Background and Purpose: Research indicates that self-reported or subjective cognitive decline (SCD) is a major risk factor for mild cognitive impairment and eventually dementia. Environmental factors, such as air pollution, have emerged as significant influencers of cognitive abilities. Olfactory loss, cognitive decline, and dementia incidence all have been independently associated with exposure to air pollution in epidemiological studies. Recent data indicate that the odds of dementia diagnosis was 10% higher for every 1 µg/m³ increase in three-year average wildfire particulate matter (PM) concentration. The goal of current study is to understand how long term fine particulate matter (PM_{2.5}) levels influences SCD among adults from the Behavioral Risk Factor Surveillance System (BRFSS). **Methods:** We aimed to answer the question: Is there a relationship between PM_{2.5} and reported/subjective cognitive decline from 2015 to 2022 on a state-by-state basis. We hypothesized that there would be a positive association between PM_{2.5} levels and SCD. Approximately 14,135 survey results from all 50 states, District of Columbia and Puerto Rico were included in this study. We measured SCD from participants' self-reported answers to the Cognitive Decline Module, a module which identifies individuals, age 45 years and older, with worsening memory loss. Data for PM_{2.5} were obtained from the US Environmental Protection Agency. These data were cleaned to retain only state identifiers and average 24-hour concentrations, then grouped by state to calculate yearly means. For SCD, data from the BRFSS (2015-2022) were filtered to exclude "Don't know" and "Refused" responses, and a binary variable was created to indicate the presence of SCD, and only states that participated in the optional module each year were included. We used linear mixed models (LMM) to assess any associations, with state as a random intercept though to account for the repeated measures from each state. Additionally, for each model, a 1, 2, and 3-year lag for PM_{2.5} levels was run. We also employed imputation for missing data and compared results for observed and imputed data and significance was set at p<0.05. **Results:** Over the 2015 - 2022 period, Indiana had the highest average PM_{2.5} while Wyoming had the lowest PM_{2.5}, with averages at 10.3 µg/m³ and 4.21 µg/m³ respectively. Adult males in Oklahoma and Tennessee reported the most cognitive decline, 15.5% and 15.0% respectively while adult females in Arkansas and Alabama each reported an average cognitive decline of 14.4% per year. Adult males and females in Puerto Rico reported the lowest cognitive decline per year, 7.03% and 5.43% respectively. LMM results indicated that, on average, cognitive decline occurs each year by approximately 0.6% and with each lagged value of PM_{2.5} (p<0.05). This implies that even after accounting for year, there is a significant increase of the percent of people reporting cognitive decline when they are exposed to higher PM_{2.5} levels in the one (p=0.020), two (p<0.001), or three (p=0.002) years prior. To assess the sensitivity of these models, states with less than three years' worth of SCD data were excluded from the analysis. Model results from this limited dataset showed that there was still a significant increase in the percent of adults reporting cognitive decline when exposed to higher PM_{2.5} levels in the one (p=0.030), two (p=0.005), or three (p=0.005) years prior. Imputed data for all states showed similar and statistically significant trends. We did not observe statistically significant results by sex (p>0.1). **Conclusions:** Regardless of the region in the US, higher PM_{2.5} concentrations was associated with an increased risk of having SCD among adults who participated in the BRFSS. Particulate air pollution-based interventions should be prioritized to lessen the impact of cognitive decline in older adults.

PS 3947 Diesel Exhaust Particles Modulate Splenic Cytokine Expression in Juvenile Mice

R. Acevedo Reyes¹, A. Catala Catala², C. M. González Rivera¹, and L. B. Mendez¹. ¹Universidad Ana G. Mendez, Carolina, PR; and ²Universidad Ana G. Mendez, Cupey, PR.

Background and Purpose: Diesel exhaust particles (DEP), a major component of fine particulate matter, can induce extrapulmonary oxidative stress and inflammatory responses. Preliminary data from our laboratory showed that juvenile mice exposed to DEP induced leukocyte infiltration in the lungs and neuroinflammation. The spleen is the largest peripheral immune organ and plays a central role in systemic immune responses. Therefore, the objective of this study was to assess if DEP exposure modulates cytokine expression and induces oxidative damage in the spleen.

Methods: Male and female C57BL/6J mice were exposed intranasally to increasing doses of DEP from postnatal day (PND) 25 to 33. Spleen tissues were collected six days after the final exposure and homogenized with RIPA buffer. Cytokines and chemokines expression were quantified with a multiplex bead-based immunoassay (23-plex) using a Luminex MagPix instrument. Oxidative alterations in the spleen were evaluated with Fourier Transform Infrared Spectroscopy (FTIR). Characteristic bands corresponding to lipids (2850-2923 cm⁻¹), proteins (amide I and II: 1650 and 1545 cm⁻¹), and nucleic acids (1080 cm⁻¹) were quantified to assess oxidative and structural changes. **Results:** Preliminary data showed a significant increase in IL-1α levels but significant decreases in IL-3, IL-9, and IL-13 levels. FTIR analysis revealed subtle alterations in spectra across exposure groups; however, no statistically significant differences were detected. Ongoing lipid peroxidation and protein carbonyl measurements will determine whether changes in FTIR spectra correlate with biochemical markers of lipid and protein oxidation. **Conclusions:** The results suggest that DEP exposure modulates splenic activity by inducing pro-inflammatory pathways and suppressing adaptive immunity. The observed spectral tendencies, combined with cytokine dysregulation, suggest that oxidative damage and inflammation occur concurrently as part of a systemic immune response to DEP.

PS 3948 Surgical Smoke in the Operating Room: Evaluating the Role of Smoke Evacuators on Surgical Staff Exposure

V. Reddy¹, W. Oslock¹, A. Chada², A. Specht³, and R. Vilcassim¹. ¹University of Alabama at Birmingham, Birmingham, AL; ²Nova Southeastern University, Davie, FL; and ³Purdue University, West Lafayette, IN.

Background and Purpose: Surgical smoke, which is the smoke generated by the burning of tissues during surgery due to the use of electrocautery devices, is known to contain harmful air pollutants such as particulate matter (PM) and volatile organic compounds (VOCs). Gaps remain in our understanding of the exposure experienced by surgeons and operating room staff to air pollutants in surgical smoke and the potential health impacts of exposure. Smoke evacuators can help remove surgical smoke from the surgical theater, potentially reducing exposures, though they are not used in all surgeries. Therefore, this study aimed to evaluate the role of smoke evacuators on PM air pollutant concentrations during procedures with frequent electrocautery use. **Methods:** PM_{2.5} concentrations and elemental compositions were analyzed from 20 surgical cases from two hospital systems, the Birmingham Veterans Affairs Medical Center and the University of Alabama at Birmingham Hospital in Birmingham, AL. The surgical cases included mastectomies, lumpectomies, and amputations. Operation details, room conditions, electrocautery use, smoke evacuator presence, and 1-minute averaged PM measurements were recorded. PM_{2.5} concentrations were measured from two locations within each operating room. The first location was near the surgical field, and the second location was at the room's periphery. PM_{2.5} concentrations were recorded using PDR-1500 DataRAM air monitor with an internal Teflon filter. Surgical cases were categorized based on smoke evacuator use. Peak and average concentrations were compared using t-tests and chi-square tests. PM collected on Teflon filters were analyzed using X-Ray Fluorescence (XRF) to evaluate the PM's elemental component levels. **Results:** Twenty surgeries were analyzed, with mastectomies being the most common (n=11, 55%). Smoke evacuators were used in 6 cases. The average electrocautery duration was 75 minutes. PM_{2.5} levels without a smoke evacuator were statistically significantly higher than PM_{2.5} levels with a smoke evacuator (22.6 vs 5.3 µg/m³, p<0.0001). While the mean differences in PM_{2.5} concentrations did not appear drastically different, cases without a smoke evacuator experienced significantly more peaks over 50 and 100 µg/m³. The frequent high peaks exhibited during cases without a smoke evacuator resulted in more acute exposures to surgical staff. Cases with a smoke evacuator had significantly smaller and less frequent peaks. Although the mean concentration was not high, cases without a smoke evacuator had a total of 197 peaks above 50 µg/m³ while cases with a smoke evacuator had a total of one peak above 50 µg/m³. The average number of peaks per case above 50 µg/m³ for cases without a smoke evacuator was 14.1 per case. The average number of peaks per case above 50 µg/m³ for cases with a smoke evacuator was 0.17 per case. Furthermore, in cases without a smoke evacuator, the peak sizes were larger than in cases with a smoke evacuator. The elemental analysis using XRF showed lower elemental chromium, cobalt, selenium, and iron concentrations in cases with a smoke evacuator than cases without a smoke evacuator. **Conclusions:** Electrocautery use without smoke evacuators resulted in statistically significantly higher PM_{2.5} concentrations and frequent pollutant peaks. The frequent and pronounced peaks demonstrated surgical staff experience more acute exposures in cases without the use of a smoke evacuator. The differences indicate the importance of using smoke evacuators during electrocautery procedures for reducing surgical staff exposure.

J. Ledesma Vicioso¹, H. J. Rosa², and L. B. Mendez¹. ¹Universidad Ana G. Mendez, Carolina, PR; and ²Universidad Ana G. Mendez, Cupey, PR.

Background and Purpose: Diesel exhaust particles (DEP), a major component of urban air pollution, pose significant health risks, including potential impacts on brain function and behavior. Mental health disorders are characterized by clinically significant disturbances in cognition, emotional regulation, and behavior with an average age of onset of 14.5 years. Therefore, this study investigated whether DEP exposure induces anxiety-related behaviors in prepubertal mice, used as a model of early adolescence. **Methods:** Both female and male C57BL/6J mice were exposed intranasally to increasing doses of DEP between postnatal days (PND) 25 to 33. Three days after the last exposure (PND36) mice locomotion, exploratory and anxiety-related behaviors were evaluated using the open field test under controlled environmental conditions. Behavioral activity was recorded for five minutes and analyzed using ANY-maze software to quantify grooming, rearing, and spatial zone preferences, among other variables. **Results:** DEP-exposed mice exhibited increased mobility, speed, grooming, and rearing behaviors compared to controls, indicating heightened stress and exploratory activity. Track plot analysis further revealed altered spatial distribution, with DEP-exposed mice spending more time in the peripheral zone. **Conclusions:** Adolescence is a transitional life stage between the ages of 10 to 19 years, in which significant cognitive and socioemotional development occurs. During this life stage, key processes in brain development might be susceptible to environmental insults. Our findings suggest that DEP exposure may influence exploratory and stress-related behaviors in prepubertal mice, reflecting potential behavioral effects of particle pollution.

PS 3950 Lipid Compositional and Spatial Alterations Associated with Pulmonary and Systemic Toxicity Following Silica Exposure

J. N. Swihart¹, E. L. Rossini², W. Zhang³, C. R. Ferreira³, A. Pitchai¹, A. Shinde¹, and J. H. Shannahan¹. ¹School of Health Sciences, Purdue University, West Lafayette, IN; ²Institute of Chemistry, Department of Analytical Chemistry, São Paulo State University (UNESP), São Paulo, Brazil; and ³Purdue Metabolite Profiling Facility, Purdue University, West Lafayette, IN.

Background and Purpose: Inhaled exposures, including ambient particulate matter and engineered nanomaterials, have been shown to disrupt lipid metabolism both locally and systemically. Despite these observations, comprehensive assessments of lipid dysregulation following inhalation exposures remain limited, and lipids are often overlooked in studies of systemic toxicity and disease. Among these exposures, silica particles (SiO₂), naturally occurring and frequently generated through human activities such as mining, construction, and manufacturing, are of particular concern. Respirable crystalline silica is a well-established cause of silicosis, chronic obstructive pulmonary disease, and lung cancer. Respiratory SiO₂ exposure has also been associated with extrapulmonary effects, contributing to chronic kidney disease, cardiovascular disease, and autoimmunity. Traditional lipidomic analyses rely on homogenized tissue preparations, an approach that may obscure localized effects since particles deposit heterogeneously within the lung. Desorption electrospray ionization mass spectrometry (DESI-MS) imaging overcomes this limitation by providing spatially resolved lipidomic data, thereby enhancing sensitivity and revealing site-specific lipid alterations. We hypothesized SiO₂ exposure induces dose- and time-dependent lipid dysregulation in both pulmonary and systemic tissues mediating health outcomes. **Methods:** To evaluate this hypothesis, mice were exposed to 0.25, 0.5, or 1 mg of SiO₂ by oropharyngeal aspiration, with controls receiving water (n=5/group). At 24 hours or 7 days post-exposure, bronchoalveolar lavage fluid and lung, liver, and kidney tissues were collected for quantitative real-time PCR of inflammatory and lipid metabolism genes. DESI-MS imaging was performed on tissues to evaluate SiO₂-induced lipid alterations while H & E staining enabled histological evaluation. **Results:** Gene expression analyses demonstrated significant upregulation of the pro-inflammatory mediators *CCL2*, *CXCL-1*, *CXCL-2*, *IL-6*, and *IL-1β* in the lung 24 hours post-exposure, with return to control levels by 7 days. While systemic tissues exhibited limited inflammatory changes, several lipid metabolism genes were altered compared to controls. Notably, *COX-2* was induced across the lung, liver, and kidney at 24 hours after exposure. DESI-MS imaging revealed dose-dependent SiO₂-induced lipid dysregulation, most prominently within the lung, with histological overlays suggesting lipid alterations localized to terminal bronchioles. MS imaging of systemic tissues demonstrated lipid alterations that may mediate extrapulmonary responses to inhalation exposures. **Conclusions:** Collectively, these findings demonstrate spatial lipidomics can provide unique insights into SiO₂-induced toxicity, uncovering lipid disruptions that may underlie exposure consequences. This approach offers a more holistic framework for understanding and ultimately mitigating the health risks of inhaled exposures. Alterations in lipids suggests they could be a regulator of systemic responses occurring following inhalation exposure.

PS 3951 Soluble Epoxide Hydrolase Inhibition Alleviates AgNP-induced Pulmonary Inflammation in a Metabolic Syndrome Mouse Model.

A. Pitchai, J. Swihart, K. Robison, A. Shinde, W. Wang, and J. Shannahan. Purdue University, West Lafayette, IN.

Background and Purpose: Evaluations of nanoparticle safety have concentrated on healthy models. Epidemiological studies have shown that individuals with metabolic diseases are more vulnerable to particulate air pollution. Our previous research identified specific alterations in lipid mediators involved in inflammatory regulation in a metabolic syndrome (MetS) mouse model, as well as an increase in lung inflammation following exposure to silver nanoparticles (AgNPs). This heightened response was associated with elevated pulmonary gene expression levels of epoxide hydrolase 2 (*Ephx2*), which encodes soluble epoxide hydrolase (sEH). sEH hydrolyzes anti-inflammatory epoxy fatty acids, facilitating their clearance. Inhibiting sEH may be beneficial for resolving inflammation by decreasing the removal of lipid mediators responsible for resolution signaling. We hypothesize the application of a sEH inhibitor, 1-Trifluoromethoxyphenyl-3-(1-propionylpiperidin-4-yl) urea (TPPU), will effectively improve the bioavailability of epoxyeicosatrienoic acids (EETs) thereby reducing enhanced AgNP-induced pulmonary inflammation due to MetS. **Methods:** C57BL/6J male mice were fed either a healthy or a high-fat Western diet for 14 weeks. Subsets of mice were treated with 0.15% DMSO (vehicle control) or TPPU (10mg/L) via drinking water *ad libitum* for one week prior to AgNP exposure to inhibit sEH. After one week, mice were exposed to either 50 µl of water (control) or 50 µl of water containing 50 µg of 20 nm AgNP via oropharyngeal aspiration. Endpoints of pulmonary inflammation and toxicity were evaluated 24 hours following AgNP exposure. **Results:** MetS mice exposed to AgNPs and receiving 0.15% DMSO treatment exhibited significantly exacerbated pulmonary inflammatory responses compared to exposed healthy mice. In mice exposed to AgNPs and treated with TPPU, neutrophil-exacerbated infiltration decreased in the MetS model. This decrease in neutrophils was associated with lower expression levels of pro-inflammatory cytokine genes, such as *IL-6*, *CCL2*, and *CXCL2*. In the DMSO-treated AgNP-exposed mice, the expression of the resolution inflammatory cytokine gene *IL-10* was reduced. However, TPPU treatment increased *IL-10* levels in both mouse models. **Conclusions:** Overall, inflammatory responses induced by particulate exposure may be treated via modulation of lipid metabolism to enhance resolution signaling thereby benefiting susceptible subpopulations.

PS 3952 Linking Airborne Particulate Exposure to VOC Emission Changes: The Role of TET1 and Oxidative Stress in HBEcs

L. L. Jones, M. Sivaprasad, A. L. Linderholm, S. P. Elston, H. Ji, and N. J. Kenyon. University of California, Davis, CA. Sponsor: L. Van Winkle

Background and Purpose: Exposure to wildfire generated fine particulate matter, less than 2.5 micrometers, (WFPM2.5) poses a significant health concern, particularly among individuals with asthma. Acute exposures to WFPM2.5 are linked to increased asthma exacerbations, emergency department visits, and short-term disease morbidity. Chronic exposure to ambient PM2.5 has been shown to induce oxidative stress signaling, impacting asthma pathophysiology. We have detected some of these PM2.5 related exposure changes in normal lung epithelial cell emissions by capturing and measuring volatile organic compounds (VOCs). The goal of our study was to test if similar changes, related to acute WFPM2.5 exposures, are detectable in VOCs and whether TET1 is involved. TET1 is an epigenetic regulator that impacts DNA methylation, histone modification, and other epigenetic mechanisms. Previous studies from our lab have demonstrated that TET1 expression is protective in severe asthma, based on association studies in children and observations from animal models of allergic asthma. Altered TET1 expression in human bronchial epithelial cells (HBEcs) and genetically modified animals, post traffic-related airway pollution (TRAP) or house dust mite exposure, has been found to down-regulate aryl hydrocarbon receptor (AhR) signaling and downstream detoxifying enzymes, resulting in increased airway inflammatory signaling and hyperresponsiveness. The objective of our study was to test the hypothesis that HBEcs exposed to WFPM2.5 emit a distinct volatile organic compounds (VOC) signature compared to unexposed HBEcs and this difference can be partly explained by decreased TET1 activity and subsequent increased oxidative stress responses. **Methods:** We cultured primary HBEcs from donors under air-liquid-interface conditions to recapitulate the pseudostratified mucociliary phenotype seen *in vivo*. We then utilized established methodology from our lab to sample, measure, and analyze VOCs emitted from the HBEcs. Briefly, well-differentiated cells were treated on the apical surface with 100µL of phosphate-buffered saline (control) or resuspended WFPM2.5 (100 µg/mL) extracted from filters following the 2018 California Campfire. After 5 days of repeated WFPM2.5 treatment and removal, headspace VOCs were collected onto Twisters® (sorbent-covered stir bars) and analyzed via gas-chromatography mass spectrometry (GC-MS). Principal component analysis (PCA) was used to create a table of all detected VOCs, and a partial least squares-discriminant analysis (PLS-DA) model was built for each experimental group to filter the list of VOCs to identify compounds related to the exposure. Basolateral media was collected to assess pro-inflammatory cytokine secretion and RNA was isolated from the cells to measure the expression of *tet1* and TET1-regulated genes. **Results:** Our PLS-DA model demonstrated that VOCs emitted from the HBEcs clearly separated the WFPM2.5 from the PBS treated groups with 0.90 accuracy, 0.78 predicted sensitivity, and 0.85 predicted specificity. Some

of the highly upregulated compounds dictating this separation were 4,6-dimethyl-dodecane, 1,3,4 Thiodiazol-2-amine, 5-methyl-, Decane, 5,6-dimethyl and Dimethyl phthalate. These compounds generally belong to the following superclasses: heterocyclic compounds, hydrocarbons, esters, and carbonyl compounds. We also found a trend of increased amphiregulin and IL-6 cytokine production with the onset of WFPM2.5 exposure that was not sustained. The expression of *TET1* demonstrated a downward trend and increased variability after 5 days of WFPM2.5 exposure. We also observed a significant decrease in AhR mRNA (*AHR*) and *CYP1B1* expression ($P=0.046$ and 0.031 , respectively) while the expression of *CYP1A1* remained significantly elevated ($p=0.011$). **Conclusions:** We have shown that HBEcs repeatedly exposed to WFPM2.5 affects *TET1* expression, downregulates AhR mRNA expression, and produces unique VOC signatures that may serve as markers of oxidative stress. We propose that *TET1* plays a protective role against oxidative stress induced by WFPM2.5 and downregulating *TET1* expression could be a key signal contributing to oxidative stress damage present in asthma. Further research will provide more information on the relationship between WFPM2.5 exposure and *TET1* activity and how this potentially affects VOCs emissions.

PS 3953 Mass spectrometry imaging (MSI) elucidates regional distribution of metabolomic and lipidomic changes in the brain following exposure to wildfire smoke in mice

E. Y. Suh¹, T. Jiang¹, H. Gu², J. Begay¹, E. Barr¹, S. Lucas¹, G. Herbert¹, L. Li², X. Liu², S. Cui², S. Noor¹, and M. Campen¹. ¹University of New Mexico, Albuquerque, NM; and ²Arizona State University, Phoenix, AZ.

Background and Purpose: Metabolomic and lipidomic methods using liquid chromatography-mass spectrometry (LC-MS) have revealed persistent changes in neurochemistry following exposures to wildfire smoke in mice. These findings are limited, however, because localization of metabolites and lipids in tissues cannot be determined in homogenized samples. To address the regionspecificity of metabolomic and lipidomic alterations from wildfire smoke, matrix-assisted laser desorption/ionization mass spectrometry imaging (MALDI MSI) was applied to visualize regional distributions of metabolites and lipids in mouse brain tissue sections. **Methods:** 21-month-old female C57BL/6 mice were exposed to either filtered air or simulated wildfire smoke (WFS; 500 $\mu\text{g}/\text{m}^3$, 4 hours every other day for 14 days) and sacrificed 1-day post-exposure. For LC-MS untargeted metabolomics and lipidomics, homogenized brain tissues were analyzed using a Thermo Vanquish UPLC-Exploris 240 Orbitrap MS system and mass spectrometer equipped with an electrospray ionization (ESI) source. For metabolomics, untargeted data from 70 to 1050 m/z were collected while for lipidomics, untargeted data from 100 to 2000 m/z were collected. For MALDI MSI analysis, we utilized a Bruker timsTOF Flex MALDI-2 mass spectrometry imaging instrument to establish a mass spectrometry imaging (MSI) method for spatial distribution of metabolites and lipids in mouse brain tissue sections. N-(1-naphthyl) ethylenediamine dihydrochloride (NEDC) and 2,5-dihydroxybenzoic acid (DHB) matrices were applied on the brain tissue sections for metabolomics and lipidomics, respectively, with HTX M3+ Sprayer. MSI data was acquired in negative ionization mode for metabolites and in positive ionization mode for lipids, in 50 μm resolution and with ion mobility separation mode on. Each whole brain sections were selected as regions-of-interest. MALDI MSI data were analyzed using SCI LS Lab, MetaboScape, and LIPID MAPS. **Results:** Phenylalanine, tyrosine, and tryptophan biosynthesis was downregulated in WFS-exposed mice, and purine metabolism was upregulated in WFS-exposed mice. Similarly, phenylalanine, tyrosine, and tryptophan biosynthesis and purine metabolism were downregulated and upregulated, respectively, in advanced aged mice. Multiple downregulated and upregulated lipids and metabolites, including neurotransmitters and amino acids, were observed in the hippocampus, cortex, and cerebellum of WFS-exposed mice. **Conclusions:** This MALDI MSI method can be used in environmental health to study regional metabolic and lipid changes in tissue sections following exposure to environmental pollutants. Wildfire smoke-induced neurochemical changes in specific regions can now be related to other phenotypes, including behavior and persistent neuroinflammation.

PS 3954 Removal of volatile organic compounds by chemical filters significantly inhibited the development of atopic dermatitis symptoms in mice: Potential implications for Air Conditioning Systems in Healthcare Environments

C. Ohira¹, K. Tomita², Y. Ota², K. Yano², M. Amano², M. Kaneki¹, A. Yamada³, R. Usui³, Y. Nagai³, M. Nagane¹, S. Takagi¹, and T. Fukuyama¹. ¹Azabu University, Kanagawa, Japan; ²Shimizu Corporation, Tokyo, Japan; and ³Fuji Industrial Co, Kanagawa, Japan.

Background and Purpose: In recent years, there has been increasing concern about the impact of indoor air quality on human health. Volatile organic compounds (VOCs) are indoor air pollutants that contain various chemical substances and are emitted as gases from solvents, detergents, building materials, and consumer or hobby products. Because indoor VOC concentrations often exceed outdoor levels, Japan has established an indoor air quality guideline of 400 $\mu\text{g}/\text{m}^3$ for total VOCs. Although the health risks of VOC exposure have been widely studied, their contribution to skin diseases such as atopic dermatitis (AD) remains unclear. The present study aimed to

measure VOC concentrations in medical environments and to elucidate the effects of VOC exposure on AD development using both cellular and animal models. **Methods:** As part of the field survey, total VOC concentrations were measured in three different types of veterinary hospitals. To examine the effects of VOCs on inflammatory skin diseases, *in vitro* studies were conducted using human epidermal keratinocytes exposed to standard VOC solutions. Cytotoxicity and production of inflammatory cytokines were measured. Furthermore, at concentrations that did not induce cytotoxicity with VOCs alone, the combined effects of co-stimulation with TNF- α (10 ng/mL) were evaluated. For *in vivo* experiments, female NC/Nga mice were used to establish an AD model by repeated topical application of house dust mite ointment. During the experimental period, a VOC mixture (10 $\mu\text{g}/\text{mL}$) was applied topically. AD symptoms, transepidermal water loss (TEWL), and skin thickness were measured weekly. At the end of the experiment, auricular lymph nodes and skin tissues were collected for immunological and histological analyses. The efficacy of a chemical filtering system for VOC removal was verified by both field investigation and whole-body inhalation exposure using the AD mouse model. **Results:** The field investigation revealed variations in indoor VOC concentrations among hospitals, with some facilities exceeding the Japanese standard value of 400 $\mu\text{g}/\text{m}^3$. Direct exposure of HaCaT cells to VOCs showed cytotoxicity at high concentrations. In addition, co-stimulation with TNF- α significantly increased the production of IL-8 and TARC. In the AD mouse model, topical application of VOCs significantly exacerbated AD symptoms and increased ear skin thickness. The number of CD4⁺ T cells in auricular lymph nodes and IL-13 gene expression in auricular tissues were significantly elevated compared with the AD control group. Moreover, the developed chemical filtering system effectively removed VOCs from actual medical environments. Inhalation of VOC-filtered air in the AD mouse model significantly reduced AD scores, skin thickness, and TEWL. Immunological analyses showed that CD4⁺ T cell populations and inflammatory cytokines (IL-4, IL-17) in auricular lymph nodes, as well as serum IgE levels, were decreased. Expression of the flaggrin gene, associated with skin barrier function, was significantly upregulated in the VOC-filtered air exposure group. In contrast, the therapeutic application of the chemical filtering system showed only limited immunological improvement. **Conclusions:** These findings indicate that elevated indoor VOC concentrations may contribute to the onset and exacerbation of AD by promoting inflammatory cytokine production and impairing epidermal barrier function. Air conditioning systems equipped with VOC-removal filters can effectively reduce VOC exposure, thereby improving allergic inflammation and skin barrier integrity. Incorporating such filtration technologies into clinical and domestic environments could represent a promising preventive strategy for managing allergic and inflammatory skin diseases associated with poor indoor air quality.

PS 3955 Repeated pharyngeal aspiration of cloth debris may cause chronic tissue damage through immune suppression

E. Park, W. Jung, J. Lee, C. Yoon, M. Yang, T. Yu, and J. Kim. Kyung Hee University, Seoul, Korea, Republic of. Sponsor: J. Kim

Background and Purpose: Textiles and clothing are a primary source of microplastic pollution, which releases microfibers. **Methods:** In this study, real tornado washing machine lint (TWML) samples were obtained from ten volunteers and pooled into a single test sample to investigate biological and cellular responses to inhaled TWML. **Results:** The dispersion contained irregularly shaped or fibrous particles and various heavy metals, including arsenic, copper, chromium, bromine, and antimony, as well as microplastic particles. 90-day repeated pharyngeal aspiration of TWML (50 μg) decreased the number of WBC and the proportion of neutrophils in WBC in male and female mice, respectively, whereas the proportion of RET in red blood cells decreased in both male and female mice. The total number of immune cells in the lungs increased with dose, accompanied by an increase in the proportion of lymphocytes and alveolar macrophages aggregating around TWML. In addition, among the inflammatory mediators measured in this study, only CXCL-1 and GM-CSF levels showed significant increases in the lungs of male and female mice, respectively. Aggregation of alveolar macrophages, infiltration of inflammatory cells, and hyperplasia of mucous cells in the bronchial epithelium were found in TWML-treated mice. When incubated at a concentration of 40 $\mu\text{g}/\text{mL}$, MH-S cells (alveolar macrophages) were aggregated around the fibrous particles, as was observed in the lungs. The production of cell signaling-related secondary mediators was significantly enhanced in TWML-treated cells. NGS analysis also indicated that the plasma membrane, cell periphery, and cell projections were among the most affected cellular components and that phosphatidylserine binding was the most affected molecular function. Expression of mitochondrial dynamics- and cellular iron uptake-related proteins was inhibited following exposure to TWML, and expression of anti-oxidant response-related proteins was clearly enhanced in the cells. **Conclusions:** Taken together, we suggest that TWML-induced immune suppression may be due to the incomplete phagocytosis of macrophages and that TWML may disrupt cellular function through oxidative stress.

B. Johnson, L. Harden, K. Osborne, and C. Roper. University of Mississippi, Oxford, MS.

Background and Purpose: Prescribed burns manage wildfires by weakening fuel loads which lowers intensity and fire duration. The burning of trees is a significant contributor to air pollution, releasing fine particulate matter (PM_{2.5}) composed of harmful chemicals including black carbon and other hazardous air pollutants. Prescribed burns are common in the southeastern United States mainly for wildfire prevention and ecosystem management purposes with Georgia burning 1.4 million acres annually. This study aims to investigate PM_{2.5} and black carbon concentrations in Georgia during 2015, specifically comparing concentrations during the prescribed burn (October 1- April 30) and burn-ban (May 1-September 30) seasons. **Methods:** PM_{2.5} was collected on Teflon filters by the Environmental Protection Division of the Georgia Department of Natural Resources (GDNR) throughout 2015 at 8 locations in Georgia every 3 days. PM_{2.5} concentrations were determined through gravimetric analysis by the GDNR. All collected filters were then analyzed for black carbon at 880nm. Average PM_{2.5} and black carbon levels were compared between sites locations were compared between seasons (burn vs. burn ban). **Results:** Site Differences: Preliminary data for four of the sampling sites (Albany, Macon, Atlanta, and South Dekalb) showed average PM_{2.5} concentrations across locations were 11.37 ± 3.87 µg/m³. Average black carbon concentrations across locations were 2.18 ± 2.21 µg/m³. PM_{2.5} concentrations were significantly different between Atlanta and the Albany and South Dekalb sites. Black carbon concentrations were also significantly different between Atlanta and all other locations (one-way ANOVA, p ≤ 0.05). Seasonal Differences: Macon and South Dekalb showed variations between burn-ban and burn seasons in PM_{2.5} concentration, with increases in PM_{2.5} concentration in burn-ban months (two-way ANOVA, p ≤ 0.05). However, Albany, Macon, Atlanta, and South Dekalb all showed seasonal differences for black carbon concentrations which were elevated during the burn season (two-way ANOVA, p < .001). Data collection and analysis for four additional sampling locations is currently underway and will be compared to the preliminary data described above. **Conclusions:** Though seasonal differences in PM_{2.5} were not present in all sites, there was significant seasonal variation in black carbon at all sites with elevated black carbon during the burn season. This demonstrates that exploring individual components of PM_{2.5}, such as black carbon, may provide more insight into the pollutants released during prescribed burns than measuring PM_{2.5} alone. Future directions include using prescribed burn records to compare PM_{2.5} and black carbon data at specific sites during prescribed burn events and expanding ambient characterization to more sites throughout the state.

PS 3957 Carbon Black particles induce emphysema and inflammasome activation: a whole-mouse lung proteome landscape

N. C. Sanchez, G. Mani, K. G. Dsouza, K. H. Patel, D. Shimoga Chandrashekar, J. A. Mobley, and R. Surolia. University of Alabama at Birmingham, Birmingham, AL.

Background and Purpose: Chronic exposure to ultrafine particles (UFP) is one of the leading causes of morbidity and mortality worldwide. The accumulation of UFP is cleared by the engulfment of these particles by alveolar macrophages (AMs). AMs are the first line of defense against pathogens, as well as also have an anti-inflammatory function for the resolution of inflammation. The effect of nCB exposures on the anti-inflammatory functions of macrophages is not explored in detail. We are exploring the effects of nCB on the anti-inflammatory function of AMs, efferocytosis, for the homeostasis, and resolution of inflammation. In our preliminary studies, we have developed a mouse model of chronic nCB exposures and its effect on the lung morphology and injury. We have performed the proteomics analysis to identify the dysfunctions and mechanisms caused by nCB exposures. **Methods:** C57BL/6 mice (n=5) were exposed to 2 doses of nCB (by oropharyngeal aspiration) each other day during one week. Nanosized Carbon Black (nCB) (15 to 75 nm) was utilized to perform these exposures. After treatment, all mice were euthanized, and lungs were harvested for histopathology and whole-proteomic analysis using mass spectrometry LC/MS. All animal protocols were approved by Institutional Animal Care and Use Committee at the University of Alabama at Birmingham (UAB). **Results:** *In vivo* study showed 1) increased inflammation by increased presence of lymphocytes in the lung, 2) alveolar macrophages full of engulfed nCBs, 3) increased alveolar space (emphysema) in the nCB lungs, and increased cell death. Our preliminary proteomic data identified 1894 total proteins across samples. We identified 178 significantly differential expressed proteins in the lung proteome exposed to nCB particles. The histology and proteomic analysis both demonstrated emphysema and increased cell death-related pathways. The functional enrichment analysis showed that nCB top differentially expressed proteins are involved in inflammasome activation, reduction of vesicle trafficking, endosome formation, and calcium signaling process. This proteomics analysis showed nCB differential expressed proteins are associated with emphysema development, such as cell death, dysregulation of ubiquitination and ROBO signaling pathways. **Conclusions:** UFP lung exposures induced a differential protein expression pattern, showing there's saturation of macrophages' capacity to clear nanoparticles and tissue damage. Inflammasome activation and suppression of endosomal and lysosomal-related proteins suggested an exhaustive of lung

macrophages' function after nCB exposure. After these studies, we will perform in-depth studies to determine the role of nCB exposures in the development of COPD and emphysema.

PS 3958 The Protective Role of Nlr1 in Air Pollution-Exacerbated Acute Lung Injury

Y. Li¹, C. Monge¹, W. T. Goldsmith¹, A. Ranpara¹, T. Nurkiewicz¹, R. Tighe², J. Harkema³, and S. Hussain¹. ¹West Virginia University, Morgantown, WV; ²Duke University, Durham, NC; and ³Michigan State University, East Lansing, MI.

Background and Purpose: Exposure to air pollution is associated with the development and severity of acute lung injury (ALI) and acute respiratory distress syndrome (ARDS). Epidemiological and experimental studies demonstrate that air pollutants increase respiratory vulnerability, resulting in a more pronounced inflammatory response and tissue damage. However, the molecular mechanisms underlying this effect remain unclear. Evidence suggests that exposure to air pollution can "prime" the immune system, leading to exaggerated inflammation and lung injury following subsequent insults. NOD-like receptor X1 (Nlr1) is a mitochondria-associated protein that regulates inflammation, mitochondrial homeostasis, cell death, autophagy, and reactive oxygen species (ROS) production. Nlr1 has been shown to protect against inflammatory diseases. We hypothesize that subacute exposure to environmentally relevant levels of ozone (O₃) and ultrafine carbon black (CB) aggravates ALI, while Nlr1 mitigates these effects by maintaining mitochondrial function and reduce excessive inflammation. **Methods:** Eight- to ten-week-old male C57BL/6J wild-type (Nlr1^{+/+}) and Nlr1 knockout (Nlr1^{-/-}) mice were exposed to a mixture of 250 ppb ozone (O₃) and 1 mg/m³ carbon black (CB) for 3 hours per day, 5 days per week, over a 3-week period using whole-body inhalation. After 3 weeks of exposure, ALI was induced by intratracheal instillation of 1.5 units of bleomycin (BLM), and the mice were euthanized 14 days post-BLM exposure. Survival, lung function, inflammatory response, and lung remodeling were assessed. **Results:** Exposure to air pollution primed for a greater mortality in bleomycin-induced ALI, with this detrimental effect being more pronounced in Nlr1^{-/-} mice. Mucous cell metaplasia and type 2 alveolar epithelial cell hyperplasia were induced by bleomycin exposure and were not altered by prior air pollution exposure in both genotypes. In Nlr1^{-/-} mice, combined air pollution exposure and bleomycin challenge resulted in heightened inflammatory responses, more severe impairment of lung function, and enhanced collagen accumulation in lung tissue. **Conclusions:** In summary, our results indicate that Nlr1 plays a critical protective role in protecting the lungs from air pollution exposure-induced priming for acute lung injury.

PS 3959 Repeated Exposure to Great Salt Lake Dust Induces Asthma-Like Phenotypes in Mice

E. Romero, C. Deering-Rice, L. Sun, S. Serna, and C. Reilly. University of Utah, Salt Lake City, UT.

Background and Purpose: Air pollution impacts human health. Understanding the mechanisms driving adverse effects can improve the management of health and facilitate the development of treatments for those affected. High wind events in the Salt Lake City urban area expose residents to particulate matter (PM) originating from the shrinking Great Salt Lake. We refer to this as GSL dust or GSLD. GSLD is a mixture of heavy metals, metal oxides, microorganisms, and various natural and man-made chemicals that have accumulated over time. Few studies have investigated the impact of GSLD on human health outcomes. We previously found that acute high-dose inhalation exposure, mimicking a dust storm, caused robust neutrophilic pulmonary inflammation in mice. Inflammatory responses were replicated in human lung cell models, driven in part by interactions with the PM sensing ion channels transient receptor potential vanilloid-1 and vanilloid-3 (TRPV1 and TRPV3). This study tested the hypothesis that repeated exposures to GSLD at a low concentration, mimicking potential daily exposures, would promote chronic inflammation and phenotypes consistent with allergic asthma. **Methods:** Here, humanized *Trpv1*^{N606D} mice were exposed to GSLD (PM_{2.5} ~5mg/m³) for 2h per day, for 15 or 25 days, using the SCIREQ inExpose inhalation delivery system. Lungs and bronchoalveolar lavage fluid (BALF) were collected 72h after the last day of exposure. Lung immune cell populations were quantified in BALF using flow cytometry and manual cell counting. Lungs were collected for histology and analysis of gene/protein expression. **Results:** Exposure for 15 and 25 days increased eosinophils, B-cells, and dendritic cells in BALF, and triggered goblet cell hyperplasia in female >male mice. Effects were exacerbated in a challenge model (3 weeks exposure, 3 weeks no exposure, 1 week exposure). **Conclusions:** To conclude, phenotypes characteristic of allergic asthma developed in female >male mice following 15 or 25 day exposure to GSLD and upon rechallenge, versus transient neutrophilia observed in prior acute high dose studies. Future studies will investigate the sex-based differences and assess pulmonary function to confirm airway hypersensitivity. Further, understanding the role of TRPV1 and TRPV3 could yield a novel therapeutic strategy for managing health effects associated with GSLD and possibly other forms of PM.

D. M. McGee, D. K. Seybold, O. P. Jegede, and A. Adhikari. Georgia Southern University, Statesboro, GA. Sponsor: D. McGee, Society of Environmental Toxicology and Chemistry

Background and Purpose: Specific activities performed in a veterinary clinic may result in the release of dust and fine particulate matter. These contaminants contribute to higher rates of asthma and other respiratory diseases among veterinary clinic workers compared to other occupational workers. Since Ammonia is a by-product of animal waste, exposure to ammonia is higher in veterinary workers and can irritate the lungs and airways. Aerosolized particulates of small sizes, such as PM_{1.0}, PM_{2.5}, and PM₁₀, can penetrate deeper into workers' airways, thereby irritating and exacerbating the pathogenesis of asthma and respiratory inflammations. The goal of the study was to assess particulate matter with aerodynamic diameters ranging from 1.0 to 10 µm and ammonia gas levels in different sections of a large veterinary clinic, in relation to workers' varying activities. **Methods:** The veterinary clinic is situated in a rural, tropical environment and is a high-traffic area, with an average of 35 pets seen daily. The mass concentrations and particle number concentrations were measured over a two-month period using the DustTrak aerosol monitor and the CEM DT-9881 particle counter during various activities and sections of the veterinary clinic. Samples were collected biweekly, on Mondays and Fridays, during working hours, in both the morning and the afternoon. A sensor measured the ammonia gas. All air samples were collected at breathing height, and environmental factors, including temperature, relative humidity, dew point, and wind velocity, were also measured. **Results:** The preliminary data across all sections showed that, combined, particulate matter concentrations of PM_{1.0}, PM_{2.5}, and PM₁₀ were significantly higher in the morning than in the afternoon. Correlating with the increased activity performed in each section, such as grooming, washing, blow drying, and handling of pets. The mean concentrations of the morning sessions for the particulate matter numbers counted for PM_{1.0}, PM_{2.5}, and PM₁₀ were 7038.81 ± 12,089.85 /m³ (mean ± SD), 1060.17 ± 1915.30 /m³ (mean ± SD), and 78.50 ± 124.1 /m³ (mean ± SD), respectively. The afternoon levels significantly dropped to 1141.3 ± 1086.42 /m³ (mean ± SD), 260.39 ± 317.72 /m³ (mean ± SD), and 78.31 ± 251.06 /m³ (mean ± SD), respectively. The total mass concentration and individual levels of PM_{1.0}, PM_{2.5}, and PM₁₀ showed a different trend of data from the particulate counter from the morning concentrations were lower which were 0.326 ± 0.166 mg/m³ (mean ± SD), 0.274 ± 0.136 mg/m³ (mean ± SD), 0.285 ± 0.135 mg/m³ (mean ± SD), respectively. The total mass concentration and individual levels of PM_{1.0}, PM_{2.5}, and PM₁₀ increased in the afternoon, coinciding with a reduction in activity, and the levels were 2.954 ± 37.012 mg/m³ (mean ± SD), 0.805 ± 7.875 mg/m³ (mean ± SD), 67.079 ± 981.82 mg/m³ (mean ± SD), and 0.625 ± 4.897 mg/m³ (mean ± SD). Ammonia levels varied between the morning and the afternoon. The levels of the morning were 0.321 ± 0.333 ppb (mean ± SD) and 0.457 ± 0.221 ppb (mean ± SD). Although particulate number concentrations (PM_{1.0}, PM_{2.5}, PM₁₀) were substantially higher in the morning, consistent with intensive grooming and handling activities that generate large quantities of fine, respirable aerosols, the total mass concentrations demonstrated an opposite trend. Mass values increased in the afternoon despite lower particle counts, suggesting fewer but significantly larger particles resuspended from accumulated dander, fur, and dust as animal traffic decreased and surfaces dried. The data indicate that workers are exposed to high fine-particle loads during active operations and elevated coarse-particle mass during periods of lower activity. **Conclusions:** Preliminary data showed that PM concentrations were significantly higher in the morning during increased activity and in certain areas where those involved in longer animal-handling activities (grooming and washing) were exposed to higher levels of particulate matter. To mitigate such exposures, workers should consider using respiratory protection in those sections. All this information will be valuable for identifying specific tasks that increase workers' exposure to fine particles and ammonia in veterinary clinics.

PS 3961 Wildland-urban interface fires: toxic physicochemical properties of emitted particulate matter and impacts on lung macrophages

L. Bazina¹, G. M. Deloid¹, L. Calderon¹, G. A. Kelesidis¹, J. Laurent¹, I. Tsiotra², N. Mihalopoulos², L. Fritzky¹, N. Vaze¹, and P. Demokritou¹. ¹Rutgers University, New Brunswick, NJ; and ²NOA, Athens, Greece.

