultant seizure activity in rats. Adult male rats were exposed to GD with or without medical countermeasures. Seven to eight hours after exposure, samples were collected from heart, kidney, liver, lungs, spleen, and brain regions, including amygdala, hippocampus, hypothalamus, piriform, medial prefrontal cortex, parietal cortex, and thalamus. Expression patterns demonstrated significant differences between seized and nonseized animals. The magnitude of gene expression changes were tissue types mapped closely to previously characterized patterns of histopathological damage, with the most significant changes occurring in the piriform cortex. Those dysregulated genes associated with seizure activity exhibited enrichment in several cellular functions including protein binding, cell division, phosphorylation, and the inflammatory response. These patterns were well conserved across tissues; amygdala, hippocampus, and piriform that exhibited histopathologic evidence of seizure activity. In the liver, seizing animals showed significant down-regulation of genes involved in oxygen reduction process. Ongoing work will fully characterize the genes and pathways altered by GD exposure and those associated with GD-induced seizure responses across different organs to identify genes and pathways which might have diagnostic, prognostic, or exposure surveillance utilities. Disclaimers: Research was conducted in compliance with the Animal Welfare Act, and all other Federal requirements. The views expressed are those of the authors and do not constitute endorsement by the US Army.
senting chromatin organization, cell cycle regulation, lipid metabolism, and other pathways. Molecular events downstream from the canonical pathways were discovered by heuristic and network inference methods. In conclusion, our systems biology transcriptomics, proteomics, metabolomics, modeling and inference methods identified the MoA of unknown agents within 30 days. Sponsored by the US Army Research Office and the Defense Advanced Research Projects Agency; accomplished under Cooperative Agreement W911NF-14-2-0020.

1946  **Elucidating Systems-Level Mechanism in Toxigenic Profiling of Hepatitis and Cholestasis Using Human Primary Hepatocytes**

Drug-induced liver injury (DILI), such as hepatitis and cholestasis, remains an elusive problem in the drug development process. Lack of connection between the clinical hepatotoxic phenotypes and associated complex molecular-level events further hinders in detecting the intrinsic toxigenic biological properties of drugs and chemicals. The ability to comprehensively relate transcriptomics data to (hepatotoxigenic) profiling could lay a foundation for future toxicity evaluation of active molecules. Thus, this study aims to elucidate the system-level mechanistic in hepatotoxic phenotypes that could be used to predict the compound’s human organ-level toxicity. Based on the drug-induced hepatotoxicity study published by the Japanese Ministry of Health, microarray data for 30 compounds (generated from human primary hepatocytes treated for 24 hours) were downloaded from Open TG-GATEs and processed using standard microarray analytics pipelines. To investigate specific gene sets associated with the respective hepatotoxic phenotypes, weighted gene coexpression network analysis (WGCNA) was performed. WGCNA clusters genes with similar expression patterns into modules and correlates each module to a biological phenotypic trait (e.g. hepatitis or cholestasis). Based on the expression patterns across 30 compounds, ~15000 genes were clustered in 65 distinct coexpression modules. Interestingly, GO enrichment and Reactome pathway analysis of statistically significant (p-value < 0.05) hepatitis- and cholestasis- correlated modules showed major functional differences between the two phenotypes. Hepatitis-specific modules were mainly associated with protein metabolism, cell cycle arrest, and apoptosis. In contrast, pathways such as DNA repair, cell cycle, Notch, Wnt, JNK pathway and other pathways. Molecular events downstream from the canonical pathways were discovered by heuristic and network inference methods. In conclusion, our systems biology transcriptomics, proteomics, metabolomics, modeling and inference methods identified the MoA of unknown agents within 30 days. Sponsored by the US Army Research Office and the Defense Advanced Research Projects Agency; accomplished under Cooperative Agreement W911NF-14-2-0020.

1947  **Evaluation of 2-Methoxy-4-Nitroaniline (MNA) in 14-Day Toxicity, Hypersensitivity, and Genotoxicity Studies**

2-Methoxy-4-nitroaniline (MNA), an intermediate in the synthesis of azo dyes used in textiles and paints, is structurally similar to carcinogenic anilines. Human exposure occurs predominantly through handling of dye dust, and the use and disposal of MNA-containing products. MNA is genotoxic; the pathology findings are suggestive of possible erythrocyte damage and reactive phagocytosis by macrophages in the liver and spleen, and regenerative erythropoiesis.

1948  **MimEX GI Is A Novel and Robust 3D Gastrointestinal Tissue Model for Toxicology and Disease Modeling**

Three dimensional cell culture models of the gastrointestinal epithelium are quickly being adopted for toxicology, drug discovery, and disease modeling. These more complex models provide a tremendous benefit over cell-line and primary cell-based methods, including the mimicking of native intestinal cytoarchitecture and importantly, the recapitulation of physiological attributes of the tissue. Researchers using current 3D models, such as gastrointestinal organoids, experience difficulties with model viability, and tissue adherence. Overcoming these obstacles is paramount for the logistical incorporation of 3D tissues into high throughput toxicity and disease modeling workflows. Here, we introduce MimEX™ GI, an innovative human tissue model system that utilizes the unique characteristics of adult “ground state” stem cells to generate 3D gastrointestinal organ tissue on a 2D surface. In this poster, we demonstrate that the MimEX™ GI platform can be used to clonally isolate and expand “ground state” stem cells from specific regions of the adult gastrointestinal tract. Using MimEX™ Differentiation Media, we show that a high-density monolayer of region-specific gastrointestinal stem cells will differentiate back into its respective tissue of origin, ex vivo. This differentiation is uniform and is oriented such that the apical surface of the mucosa is accessible within the well. Finally, using a high throughput permeability assay, we demonstrate the barrier function of MimEX™ GI tissue, and its response to multiple compounds, as evidence for the flexibility of this tissue in high throughput drug screening.

1949  **'Omics-Based Analysis of 6-Month Inhalation Study for Assessing the Effect of Cigarette Smoke and Cessation in Mouse Lung**

Smoking cessation is thought to be an effective approach to reduce the risk of cigarette smoke (CS)-related diseases. Although several studies reported that smoking cessation improved CS-induced adverse events, such as inflammatory responses, the impact of smoking cessation on global physiological changes is not fully understood. In this study, we performed a 6-month inhalation study using female C57BL/6J mice exposed to filtered air, shams, and 6% CS by volume for 6 months. The effect of smoking cessation was assessed by transcriptome analysis of lung tissue samples. The results indicated that the disruption of central carbohydrate metabolism was observed in CS-inhalation groups, and was also improved by smoking cessation. To quantitatively evaluate the impact of smoking cessation, the amplitude of both gene expression and metabolite profile were calculated as a score, based on the fold change in differential measurements. These scores increased period-dependently in CS-inhalation groups. In contrast, the scores of cessation groups decreased depending on the duration of smoking cessation, and
reached almost the same level as the sham group after 5 months of cessation. These results suggest that smoking cessation could reduce CS-induced adverse events, particularly NF-κB related inflammatory responses and central carbohydrate metabolism, in mouse lung at both the transcriptome and metabolome level.

### 1950 Assessing Genetic Risk from Chemical Exposures through Unbiased High-Content Phenotyping

Humans experience varying biological responses to chemical/environmental stimuli. Predicting differential responses involves understanding how an individual’s genetic profile can influence diverse responses to exposure/treatment. Understanding how genetics influences response to chemical exposure at the cellular level is critical for advancing personalized medicine initiatives and next generation prognosis and/or treatment methods. Genetically characterized human B-lymphoblast cell lines (LCLs) were treated for 48 hours with a panel of 9 compounds with diverse mechanisms of action over a concentration range (based upon the average LCL response). Each plate contained vehicle (0.1% DMSO) and positive controls (10% DMSO) for cell death using Jurkat control cells. The LCLs tested were stained with viability dyes and imaged. To analyze the images and extract phenotypic information, we developed an automated high content analysis pipeline (Clarity Bioanalytics) to measure 11,000+ morphological cell features. Redundant features were eliminated, and the remaining informative features were scored, ranked, and analyzed. Clarity Bioanalytics was used to manage, analyze, and score the high content analysis data. Algorithms were used to define the phenotypic signature for each chemical toxicant. SNP data for each LCL were downloaded from the dbSNP repository and processed for genome-wide association. Pharmacologic quantitative trait loci were mapped based on the genetic profiles of LCLs displaying “normal” (i.e., outliers) phenotypic signatures. Preliminary results from the feature evaluation and selection phase of the project indicate we can identify unbiased (sets of) features that are specific for one or more of the individual compounds. We have screened over 200 LCLs with the compound panel, identified phenotypic signatures that signify exposure to a specific compound and correlated differential phenotypic responses to particular genetic polymorphisms (i.e., SNPs). The identification of genetic correlations to differential response patterns is crucial for personalized assessment of biological effects of chemical exposure.

### 1951 Use of Human Derived Cell Lines to Increase the Biological Relevance of Cigarette Condensate, Non-Tobacco Materials, and E-Liquids Testing

The in vitro testing strategy of tobacco products is mainly based on the testing of extracts from cigarette smoke condensates. An accepted industry wide assay battery has been developed over recent years which delivers reliable results for the toxicological assessment of tobacco products. The testing battery comprises the Neutral Red Uptake (NRU) assay, the in vitro Micronuclei (IVM), and the Ames test. This combination of tests evaluates relevant biological endpoints and is also used for the toxicological evaluation of non-tobacco materials (NTM) like ingredients and e-liquids. All methods are based on the corresponding OECD guidelines which leave some choices regarding bacteria strains used in Ames test and cell lines utilized in NRU and IVM assays. With increasing experience the tests have been improved especially with regards to relevance. To build on this approach further, we use human cell lines to measure cytotoxicity and genotoxicity of smoke extracts, non-tobacco materials and e-liquids. Human liver HepG2 and bronchial epithelial (BEAS-2B) are used in the NRU assay where both show high sensitivity against cigarette condensate. The optimum exposure times were evaluated using a live-cell imaging system. The IVM assay is performed with the human lymphoblastoid cell line TK6. Due to the p53-competency of TK6, false positive effects are significantly reduced in comparison to widely used rodent cell lines. The assay battery is completed by the mutagenicity testing in the Ames test.

### 1952 Effects of Sub-Chronic Exposure to Arsenic on Energy Metabolism in the Liver and Brain Tissues

Arsenic is an element that is abundant in nature and has been associated with various diseases. This research work was conducted to investigate the sub-chronic effects of arsenic on energy metabolism in the cytosolic and mitochondrial fractions of the liver and brain of adult male albino rats. These rats were exposed to 25ppm, 50ppm and 100ppm arsenic as sodium-arsenate in their drinking water for eight weeks. Control animals received distilled water for the same duration after which animals were sacrificed. Activities of Hexokinase (HK), Pyruvate kinase (PK) and Lactate dehydrogenase (LDH) were determined in the cytosol while Sulfuric dehydrogenase (SDH), Malate dehydrogenase (MDH), NADH dehydrogenase (complex I), combined complexes I+III and Cytochrome C oxidase (complex IV) were determined in the mitochondrial fraction using spectrophotometric method. Arsenic significantly (p<0.05) decreased HK, LDH, MDH and complex I activities in the hepatocytes. However, the inhibition was dose-dependent for complex I. In the brain tissue, there was an up-regulation of the activities of HK and PK. Similarly, activities of complex I and combined complexes I+III had over two fold increase in animals exposed to only 100ppm arsenic. A positive dose-dependent relationship was observed in the effects of arsenic on complex IV in both tissues. These findings indicate that arsenic affects energy metabolism but its effects may differ in the tissues.

### 1953 Delineation of the In Vivo Transcriptional Regulatory Network in Livers of Rats Dosed with a Compound That Produces Electrophilic Stress

The liver is the primary site of drug metabolism. Hepatocytes express high concentrations of metabolic enzymes and transporters that enable oxidation, reduction, hydrolysis, conjugation and excretion of endogenous and exogenous molecules. Homeostasis is maintained by numerous signaling pathways which sense the metabolic needs and stressors in the cell and mediate appropriate responses. Frequently these responses are orchestrated via transcription factors (TFs) which bind target DNA and alter expression of specific gene networks. One example is nuclear factor (erythroid-derived 2)-like 2 (aka NRF2 or NFE2L2) which binds AREs to promote gene expression in response to electrophilic stress. ARE containing genes are induced in hepatocytes by the withdrawn hepatobiliary drug ticlopidine which is oxidized by CYP2C19 to form an electrophilic reactive metabolite (Takakusa et al. 2008). A multi-omics based approach was utilized to better understand the in vivo changes induced by ticlopidine at the mRNA, TF and pathway levels in rat liver. Male Sprague-Dawley rats were treated with 600 mpk ticlopidine for 4 days by oral gavage. RNA-sequencing (RNA-seq) was performed on liver samples to identify differentially expressed genes (DEGs) upon compound treatment. Unbiased pathway analyses of DEGs identify up- and down-regulated pathways as well as candidate upstream TF regulators including included oxidative stress pathways regulated by NRF2. Chromatin immunoprecipitation sequencing (ChiP-seq) was performed using NRF2 antibodies to identify genes bound directly by NRF2 in control and ticlopidine treated animals. Additional studies were performed using both direct and indirect NRF2 activating compounds in WT and NRF2 knockout rats. The integrated datasets delineate the genes and pathways directly activated by NRF2 in response to metabolic activation from indirect or orthogonal biological responses. Furthermore, we are applying this multi-omics approach of combining RNA-seq and ChiP-seq to additional pharmaceutical compounds and xenobiotic responsive TFs to elucidate the biological mechanisms of therapeutic response and/or toxicity liabilities.

### 1954 A Quantitative Systems Toxicology Modeling Framework for the Gastrointestinal Immune System

Drug toxicity in the gastrointestinal (GI) tract involves complex and dynamic combination of mucosal damage, immune responses, and the gut microbiota. A variety of gut cells and cytokines interact at multiple spatio-temporal scales, making drug-induced GI toxicity difficult to predict experimentally and complex to understand mechanistically.
To improve quantitative mechanistic understanding and prediction of drug-induced GI toxicity, a framework of quantitative systems toxicology (QST) modeling for the GI-immune system was developed. Our ordinary differential equation (ODE)-based model, adapted from previously published computational models, describes dynamic interactions among diverse cell types in the gut, including commensal and pathogenic bacteria, dendritic cells, T cells, macrophages, neutrophils, and intestinal epithelial cells. The model is used to simulate the effect of drugs with a different mechanism of action on GI mucosal integrity and inflammation. The drugs tested in silico have one of the following modes of action: intestinal epithelial cell lineage damage, T cell suppression, or neuroprotection. Third, increased post-infection recovery time and prolonged bacterial burden are observed in the presence of immunosuppressive agents. Fourth, drug-induced neutropenia leads to a higher bacterial burden post-infection. Overall, our QST framework can serve as a sustainable and expandable platform to better understand and predict the complicated dynamic behavior of the drug-challenged GI-immune system, and to facilitate more rational preclinical study design and safety risk assessment.

---

1955 Unravelling Essential Key Events in Mitochondrial Adverse Outcome Pathways

The study focuses on key events relating compound-induced mitochondrial perturbation to hepatotoxicity. The obtained data serve as input for the establishment of quantitative adverse outcome pathways (qAOPs) specific for mitochondrial toxicity. Ultimately, these qAOPs could contribute to the improvement of toxicity prediction and risk assessment of new and existing chemicals. Analytical tools for assessment of mitochondrial functioning in HepG2 cells, including membrane potential, ROS formation, GSH expression and ATP production, were optimised for use in an automated real time confocal microscopy platform. The parameters were monitored along with measurements of cell functioning, including viability. In addition, gene and protein expression are studied using TempSeq for transcriptomics and using BAC-GFP reporter technology for single cell real time analysis of candidate protein expression. Time and concentration-resolved high content analysis of mitochondrial functionality and cell fate outcome were applied in a single exposure setting for mitochondrial toxicants including complex I, II and III inhibitors. Cluster analysis based on all mitochondrial functioning parameters demonstrated a clear separation of the different complex inhibitors. CI and CII inhibitors reduced membrane potential with different potencies. CI inhibitors induced ROS formation and diminished ATP production at lower concentrations compared to CII inhibitors. No effect was observed after CII inhibition in the applied concentration range. Cell viability after CI and CII inhibition was reduced only when cells were switched from glucose- to galactose-containing medium, indicating that a switch to glucose consumption leads to a CI-dependent and adaptive response to CI inhibition. Besides compound characterisation, the data was used to develop a qAOP. Based on the relationship between parameters and the AOP paradigm: for concentrations above the threshold value a reduction in membrane potential was observed along with a subsequent induction of an unfolded protein response and thereof a loss of cell viability. Ongoing experiments address the impact of repeat dose exposures and generate information on global transcriptional changes. The obtained data provides further insight into the chain of events triggered by mitochondrial toxicants. Altogether, this will support optimisation of the testing platform for assessment of mitochondrial toxicity.

---

1956 Collaborative Cross Mouse Population-Based Dose-Response Analysis of Liver Transcriptomic Responses with Trichloroethylene at the Levels of Genes and Pathways

A. Venkatratnam, University of North Carolina at Chapel Hill, Chapel Hill, NC.

Studies of gene expression are common in toxicology and provide important clues to mechanistic understanding of adverse effects of chemicals. At the same time, gene expression is heavily influenced by the genetic background of an individual, and the genotype-expression relationships may mediate inter-individual variability in toxic effects of chemicals. To date, few studies have dissected the dose- and genetic background-dependent effects of chemicals on the transcriptome. In this study, we tested the hypothesis that the genetically-diverse CC mouse population will enable characterization of genetic background-dose-expression relationships in response to the model liver toxicant TCE. Mice from 50 CC strains were exposed to single oral dose of TCE and tissues were collected. Livers were evaluated for both the level of trichloroacetic acid (TCA), a major TCE metabolite, and gene expression using RNA sequencing. Peroxisome- and fatty acid metabolism-related pathways were among the most dose-dependent enriched gene sets across the population. However, regression modeling revealed that nearly half of the TCE-induced liver transcriptomic effects were strain-dependent, with clinical relevance.

---

1957 Application of Systems Pharmacology to Identify Exposure Response Markers in Peripheral Blood after Switching to a Candidate Modified Risk Tobacco Product: The Tobacco Heating System 2.2

As part of current harm reduction strategies, candidate modified tobacco products (MRTPs) are developed to offer adult smokers who want to continue using tobacco products alternative products as potential smoking cessation aids. Typically, studies assess effects on biomarker levels comparing MRTPs to either cigarettes, while potentially reducing individual risk and population harm compared to smoking cigarettes. One of these candidate MRTPs is the Tobacco Heating System (THS) 2.2 which does not burn tobacco, but instead heats it, thus producing significantly reduced levels of harmful and potentially harmful constituents (HPHCs) compared to combustible cigarettes (CC). The assessment of MRTPs against combustible cigarettes requires the establishment of exposure-response markers. Biomarkers derived from blood offer for the general population a less invasive alternative than sampling the primary site, such as the airways. Various diseases and exposures, including cigarette smoke, have been shown to alter the molecular profile of the blood. Leveraging this fact, a whole blood derived gene signature that can distinguish current smokers from either non-smokers or former smokers with high specificity and sensitivity was previously reported. Four controlled, parallel group, open-label clinical studies were conducted with subjects randomized to three monitored groups: (1) switching from CCs to THS2.2 (or its mentholated version, respectively); (2) continuous use of CC brand; or (3) smoking a signature consisting of only 11 genes on the blood transcriptome. Of these effects on the transcriptome were similar whether TCE dose, or level of trichloroacetic acid (TCA), a major TCE metabolite, and gene expression sets were analyzed.

1958 Identification of Human Lung Epithelial Metabolic Responses to Acute Benzo(a)pyrene Exposure

M.R. Smith, Y. Go, and D.P. Jones. Emory University, Atlanta, GA.

Polycyclic aromatic hydrocarbons (PAH) are a family of compounds commonly produced in the burning of wood, fuels, or grilled meats. Several PAH members, such as benzo(a)pyrene (BaP) have been classified as carcinogenic; however, other risk factors include acute inflammation. The concentration of BaP in plasma has been found to be in nanomolar to micromolar range based on exposure duration. Previous studies by our laboratory found alterations in gene expression, amino acid and drug metabolic pathways in the sera of individuals with elevated benzo(a)pyrene as well as several other metabolic pathways. The purpose of this study was to determine the mechanism of BaP on
metabolism and cellular function using A549 lung epithelial cells. The A549 cells were grown until 90% confluence in complete culture media (10% FBS) and then incubated in low serum media (0.5% FBS) overnight before treatment with vehicle or 3 µM BaP for 24h. Treatment at these concentrations was calculated to be approximately 3 times higher than the highest concentration observed in human plasma. The cells were then lysed in 1X RIPA buffer containing 14 internal standards and extracted samples were analyzed by a Q-Exactive mass spectrometer by following the workflow for high-resolution metabolomics as previously reported. The results show that 8532 m/z features that were detected, 621 metabolic features were significantly different after BaP treatment compared to control. Using pathway enrichment analyses, 22 metabolic pathways were significantly affected by BaP, including amino acid, urea cycle, and fatty acid metabolisms, several of which were observed in the human sera samples. Subsequent time course studies were performed as described above (0-24h) using the median physiological concentration of BaP (14.2 nm) determined from our human study. Significant alterations in amino acid metabolism, such as tyrosine, glutamine, and methionine were found using high-resolution metabolomics analysis in a time-dependent manner. Taken together, these results suggest a novel mechanism of acute BaP exposure to A549 cells by altering amino acid pathways which are critical for proper protein function as well as lung function. Future studies using an increased number of participants as well as multiple cell culture models are currently underway and will be significant to determining the effects of BaP exposure on individuals who have undergone chronic BaP exposure and the development of lung cancer.

59 Interferon Signaling Chemical, Pentachlorophenol, Identified by Percellome Toxigenomics Project

J. Nanno1,2, S. Kajita2, and K. Aisaki1. 1Japan Bioassay Research Center, Hadano, Kanagawa, Japan; and 2National Institute of Health Sciences, Tokyo, Japan.

Among about 140 chemicals tested on mouse liver in the Percellome Toxigenomics database, pentachlorophenol (PCP) was identified as a unique chemical that induces interferon signaling. Adult mouse liver transcriptome responses 2, 4, 8 and 24 hours after a single oral administration of PCP (0, 10, 30 and 100mg/kg) was monitored by Affymetrix GeneChip MOE430 2.0. The expression data were analyzed by the Percellome method and expressed as 3D surface with axes of time, dose and copy numbers of mRNA per cell. In the first 8 hours, approximately 100 probe sets (PPS) related to PXR/SXR and Cytp2A4 and other metabolic enzymes were induced, whereas c-Fos and c-Junb were suppressed. At 24 hours, about 1,200 PPSs were strongly induced. Homemade softwares Rsort and PercellomeExplorer were used for comprehensive cross-referencing against the database. Among those 1,200 PPSs, about a half belonged to metabolic pathways including Nrf2-mediated oxidative stress response networks that are shared among many of 140 chemicals. The remainder half belonged to the interferon signaling networking gene sets (ISG), and was unique to PCP. Toll like receptors and other pattern recognition receptors, interferon regulatory factors and interferon alpha itself were included. On the other hand, inflammatory cytokines were not induced. In summary, acute symptoms of PCP, such as hyperthermia and profuse sweating, might be mediated by the ISG (other than the ISG), which has been shown to modify mitochondrial uncoupling mechanism (U Toxicol Sci. 2013: 38:643-54). Recently we added a few chemicals to the Percellome database that modify the expression of ISG genes. Common features with PCP will be discussed.

60 Transcriptional Profiling in Cultured Cells to Determine Chemical Biological Activity: Genistin Case Study

J. M. Naciff1, Y. K. Shan1, X. Wang1, N. K. De Abrew1, R. Settivari2, and G. P. Daston1. 1The Procter and Gamble Company, Mason, OH; and 2DowDupont, Midland, MI.

We have used transcriptional profiling and gene set enrichment analysis, particularly the 50 Hallmark gene sets (MSigDB v6.2), as well as other annotation sources, to better define the biological activity associated with specific chemicals. Gene sets were considered active when they were populated with at least 3 genes from the transcriptional profile being evaluated (Fisher’s exact test, p<0.05). Genistin was selected as an example since it has been established that this isoflavone has multiple biological activities, including the inhibition of protein tyrosine kinases, DNA topoisomerase II and other enzymes, as well as estrogenic activity. Genistin’s transcriptional profile was determined in MCF7, HepG2, HepaRG and Ishikawa cells, after exposure (0.1 mM) for 6h, using a comprehensive (U219; Affymetrix) or a custom made (L1000; Genometry) microarray. For each cell type evaluated, the genes included in the transcriptional profile were selected by their statistical significance (false discovery rate, FDR <0.05) and fold change as compared with the appropriate control (+/- 1.2), cells exposed to vehicle (DMSO). As can be expected, the transcriptional profiles determined in the comprehensive array, in any of the cell types evaluated, include a large number of up- and down-regulated genes, and allows for a more robust gene set enrichment. However, the custom array provides data that defines biologically active gene sets various of which agree with the ones defined by the larger set of genes obtained from the comprehensive array. Overall, MCF7 and Ishikawa cells are more responsive to genistin than HepG2 and HepaRG cells, and this response is different from each cell type. There is a strong concordance of the gene sets upregulated by genistin that are part of the early and late response to estrogen, the p53 pathway and networks, mTORC1 signaling and the TNFα signaling via N-FKB, and apoptosis, among others; as well as the down regulated gene sets including cell cycle control, PI3K/AKT/ mTOR pathway and apoptosis among others.

1961 Mechanistic Modeling of Mitochondrial Biogenesis within DILIsym Could Explain Clinically Observed Adaptation of Serum Alanine Aminotransferase (ALT) Elevations

1DILIsym Services Inc., Research Triangle Park, NC; 2Cempra, Chapel Hill, NC; and 3Emshel School of Pharmacy, The University of North Carolina at Chapel Hill, Chapel Hill, NC.

Resolution of serum ALT elevations despite continued drug dosing, termed “adaptation”, is commonly observed in clinical trials, but the underlying mechanisms behind this phenomenon remain unclear. Mitochondrial dysfunction is one of the major mechanisms underlying drug-induced liver injury (DILI). When mitochondrial function is insufficient for energy demand, mitochondrial biogenesis is often activated and we speculated this may be a mechanism underlying adaptation. Solithromycin, a 4th generation macrolide developed for the treatment of community acquired pneumonia, caused serum ALT elevations in a minority of patients in clinical studies, with improvement often observed during continued dosing (or with rapid recovery thereafter). Quantitative toxicology modeling of solithromycin using DILIsym showed that ALT elevations were mediated predominantly by mitochondrial electron transport chain (ETC) inhibition, suggesting that mitochondrial biogenesis might have contributed to the adaptation observed. In the current study, biogenesis was mechanistically represented within DILIsym, and its impact on time dependent ALT elevations resulting from solithromycin treatment was assessed. In DILIsym, mitochondrial ETC enzyme content and activity are modeled based on synthesis and degradation rates. Modeled decrements in liver ATP levels were employed as a stimulus for increase in the synthesis rate of these enzymes. Kinetic parameters for biogenesis were optimized based on clinical ALT data from patients administered solithromycin (Km = 0.055 μM; Hill = 4.14-14 mmol/l; Hill = 1.5; ATP decrement delay constant = 96 hr). Solithromycin effects on serum ALT were simulated in the absence and presence of biogenesis in a human simulated population (SimPops) that includes variability in mechanistic pathways underlying DILI. Addition of mitochondrial biogenesis to the model predicted the observed behavior of ALT at continued exposure. Overall, DILIsym modeling suggests that mitochondrial biogenesis contributes to hepatic adaptation to xenobiotic stress.

1962 A Distinct Class of Antioxidant Response Elements Is Consistently Activated in Tumors with Nrf2 Hyperactivating Mutations

D. Levings1, X. Wang2, D. Bell3, and M. Slattery1. 1University of Minnesota, Duluth, MN; and 2NIEHS, Research Triangle Park, NC. Sponsor: K. Wallace.

NRF2, a key regulator of the transcriptional response to oxidative stress, regulates expression of cytoprotective genes via its interaction with DNA sequences known as antioxidant response elements (AREs). Mutations that disrupt the interaction; caused by NRF2 and KEAP1, an important inhibitor of NRF2, lead to NRF2 hyperactivation and promote tumorigenesis. The exact mechanisms underlying NRF2’s oncogenic...
properties remain unclear, but likely involve aberrant expression of select NRF2 target genes. We tested this possibility using an integrative genomics approach, combining our own NRF2-centric functional genomics data with thousands of tumor genome and transcriptome profiles, to get a precise view of the direct NRF2 target genes dysregulated in tumors with NRF2 hyperactivating mutations. This approach revealed a cancer-specific NRF2 target gene set that is consistently upregulated in NRF2 hyperactivated tumors. This set of NRF2 “cancer target genes” includes canonical redox-related NRF2 targets (NQO1, etc.), as well as several target genes that have not been previously linked to NRF2 activation; NRF2-driven upregulation of this gene set is largely independent of the organ system where the tumor developed. This critical subset of NRF2 targets is significantly enriched for genes functionally linked to oncogenesis, and several features differentiate these genes from other NRF2 targets. One of the key distinguishing features is that the NRF2’s cancer targets are regulated by high affinity, switch-like AREs that fall within genomic regions that possess a distinct, ubiquitously permissive chromatin signature. This finding implies that the NRF2 cancer target genes are highly responsive to oncogenic NRF2 in most tissues because they lack the epigenetic restraints that restrict expression of most other NRF2 target genes. Notably, the NRF2 cancer target gene set also serves as a reliable proxy for NRF2 activity, independent of mutational status, and high inferred NRF2 activity is associated with significant decreases in survival in at least 10 different cancer types, including hepatocellular carcinoma, papillary kidney carcinoma, and squamous cell carcinoma. Together, these results suggest that this prognostically valuable gene set is uniquely responsive to NRF2 activity in many cell types, and will be central to dissecting the functional implications of NRF2 activation in several cancer contexts.

1965 Mass Spectrometry Based Untargeted Metabolomics for Dose-Response Analysis of Liver Injury Compounds: Utility and Comparisons to Transcriptomic Analysis

D. M. Crizer, S. C. Ramaiahgari, S. S. Ferguson, J. R. Rice, P. E. Dunlap, N. S. Sipes, S. S. Auerbach, and M. J. DeVito, Division of the National Toxicology Program, Research Triangle Park, NC.

This work is part of our initial efforts to determine how metabolomics data can aid in analysis of compounds that are potentially toxic and may have negative effects on human health. Understanding the role that xenobiotics have on endogenous metabolism can help determine which compounds are potentially hazardous. Untargeted metabolomics of in vitro cell systems were studied in a traditional dose-response analysis to investigate the effects of cells at different concentrations of toxic compound exposure. A set of compounds at ten different concentrations were incubated with 2D confluent HepaRG cells over a period of 96 hours. After every 24 hours, a sample of media was removed from each well. A Thermo Vanquish liquid chromatography/LC system was used in conjunction with a Thermo Q Exactive Plus for untargeted analysis. LC conditions consisted of a 20-minute gradient run using a Thermo Hypersil Gold aq column. MS and MS/MS data were collected in both positive and negative mode. Thermo’s Compound Discoverer 2.0 and XCMS online were used for data analysis. One compound investigated in this work is Tamoxifen. Transcriptional analysis of HepaRG cells exposed to Tamoxifen showed changes in lipid metabolism pathways. Additionally, cell imaging showed evidence of hepatic steatosis. Untargeted metabolomics data of media from in vitro incubations of HepaRG cells with different concentrations of Tamoxifen compared favorably to the transcriptional changes observed, in that transcriptional changes were observed in lipid metabolism pathways that were coincident with changes in lipid concentrations in the spent media. Selected metabolites were used to perform dose-response analysis to determine at what concentrations tamoxifen could cause clear metabolic level changes. In the metabolomics experiment 507 metabolite features were identified with a median benchmark dose of 31.7 μM and a benchmark dose of 16 μM for the first quartile. In comparison, the median benchmark dose for the transcriptomics experiment was 57.6 μM with a benchmark dose of 33.7 μM for the first quartile. Thus, the metabolomics experiment found benchmark doses at approximately 2x lower concentrations than the transcriptomics experiments. These initial results suggest that metabolomic changes may be more sensitive than transcriptomics.
Gene Expression Profiling and Machine Learning to Characterize the Molecular Mechanisms of P38K Inhibitor-Induced Gastrointestinal Side Effects

P. Lum1, A. Fullerton1, J. Grahen1, W. Proctor2, L. Pham1, M. Tseng3, J. Fine2, B. Goldberg1, and S. Chandler1. 1Capella Biosciences, Palo Alto, CA; and 2Genentech, South San Francisco, CA.

Iatrogenic gastrointestinal disorders are among the most debilitating side effects of first line chemotherapy. In many cases, colitis, diarrhea and other drug-induced conditions limit tolerability of cancer treatment, such as taxanes where a high percentage of patients experience diarrhea. Some targeted therapies, such as P38K inhibitors, also cause gastrointestinal side effects. Thus, understanding the molecular mechanisms of GI toxicity caused by chemotherapeutic and targeted agents may provide insights into key genes and pathways, highlighting potential targets suitable for co-therapies that can mitigate them. To this end, we have used computational methods to explore the connections between the endpoints and assignment of cellular dysfunction (IBD). GI effects caused by bacteria and viruses, and GI toxicities caused by drugs or compounds. In total, we have investigated over 60 publicly available datasets that included compounds such as irinotecan, wolmanimm, methotrexate and multiple P38K inhibitors. We also performed whole-transcriptome profiling of the human Epithelial Gastrointestinal in vitro model treated acutely with diverse P38K inhibitors at their respective plasma steady-state concentrations. We show that gene expression profiles following treatment with irinotecan, a compound that causes severe GI toxicity, look most similar to GI diseases such as CD and IBD. In contrast, molecular signatures of P38K inhibitors were distinct from that of GI diseases. Surprisingly, gene expression profiles of P38K inhibitors shared similarities to the molecular signatures of a specific enteropeptic bacterial toxin with the cell cycle and autophagy pathways being most transcriptionally disrupted. This suggests that using irinotecan as a GI toxicity model may not be suitable to study molecular mechanisms for P38K-induced GI toxicity. We also found that inhibitors targeting different P38K isoforms have different levels of similarity to the bacterial toxin signature. We conclude that P38K-induced GI toxicity has a unique molecular signature that is different from GI diseases or irinotecan-induced GI toxicity. Instead, it has a novel association to the molecular mechanism of toxicity caused by an enteropeptic bacterial toxin, with some degree of isoform differences.

Mend the Gap: Organizing Toxicity Endpoints under the Hallmarks of Aging’s Nine Categories of Cellular Dysfunction

R. S. DeWoskin, and J. L. DeWoskin. elioLogic LLC, Durham, NC.

Toxicologists and medical researchers have traditionally approached the mechanistic understanding of biological dysfunction from opposite ends of the causal chain. Toxicologists develop adverse outcome pathways (AOPs) beginning with a stressor-induced molecular initiating event. In contrast, molecular signatures of P38K inhibitors were distinct from that of GI diseases. Surprisingly, gene expression profiles of P38K inhibitors shared similarities to the molecular signatures of a specific enteropeptic bacterial toxin with the cell cycle and autophagy pathways being most transcriptionally disrupted. This suggests that using irinotecan as a GI toxicity model may not be suitable to study molecular mechanisms for P38K-induced GI toxicity. We also found that inhibitors targeting different P38K isoforms have different levels of similarity to the bacterial toxin signature. We conclude that P38K-induced GI toxicity has a unique molecular signature that is different from GI diseases or irinotecan-induced GI toxicity. Instead, it has a novel association to the molecular mechanism of toxicity caused by an enteropeptic bacterial toxin, with some degree of isoform differences.

Utilization of Scrap Tires Versus Firewood and Liquefied Petroleum Gas as Fuels for Singeing Meat in Ghana: Chemical Emissions Via Smoke

E. Alitriye-Gyawu1, A. Brown1, M. Rao2, A. Adhikari2, and H. Samawi1.
1Georgia Southern University, Statesboro, GA; and 2Spring Hill College, Mobile, AL.

Utilization of scrap automobile tires for singeing food animal carcasses at meat processing facilities in Ghana (and other countries) has been ongoing for over 50 yr. This practice can release chemical pollutants such as carbon monoxide (CO), benzene, sulfur dioxide (SO2), particulate matter (PM), etc. into the air via smoke. Exposure to these chemicals has been associated with adverse health effects such as respiratory impairment, mutagenesis, and cancer. This study aimed at determining the levels of CO, benzene, SO2, PM10, and PM2.5 emitted via smoke produced at three slaughter slabs (using tires and firewood) and Kumasi Abattoir (which uses liquefied petroleum gas (LPG) as a fuel). A Chip Measurement System and an Aerosol Monitor were used to quantify the chemical levels in real time. Results indicate that the average levels of both PM10 and PM2.5 from LPG-based smoke (0.7±0.2 mg/m3; 95% CI 0.3-1.1) and tire smoke were significantly lower than that of firewood (24.2±5.2 mg/m3; 95% CI 13.1-35.3) and PM10 (95% CI 13.1-35.3, respectively) and tire smoke was lower than that of tire smoke (24.2±5.2 mg/m3; 95% CI 13.1-35.3, respectively) and tire smoke was lower than that of firewood (24.2±5.2 mg/m3; 95% CI 13.1-35.3, respectively). Tire smoke was lower than that of tire smoke (24.2±5.2 mg/m3; 95% CI 13.1-35.3, respectively) and tire smoke was lower than that of firewood (24.2±5.2 mg/m3; 95% CI 13.1-35.3, respectively). Tire smoke was lower than that of tire smoke (24.2±5.2 mg/m3; 95% CI 13.1-35.3, respectively) and tire smoke was lower than that of firewood (24.2±5.2 mg/m3; 95% CI 13.1-35.3, respectively). Tire smoke was lower than that of tire smoke (24.2±5.2 mg/m3; 95% CI 13.1-35.3, respectively).
nificantly higher compared to those of LPG. These data suggest that slaughter slab operators and residents nearby these meat processing facilities may be at high risk for adverse health effects linked to these pollutants. A more comprehensive study is warranted to sufficiently characterize this tire burning-health effect link.

### 1970 Concordance of Pathophysiologic Responses in Mice Exposed to Different Biomass Smoke Conditions Via Aspiration and Inhalation

We have previously reported that aspiration of an equal mass (100 µg) of particle matter (PM) in flaming biomass smoke condensate caused greater lung toxicity in mice than samples from smoldering smoke. In this study, we conducted inhalation exposures on a subset of the biomass smoke fuels and conditions, and compared with the previous results before and after dosimetric adjustment for inhaled PM. Biomass smoke from peat, eucalyptus and oak fuels was generated under smoldering and flaming phases with PM levels precisely maintained by an automated smoke emission controlling system. Mice were exposed for 1 hour/day for 2 days and then assessed for lung toxicity at 4 and 24 h after the second exposure. PM levels were ~40 and ~4 mg/m3 from the smoldering phases, and ~3 mg/m3 from the flaming phases, respectively. BALF neutrophils (PMN; <0.05), eosinophils (EOS; not significant) in comparison to air exposure in HDM-allergic mice. Biochemical markers of lung injury (e.g., protein, LDH, albumin, cytokines, enzymes) were measured at 4 h although effects were equivalent for both conditions by 24 h. A significant increase in ventilator timing (as measured by Penh, potentially indicating airflow obstruction), was observed in mice exposed to flaming peat and for both flaming and smoldering eucalyptus immediately after each day of exposure, in agreement with the inflammation results. No pathophysiological responses were seen following exposure to either combustion condition of oak, which mirrored the responses following aspiration exposure. Overall the results show good concordance in responses between aspiration and inhalation studies depending on type of fuel and combustion conditions and confirm that PM from flaming condition is, on a mass basis, more toxic than that from smoldering smoke. This abstract does not represent US EPA policy.