Background and Purpose: Due to growth of urban areas in close proximity to wildlands, wildfires increasingly burn both biomass and man-made materials. The physicochemical properties and hazards of particulate matter (PM) from such 'wildland-urban interface (WUI)' fires may differ substantially from those of pure wildland fire PM. However, the properties and hazards of WUI fire PM have not been studied. **Methods:** We employed our wildfire simulator (WiFS) to reproduce biomass and WUI fires by combusting pinewood and a 1:1 mixture of pinewood and polyethylene, respectively. The generated PM were size fractionated to obtain PM_{0.1} fractions, designated PM_B (biomass) and PM_W (WUI), which were comprehensively characterized and their impacts on the health and function of THP-1 macrophages evaluated. THP macrophages were exposed for 24 h to PM_B or PM_W at doses equivalent to 0.5, 5, and 50 day inhalation exposures at 375 µg/m³. **Results:** PM_W contained more than twice the concentration of toxic high molecular weight polyaromatic hydrocarbons (PAHs) as PM_B, as well as significant amounts of highly bioactive oxygenated PAHs,

which were absent in PM_B. Although both PM_B and PM_W caused significant cytotoxicity, PM_W produced greater reductions in viability and mitochondrial membrane potential than PM_B. Moreover, whereas PM_W decreased phagocytosis of 1 µm beads by ~50%, PM_B had no effect. In addition, PMW exposure caused dysregulation of 803 genes, whereas PM_B caused dysregulation of only 3 genes. **Conclusions:** These findings underscore the heightened toxicological risk associated with wildfire-urban interface particulate matter, revealing that exposure to PM_W can impair macrophage viability, mitochondrial function, and innate immune responses more severely than pure biomass wildfire particulate matter. Because macrophages represent the first line of defense against inhaled pathogens and particles, the observed impairment of THP-1 macrophage phagocytosis following exposure to PM_W (but not PM_B) suggest that WUI PM exposure could increase susceptibility to or severity of respiratory infections. Together these results raise important concerns about human health impacts from inhalation of PM generated during wildfires, particularly in regions affected by mixed biomass and plastic combustion, and highlight the need for further research into the mechanisms of toxicity and long-term health consequences of such complex environmental exposures.

PS 3962 Prenatal exposure to ultrafine particulate matter dysregulates offspring lung function and blunts IL-13 responses in asthma-like model

D. C. Mills, J. Jimenez-Chavez, A. De Vizcaya Ruiz, and M. Kleinman. University of California, Irvine, Irvine, CA.

Background and Purpose: Fine particulate matter (PM_{2.5}) and ultrafine particles (UFPs ≤100 nm) are major public health concerns due to their ability to reach deep into the lung airways, systemic distribution, and association with cardiopulmonary diseases. While numerous studies link PM exposure to asthma exacerbation and respiratory morbidity, the developmental impact of prenatal UFP exposure on later allergic airway responses remains poorly understood. Fetal development represents a critical window of susceptibility, during which inhaled toxicants can alter immune and respiratory programming. Using the LDLR^{-/-} mouse model, which exhibits airway hyperreactivity and Th2-biased responses, this study investigated whether prenatal UFP exposure alters postnatal pulmonary function and cytokine regulation in response to an asthma-like challenge. Specifically, IL-13 expression was evaluated as a key Th2 mediator of airway constriction and remodeling. **Methods:** Pregnant LDLR^{-/-} mice were exposed for 19 days to either filtered air or UFPs (3.74e⁴ particles/cm³) throughout gestation using a versatile aerosol concentration enrichment system. Offspring (F1) were evaluated at postnatal day 28 (PND 28) using whole-body plethysmography (vivoFlow®, Scireq, Canada) to assess baseline respiratory parameters and methacholine (0-50 mg/mL) induced airway responsiveness. Afterward, offspring were re-exposed to either air or UFP for two months. A subset from each prenatal exposure group was sensitized to ovalbumin (OVA) to induce an asthma-like phenotype. Pulmonary function was reassessed following methacholine challenge, and lung tissue was collected for IL-13 quantification using an ELISA immunoassay and lung histology analysis. **Results:** Prenatal exposure to UFPs resulted in significant alterations in offspring respiratory function following methacholine challenge compared with air-exposed controls. UFP-exposed offspring exhibited higher enhanced pause (Penh; 2.47 vs. 1.3, *p* = 0.0046) and longer inspiratory time (75.7 vs. 63.6 msec, *p* = 0.003), accompanied by a reduced breathing frequency (321 vs. 365 breaths/min, *p* = 0.018). Similar trends were observed after re-exposure and ovalbumin (OVA) sensitization, where both UFP-only and UFP + OVA groups showed greater functional impairment than the Air + OVA controls. Lung IL-13 levels were significantly decreased in UFP-exposed and UFP + OVA offspring, suggesting suppressed Th2-related cytokine expression associated with prenatal and postnatal UFP exposure. **Conclusions:** These findings indicate that prenatal exposure to ultrafine particulate matter disrupts normal respiratory regulation, leading to altered breathing patterns and reduced pulmonary function following airway challenge. The observed decrease in lung IL-13 protein levels in UFP-exposed and UFP + OVA offspring suggests that prenatal exposure may suppress Th2-related cytokine activity, potentially dampening immune mechanisms that support epithelial repair and airway tissue integrity.

PS 3963 Particulate matter containing environmentally persistent free radicals (EPFRs) induced oxidative stress responses in lung organoids exposed at the air-liquid interface

S. Thota, and A. Noel. Louisiana State University, East Baton Rouge, LA.

Background and Purpose: The thermal remediation of hazardous wastes can lead to the release of particulate matter (PM). During these treatment processes, aromatic hydrocarbons chemisorb onto metal oxide surfaces, leading to the formation of surface-stabilized environmentally persistent free radicals (EPFRs). These PM containing EPFRs are capable of continuous redox cycling, generating reactive oxygen species (ROS) that drive oxidative stress, inflammation, and subsequent epithelial injury in the lung following inhalation exposure. Recently, new approach methodologies (NAMs) are being recognized as key complementary approaches to provide advanced platforms for *in vitro* inhalation toxicology. These NAMs include 3D lung organoids and air-liquid-interface (ALI) exposures. Since airway epithelial

cells and macrophages act as the first defensive barrier to inhaled toxicants, initiating upon injury oxidative and inflammatory signaling, ideally *in vitro* studies replicating inhalation exposures would include these two cell types in a same model. Therefore, this study was designed to test whether EPFR exposures, conducted under submerged or pseudo-ALI conditions, would activate in a similar manner the Nrf2-Keap1-p38 MAPK antioxidant and inflammatory pathway in a lung organoid model. **Methods:** A lung organoid model was established in Matrigel extracellular matrix, which supports spheroid formation and promotes relevant epithelial-macrophage interactions. Lung alveolar type 2 epithelial (AT2) cells (A549 cells) and phorbol 12-myristate 13-acetate (PMA)-differentiated THP-1-derived macrophages, were embedded together. Organoids were exposed to EPFRs under submerged (50 µg/cm²) or pseudo-ALI conditions (ALI Cloud system, Vitrocell) (EPFR nebulized suspension 35 mg/mL) for 24 hours. Gene expression (*NRF2*, *KEAP1*, *NQO1*, *HMOX1*, *AHR*, *p38-MAPK*, *CD14*, *CD68*) was quantified by qPCR. Extracellular oxidative stress and cytotoxicity markers [ROS, nitric oxide (NO), lactate dehydrogenase (LDH)] were measured in culture media. Organoid organization and spatial distribution of AT2 cells and macrophages were confirmed using CellTracker fluorescence confocal imaging. **Results:** Deposited dose of EPFRs at the ALI (42 µg/cm²) was similar to that of the submerged condition (50 µg/cm²). Macrophage activation markers were elevated, including CD14 and CD68, which expression increased by ~1.5-fold (*p*<0.05) in both conditions, indicating differentiation of monocytes to macrophages in the lung organoid. Confocal fluorescence imaging confirmed the successful co-localization of AT2 cells and macrophages within lung organoids, indicating that both cell types were maintained together in the culture system. EPFR exposure activated oxidative and inflammatory signaling in the AT2-macrophage lung organoids. Gene expression analysis showed upregulation of *NRF2*, *KEAP1*, *HMOX1*, *NQO1*, *AHR*, and *p38-MAPK* in both submerged and pseudo-ALI conditions (*p*<0.05), indicating activation of the oxidative stress and xenobiotic response pathways. Notably, under pseudo-ALI exposure, *HMOX1* increased by ~1.8-fold (*p*<0.05) and *KEAP1* increased by ~1.7-fold (*p*<0.05), reflecting stronger engagement of the Nrf2-Keap1 antioxidant axis compared to submerged exposures. These results suggest that EPFR deposition at the surface of the organoids triggers enhanced oxidative damage. Consistent with these transcriptional patterns, extracellular injury markers were significantly elevated under both submerged and ALI conditions (NO, ROS, and LDH; *p*<0.05). **Conclusions:** EPFR exposures activated oxidative and inflammatory signaling in lung organoids under both submerged and pseudo-ALI conditions, primarily through the Nrf2-Keap1-p38 MAPK pathway. This novel human-relevant *in vitro* lung organoid model, with exposures at the ALI, provides a mechanistic platform to study EPFR-induced oxidative injury and inflammation, offering a biologically relevant complementary tool to *in vivo* inhalation models.

PS 3964 Activation of AhR and NF-κB Pathways Links Wildfire Smoke Exposure to Lymphoma Development

C. Vogel¹, K. Bein¹, D. Vang¹, J. Connolly¹, T. Haarmann-Stemann², P. Ruivo¹, and J. Tuscano¹. ¹UC Davis, Davis, CA; and ²IUF - Leibniz Research Institute for Environmental Medicine, Duesseldorf, Germany.

Background and Purpose: Exposure to wildfire smoke (WFS) has been linked to cancer development in animal models and associated with elevated risks of non-Hodgkin's lymphoma (NHL) and multiple myeloma risk in epidemiological studies. We previously demonstrated that both vehicular emissions and WFS activate the aryl hydrocarbon receptor (AhR). Our recent work further shows that particulate matter (PM) and ash collected from active California wildfires contain polycyclic aromatic hydrocarbons (PAHs), dioxin-like compounds, pathogens, and metals that activate both AhR and NF-κB signaling pathways. **Methods:** Building on earlier findings that activation of AhR by dioxin promotes lymphomagenesis in mice, we investigated whether WFS exposure might similarly drive B-cell malignancies. **Results:** Mice exposed to WFS PM exhibited enlarged cervical and axillary lymph nodes, as detected by PET/CT imaging. In contrast, control animals showed no evidence of tumor development at the same time point. At necropsy, cervical, axillary, popliteal, and inguinal lymph nodes from exposed and control mice were removed. Cervical and inguinal lymph nodes were enlarged in exposed mice (~4X size of control mice), due to marked expansion of the cortex. Supported by immunohistochemistry analysis, we found that enlarged lymph nodes from WFS exposed mice stained strongly with Pax5 supporting hyper expansion and B-cell proliferation. To further characterize these changes, we performed *in situ* single-cell RNA sequencing (scRNA-seq) on post-exposure lymph nodes. Gene set enrichment analysis (GSEA) identified transcriptional patterns consistent with early B-cell transformation which was consistent with the GSEA done on *in vitro* WFS PM-transformed primary B cells. *In situ* spatial expression analysis revealed hyper expansion of CD19+ B cells and a significant increase in proliferation. **Conclusions:** Together, these findings suggest that WFS exposure induces B-cell proliferation and transformation, potentially initiating lymphomagenesis mediated through activation of AhR and NF-κB pathways.

PS 3965 Effects of Acute Copper Ultrafine Particle Inhalation in APP/PS1 Mice

J. Enos¹, D. Chalupa¹, K. Eggleston¹, A. Gonzalez¹, R. Hussain², and A. Elder¹. ¹University of Rochester, Rochester, NY; and ²University of Maryland, Baltimore, MD.

Background and Purpose: Ambient particulate matter (PM) air pollution is a ubiquitous environmental health concern associated with respiratory, cardiovascular, and neurological disorders, including Alzheimer's disease (AD). Epidemiological studies suggest that exposure to redox-active transition metals, such as copper (Cu), may exacerbate neurodegenerative processes through inflammatory or oxidative mechanisms. Cu-containing ultrafine particles (Cu-UFPs, <100 nm) model the reactive metal fraction of ambient ultrafine PM and deposit in the alveolar region of the lung, where high surface reactivity may promote local and systemic effects. The purpose of this study was to evaluate acute pulmonary inflammation and biodistribution of Cu following short-term Cu-UFP inhalation in an AD-relevant mouse model. This work addressed the hypothesis that inhaled Cu-UFPs translocate from the lungs to distal organs, eliciting inflammatory and oxidative responses that may contribute to AD-related pathology. **Methods:** Male and female APP/PS1 transgenic and wild-type (WT) mice were exposed via whole-body inhalation to filtered air or Cu-UFP aerosols (mass concentration: 196 ± 11 µg/m³ (standard error, SE) number concentration: 8.05x10⁶ ± 1.35x10⁵ particles/cm³; count median diameter: 38.8 ± 1.6 nm; geometric standard deviation: 1.7 ± 0.03) for four hours per day over three consecutive days. Bronchoalveolar lavage (BAL) fluid and tissues were collected 24 hours after the final exposure. BAL samples were analyzed for total and differential cell counts, viability, total protein content, and lactate dehydrogenase (LDH) activity to assess pulmonary inflammation and cytotoxicity. Cu tissue burdens in BAL fluid, BAL cell pellets, and major organs (lung, liver, kidney, spleen, and brain) were quantified via inductively-coupled plasma mass spectrometry. **Results:** Cu-UFP exposure induced mild but statistically significant pulmonary inflammation, indicated by elevations in BAL neutrophils (8.1 ± 2.6% vs. 0.14 ± 0.05% in air-exposed mice) and protein content (0.21 ± 0.01 mg/mL vs. 0.18 ± 0.01 mg/mL in air-exposed mice) relative to air controls, with no significant changes in LDH activity or total BAL cell counts. Cu concentrations were significantly elevated in BAL fluid (48.9 ± 2.7 ng/g vs. 31.1 ± 4.1 ng/g in air-exposed mice) and cell pellets (25.4 ± 3.5 ng/g vs. 13.4 ± 2.2 ng/g in air-exposed mice) of Cu-exposed mice, confirming particle deposition and partial dissolution in the lung. Cu concentrations in extrapulmonary organs did not differ significantly between exposure groups, suggesting limited systemic translocation within 24 hours post-exposure. Independent of exposure, APP/PS1 mice exhibited significantly lower Cu concentrations in the frontal cortex (4.98 ± 0.58 mg/g vs. 7.41 ± 0.33 mg/g in WT mice). **Conclusions:** Acute Cu-UFP inhalation produced modest pulmonary inflammation without substantial Cu accumulation in distal tissues. These findings may suggest that the high solubility of Cu-UFPs promotes effective pulmonary clearance and limits acute systemic distribution. Transient lung inflammation may still represent an initiating event in the propagation of inflammatory and oxidative signaling to the brain during repeated exposures. These findings identify the lung as an important interface for metal-containing UFP toxicity and support a mechanistic link between reactive metal PM exposure and neurodegenerative disease risk through pulmonary inflammatory pathways.

PS 3966 Diesel exhaust particulates disrupt cardiometabolic and endocrine signaling associated with altered vascular AhR/TLR-4/Notch pathways and inflammation in female C57BL/6 mice.

V. L. Youngblood¹, P. Gilbreth¹, A. Sovero¹, T. Armstrong¹, J. L. Bradshaw², R. L. Cunningham², and A. K. Lund¹. ¹University of North Texas, Denton, TX; and ²University of North Texas - Health, Ft. Worth, TX.

Background and Purpose: Air pollution exposure has been linked to increased risk of cardiometabolic disease, obesity, and vascular dysfunction. Epidemiological and animal studies indicate that females are more susceptible to particulate matter (PM)-induced outcomes, yet the mechanisms driving these effects remain poorly defined. We hypothesized that diesel exhaust particulate (DEP) exposure induces systemic endotoxemia and endothelial activation through inflammatory and xenobiotic-sensing pathways, leading to hormonal disruption and vascular dysfunction that are further amplified by a high-fat diet (HF). Following exposures, we analyzed vascular endpoints, including the toll-like receptor (TLR)-4, aryl hydrocarbon receptor (AhR), angiotensin II type 1 receptor (AT1), as well as inflammatory signaling via tumor necrosis factor (TNF)-α, and transforming growth factor (TGF)-β. **Methods:** Female C57BL/6 mice (4-6 weeks old) were fed either a low-fat (LF) or HF diet and exposed via oropharyngeal aspiration to 35 µg DEP suspended in saline or saline alone (CON) twice weekly for 30 days. Circulating lipopolysaccharide (LPS) was quantified by chromogenic ELISA. Aortic gene expression of TLR-4, AhR, AT1R, TNF-α, and TGF-β was assessed by RT-qPCR. Endothelial activation and Notch signaling were evaluated by immunofluorescent co-localization of von Willebrand factor (VWF) and HES1. Circulating metabolic and sex hormones were quantified by multiplex immunoassay. **Results:** DEP exposure, particularly when combined with a HF diet, disrupted systemic and vascular homeostasis. Circulating LPS was markedly elevated by HF diet (*p* < 0.0001), indicating diet-driven endotoxemia modulated by DEP exposure. Aortic TLR-4 and AhR expression increased with DEP, consistent with inflammatory and xenobiotic-sensing activation. AT1R expression was significantly influenced by diet (*p* = 0.04), and TGF-β increased with DEP exposure (*p* = 0.008),

supporting vascular remodeling. VWF/HES1 co-localization was enhanced in HF + DEP groups, suggesting Notch-mediated endothelial activation. Metabolic multiplex analysis revealed broad endocrine disruption. Glucagon (diet $p = 0.0002$; exposure $p = 0.0008$), GIP ($p = 0.04$), GLP-1 (diet $p = 0.0002$; exposure $p = 0.0055$), leptin (exposure $p = 0.0061$), pancreatic polypeptide (PP) ($p = 0.0078$), and PYY ($p = 0.0024$) were significantly altered, reflecting impaired metabolic hormone regulation. Sex hormone analyses showed elevated progesterone ($p = 0.0018$) and disrupted estradiol signaling (diet $p = 0.0256$; interaction $p = 0.0053$). T3 increased with both diet ($p = 0.0043$) and exposure ($p = 0.0132$), while T4, insulin, and cortisol were unchanged. **Conclusions:** These findings demonstrate that DEP exposure may promote vascular inflammation via AhR/TLR-4/Notch activation, accompanied by systemic endotoxemia and endocrine dysregulation in female mice. High-fat diet exacerbates these effects, with coordinated alterations in glucagon, GLP-1, leptin, and estradiol signaling, suggesting a convergence of environmental and dietary stressors on vascular and metabolic pathways. Together, these results highlight sex-specific vulnerabilities to air pollution and provide mechanistic evidence linking particulate exposure to cardiometabolic disease risk. *Funded by NIEHS R00ES016586 and R15ES026795 (A.K. Lund).*

PS 3967 Late Adolescent Exposure to Concentrated Ambient Fine Particulate Matter Air Pollution (PM_{2.5}) Increases Seminiferous Tubule Degeneration in Adult Mice, While Having no Effects on Testicular/Epididymal Sperm Counts

T. Kang, F. A. Luna, C. N. Lim, J. Lim, and U. Luderer. University of Irvine, Irvine, CA.

Background and Purpose: Our recent work revealed that exposure of late adolescent female mice to concentrated ambient PM_{2.5} for significantly decreased primordial ovarian follicle numbers by about 30% and 36% in wildtype and late-onset Alzheimer's Disease (LOAD) mice, respectively. In male mice, our study showed that adolescent exposure to PM_{2.5} did not significantly decrease testicular spermatid or epididymal sperm counts in early or late adulthood. However, the effects of PM_{2.5} exposure on testicular seminiferous tubule degeneration are still unknown. Herein, we test a hypothesis that PM_{2.5} exposure during adolescence is a sensitive window for testicular germ cell damage in adulthood. **Methods:** Adolescent wildtype and LOAD male mice at 8 weeks of age were exposed to concentrated ambient PM_{2.5} for 5h/day, 4 days/wk for 12 weeks. Testes were harvested at 5 months (24 hours after last exposure, Experiment 1) or at 14 months (9 months after last exposure, Experiment 2) of age and fixed in Bouin's solution overnight, washed in 50% ethanol and stored in 70% ethanol until being embedded in glycolmethacrylate (GMA) resin. Testis blocks were sectioned at 20 μ m and stained with Periodic Acid-Schiff (PAS) for histopathological evaluation. The tubules/testis with abnormalities (multinucleated giant cells, Sertoli cell cytoplasmic vacuolation, and exfoliation of germ cells into tubular lumen) were graded. **Results:** The percentages of tubules with abnormalities were calculated for data analysis. Damage in seminiferous tubules were not significantly increased by 12-week exposure to PM_{2.5} at 5 months of age in either wildtype or LOAD mice (N=6/group). At 14 months of age, vacuolation was significantly increased by exposure to PM_{2.5} in LOAD mice. Multinucleated giant germ cells and exfoliation were not significantly affected by exposure to PM_{2.5} in either wildtype or LOAD mice. **Conclusions:** Our preliminary results show that exposure to concentrated ambient PM_{2.5} during adolescence increases damage in seminiferous tubules in late adulthood, while not significantly decreasing testicular or epididymal sperm counts.

PS 3968 Virtual Impactors as Tools for Increasing Concentration of Particulate Matter in Air Sampling to Improve Chemical Characterization for Assessing Exposure to Air Pollutants

A. Stephens, C. Hogan, B. Olson, and I. Stepanov. University of Minnesota, Minneapolis, MN.

Background and Purpose: Air pollution is a major cause of chronic disease globally, responsible for more than 10 million disability-adjusted life years annually. Physico-chemical properties of air pollution, such as chemical composition, particle size, and concentrations of dust and other particulate matter (PM), can vary substantially depending on the sources of pollution and environmental conditions. Understanding the size-dependent composition of the PM in polluted air is vital for understanding its toxicological impact on respiratory health; however, in many environments, the particles of interest are too dilute for size-fractionation and chemical analysis. Our overarching goal is to develop and optimize tools to facilitate such research. **Methods:** Recently, our group has developed a high-flow-rate virtual impactor (VI) concentrator system can be used to concentrate air particles in a wider size ranges than the previously designed VIs (less than one order of magnitude in diameter). Our system concentrates particles from an intake flow of $>1000 \text{ L min}^{-1}$ to a highly concentrated sample flow of $<10 \text{ L min}^{-1}$, and it enables concentration increases for particles ranging in size from 300 nanometers to 10 micrometers. In this study, we tested and validated this system using aerodynamic particle samplers (APS) to calculate concentration factors. **Results:** The particle number density of air from a low particle concentration environment was measured using the APS with and without the VI concentrator. A concentration factor was calculated for each particle size in the APS sampling range, sub 500 nanometers to 19 micrometers. The VI system was able

to generate a highly concentrated sample in excess of 500 times the concentration without the VI system. The system also showed a dynamic range from below one micrometer up to ten micrometers in particle size. **Conclusions:** The highly concentrated sample flow that was generated using the VI concentrators demonstrated the ability to rapidly collected and measure particles even in low concentration environments. This provides an opportunity to use these tools in with other instruments like Anderson impactors to separate particles based on size. These VI systems will allow for more in-depth analysis of air pollutant particulate matter even in low concentration environments.

PS 3969 Early biomarkers of metabolic dysfunction-associated steatotic liver disease in juvenile mice exposed to diesel exhaust particles

A. G. Catala Catala¹, D. L. Diaz Agosto², C. M. Gonzalez Rivera², N. E. Chorna³, and L. B. Mendez². ¹Universidad Ana G. Mendez, Cupey, PR; ²Universidad Ana G. Mendez, Carolina, PR; and ³University of Puerto Rico, Medical Science Campus, San Juan, PR.

Background and Purpose: Metabolic dysfunction-associated steatotic liver disease (MASLD), previously known as non-alcoholic fatty liver disease, is the most common chronic liver disease among children and adolescents. If untreated, MASLD can progress to metabolic dysfunction-associated steatohepatitis (MASH), MASH with fibrosis and cirrhosis. Although childhood obesity is often associated with MASLD, there is a gap in knowledge about the genetic and environmental factors that contribute to the onset and progression of this liver disease. Air pollutants, such as particulate matter (PM), may play a role in the development of MASLD by inducing metabolic alterations, oxidative stress and inflammatory responses in the liver. Therefore, the objective of this study was to identify early molecular changes in the liver of juvenile mice exposed to diesel exhaust particles (DEP). **Methods:** Female and male C57BL/6J mice (n=8/group) were exposed intranasally with increasing concentrations of DEP during postnatal days 25 to 33. Mice were euthanized six days after the last exposure and major organs were dissected. The median lobe of the liver was used for metabolomics profiling and the right lobe for Attenuated Total Reflectance Fourier-Transform Infrared (ATR-FTIR) spectroscopy, lipid peroxidation (TBARS assay) and protein carbonyl (FTC assay) analyses. **Results:** A total of 53 metabolites were identified and the main groups classified as amino acids (n=19), short-chain acids (n=14), unsaturated fatty acids (n=5) and saturated fatty acids (n=4). At the lowest DEP concentration, a significant increase in 4-hydroxyproline was observed when compared to controls. In addition, the levels of glyoxylic acid, a reactive intermediate of 4-hydroxyproline catabolism, had a dose-dependent increase. In contrast, serine levels significantly decreased in a dose-dependent manner. Significant changes in the FTIR spectra were also observed, with 9 of 11 prominent peaks in the lipid, amide I, amide II and nucleic acid regions having a significant decrease in peak intensity in mice exposed to DEP when compared to controls. However, there were no changes in lipid peroxidation or protein carbonyl levels. **Conclusions:** Overall, the results suggest that exposure to DEP during postnatal development can alter early biomarkers of liver dysfunction. Epidemiological studies have reported that amino acid metabolism is altered in adolescents with MASLD. Serine deficiency has been associated with MASLD and 4-hydroxyproline has been associated with metabolic disorders and fibrinogenesis. Therefore, exposure to DEP during childhood might contribute to the onset of chronic liver disease.

PS 3970 Impact of short-term inhalation of Great Salt Lake Dust Particles (GSLD PM_{2.5}) on Dravet Syndrome pathophysiology

A. Sri Hari, N. Metcalf, J. Camacho, C. Rice, C. Reilly, and C. S. Metcalf. University of Utah, Salt Lake City, UT.

Background and Purpose: Harsh climatic perturbations and the resultant increase in air pollution levels are a global public health emergency. The water level in Great Salt Lake, Utah, USA, is at record low levels, which increases the risk of exposure to dried lakebed sediments. Great Salt Lake Dust (GSLD) particle (2.5-micron size, PM_{2.5}) contains a mixture of metals, lipopolysaccharides, natural/anthropogenic chemicals, and bacteria. A landmark study demonstrated the adverse effects of GSLD exposure, including oxidative stress and inflammation in the lungs. Neurological disorders associated with central breathing disruption, like epilepsy, multiple sclerosis, and Parkinson's, may present a unique risk associated with respiratory pollutants. Dravet Syndrome (DS) is a catastrophic, childhood epilepsy caused by mutations in the *Scn1a* gene that encodes a voltage-gated sodium channel subunit (NaV_{1.1}). Clinical features of DS include drug-resistant hyperthermia-induced and spontaneous seizures, cardiorespiratory issues, and a high mortality rate due to sudden unexpected death in epilepsy (SUDEP). Repeated seizure-spread to the brainstem that controls vital autonomic functions can lead to central apnea, respiratory distress, and cardiac dysfunction, and has been shown to be a leading cause of SUDEP. Hence, the DS population is at high risk to environmental toxicant exposure-mediated adverse effects owing to their predisposition to cardiorespiratory issues and high rate of mortality. No study thus far has evaluated the impact of exposure to GSLD PM_{2.5} on the DS population. Our goal was to evaluate the effects of short-term GSLD PM_{2.5} exposure on lung function and temperature threshold for hyperthermia-induced seizures in DS mice that contain a knock-in missense mutation in the *Scn1a* gene. **Methods:** Male and female heterozygous (HET, *Scn1a*^{A1783V/WT}) DS, and age-matched

wildtype (WT) mice were exposed to GSLD PM_{2.5} by inhalation (5mg/m³ dose) using the inExpose system (Scireq) for 2 hours every day for 4 consecutive days. The instrument was set to a feed rate of 15mm/hr, and the RPM of the brush at 1200. A group of HET and WT mice were exposed to room air. This inhalation paradigm was followed to model low and slow short-term human exposure to peak concentrations of GSLD PM_{2.5}. N=5/group. On the 4th day after exposure, lung function was assessed in mice by whole-body plethysmography. On day 5 (24h post-exposure), the threshold for hyperthermia-induced seizures was evaluated in HET mice exposed to air or GSLD PM_{2.5}. **Results:** *Scn1a*^{A1783V/WT} HET mice exposed to air had significantly ($p < 0.0001$) lower tidal volume (TV), minute ventilation (MV), and breathing frequency (f) rates compared to air-exposed WT mice. WT mice exposed to GSLD PM_{2.5} exhibited significantly ($p < 0.0001$) lower TV and MV compared to air-exposed WT mice. Interestingly, exposure to GSLD PM_{2.5} significantly decreased ($p < 0.05$) breathing frequency in HET mice compared to air-exposed HET mice. TV and MV were unaltered in HET mice exposed to GSLD PM_{2.5}. The temperature threshold for hyperthermia-induced seizures was not significantly different between HETs exposed to GSLD PM_{2.5} and HETs exposed to air. However, there was a strong trend towards a decrease in the temperature threshold and time to seize in GSLD PM_{2.5}-exposed HETs compared to air-exposed HETs. **Conclusions:** DS mice exhibit altered baseline lung function parameters compared to age-matched WT. Short-term, low-dose GSLD PM_{2.5} exposure adversely impacts breathing frequency and possibly the temperature threshold for hyperthermia-induced seizures in HETs. Ongoing studies are evaluating the effects of acute, high-dose GSLD PM_{2.5} exposure on DS mice.

PS 3971 *TET1* Protects Against Diesel Exhaust Particle (DEP) - Induced Airway Inflammation and Dysfunction

S. N. Henson, T. Zhu, E. Holmes, S. Palomares, L. Cai, S. Elston, and H. Ji. UC Davis, Davis, CA. Sponsor: H. Ji, Environmental Mutagenesis and Genomics Society

Background and Purpose: Air pollution, particularly diesel exhaust particles (DEP), has been shown to exacerbate asthma severity. DEP exposure promotes oxidative stress and airway inflammation and is strongly associated with Th17-mediated immune responses, which increase the risk of severe and persistent asthma. However, the molecular mechanisms of air pollution-induced asthma, and specifically the involvement of epigenome-modifying proteins such as *TET1* (Tet Methylcytosine Dioxygenase 1), remains largely unknown. **Methods:** In this study, we investigated the role of *TET1* in DEP-induced airway inflammation and dysfunction, as well as evaluated therapeutic interventions targeting *TET1*-related pathways. *TET1* was knocked down in human bronchial epithelial cells (HBECS) via siRNA, and the cells were subsequently treated with DEP (10 µg/cm²). RNA-seq was used to examine transcriptomic changes. Additionally, *Tet1*-deficient mice (*Tet1*^{-/-}; HET) and wildtype controls (*Tet1*^{+/+}; WT) were used in a murine DEP exposure model (intratracheal challenge of 150 µg DEP × 9 treatments over 3 weeks) to assess the effect of *Tet1* deficiency on airway hyperresponsiveness, lung pathology, immune cell counts and cytokine levels in bronchial alveolar lavage fluid (BALF), and lung tissue mRNA expression. We also sought to examine potential therapeutic interventions to mitigate the effects of *TET1* loss in both *in vitro* and *in vivo* DEP exposure models. Three potential interventions were selected to target different mechanistic pathways: Dimethyl-2-ketoglutarate (DMKG) - supports *TET1* enzymatic activity, CH223191 - an aryl hydrocarbon receptor (AhR) antagonist, and SS-31 (Elamipretide) - a synthetic mitochondria-protective peptide. **Results:** Transcriptomic analysis of HBECS revealed that both *TET1* knockdown and DEP exposure significantly altered gene expression, with the most pronounced changes in the combined *TET1* knockdown+DEP group (KDDEP vs DEP: 3,983 DEGs). Ingenuity Pathway Analysis identified multiple DEP-related pathways, including the Nrf2 oxidative stress response and cytokine signaling (IL-17, IL-8). The aryl hydrocarbon receptor (AhR) pathway was particularly disrupted during DEP exposure in *TET1*-deficient cells: pro-inflammatory mediators (*IL-1a*, *IL-1b*, *GSTP1*) were upregulated, while AhR cofactor (*ARN1*) and downstream detoxification genes (*CYP1A1*, *CYP1B1*, *ALDHs*) were suppressed. These changes suggest that *TET1* loss enhances inflammation while impairing xenobiotic detoxification responses. In the murine DEP exposure model, *Tet1*-deficient mice exhibited exacerbated lung inflammation and airway hyperresponsiveness (AHR) compared to wildtype controls. Bronchoalveolar lavage fluid (BALF) analysis showed elevated neutrophils and total immune cells, with increased expression of neutrophil-recruiting chemokines (CXCL5, CXCL15) and Th17 cytokines (*IL17a*, *IL17f*) in the combined HET+DEP group. Airway hyperresponsiveness strongly correlated with *IL17a* expression, supporting a role for Th17 responses in the functional phenotype. In HBECS, the three potential therapeutic interventions (DMAKG, CH223191, SS-31) demonstrated varied results in reducing cytokine production, with some treatments leading to more pronounced reductions in certain cytokines than others. *IL-1b* was most consistently reduced by all three treatments. **Conclusions:** These findings indicate a protective role of *TET1* in DEP-induced airway inflammation and dysfunction, acting through AhR and cytokine signaling pathways. Furthermore, while individual interventions may offer partial benefits, a combination approach targeting multiple pathways may be required for effective mitigation of pollution-induced airway disease pathogenesis.

PS 3972 Distribution and Deposition of Wildfire Smoke Chemicals into Brain and Olfactory Bulb of Rats after Intranasal Installation

D. You, M. Malfatti, E. Ubick, S. McCloy, S. Gosting, L. Nguyen, S. Hok, H. Enright, and B. Buchholz. LLNL, Livermore, CA.

Background and Purpose: Epidemiological and experimental studies suggest wildfire smoke is a potential contributor to neurological dysfunction, accelerating onset of neurodegenerative diseases such as Alzheimer's Disease (AD), Parkinson's Disease (PD) and dementia. In a mouse model, wildfire smoke exposure induced neuroinflammation, characterized by proinflammatory phenotypes of microglia and peripheral immune cells in the brain. The protein pathologies used to diagnose AD and PD are positively associated with neuroinflammation. Using doses comparable to those encountered during intense wildfire events (200-300 µg/m³), we explore the absorption, distribution, metabolism, and elimination (ADME) and pharmacokinetics of representative members of major chemical classes (acid, phenol, PAH, aldehyde) in inhaled wood smoke condensates to determine components that reach the brain and examine the propensity of the compounds to cross the blood-brain-barrier. **Methods:** Male Sprague Dawley rats (n=7-10) were intranasally instilled with 50 µg/kg of ¹⁴C-palmitic acid (PA), ¹⁴C-benzo[a]pyrene (B[a]P), ¹⁴C-catechol (CAT) or 43 ng/kg ¹⁴C-benzaldehyde (BZ) reconstituted in 1mg/mL of smoldering eucalyptus woodsmoke extract (WSE). Controls received equal volume of saline. Serum was collected from 5 min to 2 weeks after dose and tissues were collected at 0.5, 2, 4, 24 h and 2 weeks after dose. Urine was collected from the 24 h exposure. Brain, olfactory bulb, esophagus, lung, liver, kidney, heart, spleen, and stomach were collected, rinsed in PBS and analyzed by accelerator mass spectrometry (AMS) for excess ¹⁴C. Aliquots of urine were counted using liquid scintillation and analyzed by reversed-phase HPLC to determine the presence of metabolites or breakdown products. **Results:** PA and B[a]P entered circulation slowly, reached maximum concentration (C_{max}) near 15 ng/mL at 2 h, and had circulating concentrations near 1/3 C_{max} 24 h after exposure. CAT and BZ rapidly entered circulation and were mostly cleared at 2 h. Excess ¹⁴C from all four chemicals was detected in olfactory bulb and brain over the first 24 h but only PA (or its metabolites) was retained in olfactory bulb, brain and kidney at 2 weeks post dose. All excess ¹⁴C was cleared from the lung at 2 weeks. Metabolite analysis of plasma (CAT) and urine (CAT, BZ and B(a)P) dosed samples did not detect any parent compound. **Conclusions:** Catechol and benzaldehyde were rapidly cleared from the biological tissues. The slower uptake and clearance of PA or B(a)P or their reactive metabolites when dosed with WSE in brain and olfactory bulb potentially provide greater opportunity for inflammatory response. This study suggests that wildfire smoke chemicals can enter the brain through two primary pathways; directly from the nasal cavity to the olfactory bulb, and via systemic circulation. This work performed under the auspices of the U.S. Department of Energy by Lawrence Livermore National Laboratory under Contract DE-AC52-07NA27344. LLNL-ABS-2013898.

PS 3973 Biochemical and Histopathological Evaluation of long-term exposure of copper oxide nanoparticles in Wister Rats

A. Patil¹, S. Kumari², and P. Tchounow¹. ¹Jackson State University, Jackson, MS; and ²Nizam College, Hyderabad, India.

Background and Purpose: Copper oxides nanoparticles (CuO NPs) are widely used for a variety of industrial and life science applications. This widespread use, however, has increased the risk of short-term and long-term toxicity to human health and the environment. **Methods:** The current study investigates the hepatotoxic effects of copper oxide nanoparticles in male Wister rats. Three groups of six male rats were orally administered CuO-NPs, once a day for 28 days with doses of 50, 100 and 200 mg/Kg, body weight. The control group was also made up of six rats. Blood and liver samples were collected 24 hours after the last treatment following standard protocols. Biomarkers of hepatotoxicity, such as Alanine aminotransferases (ALT), aspartate aminotransferases (AST), alkaline phosphatases (ALP), lactate dehydrogenase (LDH) in the serum sample, and oxidative stress assessment of reduced glutathione (GSH), along with histopathological evaluation of liver injury, were evaluated. **Results:** The investigated results revealed a statistically significant ($P < 0.05$) elevated levels of ALT, AST, ALP and LDH in the serum and a significant decline in GSH in the liver tissue of treated rats in a dose-dependent manner relative to the control group. Ultra structural assessment of liver showed significant morphological changes in accordance with biochemical parameters. **Conclusions:** The results of this study demonstrate that CuO-NP is hepatotoxic, and its toxicity may be mediated through oxidative stress. This was a preliminary study, and more mechanistic elucidation is needed before to use CuO-NPs widely in biomedical applications.

K. Day, D. Panchal, H. Alkhadrawi, K. Dese, and M. Bennewitz. West Virginia University, Morgantown, WV.

Background and Purpose: Gadolinium-based contrast agents (GBCAs) are widely used in clinical MRI but provide weak MRI signal and pose risks such as nephrogenic systemic fibrosis and tissue accumulation. Manganese oxide (MnO) and iron oxide (Fe_3O_4) nanoparticles have emerged as promising alternatives due to their stronger magnetic properties and biodegradability. However, the impact of contrast agent design on off-target interactions with the innate immune system, particularly neutrophils and macrophages, remains underexplored. Macrophages play a central role in nanoparticle clearance and immune modulation, while neutrophils can release neutrophil extracellular traps (NETs)—web-like DNA structures that contribute to inflammation and thrombosis—when stimulated by certain nanomaterials. The goal of our study is to investigate how the metal content and surface coating of metal oxide nanoparticles modulates off-target interactions with macrophages and neutrophils. **Methods:** MnO and Fe_3O_4 nanocrystals were synthesized using thermal decomposition of Mn(II) acetylacetonate and Fe(III) acetylacetonate in dibenzyl ether and oleylamine. Metal oxide nanocrystals were encapsulated with fluorescent Cy5-dye, biodegradable poly(lactic-co-glycolic acid) (PLGA) and increasing amounts of PLGA-polyethylene glycol (PEG) including 0%, 2.5%, and 5%. To determine base polymer interactions with the cells, blank nanoparticles, with no metal oxide, were also synthesized. A murine macrophage cell line, RAW 264.7, and neutrophils isolated from the bone marrow of healthy female BALB/c mice femurs via magnetic bead separation were utilized for this study. T_1 -weighted and T_2 -weighted MRI at 1 Tesla was used to assess signal intensity in macrophages and neutrophils exposed to contrast agents for 1h including Gadavist as a clinical comparator against blank nanoparticles, Nano-Encapsulated Manganese Oxide (NEMO) particles, and Nano-Encapsulated Iron Oxide (NEIO) particles. Flow cytometry quantified nanoparticle uptake, intracellular ROS generation (via CellROX), and immune activation (CD80 for macrophages, CD11b for neutrophils) after 1h incubation. **Results:** MRI analysis revealed that Gadavist produced strong T_1 signal in both macrophages ($\% \Delta R_1 = 71\%$) and neutrophils ($\% \Delta R_1 = 160\%$). In contrast, NEMO particles generated lower signal intensities in both cell types ($\% \Delta R_1 = 40\%$), which decreased with increasing PEGylation. Blank nanoparticles had negligible immune cell MRI signal. T_2 -MRI studies are ongoing. Flow cytometry confirmed that PEGylation reduced nanoparticle uptake in both cell types, with 5% PEG formulations exhibiting the lowest internalization (<8% cell uptake). ROS generation and immune activation did not decrease uniformly with PEGylation. Neutrophils exhibited higher ROS levels than macrophages across most formulations. Overall, immune activation from contrast agent exposure was low (<16%). Macrophages showed higher activation (CD80 expression) than neutrophils (CD11b) for NEMO particles, which agreed with their greater nanoparticle uptake. **Conclusions:** While PEGylation consistently reduced MRI signal and cellular uptake, its effects on ROS generation and activation were variable and cell-type dependent. Macrophages had more activation and nanoparticle uptake compared to neutrophils, but neutrophils generated much higher intracellular ROS levels from contrast agent exposure. These results highlight the importance of evaluating multiple immune parameters when designing MRI contrast agents. PEGylated MnO nanoparticles, particularly at 5% PEG, remain promising candidates for safer imaging.

PS 3975 A House Dust Mite Allergen Corona on Multi-Walled Carbon Nanotubes Amplifies Pro-Inflammatory Responses of Murine Alveolar Macrophages *in vitro*

R. D. Bartone¹, L. Tisch¹, D. Jima¹, S. Kalpattu², C. Payne², and J. Bonner¹. ¹NC State University, Raleigh, NC; and ²Duke University, Durham, NC.

Background and Purpose: Inhaled particulate air pollution is a major factor that exacerbates allergic asthma in humans. Advancements in nanotechnology world-wide have increasingly raised concerns over the toxicity of inhaled engineered nanomaterials and their potential to exacerbate the pathogenesis of allergic lung disease after occupational or environmental exposure. We previously reported that house dust mite (HDM) allergens adsorb to multi-walled carbon nanotubes (MWCNTs) to form an allergen corona that intensified lung inflammation in mice *in vivo*. In the current study, we utilized an *in vitro* cell culture model with murine alveolar macrophages to investigate possible mechanisms involved in the exacerbation of allergic lung disease by MWCNTs with HDM allergen coronas. **Methods:** Allergen coronas were prepared in a cell-free system by co-incubating MWCNTs (NC7000, Nanocyl Inc.) with HDM extract (Greer Laboratories, Inc.), followed by sequential rinsing and centrifugation of the MWCNTs to remove free HDM proteins. The resulting allergen corona was characterized by gel electrophoresis, western blotting and proteomics. For the *in vitro* study, mixtures of MWCNTs and HDM extract or MWCNTs with HDM corona were used to treat the MH-S mouse alveolar macrophage cell line (ATCC). After 4 and 24 hours, RNA extracted from MH-S cells were used for detection of cytokine mRNAs by RT-PCR and RNA-sequencing. **Results:** Approximately 7% of proteins in the HDM extract adsorbed to MWCNTs, including Der p 2 and Der p 1, which are associated with asthma in humans. Isolated mRNA from treated MH-S alveolar macrophages demonstrated significant changes in pro-inflammatory and pro-fibrotic mediator gene expression, including *Cxcl2* and *Il-1 β* , when comparing the

co-exposure treatment group and/or allergen corona treatment group to the control treatments. Also, RNA-seq results demonstrated key inflammatory pathways (i.e. STAT3 and STAT1) being activated upon co-exposure and allergen corona treatments. RNA-sequencing was completed using Qiagen IPA. **Conclusions:** The exacerbation of pro-inflammatory cytokine secretion in alveolar macrophages exposed to MWCNTs and HDM extract is enhanced via the allergen corona. The formation of nanoparticle biocoronas can be hazardous to individuals exposed via inhalation, and the intrinsic property of these nanoparticles provides new insight to the mechanisms through which inhaled nanoparticles exacerbate allergic asthma in humans.

PS 3976 Characterization of remaining titanium dioxide in Peyer's patches of rats after 90-day subchronic oral exposure

J. Akagi¹, Y. Mizuta¹, K. Matsushita¹, T. Toyoda¹, and K. Ogawa^{1,2}. ¹National Institute of Health Sciences, Kawasaki, Japan; and ²Department of Toxicology, Hoshi University, Tokyo, Japan.

Background and Purpose: Titanium dioxide (TiO_2) is widely used as a whitening and opacifying agent in pharmaceuticals, foods, and personal-care products. In 2021, the European Food Safety Authority (EFSA) concluded that TiO_2 containing more than 50% of nanoparticles (NPs; <100 nm in at least one dimension) can no longer be considered safe as a food additive, leading to a ban on its use in food in the EU from 2022. In a 90-day subchronic oral toxicity study of TiO_2 with a 6 nm crystallite size, we observed no adverse effects in male and female F344 rats (Akagi et al., *Part. Fibre. Toxicol.* 2023, 20; 23). Histopathological examination revealed deposition of TiO_2 agglomerates in Peyer's patches (PPs) of the small intestine, indicating incorporation of orally exposed TiO_2 into gut-associated lymphoid tissue. A subsequent study using TiO_2 particles with crystallite sizes of 6, 30, and 180 nm showed that deposition of TiO_2 agglomerates in PPs occurred regardless of crystallite size. Based on these findings, we investigated the post-treatment fate of TiO_2 agglomerates deposited in PPs at 8 weeks after the cessation of administration. **Methods:** Nano-grade (6 and 30 nm crystallite) and pigment-grade (180 nm crystallite) anatase TiO_2 were used as test materials. Dosing suspensions were prepared at 100 mg/mL using 0.2% disodium hydrogen phosphate as a dispersant. The test substances were orally administered to 6-week-old male F344/DuCrIj rats at a dose of 1,000 mg/kg bw/day for 90 days (10 animals per group). The control group received an equal amount of dispersant. At the end of dosing, five rats per group were necropsied, and the remaining five after an 8-week recovery period. TiO_2 particles in PPs were examined in hematoxylin-eosin-stained sections, and immunohistochemical analyses for immune-related factors, including CD68, TNF- α , and IFN- γ , as well as DNA damage marker γ -H2AX, were performed. **Results:** Administration of TiO_2 with median secondary particle sizes of 178.4, 362.1, and 252.3 nm and nanoparticle proportions of 27.2, 11.5, and 13.2% for the 6, 30, and 180 nm crystallites, respectively, did not cause treatment-related changes in mortality, clinical signs, body weights, or food consumption. Under microscopic observation, TiO_2 agglomerates were observed in PPs in all TiO_2 -treated groups, with occasional phagocytosis by macrophages but without associated inflammation or tissue injury. Notably, TiO_2 agglomerates remained detectable in all TiO_2 -administered groups after the 8-week recovery period. CD68⁺ cells contained TiO_2 particles, indicating macrophage phagocytosis of TiO_2 . In the recovery groups, focal accumulations of macrophages suggesting repeated phagocytosis were observed. No changes were observed in TNF- α , IFN- γ , or γ -H2AX staining, indicating the absence of excessive immune activation or inflammation-induced DNA damage. **Conclusions:** TiO_2 incorporated into PPs was still detectable after an 8-week recovery period. Although particle-laden macrophages were observed, no immune activation, inflammation, or DNA damage was detected. These findings suggest that TiO_2 remaining in PPs after 8 weeks of the cessation of administration was biologically inert.

PS 3977 Electrostatic vs. Covalent Doxorubicin Conjugation: Optimizing Chitosan Nanoparticles for Receptor-Mediated Cancer Cell Targeting.

A. Chand, M. Frerichs, L. Janson, M. Oyshi, M. Galib, R. Mayanovic, and K. Kim. Missouri State University, Springfield, MO.

Background and Purpose: Nanotechnology represents a dynamic area in biomedicine with transformative potential, especially in cancer biology, for diagnostics and targeted therapeutics. Among the various nanocarriers, chitosan-based nanoparticles (CSNPs) stand out for their biocompatibility and biodegradability. However, their application has been limited by low solubility, premature drug leakage, and poor stability. As such, this study aims to improve the therapeutic potential of CSNPs by conjugating doxorubicin (DOX) either electrostatically or covalently, focusing on comparing treatments based on folate receptor targeting in HeLa and HepG2 cancer cell lines. **Methods:** We synthesized and characterized DOX-CSNPs using X-ray diffraction (XRD) and dynamic light scattering (DLS). Next, we conducted cytotoxic studies on HeLa and HepG2 cells using electrostatically loaded DOX-CSNPs. We are currently working on enhancing drug specificity by adding folic acid into the structure and covalently attaching DOX and folic acid to CSNPs. Then, we plan to further study drug release kinetics via the dialysis bag method, followed by comparative cytotoxic and mechanistic studies between the two cell lines. **Results:** Our

DLS characterization data showed that DOX-CSNPs had an average size of 18-23 nm. The Zeta potential values showed that the DOX-CSNPs that were also loaded with polyvinyl acid (PVA) were positively charged (+15 mV). The XRD measurements confirmed the semi-crystalline nature of the CSNPs having a low to moderate degree of crystallinity. Furthermore, preliminary cytotoxic studies revealed that DOX-CSNPs exhibited higher anticancer activity than free DOX, with similar effects in both cell lines. **Conclusions:** Our study aims to overcome limitations of CSNPs through covalent conjugation and folate modification to improve receptor specific targeting and pH-responsive drug release. These preliminary findings highlight the potential of CSNPs as a tunable platform for cancer therapeutics.

PS 3978 Folic acid tagged and carbon quantum dot loaded liposome for targeted drug delivery of doxorubicin to HeLa cervical cancer cells

E. Braun, and K. Kim. Missouri State University, Springfield, MO.

Background and Purpose: Current cancer treatments are nonspecific, evoking side effects for many patients. While many routes for targeting cancer cells exist, using cancer specific biomarkers like the folate receptor (FAR) in HeLa cervical cancer cells is a promising route. Creating a folate tagged drug delivery system will enhance cervical cancer targeting, increasing chemotherapeutic payoff and minimizing harrowing side effects. Encapsulating fluorescent, non-toxic, carbon quantum dots and doxorubicin in a liposome structure tagged with folic acid, allows for targeted drug delivery of an otherwise poorly soluble chemotherapeutic and real time imaging. **Methods:** Carbon quantum dots (CQDs) were synthesized using an autoclave. The subsequent CQDs were then characterized using DLS, zetapotential, UV-Vis, FTIR, Fluorescence, XPS, and TEM. The CQDs were tested for toxicity using the HeLa cervical cancer cell model and a XTT viability assay. Biocompatible liposomes were creating using hydrogenated soybean phosphatidylcholine (HSPC), cholesterol (CHOL), DSPE-PEG (2000)-Malate, and DSPE-PEG (2000)-Folate. One liposome included all lipids, and the other was constructed without the DSPE-PEG (2000)-Folate. Using active loading methods, the carbon quantum dots were encapsulated by the liposomes. Subsequent active loading will be carried out to incorporate doxorubicin and further viability assays will confirm cell specific targeting. **Results:** The synthesized carbon quantum dots exhibit high fluorescent yield in the red-light range, have an overall charge of -15.4 mV, and have an average size of 4 nm. The bare CQDs show no cytotoxicity towards HeLa cells. HSPC-CHOL-DSPE-PEG (2000)-Malate liposomes have an average diameter of 143 nm. **Conclusions:** Carbon quantum dots are a nontoxic, highly fluorescent nanoparticle with potential to be used as a bioimaging probe to track drug delivery. Liposomes comprised of HSPC-CHOL-DSPE-PEG(2000)-Malate were successfully formed. Further studies will focus on finalizing the drug delivery system and testing its efficacy in HeLa cells.

PS 3979 Pulmonary mTORC1 Disruption Mediates Metabolic Syndrome Associated Susceptibility to Nanoparticle Exposure by Regulating Lipid Signaling, Autophagy and Insulin Sensitivity

A. A. Shinde, A. Pitchai, J. Swihart, K. Robison, C. Ferreira, and J. Shannahan. Purdue University, West Lafayette, IN.

Background and Purpose: Individuals with metabolic syndrome (MetS) exhibit exacerbated inflammatory responses following inhalation of particulates. MetS and other metabolic diseases cause disruption in mTORC1 signaling. mTORC1 activation mediates lipogenesis, inhibits autophagy, and causes insulin resistance. The presence of MetS may exacerbate nanoparticle (NP) exposure induced inflammatory responses and toxicity, via mTORC1 dysregulation. The potential role of increased susceptibility in individuals with MetS via mTORC1 dysregulation has not yet been elucidated. Macrophages are key components of immune system and acts as primary deposition site for inhaled NP. Macrophage-specific knockout of Raptor (mTORC1 component) will allow us to assess the contribution of mTORC1 signaling to the pulmonary response induced by inhaled NPs. Previously MetS mice with dysregulated lipid signaling has demonstrated exacerbated pro-inflammatory response marked by an influx of neutrophils and alterations in inflammatory mediators corresponding with increased production of inflammatory cytokines/chemokines on NP exposure. Additionally, cell culture studies have demonstrated upregulation of mTORC1 mediated pathways following NP exposure. Hence, we hypothesize that NP exposure may exacerbate MetS associated dysregulation of mTORC1, enhancing its susceptibility via inflammation, reduced autophagy, and insulin resistance. **Methods:** To investigate the impact of NP exposure on mTORC1 mediated lipid signaling and its susceptibility to inflammation, we utilized C57BL6/J mice with myeloid-derived cells (macrophages) lacking the mTORC1 specific component, Raptor, to examine mTORC1 dependent disruption of lipogenesis, autophagy, and insulin signaling. This model is produced by breeding Raptor^{fl} mice with LysM^{Cre} mice. An exploratory pilot study was performed to generate preliminary insights regarding mTORC1 mediated toxicity following exposures. In the primary study mice at 6 weeks of age were fed either a control diet or a high-fat western diet for 14-weeks. This generates 4 distinct groups healthy wildtype, MetS wildtype, healthy with macrophages lacking Raptor and MetS with macrophages lacking Raptor. Mice were exposed to silver nanoparticles (AgNP) via oropharyngeal aspiration or water (control). Altered mTORC1

signaling mediating endpoints of autophagy, inflammation and insulin resistance were evaluated 24 hours after exposure to capture potential variations. Genotyping assessment was performed to confirm the knockout (KO) model in myeloid-derived cells in animals of 4-5 weeks old prior to full metabolic and molecular assessments. **Results:** Genotyping assessment demonstrated removal of Raptor gene expression in macrophages of KO mice compared to wildtype (WT) mice, validating the model. Raptor expression was further reduced in isolated macrophages relative to whole lung tissue, confirming cell-specific KO. Gene expression of inflammatory markers chemokine ligand-1 (CXCL1), macrophage inflammatory protein-2 (CXCL2), interleukin-6 (IL-6), interleukin-1 beta (IL-1β), monocyte chemoattractant protein-1 (CCL2) were upregulated in WT and KO mice exposed to AgNP compared to respective control mice, demonstrating the role of mTORC1 in the AgNP inflammatory response. Pulmonary lipids are currently being evaluated utilizing an MRM profiling approach demonstrating the effect of mTORC1 mediated lipid dysregulation and induction of pro-inflammatory lipid mediators (arachidonic acid, PGE2, 12-HETE, LTB4 etc) following AgNP exposure. Samples from the MetS mice are currently being examined to determine the contribution of mTORC1 to MetS susceptibility to pulmonary exposures. **Conclusions:** Overall, our pilot study supported the role for mTORC1 in modulating the inflammatory profile in response to NP exposure. MetS is expected to result in inhibited autophagy, increased inflammation, and elevated insulin resistance following exposure to AgNP. However, mice with macrophages lacking Raptor, and thus mTORC1 activity, are anticipated to show less modifications in these endpoints, underscoring mTORC1's contribution to NP toxicity. Together, this work will provide mechanistic insights into mTORC1 dependent pathways and their contribution to MetS related susceptibility to particulate exposures.

PS 3980 A review of the association of pulmonary health effects and inhalation exposure to carbon nanotubes

P. Chrysostomou¹, and J. Lin². ¹Exponent, Washington, DC; and ²Exponent, Bellevue, WA.

Background and Purpose: CNTs are used in several products, including but not limited to gas and energy storage, electronics, sensors, optics, and as additives in various nanocomposite material, for their high electrical conductivity, optical transmission, and extremely high tensile strength properties. CNTs are cylindrical hollow tubes made of carbon with a diameter in the nanometer range (1-100 nm). Studies have demonstrated structure-activity relationship in the fiber pathogenicity pathway whereby the physical characteristics of the CNT structure facilitates deep lung access, biopersistence, pleural access and retention, and risk of chronic injury. The diameter of CNTs is the primary determining feature of lung deposition. The length of CNTs determines the degree of fiber clearance by macrophages from the site of deposition in the lung. Shorter fibers are phagocytosed and cleared more readily by macrophages, while longer fibers are prone to be biopersistent and resist clearance. Functionalization of CNTs enhances solubility, reactivity, and compatibility with various matrices, and the purity, size, length, diameter, surface chemistry, morphology, and dispersion methodology are all factors that can determine and alter the levels of toxicity potential following exposure to f-CNTs. A comprehensive literature search was conducted: (1) to evaluate the potential for development of pulmonary fibrosis with exposure to carbon nanotubes (CNTs) by inhalation; and (2) to identify health outcomes associated with exposure to functionalized-CNTs (f-CNTs) via inhalation exposure. **Methods:** The literature search was conducted in PubMed and ProQuest and resulted in over 4,000 results. Following duplicate removal, the results were screened using inclusion criteria established a priori, and assessed for study quality, in accordance with the Office of Health Assessment Translation Risk of Bias Rating Tool, prior to data extraction. Grey literature was also evaluated for authoritative assessments of CNTs. **Results:** Following literature screening and study quality assessment, 61 studies underwent full-text review and data extraction. Safe Work Australia, European Chemicals Agency, International Agency for Research on Cancer, U.S. Environmental Protection Agency, and the U.S. National Institute of Occupational Safety and Health evaluated the association of human health hazards and exposure to CNTs and concluded that there is a potential association with exposure to multi-walled CNTs (MWCNTs) and the development of fibrosis. No authoritative safety conclusions have been made on association of fibrosis with exposure to single-walled CNTs or carbon fibers, or on the association of health effects with exposure to f-CNTs. **Conclusions:** There was sufficient evidence in the public literature of an association of *in vivo* SWCNT and MWCNT exposure by inhalation or intratracheal administration with lung fibrosis, or precursors to the development of lung fibrosis, including collagen deposition, myofibroblast formation, and interstitial thickening. There was suggestive evidence that CNTs with smaller diameter and longer length are associated with severity of pulmonary toxicity, including fibrogenic effects, compared to shorter and thicker CNTs, which are cleared by macrophages. There was suggestive evidence that covalent functionalization reduces cytotoxicity by improving water solubility, promoting renal clearance and excretion through urine, and enhancing biocompatibility. In contrast, there is suggestive evidence that acid-f-CNTs may be more toxic than covalent f-CNTs.

J. P. Mogus, R. Nohoesu, E. Meadows, M. Eminhizer, and J. Hollander. West Virginia University, Morgantown, WV.

Background and Purpose: Pregnancy induces fundamental changes in maternal physiology and morphology to meet the energetic demands of both mother and offspring. By mid-gestation, for example, the human heart enlarges and alters ventricular contractility to accommodate increased blood volume and shifting vascular resistance. Prior studies show that maternal inhalation of nano-sized titanium dioxide (TiO₂)—a common industrial compound—disrupts cardiac mitochondrial function and REDOX balance in developing fetuses, with lasting effects into adulthood. However, little is known about how such exposures affect maternal cardiac adaptation during pregnancy. Here, we evaluated cardiac and mitochondrial function in pregnant mice and assessed whether gestational inhalation of nano-TiO₂ modifies typical pregnancy-induced changes. **Methods:** Beginning on gestation day 5, dams were exposed to either nano-TiO₂ (12 mg/m³) or sham control air for 6 hours/day across 6 non-consecutive days (gestation days 5-13). Age-matched non-pregnant controls were included for both exposure conditions. Echocardiogram of the maternal was conducted under light isoflurane anesthesia at GD14. On GD15 Maternal hearts were collected and snap frozen for mitochondrial analysis. **Results:** Echocardiographic analysis at gestation day 14 revealed significant pregnancy-induced changes in heart size, contractility, and performance metrics including ejection fraction, fractional shortening, and mitral valve flow. TiO₂ exposure disrupted these adaptations either by significantly modifying pregnancy effects (e.g., altered slopes between pregnant and non-pregnant groups) or by eliminating differences altogether (pregnant animals resembled non-pregnant controls). Similarly, at gestation day 15, mitochondrial complex I and IV activities were elevated during pregnancy, but this increase was mitigated following TiO₂ exposure. **Conclusions:** These findings suggest that the maternal heart and its mitochondria undergo coordinated remodeling during pregnancy to support the maternal-fetal unit, and that mid-gestation exposure to nano-TiO₂ can impair or negate these changes. Given the ubiquity of chemical exposures during pregnancy, such disruptions may compromise maternal capacity to meet the physiological and metabolic demands of gestation, potentially affecting health outcomes for both mother and offspring.

PS 3982 **Probabilistic estimation of daily total nitrosamine exposures generated from drinking water and dietary nitrate and nitrite sources.**

W. D. Klaren¹, A. East¹, M. Wheeler¹, M. Vincent², D. S. Wikoff¹, and T. Covington². ¹ToxStrategies LLC, Asheville, NC; and ²ToxStrategies LLC, Cincinnati, OH.

Background and Purpose: Research has suggested that exposure to nitrosamines can occur through endogenous generation via reaction between nitrate/nitrite and amines within the stomach, resulting in a comparatively larger exposure to total nitrosamines than to levels found in the diet and/or pharmaceuticals. Given the wide range of potential nitrate/nitrite exposure sources (e.g., drinking water, processed meats), information on the distributions of intakes, presence in food items, and constituent conversion rates are needed to understand the absolute and relative contributions of nitrosamine exposure estimates. The objective herein was to develop a probabilistic model to estimate population level exposures of daily total nitrosamines generated (DTNG) due to endogenous production from drinking water and dietary nitrate/nitrite sources. **Methods:** First, NHANES dietary survey data (2017-March 2020) based on dietary recall interviews was collected and reviewed for use within the model. Second, a targeted literature search was conducted to identify distributions of nitrate/nitrite, amine, and vitamin C content within various food groups, which were aligned to the food items reported in the NHANES dietary data. For each reported intake period in the survey data, the daily amount of nitrate/nitrite/amines/vitamin C was calculated as an input into the model. Additional literature searches were conducted to understand the range of nitrate-to-nitrite conversion rates within the saliva as well as the conversion of nitrite to nitrosamines (i.e., nitrosatability rate), the latter of which is dependent on the pH and the presence of potential inhibitors. Where possible, variables were incorporated into the model as distributions, or else accounted for via the pH change. Lastly, the model accounted for nitrosamine elimination upon exiting the stomach, where nitrosamine generation is inhibited by pH change in the small intestine. Based on available data, a range of N-nitrosodimethylamine (NDMA) half-life values was used as a surrogate for the total nitrosamine elimination distribution in the model. Ultimately, the model was run for each NHANES survey individual with random sampling from distributions for the variables indicated above. Since the survey included time of day for water and food ingestion, the model provides a minute-by-minute estimate of nitrosamine generation throughout the day for each survey participant and an estimate of the DTNG. **Results:** The probabilistic model estimated that the median DTNG for the simulated population was approximately 0.085 ug/day (IQR: 0.0159 - 0.397). The 95th percentile of estimated DTNG was 3.69 ug/day while the maximum DTNG was over 1,000 ug/day. The wide variability observed was driven by heavy tails of the distribution with much higher total daily nitrosamine generation. The drinking water and diet ingestion intervals (especially when intervals were <3-4hrs) impacted the amount of nitrosamines present at any given time due to elimination not occurring until after transiting the full stomach. A portion of the population did not ingest any

drinking water during the day (~15%) or ingested drinking water without also ingesting an amine source resulting in no nitrosamine generation. Although the model indicates a wide variability in behaviors and generated nitrosamines across the population, a range of approximately two orders of magnitude was observed for most of the population. **Conclusions:** This model uses population dietary survey data and published information on food chemical constituents and nitrate/nitrite conversion relationships to estimate the DTNG that may occur following intake of nitrate/nitrite from drinking water and the diet. Notably, the model shows that 95% percent of the population generally falls within a relatively narrow range of DTNG and, while slightly lower, is within the range reported with previous models. Importantly, this more sophisticated model offers more granularity and accounts for the variability in a large number of the model parameters compared with previous estimates or *in vitro* analyses. Furthermore, future analyses that define the relative contributions of drinking water vs. dietary nitrate sources to the generation of nitrosamines may be useful for informing regulatory standards of nitrate/nitrite.

PS 3983 **Development of a human PBMC TXG-MAPr as a mechanistic framework to interpret toxicodynamic variability across the human population**

N. Tahir¹, I. Bruns¹, L. van Schijndel², J. Rousel², D. R. Pereira², M. Moerland², S. Fu³, N. Quignot³, F. Y. Bois³, M. J. Moné¹, G. Callegaro¹, S. Le Dévédec¹, M. Niemeijer¹, and B. van de Water¹. ¹Division of Cell Systems and Drug Safety, LACDR, Leiden University, Leiden, Netherlands; ²Centre for Human Drug Research, Leiden, Netherlands; and ³CERTARA, Paris, France.

Background and Purpose: Accurately characterizing interindividual variability in toxicodynamic responses across key toxicity-related pathways is essential to improve chemical safety assessment and refine toxicodynamic uncertainty factors (UFs). However, our understanding of such variability remains limited, which emphasizes the need for human-relevant models that capture mechanistic diversity in chemical responses. Freshly isolated peripheral blood mononuclear cells (PBMCs) provide a physiologically relevant *in vitro* platform to investigate these mechanisms across the human population, as they integrate immune and stress signaling responses. The goal of this work was to establish and demonstrate the PBMC TXG-MAPr as a translational resource to explore mechanisms underlying human toxicodynamic variability and to support future refinement of toxicodynamic UFs. **Methods:** PBMCs from five healthy male donors (20-30 years) were exposed for 24 h to 45 mechanistically diverse compounds covering multiple key stress response pathways, such as ER stress, oxidative stress, DNA damage and inflammation. High-throughput whole transcriptome analysis (TempO-Seq) was performed, followed by differential gene expression analysis with DESeq2. Weighted gene co-expression network analysis (WGCNA) identified 397 gene networks (modules) of co-regulated genes representing shared biological responses. Modules were annotated using curated pathway databases to capture a wide range of responses, including cellular stress response pathways, immune signaling, and cell-cycle processes. An interactive TXG-MAPr interface enables visualization of module activation and comparison of donor- and compound-specific responses. **Results:** The human PBMC TXG-MAPr organized compound-induced transcriptomic responses into defined modules capturing coordinated gene expression changes across biological pathways. Concentration-dependent activation patterns were observed across donors, with modules corresponding to DNA damage, ER stress, and inflammation responding to compounds with expected mechanisms, such as mitomycin C, tunicamycin and PHA, respectively. Inter-donor variability was modest for key toxicity-related pathways with consistently low technical variability, demonstrating network robustness, reproducibility and the capability to characterize inter-donor response heterogeneity. Integration with benchmark concentration estimates showed transcriptional perturbations at biologically relevant concentrations, comparable to cytotoxicity measurements. The network also highlights less characterized pathways and novel modules responsive to specific chemical perturbations. As a case study, we applied the PBMC TXG-MAPr to transcriptomic data from six additional donors, further demonstrating its utility for assessing inter-donor variability in stress pathway responses. **Conclusions:** The PBMC TXG-MAPr provides a mechanism-focused framework for interpreting transcriptomic responses in the context of human toxicodynamic variability. By integrating co-expression structure, pathway annotation, and donor-specific expression profiles, the PBMC TXG-MAPr enables intuitive visualization of stress response mechanisms, supports cross-study comparisons, and aids interpretation of pathway activation across donors and compounds. This platform can support human-relevant chemical risk assessment and provide a bridge between *in vitro* data and risk characterization in human populations. Supported by the TD-TRAQ project funded by the European Food Safety Authority (OC/EFS/SCER/2021/03).

N. Tahir¹, I. B. Bruns¹, L. v. Schijndel², J. Rousel², M. v. Diemen², D. R. Pereira², M. Moerland², S. Fu³, N. Quignot³, F. Y. Bois³, M. J. Moné¹, G. Callegaro¹, S. L. Dévédec¹, M. Niemeijer¹, and B. v. Water¹. ¹Leiden Academic Centre for Drug Research, Leiden, Netherlands; ²Centre for Human Drug Research, Leiden, Netherlands; and ³Certara, Paris, France.

Background and Purpose: Accurately accounting for interindividual differences in toxicodynamic responses is essential to improve chemical safety testing and risk assessment. However, our current understanding of human variability in sensitivity to toxicity-related pathways remains limited. Characterizing this variability is therefore critical for deriving refined toxicodynamic uncertainty factors (UFs). To address this gap, freshly isolated, minimally manipulated peripheral blood mononuclear cells (PBMCs) from healthy volunteers were used and combined with high throughput imaging and transcriptomics to study population-level toxicodynamic variability. In this study, we specifically investigated whether sex influences cellular stress responses to support quantitative evaluation of toxicodynamic variability. **Methods:** PBMCs from 100 healthy young volunteers (50 White males, 50 White females; age 20-30 years) were exposed to ten compounds in a wide concentration range covering activation of key stress response pathways, including ER stress, DNA damage and inflammation. Functional readouts on cytotoxicity and mitotoxicity were assessed at 24 and 72 h using high content confocal imaging. For six donors, high throughput whole transcriptome analysis (TempO-Seq) was performed to evaluate pathway-specific transcriptional activation. Differential expression analysis (DESeq2), benchmark dose modeling (BMDEExpress), and pathway/module activity scoring (PBMC TXG-MAPr) were used to quantify donor- and compound-specific transcriptional responses. **Results:** Functional imaging of 100 donors revealed concentration-dependent effects on mitochondrial potential and cell death induction. While individual donors showed variability in both the onset concentration and magnitude of both cytotoxicity and mitotoxicity, the extent of variability was compound dependent activating specific key stress response pathways. Despite compound- and donor-specific differences, average responses of male and female donors were comparable, indicating similar overall sensitivity. These phenotypic effects were reflected at the transcriptional level in a subset of six donors, with increasing concentrations leading to progressive activation of stress response pathways, including consistent induction of DNA damage, ER stress and inflammatory signaling modules across donors. The magnitude and direction of pathway activation were largely comparable, indicating limited interindividual variability in pathway/network-level responses within this initial population subset. BMD accumulation analysis of transcriptomics data from six donors showed clear concentration-dependent increases in the number of genes with determined benchmark concentrations. Overall, these results indicate that stress response activation patterns showed some difference across these six donors, with males and females showing comparable responses, supporting use of this framework to study interindividual variability in larger populations. **Conclusions:** Integration of high-throughput transcriptomic profiling and functional phenotypic readouts with quantitative population-based modeling enhances mechanistic understanding of interindividual variability in stress response activation. These data enable derivation of data-driven toxicodynamic variability factors (TDVFs) for key events within defined adverse outcome pathways (AOPs), supporting quantitative, mechanism-informed risk assessment. High throughput transcriptomic analysis will be completed for the initial cohort of 100 young male and female donors, while the study is currently being extended to an additional 100 donors encompassing diverse age groups (20-30, 40-50, 60-70 years) and ethnic backgrounds (White, Asian, Black/African American) to characterize variability across a broader human population. Collectively, these efforts provide a framework for refining chemical risk assessment by integrating empirically derived human toxicodynamic variability beyond default uncertainty factors.

PS 3985 Risk Assessment of Flame Retardant and Plasticizer Exposures from Mattresses Considering Body Weight and Body Temperature Impact on Emission Rates

D. M. Scalise, and L. A. Haighton. Intertek Health Sciences Inc., Mississauga, ON, Canada.

Background and Purpose: Studies suggests that infants and children less than 3 years of age may be exposed to a diverse array of semi-volatile organic compounds, including flame retardants and plasticizers, among other chemicals from the covers and foam inserts of crib mattresses. These exposure levels may be higher than those measured during the product's production due to the added effects of the child's weight, movements, and body heat on the expulsion of these chemicals into the sleeping microenvironment. The purpose of our poster is to calculate potential exposures to 2 different chemical substances, one from each of the above categories, using concentrations from analytical studies, and determine if they exceed established regulatory exposure limits when considering the sleeping duration, inhalation rates, and body weights representative of a 6-month old and 3-year old child. **Methods:** Concentrations of chemicals off-gassing from mattresses were identified under conditions intended to simulate body weight and temperatures of a child. Two representative substances that have been reported to be present in mattresses

used for this assessment, butyl benzyl phthalate (BBP) which is a plasticizer and tris (2-chloroethyl) phosphate (TCEP) which is a flame retardant, were further evaluated. Using the concentration data, we conducted an exposure assessment to determine the exposures from sleeping on the mattress using information for inhalation, body weight, and sleeping duration from the exposure factors handbook. Exposures at the mean and 95th percentile were calculated using the maximum concentrations measured in the sleeping microenvironment (SME) air. The inhaled exposures were compared to no effect levels determined from toxicity studies of the most sensitive endpoint of toxicity. **Results:** For a 6-month-old and 3-year-old child, sleeping time, inhalation rates, and body weights were derived from the exposure factors handbook. For a 6-month-old child, mean and 95th percentile values, respectively, were approximately 13 hours and 18 hours for sleeping, 0.225 and 0.333 m³/hour for inhalation rates (IR), and 9.2 and 11.3 kg for body weight (BW). The mean and 95th percentile values, respectively, for the 3-year-old child were approximately 11 and 14 hours/day for sleeping time, 0.421 and 0.575 m³/hour for IR, and 18.6 and 26.2 kg for BW. The maximum concentrations of BBP and TCEP based on a simulated study to account for body weight and temperature were reported to be 76 ng/m³ and 44 ng/m³, respectively. Exposures were calculated based on the following equation: Exposure = (concentration ng/m³ x IR m³/hour x hours/d of sleep)/bw = ng/kg/d. For BBP, the mean and 95th percentile exposures were calculated to be 24.2 and 40.3 ng/kg bw/d for the 6-month-old and 19.5 and 23.3 ng/kg bw/d for the 3-year-old. For TCEP exposures calculated at the mean and 95th percentile were 14.0 and 23.3 ng/kg bw/d for the 6-month-old and 11.3 and 13.5 ng/kg bw/d for the 3-year-old. For BBP, the most sensitive endpoint was determined to be effects on development with a derived maximum allowable dose level of 1,200 micrograms/d corresponding to 20.69 microgram/kg bw/d (20,690 ng/kg bw/d). For TCEP, effects observed at the lowest dose levels were kidney and liver organ weight changes and associated hepatotoxic and nephrotoxic effects. A reference dose of 0.007 mg/kg bw/d (7,000 ng/kg bw/d), below which adverse effects are not expected to occur, was reported for TCEP. The margin of exposure (MOE) for BBP ranged from approximately 513 to 1059 and the MOE for TCEP ranged from 300 to 619. **Conclusions:** The current risk assessment indicated that potential exposures to BBP and TCEP emitted from a mattress under simulated conditions of body weight and body temperature were below dose levels that would be expected to cause adverse effects. However, while there are benefits to use of these chemicals, manufacturers should be aware that exposures to the chemicals could increase as a result of the temperature and body weight of children and, given that children up to the age of 3 years spend the majority of the day sleeping, need ensure that concentrations of these chemicals used in mattresses are as low as possible for their intended purpose.

PS 3986 Enhancing genotoxicity risk assessment through an *in silico* workflow

A. Fowkes, A. Musso, G. Kocks, and R. Foster. Lhasa Limited, Leeds, United Kingdom.

Background and Purpose: (Quantitative) structure activity relationship ((Q)SAR) systems are widely used to predict genotoxicity throughout the development lifecycle of a chemical, from prioritisation to regulatory submission. Models for bacterial mutagenicity are considered sufficiently sensitive that regulators accept predictions *in lieu* of Ames data under ICH M7. In recent years, there has been a growing interest in the development of models for predicting other genotoxicity endpoints, particularly chromosome damage. The interest in understanding the genotoxic mechanism of chemicals and regulatory requirements in the agrochemical industry is driven by the recent publication of EFSA's guidance on the establishment of the residue definition for dietary risk assessment. These models are built on *in vitro* chromosome aberration and micronucleus test data, for which there is limited availability in the public domain and there are known concerns about false positive responses in historic data. As a result, predictions from these models are used as of weight of evidence alongside, rather than *in lieu* of, assay data in regulatory assessments. **Methods:** To address these challenges, the chromosome damage model within Sarah Nexus was previously developed to support the assessment of individual predictions, included supporting examples, references to study results, and *in vivo* data to facilitate expert review. The latest versions of Sarah Nexus and Derek Nexus, statistical and expert knowledge-based (Q)SAR systems produced by Lhasa Limited, were used together to generate consensus predictions for chromosome damage. The predictive performance was tested against data extracted from eChemPortal. Improved decision support was achieved through implementation of over 50 statements to support automatic review of different prediction scenarios. Furthermore, a new workflow has been implemented to combine consensus predictions for mutagenicity and chromosome damage to provide a full genotoxicity assessment to support regulatory submissions. **Results:** Consensus predictions are beneficial for regulatory assessments as they increase the sensitivity compared to individual models and provide confidence to make negative predictions where no prediction is provided by Derek. The sensitivity of Derek and Sarah against data from eChemPortal increased from 32% (Derek) and 46% (Sarah) to 64% when combined as a consensus model for chromosome aberration data. For micronucleus data, sensitivity increased from 28% (Derek) and 44% (Sarah) to 59% with the consensus approach. The negative predictivity where Derek provided no alert increased to ~70% if Sarah is also negative compared to ~40% or ~50% if Sarah is outside domain or positive, respectively. Case studies demonstrate how these predictions can be used for genotoxicity risk assessments of agrochemical metabolites. **Conclusions:** By leveraging both expert

and statistical models, Derek and Sarah provide robust genotoxicity predictions across endpoints, supporting evolving regulatory requirements and decision-making in diverse industries including agrochemicals. The new combined genotoxicity workflow, supported by automated expert review argumentation, facilitates efficient and consistent chemical safety assessments even for challenging endpoints such as chromosome damage.

PS 3987 Screening-Level Cumulative Health Risk Evaluation: Exposures to Acetamiprid, Clothianidin, Dinotefuran, Imidacloprid and Thiamethoxam residues from Non-Agricultural Uses

P. Dodmane, S. Koshlukova, S. Tiscione, J. Adragna, and S. DuTeaux. Department of Pesticide Regulation, Sacramento, CA.

Background and Purpose: Neonicotinoid insecticides are widely used to control sucking and chewing insects on crops and companion animals. Due to their systemic activity, they are extensively used for soil applications, seed treatments, and foliar treatments. All neonicotinoids share a key structural feature with both nicotine and acetylcholine enabling binding to and blocking nicotinic acetylcholine receptors (nAChRs) in the insect nervous system. Mammalian signs of exposure include incoordination, tremors, decreased activity, reduced body temperature and at sufficiently high doses, death; the developing nervous system is the most sensitive target. In 2024, California Assembly Bill 363 (AB 363) directed the Department of Pesticide Regulation (DPR) to evaluate the cumulative impact on human health from non-production, non-agricultural outdoor use of multiple neonicotinoid pesticides. This cumulative analysis focused on five neonicotinoids (acetamiprid, clothianidin, dinotefuran, imidacloprid, and thiamethoxam) and considered multiple exposure pathways relevant to the bystander population, including children. **Methods:** This analysis was limited to acute exposures, consistent with the US Environmental Protection Agency's (US EPA) designation of neonicotinoids as a candidate common mechanism group (cCMG) for neurotoxicity under acute conditions only. Three exposure scenarios were evaluated: (1) dietary exposure from consumption of fruits and nuts from non-production trees (e.g., trees grown in a residential settings), (2) post-application bystander exposure from contact with treated turf, and (3) multi-pathway exposure combining dietary and bystander routes. These exposure scenarios were consistent with the legislation and the scope of the human health risk and exposure assessments that were conducted in parallel. DPR employed the relative potency factor (RPF) approach recommended by US EPA to calculate toxic potencies for all five neonicotinoid pesticides using acetamiprid as the index chemical. RPFs are the ratio of doses that cause similar magnitude of toxic effects between the index chemical and each CMG compound. Points of Departure (PODs) for each neonicotinoid were selected based on acute neurotoxic effects that could result from disruption of the nAChRs, including decreased motor activity and startle response, tremors and reduced brain morphometry observed in acute neurotoxicity and developmental toxicity studies in animals. The RPFs were used to convert exposures for each CMG chemical into a single index chemical equivalent, which were then summed to calculate combined exposure. A modified Tier 1 approach was used for dietary, incidental oral, and dermal exposures. The multi-pathway analysis aggregated all exposure routes for children 1-2 years old as the most sensitive subgroup. Human health risks were calculated as margins of exposure (MOE), a ratio of the critical POD of the index chemical to the estimated cumulative human exposure, which were then compared to a target MOE of 100. **Results:** All calculated MOEs exceeded the target MOE of 100, indicating no acute health risks. The 95th percentile acute dietary exposure for children aged 1-2 years was 8.965 µg/kg/day, corresponding to an MOE of 1,115. The highest cumulative exposure in the multi-pathway scenario was 79.986 µg/kg/day, corresponding to an MOE of 125. **Conclusions:** This assessment incorporated several assumptions, including full co-exposure to multiple neonicotinoids, high-end residue values, and default uncertainty factors. Even under conservative assumptions, complete co-occurrence of residues, and maximum exposure scenarios, no acute cumulative risks were identified from the combined neonicotinoid exposures from outdoor non-agricultural uses.

PS 3988 A Risk Assessment of Ethylene Oxide Release from a Sterilization Facility: A Data-Driven Case Study on Community Exposure and Risk

Q. Perry¹, K. Kissell¹, B. Deckard¹, G. Hoffnagle², and D. Paustenbach¹. ¹TRC Strategic Health Sciences, Jackson, WY; and ²TRC Environmental, Windsor, CT.

Background and Purpose: Ethylene oxide (EtO) is a widely used industrial sterilant and chemical intermediate that has been subject to increasing scrutiny in recent decades regarding its potential carcinogenicity. Historically, EtO has been released into the atmosphere through both stack emissions and fugitive leaks from sterilization facilities, hospitals, chemical plants, and storage tanks. Prior to the implementation of enhanced regulatory controls, some facilities released untreated EtO into the air, potentially resulting in localized areas with elevated concentrations. Epidemiological studies have identified two main cancers that may be associated with EtO exposure at some dose: breast cancer and lymphohematopoietic cancer (primarily lymphoid leukemia). Despite industrial emissions, ambient EtO levels are generally consistent across different environments. According to EPA monitor-

ing data, average EtO concentrations in rural (0.16 ppb), suburban (0.17 ppb), and urban (0.17 ppb) settings are remarkably similar. This suggests that, while industrial sources contribute to localized emissions, EtO emissions in urban areas do not appear to be sufficient to alter background concentrations. **Methods:** This study evaluated residential and occupational exposure to EtO in a valley surrounding two point-source emissions in proximity (~11 meters). Air samples were collected in residential and industrial areas. Eight locations, ranging from 100 to 1700 meters from the center of the point-sources in varying directions, had average concentrations between 0.290 and 3.212 µg/m³ (0.16 to 1.8 ppb) and peak levels reaching 26.4 µg/m³ (15 ppb). Exposure scenarios were developed based on daily activity patterns, long-term residency, and estimates derived from historical emissions data. **Results:** Under the most conservative assumptions, including 40 years of occupational exposure during the periods of highest recorded emissions around the facility, the maximum estimated lifetime exposure found was 591 ppm-days. When compared to epidemiological studies of EtO-exposed workers from similar facilities (studies used by the EPA and IARC in their cancer risk assessments), the highest cumulative exposures observed (13,500+ ppm-days) were at least 23 times higher than our maximum estimated lifetime exposure value (591 ppm-days). Importantly, these high-exposure groups showed no statistically significant cancer incidences, particularly for breast and lymphohematopoietic cancers. **Conclusions:** Epidemiological studies have not demonstrated a statistically significant increase in the incidence of breast or hematopoietic cancers within the evaluated exposure ranges. While some studies have noted possible associations, these do not establish causality. The available epidemiological evidence is insufficient to infer a causal relationship between EtO exposure and the development of these cancers, requiring reliance on unverified or substantial assumptions. A comparison of stack emission data from the sterilization facility evaluated in this assessment with data from other EtO-emitting facilities across the United States revealed that EtO releases are generally comparable and, in many cases, lower. This assessment encompasses exposures representative of a broader population of sterilization and chemical facilities. The findings suggest that both current and historical EtO emissions from a substantial portion of these facilities have not posed a measurable risk of cancer to nearby communities.

PS 3989 A Conceptual Framework Using Weight-of-Evidence Incorporating New Approach Methods for Risk Assessment

A. Pecquet¹, E. Freeman², S. Catalano³, J. Mehta⁴, T. Ramanarayanan¹, and A. Goetz¹. ¹Syngenta Crop Protection LLC, Greensboro, NC; ²Exponent Inc., Center for Chemical Regulation and Food Safety, Washington, DC; ³Corteva Agriscience, Newark, DE; and ⁴ADAMA Agricultural Solutions, Washington, DC.

Background and Purpose: Weight of Evidence (WoE) analysis supports hazard and risk assessment while reducing animal testing by supporting the integration of New Approach Methods (NAMs). A globally harmonized WoE framework, grounded in the OECD's key principles, can foster broader adoption of NAMs. This can be achieved by establishing best practices for implementing the core principles of problem formulation, data collection, evidence evaluation and weighing, and evidence integration and reporting. In practice, these principles must be flexible to fit into regulatory contexts and to support integrating various data types. For example, when working with *in vitro* data, it is important to emphasize assay validity, reliability, and reproducibility, whereas integrating read-across data requires a focus on structural similarity, consistency, and concordance. Therefore, WoE as a conceptual framework can only be applied as 'fit-for-purpose'. This case example applies a globally harmonized WoE framework to the human health evaluation of a chemical metabolite, implementing a NAMs approach to avoid unnecessary animal testing. **Methods:** Data collection included Threshold of Toxicological Concern (TTC) approach with QSAR analysis for Cramer classification and structural alerts (OECD Toolbox; DEREK, and SARAH); chemical analog identification (RDKFingerprint and Tanimoto) for ID of structural analogs; comprehensive field trial residue data; and dietary exposure modeling (DEEM). **Results:** QSAR modeling and structural analogs indicated no alerts for genotoxicity, and the structure did not indicate potential for *in vitro* or *ex vivo* bioactivity. The metabolite was classified as Cramer Class III, with dietary exposure at <1% of the TTC. **Conclusions:** Based on the WoE, the metabolite was not included in the residue definition, and no additional animal testing was required. This case study illustrates the successful application of a WoE framework to a common regulatory scenario, providing a solid basis for safety assessment while promoting NAMs. It demonstrates how systematic evidence collection, evaluation, weighing and integration can inform decisions, minimize animal testing, and uphold scientific rigor in pesticide evaluations.

PS 3990 Integrating Epidemiological Evidence for Dose-Response Assessment of Inorganic Arsenic-Induced Non-Cancer Effects

K. Shao¹, N. Dai¹, A. B. Afzal¹, and P. Boffetta². ¹Indiana University, Bloomington, IN; and ²Stony Brook University, Stony Brook, NY.