### 1971 Differential Effects of Wildfire Biomass Smoke Inhalation on Allergic Inflammation in Mice

Wildfires emit high concentrations of airborne particulate matter (PM) and volatile organic compounds which can impact sensitive populations such as asthmatics. Health effects of these biomass emissions may vary significantly depending on fuel type and burn conditions. We assessed the relative acute toxicity of biomass smoke produced from controlled burns of peat, oak, or eucalyptus under smoldering (SM; 510 °C; ~40 mg/m3 PM; PAH levels) and flaming (FL; 640 °C; ~3.5-4 mg/m3 PM; PAH levels) conditions via transdermal inhalation of airborne smoke with equivalent carbon monoxide levels in house dust mite (Der p1) allergen (HDM) Balb/CJ mice. Control and HDM-sensitized mice were challenged with HDM 1 day before nose-only exposure to air, SM, or FL smoke (1 h/d x 2 d). Lung inflammation and histopathology were characterized with respect to the control group. Similar finding were found for genes related to xenobiotic metabolism, Cyp1a1; DNA damage, Ddih3; metal exposure, Mt1; and aromatic hydrocarbon receptor, AhR. Histological evaluation of treated animals revealed hepatic steatosis and inflammation. This study evidenced exposure to inhalable coal dust promotes changes at molecular, cellular and histopathological levels in mice. This information should serve as a basis for government entities to implement solid environmental standards that favor sustainable mining development in the country, with minimal impact on human or environmental health. Colciencias-UNIcartagena 589-2013 and 567-2012.

### 1972 Toxic Effects of Inhalable Coal Dust in BALB/c Mice

K. Fuentes-Lopez, K. Caballero-Gallardo, and J. Oliviero-Verbel, University of Cartagena, Cartagena, Colombia.

Coal mining is a strategic sector for Colombia’s development and is one of the most widely used energy sources globally. Coal dust generated from mining operations has been associated with the increase of chronic diseases in inhabitants and in different organisms near mines. The objective of this study was to evaluate the toxic effects of coal dust with a particle size of less than 74 µm on Mus musculus BALB/c mice. For that purpose, mice were exposed during 10 weeks to sand spiked with different concentrations of coal dust (0, 0.25, 0.5, 1, 2 and 4% w/w) obtained from a sample of bituminous coal collected from a mine in Cesar, Colombia. After exposure, mice were euthanized for the extraction of blood and tissue samples for different assays. Peripheral blood smears revealed that the average values for polychromatim erythrocytes, micronuclei and microcytes were statistically greater than those in the control group. In the case of normoblasts, a significant increase was observed only at the two greatest tested concentrations. TBARS assay did not show significant differences in oxidative damage between exposed groups, although the relative mRNA expression of genes relate to oxidative stress, Nf2 and Sod1, displayed a sub-expression profile with respect to the control group. Similar finding were found for genes related to xenobiotic metabolism, Cyp1a1; DNA damage, Ddih3; metal exposure, Mt1; and aromatic hydrocarbon receptor, AhR. Histological evaluation of treated animals revealed hepatic steatosis and inflammation. This study evidenced exposure to inhalable coal dust promotes changes at molecular, cellular and histopathological levels in mice. This information should serve as a basis for government entities to implement solid environmental standards that favor sustainable mining development in the country, with minimal impact on human or environmental health. Colciencias-UNIcartagena 589-2013 and 567-2012.

### 1973 Transgenerational Effects of Coal Dust on Tribolium castaneum, Herbst

M. Alcala-Orozco, K. Caballero-Gallardo, and J. Oliviero-Verbel, University of Cartagena, Cartagena, Colombia.

Coal dust is a primary air contaminant from coal mining operations, where it has been recognized to produce harmful health effects. However, it is unclear to what extent its detrimental properties would impact future generations, and whether alterations in the progenies might be dose-dependent. The objective of this study was to determine the transgenerational effects of chronic exposure to coal dust on the red flour beetle, Tribolium castaneum (Herbst) at three life stages. Fifty insects in the adult instar were exposed during 10 weeks at different concentrations (0.0, 0.25, 0.5, 1.0 and 2.0%) of coal dust, particle size <38 µm, mixed with ground oats as food substrates. The average LC50 for F0 insects was 1.06%, whereas for larval, pupa and adults values were 0.18, 0.85 and 0.63%, respectively. Morphological damage assessed at F1 revealed a concentration-dependent frequency of several abnormalities, including larvae without antenna or extremities, and lack of T1, T2, T3 legs. On the other hand, it was found that F1 larvae derived from parental beetles did not achieve a complete conversion into the next growth stage, displaying a lack of femur, tibia, tarsus and elytron. In the same way, pupae without genital lobes were recurrently observed, and at high concentrations, those exhibited protuberances between segments IV, V and VI of the abdomen and undeveloped eyes. In short, sub-inhalable coal dust particles induced transgenerational effects on T. castaneum, highlighting the need to further study the impact of this airborne pollutant on wildlife and human populations. Colciencias-UNIcartagena, Grants: 589-2013, 567-2012 and 757-2016.
Coal is a key energy source in the world, therefore, its mining has steadily been increasing, simultaneously promoting environmental contamination. The aim of this research was to determine the morphological, physiological and behavior changes of *Eisenia fetida* exposed to bituminous coal dust from a coal open mine located in the department of Guajira, Colombia. The coal sample was obtained from the Cerrejon coal mine, and subsequently pulverized up to coal dust ≤ 38 µm. The worm cultivation was standardized under laboratory controlled conditions to evaluate lethality and physiologically-based assays using concentrations of 1, 2, 3 and 4% coal dust in artificial soil. The weight, morphological and behavior changes were visualized at 7, 14 and 28 days of exposition; an avoidance assay carried out after 48 hrs of exposition, and histopathological analysis were carried out at the end of the experiment. Mortality reached 5% at 4% coal dust in soil. The avoidance test followed a trend directly proportional to the coal concentration in soil. Morphological and behavioral alterations of the specimens were evident within 14 days of treatment at concentrations of 3 and 4%, presenting significant changes after 28 days of exposition, consisting of excessive production of mucus, lethargic and violent movements, excessive time to bury in the treated substrate and loss of weight. Histopathological findings revealed significant changes in the size of the ectodermic cells, as well as the expansion of the intercellular spaces in muscle tissues in organisms exposed to 3 and 4% coal dust in soil. In conclusion, *E. fetida* exposed to coal dust experienced morphological, behavioral and histopathological changes, suggesting this pollutant may induce population problems in macro invertebrates present in mining operation areas. *Colciencias-UniCartagena, Grants 589-2013, 567-2012 and 647-2014.*

### 1975 A High Fat Meal after Peat Smoke Inhalation Unmasks Latent Cardiometabolic Responses in Rats

Stress tests are used clinically to uncover underlying disease and predict future cardiovascular risk. Previously, we used treadmill exercise stress in rats to reveal latent effects of air pollution inhalation. Other daily stressors, when modeled experimentally, may have similar utility. For example, consumption of a high fat (HF) meal causes transient vascular changes. To evaluate the effects of air pollution exposure on cardiovascular responses to a HF challenge. Healthy male Wistar Kyoto rats were exposed once (1 hr) to filtered air (FA), or low (LP; 0.36 mg/m³) or high (HP; 3.76 mg/m³) concentrations. Rats were monitored for heart rate (HR), blood pressure (BP), electrocardiogram (ECG), and metabolic markers, and pulmonary and systemic inflammatory markers, and flow cytometry to assess circulating monocyte phenotype were carried out in sensitized mice (n= 8/group) were challenged with HDM 1 day before coming). By contrast, only exposure to LP increased sensitivity to aconitine-induced cardiac arrhythmia relative to exposure to FA (p<0.01). Few changes in systemic markers were evident. Taken together, HP caused overt responses not present with LP that were potentially mediated by autonomic responses. Perhaps of greater concern is the finding that exposure to lower levels that better approximate most human ambient exposures to smoke plumes only caused latent effects, indicating that the effects of exposure may be insidious. This abstract does not reflect US EPA policy.

### 1977 Smoldering Eucalyptus and Red Oak Smoke Inhibit Respiration in an Allergic Asthma Mouse Model

M. M. Hargrove1, Y. Kim2, C. King2, M. I. Gilmour3, and S. Gavett4. 1Oak Ridge Institute for Science and Education, Research Triangle Park, NC; and 3US EPA, Research Triangle Park, NC.

Short- and long-term exposures to biomass wildfire smoke pose significant health risks to firefighters and impacted communities. Susceptible populations including asthmatics may be particularly sensitive to the effects of biomass smoke emissions. We examined pulmonary responses to biomass smoke generated from eucalyptus, Irish peat, or red oak burns under low temperature smoldering or high temperature flaming conditions in female control and house dust mite (HDM)-allergic Balb/c mice. For each fuel type, particulate matter levels were maintained at ~40 (smoldering) or ~3.5-4 (flaming) mg/m³ while CO levels were comparable (~60-120 ppm) under both conditions. Control and HDM sensitized mice (n= 8/group) were challenged with HDM 1 day before exposure to air or biomass smoke for 1 hour/day for 2 consecutive days. Pulmonary responses were assessed using head-out plethysmography chambers to measure thoracic flow and ventilatory parameters prior to (20 min) and during (1 hr) biomass smoke exposure. Both smoldering eucalyptus and red oak reduced breathing frequency in control and HDM-allergic mice. These fuel types also significantly elevated inspiratory time under smoldering conditions compared to the flaming treatment groups. Under flaming conditions, eucalyptus and red oak significantly increased minute volume and peak inspiratory flow. These changes were observed during both days of exposure. However, relaxation time was significantly prolonged during day 1 exposure to smoldering eucalyptus only. In contrast, peak expiratory did not alter these ventilatory parameters under either condition. We conclude that exposure to eucalyptus or red oak smoke inhibits respiration to a greater degree than peat smoke under smoldering conditions. This abstract does not represent US EPA policy.
Potential exposures from burn pit emissions have raised concerns related to the significant numbers of deployed military personnel with respiratory problems and diminished exercise tolerance. As a result, there is a need to understand potential molecular changes seen upon inhalation of airborne hazards as well as development of accurate biomarkers indicating accurate exposure and individuals monitoring. A joint NAMRU-D/AFRL collaborative in vivo study using whole body exposures of male Sprague Dawley rat to air borne hazards was conducted in response to these needs. Using an ambient breeze tunnel (ABT) at Battelle, West Jefferson OH, whole body exposures of rats were conducted for five days (6 h/day) to emissions generated from a surrogate burn pit composed of mixed waste representative of materials burned in-theater. Blood samples were collected at pre-exposure and five day post-exposure. Six sets of plasma samples from each time point were pooled and processed together. Rat plasma proteins were depleted utilizing IgY immune-depletion spin columns and the depleted fractions were labeled with TMT6, reduced, alkylated, and digested with trypsin. The digested protein solutions were desalted via C18 spin columns and fractionated into seven samples using a strong cation exchange (SCX) spin column. All seven fractions were run on a reverse phase nanoAcquity UPLC-LTQ Orbitrap Velos mass spectrometer (MS) system for analysis, and acquired MS and MS/MS data were searched against the FASTA database for protein identification and quantitatively analyzed using the SEQUEST algorithm in the Proteome Discoverer software suite. About 2800 proteins and 157 protein groups were identified and found to be > 2 fold differentially expressed in pre/post exposure set comparisons. The differentially expressed protein biomarkers were exported and further analyzed using Ingenuity Pathway Analysis (IPA) software. Interestingly, proteins identified have been also identified in published inhalation exposure studies of volatile organic compounds and particulate matter with a subset shown to be involved in inflammatory lung diseases. In compliance with DODI 3216.01.

Far from being sterile, the normal lung contains an individualized micro-biome that may influence if and/or how the lung responds to inhaled airborne hazards. Military personnel exposures to sand and/or burn pit emissions and concerns on potential development of respiratory issues led to a collaborative effort between NAMRU-D and AFRL to identify molecular alterations, including changes in the lung microbiome, which are initiated by inhaled toxicants. Sprague-Dawley rats were exposed to air (control), Burn Pit emissions (BPE), sand, or sand + BPE using whole body exposure chambers. BPE exposures from mixed solid waste were conducted 6 h/d for 5 days, whereas sand exposures (PM2.5) were conducted a total of 20 h/day, 5 days/wk, for 4 weeks, with ventilatory function tests conducted on all groups. Bronchial alveolar lavage fluid removal and lung tissue collection was accomplished in euthanized animals at post-exposure time points (4, 32, 90 days), with histopathology completed on lung tissue. Operational Taxonomy Units (OTUs) of bacterial populations were identified in lavage and lung tissue using bacterial genomic DNA extraction and 16S rRNA sequencing. Compared to controls, sand exposures did not alter the inhibitory effects of pine PM on scratch wound repair. Further investigation of the significance of homocysteine and HERPUD1, as well as other elements of the ER stress response is needed to better understand how TRPV3 signaling may influence the acute and sub-acute pneumotoxic effects of wood smoke PM. Supported by ES017431, and ES027015.

**1979 The Mechanisms Underlying TRPV3s Role in Lung Pathology following Chronic Exposure to Wood Smoke Particulate Matter**

K. L. Burrell, C. F. Deering-Rice, N. D. Nguyen, and C. A. Reilly,
University of Utah, Salt Lake City, UT.

Transient receptor potential vanilloid-3 (TRPV3) is a Ca2+ channel expressed in the skin where it regulates cell growth, differentiation, and wound repair. Recently, our laboratory demonstrated TRPV3 expression in human lung epithelial cells, and a role for TRPV3 in regulating cellular responses to inhaled wood smoke particles (PM). We showed that PM-stimulated PM activates TRPV3, and that PM-induced histone deacetylation is dependent on TRPV3 activity. Additionally, mice treated sub-acutely with pine PM via oropharyngeal delivery displayed increased scratch wound repair rates, it did not alter the inhibitory effects of pine PM on scratch wound repair. Further investigation of the significance of homocysteine and HERPUD1, as well as other elements of the ER stress response is needed to better understand how TRPV3 signaling may influence the acute and sub-acute pneumotoxic effects of wood smoke PM. Supported by ES017431, and ES027015.

Combustion of solid fuels in small boilers is a widely used form of heating family houses. These combustion processes emit large quantities of harmful emissions. Epidemiological studies show that PM created in heating appliances contains carcinogens and mutagens and thus may have health impacts. Previous studies have noted that the quality of combustion is affected by the combustion technology, user operation, and fuel, all of which affect the formation of emissions. In this study, various solid fuels (hard coal, lignite, dry wood, wet wood, lignite briquettes, wood pellets) were burnt in 4 types of boilers representing both old structural designs (over-fire and under-fire boilers) and also up-to-date combustion devices (gasification and automatic boilers). Nominal and reduced performance outputs of boilers were tested to compare the concentration of organic PM components and their genotoxicity. For this purpose, the organic components of collected total particulate matter (formed by 93-100% by PM2.5) were extracted, 16 priority PAHs were quantified and the analysis of the genotoxic potential of extracts was assessed by acellular assay of DNA adducts in calf thymus DNA. We found, depending on the boiler’s technology, fuel quality and output (reduced or nominal) the mass of emitted PM2.5 varied from 0.2 to 64 kg/ton of fuel. The concentrations of the representative carcinogenic PAH - benzo[a]pyrene varied from 5 to 18,000 mg/ton of fuel. Such huge differences in PAH content are reflected by results of the genotoxic potential in acellular assay: DNA adducts in calf thymus DNA (50 μg of extract for 24 h) after metabolic activation of PAHs varied from 6 to 140 adducts/10^9 nucleotides. The results of the study suggest that: (1) The highest genotoxicity was observed for over-fire boilers; (2) Reduced output exhibited more emissions and higher genotoxicity than nominal output; (3) Modern boilers produced less emissions and exhibited lower genotoxicity. In summary, huge differences in mass, composition and genotoxic potential of complex mixtures of organic compounds forming small PM emissions from various boilers were found. Supported by Czech Science Foundation (P-503-12-G147), Ministry of Education (LO1403), and Research Infrastructure NanoEnviCz (LM2015073).

**1978 Blood Proteomic Biomarker Discovery Using an In Vivo Inhalation Model of Burn Pit Emission Exposures**

The global public health impact from household fine particulate matter (PM$_{2.5}$) resulting from heating and cooking sources is extremely large. However, there is a limited understanding of health effects associations with specific PM$_{2.5}$ chemical constituents as well as the underlying mechanisms of these adverse health effects. Use of a high-throughput screening platform enables biological response data to be collected to address these research gaps. To establish the utility of this experimental design, a subset of homes in Kheri, India that participated in the Prospective Urban and Rural Epidemiological (PURE)-AIR pilot study were selected to identify differences in chemical and biological measurements of household PM$_{2.5}$. Personal air monitors collecting PM$_{2.5}$ were worn by female participants and paired with stationary monitors, resulting in personal and home PM$_{2.5}$ filters for six households. PM$_{2.5}$ was removed from filters via sonication in methanol. Aliquots of individual filter samples were removed for chemical analysis (polycyclic aromatic hydrocarbons (n=61), elements (n=20)) and oxidative potential assessment. Remaining PM$_{2.5}$ of the same collection method was then pooled (n=6/group) and the soluble fraction of PM$_{2.5}$ from DMSO extraction was prepared for developmental toxicity testing in zebrafish (n=32/treatment) starting at 6 hours post fertilization (hpf). Pooled sample aliquots were used for chemical analysis and oxidative potential assessment with identical methods to individual filter analyses. Significant differences were observed in oxidative potential between personal and home PM$_{2.5}$ for individual and pooled samples. Significant mortality in zebrafish was observed starting at 24 hpf in personal PM$_{2.5}$ samples and by 120 hpf in home PM$_{2.5}$ compared to blank filter controls. Chemical analysis is underway to identify correlations between these biological responses and chemical constituents. This research is the first study to use paired home and personal PM$_{2.5}$ samples with chemical, oxidative potential, and developmental toxicity data, identifying differences in these measurements between household and personal PM$_{2.5}$. Importantly, it outlines procedures for large-scale analysis of the PURE-AIR study which includes planned PM$_{2.5}$ measurements in 4,000 homes and will ultimately allow for correlation of human health effects with chemical and biological data to improve identified health metrics for PM$_{2.5}$ exposures.

Mice inhaling fine air borne particulate matter (PM$_{2.5}$) exhibit defects in bone marrow stem cells. These include a depletion of hematopoietic stem cells (HSCs), as identified in a colony-forming assay, and functional impairment of cultured endothelial progenitor cells (EPCs), including decreased tube formation in vitro and attenuated vascular repair potential in vivo. One potential mechanism of PM$_{2.5}$-induced pathology is the induction of oxidative stress, leading to the oxidation of biomaterials (e.g. lipids) which are then distributed systemically through the circulation to impact the functionality of distal tissues, including the bone marrow. To test this mechanism and limit oxidative stress, we supplemented murine drinking water with 1mg/ml carnosine. Carnosine is a naturally occurring di-peptide (β-alanine-histidine) which quenches reactive oxygen species and removes toxic products of lipid peroxidation. We then exposed these mice and control mice drinking normal water to concentrated ambient particles (CAPs) or filtered air and examined effects on bone marrow stem cells. We observed that mice drinking normal water and exposed to CAPs had a 40% reduction in HSC colonies compared to control mice inhaling filtered air. In contrast, mice drinking carnosine-containing water and exposed to CAPs demonstrated no HSC depletion. Similarly, while EPCs cultured from mice drinking normal water and exposed to CAPs were deficient in forming tubes and vascular repair, comparable cells from mice drinking carnosine-containing water and exposed to CAPs had no such defects. Thus, supplementation with carnosine mitigated the adverse outcomes of PM$_{2.5}$ exposure on bone marrow stem cells and represents a practical and feasible interventional strategy for limiting the cardiovascular toxicity of PM$_{2.5}$.
1986 Increasing the Pulmonary Antioxidant Defense Prevents PM₂.⁵-Induced Changes in EPC Function and Homeostasis

P. Haberzettl, D. J. Conklin, W. T. Abplanalp, A. Bhatnagar, and T. E. O'Toole. University of Louisville, Louisville, KY.

Fine particulate matter (PM₂.⁵) exposure is associated with decreased endothelial function, suggesting that PM₂.⁵ exposure induces endothelial injury. We showed in humans and mice that PM₂.⁵ exposure decreases circulating endothelial progenitor cells (EPCs) that are considered to contribute to vascular maintenance and repair. However, it is unclear whether PM₂.⁵ exposure induces EPC dysfunction and how PM₂.⁵ inhalation affects EPC function and homeostasis. As an increase in pulmonary oxidative stress is suggested to mediate cardiovascular PM₂.⁵-toxicity, we examined whether increasing the pulmonary antioxidant capacity in transgenic mice overexpressing extracellular superoxide dismutase in the lungs (ecSOD-Tg) could prevent the PM₂.⁵-induced effects on EPCs. We exposed ecSOD-Tg and wildtype (WT) mice for 9 days (6h/day) to concentrated ambient PM₂.⁵ (CAP). Mice breathing HEPA filtered air were used as controls. In WT mice, CAP exposure decreased reduced/oxidized glutathione ratios (GSGH/GSSG) in the lungs and GSH levels in circulating and bone marrow-resident EPCs (Flk-1⁺/Sca-1⁻ cells). In contrast, no CAP-induced redox changes were found in the lungs or EPCs of ecSOD-Tg mice. Pulmonary ecSOD overexpression also restored EPC trafficking, anti-VEGF-signaling and plasma NO levels that were impaired in CAP-exposed WT mice. While bone marrow-derived EPCs from CAP-exposed WT mice formed lesser tubers and failed to migrate into injured hind limb ischemia, ECAP exposure did not impair EPC-function in vitro or in vivo in ecSOD-Tg mice. Gene array data, confirmed by qRT-PCR, showed that in bone marrow-derived EPCs of WT mice CAP-exposure increased the expression of anti-apoptotic (Bcl2, bcl-xl) genes and decreased pro-apoptotic (Bax, Bim) gene expression. In contrast, no changes were observed in ecSOD-Tg mice. In summary, PM₂.⁵ inhalation induces profound defects in EPC function, implicating a role for PM₂.⁵-exposed EPCs in vascular health. These findings suggest that the pulmonary antioxidant capacity in transgenic mice overexpressing extracellular superoxide dismutase in the lungs (ecSOD-Tg) can prevent the PM₂.⁵-induced effects on EPCs.

1988 Chemical Composition Influences the Toxicological Responses Elicted by Size-Segregated Urban Air Particulate Matter from Nanjing, China

T. J. Rönkkö1, P. J. Jalava1, M. S. Happo1, S. Kasurinen1, O. Sippula1, A. Leskinen2, J. Jokiniemi1, M. Komppula1, and M. Hirvonen1.

1University of Eastern Finland, Kuopio, Finland; and *Finnish Meteorological Institute, Kuopio, Finland. Sponsor: M. Viluksela.

Air quality events and high urban particulate matter (PM) levels are a major concern in China. PM exposure is associated with increased cardiorespiratory morbidity and mortality. PM sources include industry, traffic, construction and biomass burning. In this study, we assess how the atmospheric processes and local emission sources cause variations in the chemical composition of inhalable PM from Nanjing, China, and how this affects the toxicological responses of exposed human alveolar epithelial cells. Day- and nighttime size-segregated urban air PM was collected in Nanjing, China during August and October 2013. The PM samples underwent extensive chemical characterization and toxicological profiling using adenocarcinomic human alveolar epithelial cell line A549. The cells were exposed to four particle size ranges (PM₁₀-₂.⁵, PM₁.⁰-₂.⁵, PM₁.₀-₀.₂ and PM₀.₂) at five doses (25, 75, 150, 200, 300 µg/mL) for 24 hours, whereafter cellular metabolic activity (CMA), cell membrane integrity, oxidative stress, genotoxicity, inflammatory response and cell cycle state were measured. PM₀.₂₅ elicited very high oxidative stress, genotoxicity and inflammatory responses. For PM₁.₀₋₂.⁵, the changes in CMA, cell cycle, and inflammatory response were high. PM₁.₀₋₀.₂ caused elevated genotoxicity and inflammatory responses, and moderate changes to CMA and cell cycle. PM₂.⁵ elicited great changes to CMA, cell cycle and inflammatory responses. Metals, especially Ca and Al, were the dominant constituents of PM₁.₀₋₂.⁵, whereas in smaller size-ranges, sulfate and nitrate were the major constituents. Polyatomic hydrocarbon (PAHs) were most abundant in PM₁.₀₋₁.₀ and PM₁.₀₋₀.₂. Instead, PM₂.⁵ contained very low amounts of oxygenated PAHs, which were prominent in the other size ranges. We observed significant variations in PM chemical composition and toxicological responses between the daytime and nighttime campaigns as well as between day and night. Thus, atmospheric processes and emission sources affect the chemical composition, which in turn, affects the elicited toxicological effects.

1987 Air Pollution Exposure Activates NLRP3 Inflammasome and Exacerbates Obesity-Induced Insulin Resistance

X. Rao1, J. Zhong1, L. Chen2, and S. Rajagopalan1. 1Case Western Reserve University, Cleveland, OH; and 2New York University, Tuxedo, NY.

We have previously shown that air pollution exposure enhanced insulin resistance and increased inflammatory response in humans. However, the underlying mechanisms are not fully understood. In this study, we investigated the role of NLRP3 inflammasome in mediating the adverse effect of air pollution on glucose intolerance. Wild-type and NLRP3 knockout mice on a normal chow diet or high fat diet were exposed to filtered air or concentrated ambient PM₂.⁵, 6 hours/day, 5 days/week, for 12 weeks, using a versatile aerosol inhalation system. The cells were exposed to four particle size ranges (PM₁₀-₂.⁵, PM₂.⁵-₁.₀, PM₁.₀-₀.₂ and PM₀.₂) at five doses (25, 75, 150, 200, 300 µg/mL) for 24 hours, whereafter cellular metabolic activity (CMA), cell membrane integrity, oxidative stress, genotoxicity, inflammatory response and cell cycle state were measured. PM₀.₂₅ elicited very high oxidative stress, genotoxicity and inflammatory responses. For PM₁.₀₋₂.⁵, the changes in CMA, cell cycle, and inflammatory response were high. PM₁.₀₋₀.₂ caused elevated genotoxicity and inflammatory responses, and moderate changes to CMA and cell cycle. PM₂.⁵ elicited great changes to CMA, cell cycle and inflammatory responses. Metals, especially Ca and Al, were the dominant constituents of PM₁.₀₋₂.⁵, whereas in smaller size-ranges, sulfate and nitrate were the major constituents. Polyatomic hydrocarbon (PAHs) were most abundant in PM₁.₀₋₁.₀ and PM₁.₀₋₀.₂. Instead, PM₂.⁵ contained very low amounts of oxygenated PAHs, which were prominent in the other size ranges. We observed significant variations in PM chemical composition and toxicological responses between the daytime and nighttime campaigns as well as between day and night. Thus, atmospheric processes and emission sources affect the chemical composition, which in turn, affects the elicited toxicological effects.

1989 Respiratory Dose Analysis for Components of Ambient Particulate Matter

C. S. Kim1, and J. Choi1. 1US EPA, Durham, NC; and *Yonsei University, Seoul, Korea. Sponsor of: M. Madden.

Particulate matter (PM) in the atmosphere is a complex mixture of particles with different sizes and chemical compositions. Although PM is known to cause health hazard, specific attributes of PM that may cause health effects are somewhat ambiguous. Dose of each specific component of PM together with relevant dose metrics may shed insights into understanding of PM related health effects. We have attempted to analyze lung deposition dose of typical bimodal ambient aerosols composed of two distinct aerosols with mass median diameter of 0.3 um (A1) and 5.0 um (A2) with geometric standard deviation of 1.8-2.0. Mass fractions, MF = A1/(A1+A2), were varied in order to reflect aerosol characteristics of different regions. Lung deposition including tracheobronchial (TB) and alveolar (AL) regions was calculated by using a mathematical model built upon Weibel's lung morphology for mass, surface area and number of each of three size fractions, ultrafine (UF, PM₀.₁), fine (F, PM₀.₁₋₂.₅) and coarse (C, PM₂.₅₋₁₀) at inhalation patterns mimicking resting and mild to moderate exercise. Overall, mass deposition of C decreases whereas deposition of F increases in both TB and AL as MF increases during normal breathing at rest. Combined deposition of C and F shows a decrease in TB but an increase in AL resulting in a slight increase in TB+AL. Surface area deposition is resulted mainly by F with a minor contribution from UF at MF=0.2 whereas number deposition comes from both UF and F at a ratio of 1:5.1. During exercise, mass deposition increases greatly (~140%) in TB but decreases (15%) in AL, resulting in a moderate increase of 40% in TB+AL. In C, whereas F decreases by 15% ~ 40%. This results in variable changes (+/-20%) of F+C as compared with resting condition. Surface area and number
deposition shows a decrease of ~20% in a wide range of MF. In conclusion, PM size fractions of ambient aerosols contribute differently to lung deposition dose in terms of mass, surface area and number. Significance of roles of each size fraction and their combined effects need to be considered in toxicological and health risk assessment.

1990 Metabolic Impact Induced by Total, Water Soluble, and Insoluble Components of PM2.5 Acute Exposure in Mice

Y. Zhang, J. Duan, Y. Li, and Z. Sun. Capital Medical University, Beijing, China.

The systemic biological effects on metabolic responses induced by PM2.5 and its components were poorly understood. This study was aimed to evaluate the toxicity of different components of PM2.5 via metabolomics approach. In the present study, we adopted 1HNMR-based metabolomics approach to evaluate metabolic profiles in mice after acute exposure to Total-PM2.5, water soluble components of PM2.5 (WS-PM2.5) and water insoluble components of PM2.5 (WIS-PM2.5). First, we characterized the morphological features and chemical composition of PM2.5. Then, the metabolites changes of serum and urine in mice were systematically analyzed using 800 MHz 1HNMR techniques in combination with multivariate statistical analysis. Total-PM2.5 exposure affected metabolites mainly involved in amino acid metabolism, protein biosynthesis, energy metabolism and metabolism of cofactors and vitamins. WS-PM2.5 exposure influenced lipid metabolism and carbohydrate metabolism. WIS-PM2.5 exposure mainly perturbed amino acid metabolism and energy metabolism. The results suggested that acute exposure to the Total-PM2.5, WS-PM2.5 and WIS-PM2.5 in mice exhibited marked systemic metabolic changes. In addition, the insoluble fraction of PM2.5 contributed greatly to the toxicity of PM2.5.

1991 Not All Particulate Matter Is Equal: Examining Toxicity by Source

1University of North Carolina at Chapel Hill, Chapel Hill, NC; and 2US EPA, Chapel Hill, NC.

Exposure to particulate matter (PM) causes cardiopulmonary morbidity and mortality. PM exposures are generally classified by particle size because smaller particles can penetrate deeper into the lung, causing greater toxicity. But in addition to varying in size, PM from different sources also varies in composition. In order to screen for differential toxicity of PM from various sources, we conducted exposures of primary bronchial epithelial cells cultured at air-liquid interface from a panel of healthy human donors to identical particle masses of six different pollutants: diesel exhaust particles from two different sources (A-DEP and C-DEP), wood smoke particles (WSP), coarse (PM10), and fine (PM2.5), and ultrafine (PM0.11) concentrated ambient particulates (CAPS) collected in Chapel Hill, North Carolina. We compared the relative ability of these materials to induce the expression of oxidative stress and antioxidant defense genes and assessed the inter-individual variability in exposure outcomes. Exposure to A-DEP and C-DEP caused changes in the expression of different genes, with more genes upregulated following exposure to A-DEP. This indicates that the engine from which diesel exhaust particles (DEP) are generated and how they are processed affects their toxicity. Second, the A-DEP and WSP caused strong upregulation in the same set of genes across all donors: NQO1, HMOX1, TRBN1D, GCLC, GCLM, and SOW1. This suggests that similar mechanisms drive the toxicity of these two types of PM. Finally, coarse, fine, and ultrafine CAPS elicited different responses, with smaller CAPS causing more drastic changes in gene expression. Since the exposure setup used for these experiments does not model lung deposition, this is further evidence that differential toxicity between these particles is attributable not only to their size but also to their composition. Additionally, if a donor was less responsive to one exposure, then they tended to be less responsive to the others. This indicates that each donor may contain an overall response phenotype that influences their sensitivity to an array of air pollutants. Overall, these data highlight how the degree of PM toxicity is influenced both by PM source and by inter-individual variability. Exploring these differences in PM exposure outcomes will improve our understanding of how these toxins cause adverse health effects and help identify and protect susceptible populations. This abstract does not reflect US EPA policy.

1993 Effect of Sex and Fine Particulate Matter Exposure on Heart Rate Variability of ApoE Knockout Mice

Exposure to air pollution has been associated with increased risk of developing and exacerbating cardiovascular disease. We have previously shown that after an 8-week exposure to fine particulate matter less than 2.5 μm (PM2.5), male ApoE−/− mice, which are susceptible to developing atherosclerosis, develop atherosclerotic plaques and show changes in heart rate variability (HRV), a measure of cardiac autonomic control. In this study, the effect of sex and a long-term exposure were assessed. ApoE−/− male and female mice were implanted with electrocardiogram (ECG) telemetry devices and exposed 4 days per week for 11 weeks to either PM2.5 concentrated ambient particles (CAPs), or filtered air (n=5). Ambient particles were concentrated approximately 10 times and vented levels were maintained with the Choctaw Enrichment System. Ambient polycyclic aromatic hydrocarbons (PAH), a class of semi-volatile organic compounds, were collected and analyzed from polystyrene foam and XAD-2 polystyrene resin. Particle phase PAHs were also collected on a Teflon filters and subsequently extracted for analysis using gas chromatography-mass spectrometry. PAHs are known contributors to the toxicity of PM. Several measures of HRV were calculated from ECG data collected during the 11 weeks and averaged daily over 4 hours in the evening during the animals’ dark cycle on both exposure and non-exposure days. With this long-term exposure study, the cumulative effect of PM over time on HRV was monitored. HRV was analyzed in the time and frequency domains to assess autonomic control of the heart, and particularly parasympathetic, input to the heart. Immediate changes to HRV seen during week one were mostly dependent on if animals were subjected to exposure that day or not. As the study continued, PM elicited more chronic effects on the standard deviation of normal to normal intervals (SDNN) and low frequency (LF) root mean square of successive differences in RR intervals (RMSSD). Sex differences between the male and female heart rate variability changes were also seen. Specifically, for measures of parasympathetic nervous system input in both time and frequency domains, males show a greater response to PM2.5. These changes are thought to be related to parasympathetic control of the heart and represent a defense response to the toxic insult in the lungs. Toxicity of particulate matter may be in part due to sex and not only dependent on PM size and chemical composition as previously shown.
2018 SOT Annual Meeting

Air pollution has been associated with increased incidences of cardiovascular disease leading to increased daily mortality and hospital admissions. Fine PM (Dp < 2.5 µm) contains a mixture of metallic elements, road dust, and includes ultrafine PM (Dp < 0.1 µm) encompassing vehicle emissions which, due to their large surface area/unit mass, allows for greater adsorption of reactive organic molecules and increased availability for interaction with potential cellular targets. The objective of this study was to provide experimental evidence to elucidate the epidemiological finding that older women may be more susceptible than men to the cardiovascular effects associated with ambient particulate matter exposure. Groups of genetically altered ApoE-/- mice (preventing developing atherosclerosis) were exposed to either filtered air (FA) or to concentrated ambient PM2.5 (CAPs). Mice were exposed 5 hours/day, 4 days/week for 8 weeks at the University of California, Irvine, about 1600m southwest of a major freeway. Blood pressure was measured weekly while implanted cardiac transducers continuously monitored ECGs from the mice. ECGs were analyzed at specific post-exposure times to detect changes from the baseline measurements at various waveforms. Female mice exposed to PM2.5 CAPs experienced a decrease in both systolic and diastolic blood pressure for most of the exposure period compared to FA controls; no difference was seen between exposure groups for male mice. No loss of any sex exposed to CAPs for 1 month exhibited a decrease in RR, PR, and QT-interval compared to filtered air (FA) controls. Furthermore, the T-wave amplitude in exposed male mice increased with increased exposure time compared to controls while the ST-segment elevation of exposed female mice remained depressed for the duration of the exposure. Mice of both sexes exhibited J-point waveform depression when exposed to PM2.5 CAPs. Hypotension can result from conditions such as heart disease and bradycardia while ST-segment changes are common measures of myocardial dysfunction in humans that may lead to life-threatening cardiac events. Further investigation into the observed changes need to be performed to explicate the sex-specific mechanisms corresponding to changes resulting from CAPs exposures.

Intestinal Polycyclic Aromatic Hydrocarbon (PAH)-DNA Adducts in Beluga Whales with PAH Exposures and High Rates of Gastrointestinal Cancer

M. C. Poirier1, S. Lair2, E. E. Hernandez-Ramon1, K. V. Divi1, S. Raverty1, J. A. St. Leger3, K. A. Burek-Huntington2, S. S. Wise4, J. P. Wise4, G. Beauchamp5, and D. Martineau6. 1National Cancer Institute, Bethesda, MD; 2University of Montreal College of Veterinary Medicine, St. Hyacinthe, QC, Canada; 3National Cancer Institute, NIH, Bethesda, MD; 4University of British Columbia, Abbotsford, BC, Canada; 5Sea World San Diego, San Diego, CA; 6Alaska Veterinary Pathology Services, Eagle River, AK; and 7University of Louisville School of Medicine, Louisville, KY.