Background and Purpose: As a naturally occurring element, inorganic arsenic (iAs) is widely distributed in the environment, resulting in continuous human exposure. Consequently, an extensive body of epidemiological studies has investigated the association between arsenic exposure and various adverse health outcomes, form-

ing the principal evidence underlying recent risk assessments. In addition to certain types of cancers in humans (e.g., urinary bladder and lung cancer), exposure to high doses of iAs can cause non-cancer effects such as diabetes, which has received increasing attention in risk assessment. Modeling epidemiological dose-response data is challenging due to the diverse response metrics reported across studies, uncertainty in exposure measurements, and heterogeneity among populations. However, directly utilizing epidemiological data in dose-response assessment provides an opportunity to quantitatively characterize human variability and replace the traditional empirical uncertainty factor used in reference dose (RfD) derivation. Therefore, the purpose of this study is to develop a dose-response modeling framework that integrates epidemiological data from different populations to derive toxicity values, demonstrated using iAs-induced diabetes as an example. **Methods:** A Bayesian hierarchical benchmark dose (BMD) modeling approach was employed for meta-regression to derive an integrated dose-response relationship for BMD estimation, with uncertainty quantification of population heterogeneity. This approach utilizes the Hill model for continuous response to characterize the dose-response relationship between daily iAs intake levels and the adjusted relative risk (RR) or odds ratio (OR) of diabetes reported in various individual populations. The Hill model, within the Bayesian hierarchical structure that accounts for variability in background exposure and response sensitivity, was fitted to the integrated dose-response data and used for point of departure (POD) calculation. Five high-quality epidemiological studies (in terms of appropriate study design, clear documentation of data collection and reporting, etc.) with adequate dose-response data were identified through a systematic review and used to demonstrate the modeling approach. The same approach was applied to the epidemiological dose-response data of iAs-induced diabetes selected in the U.S. EPA's IRIS risk assessment of iAs, for the purpose of comparison and demonstration of the approach's adaptability. **Results:** Preliminary dose-response assessment suggested a POD estimate of 1.87 $\mu\text{g/kg/day}$ when the BMR was set at 0.5%, indicating that a 0.5% increase in incidence rate in the U.S. population can be expected at the BMD level. Various BMR options (from 0.05% to 1%) were attempted, and the results showed a relatively flat dose-response relationship in the low-dose region, suggesting that a threshold causing diabetes in the target population may exist. A sensitivity analysis regarding the selection of the dose-response model was performed, and it suggested that the choice of a flexible dose-response model would not have a major impact on the POD estimation. On the other hand, the same modeling approach generated lower POD values (from 0.04 to 0.15 $\mu\text{g/kg/day}$ at the BMR level of 0.5%) when different combinations of the four epidemiological studies selected by the EPA were used. **Conclusions:** This study demonstrates that a Bayesian hierarchical dose-response modeling structure with a flexible Hill model is an adequate approach for modeling epidemiological dose-response data, with the benefit of quantitatively characterizing the uncertainty and variability in POD estimation. It is also important to note that the POD estimation is highly sensitive to the selection of epidemiological studies modeled, highlighting the necessity of using high-quality epidemiological studies and considering modes of action obtained from toxicological studies as supporting evidence.

PS 3991 Risk and Exposure Assessment of Non-agricultural Uses of Imidacloprid

A. A. Kalashnikova, M. C. Geier, A. L. Rubin, B. Darsie, P. Dodmane, S. Tiscione, Q. Dong, P. Lohstroh, E. Kwok, S. Koshlukova, and S. DuTeaux. Department of Pesticide Regulation, Sacramento, CA.

Background and Purpose: Imidacloprid is a systemic and contact neonicotinoid insecticide. It is one of the most widely used pesticides worldwide, applied to soil, foliage and animals to control insects on crops, pets, and turf. Imidacloprid's pesticidal action is attributed to its binding to insect nicotinic acetylcholine receptor (nAChR) causing overstimulation and paralysis. In mammals, signs include incoordination, tremors, decreased activity, reduced body temperature, and at sufficiently high doses, death. The developing nervous system is the most sensitive target. In this assessment, the California Department of Pesticide Regulation (DPR) evaluated the potential human health effects and risks from occupational and non-occupational exposure to imidacloprid in non-agricultural settings. These included (1) professional handlers in landscape, residential, and recreational settings; (2) use of home (consumer) products; (3) post-application exposures to non-applicators; and (4) dietary and aggregate exposures. **Methods:** The critical points of departure (PODs) for characterizing risk from all exposure routes were derived from laboratory studies in animals. Short-term, seasonal, and annual exposures for professional handlers were estimated using surrogate data from the Pesticide Handler Exposure Database. Short-term post-application exposures were calculated for residential, household, and recreational scenarios. Probabilistic dietary and drinking water exposures were calculated for the US population and sensitive subpopulations, including infants, children aged 1-2, and women of childbearing age (13-49 years) using the Dietary Exposure Evaluation Model, consumption data from the 2005-2010 National Health and Nutrition Examination Survey dietary survey, and residue data from federal and state monitoring databases. Margins of exposure (MOEs) were calculated as ratios of the critical PODs to the estimated human exposures for various exposure scenarios and durations. They were compared to the target value of 100, which is equal to the total combined uncertainty factor. **Results:** The acute POD of 5.5 mg/kg/day was based on changes in physical dimensions of certain brain structures (corpus callosum and caudate putamen) in rat pups seen in an oral developmental neurotoxicity (DNT) study. The subchronic and chronic POD was 1.0 mg/kg/day based

on altered negative geotaxis (a measure of neuromotor and vestibular function in rat pups) following gestational and lactational exposure in a separate DNT study. Non-agricultural handlers exhibited the highest short-term, seasonal, and annual exposures. The non-Hispanic-other subpopulation exhibited the highest acute dietary exposure (7.22 $\mu\text{g/kg/day}$). Children aged 1-2 years had the highest chronic dietary exposure (0.57 $\mu\text{g/kg/day}$). Calculated MOEs were compared to the target MOE of 100. **Conclusions:** Potential risks (i.e., calculated MOEs <100) were identified for 5 of the numerous scenarios evaluated. These included dermal and inhalation risks for professional handlers involved in mixing/loading for aerial and groundboom applications. The only non-occupational risk was for incidental oral exposures to children aged 1-2 years from treated turf (eating grass and hand-to-mouth activities). Neither acute nor chronic dietary and drinking water exposures alone present a risk to human health for any subpopulation. In addition, for all occupational and non-occupational scenarios, aggregation with dietary exposure did not increase risks, including those for all post-application exposure scenarios for children.

PS 3992 Coexisting with Toxic Legacies: Assessing Soil Metal Levels, Sources, and Health Risks Associated with Living Amid Contamination Within a Superfund Site

T. Huynh¹, E. El Hayek², C. Van Dunk³, V. Mann³, E. Erdei², and J. Zelikoff¹. ¹NYU Langone Health, New York, NY; ²University of New Mexico, Albuquerque, NM; and ³Ramapough Lunaape Turtle Clan, Ringwood, NJ.

Background and Purpose: The Ringwood Superfund site in New Jersey (NJ) presents a controversial case of environmental injustice shaped by the interplay of mining legacy, hazardous waste dumping, and weak regulatory oversight. Uncertainty remains over the effectiveness of cleanup actions and ongoing health risks to the Indigenous Ramapough Lunaape Turtle Clan (RLTC), who maintains cultural, subsistence, and residential ties to the land. This study aims to quantify current soil metal levels in community spaces outside designated cleanup areas, delineate potential pollution sources, and estimate exposure-related health risks to support continued dialogue and cooperative remediation among stakeholders. **Methods:** Soil samples ($n = 23$) were collected from five zones in and around the Superfund site, each selected for proximity to former dumping areas or frequency of visit. Samples underwent acid digestion and were analyzed via ion-coupled plasma-mass spectrometry (ICP-MS) for 14 heavy metals. Contamination levels were quantified using the Contamination Factor (CF) and Geo-accumulation Index (I_{geo}), comparing ICP-MS results to NJ background levels. Source apportionment leveraged three receptor modeling methods, Absolute Principal Component Scores-Multiple Linear Regression, UNMIX, and Non-negative Matrix Factorization, for a balanced assessment. Ranges of non-cancer (Hazard Index [HI]) and cancer (Total Cancer Risk [TCR]) risks from metal exposure via oral, inhalation, and dermal pathways were modeled for children and adults using Monte Carlo simulations. **Results:** Among tested metals, mean soil concentrations, in mg/kg, for arsenic (22.3), chromium (62.6), and lead (270) exceeded U.S. Environmental Protection Agency (EPA) residential screening levels of 0.68, 0.95, and 200 mg/kg, respectively. CF and I_{geo} values for several metals exceeded natural baselines, with some beyond thresholds attributable to variability in geochemical background, thus implicating substantial human influence. Notably, across all samples, CF values (unitless) of cadmium (11-28) and antimony (7-15) placed these elements in the highest contamination tier (CF > 6). Despite the moderating effects inherent to I_{geo} 's (unitless) adjustments for background variability, cadmium remained within "heavy" to "heavy to extreme" categories ($I_{geo} > 3$). Other metal contamination levels fluctuated across sample zones, indicating spatial variability in the composition and relative intensity of geogenic and anthropogenic outputs. All three receptor models resolved four comparable sources. Source 1, defined by naturally abundant copper, manganese, and zinc, represented natural soil metal content. Source 2, characterized by elevated iron and iron-loving arsenic, cobalt, and vanadium near an old mine pit, was linked to the site's iron-mining and ironworks legacy. Source 3, contributing beryllium, cadmium, chromium, and molybdenum, denoted a mixed anthropogenic source arising from fuel combustion and weathered car parts and municipal waste strewn across the site. Source 4 was identified as automotive paint sludge dumped at the site, based on concurrent elevated levels of its signature metals, lead and antimony, in samples near the dumping area and in outlying areas where hydrologic connectivity and topography suggest contaminant migration beyond Superfund boundaries. Monte Carlo simulations showed that exposure to the measured heavy metal levels resulted in HI (unitless) across all pathways averaging 2.11 and 0.470 for children and adults, and exceeding EPA safety threshold (HI = 1) in 59% and 8% of simulated exposure scenarios, respectively. TCR (unitless) was higher for adults, averaging 5.59×10^{-5} compared to 3.79×10^{-5} for children, with, respectively, 12% and 10% of scenarios exceeding the threshold of acceptable excess cancer risk (TCR = 10^{-4}). **Conclusions:** Persistent contamination at the Ringwood Superfund site was associated with increased health risks beyond EPA safety thresholds for the RLTC. Source apportionment analyses suggested major contributions from the dumping activities to the measured metal levels. These findings highlight the need for sustained and community-centered intervention to safeguard both public health and environmental justice.

C. Hamaji¹, M. Streifer², and E. Fung³. ¹Integral Consulting, San Francisco, CA; ²Integral Consulting, Austin, TX; and ³Integral Consulting, Irvine, CA.

Background and Purpose: Clothing dyes are widely available for use by consumers. Aniline is a common chemical intermediate - and sometimes a contaminant - in clothing dyes. Cordin et al. (2021) reported that synthetic indigo dye contains up to 0.6% aniline. However, the potential health risks from use of at-home clothing dyes, including potential exposures to aniline, have not been thoroughly studied. California's Office of Environmental Health Hazard Assessment (OEHHA) classifies aniline as a carcinogen under Proposition (Prop) 65, and set a No Significant Risk Level (NSRL) of 100 µg/day. However, to our knowledge, no publicly-available quantitative model is available to assess dermal exposure to clothing dye ingredients and contaminants such as aniline, making compliance with the aniline NSRL difficult. As such, the purpose of this study was to develop a model to quantitatively estimate the exposure and risk of cancer resulting from potential dermal exposure to aniline under a typical at-home dyeing scenario using a synthetic indigo dye. **Methods:** Potential dermal exposure to aniline from use of synthetic indigo was calculated for home users using exposure parameters from publicly-available sources in a deterministic model. The EPA Swimmer Exposure Assessment Model (SWIMMODEL) Version 3.0 was adapted for use in the risk assessment. The SWIMMODEL is typically used to model swimmers' exposures to chemicals in pools, but can be adapted to reflect immersion of individual body parts in water as long as the exposure time, surface area of exposed skin, concentration of the chemical in water, and chemical-specific permeability coefficients are known. The NSRL of 100 µg/day for aniline reflects exposures over all exposure routes. Aniline is assumed to have high systemic absorption after ingestion, up to 100%. According to the Australian Industrial Chemicals Introduction Scheme (2023), up to 38% of a single dermal exposure to aniline may be absorbed through the skin. This information was used to derive the adjusted dermal NSRL of 263 µg/day. The daily dermal exposure estimate for aniline was compared to the dermal NSRL for aniline using a Margin of Safety (MOS) approach. Specifically, the MOS was calculated as: MOS = Dermal NSRL / Daily exposure. **Results:** Typical consumer use parameters were applied to the exposure model. Specifically, it was assumed that at-home clothing dye users handle synthetic indigo twice per year for 15 minutes per event. The number of uses per year was averaged to the number of uses per day to estimate average daily exposure. The model also assumed that a user immerses two full, ungloved hands into the dye solution during these events. The concentration of aniline in the dye solution was calculated based on the reported concentration of aniline in synthetic indigo, the amount of dye used per event, and the amount of solution in which the dye is dissolved. To assess the dermal permeation of aniline, its permeability coefficient (Kp) was calculated based on aniline's Log Kow and molecular weight. These inputs were then used to calculate a potential daily dermal exposure in µg/day. Home users of synthetic indigo were estimated to have an average daily exposure to aniline of 0.3 µg/day. This corresponded to an MOS of 890 for home users when compared to the adjusted dermal NSRL of 263 µg/day. A MOS greater than 1 suggests that risk of adverse effects is not anticipated. **Conclusions:** Through this assessment, a quantitative model for exposure and risk posed by aniline in synthetic indigo dyes was developed. This analysis suggests that adverse effects due to aniline following use of synthetic indigo dyes are not expected under typical home use scenarios at the concentration evaluated. Multiple conservative assumptions were incorporated into this assessment, including that a user's two hands are fully immersed in the dye solution during the entire handling period, and that the user does not wear gloves while handling dye. Further work in this area may include refinement of data regarding consumer use of clothing dyes, development of a probabilistic model to incorporate the variability and uncertainty in exposure parameters, and application of the model to other chemicals in consumer clothing dyes. Nonetheless, this model presents a valuable tool to quantify exposure and potential risk corresponding to synthetic indigo dye use among at-home users.

PS 3994 California Proposition 65 NSRL Derivation for Aflatoxins

M. H. Whittaker. ToxServices LLC, Washington, DC.

Background and Purpose: Aflatoxins are a group of mycotoxins produced by the fungi *Aspergillus flavus* and *Aspergillus parasiticus*. These fungi flourish under moist and warm environments and contaminate crops (corn, wheat, rice), and nuts, spices, coffee beans, and dried fruits (among other food types). Food contamination usually involves aflatoxins B1, B2, G1, and G2 (crops) and M1 (dairy products). Aflatoxins have the potential to cause acute illness and liver injury, and multiple epidemiological studies in Africa and Asia indicate that dietary aflatoxin exposure increases the risk of developing hepatocellular carcinoma (HCC). Aflatoxins have been listed on California's Proposition 65 List of Chemicals Known to Cause Cancer or Reproductive Toxicity ("Prop 65") since 1988 due to aflatoxin's carcinogenicity potential. The California Office of Environmental Health Hazard Assessment (OEHHA) has not established a safe harbor value for aflatoxin. OEHHA defines a safe harbor value as a level of exposure to a listed chemical (in units of µg/day) that does not require a Proposition 65 warning. For carcinogens on Prop 65, the safe harbor value is known as the No Significant Risk Level (NSRL). The current project derives a NSRL for aflatoxins that may be used as part of a safe harbor assessment to determine whether exposure to aflatoxin-contaminated food items have safe harbor from Proposition 65 labeling. **Methods:** As defined by OEHHA, a Proposition 65 NSRL is equivalent to an

exposure level that results in 1 excess cancer case in an exposed human population of 100,000, assuming lifetime exposure at the level in question. OEHHA risk assessment guidance outlined in 27 CCR § 25703 (Quantitative Risk Assessment) was followed to derive a NSRL for aflatoxins following a step-wise approach: 1) The aflatoxin NSRL assumes that there is no carcinogenic threshold. 2) The NSRL builds on a 0.4 µg/kg-bw/day Benchmark Dose Lower Confidence Limit (BMDL10</sub>) for aflatoxins calculated by the European Food Safety Authority Panel on Contaminants in the Food Chain (EFSA CONTAM Panel) using data from a 105 week dietary feeding study conducted by Wogan et al. (1974). The Wogan et al study identified increased HCC in male Fischer rats exposed to Aflatoxin B1 at dietary doses up to 100 µg/kg. Fischer rats are considered to be the most sensitive species among those studied, which adheres to OEHHA guidance. 3) A Human Equivalent Dose (HED) at the BMDL10 was derived through the application of a dosimetric scaling factor: $(BW_{animal}/BW_{human})^{1/4}$, as specified in OEHHA guidance. 4) A cancer slope factor (CSF) in units of (µg/kg/day)⁻¹ was estimated based on a 10% benchmark response (BMR) and HED. 5) Aflatoxin's NSRL was derived from the CSF and 1 in 100,000 (10⁻⁵) increased cancer risk, adjusted to a body weight of a 70 kg, which is also specified in OEHHA guidance. **Results:** A 0.108 µg/kg/day HED was calculated from the BMDL10</sub> of 0.4 µg/kg-bw/day multiplied by a by dosimetric adjustment factor calculated by dividing a 0.380 kg body weight for adult Fisher male rats by a 70 kg body weight for adults, taken to the one-fourth power. A CSF of 0.92 (µg/kg/day)⁻¹ was derived by dividing a 10% benchmark response by the 0.108 µg/kg/day HED. Finally, a NSRL of 0.00075 µg/day (equal to 0.75 ng/day) was derived by dividing the level of acceptable lifetime cancer risk (1 in 100,000) by the CSF and multiplying the resulting quotient by a 70 kg body weight. **Conclusions:** Aflatoxin's small NSRL value of 0.75 ng/day evidences the carcinogenic potency of aflatoxins, and can be incorporated into safe harbor evaluations for aflatoxin-contaminated food items marketed in California. In instances where daily aflatoxin exposure exceeds this NSRL, a manufacturer must warn consumers through a Proposition 65 warning.

PS 3995 Derivation of an NSRL for vinyl acetate.

M. C. Buser, A. Jachak, and J. Persky. RHP Risk Management, Chicago, IL. Sponsor: M. Buser, Society for Risk Analysis

Background and Purpose: Vinyl acetate monomer (VAM) is a synthetic chemical building-block used in the production of copolymers. These polymers are in turn used as the basis for manufacture of many industrial and commercial products, such as adhesives, textiles, and plastics. The general population may be exposed to low levels via contaminated air, food, or water. Occupational exposure occurs via inhalation of contaminated air in the workplace. Vinyl acetate has been detected at hazardous waste sites; therefore, populations living near contaminated sites may have increased exposure via ambient air, groundwater contamination, or vapor intrusion, compared to the general population. There is limited information on health effects following exposure to VAM. Studies have suggested that respiratory tract, gastrointestinal effects, and developmental effects are the likely primary targets of toxicity. Studies in animals have suggested that VAM is carcinogenic with effects likely attributable to the rapid transformation to acetaldehyde and acetic acid. IARC has determined that VAM is possibly carcinogenic to humans, and in 2024, California's OEHHA proposed to add VAM to the Proposition 65 chemical list. With the impending Prop 65 labeling requirements for VAMs, set to take effect in 2026, we propose to derive No Significant Risk Levels (NSRLs) for VAM. **Methods:** We conducted a comprehensive literature review to identify studies of potential interest. Because Prop 65 listings are based on carcinogenic potential, we focused on cancer outcomes as the primary health effect of concern. We identified principal studies and endpoints that demonstrated dose-response. There is uncertainty inherent in guidance values. We attempted to minimize uncertainty where possible. We used EPA BMDS to model the incidence data and provide recommendations on viable models that appropriately fit the data. We then collected the underlying variable estimates and standard errors for the various parameters for each model included in the standard BMDS package (e.g., gamma, Hill, etc.). This allows us to utilize the distribution of the values underlying the parameter estimates rather than discrete values. Using Oracle's Crystal Ball software to perform a probabilistic analysis, we iterated more than 10,000 Monte Carlo simulations for each of the 54 different mathematical models that BMDS had fit to the dose-response data set. This forecasted 54 unique probabilistic distributions of the benchmark dose associated with a 10% increased risk, and also 54 unique probabilistic distributions of the lower 95th percentile point estimate value (BMDL) associated with a 10% increased risk. We then applied model-weighting using AIC to generate 6 weighted functions that considers all sources of data variability and removes model selection bias. The 6 model-weighted functions pertained to analysis of the data set for each combination of exposure route (oral, inhalation) and sex (males, females, combined). The 5th percentile point estimates for each of these 6 model-weighted probabilistic functions was then selected as the POD for the NSRL derivation. **Results:** Following a literature review, we identified principal studies and critical health effects for oral and inhalation routes of exposure. We identified Umeda et al. (2004) and Bogdanffy et al. (1994) as the critical studies for oral and inhalation route. VAM tends to have portal-of-entry effects, so the primary health outcome identified were squamous cell carcinoma of the oral cavity and nasal tumors in for oral and inhalation exposure, respectively. Rats are typically the more appropriate species for extrapolation to humans. Tumor incidence across the database were relatively low. We extracted the data for males and females and ran the incidence data through BMDS for males only, females only, and combined. Following a probabilistic approach to selection of PODs, we then derived candidate oral and inhalation

NSRL values for VAM based on target risk estimates of 1 in 100,000 considering typical daily human intake for a 70-year statistical lifetime. **Conclusions:** In anticipation of the Prop 65 listing of VAM, we present here a proposed probabilistic approach to derive candidate NSRLs for inhalation and oral exposure. The approach taken here utilizes multiple modeling approaches to consider the effect of uncertainty and remove selection bias. We will then compare these candidate NSRLs to recent exposure estimates from various consumer product categories to estimate margins of safety.

PS 3996 A Review of EPA's TSCA Risk Evaluation for Site-specific Occupational Risk Assessment of Formaldehyde

N. Gowadia¹, and L. Lund². ¹Jacobs, Irvine, CA; and ²Jacobs, Shelley, ID.

Background and Purpose: EPA released the final risk evaluation under the Toxic Substances Control Act (TSCA) for formaldehyde in December 2024. EPA evaluated human health risks from formaldehyde exposure under 63 conditions of use (COUs) during manufacturing, processing, distribution, industrial, commercial, and consumer use, and disposal for workers, consumers, and general population. EPA identified unreasonable occupational risk for 50 COUs. Formaldehyde is widely used in several industries, and research and EPA TSCA identification of unreasonable occupational risk for 50 COUs leads to risk management which can include site-specific assessment. Because site-specific occupational exposure is expected to be unique and different from the exposure concentrations and parameters used in EPA's assessment, risk assessment based on site-specific concentrations and exposure conditions can provide site-specific risks and concentration limits to assist in risk management decisions regarding formaldehyde. **Methods:** A site-specific approach was used to evaluate potential formaldehyde risk for workers at an aerospace facility (Site). The following approach was used: Step 1 - Identification of Site-specific Uses and Occupational Exposure Scenario (OES) Categorization - Several site-specific uses were identified at the Site. These uses were grouped and categorized into corresponding EPA TSCA OES categories. Step 2 - Identification of Exposure Concentrations and Exposure Parameters - High end site-specific exposure concentrations and exposure parameters were identified for the Site. In addition, exposure concentrations, exposure parameters, and toxicity parameters used in EPA's TSCA evaluation were identified for Step 1 OES. Step 3 - Calculation of Site-specific Risks - Consistent with EPA's TSCA evaluation, site-specific noncancer risks were calculated for worker acute inhalation, acute dermal and chronic inhalation, and cancer risks were calculated for chronic inhalation exposure scenarios and compared with EPA's TSCA evaluation risks. **Results:** Site-specific uses were grouped into four applicable EPA OES for risk evaluation: 1. Industrial - Use of coatings, paints, adhesives, or sealants (non-spray applications). 2. Industrial - Use of coatings, paints, adhesives, or sealants (spray applications). 3. Processing - Incorporation into Article - Adhesives and Sealant Chemicals in Wood Product Manufacturing; Plastic Material and Resin Manufacturing (Including Structural and Fireworthy Aerospace Interiors); Construction (Including Roofing Materials); Paper Manufacturing. 4. Commercial - Laboratory use. Site-specific acute inhalation noncancer risk were above benchmark margin of exposure (MOE) of 3 for three OES (Industrial - Use of coatings, paints, adhesives, or sealants [non-spray applications]; Industrial - Use of coatings, paints, adhesives, or sealants [spray applications]; Processing - Incorporation into Article - Adhesives and Sealant Chemicals in Wood Product Manufacturing; Plastic Material and Resin Manufacturing [Including Structural and Fireworthy Aerospace Interiors]; Construction [Including Roofing Materials]; Paper Manufacturing) and below benchmark MOE of 3 for one OES (laboratory use). Site-specific acute dermal noncancer risk were below benchmark MOE of 10 for all four OES. Site-specific chronic inhalation cancer risks were below the target cancer risk of 1×10^{-4} for all four OES and below 1×10^{-6} for one OES (Industrial - Use of coatings, paints, adhesives, or sealants [spray applications]). However, site-specific chronic inhalation noncancer risks were above benchmark MOE of 3 for all four OES. **Conclusions:** The potential risks associated with site-specific uses of products containing formaldehyde were significantly lower than EPA TSCA risk assessment results. Site-specific exposure concentrations in formaldehyde formulations contributed to lowering the exposure and risk for workers by at least 65-fold for dermal exposure and by at least 10-fold for inhalation exposure versus EPA TSCA risks. Site-specific exposure parameters for workers contributed to lowering the exposure and risk by at least an additional 30-fold versus EPA's TSCA risks. Therefore, site-specific human health risk assessment results for formaldehyde exposure can significantly aid in risk management decisions.

PS 3997 Acute (24-hour) Nickel Inhalation Reference Concentration for Use in Air Toxics Risk Assessment

D. M. Proctor¹, A. H. Verwiel¹, T. R. Covington², and C. T. Thompson³. ¹ToxStrategies LLC, Mission Viejo, CA; ²ToxStrategies LLC, Beaver Creek, OH; and ³ToxStrategies LLC, Katy, TX.

Background and Purpose: Acute inhalation exposure to nickel has been shown to cause immune and respiratory effects in animal and occupational epidemiologic studies. Several state air toxics control programs, including those of Minnesota, Texas and Oregon, assess potential hazards for peak 24-hour exposures to protect against acute effects. However, federal sources for acute standards use differ-

ing definitions of acute exposure. For example, the Agency for Toxic Substances and Disease Registry (ATSDR) acute inhalation Minimum Risk Level (MRL) is for exposures of 1 to 14 days, and the US Environmental Protection Agency (EPA) and National Research Council Acute Guideline Exposure Levels are for exposures up to 8-hours in duration. As a result, state agencies have taken a variety of approaches to develop acute values for specific exposure durations, including adopting federal values regardless of a common definition of 'acute', adjusting the exposure durations to meet the needs of their programs, and/or developing state-specific values, resulting in considerable inconsistency. For nickel, the federal and state acute inhalation reference values vary by more than 100-fold. **Methods:** The nickel acute RfC was derived by 1) reviewing data from authoritative sources and the scientific literature to determine sensitive Points of Departure (PODs), 2) developing and applying dose adjustment factors (DAFs) to account for differences in dosimetry between animals and humans, 3) applying time adjustment factors to calculate Human Equivalent Concentrations (HECs), and 4) applying appropriate uncertainty factors. Because the ATSDR (2024) recently concluded that the most sensitive endpoints for acute nickel exposure were immunotoxicity and respiratory irritation, our literature review focused on these endpoints. Authoritative sources for acute toxicity data for nickel included the ATSDR, EPA, Texas Commission on Environmental Quality (TCEQ), and California Office of Environmental Health Hazard Assessment (OEHHA). To determine the most sensitive POD, benchmark concentrations (BMCs) and LOAECs and NOAECs from the scientific literature were compared. To calculate the DAF, the multiple-path particle dosimetry (MPPD) model was run to estimate an HEC. **Results:** The literature review supported that immune effects are the most sensitive endpoint for acute exposures to nickel. Efremenko et al. (2017) evaluated transcriptomic responses to Ni inhalation exposure for 6 hours/ day, 5 days/week for 1 and 4 weeks and found that the lowest BMCs were observed for immune responses (0.047 mgNi/m³). The POD for acute immunosuppressive response was the NOAEC of 0.081 mg Ni/m³ reported by Buxton et al. (2021) in mice administered nickel chloride for 24 hours and challenged with sheep Red Blood Cells. Buxton et al. (2021) followed the Office of Prevention, Pesticides and Toxic Substances (OPPTS) guideline #870.7800 for immunotoxicity and was good laboratory practice (GLP)- compliant. To calculate the DAF, the MPPD model was run for the mouse and the human. MPPD only has two options for a mouse model species (BALB/c and B6C3F1); however, CD-1 mice were used in the Buxton et al. (2021) study. Thus, model runs were made with assumptions for each mouse species for comparison. Most input parameters are automatically calculated in the MPPD model. The resulting HECs ranged from 0.279 to 0.439 mg/m³, with a median value of 0.318 mg/m³. Using the median value as the PODHEC and a 30-fold uncertainty factor (ten for intraspecies sensitivity and three for interspecies kinetic variability) results in an acute RfC of 11 µg/m³ which is similar to that derived by the Minnesota Pollution Control Agency. **Conclusions:** The transcriptomic BMD at one week of exposure for immune effects is considerably lower than the LOAEC for respiratory effects as reported in Efremenko et al. (2020 µg/m³) which was used by ATSDR as the basis for the acute MRL. The acute RfC of 11 µg/m³ is also supported by the transcriptomic BMCs (47 µg/m³). Further, because it is based on a Guideline and GLP study, and provides a NOAEC for 24-hour exposures, the 11 µg/m³ acute RfC developed herein is less uncertain than values developed from other studies, including those reporting respiratory effects.

PS 3998 Application of a Bayesian Network to derive a probability of causality in support of weight of evidence assessments, with a case study on a drinking water risk assessment

F. Momoli¹, G. Paoli¹, N. Farhat¹, I. Moffat², and P. Price¹. ¹Risk Sciences International, Ottawa, ON, Canada; and ²Health Canada, Ottawa, ON, Canada.

Background and Purpose: Evidence synthesis is a structured approach to identifying, appraising, and integrating findings from multiple studies to answer specific risk assessment questions. Weight of evidence, in the context of risk assessment, refers to the process of integrating multiple lines of evidence for assessing causality, typically during hazard identification. However, numerous qualitative and quantitative approaches are used for this process, often amounting to expert opinion, with little transparency in the weighting process. **Methods:** We advance ideas to dynamically create Bayesian Networks based on publication data reviewed and abstracted as part of a typical chemical risk assessment. Studies are considered within and across lines of evidence: epidemiologic studies, animal studies, and mechanistic studies. Observed evidence propagates through the Bayesian Network, which also incorporates recent ideas that introduce abstract causal indicators in the network, representing Bradford Hill considerations, such as support from the consistency of results, experimental evidence, statistical biological gradients, and temporality. Querying the resulting network provides an estimate of the probability of causality as study results are introduced, with estimates converging on 1 (certainly causal) or 0 (certainly not causal) if sufficient unambiguous and consistent evidence accumulates. **Results:** We describe a software tool created for this task, providing supporting information for risk assessors, with each piece of evidence introduced into the network, along with qualifying information such as risk of bias of individual studies and relevance of animal models for human health risk assessment. A case study is described on hazard identification using data from a recently published systematic review of human, animal, and mechanistic publications on asbestos in drinking water and stomach cancer. **Conclusions:** By incorporating probabilistic reasoning when considering evidence, Bayesian Networks can provide a sound means (enforcing

Bayes' Rule) of weighting evidence from published reports and addressing hazard identification questions in chemicals management. The approach can be used to support assessors facing challenging risk assessment problems.

PS 3999 Advancing Photoallergy Risk Assessment: Integrating the ROS Assay and UV-Vis Spectroscopy Under Full-Spectrum (UVA and UVB) Conditions for Tiered Screening of Fragrance Materials

C. Deodhar¹, G. Ritacco¹, A. Hilberer², K. Bouchard², K. Cantrell², J. Kwiatek², D. Botelho¹, and A. Api¹. ¹The Research Institute for Fragrance Materials, Mahwah, NJ; and ²Institute for In Vitro Sciences, Gaithersburg, MD.

Background and Purpose: The Research Institute for Fragrance Materials (RIFM) applies a tiered photosafety strategy addressing both photoirritation and photoallergy. While photoirritation can be assessed using validated models, no standardized *in vitro* methods currently exist for photoallergy, making its evaluation particularly challenging. To fill this gap, RIFM identified ~100 fragrance materials with significant UV absorbance but limited photoallergy data. Significant absorbance at wavelengths of 290–700 nm, covering UVB, UVA, and visible light, is of regulatory concern, and the UV-Vis spectral analysis is first used to determine specific wavelengths of absorbance. Further, some test methods employ solar simulators equipped with filters that may attenuate certain wavelengths. Therefore, the absorbance spectra of each test chemical can help inform the selection of appropriate conditions for further photosafety testing. Given the resource demands of higher-tier *in chemico* and *in vitro* testing, RIFM is exploring the integration of the Reactive Oxygen Species (ROS) assay with UV-Vis spectroscopy to enable rapid, science-based screening and prioritization. **Methods:** UV-Vis spectroscopy, performed under the guidance of OECD TG 101, was first used to identify materials with significant UV absorbance. The spectra of each material, including identification of peaks of absorption were determined. These materials were then screened in the ROS assay, to determine photoreactivity potential, as described in OECD TG 495, and in alignment with the ICH S10 photosafety document (2015). The ROS assay quantifies singlet oxygen and superoxide anion generation after UV exposure. The UV exposure conditions for the ROS assay included solar simulators equipped with filters to attenuate UVB (>320 nm) or those which included UVB (>290 nm). Materials testing negative in the ROS assay were deprioritized based on low photoreactivity potential. ROS-positive materials were advanced to higher-tier photoallergy testing. Given that the ROS assay is highly sensitive but less specific, a negative result provides strong evidence of low photoreactivity. In contrast, a positive result indicates the need for further investigation rather than a definitive outcome. To increase confidence in the outcome of ROS assay, RIFM compared results obtained under UVA-only versus UVA+UVB exposure conditions. **Results:** Thirty-eight proficiency chemicals evaluated in the ROS assay showed strong concordance with published data. Among the 57 fragrance materials evaluated, 35 were classified as non-photoreactive, 14 as photoreactive, and 8 as inconclusive. Notably, nearly 60% of the tested materials showed no photoreactivity, substantially reducing the need for further in-depth evaluation. Sulfanilamide, a known photoallergen, was predicted to be non-photoreactive under UVA-only exposure conditions but predicted as photoreactive when UVB were incorporated into the exposure conditions. In contrast, other UVB-only absorbers such as methyl cinnamate and p-methoxybenzaldehyde remained non-photoreactive after testing with UVB incorporated into the exposures, demonstrating low photoreactivity potential. These findings highlight that full-spectrum exposure conditions reduce the likelihood of false-negative predictions and improve the confidence of non-photoreactive classifications. **Conclusions:** Integrating UV-VIS spectroscopy with the ROS assay offers a practical and efficient framework for photoallergy risk assessment of fragrance materials. Testing under full spectrum UVA and UVB conditions improves accuracy by ensuring that the true photoreactive materials, particularly UVB only absorbers, are correctly identified. Notably, a negative ROS result strongly suggests low photoreactivity, while a positive result does not indicate photoallergenicity but instead signals the need for higher tier testing. This tiered, data-driven approach improves efficiency, avoids unnecessary testing, and aligns with regulatory expectations. Extending the ROS assay to fragrance materials highlights its value as a robust, broadly applicable photosafety screening tool.

PS 4001 Inhaled Mycotoxin Doses from Fungal Growth in Water-Damaged Residential Exposure Scenarios Are Orders of Magnitude Below Tolerable Daily Intake Levels

A. E. Loccisano¹, D. Singh², and B. D. Kerger³. ¹Exponent Inc, Alexandria, VA; ²Exponent Inc, Oakland, CA; and ³Exponent Inc, Tampa, FL.

Background and Purpose: Airborne mycotoxins generated from hidden indoor proliferation of fungal species have been raised as a possible human health concern for “mycotoxicosis” and certain neurological and immunological adverse health complaints that appear to correlate with associated indoor dampness and musty odors. However, the most potent and well-studied mycotoxins are nonvolatile compounds adhered to fungal hyphae and/or spores; concentrations vary depending on species-specific growth characteristics and life cycle in conjunction with environmental conditions (e.g., temperature, humidity/saturation, and growth medium) that may or may not be capable of producing measurable airborne mycotoxin concen-

trations. In common residential scenarios where fungal growth occurs behind walls and in crevices related to hidden water intrusion events, airborne mycotoxin emissions are often limited for a variety of reasons. Our study goals included evaluation of upper bound indoor airborne mycotoxin exposure concentrations based on published studies of water-damaged buildings to assess inhaled dose in comparison to tolerable daily intake levels that are considered safe for the general population. **Methods:** Six studies published between 2003 and 2016 were utilized to identify the highest reported indoor air mycotoxin concentrations from *Stachybotrys*, *Aspergillus*, *Penicillium*, and other common fungi found in water-damaged buildings in the US and European countries (Spain, Holland, Finland, Denmark, and Belgium). Upper bound concentrations in ng/m³ were directly measured for Rodin E (0.08), Aflatoxin B1 (0.15), Aflatoxin B2 (0.02), Ochratoxin A (0.23), and Sterigmatocystin (1.8); Satratoxin G and Satratoxin H from *Stachybotrys* species were nondetectable in air and dusts of the water-damaged buildings studied. These upper bound airborne mycotoxin concentrations were then utilized in two illustrative residential exposure scenarios involving hidden water intrusion-associated fungal growth: (1) in a bathroom wall space and (2) in the intake plenum of a central air conditioning (AC) system. **Results:** The bathroom scenario assessed 80 kg adult exposures at the upper bound mycotoxin concentration for 1.5 hours daily at a breathing rate of 0.8 m³/hr assuming an exhaust fan-generated ventilation rate of 8 air changes per hour. The AC plenum scenario assessed similar 80 kg adult exposures for 16 h/day at a breathing rate of 0.8 m³/hr from upper bound mycotoxin concentrations continuously emitting from the intake plenum (0.224 m³) and transmitted into a home volume of 475 m³ at a ventilation flow rate generating 2 air changes per hour for the home. The inhaled total mycotoxin dose per day in each scenario was then compared to published tolerable intake levels for the most potent *Fusarium* trichothecenes (0.06 to 1 µg/kg-day) and for Ochratoxin A (0.014 µg/kg-day). For the bathroom scenario, the upper bound inhaled mycotoxin dose was 130,000-fold below the tolerable daily intake for Ochratoxin A. Similarly, the AC plenum scenario showed an upper bound inhaled mycotoxin dose 38,000-fold below the tolerable daily intake for Ochratoxin A. **Conclusions:** These findings demonstrate that upper bound exposures to airborne mycotoxins in water intrusion-impacted residential settings are several orders of magnitude below tolerable intake levels and hence are not a credible concern for mycotoxicosis or neurological/immunological adverse health complaints in water-damaged homes.

PS 4002 Considerations and Methodologies for Determining Systemic Health-Based Exposure Limits (HBELs) for Rare and Unconventional Routes of Pharmaceutical Administration

S. B. Bandara¹, E. Fung², Y. Yu-Rice¹, and D. G. Dolan¹. ¹Amgen, Thousand Oaks, CA; and ²Integral Consulting, San Francisco, CA.

Background and Purpose: Health-based exposure limits (HBELs) are essential tools for protecting workers and patients in pharmaceutical manufacturing. While robust methodologies to determine HBELs exist for compounds administered through traditional routes (e.g., oral, intravenous, or subcutaneous), the derivation of systemic HBELs for pharmaceuticals, particularly biologics administered through rare or unconventional routes (e.g., intravitreal, intrathecal, or inhalation), remains underdeveloped. The need to address this gap is becoming evident, as biologics represent an increasing focus of modern drug pipelines and novel delivery platforms expand the range of clinical applications. A refined and harmonized approach is needed to ensure both the safety of workers handling these drugs, and the safety of patients receiving the drug from residual carryover. The vast majority of drugs are administered orally or via intravenous (IV) or subcutaneous (SC) injection. For nearly all drugs, these routes achieve therapeutic exposure concentrations (C_{max}, AUC) in target tissues with acceptable dosing and safety profiles. However, some drugs, in particular biologics, must be administered through unconventional routes in order to achieve the requisite local therapeutic concentrations at the site of action. This may be necessitated by the need to bypass physiological barriers (e.g., the blood-brain or blood-ocular barriers) or to minimize systemic effects. Consequently, systemic exposure data [nonclinical and clinical toxicity, pharmacokinetics (PK) and pharmacodynamics (PD)] are often absent or incomplete, as development programs prioritize therapeutic endpoints over full PK/PD characterization. As a result, HBEL-setting utilizing traditional/default uncertainty factors originally developed for small molecules with well-characterized systemic exposure may lead to misestimation of risk. **Methods:** In this work, we propose general considerations for setting systemic HBELs for biologics delivered via uncommon routes. Limit-setting for systemic exposure when only uncommon route-specific data is available requires integrating traditional toxicological methods with biologic- and route-specific adjustments. These include determination of the critical effect and point of departure, assessment of route-specific uncertainties, integration of mechanistic models, and application of modification and uncertainty factors where appropriate. For data poor drugs, evaluating potential systemic effects may involve adverse outcome pathway (AOP) mapping, analysis of target expression patterns, and read-across from drugs with shared pharmacological targets. **Results:** For determining systemic HBELs for intravitreal and intrathecal routes, the typical approach often involves a volume-to-volume extrapolation; however, this approach may be overly generalized and lack compound-specific considerations. Using simulated case examples for each uncommon route of administration, we demonstrate that data-driven refinements incorporating receptor density, pharmacokinetic bridging, and barriers to entry (e.g., the blood-brain and blood-ocular barriers) provide a more realistic representation of expected systemic exposure estimates. For workers handling biologics, the typical

approach for establishing airborne HBELs often assumes an inhalation bioavailability factor of 1-5% based solely on molecular size; however, our analysis shows that integrating receptor distribution and respiratory tract deposition location can further refine systemic dose estimates and yield more accurate HBELs - differences that are operationally meaningful for occupational exposure control and cleaning validation. **Conclusions:** This framework advances scientific rigor and promotes consistency in HBEL setting for biologics administered via nontraditional routes, supporting both worker protection and patient safety in an evolving therapeutic landscape.

PS 4003 Case Study of Permissible Daily Exposure Limit Derivation for Butyl Oligomer (C₂₁H₄₀): Gradient vs. ICH Q3E

I. Mohar¹, and I. Hadley². ¹Gradient, Seattle, WA; and ²Gradient, Boston, MA.

Background and Purpose: Chemical characterization and toxicological qualification of leachable compounds from pharmaceutical containers/closures and packaging is an important component of drug product safety. The ICH published a draft guideline for extractables and leachables, Q3E, in August 2025. In the guideline, a safety assessment and toxicology-based permissible daily exposure (PDE) for a relatively common leachable, butyl oligomer (C₂₁H₄₀), was presented. No published toxicology exists for butyl oligomer; hence, the risk assessment and PDE required the use of read-across. We previously assessed and derived a parenteral PDE for butyl oligomer based on a read-across approach. The objective of this case study was to compare the read-across approaches and PDEs derived from two independently conducted safety assessments butyl oligomer. **Methods:** A combination of *in silico* analyses (using Toxtree v3.1.0, VEGA QSAR v1.1.5, OECD QSAR Toolbox v4.5, EPI Suite v4.11) and publicly available toxicology data were used to support the toxicity hazard profile of butyl oligomer. Due to the lack of toxicology data for butyl oligomer, surrogate chemicals with toxicity data were identified based on known or predicted physicochemical and toxicological properties. From these data, a PDE was derived in accordance with ICH Q3C and ICH Q3D methodology. **Results:** Due to lack of complete coverage of physicochemical properties and predicted reactivity by a single surrogate, we relied on two surrogates, (1R,2S,5R)-5-methyl-2-prop-1-en-2-ylcyclohexan-1-ol (isopulegol) (CAS No. 89-79-2) and 1-octene (CAS No. 111-66-0), for the toxicological assessment of butyl oligomer. In ICH Q3E, a single surrogate, 3,3,5,5-tetramethyl-4-ethoxyvinylcyclohexanone (CAS No. 36306-87-3) was used. Based on *in silico* predictions and surrogate data, butyl oligomer was concluded to not be mutagenic, sensitizing, or irritating in either assessment. In our assessment, the point of departure (POD) for derivation of the PDE was based on the results of a 90-day oral toxicity in rats in which a no observed adverse effect level (NOEL) of 38 mg/kg/day was identified based on kidney and hematological effects. In the Q3E assessment, the POD was based on a combined repeat dose/reproductive toxicity study in rats in which a NOEL of 100 mg/kg/day was identified based on kidney, liver, and spleen effects. Based on these POD values, a default body weight of 50 kg, and application of composite modifying factors 2,500 and 5,000, parenteral PDE values of 760 µg/day and 1,000 µg/day were derived by us and ICH Q3E, respectively. **Conclusions:** Independent derivation of a parenteral PDE for butyl oligomer (C₂₁H₄₀) by Gradient and ICH Q3E resulted in very similar exposure limits despite using different surrogates for read-across. This case study highlights that best practice approaches for surrogate identification and exposure limit derivation are robust if scientifically justified.

PS 4004 Evaluation of exposure associated with use of asbestos-containing gloves of the 1940s to 1960s era

B. Deckard¹, Q. Perry¹, G. Abele², and D. Paustenbach¹. ¹TRC Strategic Health Sciences, Jackson, WY; and ²TRC Strategic Health Sciences, Denver, CO.

Background and Purpose: Asbestos-containing gloves were once common for high-temperature industrial processes until their discontinuation in the late 1970s. Despite their widespread use, few studies have provided quantitative, task-specific exposure data under realistic conditions. Prior investigations often lacked background controls, proper analytical verification, or representative work practices. This study improved on prior ones and evaluated airborne chrysotile concentrations generated during realistic simulated use of historical asbestos gloves and tongs to characterize occupational exposure potential. **Methods:** Three pairs of historical gloves (67-97% chrysotile) were analyzed in controlled simulations representing three work tasks - welding, hot material transfer, and handling laboratory equipment - along with a separate trial using asbestos-covered tongs. Simulations were conducted within a sealed 16 × 16 × 8 ft chamber ventilated at 3.5 air changes per hour to conservatively replicate typical working conditions. Personal and area samples were collected during 15-minute tasks and analyzed by both Phase Contrast Microscopy (PCM) and Transmission Electron Microscopy (TEM) to derive Phase Contrast Microscopy Equivalent (PCME) concentrations. **Results:** Average personal PCME concentrations were 0.074 f/cc for welding, 0.287 f/cc for hot material transfer, 0.092 f/cc for laboratory handling, and 0.004 f/cc for tong use. Area concentrations were approximately 22-35% of personal levels, consistent with bystander exposure models. When extrapolated to realistic durations of daily glove use, the estimated 8-hour time-weighted average (TWA) exposures were 0.018 f/cc, 0.014 f/cc, 0.005 f/cc, and 0.0001 f/cc, respectively. The average concentrations were substantially below the current

OSHA permissible exposure limit (PEL) of 0.1 f/cc. No significant differences were observed between gloves of differing asbestos content. **Conclusions:** These results showed that airborne asbestos concentrations from asbestos glove use are minimal, even under intentionally aggressive and repetitive conditions. The data align with earlier glove simulation studies (Longo and Hatfield, 2001; Cherrie et al., 2005) but incorporated improved analytical and procedural controls, including both PCM and TEM analyses, background sampling, and reproducible chamber conditions. The results provide quantitative evidence that historical uses of asbestos gloves produced airborne fiber concentrations severalfold below regulatory limits, both for workers and nearby bystanders (even under these unusually aggressive work practices). Simulated industrial use of asbestos-containing gloves and tongs yielded low airborne chrysotile concentrations under worst-case handling scenarios. Modeled daily 8-hr TWAs remained below OSHA's 0.1 f/cc PEL, suggesting negligible inhalation risk under typical historical work practices.

PS 4005 Need for Fit-for-Purpose Approaches that Integrate Dose, Mechanism, and Context of Use with Key Characteristics when Evaluating the Carcinogenic Potential of Widely Used Therapeutics: A Case Study of Acetaminophen

D. Wikoff¹, S. Fitch², G. Eichenbaum³, S. Ejaz⁴, W. Klaren¹, and M. Southall⁴. ¹ToxStrategies Inc, Asheville, NC; ²ToxStrategies Inc, Asheville, TX; ³Oaktree Life Sciences Consulting, Summit, NJ; and ⁴Kenvue Medical Clinical and Safety Sciences, Summit, NJ.

Background and Purpose: The key characteristics of carcinogens (KCCs) can provide an organizational framework for grouping data by activity type during initial review stages, but meaningful conclusions about hazard and risk require further analysis through pathway-based approaches. Though complex, pathway-based are readily performed for drugs, such as acetaminophen (APAP), a substance with well-characterized biochemical activity related to therapeutic effects as well as potential toxicity. In such a case, simple groupings of biochemical properties by KCCs oversimplify complex biological processes that do not adequately represent the state of knowledge. The objective herein was to design an approach for evaluating mechanistic data for APAP that incorporates existing understanding of toxicity and efficacy pathways as part of an assessment of potential carcinogenicity involving KCC concepts. **Methods:** Literature reporting data related to biological pathways associated with APAP toxicity and therapeutic effects and applications of KCC to APAP was identified. Key events (KEs) and Key Event Relationships (KER(s)) from the pathways identified in the literature and/or previous assessments were inventoried. This inventory included an evaluation of each pathway or event in different model systems and in humans taking into account context of use, dose, toxicokinetics and relevance to humans with mapping to relevant KCCs, where applicable. An approach for assessing APAP mechanistic data for potential carcinogenicity within the context of established pathways for toxicity and efficacy was developed based on the collective assembly of pathways and mapping of KEs and KERs. **Results:** An extensive body of evidence related to biological pathways for efficacy at therapeutic doses and toxicity following supratherapeutic exposures were identified. Pathways for toxicity result primarily in liver injury and to a lesser extent kidney injury driven by CYP2E1 metabolism of APAP to NAPQI, depletion of glutathione, protein adducts and oxidative stress, mitochondrial dysfunction, and cell death at supratherapeutic doses. These KEs map to electrophilicity and genotoxicity (KCs 1, 2), oxidative stress (KC 5), and acute cell death (KC10); however, activity within and across KE and KERs are fundamentally distinct from chronic, DNA-damaging processes of classical carcinogenesis, nuanced by context-dependent conditions that do not result in carcinogenic outcomes. Pathways for pharmacological activity largely focused on biological events resulting in analgesic and antipyretic effects via COX1 and COX2 inhibition by acetaminophen itself and metabolism of acetaminophen resulting in interactions with other nociceptive pathways (e.g., TRPV1, CB1; direct or indirect) and inhibition of prostaglandin production. Pathways related to activity at these receptors appear to have some highly context-dependent immune modulatory and epigenetic effects. While these events could conceptually map KCs for epigenetic alterations (KC 4), immunosuppression (KC7) and receptor mediated effects (KC8), the activity within these KCs are time- and context-dependent, and transient and result in outcomes that are not adverse in humans. In some instances, there is evidence that acetaminophen may provide anti-tumor effects at higher doses (e.g., acting as a free radical scavenger that reduces oxidative stress). **Conclusions:** The assembly of the KEs and contextual attributes provide an acetaminophen-specific approach for organizing and assessing mechanistic data. Some of the KEs and KERs associated with acetaminophen at therapeutic and supratherapeutic exposures map to several of the KCCs. Given that these established pathways do not lead to carcinogenic effects, the collective results from the mapping and approach proposed herein highlight the importance of assessing context around KCC activity, warranting caution that not doing so may result in misleading conclusions about carcinogenic potential. The proposed approach can be applied by investigators interested in assembling and assessing mechanistic data for APAP using a KCC approach.

A. Ortiz Balsero¹, B. Wang¹, J. Kahrizangsi¹, Y. Li¹, G. Gray², L. Fernandez-Ballester¹, C. Yan¹, M. Rashedul Hasan¹, and J. Baumert¹. ¹University of Nebraska-Lincoln, Lincoln, NE; and ²Milken Institute School of Public Health, Washington, WA. Sponsor: G. . Gray, Society for Risk Analysis

Background and Purpose: The growing ubiquity of nano- and microplastics (NMPs) has raised concern about their potential toxicity to humans. Despite a rapidly expanding body of animal toxicity studies, no systematic approach exists to integrate findings for hazard characterization, hindering the development of reference values for human health and leaving risk assessments largely underdeveloped. **Methods:** Here, a structured, two-phase approach to derive benchmark dose (BMD) from recent mammalian oral exposure studies is illustrated through neurotoxicity as a proof-of-concept application. Phase 1 involved a PRISMA-guided systematic review using seven electronic bibliographic databases (n=41,784), screened for relevance using a fine-tuned large language model (LLM) and manual process. Phase 2 applied Bayesian dose-response modeling with a benchmark response of 10%, using Bayesian model averaging and strict exclusion of poorly fitted or extrapolated endpoints using three main metrics (i) precision, BMD/BMDL < 20; (ii) interval width, BMDU/BMDL < 50; and (iii) data support, BMD/ lowest non-zero administered dose < 10. For polymers with numerous qualifying endpoints (PET and PS), a statistical prioritization step was further applied to limit design bias and emphasize the most informative regions of the dose-response curve (lower end). Endpoints at or below the most likely BMD value were retained to capture data-dense, well-supported regions, while isolated high-BMD estimates were given less weight. **Results:** Phase 1 yielded 22 eligible oral-exposure studies on NMP-induced neurotoxicity among mammalian models, all of which passed Risk of Bias (RoB) and quality assessment and quality control QA/QC evaluations (average score = 82.85%) for inclusion in further analysis. Across these 22 studies, it is shown that exposure to NMPs disrupts neural integrity and function at molecular, cellular, and behavioral levels. These effects lead to dopaminergic neuron loss, reduced neurogenesis, and behavioral impairments such as memory loss, depression-like, and even Parkinson's-like symptoms. Phase 2 processed 134 statistically and/or biologically significant endpoints across polystyrene (PS; n = 98; sun-acute, sub-chronic, and chronic; MNP), polypropylene (PP; n = 5, sub-acute; MP), polyethylene terephthalate (PET; n = 23; sub-acute; MP), low-density polyethylene (LDPE; n = 3; sub-chronic; MP), and polylactic acid (PLA; n = 5; sub-acute; MP), encompassing neuropathological, neurochemical, behavioral, and developmental outcomes. Of the 134 modeled endpoints, 79 (59.0%) satisfied all three. Subsequent statistical and expert-based prioritization in Phase 2 refined these to 26 high-confidence endpoints suitable for quantitative comparison and hazard characterization. The benchmark dose lower confidence limits (BMDLs) for these prioritized endpoints ranged from 2.22×10^{-4} to $2.36 \text{ mg}\cdot\text{kg}^{-1}\cdot\text{day}^{-1}$, representing the most statistically and biologically robust findings. Among the evaluated polymers, PS contributed to the largest and most diverse dataset (30.8%), enabling meaningful comparisons between PS-NPs and PS-MPs. In contrast, comparisons across polymer types (PP, PET, LDPE, PLA) remain limited due to the highly uneven distribution of available studies and endpoints. **Conclusions:** In conclusion, findings suggest that MNP exposure may disrupt neural integrity and function across molecular, cellular, and behavioral domains, even at low exposure levels. The derived neurotoxic endpoints offer a robust foundation for expert elicitation within multi-criteria decision analysis platforms, facilitating their evaluation alongside other systemic endpoints (e.g., hepatic, cardiovascular, reproductive, immune). More broadly, the proposed framework provides a structured approach to assessing the toxicity of emerging contaminants by integrating dose modeling, evidence synthesis, and expert judgment to inform scientifically defensible reference values. It further supports transparent risk communication and highlights critical data gaps to guide future research.

PS 4007 **Systematic Evidence Reviews: When to Stop Screening?**

B. E. Howard, A. Tandon, R. Elmore, and R. R. Shah. Sciome LLC, Research Triangle Park, NC.

Background and Purpose: Systematic evidence reviews and large-scale bibliographic screening are labor-intensive endeavors, often requiring reviewers to inspect thousands of titles and abstracts to identify the relevant literature. The software SWIFT-Active Screener introduces a dual-model approach, combining an active-learning prioritization engine with an integrated recall-estimation algorithm, to significantly reduce the manual screening burden and, critically, to provide a principled basis for **when to stop** screening. **Methods:** As screening proceeds, the tool uses a continuously updated active-learning model that reorders the unscreened document list, placing the most likely relevant items at the top based on past reviewer decisions. In parallel, it employs a statistical model (based on a negative-binomial distribution) to estimate how many relevant documents remain among the unscreened set, thereby generating a real-time estimate of cumulative recall (i.e., the proportion of all relevant documents identified so far). Once the estimated recall reaches a predefined threshold (for example 95%), the system alerts the review team that, under its model assumptions, the marginal yield of additional screening is likely to be very low. Thus, the software supplies a data-driven “when to stop” criterion, reducing wasted effort while maintaining high coverage of relevant records. **Results:** In validation across

26 diverse systematic-review datasets, the authors found that on average 95% of relevant documents were identified after screening only 40% of the total references; in larger projects ($\geq 5,000$ records) the average fraction screened to reach 95% recall dropped to 34%. Moreover, the recall estimator tended to be conservative: among simulated runs that stopped when the estimate reached 95%, the median **true recall** achieved was ~99%. These findings illustrate that integration of recall-estimation with active learning allows reviewers to stop far earlier than full-list screening while retaining strong confidence in achieving near-complete retrieval of relevant documents. **Conclusions:** SWIFT-Active Screener offers a scalable, principled framework for screening large bibliographic sets: active learning accelerates identification of relevant records, and the “when to stop” recall estimator provides reviewers with a defensible rule for terminating screening. By shifting from exhaustive manual review to targeted screening with a stopping threshold, the tool reduces resource requirements, speeds review timelines, and mitigates the key challenge of “how do we know when we’ve found enough?” Unlike tools that offer AI powered classification, where a black box algorithm classifies documents as include/exclude, our novel approach allows an expert human screener to make the inclusion decision and thus remain in control of this critical step in the literature review process while still saving a significant amount of time and achieving near perfect outcomes.

PS 4008 **Practical Predictive Risk Assessment Approaches for Chemicals**

A. Goetz¹, R. Currie², O. Alexander¹, and N. Ryan¹. ¹Syngenta Crop Protection LLC, Greensboro, NC; and ²Syngenta Crop Protection, Bracknell, United Kingdom.

Background and Purpose: Regulatory directives to reduce animal testing in chemical safety assessments have created a need for improved and modern approaches to testing and assessment. A novel integrated framework for chemical safety assessment that combines New Approach Methodologies (NAMs) with weight of evidence and read-across analysis is one such approach. This framework, specifically designed for non-genotoxic agrochemicals with established pesticidal modes of action, provides a structured approach for predicting human and ecological toxicity risk while minimizing vertebrate animal testing. **Methods:** The framework employs a tiered integration of multiple lines of evidence including published data, regulatory databases, and physicochemical properties to address endpoint-specific regulatory needs. In addition, the RISK21 platform is implemented for exposure-based risk predictions and uncertainties of each line of evidence are systematically characterized. The framework focuses on chemicals within well-characterized chemical classes, utilizing data-rich safety profiles of analogues. A corresponding framework functionality survey evaluates the applicability of this approach to new chemicals. **Results:** We will present application of the survey and the framework with an agrochemical case study that leverages existing toxicological data from source analogues to evaluate dietary and occupational exposure scenarios. Comparison of the toxicological endpoints to predicted exposures as determined by regulatory authorities confirmed that the target chemical proposed uses were unlikely to pose human health risks. This case study illustrates how systematic evidence collection, evaluation, weighting, and integration can inform decisions while maintaining scientific rigor and minimize unnecessary animal use. **Conclusions:** The framework functionality survey was a valuable preliminary assessment tool, enabling evaluation of the framework’s applicability before full implementation. This combined approach provides structured guidance for predictive toxicity risk assessment while maintaining robust safety standards and offers a practical path toward regulatory compliance with reduced animal testing and demonstrates the viability of NAMs in regulatory safety assessment. This work represents a significant step toward meeting regulatory requirements while advancing the goal of eliminating reliance on vertebrate animal toxicology testing.

PS 4009 **A Structured Protocol for Developing Adverse Outcome Pathways: Ensuring Transparency, Reproducibility and FAIR compliance**

B. Viviani¹, K. Jagiello², B. Judzińska², M. Midali¹, M. Serafini¹, M. Stepniak², K. Audouze³, D. Deepika⁴, T. Hofer⁵, C. Ibanez⁶, T. Jaymay³, A. Karakoltzidis⁷, S. Kumar⁴, V. Kumar⁴, O. Laurent⁶, C. Mandin⁶, O. Myhre⁵, N. Papaioannou⁷, E. Renieri⁷, D. R. Schultz⁷, A. Stratidakis⁸, M. Torrente⁴, and M. W. Wojewodziec⁵. ¹Università degli Studi di Milano, Milano, Italy; ²University of Gdansk, Gdansk, Poland; ³University Paris Cité, Inserm, Health Fex, Paris, France; ⁴Pere Virgili Institute for Health Research, TecnaTox, Universitat Rovira i Virgili, Tarragona, Spain; ⁵Norwegian Institute of Public Health, Oslo, Norway; ⁶Autorité de Sûreté Nucléaire et de Radioprotection, Fontenay-aux-Roses cedex, France; ⁷Aristotle University of Thessaloniki, Thessaloniki, Greece; and ⁸University School for Advanced Study (IUSS), Pavia, Italy.

Background and Purpose: For regulatory application, Adverse Outcome Pathways (AOPs) require systematic planning and robust protocol to ensure the integrity and consistency of the AOP framework. While the OECD’s guidance on AOP development is essential, additional strategies are needed to ensure transparency, reproducibility, and reliability. Central to this is adherence to the FAIR principles (Findability, Accessibility, Interoperability, and Reusability) which ensures that AOP elements, data, and processes are transparent, traceable, and usable by both humans and

machines. **Methods:** A PARC project case study was used to design a stepwise method for developing an AOP network that links organophosphate and organochlorine pesticide exposure to Alzheimer's disease. The methodology was defined a priori, before any data collection, by establishing a clear problem formulation and outlining a robust plan to guide subsequent steps and determine the scope of relevant evidence. This structured approach aims to ensure transparency, reproducibility, and confidence in AOP development. **Results:** The process for developing the AOP network was described in a protocol and can be summarised in four phases. The first step is to formulate the problem in order to define the objective, scope, evaluation criteria (biological plausibility, essentiality, empirical evidence and weight of evidence) and data sources. The second step is to define methods for mapping evidence and refining the AOP structure, starting from the official AOP repository. A decision tree has been developed to help search for specific events. One challenge is the replication of key events that address similar biological concepts, which complicates their reuse in the context of new AOPs. Early application of a protocol can guide decisions. The third step outlines whether a systematic or structured literature analysis will be conducted, paying particular attention to formulating search strategies. Collaborating with professional librarians is highly recommended to ensure effective literature retrieval. The fourth step involves appraisal tools to identify uncertainty and assess studies' reliability and relevance. Structured tools support this process. **Conclusions:** The approach has the advantage of being in line with FAIR principles and preventing data-driven judgements. This structured approach promotes stronger collaboration and coordination among contributors, as well as greater methodological consistency and transparency. A professional librarian-supported literature analysis ensures comprehensive coverage of all relevant information, providing transparent, reproducible documentation based on the best available evidence, thereby enhancing the credibility of the results. A formal appraisal of the evidence supports the overall assessment of the consistency and precision of the dataset, increasing confidence in an AOP. **Fundings:** "this work was carried out in the framework of the European Partnership for the Assessment of Risks from Chemicals (PARC) and has received funding from the European Union's Horizon Europe research and innovation programme under Grant Agreement No 101057014. Views and opinions expressed are however those of the author(s) only and do not necessarily reflect those of the European Union or the Health and Digital Executive Agency. Neither the European Union nor the granting authority can be held responsible for them".

PS 4010 Defining Best Practices for the Use of Sequence Alignment to Predict Across Species Susceptibility to Inform Taxonomic Domain of Applicability Descriptions in the Adverse Outcome Pathway Wiki

R. H. Staub¹, D. Villeneuve², P. Schumann³, J. Frisch³, T. Karschnik³, and C. A. LaLone⁴. ¹ORISE, ORD-CCTE-GLTED-STB, Duluth, MN; ²OCSP-OMCO-RASD, Duluth, MN; ³ORD-CCTE-GLTED, Duluth, MN; and ⁴OCSP-OPPT-CIPTD-TAIB, Duluth, MN.

Background and Purpose: Adverse outcome pathways (AOPs) map the progression from a molecular-level biological perturbation (often induced by hazardous chemicals in the environment) through several levels of biological organization to an adverse outcome—generally at the individual or population level—relevant for risk assessment. The Adverse Outcome Pathway Wiki (<https://aopwiki.org/>) provides a central repository for descriptions of AOP knowledge. A key aspect of the AOP framework is the definition of the taxonomic domain of applicability (tDOA) for each biological step—or key event (KE)—of a pathway, and the AOP as a whole. The tDOA captures evidence for understanding the species or taxa for which the KE is applicable. Although supporting data from *in vivo* studies carry the highest confidence in weight-of-evidence for defining tDOA, such methods require more resources and time than are practical—thus becoming restrictive in the development of comprehensive tDOAs for the AOP-Wiki. Computational approaches, such as the Sequence Alignment to Predict Across Species Susceptibility (SeqAPASS) tool have the capacity to use existing empirical information from a single species to rapidly generate *in silico* evidence across the diversity of species to support tDOA descriptions. SeqAPASS compares primary amino acid sequences across species and generates predictions of chemical susceptibility based on protein conservation. Once a protein has empirical evidence (e.g. binding/affinity/activity assays, crystallography, molecular docking/dynamics etc.) for species in an AOP—or based on external literature review—SeqAPASS can rapidly evaluate whether that biology is conserved in other (typically untested) species. Those species can then be assigned as the biologically plausible tDOA with low confidence in the weight-of-evidence for the AOP. However, multiple steps in this process require guidance, including how to identify query proteins and accessions for an existing AOP, and how to analyze results from SeqAPASS. As such, case studies were performed to define best practices to standardize the use of SeqAPASS for tDOA descriptions in the AOP-Wiki. **Methods:** AOPs 545 and 548 were used as case examples. Protein accessions were identified for each KE using the AOP-Wiki, external literature review, and the NCBI Protein Database's canonical accession designation. Accessions were submitted to SeqAPASS Level 1 and checked for >10 orthologs. SeqAPASS susceptibility predictions were used to assign low weight-of-evidence tDOA predictions for KEs, and a series of logic statements written into R code were used to combine KE tDOAs across pathways into KER and then AOP tDOAs. **Results:** SeqAPASS predicted shared susceptibility for all mammals for both AOPs, as well as individual susceptibility predictions spanning a variety of clades for the KEs contained within. In all instances, AOP-Wiki/literature-identified accessions were identical to the NCBI canonical

accession, although two accessions had insufficient orthologs for SeqAPASS analysis. Canonical accession identification reduced the time required for SeqAPASS accession identification from ~40 hours to less than 1 hour. **Conclusions:** A flow-chart was developed from the results of the present study to guide future SeqAPASS application to identify AOP tDOAs. Importantly, if the AOP-wiki does not identify a protein accession for a KE, it is recommended to default to NCBI canonical accessions—rather than further literature review—due to accordance of literature-identified protein accessions with NCBI canonical accessions and significant time-saving. If future AOP authors are using isoform-specific information in KEs, NCBI accessions should be clearly identified in the AOP-Wiki text. Usage of the aforementioned flow-chart for accession identification and tDOA combination will increase efficiency and rigor of SeqAPASS application towards identifying AOP-Wiki tDOAs, and advance understanding of how species respond to adverse effects induced by hazardous chemicals.

PS 4011 A Novel Approach to Optimizing the Efficiency of Chemical Toxicity Testing Using Multi-Task Chemical Embeddings and Active Learning

N. J. Wichrowski¹, S. L. Grady¹, M. V. Clemens-Sewall¹, K. K. Rao¹, J. Y. Liu¹, C. L. Richardson¹, S. Ton¹, S. M. Klimkiewicz¹, J. D. Resnik¹, J. G. Showalter¹, Y. Chushak^{2,3}, A. J. Keebaugh^{2,4}, T. R. Sterner^{2,3}, and R. A. Clewell^{2,5}. ¹The Johns Hopkins University Applied Physics Laboratory, Laurel, MD; ²Air Force Research Laboratory, Wright-Patterson AFB, OH; ³Henry M. Jackson Foundation for the Advancement of Military Medicine, Inc., Wright-Patterson AFB, OH; ⁴BlueHalo an AV company, Dayton, OH; and ⁵Eagle Integrated Services, Inc., Wright-Patterson AFB, OH.

Background and Purpose: Military personnel are subjected to a wide range of complex and varying environmental factors that can negatively impact their health and mission readiness. Machine learning (ML)-based predictive models can be used to maximize the utility of limited data. These models aim to support rapid decision-making and reduce the need for time-consuming and costly animal testing. However, a major hurdle to their success is the lack of sufficiently large biological data sets for training. To address this issue, an active learning (AL) approach was adapted, which combines a multi-task (MT) ML pipeline with laboratory health and mission readiness. This approach allows for more strategic model development by identifying areas of uncertainty, conducting targeted experiments, and then retraining the model with new information. **Methods:** A directed message passing neural network (D-MPNN) learned a vector representation of molecular structure, which was used to train downstream random forest models for new tasks with insufficient data to train models from scratch. AL was performed on a low-data *in vitro* endpoint for inhibition of solute carrier proteins 6A2 and 6A3 (SLC6A2/3, norepinephrine and dopamine transporters). A specialized loss function was used to select groups of 10 novel chemicals for *in vitro* experiments, balancing the goals of expanding the applicability domain, reducing uncertainty, and maintaining class balance (Active/Inactive results). *In vitro* tests were performed using overexpression cell lines, and results were used to update the D-MPNN and select additional test chemicals. Two cycles of AL were conducted for SLC6A2/3 as well as a separate cycle for a task based on inhibition of monoamine oxidase A (MAO-A) that used a cell-free assay. Model performance was quantified using test set area under the curve (AUC) values for the receiver operating characteristic (ROC) and precision-recall curve (PRC). A statistical analysis of 100 model training seeds compared AUC values of the model before AL against versions of the model after 1 or 2 AL cycles. **Results:** In the first cycle of AL performed on the SLC6A2/3 endpoint, the model identified 10 test chemicals. Four (flutolanil, 2-bromodibenzofuran, 2-acetylaminofluorene, and N-phenyl-1-naphthylamine) were found to be Active in the *in vitro* assay at non-cytotoxic concentrations. The second AL cycle identified 4 additional active compounds: hexadecyl trimethyl ammonium chloride; 4-chloro-1,1'-biphenyl; paclobutrazol; and 1,6-dinitropyrene. The first AL cycle produced modest increases in model AUC. The second AL cycle produced greater improvement, highlighting the benefit of sequential AL rounds. On average, ROC AUC values increased by a modest 0.029 per iteration; PRC AUC values slightly increased by 0.010 per iteration. For the MAO-A AL cycle, the model selected 10 chemicals, of which 7 were Active *in vitro*. Model improvements for this task were marginal due to the smaller initial dataset compared to the SLC6A2/3 dataset. **Conclusions:** This project demonstrated utility of using AL model-directed experiments to fill data gaps and improve model performance. Integrating model development and data collection shows promise for expanding the model prediction range while minimizing the need for new data collection. The proposed AL approach coupled with the MT-ML pipeline provides a more generalized model of chemical space that is robust against data scarcity. While further improvements to the MT-ML model and refinements to the AL process are needed, the approach demonstrates a step forward in implementing modernized human risk assessment for complex operational exposures. *Disclaimer:* No DoD endorsement implied.

S. Chakravarti, and M. Girireddy. MultiCASE Inc, Mayfield Heights, OH.

Background and Purpose: Assessment of chemical toxicity is fundamental to risk evaluation, yet traditional approaches like Cramer's Decision Tree (CDT) and Expanded Decision Tree (EDT) rely on rigid, expert-defined rules, lack scalability and quantitative measures of uncertainty. We introduce a data-driven framework that predicts toxicity thresholds—such as Thresholds of Toxicological Concern (TTCs)—using a dual-fingerprint similarity search that captures both global molecular features and toxicity-relevant structural alerts. This approach provides mechanistic interpretability, built-in applicability domain assessment, scalability, and quantitative uncertainty estimation, overcoming key limitations of decision tree-based methods.

Methods: A reference database of compounds with No-Effect Level (NEL) values derived from *in vivo* experiments was used. For every target compound, a dual similarity measure was computed: (1) global molecular similarity, and (2) toxicity-relevant similarity from weighted structural alerts mined from experimental data. These were combined into a weighted similarity score to retrieve reference compounds above a threshold, forming a representative collection for the target compound. Cumulative NEL distributions were used to derive TTC values and identified alerts were used for assessing toxicity mechanisms. Predictions were benchmarked against Munro and Expanded Decision Tree datasets. **Results:** • Successfully retrieved representative collection for diverse query compounds, yielding robust TTC predictions. • Demonstrated mechanistic interpretability, with structural alerts identified in both query and reference compounds. • Achieved good correlation between predicted NEL at 5% cumulative probability and actual NEL values, supporting quantitative reliability (similarity cutoff = 0.7, $r^2 = 0.44$, coverage = 85%). • Demonstrated greater flexibility and quantified uncertainty than rule-based methods, providing confidence intervals for TTC predictions and flags for structurally novel compounds. • Comparative analysis revealed better adaptability than CDT/EDT approaches, while maintaining regulatory relevance. **Conclusions:** This framework provides a general, adaptable, and mechanistically interpretable method for deriving TTC values. By combining global general molecular features with toxicity-weighted structural alerts, it avoids the rigidity of rule-based trees, allows quick incorporation of new data, and introduces systematic mechanisms for uncertainty and domain applicability assessment. Limitations remain for compounds with novel structural features, but such cases can be flagged by applicability checks. Overall, this approach represents a next-generation alternative to Decision Tree-based methods for toxicity prediction.

PS 4013 Investigating the feasibility of deriving new environmentally relevant Thresholds of Toxicological Concern (TTCs) from estimated human equivalent benchmark dose (eBMD_{HED}) values

G. Patlewicz¹, A. Mihalchik¹, C. M. Thompson², A. East³, and S. Borghoff¹.

¹ToxStrategies, Durham, NC; ²ToxStrategies, Houston, TX; and ³ToxStrategies, Asheville, NC.

Background and Purpose: The Threshold of Toxicological Concern (TTC) is a pragmatic approach used to establish safe thresholds below which there is likely no appreciable risk to human health. Kroes et al (2004) presented a tiered TTC approach that established several human exposure thresholds over several orders of magnitude, ranging from 0.0025 µg/kg-day to 30 µg/kg-day. The lowest tier is for substances that raise a concern of genotoxicity based on structural alerts for genotoxicity. For substances without structural alerts for genotoxicity, there are a series of non-cancer TTC tiers, which are based on the Cramer et al (1978) decision tree. Derivation of TTC values for each of these Cramer classes originates from work by Munro et al (1996) who compiled a dataset of NOELs for 613 substances that had been tested in subchronic, chronic and reproductive-developmental repeat-dose oral toxicity studies. In Nelms et al (2019), an evaluation was performed to explore whether TTC values derived from toxicity data on environmentally-relevant substances as compiled in the EPA Toxicity Values DB (ToxValDB) would give rise to comparable TTC values as those derived by Munro et al (1996). In that study, statistical outliers were removed, but no effort was made to review the quality of the individual studies. TTC values are calculated by taking the 5th percentile of the NOEL values and then adjusted 100-fold by default intra and interspecies uncertainty factors to derive a final value. More recently, efforts by Aurisano et al (2023) and Harrill et al (2025) have attempted to develop curated datasets restricted to effect levels, exposure routes, study designs and species relevant for deriving toxicity values. The effect levels are then adjusted to chronic human equivalent benchmark doses using the World Health Organization (WHO) framework which considers different conceptual models and magnitudes of effects for different types of endpoints within toxicity studies. **Methods:** In this study, the feasibility of deriving new oral TTCs was investigated using estimated human equivalent benchmark dose (eBMD_{HED}) values from EPA's ToxValDB v96.1. Study level eBMD_{HED} values were generated using the R code from https://github.com/USEPA/toxvaldb_dcapprep. Chemical level values, i.e. those representative of the study level eBMD_{HED} values, were derived by taking the 25th percentile of the fitted normal distribution. Chemical structural information was pulled from the EPA CompTox Chemicals Dashboard resulting in a dataset of 4076 substances. The chemical set was processed through a computational implementation of Kroes et al (2004) workflow. The 1271 substances assigned to the Cramer structural classes were then processed through the Toxtree Cramer module.

The 5th percentile of the empirical cumulative distribution function for each Cramer structural class was then derived. **Results:** The Cramer I class 5th percentile was estimated as 4.24 mg/kg-day. Applying a 10-fold intraspecies factor, resulted in a TTC of 0.424 mg/kg-day which was 14 times less conservative than the current TTC for Cramer I (0.03 mg/kg-day). The TTC derived for Cramer III gave rise to a value of 0.014 mg/kg-day, which was 9.4 times higher than the default Cramer Class III TTC value (0.0015 mg/kg-day) derived from the Munro dataset. Given there were only 56 substances in Cramer II, no TTC value was derived. **Conclusions:** Ongoing work will consider other ways to subcategorize the dataset beyond reliance on existing Cramer structural classes. TTC values derived from human equivalent chronic values (eBMD_{HED}) offer promise of establishing exposure thresholds that are more human relevant whilst still protective of human health.

PS 4014 Automating Structure-Based Analogue Selection for Read Across: The Power of Matched Molecular Pairs

M. Irshad¹, E. Byrd², L. Reinsalu², and C. Lester². ¹The University, Cincinnati, OH; and

²The Procter & Gamble Company, Mason, OH.

Background and Purpose: Read across is one of the most important animal alternative methods and is used to establish the safety of a data-poor target compound using toxicological data associated with a related data-rich analogue. The process of identifying related compounds starts by comparing the molecular structures of the target compound with those of potential analogues. The most common approach involves using algorithms to calculate the overlap of molecular fingerprints; however, this method's effectiveness hinges on the choice of fingerprints and may not accurately reflect analogue quality. To enhance this process, a matched-molecular pair (MMP) approach has been developed, linking small structural changes, defined as MMP transformation rules, to analogues suitable for read across. This poster presents a summary of the structural changes associated with analogues that are promising candidates for read-across predictions. It also illustrates how to encode these transformations using two different programming languages, ensuring that the method is accessible even to those without extensive chemistry expertise. **Methods:** MMP transformations associated with analogue quality have been summarized (Lester and Yan, 2021). Strategies and methods used to automate the approach using Pipeline Pilot and Python are presented. Matched target-analogue pairs of structures produced by one- or two-bond cuts are selected if they possess the same functional groups resulting in pairs that fall into defined structural categories. Encoding the algorithms for categorizing each target-analogue pair is described including challenges and best approaches. Lester, C. C.; Yan, G. A matched molecular pair (MMP) approach for selecting analogs suitable for structure activity relationship (SAR)-based read across. *Regulatory Toxicology and Pharmacology* **2021**, *124*, 104966. DOI: <https://doi.org/10.1016/j.yrtph.2021.104966>. **Results:** The programs output MMP transformation categories, which provide straightforward and transparent comparisons of molecular structures that are likely to exhibit similar toxicities. Each program first identifies innocuous salts of organic acids (carboxylic, sulfonic, phosphoric) or bases (amine) as well as stereoisomers. Remaining structural transformations identified include the following for aromatic compounds: addition/deletion of a small (C1-C4) alkyl group to the ring, change in alkyl substituent chain length or branching, different locations of the same substituents on the aromatic ring, or different numbers of the same substituents. For aliphatic compounds structural transformations include the following: change in alkyl chain length, branching or bond order, change in number of repeat units, or the addition of a functional group such as an OH group. To illustrate the simplicity and utility of the technique, case study examples are presented for each category type. **Conclusions:** The Matched Molecular Pair (MMP) approach for analogue selection has been successfully automated using Pipeline Pilot and Python. This automation generates output that categorizes target-analogue pairs, providing clear, structure-based analogues with strong potential for accurate read across predictions. Following selection, quantitative comparisons of similarities in metabolism, reactivity, and physicochemical properties are needed to validate the use of each analogue as a data source. This streamlined process enhances the reliability of toxicity assessments and supports informed decision-making in chemical safety evaluation.

PS 4015 Integrating Structural and Mechanistic Evidence to Select Relevant Analogs for Read-Across Assessment

T. Chan¹, G. Hilton², A. Goetz³, and A. Karmaus³. ¹Texas A&M University, College

Station, TX; ²PETA Science Consortium International e.V., Greensboro, Germany; and

³Syngenta Crop Protection LLC, Greensboro, NC.

Background and Purpose: Risk assessment for food-use conventional pesticides generally requires toxicity testing on over 20 mammalian-based studies and is estimated to consume 10,000-15,000 animals per pesticide regulatory evaluation. In working towards animal reduction, read-across assessments are being increasingly utilized to evaluate if sufficient information is available from chemical analogs to inform data needs for a scientifically sound and credible characterization of a target chemical's risk profile. The work herein explores a new approach for analog selection and inclusion criteria applied to a data-rich pesticidal chemical class, acetyl-CoA carboxylase (ACCase) inhibitors. Structural, physicochemical, pesticidal mode of

action, and biological similarity were included to identify relevant analogs with existing toxicity data. This case study supports a precautionary, health-protective assessment of pesticides while reducing reliance on animal studies. **Methods:** An inventory of 798 pesticides was compiled from three sources: 212 from the Fungicide Resistance Action Committee (FRAC), 325 from the Herbicide Resistance Action Committee (HRAC), and 261 from the Insecticide Resistance Action Committee (IRAC). Structural similarity was assessed by calculating Tanimoto scores using aggregated ToxPrint (730 bits), MACCS (166 bits), and PubChem (641 bits) fingerprints. ToxPrint data were obtained from the CompTox Chemicals Dashboard, while MACCS and PubChem fingerprints data were generated using the rcdk v3.8.1 R package. After feature reduction, the total number of aggregated bits decreased from 1537 to 1017. Biological similarity assessment to refine the list of potential analogs was anchored on identifying those that do not induce activation of the peroxisome proliferator-activated receptor (PPAR). PPAR mechanistic assay outcomes for multiple PPAR isoforms were retrieved from the Integrated Chemical Environment (ICE v4.1.1). Seventeen PPAR activity assay endpoints were evaluated; pesticides showing less than 10 percent PPAR activity across tested assay endpoints were retained. Absorption, distribution, metabolism, and excretion (ADME) information, with an emphasis on metabolic sites and routes of excretion, was also extracted from regulatory public data sources and CompTox Chemicals Dashboard. Chronic toxicity studies were identified and compiled from regulatory document searches. Candidate analogs were then prioritized based on Tanimoto score, PPAR activity, chemical class, toxicological mode of action, ADME properties, and available chronic toxicity data. **Results:** The aggregated chemical fingerprints provided a broad coverage of structural features while emphasizing toxicologically relevant descriptors. PPAR activity was used to filter out PPAR-activating compounds that would be more sensitive in producing rodent tumors. Approximately 300 pesticides exhibited PPAR activity below 10 percent. Applying a distribution-based cutoff yielded eighteen analog candidates, compared to twenty-five without PPAR activity evaluation, with spirotetramat emerging as the closest relevant analog (Tanimoto score ≈ 0.7). Visual evaluation of structural similarity among the top identified analogs by PCA analyses confirmed overlap in chemical space, reinforcing their relevance. Of the analogs with publicly available data and regulatory reviews, many exhibited comparable ADME characteristics, including good absorption, hepatic metabolism, and primary urinary excretion. Of the 18 analogues retained for further read-across assessment, the 90-day rat NOAELs ranged from 1.69 to 1509 mg/kg day, while the dog NOAELs ranged from 0.5 to 1038 mg/kg day. **Conclusions:** An effective analog selection strategy for read-across assessment integrates structural, mechanistic, and empirical evidence in alignment with the latest international read-across guidance. By incorporating computational tools and similarity cutoff criteria, the approach enhances robustness and transparency to better support read-across assessment. Overall, this approach demonstrates a systematic and evidence-based method for selecting the most suitable analogs for regulatory read-across applications.

PS 4016 Physiologically Based Kinetic Model of Dibutyl Phthalate and Reproductive Hormones in Female Mice

I. Chagolla¹, J. P. Sluka², Q. Zhang³, N. Biomi¹, G. Jiang¹, Z. R. Craig⁴, M. Zelinski⁵, A. J. Krieg⁵, and K. H. Watanabe¹. ¹Arizona State University, Glendale, AZ; ²Indiana University, Bloomington, IN; ³Emory University, Atlanta, GA; ⁴University of Arizona, Tucson, AZ; and ⁵Oregon National Primate Research Center, Beaverton, OR.

Background and Purpose: Phthalates are a group of chemicals used in the manufacturing of many plastic products. Dibutyl phthalate (DBP) and phthalates in general have been shown to have effects on the endogenous reproductive hormone levels of both sexes, and DBP historically is higher in women of reproductive age. Studies in male and female rats exposed to DBP utilized physiologically based kinetic (PBK) models to characterize the absorption, distribution, metabolism, and excretion (ADME) behavior of DBP in the body. However, to our knowledge, there are no PBK models that incorporate endogenous hormone changes due to DBP exposure. Thus, in support of our NIH Virtual Consortium for Translational/Transdisciplinary Environmental Research (ViCTER) grant, "In Vitro to In Vivo Extrapolation of Toxicant Effects on Ovarian Function" we developed a PBK model for female mice exposed to DBP orally. **Methods:** Our PBK model was designed to simultaneously simulate the behaviors of nine molecules: DBP, its metabolite monobutyl phthalate (MBP), 17 β -estradiol, testosterone, androstenedione, progesterone, inhibin B, luteinizing hormone (LH), and follicle-stimulating hormone (FSH). To achieve this, we designed a conceptual model consisting of four tissue compartments (i.e., gut, liver, ovary and "other"), and blood. We formulated mass-balance differential equations for each compartment that account for the ADME of the nine molecules. We used COPASI to build and run the model. Model parameter values (e.g., body mass, organ volumes, blood flow rates, kinetic rate constants, partition coefficients, etc.) were measured directly by experiments performed for this project when possible, obtained from the literature, or scaled allometrically. Model predictions will be evaluated with experimental data as they become available. Goodness-of-fit will be determined quantitatively. **Results:** The PBK model comprises over 30 ordinary differential equations that are numerically solved simultaneously in COPASI, enabling it to predict concentrations of the nine molecules in each compartment as a function of time. Some unique features of this model include steroidogenesis pathway reactions in the ovary that lead to the production of hormones of interest, and regulatory feedback control of LH and FSH. **Conclusions:** This study is a first attempt to develop a PBK model for DBP in mice that incorporates changes in endogenous hormones.

Additional work remains to evaluate its ability to simulate other DBP exposure scenarios. The model's predictive abilities allow us to simulate different exposure scenarios and generate new hypotheses about the mechanism of action of DBP and MBP. Finally, this model will serve as a foundation for developing a PBK model for rhesus macaques exposed to DBP.

PS 4017 FINS: An Interactive Platform for Automated Zebrafish Image Analysis and Morphological Screening

A. Tandon¹, A. B. Oktay¹, E. McAfee¹, L. Truong², A. J. Green¹, B. E. Howard¹, R. L. Tanguay², and R. R. Shah¹. ¹Sciome LLC, Research Triangle Park, NC; and ²Oregon State University, Corvallis, OR.

Background and Purpose: Zebrafish (*Danio rerio*) embryo assays are increasingly recognized as a powerful and scalable model for developmental and toxicological studies, as zebrafish embryos themselves exhibit optical transparency, rapid organogenesis, and strong genetic and physiological similarity to humans. However, traditional morphology-based phenotyping relies on manual scoring of abnormalities, which is time-consuming, subjective, and difficult to scale for high-throughput applications. The absence of standardized, automated, and interpretable tools has limited the reproducibility and regulatory acceptance of zebrafish-based screening. To address these challenges, we developed FINS (Fish Imaging and Neural Scoring), an interactive, web-based platform that combines deep learning with intuitive visualization and quality control (QC) tools for automated zebrafish image analysis and morphological screening. **Methods:** Zebrafish embryos were imaged in 96-well plates using high-resolution bright-field microscopy at 24 hours post fertilization (hpf) and 5 days post fertilization (dpf). FINS processes either single or multiple time-lapse images per well, aggregating predictions across views to ensure robust classification of developmental phenotypes. The platform employs a multitask ConvNeXt v2 architecture with dual heads: one for phenotypic classification (normal, mortality at 24 hpf (Mo24), mortality at 5 dpf (Mo5d), or abnormal at 5 dpf) and another for QC assessment (high vs. low image quality). The model was trained on a manually annotated dataset of 4,641 zebrafish embryo images, encompassing a range of morphological phenotypes, and evaluated on an independent test set of 576 images. The FINS backend integrates FastAPI and MySQL for data management, with a Django-based frontend for visualization. The interface includes a color-coded 96-well plate viewer, enabling rapid navigation between wells, visualization of convolutional neural network (CNN) confidence scores, and manual correction of predictions. Continuous model improvement is supported through MLflow, which automates experiment tracking, retraining, and deployment, allowing iterative refinement as new annotations become available. **Results:** The phenotypic classification head achieved high F1 scores across classes, 0.94 (Normal), 0.90 (Mo24), 0.79 (Abnormal), and 0.60 (Mo5d), reliably distinguishing normal, mortality, and abnormal phenotypes. The QC head attained an F1 score of 0.96 for the Good Quality category, effectively filtering out low-quality images prior to phenotypic scoring and ensuring data integrity across analyses. Compared to manual scoring, FINS greatly reduced annotation time while maintaining interpretability via confidence visualization. The system's high-throughput screening mode enables real-time plate navigation, ambiguity detection, and prioritization of wells requiring manual review. Multi-view image aggregation improved detection of abnormalities, and all user edits are stored and incorporated into the retraining pipeline, ensuring continuous improvement. **Conclusions:** FINS represents a next-generation platform for standardized, scalable, and transparent zebrafish phenotyping. Combining deep learning automation with an interactive, interpretable interface, it enhances throughput, reduces annotator variability, and promotes reproducibility. Its modular architecture and continuous model management enable extension to new imaging modalities, phenotypic classes, and LIMS integration, supporting AI-enhanced zebrafish assays in research and regulatory workflows.