For a half century, beginning in 1926, carcinogenic polycyclic aromatic hydrocarbons (PAHs) were disposed into the Saguenay River of the St. Lawrence Estuary (SLE) by local aluminum smelters (Quebec, Canada). PAHs present in the river were hypothesized to be etiologically linked to gastrointestinal cancers observed in 6.2% of 178 adult beluga found dead along the shorelines. Because DNA adduct formation provides a critical link between exposure and cancer induction, we investigated PAH-DNA adducts in paraffin blocks of SLE beluga intestine. Using an antiserum specific for DNA modified with several carcinogenic PAHs, we stained consecutive sections of paraffin-embedded intestine from 51 SLE beluga (0-63 yr), and 20 beluga (0-46 yr) living in areas with low PAH contamination (Eastern Beaufort Sea, Canada; Barrow AK, and several aquariums). Stained sections showed nuclear light-to-dark pink color indicating the presence of PAH-DNA adducts concentrated in intestinal crypt epithelial lining cells. A simple color-based scoring system of whole tissue sections revealed higher scoring values for the 51 SLE beluga compared with the 20 non-SLE controls (p = 0.003). In addition, the H-scoring system, applied to coded individual photomicrographs, confirmed that the SLE beluga had levels of intestinal PAH-DNA adducts significantly higher than the non-SLE controls (p = 0.003). The presence of high levels of PAH-DNA adducts in SLE beluga intestine strongly connoted carcinogenic PAH exposures with intestinal cancer induction in these whales.
An increasing number of pharmaceutical and industrial chemicals are being classified as endocrine disrupting compounds (EDCs). These chemicals can interfere with hormonal homeostasis and lead to developmental disorders, cancer, and other pathologies. One such EDC is 17α-ethynylestradiol (EE2) used in oral contraceptives. EE2 can inadvertently be introduced into aquatic environments through municipal wastewater treatment facilities. Exposure of male fish to EE2 is known to increase the expression of the egg yolk precursor protein vitellogenin (VTG). This induction has been predominantly used as a molecular marker of exposure to estrogenic EDCs and resulting feminization. However, the mechanisms behind VTG induction are not fully known and we hypothesize that it is regulated via DNA methylation. To test this hypothesis, we used a modified sequencing approach called targeted genome bisulfite sequencing (TGBS) to determine the percent methylation at the vtg1 promoter. DNA methylation was assessed in the livers of adult male zebrafish exposed to 20 ng/L EE2 for 0.25, 0.5, 4, 7 and 14 days. A significant increase in mRNA was observed in the EE2-exposed fish as early as 5 days. However, the increase in DNA methylation at the CpG sites, however, was not observed until after 4 days of EE2 exposure. This decrease brought the overall methylation of vtg1 promoter in male zebrafish at the same level as that of female controls suggesting that it may lead to feminization. The persistence of these changes was assessed by discontinuing EE2 exposure. We observed that mRNA levels returned to basal levels after 7 days post EE2 removal. In contrast, DNA methylation levels remained significantly decreased. These data confirm the ability of EE2 to induce a genotypic change in VTG mRNA expression that can lead to feminization. Collectively, these data suggest a role for DNA methylation in VTG induction and subsequent feminization of male zebrafish after exposure to EE2. Our work identifies a novel epigenetic marker of exposure to estrogenic EDCs and resulting feminization that may serve as an indicator of previous exposure to EE2 which will aid in ecological risk assessment of EDCs.

**1999** Toxic Effects of Coal Dust Extract on Embryonic Development of Zebrafish

A. Guerrero-Castilla1,2, J. Olvera-Verbel1, I. Sandoval1, and D. Jones1. 1University of Cartagena, Cartagena de Indias, Colombia; 2Arturo Prat University, Iquique, Chile; and 3Oklahoma Medical Research Foundation, Oklahoma City, OK. Sponsor: P. Del Valle

Coal mining has been linked to several impacts on environmental health. The aim of this study was to evaluate the phenotypic alterations and gene expression changes generated in zebrafish embryos exposed to methanolic coal extracts. Samples of coal dust obtained from a coal mine in La Loma, Colombia, were extracted with methanol in a Soxhlet apparatus, and the solid extract dissolved in dimethyl sulfoxide for biological assays. Lethal and phenotypical alterations were monitored using an Olympus SZX12 stereomicroscope and analyzed by in situ hybridization. RNA sequencing and RT-PCR were employed to determine the alterations in gene expression associated with the observed phenotypes. The coal extract showed a 48 hpf (hours post-fertilization)-LC50 of 223.68 mg L-1 (SE: 29.48) and a 48 hpf-LD50 of 161.55 mg L-1 (SE: 17.16). Using the induction of acute toxicity as read-out, morphological and physiological embryo-toxic effects were registered in a concentration-dependent manner. Three phenotypes (P1, P2 and P3) were determined in embryos exposed to methanolic coal extract and all of them showed shortening of brain regions; defects in the formation of the pineal and somites; as well as defects in heart tube in in situ hybridization. Gene expression profile analysis by RNA sequencing for the phenotype groups identified alterations of several genes related to the composition of intermediate filaments, oxidation-reduction processes, calcium ion binding, focal adhesion, and ECM-receptor interaction pathway. These findings allowed to postulate changes in gene expression of several genes as biomarkers of exposure to pollutants derived from coal mining. Besides, coal dust extract causes severe alterations in embryonic development of vertebrate aquatic organisms, which could lead to poor health of biota and humans exposed to such chemicals.

**1998** Changes in CpG-Methylation of Vitellogenin 1 in Adult Male Zebrafish after Exposure to 17α-Ethynylestradiol (EE2)

R. T. Kolli1,2, B. S. Cummings1, T. C. Glenn1, R. B. Bringolf3, and J. F. Kenneke1. 1University of Georgia, Athens, GA; and 3US EPA, Athens, GA.

The aim of this study was to evaluate the phenotypic alterations and gene expression changes generated in zebrafish embryos exposed to EE2 which will aid in ecological risk assessment of EDCs. Biologically active xenoestrogens cause severe alterations in embryonic development of vertebrates. The adhesion, and ECM-receptor interaction pathway. These findings allow for the development of new therapeutic strategies to prevent adverse developmental outcomes.

The toxicity of 17α-ethynylestradiol (EE2) on zebrafish was assessed using an estrogenic assay. Lethal and phenotypical alterations were monitored using an EthovisionTM. Tissue analysis indicated successful maternal transfer of Hg from were fed either a high or low MeHg diet to assess the effect on adult fish. Future research will characterize potential effects on early developmental and reproductive processes not captured here.

**2000** Bioaccumulation and Effects of Dietary Exposure to an Alternative Brominated Flame Retardant ( Bis(2-ethylhexyl) Tetraphosphomethylphthalate (TPBH), in Atlantic Killifish, Fundulus heteroclitus

D. Nacci1, B. Clark1, D. Champlin1, S. Jayaraman1, K. Miller2, and M. LaGuardia3. 1US EPA, Narragansett, RI; 2CSC Government Solutions LLC, Alexandria, VA; and 3Virginia Institute of Marine Science, Gloucester, VA.

Bis-(2-ethylhexyl) tetraphosphomethylphthalate (TPBH), is a high production volume chemical classified as an alternative flame retardant (FR), which replaces legacy FRs withdrawn from US markets due to health and environmental concerns. This study provides experimental data on the bioaccumulation and biological effects of dietary exposure to TBPH from an estuarine fish, Atlantic killifish, Fundulus heteroclitus. Briefly, individually tagged male and female adult fish were fed a gel-based diet amended with carrier or contaminant for 28 days, followed by 14 days consuming uncontaminated food. Dietary amendments were designed to resemble prior studies of fish dietary exposures to TBPH. Tissue concentrations achieved were ~2-TPBH_Lo to 20-TPBH_HI fold higher than those measured in a limited number of reports of TBPH in field-collected biota. Modeled estimates suggest that about 50% of the measured bioaccumulation occurred over about 12 days. Growth of males exposed to TBPH for about 22 days; there was no effect of sex or size on the rates of incorporation or loss of TBPH from fish tissue. Over the course of the experiment (42 d), male fish grew (~0.5 % body dw/d) but female fish did not; unexpectedly, reproductive condition (gonad:body weight ratios) declined in both sexes, independent of treatment. Treatment of zebrafish with extremely high dietary concentrations of TBPH can contaminate fish tissues above the highest levels observed in the environment to date, although these exposures produced few adverse biological effects on adult fish. Future research will characterize potential effects and biological outcomes in offspring.
to eggs. Overall, this contributes to the ongoing development of an ecological modeling framework in a fish with an extensive toxicological and genomic background. Ultimately, we are working to connect molecular mechanistic, physiological, reproductive, and behavioral responses to population level fitness.

2002 Effect of Cadmium Exposure on Larvae and Sperm of Prochilodus magdalenae
L. Sierra-Marquez1, M. Lozano-Guerrero1, J. Espinosa-Araujo2, V. Atencio-Garcia1, and J. Olivero-Verbel1. 1University of Cartagena, Cartagena, Colombia; and 2University of Cordoba, Monteria, Colombia.

Cadmium is a heavy metal found naturally in the earth’s crust associated with other minerals. Exposure to this metal may damage animal reproduction, decreasing the rate of fertilization of organisms, such as fish. The Prochilodus magdalenae is the most important fish species in Colombia, and it is widely used by riparian communities of many Colombian rivers. The aim of this work was to determine the toxic effects of cadmium chloride on 0, 1, 6, 7 and 8 days post-hatching larvae and sperm of P. magdalenae. The results indicated that cadmium-induced a dose-dependent effect on the lethality of the exposed larvae that depends on its development stage. The heavy metal also altered sperm quality by decreasing total motility and speed of rapid and medium swimming spermatozoas. The heavy metal also impaired sperm curvilinear and straight-line velocities in a concentration-response dose. The results evidenced that the exposure to cadmium causes physiological changes in the initial stages of development of P. magdalenae, probably increasing the risk of reducing the fertility rate of this vulnerable fish species. UniCartagena (2016-2017), Colciencias, 647-2014.

2003 Development of Wildlife Toxicity Reference Values (TRV) for Perfluorooctane Sulfonate (PFOS)

Perfluorooctane sulfonate (PFOS) is an anthropogenic compound that resists thermal, chemical and biological degradation, and vertebrae or microbial metabolism. Because of widespread use, PFOS remains a persistent environmental contaminant commonly found in wildlife and human organs, tissues and fluids. We reviewed the acute, sub-chronic and chronic toxicity of PFOS in mammalian, avian, reptilian and amphibian species with the purpose of developing toxicity reference values for mammals, birds, reptiles, and amphibians. Despite limited wildlife exposure data, available laboratory animal studies enabled identification of target organs and derivation of NOAEL and LOAEL dose-response endpoints. US Army Public Health Center Technical Guide 254 - Standard Practice for Wildlife Toxicity Reference Values (TRVs), guided our development of class specific TRVs. Although considerable data were available for mammals and birds, amphibian data were limited, and data relevant to reptiles were absent. Tentatively derived oral TRVs (mg/kg-day) based on the most sensitive species for mammals was 0.004 (NOAEL-based) and 0.04 (LOAEL-based) in male rats based on reproductive dietary studies. For the most sensitive avian species, the derived oral TRVs (mg/kg-day) were 0.015 (NOAEL-based) and 0.064 (LOAEL-based) from reproductive studies of adult mallards exposed to dietary PFOS. For amphibian species (frogs), derived TRVs (mg/L) were 0.0003 (NOAEC-based) and 0.00075 (LOAEC-based) from sub-chronic exposures. These tentative TRVs were based on the most sensitive species available, and might be protective of the entire class of wildlife species and useful in ecological risk assessments of PFOS.

2004 Evaluation of the Estrogen Receptor and the Dopamine Signaling Pathway as a Possible Target of Bifenthrin Toxicity in Zebrafish Embryos

Bifenthrin (BF) is a pyrethroid insecticide widely used in urban and agricultural applications. Previous studies in juvenile fish have shown that environmentally relevant (ng/L) concentrations of BF can affect the endocrine system causing the over production of 17β-estradiol (E2) and altering the expression of dopaminergic pathway components in the central nervous system. We have also noted that BF acts as an anti-estrogenic compound in embryos. To examine the role of the estrogen receptor (ER) embryos were exposed for 96 hours to a mixture of 0.15 and 1.5 µg/L BF and an ER agonist (Ethinyl Estradiol - EE2). Additionally, ER morpholinos (ERα, ERβ1, ERβ2) were injected in embryos and exposed to 0.15 and 1.5 µg/L BF and EE2. The relative levels of transcripts related to the dopaminergic and the hypothalamic-pituitary-gonad axis (DR1, and vitellogenin - VTG) were investigated by qRT-PCR, and dopamine and its metabolites (HVA and 3,4-dihydroxyphenylacetic acid) and E2 concentrations were evaluated by LC-MS/MS. Preliminary results show that BF decreased the estrogenic effects of EE2 in the embryonic stage. These results show that the ER might be one of the targets of BF sub-lethal effects. Further analysis of differentially expressed genes coupled with endocrine responses will help assess other potential sub-lethal targets of BF toxic and sub-lethal effects using zebrasfish as an animal model.

2005 Environmental Impact of Microbes: Its Effect on Awba Dam

Recreational use of water is often given inadequate consideration and care. In Nigeria, many of these are increasingly contaminated by domestic sewage and industrial effluents. This study is therefore relevant in assessing the environmental impact of microbes on ecotourism in Awba dam. A total of nine water (n=9) and soil (n=9) samples were collected at entry, middle and the end of the Awba dam for heavy metal analysis and microbial assay. Samples were assessed for heavy metals using an official procedure and atomic absorption spectrophotometry. Total aerobic plate count, Isolation and characterization of strains was done using standard methods. For enumeration of E. coli O157:H7, colonies were characterized using standard methods. The disc diffusion agglutination technique was utilized for serology. The presumptive E. coli isolates were subjected to agglutination tests with specific E. coli O157:H7. For the antibiotic sensitivity test, the Bauer-Kirby disc diffusion method was used to test the sensitivity of the isolates. ANOVA and Duncan multiple range test was used for data analysis. All the values obtained for the total aerobic count and total coliform count for soil and water were higher than EPA recommended value for recreational waters. For the Antibiotic Sensitivity Profile, isolates from Awba dam showed the highest sensitivity (16.17mm) to ciprofloxacin while lowest was with Augmentin (8.25mm). The isolates at the control point showed highest sensitivity to CPR and NIT (14mm) and least for AUG (5mm). Generally, E.coli O157:H7 isolates were highly sensitive to Oftoxacin and Ciprofloxacin(93.3%) while the isolate was completely resistant to Ampicilin and Cefuroxime. The presence of E.coli O157:H7 in the dam can make the dam unfit for recreational activities and also for the community household chores, if not well treated. The University management should device means of controlling waste water that enters into the dam by providing alternate channels of discharge. This will reduce the growth and spread of the microbes in the soil and water of the dam.

2006 The Effects of Pristine and Carboxylated Multi-Walled Carbon Nanotubes on Phagocytosis by Macrophages
R. Lohray, R. Wang, E. Chow, and R. Draper. University of Texas at Dallas, Richardson, TX.

The global production and applications of multi-walled carbon nanotubes (MWN Ts) have increased in recent years despite evidence that MWN Ts cause pulmonary fibrosis in lab animals that may lead to mesothelioma. Studies to understand the pathological mechanisms of MWN Ts focus on macrophages as they are first responders to invaders in the body. Recent work in our lab shows that both human and mouse macrophages preferentially accumulate pristine MWN Ts (C-MWN Ts) than pristine MWN Ts (P-MWN Ts). Preliminary results suggest that multiple types of receptors expressed in macrophages may be involved in the selective accumulation of C-MWN Ts compared to P-MWN Ts. To investigate potential impacts of accumulated C-MWN Ts and P-MWN Ts on endocytic function of macrophages, this study focused on two approaches: 1. Mouse macrophage RAW 264.7 cells were pre-exposed to C-MWN Ts or P-MWN Ts at 37 °C, washed and challenged with Alexa Flou 488 conjugated dextran, a fluorescent marker used to monitor the phagocytic activity of the cells, using fluorescence microscopy. The fluorescent intensities of the cells treated with C-MWN Ts or P-MWN Ts were comparable to the control cells. The results suggested that the MWN Ts were quenching Alexa Flou 488 fluorescence, interfering with this approach. 2. To avoid fluorescence quenching by MWN Ts, the second approach employed polystyrene beads as a phagocytic marker. Cells treated with C-MWN Ts or P-MWN Ts were washed and then challenged with non-functionalized 0.5-1.0 µm diameter blue polystyrene beads. The phagocytosed
beads were readily visible using bright field light microscopy. Moreover, a method recently developed in our lab allows the detection of MWNTs in 3D cell imaging using Confocal Raman Laser Scanning Microscopy (CRLSM). Since the polystyrene beads have a strong aromatic ring vibration Raman shift at 1000 cm-1, easily distinguished from the MWNT Raman shift at 1350-1600 cm-1, the polystyrene beads will also be detectable using the CRLSM in this approach. The evidence suggests that blue polystyrene beads avoid the quenching of fluorophores by MWNTs and that the beads are a better tool to investigate the effect of selective C-MWNT accumulation by cells.

### 2007 Bioaccumulation and Biopersistence of Model Chemical Mechanical Planarization Slurries in Daphnia magna

S. Karimi, M. Troeung, R. Wang, P. Pantano, and R. K. Draper, University of Texas at Dallas, Richardson, TX.

The purpose of this study is to determine the bioaccumulation and biopersistence in *Daphnia magna* (D. magna) of model nanoparticle (NP) slurries containing either ceria (CeO₂) or alumina (Al₂O₃). The semiconductor manufacturing industry uses these NP slurries in the chemical mechanical planarization (CMP) process to polish wafer surfaces. Semiconductor manufacturers generate high volumes of the slurries and the slurries are interesting in the impact the slurry might have on aquatic organisms. In previous studies, we reported the acute and chronic toxicities associated with model CMP slurries in *D. magna*. The key findings were that the long-term exposure of CeO₂ and Al₂O₃ CMP slurries at concentrations that imposed no life-threatening danger to *D. magna* nevertheless cause serious reduction in reproduction which may endanger the *D. magna* population in an ecosystem. In the present study, bioaccumulation (BA) and biopersistence (BP) of NPs accumulated by MPs in D. magna when exposed to CeO₂ or Al₂O₃ slurries. Adult *D. magna* (8 to 10 days old) used in the bioaccumulation studies were exposed to various concentrations of CeO₂ or Al₂O₃ NPs for 4, 12, 24, and 48 h and the amounts of NPs accumulated by MPs in D. magna were determined by digesting the organism in acid using a microwave followed by ICP-MS analysis. Preliminary results of bioaccumulation with the Al₂O₃ slurry showed that exposure time increases, the amount of Al₂O₃ NP accumulated by *D. magna* also increased. Moreover, preliminary results with the CeO₂ slurry showed that bioaccumulation increased with increasing exposure time and concentration. Biopersistence studies were performed with NPs that will determine the length of time and the NP amount that remains in *D. magna* following exposure to the slurries.

### 2008 In Vitro Bioactivity and Chemical Composition of Recipient Waters Impacted by Onsite, Small Scale, and Large Scale Waste Water Treatment Facilities

Contamination of surface water by micropollutants (MPs) is an environmental problem of concern. MPs can be contaminated by MPs from multiple sources, including waste water treatment facilities. In rural areas of Sweden, on-site waste water treatment facilities are common, and the MP removal efficiency of these facilities has been questioned. In this study, we collected seasonal water samples from seven sites along a river system. The sampling sites are differentially impacted by on-site, small scale, and large scale waste water treatment facilities, respectively. Water was sampled in a time-integrated manner, using passive diffusion samplers. Samples were analyzed for bioactivity using in vitro assays for specific toxicity mechanisms including activation of aryl hydrocarbon receptor (AhR), nuclear factor kappa-light-chain-enhancer of activated B cells (NFκB), nuclear factor erythroid-2-related factor 2 (Nrf2), estrogen receptor (ER), and androgen receptor (AR) agonistic and antagonistic effects. Furthermore, occurrence of 80 MPs, including pharmaceuticals, personal care products, pesticides, and perfluoroalkyl substances were analyzed using a target approach based on liquid chromatography coupled to tandem mass spectrometry. The highest levels of MPs were detected at the sampling sites heavily affected by a large scale waste water treatment facility. The levels of MPs showed a seasonal trend with highest levels of MPs in September. Likewise, the AhR activity showed a clear seasonal trend where the samples from most sampling sites collected in June and September activated AhR whereas samples collected in November or March did not show AhR activity. With the exception of one single water sample, we did not detect any activity of NFκB, Nrf2 or AR. One water sample showed biological activity in multiple toxicity biosassays, but the observed bioactivity could not be explained by the occurrence of target chemicals. None of the water samples activated the ER. In conclusion, the toxicological and chemical characterization performed in this study revealed a seasonal variation in both bioactivity and chemical composition of the water samples. The chemical analysis could, however, not explain the observed bioactivity.

### 2009 Role of Directly and Indirectly Acting Chemicals on Development and Oxidative Stress in Various Early Life Stages

Y. Jo, J. Corrales, and B. Brooks. Baylor University, Waco, TX.

Recent studies in our laboratory comparatively explored toxicity responses associated with oxidative stress (OS) pathways in fathead minnow (*Pimephales promelas*) and zebrafish (*Danio rerio*) at early life stages. However, discrepancies between responses of these two common fish models have not been fully investigated across developmental ages. Here we aimed: 1. to explore how oxidative stress responses vary throughout development and evaluate if these responses were conserved between these two model organisms; 2. to investigate how these responses varied between directly acting chemicals versus those that are metabolized throughout development. Fathead minnow and zebrafish were exposed to R-carvone (a directly acting compound with a Michael Addition mechanistic domain) or bisphenol-A (BPA, a metabolized, indirectly acting compound with a receptor-mediated mechanistic domain) following standardized toxicity guidelines from the Organization for Economic Cooperation and Development (OECD no. 236) for embryonic exposures and the US Environmental Protection Agency (EPA) for larval exposures. Eight studies were conducted to determine 96-h LC₅₀ values, which showed that zebrafish were more sensitive than fathead minnow embryos. R-carvone exposed to control and 40% of the 96-h LC₅₀ value. At 24, 48, 72, and 96 hours post exposure, observations were made and tissues collected for gene expression. These observations included mortality, hatching rate (embryos), and developmental deformity assessment. Expression of the measured OS associated genes using qPCR included gclc, gsp1, nrf2a, and sod1, using actb1 as a reference gene. R-Carvone, a directly acting compound, was more potent to embryos than larvae (e.g., fathead minnow embryos 4 times more sensitive than larvae). Conversely, BPA, a metabolized compound, was more potent to larvae than to embryos (i.e., zebrafish embryos 2 times more sensitive and fathead minnow almost 9 times). Hatching rate was delayed, though not statistically, following exposure to R-carvone. Both species exhibited developmental deformities following exposure to both compounds with a slightly higher prevalence following exposure to R-carvone. Results show that responses to study chemicals varied throughout development. Moreover, differences in toxicity of directly and indirectly acting compounds appear to be unique to age. Additional comparative studies are needed to better understand the uptake, metabolism and biological toxicity relationships among fish models and ages.

### 2010 Developmental Effects of Ortho-Substituted PCB-153: Evidence for Altered Glucose Homeostasis in PCB-Sensitive Killifish and in Zebrafish, but Not in PCB-Tolerant Killifish from a Superfund Site

M. E. Hahn¹, S. I. Karchner¹, C. C. Becker¹, N. Aluru¹, D. G. Franks¹, J. V. Goldstone¹, J. J. Stegeman¹, D. Champlin², D. Nacci², B. W. Clark³, S. Jayaraman³, V. Kartha³, and S. Monti³, ¹Woods Hole Oceanographic Institution, Woods Hole, MA; ²US EPA, Narragansett, RI; and ³Boston University, Boston, MA.

Atlantic killifish (*Fundulus heteroclitus*) inhabiting the New Bedford Harbor (NBH) Superfund Site have evolved resistance to toxic effects of ortho- (dioxin-like) polychlorinated biphenyls (DL-PCBs) and other compounds that act via the aryl hydrocarbon receptor (AhR). However, the majority of PCBs in NBH are ortho-substituted (non-DL, o-PCBs); their impacts on fish populations are not well understood. To determine whether the NBH killifish population has adapted to o-PCBs, we exposed embryos from NBH and a reference site (Scorton Creek; SC) to 2,3,4,4′,5,5′-hexachlorobiphenyl (PCB-153), a model o-PCB. Water-borne exposure of SC embryos produced embryo concentrations of PCB-153 equal to or greater than those in eggs of fish from NBH. PCB-153 was not acute cytotoxicity to developing F2 killfish (SC or NBH) at concentrations up to 28 μM. RNA-seq showed that SC embryos exposed to PCB-153 (28 μM for 6 h at 10 days post fertilization) had reduced expression of genes involved in glucose metabolism and homeostasis, which was not seen in the NBH embryos. In additional experiments, 10 dpf embryos from SC exposed to DMSO, 2.8 μM PCB-153, or 28 μM PCB-153 for 6 or 24 hours showed reduced expression of glucose metabolism genes. The low
concentration (2.8 µM) caused reduced expression following 6-hr exposures, while the high concentration (28 µM) increased expression after 24 hr. Parallel studies in 48-hpf zebrafish embryos exposed to PCB-153 (28 µM) for 6 or 24 hr revealed several genes that were down-regulated in common with SC killifish embryos, including genes involved in glucone metabolism and homeostasis, coagulation, and erythropoiesis, and several beta crystallin genes. The results suggest that PCB-153 may disrupt glucone homeostasis in developing embryos and that NBH killifish have reduced sensitivity to PCBs, suggesting complex adaptation to chemical mixtures at this Superfund site. Supported by P42ES007381 (Boston University Superfund Research Program) and US EPA.

2011 The Fate of Atmospheric Mercury (Hg) in Ephemeral Wetlands

D. T. Calloway1, C. Love2, D. Scott2, and S. Lance2. 1Fort Valley State University, Fort Valley, GA; and 2University of Georgia, Aiken, SC.

Bioaccumulation of mercury in aquatic food chains represents a risk both to human and wildlife that feed on fish or other aquatic organisms. Once in an environment, methylmercury (MeHg) can be formed from inorganic Hg by microbial action. MeHg is the most harmful and toxic form of Hg because it is the easiest for biota to accumulate. Mercury enters the environment from a multitude of ways including: industrial activities, mining, and atmospheric deposition. Water level fluctuation can increase levels of Hg in semi-permanent and permanent wetlands. Previous studies have focused on Hg accumulation in fish and thus did not examine wetlands that dry frequently. Such wetlands have hydroperiods ranging from 3-12 months and support tremendous biodiversity. What may be at risk of high levels of Hg exposure. Our goals were to determine if Hg levels in sediments and biofilms of ephemeral wetlands relate to hydroperiod and if Hg levels in sediments of wetlands are higher at the edge, due to increased water fluctuation. We sampled and sediments and biofilms in twelve southeastern ephemeral wetlands with hydroperiods ranging from long (9-12 month) to short (3-9 months). We sampled from three different locations within each wetland: edge, midway from center and the center. Samples were lyophilized, homogenized, sorted and weighed, and then put on a DMA 80 for mercury analysis. We found significant variation in Hg concentrations among the wetlands, but that variation was not explained by hydroperiod or location sampled for sediment or biofilm. There was a trend for shorter hydroperiod wetlands to have more Hg, but it was not a significant relationship. Contrary to our predictions, there was a trend of higher Hg in the center of the wetland, but again this was not significant. Additional studies are needed to investigate what is driving the wetland variation in Hg concentrations.

2012 Toxic Effects of Textile Waste Water Discharged on the Atoyac River: Zebrafish as Study Model

W. A. García-Suastegui1, A. Estrada-Rivera1, M. Gonsebatt1, and A. Handal-Silva1. 1Universidad Autónoma de Puebla, Puebla, Mexico; and 2Universidad Nacional Autónoma de México, México, Mexico.

70 percent of mexican’s rivers are polluted, mainly due to discharges of industrial waste water. In the states of Puebla and Tlaxcala, the textile industry has contributed to the pollution of Atoyac river due to extremely high water consumption and the complex combination of danger substances used and deposited in the river without previous treatment. The region of river located in Villa Alta (between the limits of Puebla and Tlaxcala) is very polluted, consequently its population has serious health problems. The aim of this work is to evaluate the toxicity of the textile residual water waste, using zebrafish (Danio rerio) as study model. We calculate the average volume of textile waste water discharged into the river, as 1.12 L/s, equivalent to 2,903,040 L/month. Water samples from textile waste water discharges were obtained in dry season, we measured 18 physicochemical parameters, some of which exceed the maximum permissible limits established by the Mexican Official Standard for wastewater discharges (NOM 001-SEMARNAT-1996); among them: total nitrogen 62.43 mg/L, sedimentary solids 400 mg/L, fat and oils 38.28 mg/L, Biochemical Oxygen Demand (BOD5) 969.33 mg/L, Chemical Oxygen Demand (COD) 6272 mg/L, Total Suspended Solids (TSS) 5250 mg/L. The average concentration of dyes in textile waste water was 0.0104 ppm, temperature 28 °C and pH = 7.33. Toxicity was determined through lethal dilution 50 (LD50) test, 15.2/40 L was the LD50 of textile waste water for zebrafish. Our preliminary results show that water discharged into the Atoyac river is toxic and lethal. This water affects liver and gills morphology of zebrafish, demonstrating a potential risk along the whole zone, where the river provides for agriculture and other human activities.

2013 Toxicity Effects of Leachate of Cigarette Butts on Caenorhabditis elegans and Its Use as Adsorbent of Methylene Blue

Cigarette butt (CB) waste is a public health problem because they contain chemical compounds that are toxic to living beings, moreover when they are released to water, they can adsorb other pollutants, being a risk to aquatic life; however, this risk has been understudied. In this research, cigarette butts were collected in two beaches of Cartagena (Colombia), Playa Blanca (PB) and Punta Arena (PA), and their ethanolic leachates were obtained by Soxhlet extraction. Caenorhabditis elegans was exposed to these leachates and the number of dead and alive worms after 24 hr was counted. New (NCB) and recently smoked cigarette butts (SCB) were used as control. In addition, SCB was used as adsorbent of methylene blue in an aqueous solution (0.25%) in order to evaluate their potential use in wastewater treatment. The leachate of CB decreased survival in a concentration dependent manner. The effect was major in nematodes exposed to PA and PB than those to SCB and NCB, indicating the presence of more pollutants probably adsorbed from the water. SCB leachate was more toxic than NCB, suggesting that toxic compounds from the cigarette passed to the butt during smoking. The adsorption efficiency of methylene blue by SCB was of 52%, and the toxicity of methylene blue solution (0.25%) on C. elegans was reduced from 100% to 75% after treatment with SCBs. In conclusion, the CBs are able to adsorb toxic compounds from the cigarettes and pollutants from the water environment, and this feature can be used to clean waste waters. GRANT 115 2017, Vicerrectoria de Investigaciones, Universidad de Cartagena.

2014 Alterations in Neuro and Interrenal Steroidogenic Responses in African Catfish (Clarias gariepinus) following Long-Term Exposure to Waterborne Di-(2-ethylhexyl) Phthalate

A. O. Adeogun1, O. R. Ibor2, and A. Arukwe2. 1University of Ibadan, Ibadan, Nigeria; 2University of Calabar, Calabar, Nigeria; and 3Norwegian University of Science and Technology, Trondheim, Norway.

We have investigated the effects of long-term exposure to waterborne di-(2-ethylhexyl) phthalate (DEHP) on sex and organ-specific steroidogenic responses in Clarias gariepinus exposed to waterborne DEHP at 0 (control), 10, 100, 200, and 400 µg/L for 84 days. Alterations in gonad and head kidney steroidogenic protein (STAR) and enzyme gene expressions for P450scC, cyp17, cyp19a1, 3β-, 11β-, 17β- and 20β- hydroxysteroid dehydrogenase (HSD) and 17β-HSD were analyzed using real-time PCR. Star, P450scC, and CYP19 protein levels were analyzed using immunohistochemical method with specific antibodies. Cellular steroid hormone (E2 and T) levels were analyzed using enzyme immunoassay. We observed alterations in key steroidogenic protein and enzyme genes that were apparently dependent on DEHP concentration, time, and organ. Generally, these responses increased significantly at 10 µg/L compared to control group, and decreased thereafter in an apparent concentration-specific manner, for most variables, except for T and CYP19 protein, that decreased with increasing DEHP concentration. Interestingly, all measured responses showed a higher gonadal sensitivity compared with the head kidney, indicating organ-specific response pattern. The alterations in steeroidogenic genes and proteins demonstrated in the present study could have severe implications on the production of steroid hormones with probable downstream negative effects on adaptation, sexual maturation and reproduction.

2015 Champoton River’s Water and Soluble Soils Components Toxicity by L. sativa Bioassay

The aim for this study is to evaluate toxicity indicator in seed germination and root elongation in lettuce seeds exposed to water and soils-water solutions of Champoton’s river as alternative to determine toxicity in water. The Champoton River is localized at Campeche State of Mexico country, the most important activity in the river basin is agriculture of sugar cane, also fishing and tourism. The sampling was carried out in...
two sites, CR2 was localized upstream from the most popular swimming area and CR1 was downstream. For each sampling site, 500 mL water sample at 10 cm of deep to surface and 10 cm² of soil were collected. The experiment consisted in 2 water and 2 water-soil samples, 3 treatments per sample at 100, 50 and 25% of initial solution concentration with duplicate and control of distilled water for a total of 30 experimental units. For each unit, 25 seeds of Lactuca sativa were placed in a 90 mm diameter polyethylene containers, with filter paper in the bottom as the support. Afterward 10 mL of the different solution concentration were applied. All units were kept in controlled ambient temperature of 24 °C ±1, for 120 hours. In general, no phytotoxic effects were observed on the percentage of germination among the 4 different samples, there was not significant difference with respect to the control, however, the water solutions for both sites caused a 76% reduction in root elongation, meanwhile water-soil dilutions caused 35%. The inhibitory concentration 50 (IC₅₀) of water sample of CR2 site in roots elongations was 65% and 85% at CR2 site. These results indicate that further studies of toxicity are necessary due to the presence of possible toxic agents in river water.

### 2016 Repellent Activity of Four Colombian Essential Oil on Tribolium castaneum Herbst

B. J. Arroyo1, B. E. Jaramillo-Colorado1, F. M. Palacio-Herrera1, J. L. Medrano-Ochoa1, and N. Pino-Benítez2. 1University of Cartagena, Cartagena, Colombia; and 2Technological University of Chocó, Chocó, Colombia.

Investigations have been carried out on essential oils and their components as repellents and fumigants, against insects from stored products as the weevil of Tribolium castaneum Herbst. They are the most widespread and destructive stored product pests, causing damage to storage grains directly by feed and indirectly by the secretion of quinones that are responsible for human allergies. The objective was to evaluate the volatile chemical composition of the essential oil from four plants in the department of Chocó: Croton chocoanus, Croton cabi sp, Croton pacurita, Piper pacurita, Piper hispidum and to evaluate their repellent activities against the weevil of the flour Tribolium castaneum. The extraction of essential oils was done by the hydrodistillation method, the volatile chemical composition was carried out using gas chromatography coupled to mass spectrometry and the repellent activity was evaluated by the method. Each of these tests was carried out in order to analyze the percentage of repellency of the essential oils from the species tested with respect to the commercial repellent. The principal compounds found were: Croton chocoanus Croizat, β-linalool (5.7%), α-terpineol (4.0%), 4-O-H Eudesmane (19.9%), aristolene (5.3%), trans-calamenene (7.7%), Croton cabi sp: linalool (28.0%), eucalyptol (13.35%), caryophyllene oxide (8.16%); Croton pacurita: Spatulenol (12.78%), Aromandendrene (8.09%); Piper hispidum:3-carene (35.3%), Limonene (27.1%). Essential oil (Croton cabi sp and Piper hispidum) show the majority repellent activity (90% and 84%, respectively at 1% of concentration), followed by Croton pacurita (83%) and Croton chocoanus (81%). The results show that the essential oils presents more repellent activity against Tribolium Castaneum than the commercial repellent (Ethyl butylacetaminopropionate) its repellent activity at 1% of concentration and two hours of exposure was 70%. Piper hispidum and ethanol stem bark extract of Khaya senegalensis (KNE) was also assessed. The cells were treated with graded concentrations of AFB₃, SA, curcumin, and K2S for 25, 48 and 72 h. At optimum cytotoxic concentrations, cells were exposed to toxicants with influence of non-toxic concentrations of curcumin and K2S determined. Cytotoxicity was assessed by Hoechst/PI staining technique and changes in adenosine triphosphate levels determined using Promega’s CellTiter-Glo Assay. Pre-treatment of cells with curcumin and K2S before exposure to AFB₃ reduced cytotoxicity by 3.5- and 2.9-folds, while post-treatment resulted in 1.1- and 1.3-folds reduction, respectively. Pre-treatment of cells with curcumin and K2S before exposure to SA reduced cytotoxicity by 3.8 and 3.0-folds, while post-treatment resulted in 1.2- and 1.3-folds reduction, respectively. Overall, pre-exposure of the cells to curcumin and K2S exhibited cytoprotective effects with inferred tendencies to prevent carcinogenesis.

### 2017 Curcumin and Khaya senegalensis Mitigate Cytotoxicities Induced by Aflatoxin B₁ and Sodium Arsenite in HUC-PC Urinary Bladder Cells

J. O. Olugbami1, R. Damaiseaux2, F. Bryant2, W. Yu2, S. Sharma3, M. A. Gbadegesin1, J. Rao2, O. A. Odunola1, J. K. Gmeziewski2, and A. O. Uvafo1. 1University of Ibadan, Ibadan, Nigeria; and 2University of California Los Angeles, Los Angeles, CA.

The inadvertent co-exposure to certain environmental/occupational toxicants, such as aflatoxin B₁ (AFB₁) and sodium arsenite (SA), in some regions is inevitable. Hence, the need to assess the efficacy of easily accessible, affordable, and relatively safe agents such as phytochemicals with known ethnomedicinal applications. Cytotoxic interaction between AFB₁ and SA in bladder cells was investigated. Cytotoxicity effect of curcumin and ethanol stem bark extract of Khaya senegalensis (KNE) was also assessed. The cells were treated with graded concentrations of AFB₁, SA, curcumin, and K2S for 25, 48 and 72 h. At optimum cytotoxic concentrations, cells were exposed to toxicants with influence of non-toxic concentrations of curcumin and K2S determined. Cytotoxicity was assessed by Hoechst/PI staining technique and changes in adenosine triphosphate levels determined using Promega’s CellTiter-Glo Assay. Pre-treatment of cells with curcumin and K2S before exposure to AFB₁ reduced cytotoxicity by 3.5- and 2.9-folds, while post-treatment resulted in 1.1- and 2.6-folds reduction, respectively. Pre-treatment of cells with curcumin and K2S before exposure to SA reduced cytotoxicity by 3.8 and 3.0-folds, while post-treatment resulted in 1.2- and 1.3-fold reduction, respectively. Overall, pre-exposure of the cells to curcumin and K2S exhibited cytoprotective effects with inferred tendencies to prevent carcinogenesis.

### 2018 Effect of Arsenic on Thermogenesis and Metabolic Health

F. Castriota1, S. Sanchez2, R. Lee3, J. Wang1, M. T. Smith1, and M. A. La Merrill2. 1University of California Berkeley, Berkeley, CA; and 2University of California Davis, Davis, CA.

The prevalence of type 2 diabetes (T2D) has nearly doubled since 1980. Poor nutrition, sedentary lifestyle, and obesity are among the significant risk factors for the development of this metabolic disease. Environmental pollutants however, also have the potential to alter glucose homeostasis and lead to the development of T2D. Arsenic is one of these chemicals, with epidemiological studies worldwide supporting this association. While the precise mechanism of action by which arsenic exhibits its diabetogenic effects remains unclear, we propose arsenic impairs thermogenic tissues involved in insulin sensitivity and glucose tolerance. The objective of this study was to address the effects of chronic arsenic ingestion on cellular metabolism in the adipose depot associated with thermogenesis. Since cold is a key activator of these thermogenic tissues, we hypothesize arsenic alters metabolic heat production in mice exposed to settings with decreased temperatures. To test this, we administered 300 parts per billion (ppb) of sodium arsenite to C57BL/6J male mice beginning at 5-6 weeks of age, and assessed their metabolic phenotype via the use of indirect calorimetry and body composition analyzers. After 15 weeks of exposure, arsenic treatment revealed significantly decreased lean body mass despite unchanged whole body adiposity. When challenged by cold tolerance testing (e.g. at 30, 23, 12, and 4 degrees Celsius), arsenic-treated mice showed significantly lower energy expenditure and oxygen consumption parameters. Chronic arsenic treatment also decreased core body temperatures during acute cold exposure. Caudal assessment revealed greater unilocular lipid droplets in arsenic exposed mice, suggesting a decrease in brown-like adipocytes. These findings support the hypothesis that continuous low-dose arsenite exposure disrupts energy homeostasis and adaptive thermogenesis in vivo.