PS 4018 Targeting TLR4 and NLR3: Computational Modeling Reveals Immunotoxic Mechanisms and Nutraceutical Solutions in Farmed Catfish

R. Kondatti, M. Contin Ortega, and S. Batra. Southern University and A&M College, Baton Rouge, LA.

Background and Purpose: Channel catfish (*Ictalurus punctatus*), dominating U.S. freshwater aquaculture, confronts severe immunotoxic threats from persistent pollutants pentachlorophenol (PCP) and perfluorooctanoic acid (PFOA). PCP, a banned pesticide and preservative, persists via legacy contamination, inducing oxidative stress and immunosuppression. While PFOA, a bioaccumulative "forever chemical" from industrial sources, disrupts innate immunity, amplifying infection risks and undermining sustainable farming. These toxins target key inflammatory proteins: Toll-like receptor 4 (TLR4) for pathogen sensing and proinflammatory activation, and NLR family CARD domain-containing 3 (NLR3) for inflammasome regulation. **Methods:** Channel catfish TLR4 and NLR3 interactions with PCP and PFOA were quantified through computational modeling, homology, docking, and dynamics simulations. Binding affinities and conformational changes were evaluated with and without nutraceuticals (Cyanidin 3- glucoside, Melatonin and Pterostilbene) as competitive inhibitors. **Results:** Both PCP and PFOA exhibited high affinity for NLR3

and TLR4, while may result in structural perturbations associated with inflammatory dysregulation. Cyanidin 3-glucoside significantly reduced PCP affinity for NLR3, while pterostilbene attenuated PCP and PFOA binding, indicating protective modulation. Interestingly, none of the nutraceuticals had any effect on pollutants binding with TLR4 **Conclusions:** This research asserts PCP and PFOA as critical aquatic immunotoxins and specific nutraceuticals as eco-friendly tools to fortify channel catfish immunity, advancing molecular strategies for resilient aquaculture under environmental duress.

PS 4019 An Integrated Microbial Remediation and Physiologically Based Toxicokinetic (PBTk) Model of Polychlorinated Dibenzo-p-Dioxin and Dibenzofurans

C. Song¹, D. Islam², S. A. Hashsham², and Q. Zhang³. ¹Lexington High School, Lexington, MA; ²Michigan State University, East Lansing, MI; and ³Emory University, Atlanta, GA.

Background and Purpose: Polychlorinated dibenzo-p-dioxins (PCDD) and polychlorinated dibenzofurans (PCDF) are persistent environmental pollutants. Their long half-lives, both externally at polluted sites and internally in the human body, pose significant health risk concerns for chronic exposures to these toxic compounds. Microbial reductive dechlorination and respiration have been studied as an economical strategy for remediating PCDD/F-contaminated sites. However, it is a decades-long lengthy remediation process with risk of elevated total toxic equivalency (TEQ) at some points in time as congeners of higher toxic equivalent factor (TEF) values may be transiently produced. Should microbial remediation be implemented, health risk assessment for humans living near the contaminated sites requires an integrated approach that can predict both the evolving environmental PCDD/F congeners and the tissue burdens resulting from chronic exposures to these mixtures. Here we aim to develop a computational modeling framework that can quantitatively describe the external-to-internal PCDD/F exposure continuum. **Methods:** To this end, we have adapted and integrated two models we recently published: (i) a microbial remediation model that employs first-order kinetics to predict the dechlorination of 75 PCDD and 135 PCDF congeners, and (ii) a human physiologically based toxicokinetic (PBTk) model for mixtures of dioxin-like PCDD/F congeners that can induce liver binding proteins resulting in nonlinear tissue accumulations. The integrated model is implemented in the MATLAB-compatible freeware Octave. **Results:** The model is applied to simulate dechlorination of PCDD/F by organohalide-respiring bacteria including *Dehalococcoides mccartyi* and lifetime human exposure to evolving PCDD/F mixtures starting at concentrations representative of the Tittabawassee and Saginaw Rivers in MI, USA. The model allows us to make preliminary predictions of transformation of PCDD/F congeners and TEQs at the sites and, with the assumption of proportional intake of congeners, the blood or tissue TEQs. The model predicts that the relative contributions of individual dioxin-like congeners to site TEQ evolve over time and furthermore their lifetime contributions to tissue-level TEQs also vary due to congener-congener interactions in the liver and differential half-lives. **Conclusions:** In summary, we have developed an integrated microbial remediation and PBTk modeling framework to predict evolving tissue accumulation and TEQs of PCDD/F congeners. Upon future quantification of related uncertainty and variability, the modeling framework can be used as an *in silico* tool to help assess the health risk for people living near the contaminated Superfund sites under microbial remediation.

PS 4020 Molecular Modeling and Lung Cell Studies Uncover PFOS-Induced Ribosomal Stress and Metabolic Dysregulation

G. Dupre, R. Kondati, M. Thakur, and D. Mutyala. Southern University and A&M College, Baton Rouge, LA.

Background and Purpose: PFOS (perfluorooctane sulfonate) is an environmental contaminant with documented links to respiratory dysfunction and inflammation, raising urgent public health concerns. **Methods:** Motivated by increasing evidence of PFOS toxicity, we first performed computational docking studies to examine its interactions with ribosomal proteins RPS6 and RPS7, and mitochondrial uncoupling protein UCP1. **Results:** Our computational modeling revealed strong binding efficiencies: PFOS exhibited binding energies of -6.6 kcal/mol for RPS7, -7.2 kcal/mol for UCP1, and similar high affinity for RPS6, indicating direct interference with cellular bioenergetics and protein synthesis. To translate these *in silico* predictions into a biological context, we next exposed A549 lung alveolar epithelial cells to PFOS and measured metabolic and transcriptional responses. Seahorse XF ATP Rate assays showed a significant increase in cellular ATP production driven largely by glycolysis, consistent with compensatory adaptation to mitochondrial stress during PFOS exposure. The qPCR analyses further demonstrated upregulation of RPS6 and RPS7, suggesting the activation of mTOR-S6K-RPS6 signaling. **Conclusions:** Together, these results provide new insights into how PFOS directly targets mitochondrial and ribosomal pathways, causing metabolic reprogramming and injury in lung epithelial cells. Our integrated computational and experimental approach underscores the potential health risks of PFOS exposure and points to molecular targets that could inform future prevention and intervention strategies.

PS 4021 Simulation of the uptake, metabolism and bioavailability of highly lipophilic constituents in petroleum fuels and oils

M. W. Linakis¹, H. J. Clewell III¹, J. L. Campbell Jr.¹, P. R. Gentry², and A. D. Redman³. ¹Ramboll US Consulting, Inc., Raleigh, NC; ²Ramboll US Consulting, Inc., Monroe, LA; and ³ExxonMobil Biomedical Sciences, Inc., Annandale, NJ.

Background and Purpose: Petroleum fuels are complex mixtures with a large number of chemical constituents; therefore, consideration of these mixtures requires higher throughput modeling approaches. Before considering potential interactions between the components of the mixtures, more information is needed on the characteristics of individual chemicals, as some components are well-described (e.g. benzene, toluene, ethylbenzene and xylenes, or BTEX), while other, typically more hydrophobic (log P > 4) components are data-poor. Complicating analyses, the larger constituents are often not water soluble and experimental studies typically require them to be delivered in a variety of lipid vehicles that can impact kinetic behavior. In this study, we aggregated PK data from 12 large hydrophobic constituents of fuels and oils and developed a PBPK model to help identify effects of various physicochemical and vehicle properties on the disposition of those chemicals. **Methods:** A literature search was performed to identify data on human, rat, or mouse blood concentrations of various petroleum fuel components after IV, inhalation, or oral exposure. Data from screened studies were either taken directly from tables or determined from plots using a plot digitizer. Given the models and data already available for BTEX, this set of chemicals was used to properly generate and calibrate a base multi-chemical array model. The starting structure of the model was derived from Haddad et al. (1999), which had separate blood and tissue compartments for each chemical as well as interaction terms for inhibition (or induction) of metabolism. From there, more lipophilic constituents were considered, and elements needed to capture their kinetics were added. With those elements in place, chemicals with available concentration-time data were modeled, using physiological values from Brown et al. (1997), partition coefficient estimates from the IndusChemFate model, and GI uptake and metabolism values visually optimized to the data. Blood concentrations and AUCs from simulated IV exposures were calculated based on optimized metabolism values in order to estimate bioavailability. Optimized values and bioavailability were then compared. **Results:** For non-BTEX chemicals, a total of 37 blood concentration-time courses for 12 chemicals were extracted from 15 publications. After considering the literature and models for lipophilic molecules, additional elements added on to the BTEX model included a deep fat compartment, two compartment oral uptake, and a separate lymphatic oral uptake. Comparison of observed vs. (visually-optimized) simulated concentrations for 421 data points yielded a linear regression with a slope = 1.1, $r^2 = 0.825$, and RMSE = 4.5. A total of 32 (7.6%) of simulated data was more than an order of magnitude off from the observed data, though 15 of those points were at low concentrations (<1% of maximum, typically at the end of the curve), and another 11 were from benzo[a]pyrene specifically, which showed significant variability in observed concentrations between studies. Apparent bioavailabilities ranged from 1.1-91.4% in oral dosing scenarios and 8.8-78.6% in inhalation dosing scenarios. Fluoranthene was administered orally to rats in multiple vehicles, indicating that bioavailability was slightly enhanced with a more hydrophobic vehicle (>90%, e.g. cod liver oil) vs. a more hydrophilic vehicle (85-90%, e.g. Tween 80/isotonic saline). Additionally, lymphatic uptake was relatively high (> 0.2) in 6 of 9 chemicals with oral data, though once again data from fluoranthene indicated lymphatic uptake may be vehicle dependent. **Conclusions:** This effort represents a first step towards understanding the contribution of physicochemical properties of larger constituents of oils and fuels to their overall bioavailability. Additionally, this study highlights the importance of carrier vehicle in modeling efforts as the oral uptake/bioavailability profiles may be affected by the lipophilicity of the vehicle. Being able to measure and model these trends is a key step to enable higher-throughput modeling efforts for more complex mixtures (UVCBs, like gasolines, fuels and oils).

PS 4022 Physiologically-Based Quantitative System Toxicology Thyroid Hormones Modeling Platform: Species-dependent Thyroid Hormone Changes by Test Substances in Rats and Humans

B. Riffle¹, P. Balazki², R. Lesage², E. Fabian³, S. Melching-Kollmuss⁴, S. Stinchcombe⁵, and R. Landsiedel³. ¹BASF Agricultural Solutions US LLC, Research Triangle Park, NC; ²ESQ Labs GmbH, Saterland, Germany; ³BASF SE, Experimental Toxicology and Ecology, Ludwigshafen, Germany; ⁴BASF SE, Global Toxicology, Agriculture Solutions, Limburgerhof, Germany; and ⁵BASF SE, Global Toxicology, Agriculture Solutions, Limburgerhof, Germany.

Background and Purpose: Disruption of the thyroid hormone (TH) homeostasis by endocrine-disrupting chemicals poses a potential health concern. The extrapolation of animal data to humans is of special interest because (TH) regulation differs between species. These differences may lead to species-specific sensitivities to substances that disturb TH homeostasis, for example, through the indirect mechanism of liver enzyme induction. The presented project aims to develop a physiologically based kinetics (PBK) quantitative systems toxicology (QST) model for predicting TH levels following exposure to test substances in rats and humans. **Methods:** The model was constructed using the Open Systems Pharmacology (OSP) Suite Version 12, integrating PBK models of thyroid-active compounds with QST modules for TH regulation and quantitative adverse outcome pathway (qAOP) modules. The modular architecture allows for the incorporation of new compounds and physio-

logical processes. Model validation was performed using Quarto and the (esqlabsR) package. **Results:** The QST modules encompass pituitary synthesis of thyroid-stimulating hormone (TSH), feedback-controlled synthesis of triiodothyronine (T3) and thyroxine (T4), species-specific plasma protein binding, and active transport and clearance of TH. The platform includes PBK models for the TH disrupting chemicals methimazole (MMI), propylthiouracil (PTU), and phenobarbital (PB), each with distinct mechanisms of action, such as inhibition of thyroperoxidase (TPO) or induction of T4-specific Glucosyltransferases (UGTs). Simulations demonstrate dose-dependent changes in T3, T4, and TSH following administration of MMI or PTU in rats, as well as effects of MMI and combined MMI+PTU treatment in humans. For PB, the model predicts a decrease in T4 levels by up to -20% (observed: -6 to -60%) and an increase in TSH by up to +70% (observed: +3 to +100%) in rats, with negligible effects in humans. **Conclusions:** The developed platform identified key events of thyroid toxicity in rats, with minimal impact observed in humans. Critical key events, such as UGT induction, can be addressed by specific *in vitro* assays and the results of these *in vitro* assays can be fed into the QST model to assess the overall effect on human or rat thyroid hormone level.

PS 4023 Unifying *In Vitro* Kinetics and Open-Source Mechanistic Modeling to Accelerate Informed Decision-Making in Dermal Disposition Assessments

J. Troutman¹, S. Engled¹, C. Ellison¹, A. Hamadeh², and A. Edgington². ¹Procter & Gamble Company, Mason, OH; and ²University of Waterloo, Waterloo, ON, Canada.

Background and Purpose: Recent evaluations have compared *in silico* dermal absorption models against small dose *in vitro* permeation test (IVPT) data. Our mechanistic model showed good performance for receptor fluid kinetics but generally tended to over-predict chemical evaporation and under-predict recoveries in the epidermis and dermis. These findings highlight some key challenges, including the need for better modeling of chemical volatility/vehicle evaporation from the skin surface and chemical disposition into the skin layers. Recognizing that the rate of absorption of topically applied chemicals can vary depending on the chemical, vehicle, and amount, the overall purpose of this initiative is to deploy problem-solving tools and practical workflows to advance dermal absorption and disposition prediction capabilities. **Methods:** To enhance model reliability and generate necessary data for extrapolation to untested scenarios, an iterative workflow utilizing *in vitro* lab testing capabilities was employed. This workflow includes Vehicle Dry-down Tests to calculate evaporation rates, *in Vitro* Release Tests (IVRT), and Kinetic IVPTs. Kinetic experiments were performed to characterize the absorption and disposition of permeants with varying physicochemical properties covering a range of molecular weights (100 to 400 Da), lipophilicity (LogP -0.4 to 4), ionization states, and aqueous solubilities (1 to 500 mg/mL) (e.g., Niacinamide, Caffeine, Vanillin, Methyl Paraben, Ibuprofen) using saline vehicle and three leave-on formulations (Silicone-in-water, Oil-in-water, Oil-in-water with sunscreen protection factor). **Results:** Formulation dry-down results confirm that formulations dry down to a residual mass correlating with non-volatile ingredient amounts. Although terminal recoveries between the dislodgeable dose (skin surface + stratum corneum) and dermal delivery (viable epidermis + dermis + receptor fluid) were similar between different formulations, comparisons of area under the concentration-time curve (AUC) data for the stratum corneum, viable epidermis, and dermis revealed quantitative differences between formulations that were not evident from *in vitro* release data or terminal 24-hour recoveries. These findings suggest that different interactions between formulation components and skin may impact partitioning and/or diffusivity within specific skin layers, particularly during the early time periods (<6 hours). The derived knowledge and new experimental data were used to assess and improve the performance of a unified open-access mechanistic dermal absorption model based on visual comparisons of the predicted and observed receptor fluid and terminal recoveries from the skin surface, stratum corneum, viable epidermis, and dermis. This model incorporates complexities such as volatility, formulation effects, changes in ionization state, and is applicable to small and large dose studies using *in vitro* and *in vivo* tests. The model is being implemented into the freely available, open-source modeling platform (Open System Pharmacology Suite/PK-Sim/MoBi) to facilitate transparency and compatibility with whole-body PBPK models. Ongoing work is underway to represent metabolic clearance in the skin, which has the potential to affect bioavailability and therapeutic or toxic dose-response relationships. **Conclusions:** The established mechanistic dermal absorption model and provisional workflow provide reliable informed decision-making in the risk assessment of product ingredients applied to skin, ensuring adaptability and continued improvement by the global scientific community.

PS 4024 Interrogating Sidechain Dihedral Correlation and Essential Motion as Predictors of Multi-Kinase Specificity Using Imatinib as a Model System

W. Troxel, E. Vig, and C. A. Chang. University of California - Riverside, Riverside, CA. Sponsor: L. Zhao

Background and Purpose: Drug promiscuity is when a compound interacts with many biological targets, inducing helpful and toxic side effects. It can expand treatments without high design, testing, and approval costs. Imatinib variably binds

kinases: strongly to Abl and Kit, moderately to Chk1 and Lck, and weakly to p38a and Src. The conserved ATP site renders binding factors unclear. All-atom classical molecular dynamics (MD) with novel post-analysis methods were used to predict imatinib specificity with these six kinases. All co-crystals show that imatinib binds the ATP site, except Chk1, which has no crystal. Triplicates were run for each bound- and apo-state system. Thermodynamic analysis yields imatinib-kinase enthalpy and dihedral configurational entropy. Force distribution analysis (FDA), principal component analysis (PCA), and sidechain dihedral correlation networks show how protein dynamics affect specificity. The study shows drug-bound MD accurately identifies these specificity factors. **Methods:** Abl, Kit, Lck, p38a, and Src co-crystals with imatinib were used. For Chk1 kinase, with no available co-crystal, structural alignment of indolylquinolinone-bound Chk1 and imatinib-bound Syk kinase was used to create a Chk1-imatinib complex. All systems used monoprotonated imatinib and retained crystal waters. Bioinformatics tools and SWISS-MODEL were used to add missing loops. A standard protocol was used to set up MD simulations using a cuboid box with 22,307 water molecules and counterions to balance charges. The enthalpy range is found with the total energy mean convergence, as bound-free-ligand+water captures the minimal and maximal triplicate values. The T-Analyst program finds the minimal and maximal dihedral entropy range in kinase binding sites and imatinib rotatable bonds, with bound-free-ligand for all triplicates. These values reveal the upper- and lower-bound Gibbs free energy with $\Delta G = \Delta H - T\Delta S$ for binding thermodynamics. GROMACS FDA shows force vector directions. α -carbon Cartesian PCA with the BKIT package shows essential motions. Sidechain dihedral correlation networks show a hidden communication network controlling protein conformational fidelity. **Results:** MD captures specificity trends by estimating upper- and lower-bound enthalpy, binding site dihedral entropy, and Gibbs free binding energy. Force vectors, α -carbon Cartesian PCA, and sidechain dihedral correlations show a hidden configurational network. Conformational data transmits across the protein, and the network fidelity corresponds with structural changes to let kinases facilitate phosphate transfer to natural substrates for signaling. The protein is more likely to adopt an open form, promote ATP competition, and undergo imatinib dissociation. The sidechain dihedral correlation network identifies distal mutants known to reduce patients' imatinib sensitivity. Higher imatinib-kinase affinity trends with a loss in sidechain dihedral correlations and weak secondary motif migration after binding, corresponding with a more restricted structure to reduce solvent and ATP competition. Lower-affinity proteins show enhanced sidechain dihedral correlation and exaggerated secondary motif motions, consistent with pocket exposure to solvent and more ATP competition. **Conclusions:** This study shows how kinase regulatory motifs adopt favorable configurations via coordinated Cartesian and dihedral motions not previously seen in literature. Predictive drug promiscuity methods were interrogated with imatinib and six kinases. The results show thermodynamics calculations, force vectors, PCA essential motions, and sidechain dihedral correlation networks may explain imatinib specificity. A hidden network shares information about the preferred kinase form after drug binding. Strong and moderate binding kinases, like Abl, Chk1, Kit, and Lck, undergo disrupted ATP competition from interrupted bound kinase breathing motions. Weaker kinases, like p38a and Src, enhance ATP competition from promoted breathing motions. This informs drug toxicity by revealing distinct structural changes corresponding with imatinib-kinase affinity. It may show distinct toxicity modes from interrupted kinase communication networks. Future work will consider the role of coordinated motions on toxin binding. Other deep learning methods to reveal further correlations will be pursued.

PS 4025 Using a Machine Learning QSAR Model to Predict the Half-Life of Organofluorine Pharmaceuticals

J. M. Gardella, A. D. Blanchette, and A. K. Madl. Valeo Sciences, Ladera Ranch, CA.

Background and Purpose: Organofluorine pharmaceutical compounds are a class of small organic pharmaceutical drugs with a minimum of one fluorine atom or functional group that contains a fluorine atom. Around 20% of commercially marketed pharmaceutical drugs fall into this category, with over 300 registered globally. In 2018, 45% of the 38 small molecule pharmaceuticals approved by the FDA were organofluorines. Organofluorine pharmaceuticals can account for up to 63% of the extractable organic fluorine measured in human serum and exhibit a broad range of pharmacokinetic profiles. The objective of this study was to develop a proof-of-concept machine learning quantitative structure activity relationship (QSAR) model to predict the half-life of novel organofluorine pharmaceuticals in humans. **Methods:** "Pharmaceutical organofluorine compounds" (n=340) in the EPA CompTox Dashboard list compiled by Inoue et al. (2020) were used to train and evaluate the model. The half-lives of each compound were collected from DrugBank. To ensure complete and quality data, compounds were removed if: 1) SMILES strings were not available for the compound, 2) reported human half-lives were not available, or 3) the half-life as reported on DrugBank differed by more than 50% of the upper bound by route of administration, patient population, or dosing regimen. After curation and deduplication, 193 compounds comprised the final training dataset. Over 1400 1D and 2D physicochemical descriptors were calculated using the open source PaDEL cheminformatics software. Features below a variance threshold of 0.2 and above a globally correlated threshold of 0.8 were removed for a feature set of 281 before hyperparameter tuning. Ten-fold cross-validation and feature selection was used to identify hyperparameters for optimal model performance. A random forest regression algorithm was used and evaluated based on the R² and mean absolute error. **Results:** The model was evaluated on out-of-fold predictions following ten-fold

cross validation using the 20 most important features. Predictions of half-life in hours were within one order of magnitude of the observed half-life in over 90% of out-of-fold predictions in the organofluorine dataset. The model exhibited the highest prediction accuracy in the midrange values, while error increased towards the lower and upper ends of the range. The model's top 20 most important features included 2D descriptors from the Broto-Moreau, Moran, and Geary autocorrelation type, as well as Crippen's LogP, chi cluster, electrotopological state, and information content descriptors. **Conclusions:** Physicochemical descriptors can be used as input features in a random forest machine learning model to identify the most important physicochemical features in determining half-life and to accurately predict the half-life of organofluorine pharmaceuticals. Autocorrelation, lipophilicity, and electrotopological state descriptors emerged as key predictors of half-life. Our machine learning model demonstrated a promising application for New Approach Methods (NAMs) to accurately predict the half-life of novel organofluorine pharmaceuticals.

PS 4026 Leveraging Historical Control Data to Identify Covariates in 28-Day Repeated Dose Toxicity Studies

N. Becker¹, M. Dammann¹, K. Becker¹, F. M. Kluxen², J. Cairns¹, D. Funk-Weyer¹, C. Gomes¹, R. Buesen¹, and M. Dilger¹. ¹BASF SE, Ludwigshafen, Germany; and ²BASF SE, Limburgerhof, Germany. Sponsor: D. Funk-Weyer, EUROTOX

Background and Purpose: In conventional vertebrate toxicology studies, control groups are essential for establishing a reference against which treatment effects are compared. Historical Control Data (HCD) aggregates control group data across multiple studies and provides a powerful framework for validating control responses [1]. It plays a critical role in the identification of treatment-related effects by identifying cases where control groups rather than treated groups deviate from the biological baseline. Additionally, HCD enables systematic investigation of external factors that may influence control responses, such as environmental conditions and study design variables. **Methods:** The current study presents a comprehensive analysis of HCD derived from 185 28-day repeated dose toxicity studies conducted at BASF between 2009 and 2023. Using a combination of regression analysis, significance testing, principal component analysis (PCA), and effect size estimation, we systematically identified covariates that impact the HCD distribution. **Results:** Variables such as study date, season, sex, starting age, and vehicle exhibited consistent and meaningful influence on control data. In contrast, factors including the presence of additional blood samples, number of animals per cage, cage enrichment, and the inclusion of urinalysis were found to have no or negligible effects on the assessed HCD. **Conclusions:** These findings strengthen the scientific foundation when integrating HCD in toxicological assessments by identifying filter criteria for more targeted and biologically meaningful HCD. They also challenge the current paradigm of limiting HCD usage to a five-year window in lieu of applying evidence-based applicability timespans. Additionally, our results provide a basis to reduce animal use in mandatory *in vivo* studies by constructing Virtual Control Groups (VCGs), which could serve as substitutes for concurrent controls in selected study designs [2]. References: 1.Kluxen, F. M. et al., Using Historical Control Data in Bioassays for Regulatory Toxicology. Regul. Toxicol. Pharmacol. 125, 105024 (2021). 2.Steger-Hartmann, T. et al., Introducing the concept of virtual control groups into preclinical toxicology animal testing. ALTEX 37(3), 343-349 (2020).

PS 4027 Leveraging Grouping Approaches to Strengthen Read-Across Decision-Making

F. Sweder Gold, M. L. Chilton, J. D. Vessey, and G. Kocks. Lhasa Limited, Leeds, United Kingdom.

Background and Purpose: Confidently predicting toxicity for novel compounds is a central challenge in regulatory toxicology. Read-across, which fills data gaps by extrapolating from structurally or mechanistically similar analogues, can be performed using either a single compound or a group of analogues. Grouping approaches allow for increased confidence in the chosen potency value, which is particularly important in quantitative read-across studies considering both potency and exposure. **Methods:** Data curated from ToxValDB and Vitic were used to identify potential read-across analogues for extractables and leachables, as recommended by the ICH Q3E draft guideline. This allowed the derivation of acceptable intakes for systemic toxicity for these chemicals in the form of permitted daily exposures. *In silico* solutions developed by Lhasa Limited facilitated the formation of read-across categories, enabling the examination of a distribution of point of departure (POD) values. Analogues were assigned confidence levels based on different aspects of their similarity to the target: (i) structural (ii) mechanistic (iii) metabolic (iv) physicochemical. The potency values of the highest confidence analogues were compared to those of the entire category. **Results:** Restricting read-across categories based on similarity criteria and data reliability enables the definition of robust analogue sets, that better represent the potential toxicity of leachables. Typically, the range of POD values within a category spans two orders of magnitude. For instance, 11 of the most highly relevant analogues, identified through *in silico* methods, for 1,3-di-*tert*-butylbenzene exhibited PODs ranging from 10 to 1018 mg/kg/day. The most similar analogue to the target within the category, 1,3-di-*iso*-propylbenzene, had a POD of 150 mg/kg/day, which is located in the middle of the overall range of potency

values. In the case of tris(2,4-di-*tert*-butylphenyl)phosphate, a category of 15 relevant analogues was formed, with PODs ranging from 7.3 to 1000 mg/kg/day. In this example, the most similar analogue to the target within the category, tris(2-*iso*-propylphenyl)phosphate, had a POD of 8 mg/kg/day, at the lower end of the range of potency values. This variability underscores the need for a more comprehensive read-across strategy designed to address potential outliers. Grouping chemicals and expressing toxicity as a range, rather than a single point value, was found to better reflect the diversity of chemically similar compounds and provides a more comprehensive basis for risk assessment. **Conclusions:** Read-across can be successfully conducted using either a single analogue or a group of similar analogues, depending on the use case, specific chemical entity, and quantity of relevant toxicity data available. Expressing toxicity as a range of potency values, rather than a single point, provides a more nuanced and reliable basis for risk assessment. This approach, supported by *in silico* grouping, enhances confidence in safety decisions and reduces subjectivity, especially when the range of potency values does not overlap with the likely exposure concentration.

PS 4028 Optimizing *in Silico* Approaches to Assess the Likelihood of Nitrosylation of Cysteine Residues

N. Abdelfattah, C. Guo, and A. Gow. Ernest Mario School of Pharmacy, Rutgers University, New Brunswick, NJ.

Background and Purpose: A principal mechanism of nitric oxide (NO) regulation of cellular function is the nitrosylation of cysteine (Cys) residues to alter protein function. Nitrosylation is a ubiquitous modification that regulates biological processes ranging from cell survival and growth to physiological function; and its disruption is implicated in a wide variety of pathologies. Nitrosylation can occur via a number of mechanisms and to date approximately 15,000 putative nitrosylation targets have been determined. However, there is no simple consensus sequence for the modification, which makes prediction of NO effects on cellular processes difficult. It is known that the mechanism of nitrosylation for a specific cysteine can be dictated by its microenvironment, including factors such as pKa, hydrophobicity, and surface accessibility. This suggests that the determinants of nitrosylation may be defined by 3D structure rather than merely sequence. The purpose of this study was to determine whether an AI-generated 3D model can be used to predict protein nitrosylation sites by modeling the biophysical characteristics of the sulfur moiety. **Methods:** We predicted protein microenvironments using AlphaFold (AF), a modeling software that can estimate the 3D structure of a protein. An AF-generated model was produced for the enzyme PTEN, which has ten cysteine residues and is a known nitrosylation target. Mutagenesis studies indicate that Cys83 is the primary nitrosylation site, however, Cys71, Cys124, and Cys136 have also been suggested. The variety of Cys residues in PTEN allows one to compare different microenvironments within the same structure. Computational parameters including pK_{int}, hydrophobicity, and solvent-accessible surface area (SASA) were calculated from the AF-model for each of the four cysteine residues that have been implicated in nitrosylation. These parameters were compared with potential mechanisms of nitrosylation formation namely direct nitrosylation, transnitrosation, or nitrosation. **Results:** AF modeling of PTEN revealed distinct microenvironmental signatures among the cysteine residues. Cys83 exhibited a high SASA value (89.96) and is predicted to undergo nitrosylation through transnitrosation. Cys124 displays a low pK_{int} (7.079) and is predicted to be reactive under conditions that favor nitrosation. Cys136 has a high hydrophobicity index (2.39) and is predicted to favor direct nitrosylation. These computational predictions align with previously published mutagenesis data that implicate the same residues in nitrosylation. Experimental validation using biotin-switch and LC-MS/MS analysis will be used to confirm the reaction mechanisms predicted for each of the sites. Different nitroso compounds can be used to favor the predicted reactive pathways namely S-nitrosoglutathione (GSNO) for transnitrosation, S-nitrosopropidium (SNOPPM) for direct nitrosylation, and DEANONOATE for nitrosation. In preliminary studies, 400 ng of PTEN were exposed to a 50 μM of GSNO, SNOPPM, or DEANONOATE for 45 minutes. A Biotin switch to identify nitrosylated protein was performed. Nitrosylated material was isolated using Streptavidin beads. The resultant material was examined by Western blot analysis and staining with PTEN antibody. Under these conditions, SNOPPM had the highest level of nitrosylation, while GSNO showed a low level of nitrosylation, and no SNO formation was seen with DEANONOATE. These data implicate direct nitrosylation of Cys 136 as the most efficient mechanism of NO-modification of PTEN. However, these results require further clarification by LC-MS/MS to confirm. **Conclusions:** By combining AI-predicted structural values with biochemical validation, we aim to define whether AF modeling can accurately forecast mechanism-specific nitrosylation *in vitro*. These studies will lead to a better understanding of how NO reactivity can alter cellular function.

T. Smyth, P. Clapp, and I. Jaspers. UNC Chapel Hill, Chapel Hill, NC.

Background and Purpose: Increased efforts have been made to reduce animal use in human safety and efficacy studies through the adoption of new approach methodologies (NAMs) and computational-based approaches. Techniques to grow primary human airway epithelial cells *ex vivo*, specifically at air-liquid interface (ALI), have proven to be valuable for testing pharmacologic and toxicologic endpoints. However, airway region-specific differences in epithelial cell populations and technical variability in *ex vivo* culture methods introduce concerns regarding the accuracy and comparability of results generated between groups. This study sought to compare the gene expression profiles of healthy human nasal (HNEC), bronchial (HBEC), and small airway epithelial cells (SAEC) immediately following collection as well as following *ex vivo* culturing at ALI using commonly employed methodologies. **Methods:** Transcriptomic data were obtained from the All RNA-seq and ChIP-seq sample and signature search (ARCHS4) database, which aggregates and uniformly processes publicly available RNA-seq datasets from the gene expression omnibus (GEO) and sequence read archive (SRA) to enable large-scale analyses. Data from healthy HNEC, HBEC, and SAEC samples were isolated and designated as “tissue” or “ALI culture” using key word filtering and natural language processing (NLP) of metadata and linked publications. A total of 2542 samples were isolated, including 1152 HNEC, 243 HBEC, and 109 SAEC tissue samples. Dimensionality reduction was performed using Uniform Manifold Approximation and Projection (UMAP) and differential expression analysis was conducted between key groups of interest. Key gene signatures for tissue samples were determined using an elastic net model and ALI cultures were assessed for relation to their source tissue. Gene expression patterns were compared to airway cells from the LungMap CellRef 1.0 Atlas single-cell RNAseq (scRNA-seq) dataset. **Results:** UMAP plots demonstrated clear distinctions between tissue and ALI culture samples. An elastic net model trained on HNEC, HBEC, and SAEC tissue samples demonstrated strong predictive capacity resulting in a 99.2% (373/376) accuracy rate; however, ALI cultures demonstrated mixed results when predicting source tissue with 97.5% (192/197) accuracy for HNEC, 41.6% (319/767) for HBEC, and 38.6% (277/70) for SAEC samples. Differential expression analysis identified major differences between HNEC and SAEC (317 DEGs) with slight differences between HNEC and HBEC (73 DEGs) and HBEC and SAEC (82 DEGs) tissue samples. In contrast, major differences were detected between ALI culturing methods and their source tissue resulting in between 5000 and 7000 DEGs. Using an elastic net model trained on the CellRef scRNA-seq dataset, HNEC tissue samples predicted as goblet cells (94%), HBEC tissue samples demonstrated mixed ciliated/goblet cell predictions (73/27%), and SAEC tissue samples demonstrated ciliated cell predictions (96%). ALI cultured HNEC samples retained a prediction of goblet cells while HBEC and SAEC ALI cultured samples demonstrated a mix of basal, ciliated, and goblet cells. **Conclusions:** This large-scale RNA-seq analysis revealed distinct airway compartment profiles, with the greatest differences seen between nasal and small airway regions. Across all airway regions, ALI culturing induced substantial transcriptional changes, though some compartment-specific signatures persisted; HNEC largely retained goblet-like expression, while HBEC and SAEC expressed mixed basal, ciliated, and goblet-like patterns depending on *ex vivo* culture conditions.

PS 4030 Dosimetry Models of Inhaled Flavoring Compounds in ENDs Aerosols and Estimation of Tissue Concentrations in the Mouse and Human Respiratory Tracts

T. Antonijevic¹, M. Moreau¹, J. Zhang², and M. Gutierrez². ¹ScitoVation, LLC, Durham, NC; and ²Atria Client Services, LLC, Richmond, VA.

Background and Purpose: Exposure to flavoring compounds in electronic nicotine delivery systems (ENDs) aerosols via inhalation raises potential health concerns. Although many flavoring compounds in ENDs products have been evaluated and affirmed as GRAS (Generally Recognized as Safe), this evaluation does not directly apply to exposure via inhalation. To better assess the health risk, physiologically based pharmacokinetic (PBPK) models have been used for interspecies extrapolation and route-to-route extrapolation. In this study, we developed PBPK models specifically for the ENDs aerosols, which are composed of vapors and suspended fine particles in the gas phase, to estimate the tissue level of flavoring compounds in the mouse and human respiratory tracts. **Methods:** We combined the PBPK model with the multiple-path particle dosimetry (MPPD) lung deposition model, because of the multiphase characteristics of the ENDs aerosol. The PBPK contained a multi-compartment respiratory tract model based on anatomical location and functional structure, comprising three regions of the respiratory tract (the upper respiratory tract [URT], the tracheobronchial region [TB], and the alveolar region) and a pulmonary compartment, which represents the gas exchange regions of the lung. Each region was further divided into a lumen for air passage, surrounded by epithelium and submucosa tissue layers, which account for the transport of absorbed chemicals across the anterior respiratory tract compartments. The structure of the model was the same for mice and humans, with species-appropriate anatomy and physiology. The MPPD model was executed for a mass median aerodynamic diameter of 0.8 μm with a geometric standard deviation of 1.4 μm for the ENDs aerosols. Tissue concentrations of nicotine and 38 select flavoring compounds in each previously

defined region were calculated and z-score normalized to compare the deposition of flavors within and between mice and humans. A correlation analysis was conducted to examine the impact of modeling parameters on the results. **Results:** The MPPD model predicted different deposition patterns in mice and humans: the aerosol deposition in the URT, the TB region, and the alveolar region was 53.3%, 2%, and 2% in mice, and 0.9%, 6%, and 15% in humans, respectively. The MPPD-PBPK model was validated using plasma nicotine concentrations from a mouse inhalation study and subsequently applied to flavoring compounds. Based on calculated concentrations, three groups of flavoring compounds were identified: four flavors with higher blood and low respiratory tissue concentrations due to very low liver clearance, 20 flavors with low blood and respiratory tissue concentrations, and 14 flavors with low blood but higher respiratory tissue concentrations. For the mouse model, tissue concentrations correlated to n-octanol:water partition coefficient, molecular weight, water solubility, and vapor pressure, with correlation coefficients of >0.67, >0.43, <0.53, and <0.19, respectively. For humans, the tissue concentration of the alveolar region weakly correlated with the n-octanol:water partition coefficient, molecular weight, water solubility, and vapor pressure, with correlation coefficients of 0.43, 0.28, -0.33, and -0.20, respectively. **Conclusions:** We developed dosimetry models for ENDs aerosols to predict tissue concentrations in the respiratory tracts of humans and mice. The results indicate species-specific deposition patterns in humans and in mice and suggest that lipophilic compounds tend to accumulate in respiratory tissues regardless of their partitioning in particle/vapor phases. The correlation analysis indicates that the behavior of flavoring compounds is more predictable based on their physicochemical properties in the mouse model than in the human model. Therefore, the use of a generic dosimetry model for human exposure may require additional caution to ensure relevance and accuracy.

PS 4031 Computational Modeling of In Vitro Antral Follicle Growth and Steroidogenesis as a New Approach Methodology in Reproductive Toxicology

J. P. Sluka¹, K. Watanabe², Q. Zhang³, A. J. Krieg⁴, M. Zelinski⁴, and Z. R. Craig⁵. ¹Indiana University, Bloomington, IN; ²Arizona State University, Phoenix, AZ; ³Emory University, Atlanta, GA; ⁴Oregon National Primate Research Center, Beaverton, OR; and ⁵University of Arizona, Tucson, AZ.

Background and Purpose: Millions of women face infertility issues, often due to the inability to produce a viable egg. Folliculogenesis, the developmental process of ovarian follicles, begins with the activation of primordial follicles and progresses through various stages until reaching the antral stage, capable of hormone production, and egg release. This complex process is regulated by a network of endocrine, paracrine, and autocrine signals, which can be disrupted by toxicants, potentially leading to infertility. We are developing *in vivo*, *in vitro*, and *in silico* models of gonadotropin-dependent ovarian follicle development to explore toxicant effects on reproduction. Our long-term goal is to use mechanistic, multiscale computational models for *in vitro* to *in vivo* extrapolation (IVIVE) of toxicant effects. Here we present a multiscale computational model of mouse antral follicle development *in vitro* that includes follicle cell proliferation and steroid hormone production. **Methods:** We have developed a spatial model simulating an *in vitro* cultured mouse follicle growing from the secondary to antral follicle stage under treatment by follicle-stimulating hormone (FSH). The model is in CompuCell3D (CC3D), which allows us to incorporate subcellular metabolism and hormone signaling. This model includes multiple cell types: two types of thecal cells (external and internal), three types of granulosa cells (outer and inner-layer mural, and cumulus), the oocyte modeled as a nucleus, cytosol and wall (zone pellucida), and a pseudo-cell type for the proteoglycan extracellular matrix of the expanding antrum. The simulation spans 8 days of follicle growth *in vitro*. Granulosa cells secrete proteoglycans into the antrum causing the antrum to expand. In addition, the granulosa and theca cells proliferate to maintain the proper layering of cells as the follicle expands. Each theca and granulosa cell has an embedded reaction kinetic network representing the steroidogenesis pathway. Theca cells include conversion of cholesterol to testosterone, and granulosa cells include conversion of testosterone to estradiol. We calibrate our model in terms of *in vitro* measured cell numbers, follicle geometry and steroid concentrations. **Results:** Our spatial model can reproduce the observed follicle growth, including relative abundances of theca and granulosa cells, the size of the antrum, and levels of secreted sex hormones in the follicular fluid, as a function of time. We find that the model is underdetermined with respect to some of the reaction kinetic parameters describing subcellular steroidogenesis. In addition, we find that additional granulosa phenotypes are needed to explain the range of behaviors that these cells exhibit. Nonetheless, we believe that our current model can make useful predictions of the effects of toxicants that interfere with the steroidogenesis pathways in theca and granulosa cells. **Conclusions:** An initial multiscale computational model of antral follicle development in CC3D reproduces key features of the developmental process, including cell proliferation and steroidogenesis. Our next goals include (1) coupling systemic follicle growth signals such as FSH and LH and (2) developing predictions of toxicant effects on steroidogenesis that lead to abnormal follicle growth. Our long term goals include coupling whole-body physiologically based kinetic models for hormone signaling between the ovary and pituitary as well as coupling toxicant exposure at the whole-body level to predictions of levels within the follicle. This latter goal is key to the development of *in silico* models needed to predict ovarian toxicity response based on whole-body exposure to toxicants.

J. Hsieh¹, S. Marvel¹, H. Hogberg², and C. McPherson³. ¹Predictive Toxicology Branch, Division of Translational Toxicology (DTT), National Institute of Environmental Health Sciences (NIEHS), National Institutes of Health (NIH), Research Triangle Park, NC; ²National Toxicology Program Interagency Center for the Evaluation of Alternative Toxicological Methods (NICEATM), DTT, NIEHS, NIH, Research Triangle Park, NC; and ³Mechanistic Toxicology Branch, DTT, NIEHS, NIH, Research Triangle Park, NC.

Background and Purpose: Humans are exposed to numerous chemicals with limited developmental neurotoxicity (DNT) data, underscoring the need for efficient strategies to identify potential developmental neurotoxicants. The NIEHS DNT Health Effect Innovation (HEI) program employs a battery of *in vitro* human and rat neural cell assays, together with embryonic zebrafish behavioral assays, to evaluate chemicals with or without existing DNT evidence. This screening battery comprises 17-endpoint associated Key Neurodevelopmental Processes (eKNDPs), such as neuronal differentiation, neurite outgrowth, network formation, etc. The NIEHS DNT HEI screening effort includes three phases: Phase 1 and Phase 2 screening are complete, while Phase 3 remains ongoing. This study focused on the development of an analytical methodology applied to Phase 1 data, with plans to extend its use to combined Phase 1 and Phase 2 datasets once available. Identifying a minimal yet informative subset of eKNDPs can streamline screening and improve resource allocation. This methodology seeks to investigate: Which eKNDPs are most critical for prioritizing known DNT compounds? **Methods:** Benchmark concentration (BMC) modeling was used to evaluate concentration-response data for assay endpoints categorized under each of the 17 eKNDPs. The 17 eKNDPs spans spanning proliferation, apoptosis, cell migration, neuronal differentiation, neurite outgrowth, neuronal maturation and synaptogenesis, oligodendrocyte differentiation, network formation, and neurobehavior. Endpoint-level results were summarized into five attributes: BMC, degree of selectivity, activity confidence, fraction of active endpoints, and selectivity binary call. Selectivity refers to the extent to which an observed DNT effect is distinct from general cytotoxicity. The five attributes were integrated using a Pareto Frontier approach to generate a level score for each chemical per eKNDP. The 17 eKNDP level scores were combined to produce an overall DNT hazard ranking. To address the research question, we assessed the ability of individual eKNDPs and all possible eKNDP combinations to enrich DNT-positive compounds at the top of the ranking. Performance was quantified using Receiver Operating Characteristic Enrichment at 10% (ROCE@10%). High-performing subsets of eKNDPs exceeding predefined ROCE@10% thresholds were further analyzed using association rule mining to identify eKNDPs that frequently co-occur in these combinations and thus represent core contributors to prioritization performance. **Results:** A total of 2,988 eKNDP combinations exceeded the top 1% ROCE@10% threshold, demonstrating strong enrichment of DNT-positive compounds among the highest-ranked chemicals. From these, 112 maximal itemsets (i.e., the largest sets of eKNDPs that frequently co-occur without being subsets of any other itemsets) were identified. Among these, 31 itemsets had ROCE@10% values above the top 1% threshold. Notably, four-eKNDP combinations were predominant within these 31 itemsets, accounting for approximately 77%. The eKNDP with the most frequent selection was LDTT Locomotor Activity @120 hpf (from larval zebrafish), followed by HCl hNP1 Proliferation@24h (from human neural progenitor cell line) and MEA Dev Network Formation@288h (from rat primary neocortex cultures). These relatively distinct and complex eKNDPs were consistently associated with higher ROCE@10% values, indicating their strong contribution to prioritizing DNT-positive compounds. **Conclusions:** Phase 1 data show that a focused subset of eKNDPs can substantially enrich DNT-positive compounds at the top of the ranking. This analytical framework will be applied to combined Phase 1 and Phase 2 datasets to validate these eKNDPs and enhance their utility for DNT prioritization and prediction.

PS 4033 Development of Machine Learning Models to Predict Blood Brain Barrier Permeability of Chemicals

Y. Chushak^{1,2}, T. R. Sterner^{1,2}, and R. A. Clewell^{3,2}. ¹Henry M. Jackson Foundation for the Advancement of Military Medicine, Inc., Wright-Patterson AFB, OH; ²711th Human Performance Wing, Air Force Research Laboratory, Wright-Patterson AFB, OH; and ³Eagle Integrated Services, Inc., Wright-Patterson AFB, OH.

Background and Purpose: The Blood Brain Barrier (BBB) is a highly selective semi-permeable membrane that protects the brain from harmful substances circulating in the blood. By strictly controlling which molecules can enter the brain, the BBB helps protect against neurotoxicity. However, experimental determination of chemical BBB permeability remains a resource-intensive and technically challenging process. Computational approaches offer a valuable alternative to address this data gap and facilitate rapid prediction of BBB permeability for chemicals of interest. Recently, Meng et al. (*Scientific Data*, 2021, 8(1), 289) introduced the B3DB database, a comprehensive resource containing experimentally derived BBB permeability data for 7807 compounds compiled from over 50 published sources. Utilizing this dataset and different machine learning (ML) techniques, we developed predictive models for BBB permeability of chemicals. **Methods:** The B3DB data (<https://github.com/theochem/B3DB>) contained 4856 chemicals that penetrate the BBB (BBB+) and 2851 that do not (BBB-). The final, curated dataset included 2447 BBB+ and 1521 BBB-

molecules after removing salts, stereoisomers, duplicates and invalid information. Model evaluation was carried out with two splitting methods: 5-fold cross validation (CV) and structural diversity. For 5-fold CV, the data set was split into five training (80%) and test (20%) sets so that each chemical appeared in the test set at least once. For structural diversity validation, the Murcko Scaffold module from Python's RDKit package was utilized to extract molecular scaffolds from data set compounds. Molecules were split into training (80%) and test (20%) sets such that molecules with the same scaffold appeared in a single set. Classification models were developed using three sets of molecular descriptors: Molecular ACCess System structural keys, circular extended-connectivity Morgan fingerprints, and Mordred physicochemical molecular descriptors. Two ML classifiers were utilized to construct models: random forest, and XGBoost. The recently proposed graph convolutional neural network technique, implemented in the Chemprop package (<https://github.com/chemprop>), was also employed. Four statistical parameters were used to evaluate the performance of developed classification models: balanced accuracy (BACC), sensitivity (SEN), specificity (SPE) and area under the curve (AUC). **Results:** Initially, hyper-parameters for ML classifiers were optimized by performing 20 trials with different parameter sets and final models were developed using hyper-parameters from the best trials. All models had high AUC values (range: 0.85 - 0.89) and were able to correctly identify BBB+ chemicals with a sensitivity ranging from 0.86 - 0.89. However, the models had more moderate success at identifying BBB- compounds (range: 0.6 - 0.7). Such differences in model performance can be attributed to the imbalanced number of BBB+ (62%) and BBB- (38%) compounds in the modeling data set. After applying different balancing techniques, we were able to improve model performance on BBB- compounds. The best performing model was the graph convolutional neural network model with BACC = 0.79, SEN = 0.80, SPE = 0.79, and AUC = 0.88. Finally, we combined prediction of all seven balanced ML models into a consensus model that performed with a BACC = 0.81, SEN = 0.83, SPE = 0.79, and AUC = 0.89. **Conclusions:** The developed ML models provide a first step in screening a large number of chemicals for potential neurotoxicity and quickly identify chemicals for *in vitro* testing. Binary models, such as the one developed herein, provide a rapid yes/no answer to whether the predicted effect is likely to be true, which then allows the chemicals that are unlikely to cross the BBB to be deprioritized. This helps to reduce the number of necessary tests and improves study design. Regression models are being developed to estimate the extent to which chemicals cross the BBB permeability to aid in identifying chemicals with the highest potential for central nervous system toxicity. **Disclaimer:** No DoD endorsement implied.

PS 4034 Industry Perspectives on Evolving Off-Target Assessment: Insights from a Multicompany IQ DruSafe Survey

D. Zane¹, B. Berengere², A. Lagrutta³, C. Larner⁴, A. Olaharski⁵, V. Toledo Sales⁶, F. Schmidt⁷, J. Valentin⁸, and S. Mittelstadt⁹. ¹Gilead Sciences, Foster City, CA; ²Novartis Biomedical Research, Basel, Switzerland; ³Merck & Co. Inc, West Point, PA; ⁴AstraZeneca, Cambridge, United Kingdom; ⁵Relay Therapeutics, Cambridge, MA; ⁶Takeda Pharmaceuticals, Cambridge, MA; ⁷Sanofi, Frankfurt, Germany; ⁸UCB, Brussels, Belgium; and ⁹Abbvie Inc, North Chicago, IL.

Background and Purpose: Secondary pharmacology screening of investigational small-molecule drugs for potentially adverse off-target activities has become a well-established process and an essential stage in the characterization and development of novel pharmaceuticals. This screening helps ensure candidate molecules possess an acceptable safety profile by detecting interactions with undesirable targets. A recent publication reported that about one-third of the companies surveyed apply a core test of secondary pharmacology targets during drug lead optimization and over 90% of the companies conduct a core *in vitro* panel before drug candidate selection (Brennan et al., 2024; Schmidt et al., 2025). The paper also highlights that most organizations utilize panels exhibiting a high degree of overlap in the targets assessed, indicating that industry standards for secondary pharmacology screening are becoming increasingly harmonized. Review of data and literature by the IQ DruSafe Secondary Pharmacology Working Group helped to identify 33 additional targets for inclusion in secondary pharmacology profiling, reflecting the industry's drive towards a more comprehensive characterization of off-target risks. **Methods:** With general consensus forming around the composition of a core *in vitro* screening panel, an industry survey was conducted to identify opportunities to further expand the impact of off-target assessments of new molecules. **Results:** Sixteen companies responded to a broad range of questions which sought opinions on the potential integration of advanced computational capabilities, improving the evaluation for new or novel drug modalities, and adoption of new technologies for the assessment of off-target toxicology. The survey concluded that the greatest unmet need was an improved understanding of off-target assessments of protein degraders. Additionally, it recommended that panels for specific adverse effects such as convulsions, abuse liability, and neuropathy would be useful. Furthermore, the survey concluded that an industry-wide assessment of *in silico* capabilities and computational tools would be useful. Lastly, the group acknowledged that a broader discussion to harmonize the way secondary pharmacology results are submitted to regulatory agencies is necessary and beneficial. **Conclusions:** The effort could reveal innovative approaches that help streamline secondary pharmacology profiling and impact and further strengthen the overall efficiency of drug discovery and development processes.

PS 4035 Preclinical Safety Assessment of Targeted Protein Degraders: Current Practices and Considerations

A. Sedgwick¹, Z. Rankovic², S. Karaman³, and S. Targeted Protein Degradation Safety Committee⁴. ¹Vividion Therapeutics, San Diego, CA; ²Institute of Cancer Research, London, United Kingdom; ³Novartis, Cambridge, MA; and ⁴Health and Environmental Sciences Institute, Washington, DC.

Background and Purpose: The preclinical safety assessment of Targeted Protein Degraders (TPDs) presents unique challenges due to their unique physicochemical characteristics and novel mode of action involving induced protein ubiquitination and degradation. This presentation provides an overview of current practices employed across the pharmaceutical industry and academia to identify and evaluate potential safety concerns associated with TPDs. **Methods:** Insights from stakeholders were gathered through workshops highlighting emerging strategies such as proteomics-based target profiling, degrader selectivity assessment, and species selection for *in vivo* studies. In addition, case studies and a stakeholder survey were used to collect detailed input on study design considerations, including the use of *in vitro* systems, analytical methodologies, *in vivo* selectivity profiling, and data interpretation. **Results:** Overall, current practices reflect a pragmatic integration of established small molecule safety principles with emerging, modality-specific approaches tailored to TPDs. Out of these strategies, a majority (~92%) of the stakeholders indicated the incorporation of proteomics (global and/or targeted) as a common practice to assess degrader selectivity, targeted evaluation of functional liabilities (on/off target assessment), and adaptive preclinical study designs informed by degradation kinetics and tissue-specific risk profiles. **Conclusions:** These efforts provide a snapshot of safety evaluation strategies currently in use and identify key challenges in translating mechanistic insights into predictive toxicology frameworks.

PS 4036 Development of a Population Pharmacokinetic Model to Optimize Florfenicol Dosing for Treating Lactating and Non-Lactating Goats

X. Wu¹, K. Mi¹, L. A. Tell², and Z. Lin¹. ¹University of Florida, Gainesville, FL; and ²University of California, Davis, CA.

Background and Purpose: Florfenicol is a broad-spectrum antimicrobial that is administered to goats for treating respiratory disease. However, its use in this species is extralabel in the United States, and dosing recommendations for specific physiological populations is lacking. Such gaps may lead to inappropriate drug exposure and violative residues, posing potential food safety concerns. Population pharmacokinetic (PopPK) data for goats across differing physiological states are limited. This study aimed to develop a PopPK model for florfenicol in goats and assess effects of body weight, lactation, and dosing frequency on pharmacokinetic parameters to better optimize treatment regimens for various goat populations. **Methods:** Nineteen goats, including both lactating and non-lactating animals, received two doses of florfenicol (40 mg/kg) via subcutaneous injection at a 96-h treatment interval. Plasma concentration versus time profiles were analyzed using nonlinear mixed-effects modeling in Phoenix. Model selection, variability estimation, and covariate screening were performed stepwise based on objective function reduction, diagnostic plots, and visual predictive checks. **Results:** A two-compartment model with first-order absorption and elimination best described florfenicol pharmacokinetics. The population mean estimates were: absorption rate constant (K_a) = 0.51 h⁻¹, clearance (CL) = 0.54 L/h/kg, intercompartmental clearance (CL₂) = 1.08 L/h/kg, central volume of distribution (V₁) = 20.9 L/kg, and peripheral volume (V₂) = 80.0 L/kg. Body weight did not significantly affect K_a , V₁, CL, V₂, or CL₂. Lactation was a significant covariate on CL₂, increasing intercompartmental clearance by about 16.64% compared with non-lactating animals. The inter-occasion variability (IOV) estimates for K_a , V₁, CL, V₂, and CL₂ were small (≤0.09), indicating minimal within-animal differences between the two dosing occasions. **Conclusions:** The developed PopPK model adequately captured the pharmacokinetic variability of florfenicol in goats. Lactation primarily influenced intercompartmental clearance, while dosing occasion showed minimal impact on pharmacokinetic parameters. Body weight had negligible effects. These findings provide a quantitative foundation for dose optimization and preliminary assessment of food safety in both lactating and non-lactating goats.

PS 4037 Rigorously Optimized Immunohistochemistry Methods Support Robust Assessment of Pharmacodynamic Effects in African Green Monkeys

R. Bouffard, E. Ramirez, M. Miles, S. Korte, E. Hines, N. Swierzawski, G. Jalalahmadi, M. Lawrence, and I. Mikaelian. Virscio, New Haven, CT.

Background and Purpose: Immunohistochemistry (IHC) with quantitative image analysis remains an informative and cost-effective method for assessing pharmacodynamic (PD) endpoints in nonclinical species. However, variability in reagent characterization and assay verification across species limits reproducibility and biological confidence. This challenge is increasingly critical in the era of AI-assisted pathology and image analysis, where automated interpretation may conflate valid biological signals with artifacts or algorithmic hallucinations. Consequently, there is

a growing need for rigorous, multi-layered validation frameworks that can substantiate the biological and run-to-run fidelity of IHC reagents and assays. **Methods:** Our workflow integrates orthogonal molecular approaches, notably single-cell RNA sequencing (scRNA-seq) with systematic experimental optimization. Target proteins are first characterized, leveraging publicly available scRNA-seq and proteomic datasets to define expected cellular and subcellular localization patterns. This molecular context establishes a biologically grounded expectation for staining specificity and distribution. Each IHC assay is then optimized using a tissue microarray (TMA) composed of 20-30 perfused, fixed tissues from the African green monkey (AGM, *Chlorocebus sabaeus*). TMAs represent broad tissue diversity encompassing most of the FDA-recommended list for tissue cross-reactivity studies, replicate sets from distinct animals, or fixation- and phenotype-specific cohorts. After selecting appropriate TMA(s), assay development proceeds across a range of conditions designed to generate signal intensities from near extinction to saturation, enabling fine control of dynamic range and minimizing off-target staining. Both chromogenic and fluorescent modalities are optimized in parallel, facilitating adaptation to multiplexed IHC workflows. Multiple antibodies against the same target protein are assessed for commonly used markers. Following optimization, TMA slides are digitally scanned, archived, and used as long-term reference standards to assess assay stability and reproducibility. Over 120 assays were developed on AGM samples, with many also evaluated on murine TMAs. **Results:** Assay performance, optimal conditions, and comparative antibody data were compiled into a database of annotated slide decks. Antibodies that recognize epitopes associated with the same cell types (I.E., endothelial cells) or that recognize cells belonging to the same class (I.E. different classes of T-cells) were compared and grouped together in additional slide decks. Commercially available antibodies were suitable for detecting almost all proteins we attempted to detect in AGM samples. We observed that the detection of certain proteins is fixation-dependent, such as IBA1 which is nearly impossible to detect in Davidson's-fixed samples and alternative markers of macrophages and microglia were necessary. The optimal antibody and antibody concentration were also often fixation- and species-dependent. Only 1 of 3 clones of CD31 yielded an adequate signal in AGM tissues whereas a different clone was more optimal in murine tissues. PV-1 better demonstrates neovascularization in the choroid compared to other endothelial markers, whereas Claudin-5 better visualizes vessels of the blood brain barrier. Common tissues and cell types prone to non-specific signals were also made evident by this system. Of note, G cells, plasma-rich tissues, thyroid follicular cells, and acinar cells more commonly demonstrate non-specific signals. **Conclusions:** This approach provides a robust means of assessing pharmacodynamic endpoints derived from IHC and characterizes any inherent flaws of a given assay, enhances scientific confidence, and offers a harmonized standard for a high-fidelity research environment. It is a useful tool for rapidly screening antibodies in the context of different species, tissue types, and IHC methods and reagents. It reduces interobserver variability by establishing documented and easily referenced ground truths in a database. Image analysis pipelines are enhanced by facilitating more accurate annotation and enabling quality control against robust references.

PS 4038 Assessing Fibrosis: Picrosirius Red and COL1A1 Immunohistochemistry as Alternatives to Masson's Trichrome Staining

I. Hernandez, E. Ramirez, R. Bouffard, E. Hines, G. Jalalahmadi, N. Swierzawski, S. Korte, M. Lawrence, and I. Mikaelian. Virscio, New Haven, CT.

Background and Purpose: Masson's trichrome (MT) stain, developed by Canadian pathologist Claude L. Pierre Masson in the early 20th century, remains one of the most widely applied histological methods for identifying and quantifying collagen deposition in tissues. MT and its numerous adaptations have been integral in assessing fibrosis and extracellular matrix (ECM) remodeling in a variety of disease contexts, including metabolic dysfunction-associated steatohepatitis (MASH), cardiac fibrosis, and tumor-associated stroma formation. Despite its ubiquity and low cost, MT is subject to interpretative variability and technical limitations that reduce its specificity and sensitivity, particularly when quantitative image analysis is required. **Methods:** Masson's trichrome staining was systematically compared to a modified Picrosirius Red (PSR) protocol incorporating phosphomolybdic acid and collagen type I alpha 1 (COL1A1) immunohistochemistry (IHC). The comparison was performed across a panel of 20 normal and 20 diseased tissues derived from African green monkeys (*Chlorocebus aethiops*), representing a diverse range of tissue architectures and pathologic conditions. **Results:** While MT staining reliably identified regions of dense collagen, its limitations were pronounced. Incomplete visualization of both thick and thin collagen fibers, non-specific staining of plasma and goblet cells, a broad range of blue chromatic intensities historically interpreted as "collagen," and occasional nuclear staining all contributed to challenges in both qualitative assessment and automated digital quantification. In contrast, PSR staining, particularly when enhanced with phosphomolybdic acid, produced superior fiber differentiation and more consistent contrast between collagen and surrounding parenchyma. PSR's strong birefringence under polarized light provided an additional analytical dimension, facilitating assessment of collagen maturity and organization. However, like MT, PSR remains a non-specific histochemical approach and cannot discriminate between collagen subtypes or related ECM proteins. COL1A1 IHC demonstrated the highest specificity and structural resolution among the three methods. This approach revealed extracellular matrix elements that were underrepresented or entirely absent in MT and PSR staining, including basement membranes

of hepatic and adrenal sinusoids, periadipocytic collagen, and delicate pericapillary collagen networks within the lamina propria of the small intestine. These findings were consistent with prior observations in rodent and human tissue panels from our laboratory. **Conclusions:** Overall, while MT retains value as a rapid and cost-effective stain for general fibrosis assessment, its interpretive and technical shortcomings limit its suitability for quantitative digital pathology. PSR represents an improved histochemical alternative when cost constraints preclude immunohistochemistry but may require assessment of collagen organization under polarized light. However, COL1A1 IHC provides the most biologically relevant and reproducible measurement of collagen deposition and ECM remodeling, making it the preferred method in workflows that incorporate digital image analysis or where precise mapping of collagen architecture is required. Future work will extend this comparative framework to include additional IHC reagents targeting other collagen subtypes, such as COL4A1, to better delineate the structural and functional diversity of ECM components across tissues and disease states.

PS 4039 A Sliding Scale to Evaluate Safety Margins for Drugs with a Long Half-life: Oteseconazole, A Case Study

R. Gee, S. Brand, J. Jennings, and T. Degenhardt. Mycovia Pharmaceuticals, Inc., Durham, NC. Sponsor: *M. Aleo*

Background and Purpose: While there is no mandatory FDA safety requirement that explicitly states a drug must be cleared for a specific number of half-lives, the “five half-lives rule” is a widely accepted *pharmacokinetic principle*, often adopted by the FDA, and used as a general guideline for when a drug is considered to be effectively eliminated from the body or has reached steady state, as approximately 94% to 97% of the drug is cleared after 4 to 5 half-lives. The appropriateness of this concept, in context of FDA guidelines and the impact on safety margins for drugs with a long half-life will be discussed. **Methods:** Drug safety margins are typically calculated as the exposure ratio between the no observed adverse effect level (NOAEL) in animal species and the maximum recommended human dose (MRHD). This ratio is critical for assessing risk, especially in reproductive and developmental toxicity, and is outlined in S5(R3) Detection of Reproductive and Developmental Toxicity for Human Pharmaceuticals Guidance for Industry May 2021 ICH Revision 3. Safety margins and the requirement for contraception are critical considerations in clinical trials and for the use of certain pharmaceuticals, particularly when there is a potential risk of harm to a fetus. When this margin is insufficient, contraception is often required to prevent pregnancy. Patient-centered approaches now prioritize a person’s preferences and autonomy in making contraceptive decisions, but safety concerns remain a core consideration. Typically, small molecules may require the use of effective contraception for five terminal plasma half-lives. This period ensures that the systemic concentration of the drug has been sufficiently cleared. For drugs with exceedingly long half-lives, ensuring strict adherence to contraception use could prove overtly challenging and delay access to an important treatment option. This rule does not take into consideration that safety margins change over time as the drug is eliminated and a larger safety margin that is considered minimal risk could be achieved much sooner than 5 half-lives. **Results:** Oteseconazole (VIVJOA®) is approved in the USA and in China for the treatment of recurrent vaginal candidiasis, and severe vaginal candidiasis, respectively, in women who are not of reproductive potential. Oteseconazole was rationally designed to target fungal cytochrome P51 while avoiding human cytochromes thus avoiding safety concerns often associated with the azole drug class. By avoiding host cytochromes typically responsible for drug metabolism and elimination, the resulting terminal half-life is calculated to be 138 days, and pharmacokinetics are further influenced as the drug is 99.5-99.7 bound to plasma. Based on ocular abnormalities reported in rat pre- and postnatal development studies, and in accordance with the FDA Guidance S5(R3), a 3.5-fold safety margin was established for oteseconazole at the time of last dose. This is considered to be a safety margin corresponding to a threshold for “increased concern.” Pharmacokinetic analysis of plasma from women participating in Phase 3 studies indicated that at the 12-month time point from last dose (approximately 3 half-lives) a safety margin of >25-fold is established. Based on the FDA Guidance, a 25-fold safety margin is considered a “minor concern” for clinical use of a drug. **Conclusions:** The modeling supports the position that acceptable safety margins can be readily achieved for drugs with a long half-life and the “five half-lives rule” is potentially unnecessary and may limit patient access.

PS 4040 Implementation of the Modified Irwin Test as a General Functional Observation Battery for the African Green Monkey

S. Korte, R. Hancock, R. Pike, K. Cruz, I. Castor-Colmanar, C. Anselm, R. St Hilaire, and M. Lawrence. Virscio, New Haven, CT.

Background and Purpose: The use of neurobehavioural methods for determination of neurotoxic potentials of NCEs (new chemical entities) is recommended and implemented in the ICH S7A, 2000. As nonhuman primates are the closest phylogenetic relatives to human, they play an indispensable role in biomedical research due to their highly evolved behavioral repertoire which makes them valuable animal models for studies of the functional effects of potential drug therapies and neurotoxins (Sibal and Samson, 2001; Burbacher and Grant, 2000). While general functional

observation batteries (FOB) are well described for macaques (e.g. modified Irwin test; *Gauvin and Baird, 2008; Korte, 2007*), limited literature is available for safety assessments in the African green monkeys (AGMs). As these examinations are an essential part of toxicity studies in AGM’s when undergoing nonsystemic ASO, AAV and other gene therapies, or embryonic stem cell delivery in the intrathecal space or the brain, background data were required to allow adequate safety assessment. **Methods:** In two regulatory safety studies in which 50 AGMs underwent serial morning non-sedated cage side assessment of peripheral and central nervous system activities pre-dose and pre-study, excluding test article effects. At each timepoint, the recorded observations included respiration, head twitches, vocalizations, body position, jumping, auditory reflex, locomotor activity, tremor, righting reflex, sedation / excitation, twitch, ataxia, seizures, piloerection, lacrimation, aggressiveness toward handler, salivation, unusual behavior, grooming. In addition, neurological exams with non-sedated animals were conducted at designated intervals by a veterinarian and included the following tests: gait, proprioceptive positioning, placing reactions (visual and tactile), head movements, head muscle tone, eye reactions, eye symmetry, eye position, vestibular nystagmus, pupillary light reflex, nasal septum, palpebral reflex, eye tracking, jaw tone, muscle tone, perineal reflex, and withdrawal reflex. **Results:** Experimenters noted increases, decreases, and severity of the behavioral symptoms or physiological manifestations in comparison with (a) normal stock animals and (b) the control group. The standard rating system consisted of a score of 0 = normal activity of each specific outcome. Scores of 0, 1, 2, 3, or 4 grade the level of behaviors observed as normal (healthy stock animal), slight, moderate, extreme, or severe. **Conclusions:** In summary, the normalized FOB database now allows robust comparison with test article treated AGMs and provides a citable historical normal reference range.

PS 4041 Cardiovascular and Respiratory Safety Pharmacology Study of Mitragynine in Telemetered Dogs

M. Durai¹, T. Horn², C. McCurdy³, A. Sharma³, A. Hampson⁴, J. Donnelly⁴, and P. Terse¹. ¹National Center for Advancing Translational Sciences (NIH), Rockville, MD; ²ITRI, Chicago, IL; ³University of Florida, Gainesville, FL; and ⁴National Institute on Drug Abuse (NIH), Bethesda, MD.

Background and Purpose: Opioid Use Disorder (OUD) is a chronic condition, characterized by increased opioid tolerance, compulsive and continued use of opioid despite having harmful effects and a significant risk of lethal overdose. OUD significantly diminishes quality of life, contributing to a widespread epidemic and it has been designated as “Public Health Emergency” in the United States. Buprenorphine and methadone are the first-line treatment options for OUD patients. Methadone is a long-acting, full mu-opioid receptor (MOR) agonist, available in single daily doses at highly regulated clinics. However, buprenorphine is a partial MOR agonist with a lower risk of lethal overdose and can be taken with fewer restrictions. Most of the buprenorphine patients aim to ultimately discontinue the opioid use, with the support of naltrexone (MOR antagonist) therapy. Like other opioids, buprenorphine can lead to dependence and withdrawal symptoms if stopped abruptly, in addition to the risk of serious respiratory depression with high doses. Mitragynine is a primary alkaloid derived from *Mitragyna speciosa*, commonly known as *kratom*, a tropical tree native to Southeast Asia. Its leaves have been consumed orally, either as tea or by direct chewing and used as an analgesic, a stimulant, and a mood enhancer. Mitragynine is a less potent MOR partial agonist, with lower agonist activity than buprenorphine and possesses milder withdrawal symptoms. In addition, mitragynine acts as an alpha 2 adrenergic receptor agonist. The low MOR activity makes mitragynine an appropriate bridging therapeutic for transition from long term buprenorphine to naltrexone therapy for OUD. Thus, we are developing mitragynine as an oral therapy for successful taper-off of buprenorphine in OUD patients while transitioning to naltrexone therapy to achieve opioid-free life. **Methods:** The objective of this study was to evaluate the acute effects of mitragynine following a single oral administration (0, 2.5, 7.5 and 12 mg/kg) on cardiovascular and respiratory functions in the conscious beagle dogs. Four male and four female dogs were assigned to four oral dose levels on four dosing days with assignments determined using a balanced Latin-Square crossover design, to maximize the number of dosing combinations possible (N = 4 doses/sex/group). Each dose was followed by a wash out period of at least seven days. Surgically implanted telemetry devices in the beagle dogs monitored the following parameters continuously for at least 24 hours prior to dosing and through 48 hours after dosing; body temperature (degrees Celsius), heart rate (beats per minute), diastolic, systolic and mean blood pressure (mm Hg), electrocardiogram (ECG) (in milliseconds; PR, RR, QTc and QRS intervals), and respiratory parameters [respiratory rate, tidal volume (measured), minute volume (calculated)]. Additional measurements from the study animals included moribundity/mortality, cage-side clinical observations, detailed physical examinations, body weight/body weight change, and clinical pathology parameters (clinical chemistry, hematology, and coagulation). **Results:** Administration of a single dose of mitragynine in beagle dogs did not result in any toxicologically significant findings in all the parameters evaluated. Decreases in heart rate and corresponding increases in the RR interval were observed during the study in all mitragynine-treated groups. There was an increase in systolic blood pressure in all mitragynine treated males; however, this effect was not seen in females except slight increases in the high dose group. **Conclusions:** Overall, these changes were mild and transient and were resolved usually within 24 hours of

dosing, hence considered as non-adverse. (Confidential; Supported by Contract No. HHSN2712017000161 under HEAL/NCATS program; NIDA R01 DA047855 and UG/UH3DA048353 to AS and CM).

PS 4042 Preclinical Toxicity Assessment of IS-002, a Novel Imaging Agent, in the 7-Day Toxicity Study

K. Kabirov¹, J. Fischer¹, A. Zakharov¹, S. Dutta², A. Antaris², K. Hleb², and A. Lyubimov¹. ¹Toxicology Research Laboratory, UIC, Chicago, IL; and ²Intuitive Fluorescent Imaging, Sunnyvale, CA.

Background and Purpose: IS-002 is a small molecule and near-infrared (NIR) imaging agent. This compound is under development by Intuitive Surgical (Sunnyvale, CA) as an imaging agent to aid in the visualization of prostate tumors with Firefly Fluorescence Imaging during robotic-assisted prostatectomies. The purpose of this study was to evaluate the toxicity and toxicokinetics of IS-002 in CrI:CD (SD) (Virus Antibody Free) rats following single daily intravenous administration for 7 days, with a subsequent two-week recovery period. **Methods:** The IS-002 dose levels studied were 0 (control), 0.2, 1.6, and 16 mg/kg. The test article formulation and the vehicle (0.9% Sodium Chloride Injection, USP) were administered into the tail vein once each day for seven consecutive days. CrI:CD (SD) rats were obtained from Charles River Breeding Laboratories. The following tests and measurements were used: mortality, clinical signs, physical examination, body weight, food consumption, ophthalmologic examination, clinical pathology, plasma drug level determination, pharmacokinetic analysis, and histopathology. **Results:** No adverse clinical signs were observed. There were no test article-related differences in body weight, body weight changes, or food consumption between the dose groups administered with IS-002 and the control group. Post-dose ophthalmic examination on Day 7 did not reveal any abnormalities in the eyes. There were no test article-related changes in hematology, coagulation, and urinalysis parameters at the end of the treatment period (Day 8) or after the recovery period (Day 22). On Day 8, there were substantial (males) and statistically significant (females) increases in mean creatinine in Group 4 when compared with the control group. On Day 22, in males, there were statistically significant increases in mean creatinine in Group 4 compared to the control group. There were no test article-related changes in the other clinical chemistry parameters on Day 8 or Day 22. The test article was not detected (i.e., concentration < 0.05 µg/mL) in the plasma of control group animals. In all IS-002 dose groups, peak plasma levels ($C_{max-obs}$) occurred at the 2-minute time point after single or 7-day consecutive IS-002 administration at 0.2, 1.6, or 16 mg/kg. In all IS-002 dose groups, the test article was quantifiable until the last time point (i.e., 30 hours after dosing on Days 1 and 7). The IS-002 $t_{1/2-\lambda_z}$ ranged from 7.85 to 10.74 hours, CL from 0.15 mL/min/kg to 0.23 mL/min/kg, and V_{ss} from 0.13 L/kg to 0.16 L/kg across dose, administration day, and sex cohorts. IS-002 CL, V_{ss} , V_{ss}/V_{ss} , λ_z , and $t_{1/2-\lambda_z}$ were not meaningfully influenced by dose, single-dose versus multiple-dose administration, or sex. Dose proportionality was observed for IS-002 peak and total systemic exposure between 0.2 mg/kg and 16 mg/kg intravenous doses. On Day 22, there was a statistically significant increase in the mean testes/brain weight ratio in Group 4 rats compared with the control group animals. **Conclusions:** Seven-day once daily intravenous administration of IS-002 at 16 mg/kg resulted in statistically significant increases in clinical chemistry parameters (creatinine) and relative organ weights (testes/brain weight). The no-observed-adverse-effect level (NOAEL) was established at the IS-002 dose level of 1.6 mg/kg. The results of this study were used to support the IS-002 clinical trials.

PS 4043 Pulmonary injury and resulting hypoxia as a mechanism of hemangiosarcoma induction in mice treated with amiselimod, a sphingosine-1-phosphate receptor 1 modulator

M. Mizukawa, M. Miyake, S. Nishikawa, and T. Yamamoto. Tanabe Pharma Corporation, Fujisawa, Japan. Sponsor: S. Nishikawa, Japanese Society of Toxicology

Background and Purpose: Amiselimod is a modulator of sphingosine-1-phosphate receptor 1 (S1P1). In rodent carcinogenicity studies of amiselimod, the incidence of hemangiosarcoma (HSA) was increased in male mice, but not in female mice or in rats. Several drugs are known to induce HSA in mice, and previous research suggests that hypoxia is a key event in this process. Meanwhile, for siponimod, another S1P1 modulator, the increased incidence of HSA in mice has been linked to the induction of placental growth factor 2 (PLGF2) production in vascular endothelial cells (VEC) by a mechanism that has not yet been fully elucidated. This suggests that, in addition to hypoxia, PLGF2 induction may play an important role in the development of HSA in mice. Pulmonary lesions were observed in short- and long-term mouse toxicity studies with amiselimod, which may have caused hypoxia. Therefore, this study aimed to investigate whether low oxygen (hypoxia) is involved in amiselimod-induced HSA in mice. **Methods:** 1) Toxicogenomics: Amiselimod was administered to CrI:CD1(ICR) male mice by oral gavage at doses of 0 (vehicle) or 30 mg/kg/day once daily for up to 2 weeks. Liver and spleen were collected and processed for transcriptomic analysis at 6 and 24 hours after the first dose, and at 6 hours after the 4th and 14th doses (n=3 animals/timepoint/group). 2) Immunohistochemistry (IHC): Amiselimod was administered to CrI:CD1(ICR) mice (8 males/group) once daily by oral gavage at doses of 0 (vehicle), 30, or 100 mg/kg/day for 2 or 4 weeks. To detect tissue

hypoxia, hypoxyprobe (HP; pimonidazole) was administered via intraperitoneal injection approximately 90 minutes prior to necropsy. Liver and spleen sections were anti-pimonidazole antibody and HP-positive areas were analyzed using HALO image analysis software. To detect VEC proliferation, liver specimens were triple-immunostained with anti-Ki67 (proliferation marker), anti-Iba1 (Kupffer cell marker), and anti-CD31 (endothelial cell marker) antibodies, then analyzed by HALO image analysis software. **Results:** Toxicogenomics: The transcriptomic analysis indicated that amiselimod up-regulated the expression of macrophage activation related genes both in liver and spleen after single dosing as well as the expression of erythropoiesis and cell cycle related genes only in spleen after single dosing. IHC: In spleen, there was significant immunostaining with HP (2W,100 mg/kg), with HP positive staining observed in some animals (2W:3/16(19%),4W:2/15(13%). As for the liver, no statistically significant changes were observed in positive staining areas in any of the test conditions. VEC proliferative activity in the liver was significantly increased at 30 and 100 mg/kg/day following 4 weeks of amiselimod treatment relative to vehicle control. Collectively, these results demonstrated induction of hypoxia, macrophage activation, dysregulation of hematopoiesis, and enhanced vascular endothelial cell proliferation following amiselimod administration to mice. These findings support a mechanism similar to the hypoxia-driven pathway for mouse vascular sarcoma induction proposed by Cohen et al. Notably, there were no hypoxia-related pulmonary lesions in amiselimod chronic toxicity studies in rats or monkeys, and no changes in pulmonary function in amiselimod clinical trials. **Conclusions:** In our study, we observed that the pulmonary injury previously noted with amiselimod administration in mice was associated with hypoxic conditions, which promoted VEC proliferation. Consistent with hypoxic conditions, genes related to macrophage activation and hematopoiesis dysregulation were up-regulated. Considering these findings, the increase in HSA incidence following amiselimod exposure is likely associated with hypoxia-driven resulting VEC proliferation. Finally, considering that no pulmonary lesions were observed in chronic toxicity studies in rats and monkeys, and that no changes in pulmonary function were detected in amiselimod clinical trials, the occurrence of HSA following amiselimod administration appears to be highly specific to mice, with low extrapolability to humans.

PS 4044 CSTF2/2T CELMoD Degradors and Double Knockout Studies: On-Target Toxicological Liabilities

V. Bhaskaran¹, J. Nicklay¹, J. Zalaznick¹, E. Ciccamaro¹, S. Wagh², A. Jadhav², Y. Cho², K. DiPetrillo³, D. Johnson⁴, T. Tsuji⁴, M. Ammirante⁴, N. Katenahalli⁵, and K. Augustine¹. ¹Bristol-Myers Squibb, Princeton, NJ; ²Bristol-Myers Squibb, Cambridge, MA; ³Bristol-Myers Squibb, New Brunswick, NJ; ⁴Bristol-Myers Squibb, San Diego, CA; and ⁵Biocon, Bengaluru, India.

Background and Purpose: Cleavage stimulation factor subunit 2 (CSTF2) and its paralog CSTF2T are involved in pre-mRNA processing via alternative polyadenylation (APA), a regulatory mechanism impacting mRNA stability and translation. Dysregulation of APA is common in cancer, including hepatocellular carcinoma (HCC), and CSTF2 regulates APA dynamics in cancer-related genes. CSTF2 overexpression correlates with poor clinical outcomes. The therapeutic hypothesis was that a CSTF2/2T CELMoD would impair proximal polyadenylation site usage of mRNA, thereby regulating oncogenic transcripts and cancer growth. **Methods:** Two potent CSTF2/2T dual degradors (BMS-A and BMS-B) demonstrating favorable ADME characteristics were synthesized, tested, and subjected to toxicity assessment at doses ranging from 30 mg/kg to 300 mg/kg for up to 7 days in humanized cereblon mouse models (NSG hCRBN and C57 hCRBN). CSTF2/2T loss-of-function was assessed in inducible double-KO (iKO) mice over 1-month and 6-month durations using varying doses of tamoxifen. **Results:** BMS-A and BMS-B evaluated in the NSG and C57 hCRBN mice revealed significant toxicities. BMS-A was administered at 100 and 300 mpk 7 days in C57 hCRBN mice and caused multiple organ toxicities. In another study, BMS A was dosed at 120 mg/kg and BMS-B was dosed at 30, 60 and 120 in NSG CRBN mice for 6-7 days. In this study BMS-A caused renal tubule degeneration and BMS-B caused both renal tubule degeneration and hepatotoxicity (elevated liver enzymes at all doses and hepatic vacuolation at 60 and 120 mg/kg). To better understand whether these toxicities were target-mediated, inducible CSTF2/2T double knock out (iKO) mice were generated and evaluated. In 1-month inducible knockout (iKO) study where target expression was excised with 5-days intraperitoneal (IP) treatment with 75mg/kg tamoxifen, mice showed good tolerability with no adverse clinical signs or body weight changes but had mild increases in AST and ALT liver enzymes. LC-MS/MS showed CSTF2 protein expression decreased significantly in spleen and kidney, while CSTF2T expression increased. A 6-month iKO mouse study was conducted with 5-days IP treatment with 150 and 200 mg/kg tamoxifen to achieve improved excision of CSTF2 and CSTF2T in peripheral tissues and in the brain. Significant and severe adverse effects including mortality in some mice were observed on study days 9 and 10. Adverse effects included 15 to 20% body weight loss, abnormal gait, half closed eyes, hunched posture, decreased activity, elevated liver enzymes and decreased glucose. Most frequent macroscopic findings included small spleen, fluid filled intestines, dark or pale caecum, male reproductive findings, and mottled, friable liver and/or enlarged gall bladder. Histopathology of liver and kidney revealed vacuolation in these tissues. Like the 1-month study, LC-MS analysis in liver revealed that CSTF2 protein levels decreased, whereas CSTF2T protein levels increased. RT-PCR using primers spanning the full length of CSTF2 and CSTF2T transcripts indicated lower CSTF2 mRNA expression, with CSTF2T showing minimal change in the liver. No evidence of mRNA truncation was detected by transcription

analysis suggesting possible translational/post-translational compensatory increase in CSTF2T protein might have occurred due to the loss of CSTF2 protein expression. **Conclusions:** Dual CSTF2/2T degradation in hCRBN mice or dual CSTF2/2T knock-down in inducible knockout mice revealed significant on-target toxicities affecting many organs including the liver and kidney and revealed an unexpected increase in CSTF2T protein, suggesting potential imbalances in expression of these proteins may lead to toxicity.

PS 4045 A Case of Cardiac Myocyte Degeneration in Cynomolgus Monkey with characteristic Concentric change of myofiber cross section: a histopathological case study from a safety assessment perspective

A. Morita, A. Goto, Y. Seki, and E. Ohta. Eisai Co., Ltd., Tsukuba, Ibaraki, Japan. Sponsor: S. Asakura, Japanese Society of Toxicology

Background and Purpose: Accurate evaluation of drug-induced effects in nonclinical safety studies requires a thorough understanding of background lesions and secondary changes associated with deteriorating animal conditions. In our experience, a cynomolgus monkey that exhibited chronic weight loss followed by acute deterioration and reduced activity showed distinctive myocardial degeneration characterized histologically by a concentric appearance of cross sectional myofibers. This study aims to characterize histological feature of the myocardial changes and discuss their implications for histopathological interpretation in this animal with compromised health status. **Methods:** A 9-year-old female non treated cynomolgus monkey exhibited chronic weight loss and was euthanized due to acute moribundity of decreased activity and hypothermia. Macroscopic examination and histopathologic evaluation by hematoxylin and eosin (H&E) staining were performed. Additional analyses in the heart included phosphotungstic acid hematoxylin (PTAH) as well as transmission electron microscopy. Macrophage infiltration was assessed by Iba-1 immunostaining. Comparative evaluation was conducted against an age-matched normal animal. **Results:** In histopathologic evaluation of this animal, degenerative myocardial fibers exhibiting a concentric myofibrils structure was observed without macroscopic findings in the heart. The lesion was accompanied by coagulative necrosis of the fibers. PTAH staining and ultrastructural examination revealed abnormal localization of the myofibrils, characterized by their centralized clustering around the nucleus and decreased density in the peripheral cytoplasmic area. Iba-1 immunostaining demonstrated increased macrophage infiltration surrounding the degenerated and necrotic myofibers. **Conclusions:** To our knowledge, this distinctive myocardial lesion has not been clearly documented in terms of its histological features and pathological implications, and it may represent as one form of myocardial degeneration. We considered its pathogenesis was likely contributed by various complex factors, including systemic condition and metabolic state by altering myocardial energy metabolism, oxygen supply, or cellular resilience under stress conditions. Deeper understanding of these background or secondary myocardial changes helps distinguish spontaneous or secondary degenerative processes from potential drug-induced changes, thereby improving the reliability of pathological interpretation and overall toxicologic evaluation.

PS 4046 Body weight loss without reduction in food consumption observed in cynomolgus monkeys during non-clinical toxicity studies

K. Takahashi, N. Hike, H. Ogura, T. Okamura, D. Yamamoto, and J. Sato. Mediford Corporation, Kamisu, Japan. Sponsor: K. Takahashi, Japanese Society of Toxicology

Background and Purpose: Cynomolgus monkeys have been used in non-clinical toxicity studies because they are anatomically and physiologically homologous to humans compared to other mammals such as rats and minipigs. Toxicity studies involving monkeys provide valuable data for drug development regarding the potential effects of drugs on humans. Weight loss is occasionally observed in monkeys during toxicity studies and can be difficult to differentiate from drug effects. This study retrospectively analyzed data from control group monkeys without drug treatment to investigate the incidence of weight loss and its physiological and pathological characteristics. We also investigated potential improvements through enhanced animal welfare. **Methods:** Animals in the control groups of the 4-week and 13-week repeated-dose monkey toxicity studies conducted at the test facility were retrospectively analyzed. The study included data from forty-six 4-week repeated-dose toxicity studies (male: n=206, female: n=196) and thirty-three 13-week repeated-dose toxicity studies (male: n=146, female: n=136) in monkeys conducted at the test facility from 2010 to 2022. Animals were weighed before feeding. The weight change rate (%) was calculated from initial body weight of the acclimation period to final body weight during the treatment period. Data of clinical observation, food consumption, hematology, blood chemistry, organ weight, necropsy, and histopathology were also investigated. Since September 2015, measures to improve animal welfare have been implemented at the test facility such as providing enrichment items, overproviding treats, and full-scale group rearing before the start of studies. We compared weight change rate before and after the start of the enrichment program. **Results:** Among the animals in the control groups, 3 animals in the 4-week toxicity studies and 5 animals in the 13-week toxicity studies showed a weight change rate of less than

-10%, resulting in an incidence rate of 1.2%. However, these animals had adequate food consumption. The animals in the 4-week toxicity studies showed signs of stress in histopathology. Additionally, 2/3 animals in the 4-week toxicity studies had decreased blood glucose levels and 1/5 animal in the 13-week toxicity study fell into a crouching posture, suggesting hypoglycemia that was alleviated with glucose administration, indicating stress-induced metabolic abnormalities. From 2015, an enrichment program was implemented to improve animal welfare. Prior to this program, 2.4% of animals showed a weight change rate of less than -10%, which dropped to 0.25% post-implementation, suggesting the program's effectiveness in reducing stress. **Conclusions:** These results clarify the characteristics of animals that lose weight during toxicity studies and suggest that improving animal welfare can reduce the incidence rate. Reference: Takahashi, et al., Experimental Animals, in press.