### 2019 Neurobehavioral Effects of Neonicotinoids on Embryo-Larval Zebrafish at Environmentally Relevant Concentrations

M. M. McManus, J. E. Cañas-Carrell, and J. Crago. Texas Tech University, Lubbock, TX. Sponsor: K. Singh

Neonicotinoids are common surface water contaminants in both urban and agricultural landscapes. Mean stream concentrations in the US were recently reported at 175 ng/L and 66 ng/L for imidacloprid and clothianidin, respectively (Bradley et al., 2017). Neurobehavioral effects on larval fish are known to occur at concentrations higher than those reported; however, behavioral effects have yet to be investigated at environmentally relevant concentrations. For this ongoing study, the developmental neurobehavioral effects of neonicotinoid exposure on embryo-larval zebrafish (Danio rerio) were assessed using a larval zebrafish behavior assay. Three of the most common neonicotinoids (clothianidin, imidacloprid and thiamethoxam) and two environmental imidacloprid metabolites (desnitro-imidacloprid and 6-chloronicotinamide) were assessed individually and as part of environmentally relevant mixtures. Embryos were exposed to neonicotinoids at 1000, 100, 1, 0.1, 0.01 µg/L starting at 4 h post-fertilization (hpf) to 3 d post-fertilization (dpf). Behavior assays assessing swimming behavior (distance traveled and velocity) were conducted at 5 dpf. Data were analyzed using one-way ANOVA with Tukey HSD post hoc test. Zebrafish larvae traveled a significantly greater distance at 1000 µg/L Imidacloprid (p < 0.05) compared to 100, 10, 1, 0.1, 0.01 µg/L. All treatments groups traveled greater distance than the control group. Velocity of larva exposed to 1000, 100, 1 µg/L imidacloprid were significantly higher than those in the lowest treatment group 0.01 µg/L. All treatments groups traveled greater distance than the control group. Velocity of larva exposed to 1000, 100, 1 µg/L imidacloprid were significantly higher than those in the lowest treatment group 0.01 µg/L and control group. The results for the other neonicotinoids, imidacloprid metabolites, and mixtures are forthcoming; however, the preliminary imidacloprid data indicates that larval exposure to neonicotinoids causes behavioral changes at 1000 µg/L and may also cause behavioral changes at lower, more environmentally relevant concentrations.
Metals are one of the most abundant pollutants in river sediments in countries with mining activity, and their toxicity could differ when they are in a complex mixture. In Colombia, San Jorge River is an important freshwater source that receives polluted waters from nickel mining. In this study, sediment samples were collected in twelve sites along the San Jorge River and analyzed for 47 metals. Sediment metal concentrations were compared with the threshold effect concentrations, TEC, the midpoint effect concentration, MEC, and the probable effect concentration, PEC, for freshwater sediments. The level of metal contamination was determined by calculating the contamination factor, fi; pollution load index, PLI; and the potential ecological risk index, RI. Toxicity assessment was carried out exposing Caenorhabditis elegans to pore water samples obtained by centrifugation, evaluating survival, growth, locomotion, and changes in the expression of stress response genes using gfp transgenic strains. Samples taken near the nickel mine showed Cr and Ni concentrations above the PEC. According to fi, most sampling sites have high contamination by B, Se, Sh, and W. Regarding RI, eight locations were moderately polluted by Cd. Pore water samples affected the growth, locomotion, and survival of C. elegans. Samples from Boc de Ure increased the expression of mit-2 and sod-4 compared to control. Ni and Cr were associated with survival, and the expression of stress response genes, while V, Sc, Co, Ga, Ge, Se, Y, Zr, Nb, Mo, Mo, Eu, Tb, Dy, Ho, Er, Tm, Yb, Lu, Hf, and Ta were strongly correlated with all toxicological effects on C. elegans. In conclusion, the presence of metals in San Jorge River sediments was associated with the toxicity on the biological model C. elegans. Colciencias 110771451049.

Microplastic pollution is a growing problem in the oceans of the world, as these particles impact marine biota at most trophic levels. Despite their widespread distribution, few studies have been carried out in the Caribbean. The objective of this research was to determine the distribution of microplastics on beaches and fish from Cartagena, Colombia. Pellets were obtained from two different places, classified according to color and characterised based on their surface features and IR spectra. White pellets, mostly composed of polyethylene or polypropylene were the most abundant, although some displayed signs of degradation with oxidation-related characteristics. Black pellet samples were subjected to extraction with organic solvents, and the GC-MS analysis revealed the presence of several high molecular weight hydrocarbons, eicosane, heneicosane, tetracosane; terpenoids, organometallic compounds, hormones, pesticides and phthalates, among others. The stomach content of several carnivorous fish species was scrutinized and showed the presence of microplastic fibers of different nature. Water- and methanolic-based extracts from granular pellets exhibited several toxicological effects on Caenorhabditis elegans, suggesting these particles release and accumulate chemicals than can be leached inside the body of organisms that eat them. Both pellets and fibers represent toxicological hazards for marine life, and therefore different actions must be taken to avoid their incorporation into the oceans. UniCartagena (2016-2017), Colciencias, 647-2014.

Panama Channel has been a milestone in world history as it has shortened the distance and navigation time between nations. Despite these benefits, there are environmental risks associated with the emission of air and water pollutants by the shipping and associated industrial activities. In order to determine the relationship between the composition of trace elements and the toxicity of the surface sediments at Panama Channel basin, sampling was carried out in twelve points from November to December 2016 and analyzed for 47 trace elements by ICP-MS, and total Hg in a Direct Mercury Analyzer. Sediment fractions were also extracted with water and their toxicity evaluated on wild type and mutant strains of Caenorhabditis elegans. Results showed some environmentally-relevant elements had the greater concentrations in sediments, decreasing in the order Sr>V>Zn>Ba>Cu>B>Zn>Cr>Hg. Sediment aqueous extracts inhibited locomotion of C. elegans, in particular the sample from Gatun Lake, and induced expression of oxidative stress and metal exposure-related genes. A multiple linear regression model suggested the relative expression of metallothionein-2 is a function of As, Sn and Co concentrations. In short, sediments from Panama Channel basin possess high potential to activate toxicity mechanisms associated with the production of metallothioneins and oxidative stress, processes that can negatively affect the viability of benthic organisms. UniCartagena (2016-2017), Colciencias, 647-2014.
Breast cancer is a heterogeneous disease and accounts for 25% of all cancer cases. Current treatment options target either the estrogen receptor or the human epidermal growth factor 2 receptor. To date there is no FDA-Approved targeted treatment for triple negative breast cancer (TNBC), which has a poor prognosis. Hence, this study focused on second-generation curcumin analogue, RL71, in a nanomicellar form for TNBC treatment. Previous studies have shown RL71 to have submicromolar cytotoxicity in TNBC cells, however, no regression in tumor growth was demonstrated in vivo following daily oral administration for 70 days. Styrene-co maleic acid was used to encapsulate RL71 (SMA-RL71), to take advantage of the enhanced permeability and retention effect, and was administered intravenously twice a week for 24 days in a xenograft model of TNBC. Nicotine, a major component of tobacco, significantly increased proliferation between the effect of SMA-RL71 (10 mg/kg) and duration of treatment on the suppression of tumor growth via molecular mechanisms including anti-angiogenic and pro-apoptotic effects, as well as inhibition of EGFR and AKT/mTOR/4EBP1 signaling. GNL1 is a member of the HSF1 transcription factor family. GTPases including GNL3 and of subfamilies GNL1 and GNL3 are associated with breast cancer and localized in the nucleus which promotes G1 to S phase transition of cells or cell proliferation by the wnt/beta-catenin pathway, respectively. However, GNL1 is a nucleocytoplasmic shuttling protein localized in the nucleus at the G2-phase of cell cycle but its function is unknown. The effect of SMA-RL71 on the protein expression of GNL1 was investigated in vivo and in vitro due to previous work showing an increase in gene expression in vitro. GNL1, was downregulated upon SMA-RL71 (10 mg/kg) treatment in TNBC tumors. Its expression was also decreased 55% in MDA-MB-231 and 82% in HSS578i cells treated with SMA-RL71 (1 μM) for 24 h. Furthermore, to determine if GNL1 could be a potential therapeutic target, a G-protein inhibitor, Brefeldin-A was used. Brefeldin-A showed an IC50 of 56 nM and 49 nM on MDA-MB-231 and HSS578i TNBC cells, respectively using sulforhodamine B assay. Brefeldin A (0.1 μM) further inhibited the expression of GNL1 protein by 48% in MDA-MB-231 and 45% in HSS578i by western blotting after 24 h of treatment. GNL1 may therefore play important role in tumorigenesis and serve as a potential therapeutic target for TNBC.

Orally Administered Nicotine Effects on Rat Urinary Bladder Proliferation and Carcinogenesis

S. Suzuki1, S. M. Cohener2, S. Fuji3, L. L. Arnold2, K. L. Pennington2, and S. Takahashi3. 1Nagoya City University Graduate School of Medical Sciences, Nagoya, Japan; and 2University of Nebraska Medical Center, Omaha, NE.

Tobacco smoking is a major risk factor for human cancers including urinary bladder carcinoma. Cigarette smoke inhalation in mice and orally administered nicotine in rats and mice increased urothelial cell proliferation. Nicotine, a major component of tobacco, induced proliferation in multiple cell types in vitro. In the present study, the enhancing effects of nicotine on F344 rat bladder carcinogenesis induced by N-butyl-N-(4-hydroxybutyl)nitrosamine (BNB) were examined. Nicotine administered in drinking water for 32 weeks following 4 weeks of BBN treatment significantly increased the incidence of bladder tumors and the number of the BBN-induced bladder carcinomas dose-dependently. Ki67 and PSTAT3 labeling indices and expression of nicotinic acetylcholine receptor alpha 7 (nAChRα7) in non-tumor bladder urothelial lesions were significantly increased by nicotine, but the TUNEL assay for apoptosis showed no increase. In a 4-week study, nicotine did not express nicotine receptors below micromolar concentrations, nor in human RT4, T24 or UMUC3 urothelial carcinoma cells (express nicotine receptors). However, nicotine slightly, but statistically significantly, increased cell proliferation at micromolar concentrations in human urothelial carcinoma cells. These data suggest that nicotine enhances urinary bladder carcinogenesis by inducing cytotoxicity with regenerative proliferation and possibly direct mitogenesis, which may involve nAChR and STAT3 signaling. The role of nicotine receptors appears uncertain.

SMA-RL71 Downregulates GNL1 following Tumor Suppression in a Xenograft Model: A Potential Therapeutic Target in Triple Negative Breast Cancer

Although induction heating devices and wireless power transfer systems utilizing intermediate-frequency magnetic fields (IFMFs) are widely used, assessment of health risks associated with exposure to these magnetic fields has been insufficient. Previous studies involving rats demonstrated the absence of toxicities for up to 18 months. The purpose of this study was to assess the carcinogenicity of these IFMFs, because other lines of evidence have indicated a lack of carcinogenicity in both male and female B6C3F1 mice. In addition, the tumor ratio (TR) of 0.005 was used as an endpoint for tumor incidence, and the differences were significant. Mice were divided into nine groups with four replications each. The treated groups were exposed to a 20-mW/m² vertical field with a uniform horizontal intensity of 150 μT. A 4-mm cellulose acetate filter was used to filter out the 50-Hz power line. Four horizontally layered Merritt-type coils produced a very uniform vertical field with a sinusoidal waveform and the adopted field strength was 7.4-fold greater than that in the exposure guidelines for the public set by the International Commission on Non-Ionizing Radiation Protection in 2010. Experimental procedures were performed, including histopathological evaluations, were conducted by a blinded GLP-licensed laboratory to assure toxicological quality. In accordance with the Standards Related to the Care and Management of Experimental Animals, moribund animals were euthanized during the exposure, and surviving mice after the exposure were sacrificed for complete necropsy. Tissues and organs were excised and examined macroscopically and microscopically. Histopathological examinations revealed spontaneous neoplastic lesions, either benign or malignant, in field- and sham-exposed male and female mice. Observed neoplastic lesions included hemangiosarcomas in the spleen and thymus, squamous cell papillomas of the stomach, and malignant lymphomas. The frequencies of the neoplastic lesions were 1 to 3 per group. No statistically significant differences were found between the field- and sham-exposed groups. In the positive control group, malignant lymphoma bearing metastasis manifested in 8 out of 10 males and in all 10 females. The results indicate no carcinogenicity of IFMF exposure in rhesi2 transgenic mice.

Toxicogenomics Study of Pentabrominated Diphenyl Ether in Rat Liver during Early Life Exposure

K. R. Shockley. NIHES, Research Triangle Park, NC. Sponsor: J. Dunnick

Pentabrominated diphenyl ethers (PBDEs) have been used as flame retardants in polyester foams and other household products, leading to continued widespread exposure in the United States. Early-life exposure to PBDEs has been associated with loss of Intelligence Quotient and altered thyroid hormone levels. In 2-year studies, a PBDE mixture (DE-71) caused liver tumors and liver fatty change in male and female Wistar Han rats and B6C3F1/N mice. The PBDE mixture reduced serum thyroid hormone (T4) levels in a 13 week study in male and female F344/N rats, and induced genes involved in xenobiotic metabolism and reduced genes associated with lipid metabolism in rats in a separate study. In humans, the most prevalent PBDE congener is pentabrominated diphenyl ether-47 (PBDE-47). Here, PBDE-47 and PBDE mixture liver toxicity was characterized at PND22 in Wistar Han rat pups after in utero/postnatal exposure (0, 0.1, 15, or 50 mg/kg; dams, GD6-21; pups, PND12-PND21; oral gavage daily dosing). We found that PBDE-47 induced liver fatty change and T4 levels, similar to that previously observed with exposure to the PBDE mixture. Global gene expression patterns in the liver were obtained using the Affymetrix Rat Genome 230 2.0 Array platform. There were 628 differentially expressed gene transcripts between control and BDE-47 (50 mg/kg): at a false discovery rate threshold of 5%. These transcriptional changes were associated with the induction of cytochrome p450 enzymes that metabolize xenobiotics to more water-soluble compounds, Nr2f2-mediated oxidative stress response and ABC transporters involved in xenobiotic exporter systems. Downregulation of ABC liver transport genes provided a plausible mechanism for lipid accumulation, characterized by a treatment-related
increase in hepatic steatosis. The upregulation of the Nrf2 antioxidant pathway and changes in metabolic transcripts after PBDE-47 and PBDE mixture exposure seen in this study suggest that PBDE-47, like the PBDE mixture (National Toxicology Program 2017, Technical Report 589), might also be a liver carcinogen after continued long-term exposure.

2029 The Role of EGFR and AKT Activation in Cadmium-Induced Prostate Carcinogenesis

C. Damodaran, V. Kolluru, A. Tyagi, B. Chandrasekaran, and J. H. Freedman. University of Louisville, Louisville, KY.

Cadmium is a non-essential metal and significant correlations between chronic cadmium exposure and the risk of human prostate cancer have been reported. Although an association has been established, the molecular mechanism by which this metal induces cellular transformation has yet to be delineated. One underexplored process that may be affected by cadmium is EGFR/AKT activation and autophagy. Autophagy promotes cancer cell survival (oncogenic autophagy) by protecting cells from nutrient deprivation, starvation, and oxidative stress. The aim of the study is to understand the molecular mechanisms of cadmium-mediated prostate carcinogenesis by focusing on the unexplored roles of EGFR activation on autophagy. Acute exposure to cadmium significantly inhibited the growth of RWPE-1 cells. In contrast, CTPE cell growth was not significantly affected, suggesting that these cells are resistant to cadmium. Induction of EGFR and AKT-activation with concomitant upregulation of autophagy markers were evident in CTPE cells. These molecular events correlated with the induction of autophagy. Similarly, immunohistochemical staining showed increased expression of EGFR, AKT, Plac8, LC3B and Lamp2 in cadmium CTPE tumors confirming our in vitro findings. CTPE cells challenged with EGFR and AKT inhibitors demonstrated significant growth inhibition and downregulating EGFR, AKT and autophagy signaling. Autophagy inhibitors however, did not affect EGFR and AKT expression resulting resistance in CTPE cells. Finally, the levels of EGFR/AKT and other autophagy proteins in human prostate cancer were analyzed, which correlated with aggressiveness of the prostate cancer. The results suggest that EGFR and AKT activation may responsible for pro-survival function of autophagy, inhibition of these signaling may inhibit cadmium-induced prostate carcinogenesis.

2030 Novel Strategies for the Treatment of Crizotinib Resistant EML4-ALK+ Lung Cancer

Receptor tyrosine kinases (RTKs) have been discovered to play a role in the development of cancer through the generation of an oncogenic RTK. The anaplastic lymphoma kinase (ALK), which usually fuses with EML4 produces a specific subtype of lung cancer found in 2-7% of patients. Crizotinib is the first-line treatment for ALK+ lung cancer with a greater progression free survival and overall response rate compared to standard chemotherapy. However, acquired resistance usually develops within 12 months. We investigated the antitumor activity of two distinct drug classes; novel curcumin derivatives (RL66 and RL118) and the combination of crizotinib with a MEK inhibitor, selumetinib. The sulfonofuridine B assay was performed to investigate cytotoxicity. ALK+ H3122 cells exhibited greater sensitivity to RL66 and RL118 with IC50 values of 0.97 and 0.70 µM, respectively, when compared to ALK- A549 cells (2.65 and 1.15 µM, respectively). Interestingly the crizotinib resistant cells were sensitive to RL66 and RL118 (2.15 and 1.44 µM, respectively) when compared to crizotinib, which had a 13-fold increase in the IC50 compared to the parental H3122 cells. We concluded from these results that the mechanism of RL66 and RL118 toxicity does not involve direct effects on ALK. We also investigated the effect of the combination of crizotinib and selumetinib in H3122 and A549 cells. The combination had a synergistic cytotoxic effect. In the ALK- A549 cells no synergism with the combination was found showing the combination is specific to ALK. Further analysis using crizotinib resistant cells demonstrated that the combination of crizotinib and selumetinib was more potent than crizotinib alone, allowing a synergistic growth suppression of the cells. Western blotting and densitometry revealed that the protein expression of p-ALK and p-ERK decreased with the combination compared to the control treatment. From these results we can conclude that the combination of the two drugs has potent cytotoxic effects in parental ALK+ cells and crizotinib resistant cells. RL118 has a greater anticancer effect compared to RL66 and the mechanism of these compounds is under further investigation. Also the combination of crizotinib and selumetinib shows a promising therapy for crizotinib resistant ALK+ lung cancers.

2031 A Saturated Fat Diet Promoting Hepatic Cancer in a Mouse Model Is Associated with Increased Hepatic Expression of the Proto-Oncogene AGAP2

A. Patel1, K. Pedersen1, C. Pulliam1, C. Hicks1, K. Shankar1, U. Wankhade2, and M. Ronis1. 1Louisiana State University Health Sciences Center, New Orleans, LA; and 2University of Arkansas for Medical Sciences, Little Rock, AR.

The dietary effects of different fat types on mechanisms driving the progression of hepatic tumors is poorly understood. A mouse model of chemical carcinogenesis was used in the current study. Male C57BL/6 mice were given a single 10 mg/kg i.p. injection diethylnitrosamine (DEN) on postnatal day 13. The mice were subsequently fed at low fat (10%) control diet or various high fat (35%) diets. The fats in the high fat diets were of four different types: corn oil (polyunsaturated omega-6 fat), cocoa butter (saturated fat), olive oil (monounsaturated fat), and corn oil + DHA (omega-3 and omega-6 fats). We previously observed that feeding the saturated fat diet with cocoa butter for 30 weeks promoted tumorigenesis specifically relative to the other high fat diets (P<0.05). We subsequently hypothesized that the cocoa butter diet alters expression of genes promoting tumorigenesis in the liver. RNA-Seq analysis of a subset of the mice livers demonstrated the expression of 7 genes, AGAP2, VDli, lild2, Cyp4a14, Cyp4a16, Cyp5a11, and Chnn4 were altered at least 2-fold in cocoa butter fed males compared to males fed other high-fat diets (P<0.05). We performed qRT-PCR analysis of these genes from all the mice in the study, which confirmed the altered expression as indicated by RNA-Seq. AGAP2 (ArfGAP with GTPase domain, anykinin repeat and PH domain) 2 seemed the most interesting gene, as it is a proto-oncogene, i.e. a gene that promotes cancer if over-expressed. It encodes a GTP-binding protein that is a phosphoinositide 3-kinase enhancer (PIKE). Furthermore, AGAP2 had highest expression in males fed the cocoa butter diet and showed the highest correlation among the 7 genes (R= 0.494, p < 0.001) with the number of visible liver tumors. We also extracted liver RNA from mice fed high-fat diets for just 15 weeks before visible tumors appear. The highest expression of AGAP2 at 15 weeks was likewise observed in males fed the cocoa butter diet, indicating that increased AGAP2 expression is a consequence of the dietary regime and not the cancer phenotype. We conclude that AGAP2 expression is stimulated by the cocoa butter diet, indicating that increased AGAP2 expression is a consequence of the dietary regime and not the cancer phenotype. We conclude that AGAP2 expression is stimulated by the cocoa butter diet, indicating that increased AGAP2 expression is a consequence of the dietary regime and not the cancer phenotype. We conclude that AGAP2 expression is stimulated by the cocoa butter diet, indicating that increased AGAP2 expression is a consequence of the dietary regime and not the cancer phenotype. We conclude that AGAP2 expression is stimulated by the cocoa butter diet, indicating that increased AGAP2 expression is a consequence of the dietary regime and not the cancer phenotype.

2032 Aberrant DNA Methylation in Radon or Cigarette Smoke-Induced Maglinant Transformation in BEAS 2B Cell

J. Li, and Y. Chen. Soochow University, Suzhou, China.

It is well known that cigarette smoking and/or radon induce malignant transformation in lung cells. To investigate the mechanisms underlying lung carcinogenesis induced by cigarette smoke (CS), radon (Rn); or Rn followed by CS using BEAS-2B cell line derived from human bronchial epithelial cells. BEAS-2B cells were exposed to either R (20,000 Bq/m3) for 30 min or CS (20%) for 10 min or Rn followed by CS for 40 min. Global and gene-specific DNA methylation modifications were measured by microarray and methylation-specific polymerase chain reaction (MSP). Cell cycle and apoptosis were determined by flow cytometry, while soft agar colony formation was conducted to assess the characteristics of malignant transformation. Data demonstrated global hypomethylation as well as gene-specific DNA methylation alterations in all treatment groups compared to unexposed control cells. In addition, Rn and CS produced DNA hypermethylation of protein tyrosine phosphatase receptor type M (PTPRM) and ectodysplasin A2 receptor (EDAR2), two genes related to malignant transformation. In all treatment conditions, cell proliferation and survival of malignant cells was increased, while apoptosis was initially first passage elevated but decreased at passages 5-15. Our results indicate that aberrant DNA methylation plays an important role in Rn- and/or CS-induced malignant transformation. In addition, BEAS-2B cell line may be used as an in vitro model to investigate mechanisms underlying malignant transformation induced by ambient environmental contaminants.
Obesity is a global epidemic with a predicted rate of 42% in the USA by 2050. Epidemiological studies show that obesity is a risk factor for developing cancer, however; the molecular mechanism has not been fully elucidated. Our published data demonstrate that fibroblast growth factor-2 (FGF2) released from fat cells (adipocytes) in the visceral adipose tissue (VAT) induces transformation/tumorigenicity in the skin and mammary epithelial cells. Specifically, FGF2 released from VAT stimulates epithelial cell growth in soft agar by inducing the proto-oncogene c-Myc. Growth in soft agar is a measure of transformation/tumorigenicity; neither transformation nor c-Myc induction in epithelial cells was reversible. c-Myc overexpression can initiate a process of genetic instability linked to tumor initiation. Our discovery of this novel direct path of VAT-stimulated tumorigenesis adds mechanistic insight to our earlier discovery that VAT secretions promote UV-induced non-melanoma skin cancer. The objective of our current study was to determine the mechanism by which FGF2 stimulates malignant transformation. We hypothesized that FGF2 from VAT induces c-Myc and subsequent genomic instability in epithelial cells leading to increased carcinogenesis. To test hypothesis we generated a filtered conditioned-medium from the human VAT, treated MCF-10A (mammary epithelial) and J86 P+ (skin epithelial) cells and measured several downstream mediators of FGF2 and FGF2 receptor. Following VAT treatment, epithelial cells demonstrated induced c-Myc protein expression along with ROS accumulation, elevated γ-H2AX foci, and increased micronucleus (MN) formation. We found that inhibition of c-Myc attenuated VAT-induced neoplastic transformation of MCF-10A and J86 P+ cells, while constitutive activation of the c-Myc induced spontaneous neoplastic transformation of J86 P+ cells. Collectively, our data suggested FGF2 released from VAT interacts with FGFFR-1 and activates c-Myc. The role of c-Myc in the formation of MN and DNA damage is under investigation. Determining the impact of excess VAT on cancer will lead to strategies to help prevent adiposity-associated cancers and identify individuals at risk for disease or individuals that may be susceptible to compound-induced genotoxicity due to DNA damaging environmental exposures.
aerosol for 4 h/day for 8 weeks, at a target concentration of 40 mg/m³. Lung nodules were enumerated at 30 weeks post-initiation. GMA-SS and GMA-MS fumes significantly promoted lung tumor multiplicity in A/J mice initiated with MCA (16.11 ± 1.18; 21.86 ± 1.50, respectively) compared to MCA/air-exposed mice (7.93 ± 0.82; 8.34 ± 0.59, respectively). Oropharyngeal aspiration of GMA-SS and its component metals showed that GMA-SS fume was more pneumotoxic than the individual components. Component Fe₂O₃ was the most toxic and also the only metal to promote lung tumors in A/J mice. In conclusion, this study demonstrates that inhalation of GMA-SS and GMA-MS welding fume as well as Fe₂O₃ promotes lung tumor formation in vivo and provides support for the epidemiological study that shows welders, using mild and/or stainless steel, are at an increased risk for lung cancer.

**2038 Direct Formalin Fixation Induces Widespread Genomic Effects in Archival Tissues**

Recent advances in next generation sequencing have dramatically improved transcriptional analysis of degraded RNA from formalin-fixed paraffin-embedded (FFPE) samples. However, little is known about potential genomic artifacts induced by formalin fixation, which could affect toxicological and clinical studies being conducted in FFPE samples. Previously, we identified a consistent shift in RNA-sequencing profiles between matching frozen and FFPE samples. We hypothesized that this shift was due to a core set of transcriptional changes induced when fresh tissue is fixed in formalin. To test this idea, liver samples were collected from C57BL/6 mice treated with 600 ppm of pentoxyresin, parabital (PB) or vehicle control (Con) for 7 days. Samples were divided into the following conditions: 1) fresh-frozen (FR); 2) directly fixed in 10% buffered formalin for 18 hours and processed to FFPE (FIX); and 3) processed as for FIX but initially frozen (FR-FIX) (n=6/group/condition). The FR-FIX group served as a control for tissue processing and sequencing after collection. Total RNA libraries were prepared and ribo-depleted prior to sequencing on an Illumina Hi-seq 2500. Reads were aligned using Star (2.4) and analyzed in Partek Flow (6.0). Direct fixation (FIX vs. FR) resulted in 2946 differentially expressed genes (DEGs), 98% of which were down regulated. Freezing prior to fixation (FR-FIX vs. FR) resulted in 95% fewer DEGs, indicating that the majority of formalin effect occurred at the time of fixation (i.e., as a transcriptional response) rather than during tissue processing or sequencing. Comparative analysis of this formalin-induced gene set with two independent studies in Ingenuity Pathway Analysis identified consistent enrichment in oxidative stress, mitochondrial dysfunction, and transcription elongation pathways. However, direct fixation did not have a clear impact on chemotherapeutic resistance, PB treatment induced 180 DEGs within the FIX group and 159 in the FR-FIX group of which 120 were shared. The DEGs in each list were consistent with CAR/PXR activation and PB exposure, suggesting that formalin fixation did not confound the chemical response. Our results highlight distinct transcriptional effects of formalin fixation that could impact RNA-sequencing studies using FFPE samples. This abstract does not reflect US EPA policy.

**2039 Effect of Resveratrol on Gut Microbiome in Colorectal Cancer**

H. R. Alrafas, B. Busbee, P. Nagarkatti, and M. Nagarkatti. University of South Carolina School of Medicine, Columbia, SC.

Colorectal cancer (CRC) is a heterogeneous disease with recognizable clinical and molecular features, with wide range of prognostic and treatment responses observed among CRC patients worldwide. Currently, the treatment of patients suffering from CRC, and most tumors involves the surgical removal of the cancer and chemotherapy that are not effective in most cases and have adverse side effects or increase the toxicity. In current study, we investigated the effects of resveratrol (RES), a natural component found in grapes, strawberries and raspberries on murine azoxymethane-dextran sodium sulfate (AOM-DSS) induced CRC model. Our data shows that administration of RES alleviates symptoms in AOM-DSS group, with normal body weight, normal food intake, and normal survival of the mice. The histopathological changes in the colon tissues were analyzed by H&E staining. We observed normal colon architecture without evidence of in vivo tumourigenesis, goblet cell hyperplasia, or inflammation. These results suggest that RES has a protective effect on CRC development. In conclusion, this study demonstrates that RES supplementation may be a potential therapeutic strategy for the prevention and treatment of CRC.

**2040 Cells That Escape Cr(vi)-Induced Cell Death Exhibit Chromosome Instability**

S. Wise, and J. P. Wise. University of Louisville, Louisville, KY.

Hexavalent chromium (Cr(VI)) compounds are established human lung carcinogens; however, the mechanism remains poorly understood. Cr(VI) induces DNA damage which under normal circumstances triggers the protective apoptotic machinery to avoid transformation and carcinogenesis. Evasion of apoptosis is a hallmark of carcinogenesis, however it is unknown how Cr(VI)-damaged cells are able to escape cell death and become tumorigenic. In the current study we exposed human lung cells to low concentrations of zinc chromate continuously for 6 months. Because at various intervals during treatment we assessed growth parameters using a colony forming assay. We also monitored changes in chromosome number and structure of surviving cells using traditional karyotyping methods. We found that Cr(VI)-treated cells produced a decrease in cell death in the first 25 days of exposure. The lower concentrations (0.0125 and 0.025 ug/cm²) showed decreased plating efficiency relative to the control, indicative of cell death, for the entire length of treatment. Interestingly, the highest concentration, 0.05 ug/cm², initially caused significant cell death, but was followed by a period of enhanced survival at day 70 of treatment, and then decreased plating efficiency after day 120 which remained throughout exposure. Although plating efficiency decreased, cell growth was accelerated in the high treatment group. Additionally, cells that escaped particulate Cr(VI)-induced cell death exhibited significant amounts of both structural and numerical changes. Control cells at all time points showed normal chromosomes; at day 5 there were 24, 26, and 30 percent of cells with normal karyotypes at 0.0125, 0.025 and 0.05 ug/cm² zinc chromate, respectively; at day 70 there were 46, 52, and 48 percent of cells with normal karyotypes; at day 180 there were 18, 72, and 84 percent of cells with abnormal karyotypes. Increases in aneuploidy earlier were observed at earlier time points compared to structural alterations. These data support a hypothesis that Cr(VI)-treated cells can evade apoptosis and transform into chromosomally unstable cells yet continue to survive. These cells have the potential to become carcinogenic. Further work will elucidate the mechanism behind the evasion of apoptosis. By considering both mutagenic and epigenetic alterations, this work will contribute to the understanding of carcinogenicity of Cr(VI).

**2041 In Vitro Investigations of Adjuvant Chemotherapy for Prevention of Breast Cancer Tumor Recurrence**

C. T. Bot¹, O. Reinhardt², K. Hužas³,⁴, S. Stölzle-Feix¹, F. Alves²,⁵, R. Haedo⁶, and N. Fertig⁷. ¹Nanion Technologies Inc., Livingston, NJ; ²Max Planck Institute for Experimental Medicine, Göttingen, Germany; ³Nanion Technologies GMBH, Munich, Germany; ⁴Technische Universität München, Munich, Germany; ⁵University Medical Center Göttingen, Göttingen, Germany.

Breast cancer is the most common cancer among women. Once identified and tumor excised, the risk of local breast cancer recurrence (or return of cancer within the breast) depends on tumor characteristics. Adjuvant therapies are used to ensure that remaining microscopic disease will be eradicated, and to help extend survival time of the patient. A standard clinical regimens is a combination of cyclophosphamide, adriamycin (doxorubicin) and 5-fluorouracil (CAF) that is administered for four months. Despite the initially successful multimodal therapy, tumor recurrence remains a major cause of mortality in breast cancer patients (1). Hence, better treatment options are necessary. In this study, responses from murine H8N8 and H8N8 T3.2 cells were investigated via two different assays: via image-based live-cell analysis and an impedance-based cell monitoring system. The H8N8 cells are an immortal mammary carcinoma cell line with tumor stem cell properties, and the H8N8 T3.2 cells are a recurrent tumor variant. H8N8 T3.2 cells were established from a solid breast tumor that received the CAF clinical regimen in vivo. For further in vitro tumor recurrence investigation,
In Vitro Anticancer Potential of a Specific Polyphenol Mixture of Curcumin, Quercetin, Cruciferous Plants, and Green Tea Extracts, and Resveratrol on Human Prostate Cancer Cell DU-145

M. Roomy, A. Niedzwiecki, and M. Rath. Dr. Rath Research Institute, Santa Clara, CA.

In vitro anticancer potential of a specific polyphenol mixture of curcumin, quercetin, cruciferous plants and green tea extracts and resveratrol on human prostate cancer cell DU-145. Prostate cancer is one of the most common diagnosed cancers in men aged 50 and older. Metastasis is a major cause of mortality. Current treatments include surgery, hormone therapy, radiation therapy and chemotherapy, all of which are associated with adverse side effects.

We investigated the effect of a specific polyphenol combination (PB) of curcumin, quercetin, green tea extract, cruciferous and essential oil, on viability, invasion, MMPs secretion, cell migration and morphology on human prostate cancer cell lines. Human prostate cancer cell cell DU-145 (ATCC) was cultured in DMEM media and supplemented with bovine serum and antibiotics in 24-well tissue culture plates. Cell viability, invasion, MMPS secretion, cell migration and morphology were measured using Western blotting, zymography, cell invasion using Matrigel, cell migration by scratch test, and H&E staining.

PB at 0, 10, 25, 50 and 100 µgm/ml concentration, respectively. Zymography demonstrated expression of only MMP-9 which was inhibited by PB in a dose response fashion with total inhibition at 50 µg/ml. PB at 10, 25, 50 and 100 µg/ml concentration, respectively. Zymography demonstrated expression of only MMP-9 which was inhibited by PB in a dose response fashion with complete block at 50 µg/ml. H&E staining showed apoptotic changes at 50 and 100 µg/ml concentration. These results suggest therapeutic potential of PB in the treatment of prostate cancer.

Ligand Activation of PPARβ/δ Inhibits UV-Induced Skin Cancer by Targeting p53 Mutant Cells

D. Ralph1, T. Achuff1, K. Lee1, F. J. Gonzalez2, and J. M. Peters3. 1Pennsylvania State University, University Park, PA; and 2National Cancer Institute, Bethesda, MD; and 3Pennsylvania State University, University Park, PA.

Non-melanoma skin cancer is the most common type of cancer with an estimated 2.5 million new cases each year. 90% of non-melanoma skin cancers result from UV-induced skin cancer. UV-induced skin cancer was examined in this study. Female SKH-1 mice (wild-type or Pparβ/δ-null) were UV exposed (180 mJ/cm²) 3 times/week followed by topical application with vehicle control, the highly specific PPARβ/δ ligand (1.6-fold), whereas no increase in proliferation was observed in CAR-KO mice. The selective repressive ligand also inhibited growth of DLD1 spheroids but this effect was not found in RKO spheroids. Interestingly, DLD1 cells had a reduction in the APC gene while RKO cells did not. This suggests that selective repression of PPARβ/δ may preferentially target cells with APC mutations, a common risk factor for human colon cancer. Combined, these results suggest that ligand activation and/or selective repression of PPARβ/δ is a potential cancer therapy and invasion, but the detailed mechanisms need further investigation.

Carinogenesis, p53 mutant cells may be particularly susceptible to inhibition of the ER stress response pathway because of increased protein production. Cytosolic expression of ER stress response protein, IRE1α, was decreased in wild-type UVB-induced skin samples compared to Pparβ/δ-null samples. It was also found that nuclear expression of p107, a transcription factor that represses the cell cycle, was increased in wild-type UVB-induced skin samples compared to Pparβ/δ-null samples. Results from these studies provide strong evidence that ligand activation of PPARβ/δ inhibits UVB-induced skin cancer by targeting TP53 mutant cells and inhibiting UVB-induced DNA damage. Supported by CA124533, and CA140369.

2044 PPARβ/δ Inhibits Proliferation and Invasion of Human Colon Cancer Cell Lines

X. Wang1, F. J. Gonzalez2, and J. M. Peters3. 1Pennsylvania State University, University Park, PA; 2National Cancer Institute, Bethesda, MD; and 3Pennsylvania State University, University Park, PA.

Whether PPARβ/δ promotes or potentiates colon cancer is not fully understood. While some studies have shown that the expression level of PPARβ/δ is reduced in human colon tumors compared to normal tissue control, and is negatively correlated to survival of colorectal cancer patients, others have suggested the opposite. In this study, the hypothesis that ligand activation of PPARβ/δ inhibits human colon cancer cell line proliferation and reduces their potential of migration and invasion was examined. Ligand activation of PPARβ/δ inhibited growth of HT29 cells, and selective repressive transcription of PPARβ/δ inhibited growth of DLD1, HCT116 and HT29 cells. Additionally, both ligand activation and selective repression of PPARβ/δ inhibited migration of DLD1 cells, with only ligand activation inhibited RKO cell migration. Selective repression of PPARβ/δ reduced expression of EMT markers in RKO and HCT116 cells, further suggesting an anti-invasion role of PPARβ/δ in these human colon cancer cell lines. The selective repressive ligand also inhibited growth of DLD1 spheroids but this effect was not found in RKO spheroids. Interestingly, DLD1 cells harboring a mutation in the APC gene while RKO cells do not. This suggests that selective repression of PPARβ/δ may preferentially target cells with APC mutations, a common risk factor for human colon cancer. Combined, these results suggest that ligand activation and/or selective repression of PPARβ/δ is a potential cancer therapy, but the detailed mechanisms need further investigation. Supported by CA142533, and CA140369.

2045 Driving into the Future with CAR: Moving from Current Mode-of-Action to Predictive Approaches for Addressing Nuclear-Receptor Mediated Hepatocarcinogenesis

J. LaRocca1, M. J. LeBaron2, K. J. Johnson1, and R. J. Rasoulpour1. 1Dow AgroSciences, Indianapolis, IN; and 2The Dow Chemical Company, Midland, MI.

There are several well-characterized modes of action (MoA) for hepatocarcinogenesis, and the analysis of robust mechanistic data can provide a reasonable basis for extrapolation of a rodent MoA to human relevance. While in the past MoA programs were triggered in response to observed liver tumors in cancer bioassays, predictive approaches are now being undertaken to better characterize carcinogenic potential early in discovery testing programs. As a case study, the agrochemical nitrapyrin, which induces hepatic tumors in mice, was put through a series of MoA experiments and proof of principle predictive toxicogenomics experiments to serve as a backdrop for future predictive approaches. In the MoA experiments, nitrapyrin induced a dose-related increase in the Cyp2b10/CAR (constitutive androstane receptor) transcript and protein, an increase in hepatocellular proliferation, and ultimately, tumors. Nitrapyrin exposure in wild-type mice resulted in an increase in panlobular hepatocellular proliferation (1.6-fold), whereas no increase in proliferation was observed in CAR-KO mice, providing compelling evidence of the role of CAR in nitrapyrin-induced liver tumour formation. Furthermore, nitrapyrin exposure induced a clear, concentration-responsive increase in cell proliferation in mouse, but not human, hepatocytes in vitro. These data support a MoA characterized by CAR activation, which due to qualitative differences between mice and humans is not relevant for human health risk assessment. New approaches to predict toxicity are now being embraced by employing toxicogenomics. A retrospective in vivo toxicogenomics experiment with nitrapyrin was conducted, where rats were exposed to nitrapyrin for 28-days and RNASEq was performed on treated and control liver samples. The toxicogenomics data reveal that CAR-mediated hepatocarcinogenesis may be observed in rodents, as indicated by hierarchical
clustering of gene set enrichment where nitrapyrin clustered closely with other CAR hepatocarcinogens, including phenobarbital. These data support the utility of predictive toxicogenomic approaches to characterize potential hepatotoxicity, which can be used to guide early-stage discovery molecule decisions and proactively drive future MoA testing programs.

2046 Exosomal ID3 Aids in Estrogenic Chemical Dependent Vascular Guiding of NRF1-Driven Secondary Breast Cancer Lesions

J. K. Das1-3, M. Dokie1, A. Deoraj1, Q. Feltly1, and D. Roy1,2. 1Florida International University, Miami, FL; and 2Bruce W. Carter VA Medical Center, Miami, FL.

During blood-borne metastasis, upregulation of endothelial cell adhesion molecules can accelerate metastatic processes of breast cancer stem cells (BCSCs) through increased adhesion of tumor cells to the endothelium. In this study, we have examined whether exosomal ID3 aids in estrogenic chemical dependent vascular guiding of NRF1-driven secondary breast cancer lesions. Besides NRF1 mediated stochastic transcriptional programming of BCSCs, our studies support a novel concept that ID3 expressing vascular EndSCs are not just contributing in new blood vessel formation, but also increased the adhesion and transmigration of BCSCs. Differential effects were demonstrated with endocrine disruptors PCB 153 and PCB 77. Only PCB 153 treatment exacerbated growth of BCSC tumors spheroids in vivo mimicking deviant microvascular ID3+ endothelium and NRF1+ BCSCs in tissue culture. PCB 153 also increased tumor cell adhesion to microvascular endothelium and transendothelial migration of BCSCs. Exosomal ID3 from endothelial cells aids in the propensity of mesenchymal NRF1+ BCSCs to specify and commit to a particular lineage. Organized growth of organ-specific ID3+ EndSCs accompany and guide a specific subtype of mesenchymal NRF1+ BCSCs to spread to a colonizing organ site. ID3+ EndSCs not only supported the growth of BCSC tumorspheres, but guided the in vivo migration of tumor stem cells to the brain in the zebrafish embryo. These studies provide convincing support to our postulate that gain-of-function by NRF1 in BCSCs and ID3 in EndSCs will lead to stochastic transcriptional programming of their target genes controlling the specification and guidance of BCSCs to spread to distant sites in exposed individuals. Moreover, the effect of the estrogenic chemical PCB 153 has expanded our understanding of environmental exposure to endocrine disruptors may influence the specification of NRF1+ BCSCs and their guidance by ID3+ EndSCs to secondary target organs. Thus, establishing a role for NRF1/ID3 in speciation and guidance of BCSCs to spread to secondary target organs will directly link environmental exposure to estrogenic chemicals, including PCB153.

2047 Bortezomib Inhibits Growth of Multiple Myeloma Cells through Downregulation of Specificity Protein Transcription Factors

K. B. Karki, S. Safe, and J. Un Ho. Texas A&M University, College Station, TX.

Bortezomib is a member of a relatively new class of drugs that act as proteasome inhibitors and it is the first proteasome inhibitor approved by FDA for treatment of multiple myeloma (MM). Several studies demonstrated that Sp1 Transcription Factors (TFs) is overexpressed in multiple myeloma cells and Sp1 regulates expression of genes important for cell growth, proliferation, and survival, however, the role of Sp1 and other Sp TFs has not been thoroughly investigated in Multiple myeloma cells and interactions of Bortezomib and Sp TFs have not been determined. Initial studies shows that not only Sp1 but also Sp3 and Sp4 are highly overexpressed in multiple myeloma cells. Treatment of cells for 24 and 48 hours with 10, 15 and 20 nM Bortezomib significantly inhibited cell viability. Moreover, treatment of the cell lines with 10, 15 and 20 nM of Bortezomib induced Annexin V staining and several markers of apoptosis including cleavage of caspase-8, caspase-3 and cPARP. Using these same treatment protocol we show that Bortezomib also downregulates expression of Sp1, Sp3 and Sp4 and several pro-oncogenic Sp-regulated genes. RNA interference (RNAi) studies show that the knockdown of Sp1, Sp3 and Sp4 individually resulted in inhibition of cell growth and induction of apoptosis in untreated 2218 and ANBL-6 cell demonstrating that not only Sp1 but also Sp3, Sp4 and Sp4 contribute to MM cell growth and survival. In addition, we also observed that Bortezomib-mediated downregulation of Sp proteins involved activation of caspase-8 and the mechanism of this effect is currently being investigated. Our results demonstrate for the first time that the anticancer activity of Bortezomib is due, in part to Sp downregulation.

2048 IDH Mutation-Inspired Oxidative Therapy to Higher Grade Gliomas

H. Madala, S. Pungunuru, and K. Srinivengopal. Texas Tech University Health Sciences Center, Amarillo, TX.

Glioblastoma multiforme (GBM) is the deadliest brain cancer among gliomas with a median survival below one year. Despite the Spartan efforts taken to advance the therapeutic strategies, the prognosis remains grim for this devastating disease with the current combination therapy, mostly because of the resistance offered by the overexpression of 6-methyl guanine methyl transferase (MGMT). MGMT is a DNA repair enzyme, which by its action, removes the methyl adducts induced by TMZ, leading to resistance. Attempts to inhibit MGMT with pseudo substrates failed mostly because of toxicity. MGMT is a redox sensitive protein owing to the cysteine in its active site. Whole genomic sequencing disclosed the existence of mutations in isocitrate dehydrogenase 1/2 (IDH1/2) in majority of low grade gliomas. Mutations in IDH causes loss of normal and gain of new enzymatic activity causing accumulation of the oncometabolite, D-2 hydroxylglutate (D-2HG), leading to oncogenesis. In addition, D-2HG accumulation leads to loss of redox balance. It is established in clinic that glioma patients harboring IDH mutations respond well to chemotherapy. We hypothesize that, small molecules that mimic α-KG, can replicate the beneficial aspects as seen in the case of IDH mutations, in GBM in vivo or in vivo tumor models. We synthesized a library of molecules that mimic α-KG, out of which DMG, showed synergistic cytotoxicity in combination treatment with TMZ and BCU2 against various GBM cells. Enzymatic assay to see its role against α-KG dehydrogenase enzyme revealed its potent inhibitory role which further perturbs the redox balance. Induced ROS levels found to induced loss mitochondrial membrane integrity. Later, western and in vivo activity assay showed dose dependent inhibition of MGMT in ROS dependent manner. We then performed extracellular flux analysis and found a significant decrease in oxidative consumption rate (OCR) with in situ or pretreatment with DMG. Proteomic analysis using LC-MS/MS, ELISA studies to measure ATP, NADH revealed metabolic and energy stress. Immunofluorescence studies confirmed the nuclear translocation of cytochrome C and apoptosis inducing factor and inhibition of ROS mediated AMPK activation. Notably, the efficacy of DMG was evaluated in vivo against subcutaneous xenografts developed in nude mice. DMG treatment resulted in a significant reduction in tumor growth. Supported by CPRIT grant RP130266 and RP170207 to KSS.

2049 Mode-of-Action Analysis for Uterine Adenocarcinomas Associated with High Dietary Ingestion of the Insecticide Aldofypropen

A. Van Cott1, M. Frericks2, C. Hastings1, N. Honarvar2, B. Flick2, E. Fabian1, M. Badding1, B. Gollapudi3, J. Bus1, and B. van Ravenzwaay2. 1BASF, Research Triangle Park, NC; 2BASF, Ludwigshafen, Germany; and 3Exponent, Inc., Alexandria, VA.

Aldofypropen (CAS # 915972-17-7) is a novel insecticide that acts as a TRPV channel modulator in the chordotonal organs of target insects. In two carcinogenicity studies with Fischer rats, an increased incidence of uterine adenocarcinomas was observed (incidences of 4/50, 1/50, 2/50 and 10/50 in the first study at doses of 0, 1000, 3000 ppm respectively). The key events responsible for the uterine tumors were investigated through a series of mechanistic and toxicokinetic studies with Aldofypropen. The IPCS framework was used to analyze the relevance of the rat uterine tumors to humans. The results indicate that the uterine tumors were mediated through a mode of action (MoA) of dopamine enhancement, subsequent hormonal alterations, endometrial hyperproliferation, and promotion of uterine adenocarcinomas. Specifically, the findings of dopamine receptor 2 agonism, decreased serum prolactin levels, decreased mammary gland dilation (indication of delayed entry into senescence), and a late onset of endometrial hyperplasia and progestin dominated changes in hormone profiles consistent with endometrial adenocarcinomas in rat uteri. This MoA is considered to be rat-specific and not relevant to pathophysiologic conditions in human. Furthermore, both of the doses where tumors were observed in rat, 1000 ppm (50.4 mg/kg bw) and 3000 ppm (146.9 mg/kg bw), exceed the kinetically derived maximum tolerated dose (KMD) of 15 mg/kg bw established for Aldofypropen. Effects that occur at doses above the KMD, regardless of MoA, are quantitatively not
relevant to humans when the expected human exposures are below the KMD. Exposures to Afidopyropen are expected to be thousands-fold lower than the established KMD. In conclusion, the tumor incidence associated with high doses of dietary Afidopyropen in the rat is not expected to pose a carcinogenic risk to humans.

**2050 Nfe2l1 Silencing in Insulinoma Cells Causes the Emergence of an Aggressive and Chemo-Resistant Tumor Phenotype Via Metabolic Reprogramming**

J. Fu1, H. Zheng1, Q. Cui1, C. Chen5, S. Bao5, J. Sun1, L. Li1, H. Wang1, Y. Hou1, Y. Xu1, Q. Zhang2, and J. Pi1. 1China Medical University, Shenyang, China; and 2Emory University, Atlanta, GA.

Nuclear factor erythroid 2 like 1 (NFE2L1, also known as NRF1) is a transcription factor known to be key to embryonic development, maintenance of the ubiquitin-proteasome system, and regulation of the cellular antioxidant response. We previously found that pancreatic β-cell-specific Nfe2l1-knockout mice showed severe hyperinsulinemia, and silencing of Nfe2l1 in MIN6 β-cells and mouse islets resulted in elevated basal insulin release and altered glucose metabolism. In the present study, we examined the tumorigenicity of Nfe2l1 deficient insulinoma MIN6 cells (Nfe2l1-KD) and their sensitivity to chemotherapy. We found that Nfe2l1-KD insulinoma cells grew faster and were more aggressive than Scramble cells in vitro. Insulinoma arising from Nfe2l1-KD cells in an allograft transplantation model was more aggressive and chemo-resistant. This conclusion was confirmed by streptozotocin (STZ) administration in an allograft transplantation model in diabetic Akita background mouse. In addition, we found that Nfe2l1-KD cells were resistant to chemotherapeutic drugs STZ and 5-fluorouracil-induced damage, which was linked to binding of hexokinase 1 with mitochondria, enhancing mitochondrial potential membrane closing mitochondrial potential transition pore. Overall, both in vitro and in vivo data from Nfe2l1-KD MIN6 insulinoma cells indicate a previously un-appreciated action of NFE2L1 in suppression of tumorigenesis and sensitizes cells and their derivative tumors to chemotherapeutic-induced damage and apoptosis, likely via metabolic reprogramming. These data indicate that NFE2L1 could potentially play an important role in the carcinogenic process and impact chemotherapeutic efficacy, at least within a subset of pancreatic endocrine tumors.

**2051 Xenobiotic Nuclear Receptors Expression in High Fat Diet-Induced Non-Alcoholic Fatty Liver Disease: A Time-Course Study**

J. E. Klaunig, X. Li, and Z. Wang. Indiana University, Bloomington, IN.

Non-alcoholic fatty liver disease (NAFLD) is a common chronic liver disease. The pathologic progression of NAFLD includes steatosis, steatohepatitis, fibrosis, cirrhosis and possible hepatocellular carcinoma (HCC). Nuclear receptors regulate physiological and pathological pathways in response to environmental and endogenous stressors. Modification of hepatic nuclear receptor expression during NAFLD, which has been suggested to modulate metabolism of nutrients and chemicals in the liver. The current study was designed to systematically characterize the time-dependent modulations of nuclear receptors including peroxisome proliferator activated receptors (PPAR), constitutive androstane receptor (CAR), pregnane X receptor (PXR), liver X receptor (LXR), and farnesoid X receptor (FXR) in the progression of NAFLD. Male C57BL/6 mice were fed a high fat diet (HFD) to induce NAFLD. Hepatic steatosis was detected after 8 weeks on HFD. Further progression to fibrosis was seen after 24 and 32 weeks on diet as evident by Sirius red staining and a 6-8 fold increase of Col1a1 and Timp1 expression in the liver. DNA synthesis level (Brdu labeling index) significantly increased up to 6-fold in the liver with steatohepatitis. Transcriptome analysis of liver samples after 16 weeks on HFD increased the expression of PPARα, CAR, and PXR (p < 1.0e-10) compared to normal chow fed control mice. In the time-course analysis, PPARα was activated (4 fold) as indicated by Cyp4a10 gene expression and a significant increase in acyl CoA oxidase activity. PPARα mRNA was moderately elevated while PPARδ was down regulated to 20-40% comparing to controls. PXR target gene Cyp3a11 was consistently increased 3-4 fold in addition to the increased microsomal Cyp3a enzymatic activity in the stages of steatois, steatohepatitis and fibrosis. In contrast, activation of CAR related genes was not as robust as the PPAR related genes. LXR target genes Abcg5 and Abcg8 were also significantly elevated (2-3 fold) that correlated with the development of hepatic steatosis, indicating its role in lipid and cholesterol metabolism. The mRNA of FXR was downregulated at 24 and 32 weeks after high fat diet treatment, which may correlate with hepatic fibrosis. This study provides a systematic characterization of the changes in important hepatic gene expression pathways that correlated with biochemical and pathologic changes related to the progression of NAFLD induced by HFD.

**2052 Correlation between Genome-Wide Histone Acetylation Changes and Repression of Gene Expression by Ochratoxin A**

E. Limbeck, and A. Mally. University of Würzburg, Würzburg, Germany.

Ochratoxin A (OTA) is a potent renal carcinogen but its mechanism has not been fully resolved. Using a novel mass spectrometry approach employing chemical 15C-acetylation of unmethylated lysine residues for quantitative analysis of site-specific alterations in histone acetylation in human kidney epithelial cells (HK-2) exposed to OTA, we previously established that OTA causes global reduction of histone acetylation, including loss of acetylation at histone H3 lysine 9 (H3K9), a well-known euchromatic hallmark that is typically elevated at promoter regions of transcriptionally active genes. Considering that the predominant transcriptional response to OTA in vitro and in vivo is down-regulation of gene expression, we employed ChIP-Seq to test if OTA mediated changes in gene expression may at least in part be mechanistically linked to H3K9 hypoacetylation at respective promoter sequences. Integrated analysis of OTA mediated genome-wide changes in H3K9 acetylation with published gene expression data demonstrated that among OTA responsive genes almost 80% of hypoacetylated genes were down-regulated, thus confirming an association between H3K9 acetylation status and gene expression of these genes. However, only 7% of OTA-repressed genes showed loss of H3K9 acetylation within promoter regions. Interestingly, however, GO analysis and functional enrichment of down-regulated genes showing loss of H3K9 acetylation at their respective promoter regions revealed enrichment of genes involved in the regulation of transcription, including a number of transcription factors that are predicted to directly or indirectly regulate the expression of 98% of OTA repressed genes. Thus it is possible that histone acetylation changes in a fairly small set of genes but with key function in transcriptional regulation may trigger a cascade of events that may lead to overall repression of gene expression.

**2053 Atovaquone: An Anti-Protozoal, Anti-Malarial Drug Suppresses Breast Tumor Growth by Inhibiting Her2/β-Catenin Signaling**

N. Gupta, and S. Srivastava. Texas Tech University Health Sciences Center, Amarillo, TX.

Breast cancer is the second highest cause of cancer-related mortality in women, HER2 is an oncoprotein overexpressed in about 30% of breast cancer patients and β-catenin, a proto-oncogene plays a pivotal role in breast cancer metastasis and drug resistance leading to poor prognosis. In the current study, we evaluated the anti-cancer effects of an anti-protozoal drug, atovaquone against several breast cancer cell lines such as MCF-7, 4T1, HCC1806, C66, SKBR3 and T47D. Our results showed that atovaquone treatment induced apoptosis as exhibited by PI/annexin assay and cleavage of caspase-3 and PARP, and inhibited the growth of all the breast cancer cell lines tested. Similar observations were made in mice with orthotopic breast cancer cell lines. In addition, atovaquone treatment significantly reduced the expression of HER2, β-catenin and its downstream molecules such as pGSK-3β, TCF-4, cyclin D1 and c-Myc in these cell lines. Treatment of HCC1806 cells with 5 µM atovaquone resulted in significant reduction in mammosphere forming efficiency (MFE) of breast cancer cells. Mammosphere-forming cells are known to exhibit cancer stem cell (CSC)-like properties together with drug resistance. Efficacy of atovaquone was evaluated in the in-vivo tumor model by orthotopic implantation of two highly aggressive 4T1 and C66, triple negative breast cancer cells in the mammary fat pads of female mice. Our results demonstrate that atovaquone administration suppressed the growth of C66 and 4T1 tumor by 70% and 60% respectively. Atovaquone treated tumors collected from orthotopic model exhibited reduced HER2, β-catenin and increased apoptosis when analyzed by western blot. Atovaquone is highly safe, non-toxic and well tolerated drug in humans. Moreover, we have found in our study that the intended dose of atovaquone to induce anticancer effects is about 6.6 fold less than its highest anti-malarial dose. Conclusively, our results indicate that atovaquone effectively reduces the growth of primary breast tumors by inhibiting HER2/β-catenin signaling. Most importantly, atovaquone is already in
clinical use with an established safety record therefore, any positive findings from our studies will prompt further clinical investigation into repurposing atovaquone for the treatment of advanced breast cancer patients. Supported in part by R01 grant CA 129038 awarded by National Cancer Institute, NIH.

2054 γ-H2AX Formation Induced by the Bladder-Carcinogenic Aromatic Amines o-Toluidine and o-Anisidine in the Urinary Bladder of Rats

T. Toyoda1, K. Matsushita1, T. Morikawa1, T. Yamada1,2, N. Miyoshi3, and K. Ogawa1. 1National Institute of Health Sciences, Kawasaki, Japan; 2Tokyo University of Agriculture and Technology, Tokyo, Japan; and 3University of Shizuoka, Shizuoka, Japan.

Although aromatic amines are widely used as raw materials for dyes, there have been concerns about carcinogenicity, particularly in the urinary bladder. In the present study, we examined the formation of γ-H2AX, a biomarker of DNA damage, in the urinary bladder of rats using immunohistochemistry to detect early changes induced by five monocyclic aromatic amines that exhibit similar structures. Six-week-old male F344 rats were administered 0.4% or 0.8% o-toluidine, 0.3% or 1% o-anisidine, 0.4% 2-xylyl, 0.2% p-toluidine or 0.6% aniline in their basal diet for 4 weeks. Five animals in each group were sacrificed at day 2 and weeks 1, 2, 4, and 6, and histopathological and immunohistochemical analysis was performed. In the 0.8% o-toluidine group, we observed sequential progression of bladder lesions, characterized by intrumoral hemorrhage and interstitial necrosis at day 2 and formation of granulation tissue with mononuclear cell infiltration at week 1, to diffuse hyperplasia at weeks 2 and 4. In the 1% o-anisidine group, simple hyperplasia without obvious infiltration of inflammatory cells was detected from weeks 2 to 4 whereas γ-H2AX-positive bladder epithelial cells in the 1.0% o-anisidine group were significantly increased in a time-dependent manner, transient increases of γ-H2AX-positive cells were detected at day 2 and week 1 in the 0.8% o-toluidine group. No apparent bladder lesions or significant increases in γ-H2AX formation were observed in the 0.4% 2-xylyl, 0.3% o-anisidine, 2.4-xylyl, p-toluidine, and aniline groups. Results of this study suggest that o-toluidine and o-anisidine may induce in vivo genotoxicity in the urinary bladder of rats. Moreover, histopathological examination revealed different mechanisms of bladder mucosal injury associated with both compounds.

2055 Using Transgenic Zebrafish Larvae for Xenotransplantation of Human Breast Cancer Cells and Screening of Natural Compounds for Anti-Cancer Activity

T. Dhawan, N. M. Ashpole, and K. L. Willett. University of Mississippi, University, MS.

Zebrafish are widely accepted as a model organism for developmental research and human disease pathways. Transgenic zebrafish are used for xenotransplantation human cancer cells to study the mechanisms involved in growth, proliferation, and metastasis of cancer cells in an amenable tumor microenvironment. Zebrafish xenografts also offer the opportunity for high-throughput screening of potential anti-cancer compounds for toxicity and therapeutic efficacy. In our xenotransplantation studies, estrogen receptor positive MCF-7, and human triple negative breast cancer cells were used to model benign and malignant types of breast cancer, respectively. A lipophilic red fluorescent dye (CM-DiI) was used to label cells and traditional chemotherapy agents were used to determine in vitro cell viability. We also measured cytotoxicity of extracts from the plant Tinospora crispa supported by the American Beverage Association.

2056 Topical Application of Mycotoxin-Alternariol Induces Inflammation and Tumor Initiation in Swiss Albino Mouse Skin

M. Bansal1,2, N. Singh1, and K. M. Ansari1. 1CSIR—Indian Institute of Toxicology Research, Lucknow, India; and 2Academy of Scientific and Innovative Research (AcSIR), Chennai, India.

Alternaria alternata produces various secondary metabolites including Alternariol (AOH), which is a natural contaminant processed refrigerated and stored food and feed products. Although preferably humans are exposed to mycotoxins through dietary exposure, however, exposure through dermal route can not be ruled out. Considering this possibility, WHO has highlighted the need for toxicological studies regarding dermal exposure of mycotoxins. Susceptible populations for dermal exposure of mycotoxin may include agricultural field workers and elderly persons with impaired skin barrier functions. In the present study, dermal toxic potential of AOH was assessed using mouse as an animal model. Swiss Albino mice (n= 5/group) were topically exposed with different doses of AOH from weeks 4 to 12 whereas γ-H2AX-positive cells were counted at day 2 and week 1 in the 0.8% AOH group. No apparent bladder lesions or significant increases in γ-H2AX formation were observed in the 0.8% o-toluidine or 0.3% 2,4-xylidine, 0.8% aniline in their basal diet for 4 weeks. Five animals in each group were sacrificed at day 2 and weeks 1, 2, 4, and 6, and histopathological and immunohistochemical analysis was performed. In the 0.8% o-toluidine group, we observed sequential progression of bladder lesions, characterized by intrumoral hemorrhage and interstitial necrosis at day 2 and formation of granulation tissue with mononuclear cell infiltration at week 1, to diffuse hyperplasia at weeks 2 and 4. In the 0.8% o-toluidine group, simple hyperplasia without obvious infiltration of inflammatory cells was detected from weeks 2 to 4 whereas γ-H2AX-positive bladder epithelial cells in the 1.0% o-anisidine group were significantly increased in a time-dependent manner, transient increases of γ-H2AX-positive cells were detected at day 2 and week 1 in the 0.8% o-toluidine group. No apparent bladder lesions or significant increases in γ-H2AX formation were observed in the 0.4% 2-xylyl, 0.3% o-anisidine, 2.4-xylyl, p-toluidine, and aniline groups. Results of this study suggest that o-toluidine and o-anisidine may induce in vivo genotoxicity in the urinary bladder of rats. Moreover, histopathological examination revealed different mechanisms of bladder mucosal injury associated with both compounds.

2057 Assessing Responses of Mouse Lung and Liver to 4-Methylimidazole Using Whole Genome Gene Expression Analysis after Oral Dosing for 2, 5, and 28 Days

M. E. Andersen, M. B. Black, S. N. Pendse, and P. D. McMullen. Scitovation, LLC, Research Triangle Park, NC.

4-Methylimidazole (4-MeI) increased lung tumors in 2-year studies in female and male mice. Changes in gene expression were evaluated in lung and liver of B6C3F1 mice exposed to 4-MeI for 2, 5, or 28 days using RNA-seq. The magnitude of change in differential expressed genes (DEGs) were small for any one gene, but relatively large numbers of DEGs were seen at 2-days in both tissues followed by decreasing numbers at longer exposures. Pathway enrichment was determined using specific selection criteria - both fold-change expression (|FC|) and a false discovery rate (FDR) - or by ranking genes in order of fold-induction and iteratively calculating enrichment for gene lists of different sizes. There were some significant differences in enrichment patterns in male and female lung at 2-days. However, several changes, including regulation of circadian clock genes at 2-days, downregulation of mitochondrial functions at later times, and various effects on G-protein coupled receptor (GPCR) signaling pathways were present in both males and females. The liver had upregulation of mitotic pathways at early times and downregulation of various metabolic pathways and GPCRs at later times. Based on (1) structural similarities of 4-MeI with histamine, (2) known short-term CNS and testicular toxicity of 4-MeI, (3) changes in arachidonic acid metabolism pathways, (4) rapid accommodation of the gene expression changes and (5) changes in GPCR pathways, it is hypothesized that 4-MeI may interact with histaminergic GPCR functions that are associated with numerous biological activities and functions. This study was supported by the American Beverage Association.

2058 Xenotransplanted larvae will be exposed to established chemotherapy drugs (e.g. 4-hydroxytamoxifen) to validate the effect of the chemotherapeutic drugs in vivo and subsequently to novel natural products to screen in vivo safety and potential efficacy of anti-cancer compounds. Supported by UM ORSP and UM GSC.

2059 Innovative Research (AcSIR), Chennai, India.

2060 Skin
While second-hand smoke exposure (SHS) is a risk factor for lung cancer, it is unclear whether there is an association between in utero SHS exposure and this lung disease. We previously showed in 15-week old mice exposed solely to in utero SHS that Dnmt3a, which 1) is responsible for de novo DNA methylation, 2) plays a key role in epigenetic mechanisms, and 3) whose deficiency in mice is associated with lung cancer, was significantly down-regulated. The current studies suggest that in utero SHS exposure alone may predispose to respiratory morbidity, including lung cancer. Here, we hypothesized that in utero SHS exposure promotes the development of carcinomas in a urethane-induced lung cancer model. Pregnant BALB/c mice were exposed from gestational days 6-19 to 10 mg/m³ of SHS or filtered air. From 13-16 weeks of age, male offspring were treated with 4 weekly injections of urethane or saline. At 44 and 58 weeks of age, mice were sacrificed and broncho-alveolar lavage fluids were collected. Tumors were analyzed for number, volume, and histopathology (adenoma; carcinoma; metastasis). Additionally, lung cancer-related gene expression was assessed. At 44-week of age, mice exposed in utero to SHS and treated as adults with urethane (SU), exhibited significantly (p<0.05) higher number of large tumors, increases in tumor volume, percentages of lymphocytes and levels of oxidative stress in the lungs, compared to their respective air-urethane controls (AU). Compared to 44-week old mice at 58-week of age the SU treatment significantly increased the number of intrapulmonary metastases. SU cancer-dysregulated genes were part of functional clusters associated with non-small cell lung cancer (Cdkn2a, Egr, Rb1), tumor suppressors (Cadm1, Cdkn2a, Dicl1), and Ras signaling pathway (Rassfl1, Hgf, Vegfa). Furthermore, SU vs. AU showed 15 differentially expressed cancer-related genes. Among these, Mmp1a and Mmp9 were up-regulated, and 10 were down-regulated, including Dg2 and Sostd1, both tumor suppressor genes. Our data provide in vivo evidence that in utero SHS aggravates urethane-induced lung cancer by dysregulating the expression of genes related to tumor suppressors, Ras signaling pathway and extracellular matrix remodeling, which play key roles in cancer progression and metastasis.
Methyl acrylate (MA), ethyl acrylate (EA), n-butyl acrylate (BA), and 2-ethylhexyl acrylate (EHA) are well studied industrial materials by conventional toxicological methods. Credible available data from in vitro, in vivo, and in silico experiments reveal the similarities and differences in biological response as the alkyl moiety of these esters changes. The genotoxicity, carcinogenicity and new mechanistic data available for these compounds are summarized to illustrate use in hazard classification and in support of development of modes of action (MOA) or adverse outcome pathways (AOP) relevant for human health assessments. This analysis is used to demonstrate the applicability and limitations of these types of data for materials, such as these esters, whose chronic effects are considered primarily related to sustained irritation, with or without a genotoxic component. Irritation severity, dose related impact on metabolism (rates, preferred pathways, and resulting by-products), and derivation of the maximum tolerated dose (MTD) at target organ sites are used to support or discount the proposed mechanisms leading to the observed chronic outcomes in the various test animals or systems and to ascertain the appropriate framework for determination of the relevance for humans. The contribution of genotoxicity to a mechanism is dependent upon the ability of a material or a relevant metabolite to cause the generation of a DNA adduct or mutation at the target DNA site. This exercise illustrates both the utility of supportive data from a family of materials as well as the need for compound specific data when conditions cause an alteration in the primary homeostatic pathway to occur. Critical review of the support for proposed pathways helps determine if the existing toxicological data are adequate or may indicate where additional data could serve to improve the confidence in the assessment of the impact on human health.

Twelve Weeks Exposure to Dimethylnitrosamine (DMN) Induces Rare Forms of Spleen and Duodenal Cancers

C. Ford, N. Suhail-Amacher, A. Bazzi, and S. D. Ray, Manchester University College of Pharmacy, Fort Wayne, IN.

According to American Cancer Society (ACS), there will be an estimated 1,688,780 new cancer cases diagnosed and 600,920 cancer deaths in the US in 2017. Besides genetic etiology, other factors, such as environmental, food-borne and sedentary life style can precipitate causes of many cancers. Among cancer types, reports indicate that prostate, lung and colorectal dominate in men, whereas, breast, lung and colorectal dominate in women. Most cancers are categorized by the anatomic site and tissue of origin, although genetic information is frequently used to group cancers according to a tumor’s biological makeup. This results in the subdivision of some more common cancers into a collection of rarer cancers. Nearly 13% of all cancers are rare (1 out of 8) based on ACS’s definition (possible 208,000 new cases in 2017); commonest of the rare cancers of the digestive system is cancer of the small intestine, which is not well known. Here, we test this using epigenomic and transcriptomic alterations in a range of tissues. Whether Cd alters epigenetic reprogramming during human breast stem cell proliferation and differentiation is not well known. Here, we test this using epigenomic and transcriptomic profiling of Cd exposed patient-derived normal breast stem cells grown in three-dimensional cultures. We generated and analyzed two datasets, using ERRBS dsDNA methylation tools cultured in the presence of two physiologically relevant doses of cadmium chloride, 0.25 µM or 2.5 µM, or control. Cd exposed cells show transcriptomic alterations of cancer relevant pathways, including upregulation of genes involved in metal homeostasis and oxidative stress, and downregulation of genes involved in extracellular matrix formation and focal adhesion. Analysis of differentially methylated regions found enrichment for GO terms related to ion channel activity or metal transporter activity. There was also enrichment for differentially methylated genes related to cell migration or regulation of development. Many genes (141 genes with FDR < 0.1) are accompanied by changes in DNA methylation. For example MT1X, TXNRD1, EEF1A2, HMOX1 were upregulated in Cd treated cells and also hypo-methylated. PGBD3, APOD, LRP1, and COL6A1 were downregulated and hypermethylated. Some genes (MT1E, TKT, AKR1C3, AKR1C2) were both up and hypomethylated. These findings suggest alternative regulatory mechanisms for expression than gene promoter CpG methylation. These results show that Cd exposure in breast stem cells can induce epigenetic and transcriptional changes in genes and pathways associated with development and cancer progression.

Novel Non-Toxic Peptides for Cancer Treatment

U. Wormser1, B. Brodsky2, Y. Finkelnstein3, and E. Prosukra1. 1The Hebrew University, Jerusalem, Israel; and 2Shaare Zedek Medical Center, Jerusalem, Israel.

Cancer is a leading cause of death worldwide. Due to the limited therapeutic effect of both traditional and advanced anti-neoplastic agents there is a great need for safe and efficacious drugs for cancer. In the present study we propose a novel peptide, termed YH11, for treating solid tumors. Three types of highly metastatic tumor cells were used, D122 lung carcinoma, 4T1 mammary carcinoma and B16-F10 melanoma. The experimental systems included two procedures a) the local model - subcutaneous injection of tumor cells into the footpad or lateral thoracic-abdominal area of mice, b) the metastatic model - intravenous injection of tumor cells leading to lung metastasis after several weeks. YH11 demonstrated a marked anti-tumor effect at extremely low doses in both metastatic and local models using the three types of tumor cells. A significant reduction of 64% in tumor growth (local model) was observed in YH11-treated group (100ng/kg) inoculated with D122 lung carcinoma cells. A lower dose of 10ng/kg YH11 (onset of treatment - 7 days after cell inoculation) caused a pronounced effect in the metastatic model expressed by marked reduction in lung weight (88%), number of lung foci (67%) and histopathological parameters (67%). Similar results, at the same range of YH11 doses, were observed with 4T1 mammary carcinoma cells at the metastatic model. The peptide was also efficacious against B16-F10 melanoma cells at both metastatic and local models. Interestingly, YH11 exhibited its anti-tumor effect exclusively in in vivo systems but not in vitro. Namely, the peptide did not show anti-proliferative or cytotoxic effect in cell cultures. In order to elaborate the mechanism of action of YH11 we propose two hypotheses: a) Plasma of a healthy person contains a short half-life factor that protects the body against cancer cells. It serves as a sentinel that kills or inactivates tumor cells as they start to develop; b) YH11 increases levels of this plasma factor by blocking or slowing down its degradation resulting in augmentation of body response against tumor cells. LC/MS/MS analysis of human plasma incubated with YH11 resulted in the appearance of an additional peptide that showed marked anti-tumor activity in both in vitro cultured tumor cells and in vivo mouse models of metastatic mammary carcinoma and melanoma. Both this peptide and YH11 had no toxic effects in in vivo studies. In summary, the present study proposes two efficacious and safe candidates for cancer therapy.
Inorganic arsenic (iAs) is a ubiquitous environmental toxicant implicated in the induction of different diseases, including cancer. Chronic, low dose iAs exposure leads to changes in gene expression and epithelial-to-mesenchymal transformation. During this transformation, cells adopt a fibroblast-like phenotype accompanied by profound gene expression changes. While many mechanisms have been implicated in this transformation, studies that focus on the role of epigenetic alterations in this process are just emerging. Epigenetic regulation is a potential mechanism by which iAs causes cancer. To decipher this mechanism, we carried out high-resolution profiling of the epigenetic changes as cells go through iAs-mediated cellular transformation. We performed genome-wide analysis of both DNA methylation (MethyLMini-Seq) and hydroxymethylation (RRHP) patterns in iAs-transformed cells. Global DNA methylation was found to be globally the same; however the S-hydroxymethyl levels were globally increased. In both data sets there are changes at individual loci that lead to changes in gene expression seen in the iAs-induced transformed cells. Further analysis reveals that CTCF, a master transcription factor, shows differential occupancy, in the iAs-transformed cells, at strong and weak binding sites, controlling the expression of both TET and DNMT gene families. iAs disrupts CTCF binding through disrupting the eleventh zinc finger, which leads to lowered occupancy at weak binding sites, especially in the DNMT and the proximal TET promoters. However at strong binding sites, as in the distal TET promoters, binding is stronger, allowing this distal site to act as an enhancer, driving TET overexpression in the iAs-transformed cells. The differential binding drives differential expression, leading to the changes in global DNA modifications. These analyses provide the first step towards understanding the functional significance of epigenetic changes in iAs-mediated transformation. Additionally, they set a platform for the development of potential therapeutic agents in iAs-carcinogenesis.

Structure-activity relationship (SAR) models for carcinogenesis typically use chemical descriptors and develop models based on chemicals that are classified as carcinogenic or non-carcinogenic. We report the application of an SAR approach using virtual biological descriptors (i.e., receptor interactions) for 12 tumor site rat carcinogen sets (i.e., clitoral gland, esophagus, hematopoietic system, kidney, large and small intestine, liver, lung, mammary gland, muscle, ovaries, skin, and uterus). Previous studies have demonstrated that similar receptor-based SAR models are capable of analyzing and predicting non-mutagenic carcinogens (i.e., through mechanisms other than DNA-reactivity). The first group, the Target-Site Carcinogen - Non-Carcinogen (TSC-NC) models were validated in a set of active chemicals that were not target site and inactive chemicals that were whole animal non-carcinogens. The second group, the Target Site Carcinogen - Non-Target Site Carcinogen (TSC-NTSC) was composed of active chemicals that again were carcinogenic to the target site but the inactive category was composed of carcinogens to any/all other sites except the target site. Furthermore, rather than traditional chemical descriptors, the novel SAR biological descriptors used herein were derived from the virtual screening for chemical-receptor interactions of carcinogens and non-carcinogens to a set of 9277 protein targets. Leave-one-out cross-validation of triplicate TSC models resulted in the models concordance value of 87% for the esophagus and 79% for the kidney. The TSC-NTSC triplicate models resulted in a range of concordance values for the small intestine model at 82% to the kidney model at 66%. Voting models, on the other hand, returned TSC-NC accuracy values between 95% for the esophagus and 79% for the kidney. The TSC NTSC voting results ranged between 93% for the small intestine and 75% for the liver. This new approach for organ-selective carcinogens, by contrasting carcinogenic agents between tumor sites and incorporating biologically-based descriptors (i.e., chemical-protein interactions) into the SAR models can enhance model predictivity, help bridge the gap between chemical exposure and carcinogenesis, and identify novel molecular targets for tumor site specific anticancer drug discovery.

Structure-activity relationship (SAR) models for carcinogenesis typically use chemical descriptors and develop models based on agents that are classified as carcinogens or non-carcinogens. We report the application of a SAR approach using virtual biological descriptors (i.e., receptor interactions) for chemicals with anticancer activity. Previous studies have demonstrated that similar receptor-based SAR models are capable of analyzing and predicting non-mutagenic carcinogens (i.e., through mechanisms other than DNA-reactivity). The National Toxicology Program has tested nearly 600 chemicals. An important component of these long-term studies is data on agents that decrease the rate of spontaneous tumors in treated animals (i.e., anticarcinogenesis). Based on determination by the NTP, 96 chemicals were identified for structure-activity relationship modeling with anticancer activity to the rat mammary gland. For these analyses, a traditional fragment-based SAR approach was used along with new virtual receptor interaction models. The receptor models used a technique for developing SAR model descriptors based on virtual ligand binding affinity for agents to agonize receptors. Based on the NTP compounds that interacted with anticancer activity, three sets of models were developed by varying the makeup of the inactive category. These were mammary anticancerogens with non-carcinogens, mammary carcinogens, and non-mammary carcinogens. Averaged leave-one-out validations resulted in correct rate values between predicted in vitro activity and the 96 chemicals that were tested against the respective receptors. Based on these models, we hypothesize that estrogen and estrogen receptors (ERs) which negatively affect ER-mediated transcription. This pathway to abrogate sustained AR-mediated signaling in CRPC.

2072 Capsaicin Negatively Regulates Warburg Effect in Pancreatic Cancer and Enhances the Effect of Gemcitabine

S. Ramachandran, Texas Tech University Health Sciences Center, Amarillo, TX.

Tumor cell metabolism is considered to be a hallmark of tumorigenesis progression. Pancreatic cancer cells are shown to develop addiction towards the metabolic pathways by glycolysis and mitochondrial respiration to meet energy demands. Pancreatic tumor cells predominantly utilize cytosolic aerobic glycolysis for energy production (Warburg effect). Our results indicated that the extra-cellular acidification rate (ECAR), an indicator of glycolysis was significantly up-regulated in pancreatic cancer cells BxPC3, AsPC1, MiaPACA2 and P202 when compared to normal human pancreatic ductal epithelial (HPDE) cells. In this study, we have shown that capsaicin treatment inhibits the survival of AsPC-1, BxPC-3 and MiaPACA2 pancreatic cancer cell lines. We evaluated the effects of capsaicin on regulating glycolysis in pancreatic cancer cells. Capsaicin treatment reduced the extra-cellular acidification rate (glycolysis) in AsPC-1 and BxPC-3 cells in a concentration-dependent manner after 24h of treatment. Capsaicin treatment caused 86% and 55% down-regulation of glycolysis process in AsPC-1 and BxPC-3 cells respectively. Treatment of AsPC-1, BxPC-3 and MiaPACA2 with capsaicin for 24h inhibited the expression of glycolytic enzymes LDH-A, Enolase-1, Aldolase A and its upstream regulators such as HIF-1α, HIF-2α, HIF-1α and HIF-1α as evaluated by Western blot. Capsaicin treatment suppressed the activity of LDH-A in BxPC3 cells after 24h of treatment as evaluated by LDH-A enzymatic activity assay. Furthermore, treatment of AsPC-1 and BxPC3 cells with capsaicin in combination with gemcitabine displayed synergistic effects when compared to gemcitabine treatment alone in a cytotoxicity assay and western blot. Our study thus indicates that capsaicin inhibits pancreatic tumor growth by suppressing glycolysis and potentiates the effects of gemcitabine. Further mechanistic studies are in progress. Supported in part by R01 grant CA129038, awarded to (S.K.S.) by the National Cancer Institute.

2073 Riluzole Induces DNA Damage in GRM1+ Human Melanoma Cells through the Accumulation of Reactive Oxygen Species

R. M. Cerchio, Rutgers, The State University of New Jersey, Scotch Plains, NJ.

Riluzole Induces DNA Damage in GRM1+ Melanoma Cells through the Accumulation of Reactive Oxygen Species. Our group described the oncogenic activity of a normal neuronal receptor, metabotropic glutamate receptor 1 (GRM1), when aberrantly expressed in melanocytes, the pigment producing cells. Deregulated melanocytic cell proliferation gives rise to transformed melanocytes and progressive aggressive melanoma, the most aggressive form of skin cancer. The natural ligand of GRM1 is glutamate and it is well known that all cells, particularly cancer cells, depend on glutamate/glutamate for growth. We showed that GRM1 expressing cells establish an autocrine loop regulates in the extracellular space to constitute enzymatic activation of GRM1 and cell growth. Treatment of these cells with pharmacological reagents by reducing GRM1 expression by silencing RNA led to cell cycle arrest at the G2/M phase after 24 hours and most of the cells then enter the apoptotic G0 phase. One of the pharmacological reagents we have used is riluzole, which is FDA approved for the treatment of amyotrophic lateral sclerosis (ALS). One of the functions of riluzole is inhibition of glutamate release, which allows the drug to functionally act as an antagonist to GRM1. Riluzole treated melanoma cells arrested at the G2/M phase of the cell cycle is indicative of DNA damage. Examination of GRM1 treated melanoma cells revealed enhanced phosphorylated histone H2AX (pH2AX) and p53-binding protein (53BP1) levels, two protein markers for DNA double stranded-breaks (DSBs). Furthermore, elevated Reactive Oxygen Species (ROS) levels were also detected in riluzole-treated melanoma cells. Currently we are assessing if inclusion of an ROS scavenger such as N-Acetylcysteine (NAC) could alleviate and reduce ROS levels. We are also examining protein markers of single-stranded DNA breaks such as

2070 Fragment- and Receptor-Based Structure-Activity Relationship Models for Rat Mammary Anticarcinogens

A. R. Cunningham1, A. C. Carraquer2, S. Qamar1, J. M. Maguire1, S. L. Cunningham2, and J. O. Trent1. 1University of Louisville, Louisville, KY; and 2Gnarus Systems Inc., CRESTWOOD, KY.

Structure-activity relationship (SAR) models for carcinogenesis typically use chemical descriptors and develop models based on agents that are classified as carcinogens or non-carcinogens. We report the application of a SAR approach using virtual biological descriptors (i.e., receptor interactions) for chemicals with anticancer activity. Previous studies have demonstrated that similar receptor-based SAR models are capable of analyzing and predicting non-mutagenic carcinogens (i.e., through mechanisms other than DNA-reactivity). The National Toxicology Program has tested nearly 600 chemicals. An important component of these long-term studies is data on agents that decrease the rate of spontaneous tumors in treated animals (i.e., anticarcinogenesis). These were mammary anticancerogens with non-carcinogens, mammary carcinogens, and non-mammary carcinogens. Averaged leave-one-out validations resulted in correct rate values between predicted in vitro activity and the 96 chemicals that were tested against the respective receptors. Based on these models, we hypothesize that estrogen and estrogen receptors (ERs) which negatively affect ER-mediated transcription. This pathway to abrogate sustained AR-mediated signaling in CRPC.

2071 Role of Aryl Hydrocarbon Receptor (AhR) and Estrogen Receptor Beta (ERβ) Crosstalk in Benzo(a)pyrene-Induced Colon Cancer

K. J. Harris1, K. L. Harris1, M. K. Washington1, A. E. Archibong1, J. Amos-Landgraf1, S. E. Adunyah1, and A. Ramesh1. 1Meharry Medical College, Nashville, TN; 2Vanderbilt University, Nashville, TN; and 3University of Missouri, Columbia, MO.

Colorectal cancer (CRC) is the third leading cause of cancer-related deaths in the United States. Epidemiological evidence show estrogen might influence the incidence of CRC in women by acting in a protective role via estrogen receptor beta (ERβ) but the underlying mechanism is not known. Benzo(a)pyrene (BaP), a well-characterized toxicant has been proven to be one of the contributors to the development of sporadic colon cancer. Literature provides evidence of crosstalk between AhR and ERβ. In our study, we used CRC canine cell line AsPC-1 and BxPC3 cells expressing GRM1 as our model system. We showed increase in CYP181, SULT1A1 and GST when compared to males in various treatment groups. It is possible that the increase in Phase II enzymes may provide clearance of BaP, preventing polyp development in female PIRC rats. In future studies, by measuring the expression of other drug metabolizing enzymes (DME), along with measuring circulating estrogen levels, analyzing [BaP] metabolite and BaP-DNA adduct profiles, we will provide insight into how estrogen can protect females from developing CRC. Funded by NIH grants SR25GM059944-3, G12MD007586-29, 5SU54CA163069-04 and SROI CA142845-04.
phosphorylated Replication Protein A (pRPA) plus alkaline and neutral conditioned Comet assays to further elucidate the mechanism and types of DNA damage elicited by Riluzole. The brain is a common metastatic site of melanoma and riluzole is known to cross the blood-brain barrier, it is possible that riluzole could be used as an enhancer for γ-irradiation, a common approach to treat brain metastases.

2074 Development of a Novel RON-Targeted Antibody-Drug Conjugates Using Cysteine Bridging Technology for Potential Treatment of Pancreatic Cancer

S. Suthe1, H. Yao2, P. C. Tippier1, and M. Wang. 1Texas Tech University Health Sciences Center, Amarillo, TX; and 2Zhejiang University School of Medicine, Hangzhou, Zhejiang, China.

Therapeutics targeting known oncoproteins have been applied for pancreatic cancer treatment but clinical outcomes are not promising. Hence, there is an urgent need to identify novel targets and develop effective drugs to improve pancreatic cancer therapeutic index. Antibody-drug conjugates (ADC) represent a promising class of drugs for targeted cancer therapy. Here we developed a novel ADC targeting RON receptor tyrosine kinase for potential pancreatic cancer treatment. To this end, we have synthesized a bis-alkylating linker (BL), attached to a lysosomal protease-cleavable dipeptide with payload Monomethyl auristatin E (MMAE). The BL-MMAE was then conjugated to Zt/g4 (anti-RON mAb) through cysteine bridging technology to produce Zt/g4-BL-MMAE with a relatively homogeneous conjugation profile and an antibody to drug ratio of 1:4. Zt/g4-BL-MMAE showed significant improvement in drug conjugation homogeneity and serum stability over conventional ADCs prepared through maleimide-based linkers. In pancreatic cancer cell lines overexpressing RON, Zt/g4-BL-MMAE specifically targeted RON-expressing tumor cells and was effective in rapid induction of cell surface RON endocytosis. Functional analysis revealed that Zt/g4-BL-MMAE caused cell cycle arrest at G2/M phase, reduction of cell viability and subsequently resulted in massive cell death. The calculated IC50 is in the range of 1 to 2 µg/ml. We conclude that Zt/g4-BL-MMAE is a novel anti-RON ADC with excellent conjugation profile, serum stability, and selective cytotoxicity for pancreatic cancer cells. This work provides a pharmaceutical opportunity for evaluating potentials of RON-targeted ADCs in pancreatic cancer treatment in the future.

2075 Open Access Gradient-on-a-Chip to Study the Role of Environmental Factors in Breast Cancer Risk

S. Chittiboyina, R. Rahimi, B. Zaie and S. A. Lelievre. Purdue University, West Lafayette, IN.

The common metabolic consequence of exposure to several environmental risk factors (diet, cigarette smoke, alcohol consumption, exposure to heavy metals and toxicants) associated with cancer oxidative stress (OS) created by an imbalance between reactive oxygen species (ROS) generated and cleared from the body. It is known that OS changes nuclear morphology and chromatin structure by stimulating global heterochromatin loss and induces H3K9me2 overexpression that suppresses gene expression. Yet, the nuclear mechanisms by which OS promotes carcinogenesis (a phenomenon greatly linked to modifications in gene transcription) remain to be understood. We have identified that the nuclear mitotic apparatus protein (NuMA), involved in chromatid organization and DNA repair, processes altered in cancer, interacts with a stress related transcriptional activator, lens epithelium derived growth factor (LEDGF) that is known to protect against OS, suppressed by H3K9me2 and is altered differentially in non-neoplastic cells versus preneoplastic triple negative breast cancer cells. Our central hypothesis is that a sustained gradient of OS influences NuMA-LEDGF expression, thus altering transcriptional regulation and triggering carcinogenesis. To test our hypothesis we used a 3D cell culture model of polarized mammary epithelium formed by human mammary non-neoplastic epithelial HMT-5322 S1 cells and exposed to acute OS by treating cells in 3D culture with 250 µM H2O2 for four hours that lead to a decreased expression of NuMA and yet this protein’s interaction with LEDGF was further strengthened. Using a gradient-on-a-chip that facilitates the continuous flow of a gradient of H2O2, as seen in vivo, in microfluidic channels diffused into 3D cultures of cells, we have shown that in preneoplastic triple negative breast cancer (TNBC) like S2 cells, nuclear morphology and cell response such as oxidative DNA damage to ROS are dose dependent.

To further investigate the effect of chronic OS on breast epithelium and carcinogenesis in association with NuMA-LEDGF pathway and an epigenetic impact, we plan to further modify our model to a risk-on-a-chip system to allow long term exposure of different microenvironmental factors such as ROS, and stromal factors to the normal tissue and study the synergism among these factors and related nuclear events that lead to cancer.

2076 Evaluation of T-Cell Receptor Codon Usage Reveals Immature Thymic Phenotype in ROYT Knockout Mice

ROYT, a sequence variant of ROY expressed exclusively in the thymus, is a nuclear hormone receptor and transcription factor that functions in thymocyte development and maturation. ROYT-/-mice develop thymic lymphoma with high penetrance and short latency, but the mechanisms underlying these changes are not well understood. In the present study, T-cell receptor alpha variable (TCRα) rearrangement was evaluated in constitutive (ROYT-/-) and inducible ROY KO mice by quantitative PCR analysis. In ROYT-/-mice, TCRα V regions were used at low frequency at the 5’ end while codon usage at the 3’ end increased in frequency by up to 3.88-fold in the thymus relative to wildtype (WT) littermates, indicative of a less mature genotype for TCRα. PCR analysis of a panel of thymic genes involved in ROYT-mediated lymphocyte development or implicated in tumorigenesis revealed marked changes in expression in ROYT-/-mice relative to WT littermates. These included decreases in Bcl-XL (0.03-0.10x WT), Rag1 (0.02-0.28x WT), Nab1 (0.04-0.12x WT), and Pten (0.04-0.43x WT), and an increase in Gzma (3.08-6.12x WT) in ROYT-/- mice, little to no change in expression of these genes was observed. These results indicate that the mouse thymus, lack of ROY function alters T-cell receptor codon usage and alters the normal balance of apoptosis and proliferation required for thymocyte differentiation. Additional studies are ongoing to determine whether these early changes are causally related to the development of thymic lymphomas.

2077 Biosynthesis of Estrogens in Mesothelioma Cancer Cells and Effect on Cell Growth

Malignant mesothelioma (MM) is a highly aggressive cancer with only about 10% patients surviving five years, but this period can be shorter depending on gender and subtype. The disease is associated with occupational and environmental exposure to asbestos, however, a higher prevalence of MM is seen in women due to environmental exposure. Inverse correlations between the levels of estradiol (E2), the most potent estrogenic hormone in women, and mesothelioma cancer patient survival post diagnosis suggests that decreased E2 levels inhibits mesothelioma cancer growth. Here we investigated whether MM cells could conduct denovo synthesis of the estrogenic metabolites estrone (E1) and E2 via the aromatase pathway using 4-androstene-3,17-dione (4-Adione) and testosterone (T) as precursors or via the sulfatase and 17beta-hydroxysteroid dehydrogenase pathway using E2 sulfate (E2S) as substrate. We also determined whether the estrogenic metabolite 5-androstene-3b,17b-diol (5-Adiol) could be formed from DHEA. All steroid measurements were made using stable isotope dilution liquid chromatography tandem mass spectrometry (LC-MS/MS). These metabolites were also tested to see if they affect MM cell growth. Our results showed that in M500-211H MM cells, E1 and E2S are converted to E2; by contrast the aromatase substrates 4-Adione and T were not converted to E1 or E2. In REN cells, only the conversion of E2S to E2 was observed. These data support the dominance of the sulfatase pathway over the aromatase pathway for estrogen synthesis in MM. We also showed that 5-Adiol is formed from the precursor DHEA in M500-211H cells. Our preliminary data showed that T and E2 modulated MM cell growth. This is the first documentation that MM can form estrogenic metabolites from precursors. This study will not only improve our understanding of the roles of estrogens and androgens in mesothelioma, but will also determine whether inhibiting steroid synthesis or using adjuvant hormonal therapy has a role in the treatment of mesothelioma.
The 2-year rodent carcinogenicity assays involving conventional rats and mice have been conducted for over 3 decades. As an alternative to the 2-year rodent carcinogenicity bioassays, 26-week short term carcinogenicity bioassays were approved using transgenic mouse strains, including Tg.rasH2. The Tg.rasH2 model, which can be used for both genotoxic and non-genotoxic compounds, has gained popularity and its use has increased over the years. Currently, more than 75% of all mouse carcinogenicity studies are being conducted in Tg.rasH2 mice. The Tg.rasH2 model predicts neoplastic findings relevant to human cancer risk assessment, produces fewer non-biologically significant neoplastic outcomes, and is thus often preferable to a 2-year rodent study. We published the largest historical control database for both neoplastic and non-neoplastic lesions in Tg.rasH2 mice. Our current historical control data base has grown sufficiently that we can now begin to look at the effects of vehicles or vehicle components on both non-neoplastic and neoplastic findings. We recently evaluated the incidence of tumors in male and female mice in 26-week Tg.rasH2 oral gavage carcinogenicity studies with methylcellulose as one of the ingredients of the vehicle versus various non-cellulose vehicles. Review of the data indicated that the total incidence of tumors in 475 mice administered with methylcellulose and 585 mice administered with non-methylcellulose vehicles was similar. Our analysis showed that the total incidence of tumors was 20.84% and 25.68% in males and females, respectively, with methylcellulose administered mice. The remainder of the historical control data base had a total tumor incidence of 24.1% and 21.37% in males and females, respectively and was considered similar to the studies where methylcellulose was a component of the vehicle. Additional comparisons by tumor location (lung, spleen and Harderian gland) is ongoing.

Arsenic is a naturally occurring and highly potent metalloid known to elicit serious public health concerns. Today, approximately 200 million people around the globe are exposed to arsenic-contaminated drinking water, and it is thus often preferable to a 2-year rodent study. We published the largest historical control database for both neoplastic and non-neoplastic lesions in Tg.rasH2 mice. Our current historical control data base has grown sufficiently that we can now begin to look at the effects of vehicles or vehicle components on both non-neoplastic and neoplastic findings. We recently evaluated the incidence of tumors in male and female mice in 26-week Tg.rasH2 oral gavage carcinogenicity studies with methylcellulose as one of the ingredients of the vehicle versus various non-cellulose vehicles. Review of the data indicated that the total incidence of tumors in 475 mice administered with methylcellulose and 585 mice administered with non-methylcellulose vehicles was similar. Our analysis showed that the total incidence of tumors was 20.84% and 25.68% in males and females, respectively, with methylcellulose administered mice. The remainder of the historical control data base had a total tumor incidence of 24.1% and 21.37% in males and females, respectively and was considered similar to the studies where methylcellulose was a component of the vehicle. Additional comparisons by tumor location (lung, spleen and Harderian gland) is ongoing.

DCE is a chlorinated hydrocarbon used as a chemical intermediate including in the synthesis of vinyl chloride which is used to make polyvinyl chloride. While DCE has induced tumors in both rats and mice, the overall weight of evidence for genotoxicity suggests that DCE is a non-genotoxic carcinogen. The present study was conducted to further assess the in vivo genotoxicity of DCE and explore a potential mode of action for tumor formation in rat mammary tissue. Fischer 344 rats were exposed to target concentrations of 0 or 200 ppm of DCE vapors (six hours/day, seven days/week) for 28 days. This concentration of DCE is approximately 20% higher than that reported to induce mammary tumors in rats. Endpoints examined included DNA damage (via Comet assay), GHS/GSSG levels, tissue adduct levels, cell proliferation and serum prolactin levels. One MoA hypothesis was that alterations in serum prolactin and cell proliferation were potential non-genotoxic key events leading to tumor formation. Exposure to DCE did not have an effect on serum prolactin levels or cell proliferation in mammary epithelial cells. DNA adducts were identified including the N7-guanylyl glutathione (GEG) cross-link adduct which was considered as a biomarker of exposure with higher adduct levels measured in the non-target tissue compared to mammary tissue isolated from the same rats. The results of the comet assay in mammary epithelial cells indicated that DCE did not result in increased DNA damage while the positive control N-Nitroso-N-methylurea resulted in a statistically significant increase relative to controls. While the results of this study do not identify a mechanism for DCE-induced mammary tumors in rats, the lack of any exposure-related genotoxic effects in the Comet assay or relevant target-tissue-specific DNA adducts further contributes to the weight of evidence for DCE as a non-genotoxic carcinogen.

Humans respond to an array of chemicals every day, including those that are endogenously produced like stress-induced hormones. However, the potential toxicological impacts of mixtures consisting of stress hormones and chemical exposures are rarely explored. To further investigate a mixture of induced stress and organophosphates, adult male C57BL/6J mice were exposed to corticosterone (Cort; 200μg/ml) in the drinking water for 7 days, and on the 8th day, were given a single intraperitoneal injection of diisopropyl fluorophosphate (DFP, a sarin surrogate; 400mg/kg). Mice were euthanized 30 minutes, 2 hours, and 24 hours post-exposure via a focused microwave radiation. To fully understand the effects of DFP and DFP+Cort on the brain, post-translationally modified proteins were isolated from the mice using a tris-EDTA buffered ELISA for the cortex. To optimize analysis of the specific data sets, a network parameter approach corresponding to radiality was used to assess the response of the phosphoprotein targets in relation to all other responses. This approach identified proteins that were substantially activated or inhibited within this network, and is informative with regard to the mechanisms of interactions that are occurring as a result of this mixture exposure.
**2082 Disruption of Thyroid Hormones by PBDE Mixtures: Potential for Co-Exposure Bias**

T. F. Webster, Boston University School of Public Health, Boston, MA.

PentaBDEs are ubiquitously found in human serum with highest average levels found in North America. Toxicological research in rodents generally shows that increased exposure leads to decreased thyroid hormone (TT4). Epidemiologic studies have been more inconsistent; one difficulty has been that PentaBDEs are typically highly correlated in human serum (r=0.4-0.97) and studies analyze one congener at a time. This can lead to confounding by co-exposure if only a subset of the mixtures is active; collinearity can make standard multiple linear regression on several exposures problematic. The current research therefore uses a recent mixtures statistical approach and discusses a newly discovered potential issue. Serum PBDEs and thyroid hormones were measured in a longitudinal cohort of Boston office workers sampled in 2010-2011; single congener results were previously published. Here, all major congeners were examined simultaneously using weighted quantile sum regression. For every quartile increase in weighted PBDEs, TT4 decreased by 0.4 µg/dL. The highest weighted congener was BDE-99 followed by BDE-47 and BDE-153. A newly discovered potential issue with mixtures study is co-exposure amplification bias; this problem is most stark when correlations between exposures are high and there is uncontrolled confounding for one or a subset of exposures. In multiple linear regression, this can lead to amplification of bias for some estimated coefficients and sign reversal for others. Uncontrolled confounding by physiology is a potential issue for studies of serum PBDEs and thyroid hormones. However, we showed that weighted quantile sum regression is not subject to co-exposure amplification bias. Further investigation of causal mechanisms vs. confounding for PBDE-TT4 associations are needed.

**2083 Binding Ratio of Highly-Bound Ligands to Albumin and Alpha-1-Acid Glycoprotein**

M. Bteich1, P. Poulin1,2, S. Piette1, and S. Haddad1. 1IRSPUM, Université de Montréal, Montréal, QC, Canada; and 2Consultant Patrick Poulin Inc., Québec City, QC, Canada.

Plasma protein binding is a key factor studied in pharmacokinetics/toxicokinetics of drugs. Many xenobiotics could extensively bind to two important plasma proteins, albumin (ALB) and alpha-1-acid glycoprotein (AGP). For the accurate determination of exposure, Perapamelan, a cell line, was used as a non-competitive antagonist of AMPA receptors is one of these xenobiotics. The main objective of this study is to determine for highly bound drugs if binding parameters (Bmax, KD and Cfree) to both proteins could be used to predict the binding ratio (RAGP/ALB). Thus, in vitro binding tests are made using rapid equilibrium dialysis. The test concentrations for PerapameLAN are 2.5, 7.5, 15, 20, 25, 35 µM. Four binding scenarios are suggested: 1) bovine ALB (40g/L), 2) bovine AGP (1g/L), 3) serum (Ser); containing the same concentrations of both plasma proteins injected in the same test chamber, and 4) with both proteins; each protein is injected in a different chamber of the insert. The Bmax values for are 84.3 µM, 57.52 µM and 7.60 µM with Ser, ALB and AGP, respectively. The KD values are 8.54 µM, 6.74 µM and 7.25 µM, respectively. Data from scenario 1 and 2 can accurately predict RAGP/ALB when Cfree < Bmax (AGP, 7.60 µM). Data from scenario 3 (Cfree) and 4 (Total) can accurately predict the bound concentrations of PerapameLAN to each of the proteins in serum. These preliminary binding kinetics (Bmax, KD and RAGP/ALB) would eventually guide us in suggesting and validating an in vitro-in vivo extrapolation model for hepatic clearance of highly bound ligands to both plasma proteins.

**2084 Effects of Low to Moderate Levels of Deoxynivalenol and Its Metabolites Combinations in HepG2**

The presence of mycotoxins in food matrix is not related with the presence of only one fungi strain in the matrix of analysis. The relation of mycotoxin/fungi strain is one-to-one, since one fungi can produce more than one mycotoxin. Fusarium mycotoxins (Fusarium moniliforme) after co-exposure to Fusarium deoxynivalenol (DON) and 3-acetyl-Deoxynivalenol (3-ADON) and 15-Acetyl-Deoxynivalenol (15-ADON). Both occur in significant amounts jointly deoxynivalenol (DON), in various cereal crops and processed grains. Mycotoxins' cytotoxic potential has been reported in several directions as generation of reactive oxygen species, lipid peroxidation, DNA damage and apoptosis-necrosis. The objectives of this study were to compare the cytotoxicity of DON, 3-ADON and 15-ADON alone or in combination in human hepatoma (HepG2) cells using the NR assay after 24 h of exposure; to evaluate the interactions of mycotoxins mixtures by the isobologram analysis and to compare the in vitro genotoxic effect by induction of micronucleus (MN) by flow cytometry of these mycotoxins alone and in combination. The HepG2 cells were exposed to DON, 3-ADON, 15-ADON combinations at concentrations from 0.6 to 4.5 µM DON, and from 0.1 to 1.5 µM for 3-ADON and 15-ADON. The results revealed that the IC50 values obtained for individual mycotoxins range from 4.3±0.4 to 10.2±0.4 µM, from 1.9±0.4 to 3.9±1.3 µM and from 2.0±0.3 to 6.0±1.0 µM for DON, 3-ADON and 15-ADON. Isobologram analysis provides a combination index (CI) value to determine the type of interaction that occurs. The interactions of DON, 3-ADON and 15-ADON became slightly synergism at low concentrations tested in the combinations (CI from 0.01±0.01 to 0.42±0.18) and turned into additive effect at higher concentrations (CI from 1.15±0.22 to 19.30±0.20). Moreover, all mycotoxins produce MN induction. MN test represents damage. Triple and the binary combination 3-ADON+15-ADON reached the highest MN score. In conclusion, mycotoxins combinations have higher cytotoxic effect than mycotoxins alone tested. Therefore, more assays on combinatorial effects are needed to understand the realistic exposure scenario of consumers. This work was supported by the Spanish Ministry of Economy and Competitiveness (AGL2016-77610-R).

**2085 Variations in Histopathological Responses within the Liver and Spleen to Various Acute Crude Oil Exposures**

S. A. Martinez1, J. T. Salley1, R. A. Suliman1, S. Jalilgama2, and S. A. Meyer1. 1University of Louisiana at Monroe, Monroe, LA; and 2*Battelle Memorial Institute, Columbus, OH.

Observed toxic effects from crude oil exposure can vary based upon their constituent composition. We have determined values for several toxic effects of acute exposure to the following crude oils: LA Sweet, Nigerian ‘Qua Iboe’, Iraqi ‘Basra’, Venezuelan Merey and Leona, Ecuadorian Oriente, and Colombian Vasconia (all from ONTA, Inc., Toronto), and Deepwater Horizon (DWH) samples A0083Q “Mass Aug 15” and A001EP/EQ “SOB MAY 22” plus an oil mix prepared to mimic the composition of the DWH samples A010G4 “Surrogate” (AEOM, Inc., Fort Collins, CO). Female Sprague Dawley rats were treated with 2 daily doses of 0, 2.5, and 5 mL/kg, (p.o.) and whole blood and serum were collected 48 hours later for hematology and clinical chemistry analyses. Liver and spleen were also obtained 48 hour later upon necropsy, weighed and then immediately fixed in formalin. Rats treated with all crude oils had elevated relative liver weights and alkaline phosphatase, and decreased relative spleen weights. For histopathology, 5 µm sections were cut from formalin-fixed, paraffin-embedded livers and spleens, and stained with H and E. Hepatocytes showed treatment-related differences: centrilobular hypertrophy, vacuolization, sinusoidal disruption, and periportal necrosis. Within the periarterial lymphatic sheaths (PALS) of spleens were observed differing numbers of apoptotic lymphocytes following exposure to different crude oils in treated rats when compared to control. Spleens with crude oil induced-lymphoid apoptosis display an increase in macrophage infiltration giving the classical “starry night” pattern within the PALS. These apoptotic lymphocytes were observed with degeneration and necrosis, and seen being phagocytized by macrophages. These data suggest that variations of occurrence and severity in the observed toxic effects within the liver and spleens of acutely treated animals reflect the different composition of the crude oils.

**2086 Anti-BPDE-DNA Adducts after Exposure to Benzo[a]pyrene Are Increased in the Presence of Aromatic Amines in RT4 Cells**

S. Plöttner, H. U. Käferlein, P. Welge, and T. Brüning. IPA, Bochum, Germany.

Exposures to both, aromatic amines and polycyclic aromatic hydrocarbons are associated with increased risk of bladder cancer. However, only little information is available on the cellular and molecular effects of co-exposures on the urothelium. The aim of the present study was to investigate the activity and induction of cytotoxicity P450 1A1 (CYP1A1) and the formation of specific DNA adducts of benzo[a]pyrene (BaP) in human bladder cell lines RT4 bladder papilloma cells to BaP and various concentrations of 2-naphthylamine (2-NA) and 4-amino-benzene.
phenyl (4-ABP). For this purpose, the cells were co-incubated for 24 h with 1 µM B[a]P + 10-100 µM 4-ABP and 1 µM B[a]P + 10-100 µM 2-Na. Compared to 1 µM B[a]P alone, co-treatment with 2-Na resulted in enhanced CYP1A1 activities (luminescent assay) and induction (immuno-noblots), whereas decreased activities and induction were observed for co-incubation with 4-ABP. In contrast, increased anti-BPDE-DNA adduct rates were observed for both co-exposures of B[a]P + 2-Na and B[a]P + 4-ABP and compared to 1 µM B[a]P alone. The effect was even more pronounced for co-exposures with 4-ABP than for 2-Na. We repeated the experiments in the presence of a specific arylhydrocarbon receptor (AhR) antagonist. Although, as expected, CYP1A1 activities and protein were no longer measurable, anti-BPDE-DNA adducts and adducts were still detectable. In case of co-exposures of B[a]P and 2-Na, the observed anti-BPDE adduct rates were even higher than in the absence of the AhR antagonist. Our results suggest that additional enzymes are responsible for the enhanced formation of anti-BPDE adducts in the presence of 2-Na and 4-ABP rather than CYP1A1 alone. Since the highest adduct rates were observed when CYP1A1 activities were low (4-ABP without AhR inhibitor) or completely inhibited (2-Na with AhR inhibitor), CYP1A1 appears to even have some detoxifying properties in the used cell model.

**2087** Coupling In Vitro and Computational Methods to Investigate the Transport of Herbicide/Insecticide Mixtures into Saliva

A. A. Han, Z. A. Carver, T. J. Weber, C. Timchalk, and J. N. Smith. Pacific Northwest National Laboratory, Richland, WA; and Columbia Basin College, Pasco, WA.

Portable sensors and PBPK models have previously been developed to describe the relationship between salivary and plasma concentrations of commonly applied herbicide and insecticide metabolites, 2,4-Dichlorophenoxyacetic acid (2,4-D) and 3,5,6-trichloro-2-pyridinol (TCPy). These efforts not only offer a better understanding of potential adverse health effects elicited by common household chemicals but further provide justification for biomonitoring saliva to assess risks associated with occupational exposures. While understanding the pharmacokinetics of a single chemical is necessary, chemical mixtures are more reflective of the reality of everyday exposures. An in vitro system was employed to evaluate the chemical transport of a simultaneous dosing of 2,4-D and TCPy across a monolayer of serous-acinar cells cultured from the submaxillary saliva glands of Sprague-Dawley rats. The transport of chemicals across the cell layer (via passive diffusion) was influenced by the binding of proteins (i.e. unbound chemicals were able to pass through the cell layer). At a constant concentration of TCPy (200 µM), levels of protein bound to TCPy in cell culture media (Advanced DMEM:F12 supplemented with 2% fetal bovine serum) decreased much as 52% with an increasing co-exposure to 2,4-D (0-2300 µM), indicating that these chemicals compete for common binding sites on proteins. This suggests that exposure to chemical mixtures may influence measureable levels of herbicides/insecticides in saliva samples. Additional protein binding (at physiological conditions) and kinetic-cellular transport experiments quantifying chemical transport and binding rates were conducted to further explore implications of chemical mixture transport. Supported by Centers for Disease Control-National Institute for Occupational Safety and Health (CDC-NIOSH) grant R01 OH011023.

**2087a** Combined Cytotoxic Effects of Lead (Pb) and Disinfection Byproducts (DBPs) on Chinese Hamster Ovary (CHO) Cells and Heterogeneous Human Epithelial Colorectal Adenocarcinoma (Caco-2) Cells

J. Liu, V. K. Sharma, and C. M. Sayes. Texas A&M University, College Station, TX; and Baylor University, Waco, TX.

Disinfection aimed at inactivating pathogens is an essential process in drinking water treatment plants. Chlorine and chloramine are common disinfectants used in this process today. During disinfection, halogenated disinfection byproducts (DBPs) can be generated from the reactions of chlorine with natural organic matter (NOM) and bromide ions in surface water. As halogenated DBPs have been shown to induce adverse effects on cells in culture and rodent models. A certain amount of disinfectant residue is maintained in the water distribution system to prevent the regrowth of microorganisms. Lead (Pb)-containing plumbing materials are widely present in water distribution pipelines in the U.S. Disinfectant residues can react with the pipe materials and enable the release of lead (in the form of Pb2+) into water. Pb2+ is an abundant toxic metal ion that primarily affects the peripheral and central nervous systems, kidneys, red blood cells, and calcium metabolism after ingestion. In this study, we measured the toxicity of lead (Pb2+) and halogenated DBPs on Chinese hamster ovary (CHO) cells and heterogeneous human epithelial colorectal adenocarcinoma (Caco-2) cells separately as well as the synergistic toxic effects of Pb2+ and DBPs co-exposures. Data was collected over a dose-response and time-response experimental design and compared to series of controls. The results showed the combined toxic effect of lead and each DBP on the cell cultures were both dose and time dependent. Our data suggest that lead (in the form of Pb2+) affects the formation of DBPs and the overall quality of drinking water.

**2078b** Report of the 2017 Society of Environmental Toxicology and Chemistry (SETAC) Conference on Risk Assessment of Chemical Mixtures

M. Mumtaz, M. Johnson, E. Genderen, M. Ottinger, A. Beasley, E. Furlong, K. Brix, T. Schlekat, and T. Backhaus. CDC/ATSDR, Atlanta, GA; 7US Army, Aberdeen Proving Ground, MD; 7International Zinc Association, San Rafael, CA; 7University of Houston, Houston, TX; 7The Dow Chemical Company, Midland, MI; 7US Geological Survey, Denver, CO; 7EcoTax, Miami, FL; 7SETAC, Pensacola, FL; and 7University of Gothenburg, Gothenburg, Sweden.

Exposure to complex mixtures, sequentially or simultaneously, has the inherent potential to impact our health and that of the environment. Presence does not mean risk, hence assessments are conducted to evaluate the degree of risk(s) and when necessary mitigate exposures. SETAC recently held a Focused Topic Meeting on mixtures to review the current state of the science for conducting and interpreting the risk of chemical mixtures using a “One Health” approach. International experts invited from Asia, Europe, and the United States presented their perspectives and opinions on various facets of the risk assessment paradigm for mixtures of pharmaceuticals, pesticides, industrial organic pollutants, and metals. Examples and case studies from the conference included reanalysis of the dose and adversity assessment, incidence of non-additive interactions, approaches for assessing undefined mixtures, use of adverse outcome pathway (AOP), and priority mixtures warranting specific attention. A general conclusion was that mixtures matter, and the dose addition approach was considered to be generally applicable for mixture toxicity assessments using a variety of human and ecological life cycle assays. Currently available models provide the necessary degree of flexibility, including the use of in vitro data as research continues to fill data gaps. However, additional empirical data are needed to prudently regulate mixtures in environmental as well as human health contexts. These findings and conclusions in this presentation have not been formally disseminated by the Centers for Disease Control and Prevention/the Agency for Toxic Substances and Disease Registry and should not be construed to represent any agency determination or policy.

**2088** Computational Association of Chronic Phosphate Consumption, Exafk Consumption, and Celiac Disease in the Saharawi People of Western Sahara

Celiac disease (CD) is a long-term autoimmune disease affecting 1% of people globally; whereas, the Saharawi people of Western Sahara have an unusually high incidence of 5.8%. The Saharawi people possess HLA-DQ2 isoforms making them genetically predisposed to CD. A change in dietary habits over the last few decades may also be responsible for the Saharawi’s high incidence of celiac disease. Prior to the introduction of the European diet, the Saharawi subsisted on mainly camel meat and milk. While it is possible that the increase consumption of gluten-heavy foods may play a role in elevated disease incidence, other populations have a much lower prevalence of CD with similar diet consumption and HLA-DQ2 frequencies. The aim of this study was to determine whether there is an additional environmental component that increases the susceptibility of the Saharawi. The Saharawi live on 75% of the world’s phosphate rock and consume a local plant Askaf in large amounts, primarily in camel milk. A systems approach was used to determine chemical–gene interactions for phosphate and relevant phytochemicals in Askaf. Research shows that phosphate can stimulate Akt signaling, leading to increased downstream T-cell activation, B-cell activation and antibody production, resulting in greater CD pathology. In addition, flavonoids in Askaf can increase the expression of CTLA-4, an inhibitory receptor on regulatory T-cells, thereby suppressing the immune system. Saponins in Askaf can decrease Akt signaling, thereby decreasing T-cell activation and B-cell antibody production. From these findings, it was concluded that chronic phosphate exposure may contribute to a high incidence of CD in the Saharawi, and the decreased
The conjugated linoleic acid (CLA) isomers, trans-10, cis-12 (CLA10c12) and cis-9, trans-11 (CLA9t11), have opposite effects on early collagen-induced arthritis (CA); however, initial studies comparing these two isomers had major differences in design. The individual isomer's effects on autoimmunity suggest that CLA10c12 may play a more harmful role during the initial stages of disease than CLA9t11. Currently mixed isomer CLA is used as a treatment for inflammation; a direct comparison of the primary CLA isomers was performed to determine the effects each has on arthritis prevention. DBA/1 mice were fed a semi-purified diet containing 0.5% CLA10c12, 0.5% CLA9t11, or 1% corn oil (CO) starting three weeks before CA induction. The effects on disease incidence and severity as well as, anti-collagen antibodies, cytokines, and hepatic fatty acids were measured. Maximum arthritis incidence was reduced at least 34% in mice fed either CLA isomer compared to those fed a CO diet (P = 0.06). In mice that did develop arthritis, CLA10c12 reduced arthritic severity to a greater extent than CLA9t11 and CO (P = 0.03). One week prior to arthritis onset CLA10c12 fed mice had decreased plasma anti-collagen IgG (P = 0.04). CLA10c12 increased the 16:0 to 16:1c9 ratio supporting delta-9 desaturase enzyme inhibition by this fatty acid (P = 0.004). This new data supports continued exploration into the utility of CLA isomers as preventive treatments for chronic inflammation.

The Procter & Gamble Company, Mason, OH; and 2Research Institute for Fragrance Materials, Woodcliff Lake, NJ.

The ability of a chemical to bond covalently to protein has been identified as the first key event in the skin sensitization adverse outcome pathway and is the basis for the Direct Peptide Reactivity Assay (DPRA), a validated skin sensitization alternative test. While the DPRA is applicable to a wide variety of chemicals it lacks a metabolic component which is critical for detecting chemicals identified as pro-haptens, non-sensitizing chemicals that are transformed into protein reactive haptens while not compromising the assay's ability to detect pro-haptens.

The Peroxidase Peptide Reactivity Assay (PPRA) was developed. The PPRA includes a horseradish peroxidase-hydrogen peroxide (HRP/P) metabolic component for the enzymatic activation of pro-haptens sensitizers. In the PPRA chemicals are incubated with cysteine-containing (CYS) and lysine-containing (LYS) peptides in the absence of HRP/P (CYS-, LYS-) and with CYS in the presence of HRP/P (CYS+). Evaluation of an expanded set of 209 chemicals tested in the PPRA revealed false negative results for 12 aldehydes and 4 thiazolines. A subset of 8 aldehydes and 2 thiazolines was selected to evaluate protocol modifications aimed at improving detection of these chemical classes. Dithiothreitol (DTT), a strong reducing agent added to the CYS reactions to prevent formation of CYS dimers via oxidation, was identified as the primary cause for low CYS depletion which resulted in the false negative result. When tested in a modified PPRA the maximum percent CYS depletion (DPMax) was increased approximately 3- to 27-fold in the CYS- without DTT reactions compared to CYS- with DTT, with 9 of the 10 chemicals having DPMax values which exceeded the positive cut-off value of 25%. Use of DTT only in the CYS with HRP/P reaction improved detection of reactive aldehydes and thiazolines while not compromising the assay's ability to detect pro-haptens.
Exposure to trichloroethene (TCE) is associated with autoimmune hepatitis (AIH). However, mechanisms contributing to TCE-mediated AIH are not known. We hypothesized that increased apoptosis and delayed clearance of apoptotic bodies, due to compromised Kupffer cell (KC) function, will result in breakdown of self-tolerance, autoimmunity, and ultimately AIH. Earlier, we have shown that dichloroacetic acid (DCA), one of the metabolites of TCE with strong acylating capability, can elicit an autoimmune response at much lower dose than TCE in MRL/+ mice. Furthermore, KCs, the liver resident macrophages, are crucial for hepatic homeostasis, but can also participate in the immunopathogenesis of AIH. However, contribution of KCs in TCE-mediated AIH and the underlying mechanisms are not understood. Therefore, using an in vitro model of immortalized mouse KCs and a reactive metabolite of TCE, DCAC, we investigated the molecular mechanism of TCE-mediated AIH. KCs were pre-treated with different concentrations of DCAC for 24 hours, followed by addition of lipopolysaccharide (LPS) to the culture system for 4 hours before harvesting the cells. Markers of apoptosis (PD1, MFG8 and Caspase1) and inflammasome (NLRP1 and NLRP3) were analyzed by real-time PCR. Also, the phagocytic potential of KCs was evaluated by using fluorescent labeled beads. DCAC treatment resulted in the activation of inflammasome cascade (NLRP1, caspase1 and IL18) and apoptosis-related MFG8. Interestingly, DCAC treatment resulted in decreased phagocytic activity of KCs in a dose-dependent manner. These findings suggest that DCAC induced apoptosis and inflammasome activation, while inhibiting phagocytic function of KCs. Our data support that increased apoptosis and impaired KC function by DCAC could be contributory to TCE-mediated AIH. Supported by NIH ES026887.

**Comparison of the Acute Respiratory Response to Crystalline Silica and Multi-walled Carbon Nanotubes in Male and Female Mice**

J. L. Ray, R. F. Hamilton, and A. Holian, University of Montana, Missoula, MT.

Systemic lupus erythematosus (SLE) is a complex chronic disease and patients often have a poor prognosis. As with many autoimmune diseases, the occurrence of SLE is dramatically higher in women than in men, with a ratio of 9:1. However, the reason behind women’s increased susceptibility is unknown. In addition to genetics, environmental factors are thought to contribute to the development of autoimmune disease. However, there remains a gap in our knowledge of how sex-based differences in response to environmental stimuli contribute to the etiology of autoimmune disease. Epidemiological evidence has linked the inhalation of crystalline silica (SiO2) with the development of SLE, however, sex-differences in inflammatory responses to SiO2 are not understood. Additionally, engineered nanomaterials such as multi-walled carbon nanotubes (MWNTs), are becoming an increasing concern in the etiology of lung disease, but the relatively few studies evaluating sex-differences are inconclusive. This study compared the acute respiratory responses of female and male C57BL/6 wild-type mice to SiO2 and MWNTs, in order to characterize differences in the immune response and susceptibility to lung injury. Most comparisons were similar between sexes. However, twenty-four hours after a single exposure to SiO2, males had significantly fewer alveolar macrophages in their lung lavage fluid, but a greater number of neutrophils than treatment-matched females. Furthermore, one week after a single exposure to SiO2, both sexes of mice had an equal number of AMs, but a higher percentage of these AMs were activated in male mice, as determined by MHCII expression. Our results demonstrate a differential macrophage response between sexes in response to SiO2, which may provide a basis for sex-based differences in antigen processing and presentation mediating the development of SLE. Funded by NIH grant R01ES023209.

**Oral Sensitization of Mice to a Cow's Milk Allergen Induces Increased Grooming Behavior and Epigenetic Changes in the Brain**

K. Nagamoto-Combs, N. A. Smith, and D. L. Gemmudson, University of North Dakota, Grand Forks, ND.

Consumption of a certain food item, such as cow’s milk or wheat gluten, is reportedly associated with behavioral changes in susceptible individuals although causative evidence is rather limited. We hypothesize that such behavioral changes may be a type of allergic manifestation that affects the central nervous system (CNS) in individuals with sub-anaphylactic food hypersensitivity. To determine whether a food allergen would induce behavioral changes, we used a mouse model of milk allergy and investigated peripheral events that might contribute to alterations in CNS function and ultimately behavior. Four-week-old male and female C57BL/6 mice were subjected to weekly oral sensitization to either a vehicle or β-lactoglobulin (BLG), one of the major allergens in the whey protein fraction of cow’s milk. After a 5-week sensitization period, all animals were challenged with BLG during the 6th week and their behavior was assessed before sacrifice. We observed that BLG-sensitized males, but not females, exhibited increased grooming behavior. Associated with the behavioral deviation, immunoglobulin E (IgE) was elevated in the male BLG-sensitized mice when compared to sham mice using BLG-specific IgELISA. Quantitative RT-PCR analyses from intestinal tissue suggested that proinflammatory cytokines increased in the BLG mice. Interestingly, immunohistochemical staining of the brains from these mice showed distinct 5-hydroxymethylcytosine changes in the hippocampus and thalamus, and parts of the cerebral cortex. These results indicated a food allergen-induced epigenetic modification in specific areas of the brain, providing evidence for food allergen-mediated inflammatory responses and molecular alterations in the brain.
2098 Assessment of Dermal Sensitization Risk Potential of Cured Inks Utilizing a Novel Extraction Method in the Local Lymph Node Assay (LLNA)

L. R. Glass1, M. R. Carathers2, P. Vij3, B. J. Varsho2, and G. L. DeGeorge4. Xerox Corporation, Webster, NY; and MB Research Labs, Spinnerstown, PA.

Humans come in contact with a variety of different materials that have been printed with cured inks. Currently, there are a number of different cured inks on the market that have little to no assessment of hazard or risk. It is known that during the curing process that not all the polymers are cured to the printed material, whether it is molskien or a number of different plastics. When humans use, little has been done to assess the sensitization (allergic response) to humans. The Local Lymph Node Assay (LLNA) has been used for more than two decades to assess a material’s potential to induce an allergic response. The normal convention of the LLNA is to solubilize the material in a number of different organic solvents and topically dose the mice with this material. We modified this process to determine a more risk-based assessment instead of a hazard assessment. If there is no exposure potential, then there is no hazard or risk associated with a material. We designed an extraction process to model a realistic human exposure. In this project, the LLNA was used to assess 1) the uncured ink that could prior to cause an allergic response; 2) if the cured ink could be extract from plastics with either 0.9% physiological saline or 100% ethanol. The saline was used as an extractant to determine if there is an exposure risk if a human holds either a printed plastic water bottle, ink printed molskien, and ink printed plastic cup. The extraction was conducted at 37°C for approximately 24 hours, which was modified from the ISO 10933-12. The LLNA determined that the uncured ink is definitively a dermal sensitizer. The uncured ink was tested at 5, 10, and 25%, which produced stimulation indices (SI) of 3.8, 5.8, and 7.1, respectively. However, when the extractions were conducted in saline, there was no sensitization seen in the cured ink printed on a plastic bottle or molskien. Topical application of the saline extractions of the ink applied to bottle and molskien at 10%, 25%, and 50% resulted in SI values less than 1.6. Therefore, these are not dermal sensitizers in the Local Lymph Node Assay.

2099 Organochlorine Insecticide Exposure Effect on Changing Spraying Farmers’ Thyroid Stimulating Hormone (TSH) Level in Kertasari District, Bandoeng Regency

The use of insecticides in agriculture is now often done by farmers to achieve sustainable agriculture against insect pests. One insecticide widely used in Indonesia is class of organochlorine insecticides. Organochlorine insecticides are persistent both in the environment and in the body of living things that are exposed. Long-term exposure to organochlorine insecticides can have an impact on the health changes on sprayer farmers, one of which is a thyroid disorder in the form of increasing level of thyroid-stimulating hormone (TSH). This research was conducted on spraying farmers in Kertasari district, Bandoeng regency. Sampling was taken when farmers do insecticide spraying activity using bad sampling to check dermal exposure. This report describes organochlorine concentration, which exposes spraying farmers and then convert to the accumulation of the intake to see the effect on TSH level in farmers’ blood. This paper also described the factors that can affect TSH levels in the farmers’ blood and the risk value between an exposed farmer and unexposed farmer. Organochlorine insecticides that were detected in the field, namely lindane, heptachlor, aldrin, endosulfan, DDT, dieldrin, and endrin, with each highest value of exposures, were 07818 mg/cm², 0.021 mg/cm², 0.5824 mg/cm², 0.0464 mg/cm², 0.0025 mg/cm², 0.0014mg/cm², and 0.1108 mg/cm². The results of statistical calculation there is a relationship between the intake and the increasing of TSH level which the factor has a strong relationship was lindane intake (Pearson correlation. r=0.656,p<0.000). The risk value also showed that exposed farmers have higher risk of getting hypothyroid disease than unexposed farmers.
in an effort to reduce animal use. In silico approaches present a rapid and cost-effective way to screen novel compounds for potential reactivity with biological nucleophiles. Currently, two in silico approaches are available to screen chemical: profilers (which identify reactive groups within chemicals) and quantitative structure-activity relationship (QSAR) models (including expert knowledge-based systems). To understand the utility of QSAR models in predicting in vivo outcomes, we curated a database of 581 compounds with local lymph node assay (LLNA) data from the public literature and internal sources. The local lymph node assay (LLNA) measures the lymph node proliferative responses of treated mice. Compounds that elicit a stimulation index (SI) $\geq 3$ are considered sensitizers. The EC3 (estimated concentration in % required for SI=3) values are used for comparison of sensitizing potential derived from local lymph node responses. The sensitization potential of the compounds in our database was assessed with three QSAR models (DEREK Nexus, TIMES-OASIS and MultiCase) with metabolism predicted using the skin metabolism simulator in the OECD Toolbox or the OASIS metabolizer module. When metabolites predicted by either simulator were included in the analysis, the three QSAR models predicted a positive LLNA result with reasonable sensitivity (>79%). Similar findings were seen for extreme and strong sensitizers (those with LLNA ECFIC $\geq 0.1$ - 1% and ECFIC $\geq 0.03$ - 0.1% respectively), with marginal sensitivities for less potent sensitizers. When the analysis was restricted to compounds curated from internal sources, the power of these models to predict the LLNA outcome of the parent compound or its metabolites was reduced (sensitivity range of 58.3% - 85.3%). Finally, we demonstrate the utility of a consensus approach wherein assessment of compounds with multiple models improves the sensitivity of the analysis (97.6% - 100% for compounds being flagged by one or more models, with metabolites predicted via the OECD Toolbox or OASIS metabolizer modules).

## 2102 Development of an Updated Carcinogenicity Potency Database and Analysis of Thresholds of Toxicological Concern

M. Cronin, S. Belfield, S. Escher, J. Firman, J. Liu, C. Marsaux, A. Mostrag-Szlichtyng, K. Przybylak, J. Rathman, A. Tarkhov, and C. Yang. Liverpool John Moores University, Liverpool, United Kingdom; 2Franhofer IEM, Hanover, Germany; 3Altamira LLC, Columbus, OH; 4ILSI Europe, Brussels, Belgium; 5The Ohio State University, Columbus, OH; and 6Molecular Networks GmbH, Nuremberg, Germany.

The existing Carcinogenicity Potency Database (CPDB) has been curated and extended with new data to facilitate a re-evaluation of the Threshold of Toxicological Concern (TTC) for carcinogenicity. New data have been added from the National Toxicology Program (NTP) and other open sources. All data were subject to a thorough review to ensure accuracy of the chemical structure as well as toxicological information. The new CPDB now comprises data for more than 650 chemicals with acceptable studies, according to defined criteria, of which $\geq 570$ were carcinogenic with $\geq 450$ associated with reliable genotoxicity data. The CPDB was subjected to various analyses to determine points of departure, notably TD25 and TD50 as well as Benchmark Dose Levels. These analyses were compared and demonstrated the need for appropriate dose response data. A strategy was also implemented to identify mode of action with regard to genotoxicity. In vivo, in vitro and in silico data were applied through a defined strategy to identify genotoxic and non-genotoxic carcinogens. Specifically, where available, experimental genotoxicity (mutagenicity or clastogenicity) data or information from computational models (QSARs and structural alerts) for DNA reactivity, in vivo micronucleus effects and chromosomal aberration were utilized. Analysis of the new CPDB confirmed the conservative nature of the current TTC values for carcinogens. The new CPDB is publicly available as an Access file and searchable via COSMOS DB (cosmosdb.eu) and is intended to support further TTC evaluations for carcinogenicity. The funding of the CEFIC LRI-B18 Project is gratefully acknowledged.

## 2103 Identifying and Annotating Hallmark Genes Relevant to Toxicogenomics

B. Kiro, 1D. May, 2L. Everett, 1R. Shah, 3R. Paules, and 4A. Scott. 1NEHS, Durham, NC; and 2Sciome LLC, Research Triangle Park, NC.

Fifty (50) Hallmark gene sets were derived from an integrated analysis of the Broad Institute’s Molecular Signatures Database (MSigDB). These gene sets are ideal for interpretation of toxicogenomic studies as their derivation considered a number important factors including gene coregulation, links to canonical pathways and biological processes, links to mechanistic and disease signatures, and limits on redundancy with other Hallmark gene sets. One significant challenge in using these gene sets is their limited coverage of gene space (~4500 genes). To extend the 50 Hallmark gene sets we have performed WGCNA on approximately 124,000 curated studies from the GEO database to identify co-regulated modules that do not overlap with the existing Hallmark gene sets. From this exercise, we have identified ~76 additional gene sets. Using NextBio’s ontology search database, the function and co-regulation features of these new hallmark gene sets were annotated at the same levels including canonical pathway association, biotest connectivity, cell/tissue expression and disease association. Once fully populated and curated, these Hallmark gene sets will be evaluated for utility to serve as a basis for interpretation of in vivo genotoxic dose-response studies performed by the NTP.

## 2104 Evaluation of the Applicability of Existing QSAR Models for Predicting the Genotoxicity of Pesticides

E. Fioravanti, A. Bassani, A. Ciacci, M. Fuort Gatkni, O. Tcheremenskaia, C. Bossa, M. Battistelli, and R. Benigni. Istituto Superiore di Sanità, Rome, Italy; and 4Alpha-Pretox, Rome, Italy.

The guidance document issued by the European Food Safety Authority (EFSA) Panel on Plant Protection Products and their Residues (doi: 10.2903/j.efsa.2016.4549) establishes a process for the definition of pesticide residues, including the evaluation of the potential risk based on toxicity potential for dietary exposure. While the toxicological dossier is developed for active substances, often none or only limited information about toxicological properties of their metabolites is available. Thus, the use of QSAR models and read across is proposed for the assessment of genotoxic potential of all identified metabolites as a first step in the residue identification procedure. Within an ongoing EFSA-fund project (OC/EFEA/PRAS/2016/01) the applicability and reliability of existing 52 commercial and freely-available QSAR models were critically evaluated for the prediction of genotoxicity of pesticides. The test set was provided by EFSA and it contains experimental genotoxicity data for 54 pesticide active substances and the comparison between the test set and a reference pesticides dataset showed the same range in physico-chemical properties, logP, pKa and solubility. Results from five endpoints were taken into consideration for the evaluation of models: bacterial reverse mutation, in vitro mammalian chromosome aberration, in vitro mammalian cell gene mutation, mammalian bone marrow chromosome aberration, mammalian erythrocyte micronucleus. The models were evaluated from the following perspectives: a) fraction of pesticides compounds of the test battery falling within the applicability domain of the model; b) number of false positives, false negatives, true positives, and true negatives. The overall comparisons of the sets of predictions showed that, depending on algorithms, assumptions, training sets and applicability domains, the QSARs have different strengths and weaknesses. Disclaimer: The results shown here have been produced under a contract with EFSA. The opinions expressed are those of the contractor only and do not represent EFSA’s official position.

## 2105 Gene Signatures Reveal Differences Between Preclinical Rat Liver Testing Systems

Z. Liu, US FDA/NCTR, Jefferson, AR.

Toxicogenomics (TGx) combines toxicology with genomics or other high-throughput molecular profiling technologies to gain an enhanced understanding of the molecular mechanism of toxicity. In the molecular toxicogenomics area, we developed a pair ranking (PRank) method to assess in vivo to in vitro extrapolation (IVIVE) using toxicogenomic datasets from the Open Toxicogenomics Project—Genomics Assisted Toxicity Evaluation System (TG-GATEs) database. Using this approach, we demonstrated that toxicogenomic data generated in hepatocytes in vitro can predict the ranking of a drug’s potential to cause hepatotoxicity in vivo. To further understand the capabilities of preclinical models of hepatoxicity, we applied PRank methodology to toxicogenomic data in TG-GATEs from three different assay systems: primary rat hepatocytes at 24 hours, in vivo single dose rat, and in vivo 28-day rat studies. A high similarity between the two in vivo assay systems was noted (PRank score = 0.90), indicating the potential utility of shorter-term in vivo studies to predict outcome in longer-term and more expensive in vivo model systems. There was a moderate similarity between rat primary hepatocytes and in vivo repeat-dose studies (PRank score = 0.77) but a low similarity (PRank score = 0.56) between rat primary hepatocytes and in vivo single-dose studies. When the comparison was limited to gene sets relevant to specific toxicogenomic pathways, we found pathways such as lipid metabolism were consistently over-represented in all three assay systems. Similarly, all three assay systems could distinguish compounds from different therapeutic categories. This suggests that any
noted differences in assay systems was biological process-dependent and, furthermore, that all three systems have utility in assessing drug responses within a certain drug class. In conclusion, this comparison of three commonly used rat TGx systems provides useful information in utility and application of TGx assays.

2106 A Case Study to Establish a Standardized Read-Across Process for Pesticide Active Substances and Their Metabolites for Assessment of Genotoxicity

C. Yang1,2, J. Rathman2,3, A. Mostrag2, A. Bassan4, E. Fioravanzo6, M. Fuart-Gatnik4, and O. Sacher1.  
1. Molecular Networks GmbH, Nuremberg, Germany; 2. Altairnica LLC, Columbus, OH; 3. The Ohio State University, Columbus, OH; and 4. IN Solutions Informatiche Srl, Vicenza, Italy.

The European Food Safety Authority (EFSA) Panel on Plant Protection Products and their Residues issued a guidance document for identifying pesticide residues and evaluating their potential risk based on their toxicity and dietary exposure potential. Although a comprehensive toxicological dossier is developed for each active substance, toxicity data of metabolites are limited. While the possibility of applying in silico approaches to fill the data gap is currently being evaluated, EFSA recently released a new public genetic toxicity database file (EU OPEN Data Portal) containing 293 unique test substances and 766 related components to create 819 chemical species comprised of parents and related components (i.e., metabolites, mixtures or formulations). Data for 33 genetic toxicity endpoints were made available in 17,927 studies.

In vitro toxicokinetics data of blood partitioning and metabolic clear-

2109 In Silico Mutagenesis and Molecular Docking of Mouse and Rat Estrogen Receptor α with Paraben Analogs

T. L. Gonzalez, and R. J. Richardson, University of Michigan, Ann Arbor, MI.

Numerous structures of human estrogen receptor α (ERα) ligand binding domain (LBD) in complex with agonists or antagonists have been reported and used to identify and characterize endocrine disruption (EDs) that mimic the LBD interactions exhibited by 17β-estradiol (E2). However, although rats and mice are used for in vivo studies and as tissue sources for in vitro studies of EDs, extrapolations to humans are hampered because crystal structures for rodent LBDs are lacking. Whereas the sequences of rodent and human LBDs are >96% identical, subtle differences in 3D structure could create differences in ligand binding. To address this knowledge gap, we used the human ERα LBD structure (PDB 3UJD) as a template to create structures of rat and mouse LBDs by in silico mutagenesis followed by energy minimization and molecular dynamics refinement with the YASARA molecular modeling suite. Model quality was assessed using MolProbity, and the best mouse and rat ERα LBDs were employed to compare molecular dockings of 21 paraben analogs using Autodock VINA with YASARA as the graphical front-end. All 21 paraben analogs displayed a general preference to localize to the known LBD of human ERα. We further compared all ERα LDB amino acid identified using YASARA for each ligand docked either to the mouse or rat receptor relative to the human ERα LBD docked structure. Sorensen similarity coefficients for receptor contacting residues with each ligand (mean ± SEM) were 93.1 ± 7.5% and 92.5 ± 7.1% between human and mouse or rat receptors, respectively. The number of receptor contacting residues between human and mouse or rat ERα among all ligands tested was found to have Pearson correlation of 0.913 and 0.914, respectively. The number of receptor atom contacts between human and mouse or rat ERα among all ligands tested was found to have a Pearson correlation of 0.976 and 0.979, respectively. The results indicate that our constructed mouse and rat ERα LBD receptors interact with ligands in like manner to the human receptor, thus providing a high level of confidence in extrapolations of rodent to human ligand-receptor interactions. Supported in part by NIEHS T32ES07062.

2018 Application of In Vitro Toxicokinetics for Dose-Exposure Estimates of Substituted Phenols and Alkyl Glycols

Advances in toxicity testing have led to a rise in the application of in vitro and high throughput approaches to predict potential adverse effects following chemical exposures. As a result of this progress, new exposure and in silico methods were developed to help interpret and relate these measures with animal and human dose exposure estimates. The objective of this research applied new in vitro toxicokinetic data and models to predict doses where potential toxicological effects would be anticipated in vivo based on measures from the US Environmental Protection Agency ToxCast™ high throughput in vitro assay toxicity database. In vitro toxicokinetics data of blood partitioning and metabolic clearance were generated for Health Canada Chemical Management Plan grouping of substituted phenols (dimethylated alkyl benzenedioxils, methylated alkyl phenols, and methylated alkyl ester benzenepropanoic acids) and alkyl glycols (ethylene glycols and glycol esters). Using in vitro estimates of the parameters, toxicokinetic models were able to convert the toxicity assays concentrations into oral equivalent human doses. The estimated doses for liver cell activity were greater than 50 mg/kg/day for both chemical grouping. Responses range from cytotoxicity, cell cycle perturbation, DNA binding or even deregulation of steroidal and non-steroidal receptors. The data was collected using Dream.TK (Dose-Response Extrapolation & ASSay Modelling with Toxicokinetics) a new R package designed to work with the raw ToxCast™ database. The package features several table outputs used to retrieve the results of various assays, including effective concentrations and assay receptor targets, and incorporates various data analysis tools (e.g. clustering and principle component analysis). Advances in exposure characterization such as in vitro toxicokinetics and in silico tools can conservatively help translate in vitro toxicity screening information into biologically relevant point of interest for chemical prioritization and risk assessment.

2110 Comparative Toxicogenomics Database (CTD): An Integrated Resource for Chemical, Gene, Phenotype, and Exposure Data

C. Mattlingly, C. J. Grondin, R. Johnson, D. Scialy, J. Wiegers, T. C. Wiegers, and A. P. Davis. North Carolina State University, Raleigh, NC.

The Comparative Toxicogenomics Database (CTD; http://ctdbase.org) is a freely available resource that advances understanding about the mechanisms by which environmental exposures impact human health. Since its public release in 2004, the content of CTD has evolved to meet the evolving needs of the environmental health research community. Today CTD provides manually curated content describing chemical-gene interactions, chemical- and gene-diseases relationships, chemical-phenotype (non-disease) and population-based exposure data. CTD data are updated manually and currently comprise over 1.6 million chemical-gene interactions, curated information on approximately 15,000 chemicals, 43,000 (cross-species) genes, and 7,000 diseases. In addition, over 1,000 population-based exposure studies have been curated, including data for 975 chemicals, 326 genes, 371 diseases, and 282 phenotypic outcomes in populations from over 150 countries. All CTD curation is captured using community-accepted ontologies and controlled vocabularies, allowing integration across curated content as well as external data sets to make novel inferences. These data can be explored with user-friendly query and analytical tools to inform hypothesis development connecting chemicals/drugs, genes/proteins, diseases/phenotypes, taxa, functional annotations, pathways, and exposure events. These data also provide unique opportunities to generate predictive adverse outcome pathways, connecting molecular
initiating events to population-level health outcomes. CTD has become an invaluable research tool for the toxicology community that aims to advance understanding about environmental influences on human disease and underlying mechanisms from model systems to population-based studies.

### 2111 Hepatic Transcriptome Analysis to Assess the Effects of Prenatal Bisphenol A Exposure on Developing Chicken Embryos

S. Ito1, M. Iida1, T. Hoa1, T. Aguas2, M. Hirano1, M. Ochiai3, E. Kim4, and H. Iwata5. 1Ehime University, Matsuyama, Japan; 2Prefectural University of Kumamoto, Kumamoto, Japan; and 3Kyung Hee University, Seoul, Korea, Republic of.

There is a growing concern about the toxic effects of bisphenol A (BPA) in developing organisms because the early life stage is a critical window to chemical exposure. However, there is less information regarding the effects of BPA on avian embryos. We thus performed in ovo BPA injection test of chicken eggs and investigated the effects on the developing embryos by analyzing their hepatic transcriptome with next generation sequencing (NGS). Fertilized chicken eggs were divided into five groups: control (corn oil), BPA-L (BPA 10 ng/g egg), BPA-M (BPA 1,000 ng/g egg), BPA-H (BPA 100,000 ng/g egg), and E2 (17β-estradiol 10 ng/g egg). On the 2nd incubation day, test chemicals were injected into the air sac. On the 21st incubation day, RNA solutions were extracted from liver samples and used for NGS. In order to detect embryonic death, eggs were observed on the incubation day 7, 14, and 21. To predict the high-risk diseases and its mechanisms, phenotype, gene ontology (GO), and transcription factor enrichment analyses of the genes differentially expressed by BPA- or E2-treatment were carried out by R, Comparative Toxicogenomics Database (CTD), TFaction, and Enrichr. Measurement of phenotypes showed that survival rates were significantly decreased in the BPA-H. This result suggested that BPA could affect the development of avian embryos. Data analyses of NGS indicated that miRNA levels of 204, 4078, 1766, and 3006 genes were significantly changed in BPA-L, BPA-M, BPA-H, and E2, respectively. This demonstrates that more pronounced effects on the transcriptome were induced in BPA-M, BPA-H, and E2 than in BPA-L. Phenotype enrichment analysis suggested that liver cirrhosis and reperfusion injury may be induced by BPA treatment in developing chicken embryos. Considering that reperfusion injury is one of the cardiovascular diseases, the abnormal development of blood circulation system induced by BPA exposure may contribute to an increase in the embryo mortality. GO enrichment analysis revealed effects on cell cycle in the BPA-treated groups, suggesting a higher risk of liver cirrhosis triggered by disrupted cell cycle in the later growth stage. Transcription factor enrichment analyses identified that activation of MYC, TP53, SP1, and E2F by BPA were important molecular initiating events in the adverse outcome pathway of BPA.

### 2112 Evaluation of Bioinformatics Approaches for Next-Generation Sequencing Analysis of microRNAs with a Toxicogenomics Study Design

H. Bisgin1,2, B. Gong1, Y. Wang1, and W. Tong1. 1US FDA/NCTR, Jefferson, AR; and 2University of Michigan-Flint, Flint, MI.

MicroRNAs (miRNAs) are key post-transcriptional regulators that affect the protein translation by targeting miRNAs. Its role in disease etiology and toxicity is well recognized. Given the rapid advancement of next-generation sequencing techniques, miRNAs profiling has been increasingly conducted with RNA-seq, namely miRNA-seq. Analysis of miRNA-seq data requires several steps: (1) mapping the reads to miRBase, (2) considering mismatches during the hairpin alignment, and (3) counting the reads. The choice made in each step with respect to the parameter setting could affect the results. Computational simulations including miRNAs bioinformatic analysis would significantly enhance miRNA detection and novel miRNA identification. Furthermore, these parameters do not act in isolation and their joint effects impact miRNA-seq results and interpretation. In toxicogenomics, the variation associated with the parameter setting should not overpower the treatment effect such as dose/time-dependent effect. In this study, four commonly used miRNA-seq analysis tools were comparatively evaluated with a standard toxicogenomics study design. We tested 30 different parameter settings on miRNA-seq data generated from thioacetamide-treated rat liver samples for 3 dose levels across 4 time points, followed with four normalization options. Because both miRDeep and miRNAkey yielded the larger variation across different parameter settings than that resulted from the treatment effects, our analyses were mainly focused on the side-by-side comparison between miRDeep2 and stRNAbench. While the number of miRNAs detected by miRDeep2 was almost the subset of these by stRNAbench, the number of DEMs identified by both tools was comparable under the same parameter settings and normalization method. Change in the number of nucleotides out of the mature sequence in the hairpin alignment (window option) yielded the largest variation for miRNA quantification and DEMs detection. However, such a variation is relatively small compared to the treatment effect when the study is focused on DEMs that is more critical to interpret the toxicological significance. These results indicated that a larger variation across different toxicogenomics databases, such as TOX21, TOXG, and TOXSeq, may also exist in the literature. Therefore, it is recommended to use multiple miRNA-seq tools for microRNA analysis in toxicogenomics studies.

### 2113 Facilitating Exposure Data Analysis in the Comparative Toxicogenomics Database: A Case Study of Heavy Metals and Metabolic Syndrome

C. J. Grondin, A. P. Davis, J. Wiegars, T. C. Wiegars, A. Green, A. Planchart, and C. Mattingly. North Carolina State University, Raleigh, NC.

Exposure science aims to connect environmental stressors, such as chemicals, to health outcomes in human populations. Exposure science data is now a prominent component of the Comparative Toxicogenomics Database (CTD; http://ctdbase.org), a freely available resource that promotes understanding about the role of the environment on human health by providing manually curated information on chemical, gene, phenotype, and disease relationships. Over 50 exposure-related details, including stressor sources, population demographics, detection levels, geographic information, and health outcomes are curated using the exposure ontology (ExO) and other controlled vocabularies. CTD provides a centralized, searchable repository of exposure data that aims to facilitate meta-analyses and inform study design by allowing comparisons across studies and experimental parameters. Summary and detailed views of exposure data can be retrieved and downloaded using customized query sets and user-refined displays of data. Currently, over 1800 exposure articles have been curated identifying relationships among 975 chemicals, 326 genes, 371 diseases, and 282 phenotypic outcomes in populations from over 150 countries. We demonstrate the value and scope of exposure data integration in CTD through a case study assessing the potential connection between heavy metal (cadmium, lead, and mercury) exposure and metabolic syndrome. CTD tools and curated content provide immediate perspective on the state of the data, differences in study designs and foci as well as research gaps. Centralization and integration with mechanism-based experimental data also uniquely enable comparisons between exposure-related responses in human populations and model systems. This presentation will outline the current exposure data content and analysis capabilities with a focus on heavy metals and metabolic syndrome.

### 2114 Impact of Deleterious Single Nucleotide Polymorphisms in Catechol O-Methyltransferase Conferring Risk to Post-Traumatic Stress Disorder

K. Chitraa, P. Nagararkattii, and M. Nagarkattii. University of South Carolina School of Medicine, Columbia, SC.

One of the prevalent neurological disorders includes post-traumatic stress disorder (PTSD) which is drawing attention over the past few decades. It occurs as a consequence of a life-threatening event such as physical or sexual assault, combat, car accident, or natural disaster. Some of the risk factors for PTSD include environmental and genetic factors. Among the genetic risk factors, polymorphisms in the catechol-O-methyltransferase (COMT) gene have been associated with risk for PTSD. In the present study, we aim to analyse the impact of deleterious single nucleotide polymorphisms (SNPs) in COMT gene associated with PTSD using computational-based screening and molecular dynamics simulations. The data on the COMT gene associated with PTSD were collected from Online Mendelian Inheritance in Man (OMIM) database and PubMed search. The SNP datasets were downloaded from the dbSNP database. The amino acid sequence of the COMT protein was retrieved from the Uniprot database, and its three-dimensional structure was downloaded from protein databank. To study the structural and dynamic effects of COMT, wild-type, and mutant forms we have retrieved from the Uniprot database, and its three-dimensional structure was downloaded from protein databank. To study the structural and dynamic effects of COMT, wild-type, and mutant forms we have performed molecular dynamics simulations (MDS) at a time scale of 300 ns. Results from computational screening using the computational tools SIFT and Polyphen-2 showed that the SNP rs4680 (V158M) in COMT conferring deleterious with a phenotype in PTSD. Results from MDS showed some major fluctuations in the structural features, such as root mean square deviation (RMSD), radius of gyration (Rg), root mean square fluctuation (RMSF) and secondary structural elements including α-helices, sheets,
and turns between wild-type and mutant forms of COMT protein. In conclusion, our study provides new insights into the deleterious effects of the V158M mutation on the COMT structure. Supported by NIH grants R01MH094755, RO1AI23947, RO1 AI129788, P01 AT003961, P20 GM103641, and RO1 AT006888.

2115 Predicting Risk of Cardiac Liabilities in Drug Discovery Using Venn-Abers Predictors

E. Ahlberg1, L. Carlsson1, A. Pointon2, and N. Greene1. 1AstraZeneca, Mölndal, Sweden; 2AstraZeneca, Cambridge, United Kingdom; and 3AstraZeneca, Waltham, MA.

Cardiovascular (CV) safety liabilities are a major cause of drug attrition in all stages of drug discovery and development. In early stages of drug discovery, compounds can be screened to reveal potential CV risk using in vitro assays of selected ion channels that regulate heart function, hERG (Kv 11.1), NaV1.5, CaV1.2, Kv4.3, and Kv7.1. Inhibition of these ion channels is an early indicator of CV risk, so the assays can be used to rank compounds. Quantitative structure-activity relationship (QSAR) models have been used to predict the outcome of these assays for specific compounds. In practice, screening data have been preferred since such predictions generally lack a good measure of the risk for the individual compounds. In 2005 Vovk, Gammerman and Shafer introduced the concept of Venn predictors. Venn predictors offers a way to assign a calibrated probability to predictions and are a part of the conformal prediction framework that uses past experience to determine precise levels of confidence in new predictions. Venn-Abers is a special case of Venn predictors that can be applied on top of a scoring classifier under standard assumptions regarding data generation. In essence this means that the obtained confidence capabilities can be trusted as a probability. Given the data, it is the best estimate of the probability. Assessing potential safety risk for a compound is commonly done in terms of bounds above expected Cmax. To mimic that, we propose to compute the probability that the IC50 of an assay is below n-folds of Cmax and thus create an individualized prediction for the compound rather than a fixed limit. In this work, we show how Venn-Abers predictors can be applied to a panel of assays, how it can be used together with Cmax to assess cardiac risk of potential drugs, and be an effective way to deliver enhanced decision-making capabilities to projects.

2116 Differential Gene Expression and Concentration-Response Modeling Workflow for High-Throughput Transcriptomic (HTTr) Data: Results from MCF7 Cells

J. A. Harrill1, L. Shah1, W. Setzer1, M. Martin1, D. Haggard2, and R. Thomas1. 1US EPA, Research Triangle Park, NC; and 2Oak Ridge Institute for Science and Education, Research Triangle Park, NC.

Increasing efficiency and declining cost of generating whole-transcriptome profiles has made high-throughput transcriptomics a practical option for chemical bioactivity screening. The resulting data output provides information on the expression of thousands of genes and is amenable to a variety of downstream applications. However, HTTr chemical space coverage and routes to submission challenges that are not inherent with traditional cell-based screening assays, which produce univariate outputs. We present a microfluidics-based laboratory workflow for HTTr screening of MCF7 cells in 384-well format and a HTTr analysis pipeline for data quality control, differential gene expression, and concentration-response modeling. MCF7 cells were plated in either DMEM+10% HI-FBS or phenol red-free DMEM+10% CS-HI-FBS and allowed a 24 h recovery period prior to exposure. A total of 44 chemicals were screened in 8-point concentration-response (0.03-100 µM) in each media at three exposure durations (6, 12, 24 h) in three independent cultures (n=1 /treatment/culture). Chemicals were tested using an acute assay, which was uniquely randomized with respect to treatment positioning. Cell lysates were analyzed using a TempO-Seq human whole-transcriptome assay to a target read depth of 3M. Cell viability and apoptosis assays were run in parallel to exclude conditions causing cytotoxicity. For count data, total and differential mapped reads were used with no unique reads used for performance. Data were subset by chemical x media x time with matching controls. Probes were filtered using a median raw read count > 5. Count data were scaled and transformed, and differentially expressed genes (DEGs) were determined using DESeq2. Reproducibility of read counts in technical replicas was high, with pairwise correlations >0.85 and median CVs of between 20 and 40%. The correlation of log2FC values for DEGs among biological replicates was also high (median > 0.75) within each media x time condition. ANOVA results demonstrated a broad range (10s to 1,000s) in the number of concentration-respon-
sive genes across chemicals. Concentration-response modeling demonstrated a broad range of probe and pathway level BMDs across chemicals for each media x time combination, and facilitated identification of no observable transcriptional response levels. This abstract does not necessarily reflect US EPA policy.

2117 Authoritative Listings of Carcinogenic Compounds, Identification, and Comparison to QSAR Modeling Tools’ Results

C. McLoughlin, P. J. Beatie, M. C. Ruhter, and J. P. Rinkevich. Scivera, Charlottesville, VA.

Carcinogenic compounds have been identified by the National Toxicology Program (NTP), International Agency on Research for Cancer (IARC), and listing through California Proposition 65. These are considered authoritative sources for hazard assessment and Restricted Substance Lists (RSLS). Often such resources and RSLS identify groups of compounds without full lists of applicable Chemical Abstract Services Registry Numbers (CASRNs) or substance names. Scivera, through SciveraLens® and Rapid Screen has developed comprehensive versions of these lists. For example, IARC lists 851 CASRNs in monographs volumes 1-111 while Scivera has identified over 6000 CASRNs by including those associated with subgroups. For the current project, the Scivera Toxicology Team compared carcinogenicity modeling tool alert results with the IARC Group 1 compounds. From the comprehensive Scivera IARC Group 1 list, 1,068 CASRNs had a SMILES notation which allowed for modeling: 446 CASRNs returned a structural alert for carcinogenicity from these tools, while 622 had no alert found. Among these IARC Group 1 compounds that did not return a structural alert were polychlorinated biphenyls (PCBs) and nickel and cadmium compounds. This highlights and demonstrates the need for methods to fill data gaps for carcinogenicity by either ensuring all compounds in sublists are appropriately identified and/or using additional structures to trigger alerts. The Scivera Team is currently working on further comparisons to identify opportunities to support and improve commonly used modeling tools including using other carcinogenicity lists and other hazard endpoint models and lists.

2118 In Silico Prediction of DILI: Extraction of Histopathology Data from Preclinical Toxicity Studies of the etOX Database for New In Silico Models of Hepatotoxicity

A. Amberg1, L. Anger1, M. Stolte1, J. Hemmerich1, H. Matter1, L. Fisk2, I. Tluczkwiecz3, K. Pinto-Gill4, O. López-Massagué5, and M. Pastor4.

1Sanofi, Frankfurt, Germany; 2Usha Limited, Leeds, United Kingdom; 3Fraunhofer ITEM, Hannover, Germany; and 4IMIM, Barcelona, Spain. Sponsor: D. Keller.

The etOX consortium extracted in vivo data from unpublished preclinical toxicity studies of 13 industry partners. This new database contains high-quality toxicity results in high detail level from 1,947 drug candidates (8,196 studies) supplemented with 1,286 chemicals from the RepDose database (2,695 studies). Different compilation steps were applied to transform these data into usable in silico model training datasets. Initially, all toxicology findings were extracted from study reports (paper/PDF). Then the verbatom terms for all treatment-related hepatotoxicity findings were harmonized using special ontologies. Finally, to receive model training sets with sufficient compound numbers and chemical space coverage, all primary histopathology terms were combined and grouped to different first- and then second-level clusters of similar toxicity mechanisms: e.g., primary necrosis terms such as “centrilobular,” “periportal,” etc. were grouped to first-level cluster “necrosis,” then clusters such as “necrosis,” “vacuolization,” etc., were grouped to second-level cluster “degenerative lesions.” With this approach, various training datasets were compiled depending on the species (rat, dog, and monkey), treatment durations (2 weeks-2 years) and administration routes. Then, different modeling approaches were applied on these datasets, including structural alerts, fragment-based and molecular descriptor-based machine learning approaches (e.g., random forest, decision tree, k-nearest neighbor). Models were validated and externalized, first by internal validation (test set) and then through external validation using Sanofi’s confidential data. For example, best external validation results (n=66) were achieved for the first-cluster rat necrosis models (229 positives, 198 negatives) using fragment-based (Sensitivity: 0.80, Specificity: 0.77) and a molecular descriptor-based decision tree approach (Sensitivity: 0.81, Specificity: 0.68). These validation results show that by reasonable clustering histopathology data from etOX, it is possible to develop highly predictive in silico models for drug-induced liver injury (DILI).
Breast cancer is a leading cause of cancer death among women. The human epidermal growth factor receptor 2 (ERBB2/HER2-Neu) has expanded expression in about 15% of breast cancer samples. The presence of such HER2-enriched samples is generally associated with poor prognoses. Resistance to therapy with the HER2-targeting monoclonal antibody, Trastuzumab, remains an issue in treatment of HER2-enriched breast cancers. In this study, we explored the transnational regulation of HER2 expression across a variety of intrinsic subtypes of breast cancer to help identify targets for adjunctive therapy. The PAM50 algorithm was applied to data from breast invasive carcinomas (BRCA) RNAseq version 2 samples from the Cancer Genomics (ATCCGA). Using the mutual information-based Algorithm for the Reconstruction of Accurate Cellular Networks (ARACNe), transcriptional regulatory network-wrks were constructed using basal-like samples only, HER2-enriched samples only, and all samples. A trees-based learning algorithm, Gene Network Inference with Ensembl of Trees (GENIE3), was also used for that same purpose. In the aggressive basal-like subtype, in which there is practically no expression of HER2, the gene’s expression is uniquely dependent on the tumor-suppressing gene, BATF2 (which has increased expression in basal-like samples relative to HER2-enriched samples), predicted a direct and indirect role of TOX3. In HER2-enriched samples, HER2 is uniquely dependent on the regulatory network of relationships, of which the progesterone receptor (which is absent in both basal-like and HER2-enriched samples) plays both a direct and indirect role. Also in this pan-subtype network, FXBP1, RARG, FOXM1, FOXA1, NFE2L1, POU2F3, ZNF500, and ZNF213 play direct regulatory roles in HER2 expression. The results indicate differences in regulating genes for HER2 across subtypes. The activities/expressions of E2F2, HOXAS, and CRY2 are candidates for targeting in potential adjuvant therapy in the treatment of Trastuzumab-resistant HER2-enriched breast cancers.

For pesticides registered in the United States, cumulative risk is assessed for chemicals that share a common mechanism of toxicity. Recently, the Environmental Protection Agency’s (EPA) Office of Pesticide Programs developed a screening framework to help address its statutory obligation to assess potential cumulative risks. As part of this evaluation, all available toxicological information for a pesticide group is evaluated to determine if the information supports a testable hypothesis of a common mechanism of toxicity. High-throughput screening data from the EPA ToxCast program offer potential mechanistic insight for many pesticides. The utility of such data to assess common mechanism groups has not yet been evaluated. In this study, a workflow was developed to categorize the chemical activity of 615 ToxCast substances using the Alan Wood Compendium of Pesticide Common Names. Computational analyses were conducted using the half-maximal activity values (AC50) and chemical specificity metrics (IZ-score) for 1,900 in vitro assays. A case study was conducted with anilopyrimidine pesticides (cyprodinil, pyrimethanil, mepanipyrim) to evaluate how ToxCast can be used with chemical structure, apical outcome and pesticidal mode of action information to evaluate potential common mechanisms of mammalian toxicity. Hierarchical clustering indicated greater similarity between the bioactivity profiles of cyprodinil and pyrimethanil which were also the most structurally similar. Analyses of the genes and pathways perturbed upon exposure to cyprodinil and pyrimethanil revealed potent (AC50 < 10 µM) and specific (Z-score > 2) activities for key molecular targets involved in neurotoxicity and liver function. In vitro data suggests observed following acute (decreased motor activity, hypothermia) and repeated-dose (liver necrosis/hypertrophy, spongiosis hepatis) exposure to pyrimethanil and cyprodinil. In contrast, mepanipyrim showed liver effects (fatty liver) and no evidence of neurotoxicity. These results may be used to support a testable hypothesis for a common mechanism of toxicity in mammals for pyrimethanil and cyprodinil. Overall, this research demonstrates how ToxCast data can facilitate the identification of common mechanisms which are pertinent to sensitive endpoints obtained from animal studies.
The underlying principle of read-across is that the biological activity of a compound is inherent in its molecular structure. Analogues are typically identified by structural similarity then evaluated on the basis of their bioavailability, reactivity, and metabolic similarity. While structural similarity is the most common read-across, a critical consideration is whether structural differences impact biological activity. This source of uncertainty can potentially be addressed with toxicokinetic (TK) information. We report progress on a case study to investigate the feasibility of using in vitro high-throughput metabolism experiments in concert with in silico metabolism predictions to substantiate biological similarity to enable quantitative read-across. Parent chemicals were incubated with a suspension of primary rat hepatocytes. Possible metabolites were predicted in silico using expert systems (Meteor Nexus & TIMES). Suspect screening analysis was performed using liquid chromatography-mass spectrometry (LC-MS/MS) in silico and the in silico predicted chemicals representing different read-across scenarios were identified: two proof-of-concept examples and two test cases. Candidate source analogues were identified based on structural similarity and information availability for the two proof-of-concept chemicals (similar metabolism [methyl estrogenic metabolite] and different metabolism [2-nitrotoluene vs 4-nitrotoluene]), whereas for the two test cases, the experimental and in silico results will be integrated to substantiate the validity of the source analogues to inform selection of the most appropriate analogue. To date, in silico metabolism predictions have been generated for the proof-of-concept chemicals and compared to the in vivo metabolic profiles reported in the literature to assess their agreement. The metabolism predictions from the different tools complemented each other in capturing the primary pathways and, in particular, the pathway that has been associated with the genotoxicity of the nitrotoluennes, but no tool correctly captured all the metabolites observed. This abstract does not necessarily represent US EPA policy.

Heavy metals are a prominent environmental concern due to the association between the rate of disease primarily from environmental exposures and occupational hazards. Heavy metals present in sediment or water can easily enter into the food chain and affect humans, animals, and ecosystem. Metatranscriptomics has been used to assess microbial community activities and functions, as well as seawater communities. Here we propose to develop transcriptomic predictive benchmarks for ecosystem recovery and remediation success of heavy metals in river water as well as discover key regulatory elements. We propose to apply transcriptomic technology to test heavy metal remediation because of its sensitivity and because it allows for comprehensive examination of genomic and epigenomic molecular changes that hyperaccumulation of low levels of Zn, Cd and Ni may produce and that are not detectable by monitoring and surveillance of water surface or sediment levels of these chemicals. Hazard identification based on experimental and ecologic studies suggest that exposure to metalloestrogens Cd, As, and Ni produced health deficits in aquatic organisms, including in bottom- and surface-dweller species of sport fish. Gene set enrichment analysis of ESTs and RNA-Seq data revealed that nuclear respiratory factor (NRF1) regulatory genomic and epigenomic networks were highly sensitive to environmental heavy metal stressors. Further analysis of our metatranscriptomic findings of heavy metals should provide insight into health of fish communities for ecosystem recovery and remediation success of heavy metals.
Molecular Determinants of Brain Vascular Disorders from Exposure to Polychlorinated Biphenyls
C. M. Perez, M. Doke, C. Yoo, and Q. Felty. Florida International University, Miami, FL. Sponsor: Q. Felty.

Autism is a brain-based disorder resulting in a wide spectrum of abnormal behaviors and difficulties with social communication and interaction. Genome-wide expression analyses on human autopsies show a significant increase in plasticity markers CD34 and nestin, and suggest that autistic brains undergo a constant state of angiogenesis. The constant fluctuation in the cellular structure of blood vessels may impact the blood delivery system to the brain and ultimately be neurologically limiting. Environmental risk factors associated with the development of autism are largely unknown. Population studies have recently demonstrated an association between autism spectrum disorder in children with maternal pregnancy serum levels of polychlorinated biphenyl 153 (PCB153). PCB153 is one of the largest contributors to total PCB body burden in humans that has been shown to accumulate specifically in the brain in vivo. We have previously shown that PCB153 activates the transcription regulator ID3 in exposed human blood-brain barrier endothelial cells. ID3 is biologically relevant to neurological and behavioral research because of its involvement in the stress response, neural plasticity, and neural circuitry. Here we propose to apply transcriptomic technology to the question by testing for ID3 regulated animal models that may explain brain vascular toxicity and allow for comprehensive examination of genomic and epigenomic molecular changes. Using transcriptomic studies of PCB exposed children, we identified an ID3 gene regulatory network that can be used to predict molecular risk factors of autism in the population. Gene network enrichment analysis using genome wide ChiP-seq data identified ID3 target genes associated with PCB exposure and brain vascular processes. Bayesian algorithm BANJO suggest that modified expression of several “key Markov genes” may be required for the development of autism, and its application may be useful in identifying individuals who are susceptible to brain vascular toxicity from exposure to PCBs.

Revealing DMSO-Induced Bias in ‘Omics Analysis In Vitro
M. Verheijen1, M. Lienhard2, Y. Schrooders1, O. Clayton3, R. Nudischer4, S. Boerno5, N. Selevsek4, H. Gmuender4, R. Herwig2, J. Kleinjans1, and F. Caiment1. 1 Basel, Switzerland.

landscape, suggesting that DMSO can interfere with regulatory systems (FDR <0.05) found in both tissues indicate changes in the epigenetic state and altered genes, processes of transcriptional regulation were investigated in untreated microtissues). Pathway analysis of these DEGs identified hundreds (DEGs; FDR >0.05) in both cardiac and hepatic tissue (compared to untreated microtissues). Since affected pathways displayed a majority of downregulated genes, processes of transcriptional regulation were investigated in detail, focusing on DNA methylation. Differentially methylated regions (FDR <0.05) found in both tissues indicate changes in the epigenetic landscape, suggesting that DMSO can interfere with regulatory systems in cardiac and hepatic tissues. While the field is evolving towards more sophisticated in vitro models, using 3D conformation and/or physiologic-consistent low dose concentrations, omics technologies clearly demonstrate that the effect of DMSO on cell regulation has to be kept in mind when designing in vitro studies and interpreting the data. Consequently, the lowest possible dose of DMSO should be used as even low incubation concentrations may induce solvent-induced bias.

Vector Mapping Technology (VMT) for High-Resolution Tracking of Gene Therapies in Live Animals

New molecular tools, such as CRISPR/Cas9, have revolutionized the field of gene therapy. Nonetheless, significant challenges remain for directing genetic modifications to diseased sites with high specificity. Viral vectors engineered for organ-specific transgene expression could yield safe and efficacious delivery routes for gene therapy. However, the development of such vectors is hampered by conventional methods for tracking biodistribution (i.e. quantitative PCR (qPCR) and immunohistochemistry (IHC)); which are inaccurate, invasive, laborious and were historically prone to sampling error. These assays also typically require a large number of experimental animals, thus raising important ethical concerns and increasing overall costs. Noninvasive reporter gene imaging offers an alternative to traditional assays with the potential to streamline biodistribution studies while reducing animal use. The sodium iodide symporter (NIS) is a self-protein expressed endogenously in the thyroid and stomach. Beyond its physiological role in trapping iodide within cells, NIS can function as a reporter gene to enable noninvasive, tomographic SPECT or PET imaging via uptake of radiotracers. Unlike luciferase, NIS reporter gene imaging is high-resolution and can be used in store organs and to monitor the skeletal muscle. In contrast, background signal in control mice was restricted to sites of endogenous NIS expression (e.g. thyroid and stomach). Endpoint qPCR and IHC analyses confirmed AAV transduction and NIS expression in the heart, liver, and muscle. Combined, these data establish NIS reporter gene imaging as a powerful, noninvasive alternative to traditional biodistribution assays.
Advantages of combining BLI and SPECT or PET imaging of NIS for tumor tracking in pre-clinical studies. BLI can be used for sensitive early detection and relatively easy monitoring of tumor growth, while NIS imaging at later times can be used to achieve superior resolution, deep tissue imaging, and precise anatomical localization.

2133 Evaluation of Targeted Sequencing for Transcriptional Analysis of Archival Formalin-Fixed Paraffin-Embedded (FFPE) Samples

Next-generation sequencing provides unprecedented access to genomic information in archival FFPE tissue samples. However, costs and technical challenges related to RNA isolation and enriched use of whole-genome RNA sequencing for large-scale studies of FFPE specimens. Recently, a targeted sequencing platform called TempO-Seq was developed for gene expression profiling without the need for RNA isolation or pre-amplification. In this study, we compared genomic responses between the new TempO-Seq mouse array (containing 3,045 probes targeting 2,756 genes) and the Illumina-based whole-genome platform (RNA-Seq) in FFPE and paired frozen (FROZ) samples. Archived liver specimens were analyzed from control mice (CON) and mice treated with 600 ppm of phenobarbital (PB) for 7 days (n=6/group). Portions of each liver were (a) snap frozen and (b) fixed in 10% buffered formalin for 18 hours before processing to FFPE blocks. Quality sequencing metrics and expression of the preselected PB response genes Cyp2b10 and Cyp3a11 were evaluated. RNA-Seq used a higher read depth (68.5 ± 1.4 million/sample) than TempO-Seq (2.4 ± 0.1 million/sample) but provided similar alignment patterns to the mouse genome (86% and 81%, respectively). Total mapped reads were 52% lower for FFPE vs. FROZ samples but similar for TempO-Seq (2% higher for FFPE). On RNA-Seq, total reads mapped to Cyp2b10 were ~2,374-fold higher for PB (23,739 ± 1,647 vs. controls ≤10 in FROZ and ~629-fold higher in FFPE ≤10 in CON vs. 8,292 ± 547 in PB), indicating a signal loss of ~65%. For Cyp3a11, total reads were 78% lower in PB-treated FFPE vs. FROZ samples, but fold-change values were comparable: 58-fold higher in FROZ (1,754 ± 441 in CON vs. 102,297 ± 13,747 in PB) and 68-fold higher in FFPE (327 ± 77 in CON vs. 102,297 ± 13,747 in PB). Using TempO-Seq, Cyp2b10 reads were ~2,736-fold higher in PB (17,272 ± 1,567) vs. controls ≤10 in FROZ and ~2,201-fold higher in FFPE ≤10 in CON vs. 22,008 ± 2,197 in PB), while Cyp3a11 reads were 49-fold higher in FROZ (29 ± 3 in CON vs. 1,409 ± 86 in PB) and 50-fold higher in FFPE (67 ± 11 in CON vs. 3,347 ± 503 in PB). In FFPE samples, counts for Cyp2b10 and Cyp3a11 correlated strongly between TempO-Seq and RNA-Seq platforms (R² > 0.96, P < 0.05 for both markers). These findings support the idea that targeted sequencing can be used as a streamlined alternative method for analysis of RNA expression in FFPE samples. This abstract does not reflect US EPA policy.

2134 Development of pH-Targeting Fluorescent Probes to Map Inflammatory Response

N. Prince¹, J. Mouch¹, A. Han², and J. Boyd¹. 1West Virginia University, Morgantown, WV; and 2Pacific Northwest National Laboratory, Richland, WA.

Elevated extracellular acidity due to increased glycolytic flux is a hallmark of many pathological states. Exploiting acidity to develop probes that monitor and track inflammation is a viable approach with the flexibility to range across a spectrum of toxicologically-relevant endpoints, from bioenergetic measurements to tumor diagnosis. pH-Low-Insertion-Peptide (pHLP) is a pH-sensitive peptide that is capable of cellular transmembrane insertion through a helix formation that is reliant on the protonation of aspartic acid residues under localized acidic conditions. Upon insertion, the C-terminus translocates inside the cell while the N-terminus remains extracellular. By tethering a fluorophore to the N-terminus, researchers may visualize inflammatory response, following xenobiotic exposure, in real time, which provides an orthogonal view to complement the findings of biomarker profiling in vivo. In vitro studies using pHLP-1 allow for the targeting and sorting of metabolically compromised cells for further study. Our laboratory has been optimizing pHLP variants clustered to fluorescein isothiocyanate to target transmembrane successful targeting of L6 rat skeletal myoblasts post-exposure to mitochondrial electron transport chain inhibitors. Our techniques have achieved 100% localization to acidic cells in under one minute. Furthermore, our in vitro work has investigated the binding constants associated with pHLP to pinpoint optimal concentrations for further in vivo work, as well as establishing a dose-response relationship between amount of pHLP and extent of cellular injury.

Noninvasive bioluminescent imaging (BLI) of tumor cells expressing luciferase can be used to track tumor growth and metastasis in living animals. High sensitivity and relative ease of use have made BLI common in pre-clinical studies. Nonetheless, BLI is limited by poor signal penetration, making it unusable for deep tissue or large animal studies. In vitro, Fluc and NIS models expressing firefly luciferase (Fluc) and the sodium iodide symporter (NIS). To this end, we generated tumor microtissues and the Visikol HISTO-M clearing agent to illustrate the pound are greatest. It was sought to solve the problem of 3D cell culture opacity by employing an optical clearing agent designed specifically for these tissues. Here, we combine 3D InSight™ Primary Human Liver Microtissues and the Visikol HISTO-M clearing agent to illustrate the effect of tissue clearing on high content confocal screening of steatosis and cytotoxicity measured by several known anchors was demonstrated that the addition of tissue clearing allowed for a 3-fold increase in cells detected, the ability to characterize dose response as a function of tissue depth and an increase in dose response sensitivity.

Imaging of testis revealed that the parent drug was mostly detected in the subcapsular region at both time points: 2 and 8h after dosing. The parent drug was observed in all histological regions of the testes; the strongest signal was in the vascular interstitial tissue, whereas the signal in the germ cell layer and lumen was weaker. The latter findings are related to the lack of blood vessels in these regions. A weak signal was evident in these compartments; it cannot be excluded that parent drug penetrates the blood-testes barrier to some extent. The combination of QMSI and histology can be used to study the location of a test substance and its metabolites in a PKPD study without the use of radio-labeled compounds.

The use of in vitro three-dimensional (3D) cell cultures has increased dramatically for drug screening as 3D culture models more accurately mimic the in vivo environment compared to traditional monolayer cultures. However, unlike for traditional cell culture, imaging analysis of 3D cultures is limited due to the thickness of 3D cell cultures, typically >100 µm, which causes light scattering, limiting imaging of the surface-layer cells of the 3D culture. This limitation prevents complete characterization of the cell population within whole-mount 3D cultures. Furthermore, this technical limitation introduces an unavoidable sampling bias in imaging analysis, since only the exterior cells can be imaged where concentrations of nutrients, oxygen, and drug compound are greatest. It was sought to solve the problem of 3D cell culture opacity by employing an optical clearing agent designed specifically for these tissues. Here, we combine 3D InSight™ Primary Human Liver Microtissues and the Visikol HISTO-M clearing agent to illustrate the effect of tissue clearing on high content confocal screening of steatosis and cytotoxicity measured in several known anchors was demonstrated that the addition of tissue clearing allowed for a 3-fold increase in cells detected, the ability to characterize dose response as a function of tissue depth and an increase in dose response sensitivity.

2131 Improved Characterization of Compound Toxicity through the Application of a Tissue-Clearing Technique to 3D In Vitro Model Screening

2132 Precise Anatomical Localization and Deep Tissue Imaging of Tumors Expressing Luciferase and the Sodium Iodide Symporter (NIS)

I. P. 2018 SOT Annual Meeting
Mitochondrial toxicity has been implicated in several high profile clinical trial failures and withdrawals. Standard approaches to monitoring metabolic perturbations are limited to endpoint assays that provide population-based measurements and limited kinetic information. We developed a genetically encoded ATP sensor to enable direct, automated live cell analysis of cellular ATP levels using IncuCyte® S3. In this study, our live cell imaging approach to categorizing compounds as nontoxic, cytotoxic, or mitotoxic using the glucose/galactose switch model was evaluated. Substituting galactose for glucose in growth media blocks the ability of cells to generate ATP via glycolysis, conferring reliance on mitochondrial oxidative phosphorylation to generate ATP and enhancing sensitivity to mitochondrial-driven toxicity. Cell lines stably expressing a genetically encoded, fluorescent ATP sensor or a control (non-ATP binding) sensor were adapted to and plated in glucose or galactose media. ATP levels were monitored using an IncuCyte® S3 equipped with a specialized filter set and data acquisition module. Cellular ATP levels were measured over the course of 24 hours following treatment with a panel of compounds previously classified as nontoxic, cytotoxic, or mitotoxic. Little to no change in ATP was observed following administration of nontoxic compounds. Cytotoxic compounds induced similar reductions in ATP in both glucose- and galactose-grown cells. In contrast, mitotoxic compounds displayed a leftward shift in potency and more substantial and/or prolonged decreases in ATP under galactose grown conditions. Reductions in ATP levels could be observed within minutes of compound treatment, highlighting the sensitivity and specificity of the IncuCyte® S3 sensor assay. Transient reductions in ATP followed by recovery, which would have been missed by typical endpoint assays, were also observed using our live cell analysis approach. Visualization of morphology and quantification of phase confluency in tandem with automated ATP sensor analysis provided by IncuCyte® S3 adds additional insight into the heterogeneity of cellular responses to compound addition. Overall, our data demonstrate that direct measurement of ATP by live cell imaging provides a robust, predictive tool for mitochondrial toxicity screening.
Evaluation of biological activities of compounds has been greatly advanced by transcriptionomics. However, gene signatures provide only indirect information about the underlying biological phenomena. Here, we present an alternative approach, wherein cell response is characterized by changes in the network of signal transduction pathways that regulate gene expression. Using a multiplexed reporter assay, we assessed the activity of transcription factors that lie at the apexes of these pathways, generating a quantitative signature (TF activity profile [TFAP]). We show that perturbations of human cell systems and biological pathways produce distinct TFAPs. Strikingly, perturbagens of a given system, regardless of structural and mechanistic dissimilarities, have produced an invariant TFAP, representing an "archetypal signature" of bioactivity. We found archetypal signatures for multiple bioactivities, including mitochondrial, HDAC, and ubiquitin/proteasome pathway inhibitors; cytoskeleton disruptors; and DNA-damaging agents. These TFAPs enabled correct identification of compounds with given bioactivity among uncharacterized chemicals. Furthermore, we show that observing changes of a compound's TFAP with concentration enables the identification of multiple target systems and reveals the on-target and off-target activities of drugs. Thus, TFAPs represent a new kind of descriptors that enable a straightforward, mechanism-based evaluation of compound polypharmacology. Support for the NIH grants R44GM125469. The views expressed in this presentation are those of the authors and do not necessarily reflect the views or policies of the US EPA. Mention of trade names does not constitute an endorsement by the US EPA.

Intestinal microbiota play a role in a variety of host physiological aspects. Thus, when assessing the toxicological profile of a substance its effect on the microbiome cannot be ignored. In this study, an antibiotic alteration of the gut microbiome was carried out. During 28 days, clindamycin or lincomycin were administered orally to Wistar rats. With the aim of identifying metabolites derived from the gut microbiome, metabolic profiles of fecal and plasma were assessed. As these antibiotics have an almost negligible systemic toxicity, the metabolomics findings in the plasma of treated animals is, most likely, exclusively related to changes in the gut microbiome. An increase of taurocholic acid and 2-hydroxybutyrate together with a decrease of glycochenodeoxycholic acid was found as common changes in plasma and feces profiles of antibiotic treated rats. Taurocholic acid and cholic acid were both highly increased in feces. However, cholic acid was decreased in plasma profiles whereas taurocholic acid was increased. Latest findings show that there is an evident accumulation of primary bile acids like cholic acid and taurocholic acid in the gut. This is likely owed to the disruption of microbial communities and an increase of bile production via the liver derived from a lack of secondary bile acids. Additionally, 7a-dehydroxylation bacteria can convert the small amount of secondary bile acids to yield cholic acid and taurocholic acid and are favored after antibiotic treatment. However, the significant lowering of cholic acid in plasma indicate that this metabolite is not being reabsorbed from the gut into the portal vein presumably because of its limited aqueous solubility and precipitation in the protonated form in the intestinal tract. The results of these metabolomic investigations show that antibiotic treatment has a great impact on the microbiome and that they may be greatly affected by microbial community structure and function. The finding suggests that through metabolic analysis it is possible to assess the bile acid pool composition shifts derived from microbiome perturbations. Since bile acids and the composition of the bile acid pool have been hypothesized to be related with several disease states, the investigations of these metabolites is of high significance in the field of toxicology.
Trivorex® is a polyvalent neutralizer and absorbent for chemical spills in industries and hospitals. It is a yellow powder including colored pH indicators. Trivorex® can neutralize both acids and bases and absorb both aqueous and lipophilic solutions. It is nonflammable and does not contain VOCs. None of its components are toxic or suspected carcinogens, and it does not contain any crystalline silica. In vitro tests have been performed in order to show its efficiency. It has been tested on 20 ml of standard corrosives and irritants at different concentrations. Capacity of Trivorex® was recorded based on the amount needed for absorption and neutralization. According to the European waste legislation (commission regulation EU N° 1357/2014 and commission decision 2014/935/EU), for a waste to be classified as nonhazardous, the producer has to prove the waste does not have any hazardous properties. This proof needs to be provided based on experimental tests or a study of the potential, or real danger of the mixture has to be provided. We report here a way to transform a chemical waste into a nonhazardous waste with Trivorex® neutralizing absorbent. This decancellation process has been, up until now, only possible for some corrosive chemicals (i.e., hydrochloric acid or sodium hydroxide). The decancellation process creates a safe waste that can be manipulated easily and safely by any operator. Laboratoire Prevor has developed a method to evaluate if a chemical can be neutralized by Trivorex® and the hazards of the created waste. It is then possible to ensure that the neutralized chemical can be evacuated as a nonhazardous waste with the waste code 15 02 03. This evaluation method has been validated by INERIS (French National Institute for Industrial Environment and Risks). The list of accredited chemicals is now available online. Based on these results, Trivorex® appears to be a good way to deal with dispersal of chemicals in industries and legally transform these wastes into nonhazardous waste due to the neutralization process.

**2146 Thrombogenicity Testing for Blood-Contacting Medical Devices in a Human Blood Loop: Continuing Model Validation**

Y. Chen, M. Cunningham, A. Beltrame, and S. Howard. American Preclinical Services, Minneapolis, MN.

ISO 10993-4 thrombogenicity testing is widely used for meeting regulatory requirements for approval of blood-contacting medical devices. We have successfully developed an in vitro model using minimally heparinized ovine blood that has been successfully used in lieu of the NAVI model in recent submissions. This study describes the translation of the methods from the ovine assay to a human blood assay to enhance the predictability of clinical outcomes. Fresh human blood was collected from a healthy donor and heparin added to a final concentration range from 0.7 to 1.4 IU per mL of blood. Blood was introduced into the loop (total volume ~100 ml) no more than 4 hours after the completion of the draw. Activated clotting time (ACT) of the blood was measured prior to addition to the loops and after the exposure period. Up to 3 positive or negative controls (polyurethane medical grade tubing, ~10 cm in length) simulating catheter type devices were inserted into the loop. Each loop was filled with blood and air was removed and the loop was closed. The blood was circulated using a peristaltic pump at a flow rate ~0.5 L/min. Up to four loops were prepared for testing with positive or negative controls. After 4 hours, the loop sections containing the positive and negative controls were opened, photographed in situ and evaluated for the presence of thrombus in accordance with standard in vivo thrombogenicity scoring for acutely implanted devices. The percent of the total surface of the control articles covered by thrombus was determined (the primary scoring parameter). A thrombogenicity score was then assigned to each individual article based on % surface area using a scale of 0-5, where: 0 = thrombus present on <2% total surface area up to a score of 5 = thrombus present on >75% total surface area; more consistent with the ISO 10993-4 guidance. Typical scores using standardized positive and negative control materials were reproducible over several months of testing resulting in scores of 0-2 (0 to 25% surface area) for the negative controls and scores of 4-5 (51-100% of the article surface area covered with thrombus) for the positive control. A head-to-head comparison of the performance of the ovine and human blood assays using similar anticoagulation (minimal heparin) and identical test and control articles will allow a higher confidence in translatability of in vitro assays using animal blood (ovine or porcine) to predict clinical safety.
Chemical characterization (described in ISO 10993-18) refers to the determination of chemical identities and quantities of substances contained in a medical device. The results of these determinations are used to conduct toxicological risk assessments wherein the potential for patient harm due exposure to these substances are evaluated. Extractables studies, which are often chemically untargeted, are used to produce comprehensive and accurate information regarding potential leachable substances of a spectrum of chemical properties. The untargeted and chemically diverse nature of extractables studies and the need to achieve low levels of detection creates a challenge for the analyst. The current work is intended to establish improved methodology for untargeted chemical characterization. Selected materials include silicone tubing, polyvinyl chloride (PVC) tubing, ethylene propylene diene monomer (EPDM) rubber. These materials were extracted in hexane, iso-propanol, and water at a sample mass-to-extraction volume ratio of 45 mg/mL. Extractions were performed in a shaking incubator at 37 and 50 ºC in sealed scintillation vials at 200 rpm for 24 h and analyzed by direct injection on an Agilent 7890B-5977B GC/MS equipped with a 30 m DB-5MSUI column. Extractions were compared to matrix matched controls. Agilent Unknown Analysis software with the NIST 2014 library was used to perform chemical identification and scoring using the internal algorithm. Various compounds were detected in all extracts of the materials. Generally, the number of extractable compounds was greatest in hexane (40), followed by iso-propanol (3 to 16), and then water (1 to 6). While the number of compounds in water and iso-propanol appeared equivocal between 37 and 50 ºC, a consistent increase (range 140-218%) in the number of compounds in hexane at 37 degrees versus 50. Examples of individual identifications include various phthalates, pyrene, and benzothiazole. Investigation of semi-quantitative measurement of identified species is ongoing. The current results indicate the successful GC/MS work-up of three materials from extraction to data analysis. The work has highlighted the need to focus on method development in areas including extraction conditions, analytical methodology, identification assignment, semi-quantification of analytes, and statistical analysis.

Hydrogen peroxide (H2O2) is a chemical of toxicological concern because it elicits clinically relevant adverse health effects: embolism, hemo-lysis, and methemoglobinemia (Bek et al., 2009). To minimize risk from infections, hospitals have been reported to add silver-stabilized H2O2 to the facility water system, resulting in unintentional exposure of patients undergoing hemodialysis to H2O2, which caused toxicity (Davidovits et al., 2003). Maintenance of heater-cooler units (HCU) with 3% H2O2 for preservation against bacterial contamination within the HCU water circuit is also reported (Sax et al., 2015). HCU play a critical role in cardiovascular surgery by supplying temperature-controlled water to the cardiopulmonary bypass and cardioplegia heat exchangers in order to control patient temperature. Many HCU contain polymeric heat exchange fibers rather than stainless steel, and because of its small size, H2O2 may cross the semi-permeable membrane and adversely impact patients’ blood (Hoenich, 2009). To address this safety concern, a dose-response assessment was conducted to derive a parenteral provisional tolerable intake (pPTI) value below which additional risk control measures would be unwarranted to prevent toxicity. Embolism is identified to be the critical adverse health effect of H2O2 because the point of departure (POD) is lower as compared to other adverse effects. The critical adverse health effect study is by Lorincz et al. (1948), who administered H2O2 into rabbit blood up to 15 minutes, and reported the NOAEL for embolism to be 6 mg H2O2/L blood/min. To derive the pPTI value, uncertainty factors were applied that accounted for interspecies differences (i.e., 10) and reliability of the critical adverse health effect study (i.e., 100). Additional uncertainty factors (e.g., interspecies difference in potency) were not applied because (a) the mechanism by which H2O2 elicits embolism is thought to be the release of undissolved oxygen, and (b) H2O2 is rapidly converted within blood into undissolved oxygen; the latter is the toxicant for embolism. Based on the identified POD and uncertainties described, the TI for unintentional H2O2 exposure to blood circulation from HCU is calculated to be 6 µg/L blood/min, which is 1,000x lower than the NOAEL reported in Lorincz et al. study. Because the critical adverse health effect study does not meet current reliability criteria (e.g. ToxRTool), the pPTI should be verified.
Implantable medical devices can release metal ions that accumulate in peri-implant tissues. Although risk assessment approaches have been developed to assess the potential for adverse health effects to occur following the release of compounds from devices into the systemic circulation, it is difficult to predict the likelihood for toxic effects to occur in tissues adjacent to an implanted device. To overcome this problem, it may be possible to use in vitro cytotoxicity data as a surrogate for effects occurring in local tissues in vivo. The goal of this study was to compare the concentration of nickel (Ni) that results in decreased cell viability in vitro to the concentration of nickel that results in necrosis and inflammation in tissues surrounding an implanted Ni alloy wire. NOAEC values ranging from 3 to 15 µg Ni/mL were obtained following 24-hr treatment of L929 fibroblasts with concentrations of Ni chloride and Ni sulfate from 0.005 to 50 mM. Cell viability was assessed using MTT and Alamar Blue assays; morphology was evaluated using fluorescent microscopy. Previously published data have shown that Ni concentrations of 5-10 µg/g are associated with a mild inflammatory response in tissues 7 days after subcutaneous implantation of a Ni-alloy wire in rats; higher Ni concentrations in tissue closer to the implant produced severe inflammatory response and necrosis. The in vitro NOAEC for these effects was less than 5 µg Ni/g tissue. Similar values were obtained using a biofilm model to predict tissue concentrations of nickel in tissue adjacent to a nickel-containing implant. The concentration of Ni required to produce an inflammatory/necrotic response in tissues in vivo (5-10 µg/g) corresponds well to the concentration of Ni that results in decreased cell viability in vitro (greater than 3-15 µg/mL). As a result, in vitro cytotoxicity studies may serve as a promising alternative to predict the concentration of Ni that produces adverse effects in tissues adjacent to an implanted nickel-containing device.

Cytotoxicity of a Lithium Phenyl(2,4,6-trimethylbenzyl)Phosphinate (LAP) and Gelatin Methacryloyl (GelMA) Hydrogel in Human Kidney Primary Proximal Tubule Cells (hRPTEC)

Bioplotting is a type of 3D printing that uses photopolymers to encapsulate cells, and exposes cells to shear stress, UV light, and chemicals whose toxicity can be fully understood in vitro. Combining the photoinitiator LAP produces a photopolymer commonly used in bioplotting; however, unrelated monomer and/or the presence of photoinitiator can result in cytotoxicity. In this study, hRPTEC were exposed to extracts of GelMA hydrogels that were photoinitiated with the LAP concentration and UV exposure time. Rheological properties, cell viability, and cell proliferation were assessed to gauge the mechanical properties and cytocompatibility of the formulations. Samples of 10% w/v GelMA with 1, 0.5, 0.25, or 0.1% w/v LAP were exposed to 86, 342, or 855 mJ/cm2 of 365 nm light in a UV curing oven. Shear storage (G′) and loss moduli (G″) were measured for 20 mm diameter x 1 mm thick gels between 0.02 and 2% shear strain at 5 Hz and 37 °C. In addition, each sample was weighed and extracted in 10x the mass of cell medium at 37 °C for 24 h; extracts were frozen at -20 °C until use. The prototypic neuropathicostasins cisplatin (CisPt) and cadmium chloride (CdC12) served as positive controls at 10, 25, and 50 µM concentrations. hRPTEC were exposed to the extracts and positive controls for 24 h. Viability and proliferation were assessed using Alamar Blue and the CyQuant Direct Cell assay, respectively. Below 0.1% shear strain, G′ values ranged from 1385 to 19.5 Pa and G″ values ranged from 33.7 to 13.0 Pa for GelMA with 1% LAP at 855 mJ/cm2 and 0.1% LAP at 86 mJ/cm2 exposure, respectively. Both CisPt and CdC12 significantly reduced viability at 25 and 50 µM and reduced proliferation in a concentration-dependent manner. No significant effect on cell viability was found in extracts under the tested LAP concentrations or UV exposures; however, proliferation was reduced by 30% at the highest LAP concentration. No statistically significant difference in cell proliferation or viability was found among the UV exposures. The common GelMA-LAP combination was found to be cytocompatible albeit with a reduction in proliferation. Furthermore, gels were fabricated over a wide range of mechanical properties with minimal to no cytotoxicity. Therefore, GelMA gels photoinitiated with LAP show promise for use in acellular tissue engineering scaffolds.

An Assessment of Gender-Specific Risk of Implant Revision following Primary Total Hip Arthroplasty: A Systematic Review and Meta-Analysis

A. Riordan1, K. Towle2, and A. Monnot2.