PS 4047 Method Qualification for the determination of Total antibody, ADC and free payload from ADC using LC-MS/MS

Y. Zhong, and M. M. Xu. Pharmaron (Ningbo) Bioscience Services Co., Ltd., Ningbo City, Zhejiang Province, China. Sponsor: S. Luo

Background and Purpose: Antibody-Drug Conjugates (ADCs) are a class of targeted anticancer therapeutics composed of an antibody, a linker, and a payload/cytotoxic drug. Traditional analytical methods for ADCs predominantly rely on ELISA. However, ELISA analysis is often limited to intact ADC and total antibody, with method development being relatively slow and constrained by antibody validation requirements. In contrast, LC-MS/MS provides crucial technical support for ADC bioanalysis due to its high specificity, independence from affinity reagents, accurate quantification of key components (total drug, ADC, and free cytotoxic drug), and faster method development. Here, we present a two-in-one approach for the simultaneous measurement of total antibody and protease-cleavable cytotoxic drug, along with a separate method for detecting free cytotoxic drug. **Methods:** The process of the two-in-one approach for measuring total antibody and protease-cleavable conjugated cytotoxic drug is as follows: analytes in the test sample are captured using magnetic beads, and a portion is aliquoted for the analysis of the protease-cleavable cytotoxic drug. Papan and β -glucuronidase are added to the aliquoted sample for enzymatic cleavage. Following cleavage, proteins are precipitated using high-concentration acetonitrile and centrifuged, after which the supernatant is collected for LC-MS/MS analysis of the protease-cleavable cytotoxic drug. The remaining sample is used for total antibody analysis: it is digested with trypsin to generate signature peptide fragments of the antibody, and these signature peptides are then analyzed via LC-MS/MS as surrogates for the total antibody. The approach for measuring free cytotoxic drug: high-concentration acetonitrile is added to the sample, followed by vortexing and centrifugation; the supernatant is then injected for analysis. The LC-MS/MS system conditions are identical to those used for the protease-cleavable cytotoxic drug. **Results:** The quantitative linear range for total antibody and protease-cleavable cytotoxic drug was 0.5 - 60 μ g/mL, while that for free cytotoxic drug was 0.01 - 2 ng/mL. The method demonstrated excellent robustness and reliability during validation, and is suitable for the accurate quantification of target analytes in complex biological samples, thereby, providing a reliable tool for pharmacokinetic and biodistribution studies. **Conclusions:** This method has been successfully applied to the analysis of ADC therapeutics, consistently generating reliable and reproducible data. The results confirm its significant value for the critical quality attribute assessment and stability monitoring of complex biopharmaceuticals.

PS 4048 Antisense oligonucleotides (ASOs) for gene therapy: A retrospective analysis of toxicology and safety pharmacology study designs and class effects.

C. Pin  tre¹, S. Authier¹, S. Quilez¹, C. Beaulieu¹, C. Paquette¹, D. Mayamee¹, S. Bulera², and K. Wong¹. ¹Charles River Laboratories, Laval, QC, Canada; and ²Charles River Laboratories, Reno, NV.

Background and Purpose: The rapidly evolving field of gene and nucleic acid therapy has presented exciting options for the treatment of many previously untreatable or poorly managed diseases and disorders. These therapies include several different families of molecular tools, such as antisense oligonucleotides (ASOs), designed to modulate gene and protein expression. In order to bring ASO-based therapies into a clinical setting, researchers must assess their short- and long-term toxicity profiles in pre-clinical studies to establish conditions for safe clinical use. **Methods:** A retrospective analysis of ASO-specific toxicology and safety pharmacology studies conducted across multiple test sites over a span of five (5) years are presented, with a focus on study designs and class effects. Emerging industry trends are highlighted with respect to dosing regimens, species selection, study duration, and study endpoints, and provide insights and recommendations on the design of ASO therapy toxicology and safety pharmacology studies, including a commentary on biologically relevant dose ranges for these promising molecular tools. As well, ASO therapy-associated clinical signs, histopathological and clinical pathology findings were summarized to highlight class effects to consider during program design. **Results: Species and Experimental design:** Mice were most frequently used, followed by rats and non-human primates. Subcutaneous administration predominated, with intravenous

and intrathecal routes also common. Most studies employed repeat-dose regimens. Extended recovery phases (>1 to 3 months) were common, supporting long-term observation of potential effects. **Safety Pharmacology:** Only 35% of studies included safety pharmacology assessments, often limited to one parameter (e.g., ECG, respiratory, or neurobiological evaluations). ECG monitoring was frequent in NHP studies. Neurological and/or neurobehavioral evaluations were routinely included in rat and NHP studies but rarely included in mice. **Clinical Observations:** Most studies reported no significant findings. Occasional neurobehavioral signs were observed at higher doses (e.g., tremors, abnormal posture and/or decreased activity). **Respiratory and Neurological Findings:** Respiratory changes were rare (e.g., increased minute volume in ~10% of cases). Neurological findings were more common in rats and NHPs than in mice. **Clinical Pathology:** • **Hematology:** Minimal changes overall, most values remained stable; occasional increases in white blood cells (mostly lymphocytes, neutrophils and monocytes) and reticulocytes, while decreases in red blood cell mass parameters and platelets occasionally observed in some studies. • **Coagulation:** Minimal changes overall, most values remained stable; occasional increases in fibrinogen, D-dimer, and prolongation of APTT and PT observed on some studies. • **Clinical Chemistry:** Minimal changes overall, most values remained stable; occasional increases in ALT, AST, ALP, and creatinine and decreases in albumin and total protein observed in some studies. **Pathology:** Injection site reactions and histological changes in liver, kidney, spleen, and lymph nodes were most common, generally with similar sensitivity across species. No unexpected severe toxicities were identified. **Conclusions:** ASO studies demonstrate recognizable class effects with generally mild clinical, clinical pathology and pathology findings, supporting their safety profile when appropriately dosed. Opportunities may exist to improve study designs by incorporating more comprehensive safety pharmacology evaluations into toxicology studies, therefore reducing the overall number of animals used.

PS 4049 Establishing Delivery Routes and Volumetric Compartment Measurements for Nonclinical Pediatric Antisense Oligonucleotides Assessment using Repeated Administration in Intrathecal Port Catheterized 3- and 12-Month Old African Green Monkeys

E. Oyarzabal, S. Korte, and M. Lawrence. Virscio, New Haven, CT.

Background and Purpose: Antisense oligonucleotide (ASO) drugs are a rapidly expanding drug class with proven success in significantly altering the course of heritable diseases. When targeting inherited neurodevelopmental disorders, early diagnosis and therapeutic intervention are critical. To appropriately model IT delivery of ASOs to the brain in infant and juvenile St. Kitts African green monkeys (AGM; *Chlorocebus sabeus*), this study optimized the surgically implanted ported IT catheter selection and evaluated long-term port patency for repeated IT deliveries using contrast-enhanced MRI. **Methods:** To determine a safe volume limitations for dosing infants and juveniles, baseline T2-CSF DRIVE MRI sequences were acquired and volumetric measurements of the CSF were made in both spinal cord and brain. Following healing of ported IT catheter surgery in infants and juveniles, patency was assessed via contrast MRI at 2 weeks, 1.5 months, and 3 months post-implantation. Infants and juveniles showed no signs of pain or distress following surgery and demonstrated full mobility within hours of the surgery. Additionally, we evaluated the post-surgery healing capacity and improved methods to enhance infant-mother bonding while observing for maternal rejection behaviors. **Results:** We found cleaning/masking surgical-related smells (e.g., aseptic substances and ECG electrode adhesives), leaving low-profile sutures with no skinfolds, and only permitting home cage reunions when both infant and mother are fully awake reliably resulted in no maternal rejections. Infants had variable port patency issues based on port and catheter selection. At 2 weeks following implantation, all infants showed delayed contrast movement—taking nearly 1-1.5 hours to reach the brain. By 1.5 and 3 months, only the low-profile port with 2 French catheter had successful patency in infants with contrast reaching the brain within 15-20 minutes of dosing in most subjects. Juveniles with low-profile port with 3 French catheter remained patent across all timepoints with contrast taking nearly 40-60 minutes to reach the brain at 2 weeks following implantation and improving to within 15-20 minutes at 1.5 and 3 months in most subjects. All ported IT catheters and delivered contrast and flush volumes were well tolerated in subjects after multiple IT administrations with no adverse event findings. **Conclusions:** We identified reliable low-profile port heads and appropriately sized catheters for infant and juvenile AGMs to support IND-enabling nonclinical research studies and successfully demonstrated they could safely undergo ported IT catheter surgery and maintain patency for up to 3 months.

PS 4050 Impact of Target Sequence and Pretreatment Conditions on ddPCR-Based Quantification of AAV Dosing Formulations

N. Kaname, S. Lee, Y. Okawa, S. Uehara, S. Nakazono, Y. Arimura, A. Suzuki, N. Ijichi, H. Inoue, A. Uchiyama, and T. Yoshikawa. SNBL, Kagoshima, Japan.

Background and Purpose: In non-clinical safety studies of AAV vector products, accurate quantification of vector genome titers in dosing formulations is critical for dose setting and safety evaluation. Droplet digital PCR (ddPCR), which enables absolute quantification, has been widely adopted as a standard method for confirming the

dosing formulation concentrations, and the inverted terminal repeat (ITR) sequence is commonly used as the target for this assay due to its versatility. However, recent findings have revealed that the ITR sequence has structural challenges, such as stable hairpin secondary structures and mutations or deletions occurring during replication, which can hinder primer binding and amplification efficiency. As one approach to addressing these structural challenges, we focused on pretreatment methods, which are considered to cause variation in quantitation among testing facilities. To identify issues specific to the ITR sequence, we used the GFP sequence—a structurally simple and stable gene of interest (GOI) used as a control—to examine how the structural complexity of ITR influences ddPCR quantification accuracy and to assess to what extent these issues can be mitigated. **Methods:** First, singleplex ddPCR assays targeting ITR and GFP were conducted using an AAV2-CAG-GFP preparation. Quantification performance was assessed by evaluating dilution linearity and reproducibility. AAV dosing formulations were prepared at each concentration, followed by DNase treatment to remove unencapsidated DNA from samples. Samples were then lysed at 95°C for 10 minutes to disrupt the viral capsids, release genomic DNA, inactivate DNase, and prepare the test samples for the ddPCR assay. Next, to investigate how the structural complexity of the ITR affects measurement outputs under different pretreatment conditions, we focused on the effects of Proteinase K and heat treatment. The former was intended to facilitate capsid disruption and improve accessibility to the ITR; the latter aimed to completely disrupt the capsid and help resolve higher-order structures within the ITR. As an additional condition for ITR, we added HpaII, a restriction enzyme, to the master mix to reduce secondary structures and assessed its impact on quantification results. Measurement outputs obtained under each condition were converted to vg/mL and compared. **Results:** We first evaluated the effect of the target sequences, ITR and GFP, on the variability, accuracy, precision, and reproducibility of the measurement outputs. Both targets provided reliable and reproducible quantification under the tested conditions. We then examined the effect of pretreatment conditions on measurement outcomes. Proteinase K treatment alone did not affect the measured outputs. Without restriction enzyme treatment, the ITR target showed higher measured outputs than the GFP target, regardless of heat treatment. Since the ITR sequence is located at both ends of the viral genome, restriction enzyme treatment was expected to produce twice as many detectable copies as untreated samples. However, the observed increase was limited to 1.65-fold, suggesting that the complexity and incompleteness of ITR higher-order structures may influence the measured output. When restriction enzyme treatment was applied, the measured concentration (vg/mL) of the ITR target was lower than that of the GFP target after 10 minutes of heat treatment. However, extending the heat treatment to 30 minutes resulted in an increase in the measured outputs. **Conclusions:** These findings suggest that repeated measurements using consistent pretreatment methods yield good reproducibility. However, when ITR is used as the target, variations in pretreatment conditions caused fluctuations in measured outputs, indicating that the measurement may not accurately reflect the actual concentration of the dosing solution. Furthermore, the complexity and incompleteness of ITR secondary structures may significantly affect quantification accuracy. Therefore, careful optimization of pretreatment conditions is essential to overcome structural challenges and ensure accurate, consistent, and scientifically robust quantification when using ITR.

PS 4051 Evaluation of Intravenous Oncolytic Virus Delivery in a Hamster Syngeneic Pancreatic Cancer Model

H. Lu¹, N. G. Chen², H. J. Wang², H. Wu³, L. Wei³, Q. Ren³, A. Yang³, P. Wang¹, B. Liu¹, and S. Luo¹. ¹Pharmaron (Ningbo) Bioscience Services Co., Ltd., Ningbo City, Zhejiang Province, China; ²Viromissile, Inc., La Jolla, CA; and ³Xihua Scientific Co., Ltd., Shanghai, China.

Background and Purpose: With advances in understanding cancer-driving mechanisms, personalized and targeted therapies have become increasingly important. Oncolytic viruses (OVs) represent a promising class of therapeutics that enable selective delivery of vaccinia virus to tumors via intravenous administration. Armed vaccinia viruses can convert tumors into localized “anti-tumor drug factories,” secreting cytokines and chemokines that promote tumor cell destruction while minimizing systemic exposure and long-term adverse effects. This study evaluated the potential toxicity of an oncolytic vaccinia virus following a single intravenous dose in LVG golden hamsters bearing Hap-T1 syngeneic pancreatic tumors. **Methods:** • Tumor model: Hap-T1 cells (5×10⁷ cells/mL) were subcutaneously inoculated into the flank. • Doses: 1×10⁶, 1×10⁷, and 1×10⁸ PFU/animal (i.v.). • Observation period: 21 days. • Parameters: Clinical signs, body weight, food intake, tumor growth, clinical chemistry, organ weight, histopathology, TK, biodistribution, neutralizing antibodies, and cytokines. **Results:** • Survival/Tolerability: All animals survived to termination. Mild decreases in body weight and food intake at ≥1×10⁶ PFU on Day 8. Minimal adrenal cortical necrosis/inflammation (non-adverse) at higher doses. No abnormal cytokine changes. • Tumor inhibition: On Day 22, inhibition reached 33%, 65%, and 81% in males and 27%, 72%, and 76% in females at ascending doses (all p<0.05 or p<0.001). • Cytokines: Elevated human CXCL-9 and IL-12p70 in a dose-dependent manner. TK/Immunogenicity/Biodistribution: Dose-dependent exposure declining over time; 100% neutralizing antibody positivity by Day 22; virus mainly detected in adrenal glands and ovaries. **Conclusions:** A single intravenous dose of the oncolytic vaccinia virus demonstrated a NOAEL of 1×10⁷ PFU/animal in LVG golden hamsters. The virus mediated tumor suppression through direct oncolysis, IL-12p70- driven

immune activation, and CXCL-9- dependent effector cell recruitment, establishing a local, self-sustaining anti-tumor loop while avoiding systemic cytokine toxicity. These findings indicate a favorable safety profile and durable anti-tumor efficacy.

PS 4052 Risk Assessment of Germline Transmission for Gene Therapy Drugs

X. Zhao, Z. Li, N. Wei, Y. Dong, and Q. Wang. Safe Pharmaceutical Services Corp, Great Falls, VA. Sponsor: X. yang

Background and Purpose: This study aimed to evaluate the potential germline transmission risk of a gene therapy drug by assessing gene editing efficiency in C57BL/6J mice semen and F1 offspring tissues. Males received a single tail vein injection with a 10-week recovery period to measure gene editing efficiency in semen. Females received a single tail vein injection and were mated with untreated wild-type males. Gene editing efficiency in the tail tip tissues of F1 offspring at postnatal day 7 (PND7) was measured. The results provide a scientific basis for clinical research. **Methods:** Twenty 9-10-week-old male C57BL/6J mice received a single intravenous injection of the test article at 10 mL/kg. Semen was collected from the epididymis, and DNA was extracted for gene editing efficiency measurement after a 10-week observation period. Twenty 10-week-old female C57BL/6J mice were mated with untreated males one week after administration. The day of successful mating was defined as gestational day 0 (GD0), and the day of birth was postnatal day 0 (PND0). Tail tips of all F1 offspring were collected at PND7, and tissue DNA was extracted for gene editing efficiency measurement. **Results:** In male mice, the mean gene editing efficiency in semen samples collected 10 weeks post-dosing (after one complete spermatogenesis cycle) was less than 0.03%. In a concurrent toxicity study, the mean gene editing efficiency in the epididymis at the same dose was below 0.40% (comparable to the vehicle control group). In comparison, it exceeded 50% in the target organ (liver). These results indicate that the test article did not effectively enter the spermatogenic microenvironment, and no gene editing occurred in sperm. In female mice, the gene editing efficiency in the tail tip tissues of F1 offspring was below 0.05%, significantly lower than the mean editing efficiency in the target organ (liver) of female mice in the toxicity study (exceeding 50%). The mean editing efficiency in the ovary was below 0.10% (comparable to the vehicle control group). The editing efficiency in offspring tail tips (<0.05%) was far below the level required for stably heritable levels (literature reports indicate that germline editing must exceed 1% to be biologically significant) and consistent with ovarian background levels (0.03%). This suggests that the test article did not affect germ cells or early embryonic genomes. **Conclusions:** This study evaluated the gene editing efficiency in male semen and female oocytes (assessed via F1 offspring tissues) to investigate the potential germline transmission risk of the gene therapy drug. The results showed no significant gene editing signals in male semen or F1 offspring tail tip tissues. Compared with vehicle control groups and toxicity study data on reproductive organs, the editing efficiencies were at background levels. Under the current study conditions, the test article shows no apparent risk of germline transmission.

PS 4053 Application and Case Sharing of Disease Model Animals in Toxicology Studies of Gene-Edited Cell Therapies

X. Li, N. Wei, Z. Li, X. Gao, and Y. Dong. Safe Pharmaceutical Services Corp, Herdon, VA. Sponsor: X. Yang

Background and Purpose: Disease model animals can be used in toxicological studies of gene-edited cell therapies to evaluate biodistribution, immunotoxicity, tumorigenicity, treatment-related side effects, and gene editing safety. Through tumor models, immunodeficient animals models, and cardiovascular or neurological disease models, etc., the clinical pathological environment can be simulated to study risks such as cell migration, homing, abnormal proliferation, and immunogenicity, providing critical data for preclinical safety assessment. This study uses NPG tumor-bearing mice as an example to illustrate the application of disease model animals in the toxicity study of UCAR-T cells. The UCAR-T Cell Injection is clinically intended for the treatment of B-cell acute lymphoblastic leukemia (B-ALL). NPG tumor-bearing mice were intravenously injected with UCAR-T cells once and observed for 5-6 weeks to evaluate the nature, severity, and reversibility of potential toxic effects, identify target organs or tissues, and conduct accompanying safety pharmacology and cell persistence studies to provide reference for clinical application. **Methods:** A human acute B-cell lymphoblastic leukemia (NALM6 cell) model was established in NPG mice. Based on body weight or tumor burden (*in vivo* imaging), mice were randomly divided into five toxicity test groups (n=40/group): non-tumor-bearing vehicle control, tumor-bearing vehicle control, T-cell control, low-dose UCAR-T (1×10^7 CAR-T cells/animal), and high-dose UCAR-T (3×10^7 CAR-T cells/animal). Three toxicokinetic satellite groups (n=16/group) were also included: non-tumor-bearing vehicle control, low-dose UCAR-T, and high-dose UCAR-T. Animals were equally distributed by sex and dosed once, with the dosing day defined as Day 1 (D1). During the study, the general status of mice was observed daily, and body weight and food consumption were measured weekly. Functional observational battery (FOB) tests were performed on subsets of animals before dosing and at 2 h, 48 h, D8, D15, and D28 after dosing. Scheduled necropsies were conducted on D8 and at the end of the observation period (which was terminated early due to high tumor-related mortality: on D30 [females]/

D34 [males] for the low-dose group and on D37 for all other groups) for ophthalmological examination, hematology, clinical biochemistry, immunotoxicity indicators (cytokines, T-lymphocyte subsets), organ weights, gross pathology, and histopathology. Whole blood was collected for cell persistence (TK) analysis on D8 and D37 for the non-tumor-bearing vehicle control and high-dose groups, and for the low-dose group on D8 and D30 (females only), with males sampled only on D8. **Results:** In this study, no deaths/morbidity or severe toxic reactions directly related to UCAR-T were observed. Tumor-related deaths/morbidity were observed in tumor-bearing animals. UCAR-T significantly inhibited tumor proliferation and extended mean and median survival times, accompanied by increases in peripheral blood lymphocytes (LYMPH), CAR⁺ cells, and IFN- γ related to the pharmacological antitumor effect. At the end of the observation period, progressive tumor burden-related abnormalities were observed in clinical pathology parameters, including AST, ALT, WBC, MONO, and LYMPH. No obvious test article-related changes were found in safety pharmacology (central nervous system), gross pathology, or histopathology. Cell persistence results showed detectable UCAR-T cells only in the high-dose group on D8, with no detection at other time points. **Conclusions:** For approximately 6 weeks after a single intravenous injection of UCAR-T (1×10^7 CAR-T cells/animal or 3×10^7 CAR-T cells/animal) to NPG tumor-bearing mice, no deaths or other serious toxic reactions related to UCAR-T were observed in either sex. The severely toxic dose in 10% of animals (STD₁₀) was 3×10^7 CAR-T cells/animal for both sexes.

PS 4054 Toxicologic Profiles of Lipid Nanoparticle (LNP) used as Delivery Systems for Nucleic Acid Therapeutics in Cynomolgus Monkeys: Insights from Cross-Study Analysis of Various LNP Formulations

Y. Chen¹, T. Arndt¹, E. Deben¹, K. Snyder², S. Nakatsuji¹, J. Forget¹, and W. Davis¹. ¹Altasciences, Seattle, WA; and ²Certara, Radnor, PA.

Background and Purpose: Lipid nanoparticles (LNPs) are widely used as delivery vehicles for nucleic acid therapeutics. While extensive research has addressed LNP-mRNA vaccine safety in clinical settings, LNP-only toxicological responses remain insufficiently characterized (in preclinical evaluations) in nonhuman primates (NHPs). The review by Wang et al. (2024, Vaccines) summarized that LNP toxicity involves several mechanisms, including inflammation, immune responses, and off-target accumulation in organs such as the liver, lungs, and spleen, and highlighted the lack of LNP-specific human and NHP data. To address this translational gap, we conducted a cross-study characterization of lipid-based carriers without a therapeutic payload or empty LNP-induced toxicity in cynomolgus monkeys to establish a nonclinical vehicle baseline to compare with LNP-encapsulated nucleic acid products. **Methods:** We utilized Certara's SEND Explorer (Warehouse version) to integrate multiple LNP preclinical studies (2022-2025) into a cross-study toxicity profile, which enabled the detection of reproducible organ/system findings, quantification of incidence/severity trends, and data-driven ranking of LNP reactivity. Data was obtained from >20 single- and repeat-dose toxicity studies involving empty LNP formulations and selected representative formulations differing in ionizable lipid chemistry and dosing regimen (up to 8 mg/kg; IV or IM). Clinical pathology data consisting of hematology and serum chemistry results (including acute-phase proteins: C-reactive protein [CRP], fibrinogen, and albumin) were reviewed in conjunction with microscopic findings across major organs (liver, spleen, lymphoid tissues, and bone marrow). Clinical and macroscopic observations were also reviewed. **Results:** Transient and reversible pronounced increases in liver transaminase activities (i.e., ALT, AST) and acute phase protein concentrations (e.g., CRP) were observed approximately 2 to 5 days post-administration across these studies. Notable microscopic findings included single-cell necrosis of the hepatocytes, inflammatory cell infiltration, hypertrophy of the hepatocytes and Kupffer cells in the liver, and extramedullary hematopoiesis in the spleen and lymph nodes. Similar results were discovered in repeated toxicity studies of patisiran (siRNA-LNP), single-cell necrosis of hepatocytes was commonly observed with associated hepatic enzyme increase, and this toxicity was considered to be caused by LNP itself rather than mRNA-LNP (EMA/CHMP Assessment Report, 2018). In some of the investigative studies, necropsies were performed more than a week after administration, which may indicate that hepatocellular injury (accompanied by elevated liver enzymes) that occurred a few days after administration was in the process of recovery or had resolved at the time of necropsy. The clinical observations remained unremarkable. These reproducible patterns align with mechanistic evidence from the literature (Wang et al., 2024), showing that ionizable lipids may activate and further induce hepatic and/or immune responses. **Conclusions:** These findings establish a vehicle-specific baseline that distinguishes payload-independent effects and supports standardization of nonclinical LNP safety evaluation through historical-control integration. This dataset provides a foundation for future benchmarking of LNP-based therapeutics.

L. Zhang¹, S. Zhang¹, and Y. Zhang². ¹JOINN Laboratories, Suzhou, China; and ²JOINN Laboratories, Beijing, China.

Background and Purpose: Lipid nanoparticles (LNPs) serve as carrier vehicles that protect RNA from rapid degradation and facilitate intracellular delivery and endosomal escape, thereby significantly advancing mRNA-based vaccine development and related therapies for cancer and rare diseases. The LNP platform promotes robust humoral immune responses, indicating adjuvant activity. However, animals receiving LNP-mRNA vaccines often exhibit side effects with various tissue and organ reactions. These adjuvant effects and reported side effects may arise from the inflammatory properties of LNPs. In preclinical safety studies, such side effects can obscure the toxicological impact of the test substance and lead to misinterpretation. Based on these observations, this study aims to identify specific parameters and methods for evaluating LNP-associated side effects in preclinical safety studies involving NHPs. **Methods:** To investigate LNP-associated side effects in preclinical safety evaluations performed in NHPs, data from 19 preclinical toxicity studies conducted over the past five years which evaluated the safety of LNP-containing substances, were analyzed. A series of parameters were assessed, including animal information, clinical signs, body weight, and related laboratory indices such as clinical pathology, immunocyte phenotyping, cytokines, and tissue responses. **Results:** Data analysis revealed that LNP-associated safety studies in NHPs were primarily conducted at dose levels of 1 to 2000 µg/kg in various dosing routes, using animals aged 1.1 to 5.3 years. Clinical signs were not age-related but were dose-dependent and varied significantly based on LNP dose levels. Most clinical signs were related to the dosing site, including erythema and/or swelling, with incidences ranging from 20.3% to 46.5%. These signs typically emerged on the second day after inoculation, resolved within 1 to 4 days, but might lead to ulceration and/or mass formation later. Some animals exhibited reduced body weight gain (up to 11.2%) attributable to irritation/inflammation at dosing site induced by LNPs. Concurrent with inflammation, several clinical pathology changes were commonly observed. These included mild reductions in red blood cell (RBC)-related parameters—RBC count, hemoglobin (HGB), hematocrit (HCT), and mean corpuscular hemoglobin concentration (MCHC) ranging from 1.3% to 47.6%, as well as increased white blood cell (WBC) counts and decreased lymphocyte counts (Lymph), ranging approximately from 21.3% to 138.2%. The rise in WBC was predominantly characterized by an increase in neutrophils. Coagulation changes were also frequently noted, with elevated APTT and fibrinogen (FIB) levels ranging from 17.3% to 155.1%. Additionally, clinical chemistry changes included decreases of albumin (13.2% to 32.7%) and albumin-to-globulin ratio (A/G, 21.5% to 48.2%), alongside increased globulin (6.1% to 37.2%) were observed in LNP-treated animals. Cytokine levels, analyzed as indicators of tissue response, showed changes correlated with LNP-induced tissue reactions. These consisted primarily of elevated IL-6 levels (53% to 4034%) observed 1 to 6 hours post-dosing, as well as increased C-reactive protein (CRP) levels (47% to 704%), without changes in lymphocyte phenotyping or serum complement, regardless of dosing route or dose level. Histopathological findings associated included inflammatory reactions and/or muscle degeneration/necrosis at the dosing site, reduced lymphocyte cellularity in thymus, hepatocyte vacuolation and/or increased Ito cells in liver, hemorrhage, mineralization, and/or inflammatory cell infiltration in the adrenal gland, as well as atrophy in the mammary and prostate glands. The incidence of these findings ranged from 8.3% to 72.3%. These clinical and laboratory changes in NHPs should be distinguished from the toxicological effects of test materials containing LNP during preclinical toxicity studies. **Conclusions:** The results of this review offer valuable reference for preclinical toxicity studies of drug candidates utilizing LNPs in NHPs. Although NHPs have proven to be a reliable animal model for predicting human toxicological impacts and physiological effects of biologics, the side effects associated with the LNP delivery platform may mask the actual toxicity of the test substance and complicate data interpretation in preclinical safety studies.

PS 4056 Non-Clinical Safety Evaluation of Exosomes derived from Human Adipose Tissue-Derived Mesenchymal Stem/Stromal Cells

J. Lee¹, B. Cho¹, B. Son¹, M. Kang¹, H. Lee¹, S. Moon¹, E. Shin¹, H. Choi¹, K. Lee¹, D. Ha¹, S. Cui², S. Yoon², E. Park², and S. Kim². ¹ExoCoBio Exosome Institute (EEI), ExoCoBio Inc, Seoul, Korea, Republic of; and ²Nonclinical Clinical Institute, CORESTEMCHEMON Inc, Yong In, Korea, Republic of.

Background and Purpose: Extracellular Vesicles (EV), often also called exosomes, can shuttle multiple molecules between cells, and are being developed as functional nanomedicines for human use. Exosomes are nano-sized extracellular vesicles that are transferred to target cells for cell-to-cell communication. Although MSC-derived exosomes are suggested as novel cell-free therapeutics for various human diseases, evaluation studies for the safety and toxicity of MSC-derived exosomes are limited. The purpose of our study was to evaluate the toxicological profile, including general toxicity, genotoxicity, and safety pharmacology tests using exosomes derived from human adipose tissue-derived MSCs (ASC-EXO) in accordance with the OECD guidelines and the principles of Good Laboratory Practice. **Methods:** To evaluate the toxicological profile of ASC-EXO, we carried out general toxicity test including the 4 weeks repeated-dose toxicity and genotoxicity including Ames test and *in vitro* and *in vivo* micronucleus tests. In addition, the core battery of safety pharmacol-

ogy tests, including assessments of the central nervous system, respiratory system, and cardiovascular system (*in vitro* hERG assay and *in vivo* telemetry system) were performed under GLP regulation. **Results:** No toxicological changes in clinical signs, body weights, water and food consumption, urinalysis, hematology, clinical biochemistry, gross findings, or histopathological examinations during the repeated-dose toxicity, including the 4-week dosing periods. In addition, ASC-EXO was classified as non-mutagenic and non-clastogenic in the genotoxicity tests. Additionally, no animal toxic effects were observed, including no changes in body weight or clinical signs in the *in vitro* and *in vivo* micronucleus tests. In safety pharmacology studies, ASC-EXO did not show any pharmacologically adverse effects in the modified Irwin's test for the central nervous system, whole-body plethysmography for the respiratory system, and hERG assay and telemetry system for the cardiovascular system. **Conclusions:** Our findings are the first to suggest that ASC-Exosome safe for use as a treatment, with no adverse effects observed in general toxicological testing including genotoxicities as non-mutagenic and non-clastogenic and in safety pharmacology testing. It shows potential application as a therapeutic agent, cosmetic ingredient, or for other biological uses.

PS 4057 Predicted Liver Safety of GlyphAgo, a Lymphatic Targeted Prodrug of Agomelatine That Avoids First-Pass Hepatic Metabolism

D. K. Bonner¹, J. S. Simpson¹, S. Tyler¹, R. Miller^{1,2}, L. Shoda³, and M. Chen¹. ¹Seaport Therapeutics, Boston, MA; ²Apex Drug Discovery and Innovation Strategies, Apex, NC; and ³Simulations Plus, Research Triangle Park, NC. Sponsor: L. Shoda, American Association for the Advancement of Science

Background and Purpose: Agomelatine (AGM), a melatonin 1 & 2 receptor agonist and serotonin 2C receptor antagonist, has demonstrated clear clinical efficacy and best-in-class tolerability in generalized anxiety disorder and major depressive disorder. However, AGM undergoes extensive first-pass hepatic metabolism, resulting in low bioavailability, variable exposure, and occasional drug-induced liver injury (DILI), generally manifesting as dose-dependent elevations in alanine aminotransferase (ALT) or aspartate aminotransferase. Therefore, liver monitoring is frequently required in regions where it has received regulatory approval, a requirement cited as a significant barrier to clinical use. The culprit mechanism is not definitively known, but serum transaminase elevations are dose dependent. GlyphAgo™ (SPT-320 or Glyph™ Agomelatine) is an oral prodrug of AGM being developed using the Glyph platform, a prodrug technology that shifts absorption toward intestinal lymphatics, avoiding first-pass hepatic metabolism. GlyphAgo has the potential to achieve therapeutically efficacious exposure levels at a lower dose, which may reduce liver exposure and reduce/eliminate the need for liver enzyme monitoring. This abstract reports the results of DILSym, a quantitative systems toxicology model, to predict DILI reduction for GlyphAgo relative to AGM. **Methods:** DILSym combines compound exposure at the site of action (i.e., liver) with concentration-dependent hepatocyte toxicity and inter-individual variability to predict liver injury. A physiologically based pharmacokinetic (PBPK) model of AGM exposure was applied to predict liver concentrations of AGM and selected metabolites following oral administration of approved doses. A CYP1A2-derived AGM metabolite was optimized to induce hepatocyte cell death, empirically reproducing dose dependent ALT elevations ≤10% at approved doses of AGM in a simulated population (SimPops). The AGM PBPK model was adapted to represent GlyphAgo, where lymphatic distribution bypassing first-pass metabolism was represented by intravenous administration. Simulations were conducted in SimPops where approved 25 and 50 mg once daily (QD) dosing of AGM were set as the standard. GlyphAgo dosing included doses achieving comparable AGM plasma concentrations to oral AGM and were simulated to predict GlyphAgo DILI in SimPops. **Results:** The AGM PBPK model produced output comparable to published data on exposure dynamics of AGM and two key metabolites, with C_{max} and AUC values generally falling within 0.5x-2x of reported values. In DILSym, a CYP1A2-derived metabolite was optimized to induce hepatocyte death, yielding 1.4% and 9.5% ALT elevations in SimPops following treatment with approved 25 or 50 mg QD AGM dosing. While 9.5% is significantly higher than the observed 50 mg ALT elevation rate of 2.4%, this was allowed to provide an additional safety factor for estimated GlyphAgo ALT elevation rates. Together, these modeling efforts were consistent with the known exposure and hepatotoxicity data for AGM. The AGM PBPK model was then modified to represent GlyphAgo using AGM equivalent doses. In DILSym, dosing of GlyphAgo yielded no ALT elevations in SimPops, supporting the hypothesis that partial bypass of first-pass metabolism by the prodrug reduced DILI risk while maintaining clinically relevant exposure to AGM. In SimPops, GlyphAgo did not precipitate ALT elevations until the dose was significantly escalated beyond the approved AGM dose, suggesting the potential to deliver more active drug with minimal hepatic consequences. **Conclusions:** By leveraging absorption through the intestinal lymphatics with the Glyph platform, GlyphAgo may be able to reduce DILI risk by avoiding first-pass hepatic metabolism. These results support the phase 1 proof-of-concept clinical trial of GlyphAgo in healthy volunteers evaluating the safety, tolerability, and pharmacokinetics compared to AGM. Further, the Glyph platform has the potential to be widely applied to other therapeutic molecules that have clinical limitations from high first-pass hepatic metabolism leading to low oral bioavailability and side effects like elevated liver enzymes or hepatotoxicity.

D. Thomas¹, C. Noban², and O. Barberan². ¹Elsevier, Inc., San Diego, CA; and ²Elsevier, Inc., Amsterdam, Netherlands. Sponsor: D. Thomas, International Society for the Study of Xenobiotics

Background and Purpose: Unexpected toxicity remains a major contributor to drug development failure, accounting for roughly 30% of discovery-stage attrition [1] and millions of adverse drug reaction-related medical visits annually [2]. Early evaluation of off-target pharmacology is a key strategy for identifying potential safety risks before clinical development. Most pharmaceutical organizations employ *in vitro* pharmacological profiling to detect off-target activity during early discovery [3]; however, screening data alone are often insufficient to quantify clinical safety risk [4]. To address this limitation, the Safety Margin Tool within PharmaPendium was developed to integrate data on clinical adverse drug reactions, therapeutic free exposure, and *in vitro* target affinities from well-established safety pharmacology panels [5-7]. This framework enables systematic estimation of safety margins that link target engagement with clinical exposure, supporting quantitative risk assessment and interpretation of mechanistic safety findings, particularly in the context of polypharmacy. [1] Bai C. et al., *Adv. Sci.*, 2025; 12(16): 2413405. [2] Howard I. et al., *Sci. Rep.*, 2022; 12(1): 2622. [3] Valentin J.-P. et al., *J. Pharmacol. Toxicol. Methods*, 2018; 93: 7-14. [4] Urban L. et al., *Drug Discov. Today*, 2016; 21(8): 1232-1242. [5] Brennan R. et al., *Nat. Rev. Drug Discov.*, 2024; 23: 525-545. [6] Bowes J. et al., *Nat. Rev. Drug Discov.*, 2012; 11(12): 909-922. [7] Lynch J.J. 3rd et al., *J. Pharmacol. Toxicol. Methods*, 2017; 87: 108-126. **Methods:** A systematic workflow was implemented to estimate safety margins across key off-target classes, including G protein-coupled receptors (GPCRs), kinases, ion channels, nuclear receptors, enzymes, and transporters. *In vitro* affinity data (IC₅₀, EC₅₀, Ki) were compiled and standardized from published studies and patent literature for drugs with established pharmacological mechanisms. Corresponding pharmacokinetic data (C_{max}, AUC, unbound fraction) were retrieved primarily from regulatory submissions and literature sources to reflect free therapeutic exposure. Safety margins were calculated as the ratio between *in vitro* potency and observed clinical exposure. A permutation-based uncertainty analysis incorporating affinity and exposure variability was applied to derive drug-specific and target-level safety margins. Statistical approaches were compared to evaluate conservative versus relaxed methods for quantifying uncertainty and classifying potential safety risks. **Results:** Application of the workflow resulted in the estimation of 58 target-level safety margins across well-characterized off-target panels. Refinement of the analytical approach enabled two complementary risk assessment modes: (1) a conservative approach designed to minimize false negatives by prioritizing sensitivity to potential safety risks, and (2) a relaxed approach that reduces false positives by accounting for variability and therapeutic context. The conservative mode supports early-stage risk identification, while the relaxed mode minimizes unnecessary exclusion of viable candidates. Comparative analysis across molecular targets highlighted trends linking specific target classes with distinct adverse drug reaction profiles, offering a framework for interpreting potential mechanistic contributors to observed toxicities. **Conclusions:** The Safety Margin Tool provides a systematic and data-driven approach for estimating safety margins that integrate *in vitro* pharmacology with clinical exposure data. This methodology supports early identification of potential off-target risks, improves the interpretation of observed adverse drug reactions, and enhances mechanistic understanding of target liability. Incorporating safety margin analysis into discovery and development workflows can strengthen evidence-based decision-making and contribute to more consistent, transparent safety evaluations, particularly in complex therapeutic settings involving polypharmacy.

PS 4059 *In Vitro* Cytotoxicity and Genotoxicity Assessment of Pyridinium and Quinuclidinium Oximes using a 3D Human Liver Spheroid Model

I. Vrhovac Madunic¹, K. Fras², J. Madunic¹, M. Katalinic¹, B. Zegura², and M. Stampar². ¹Institute for Medical Research and Occupational Health, Zagreb, Croatia; and ²National Institute of Biology, Ljubljana, Slovenia. Sponsor: I. Vrhovac Madunic, EUROTOX

Background and Purpose: Organophosphate (OP) poisoning continues to pose a significant global health threat, and oximes remain the primary therapeutic agents due to their capacity to reactivate acetylcholinesterase. Although the clinically established oxime HI-6 exhibits strong reactivation potential, its limited spectrum of efficacy highlights the need for improved alternatives. This study aimed to evaluate and compare the safety profiles of bis-pyridinium HI-6 and two newly developed oximes, pyridinium GM508 and quinuclidinium Q5 using a physiologically relevant 3D human liver spheroid model. **Methods:** Human HepG2 spheroids were exposed for 24 hours to HI-6 at 800 µM and increasing concentrations of GM508 and Q5 ranging from 6.25 to 50 µM. Cytotoxicity was determined using the tetrazolium-based (MTS) assay, while DNA strand breaks were assessed by the alkaline comet assay on single-cell suspensions obtained after enzymatic disaggregation of spheroids. Flow cytometry was employed to simultaneously evaluate cell cycle distribution, proliferation (Ki67), DNA damage (γH2AX), and mitotic activity (phosphorylated histone H3). Specific positive controls, 15% DMSO for viability and etoposide (17 µM or 1.7

µM) for genotoxicity and flow cytometry were included in each assay. **Results:** All oximes demonstrated low cytotoxicity at the tested concentrations with cell viability comparable to untreated controls. DNA strand break analysis using the alkaline comet assay showed no significant increase in DNA damage in any treatment group. Flow cytometric evaluation revealed no alterations in cell cycle phase distribution and preserved proliferative activity, as indicated by Ki67 staining. In addition, there was no induction of γH2AX or phosphorylated histone H3 signals, confirming the absence of DNA double-strand breaks or mitotic disruption. **Conclusions:** The novel oximes GM508 and Q5 exhibited favorable safety profiles in the 3D human liver spheroid model. All compounds showed minimal cytotoxic and no detectable genotoxic effects, with preserved cell viability, proliferative capacity, and genomic stability. These findings provide strong support for their continued evaluation as promising candidates for next-generation antidotes in organophosphate poisoning. **Funding:** This research was funded by the Slovenian Research Agency ARIS [P1-0245, J1-2465, Z1-3191], bilateral projects [BI-HR/18-19-003; BI-HR/20-21-019], European Regional Development Fund project KK.01.1.1.02.0007 (Rec-IMI), European Union-Next Generation EU 533-03-23-0006 (BioMolTox) and Croatian Science Foundation (grant UIP-2017-05-7260 (CellToxTargets)).

PS 4060 Age accelerates memory deficits in offspring with perinatal electronic cigarette exposure

C. Alkire, N. Ibinson, G. Morales, T. Poling, A. Hurley, D. Lakhani, A. Stewart, P. Chantler, and I. Olfert. West Virginia University, Morgantown, WV.

Background and Purpose: Electronic cigarette (Ecig) use has shown to elicit harmful effects on multiple body systems, including changes in behavior and memory. Hippocampus deterioration is associated with memory impairment in mice, in which long term memory is interrupted when mice are performing memory tasks. With normal aging, hippocampus dependence on memory is also reduced. Novel object recognition (NOR) testing is a hippocampal-dependent memory based task in rodents that evaluates the ability to detect changes in a familiar environment. Aging has been shown to impair NOR, but changes related to Ecig exposure and advancing age in offspring with *in utero* exposure are not yet known. We tested the hypothesis that memory defects would be worse with increasing age in mice with history of *in utero* Ecig exposure. **Methods:** We studied offspring from time-mated pregnant C57BL/6J mice with exposure to either Air (control, n=14 dams) or Ecig aerosol (using 50:50 VG:PG, no flavor or nicotine; n=13/dams) from gestational day 7 to 21. The NOR test was performed at ~6-months (n=29 male, n=29 female), and again, at ~12-months (n=27 male, n=27 female) to assess memory function in offspring. On the first day of NOR testing, mice were familiarized with the environment (i.e. box) without any objects. The second day mice were given 10 minutes with two of the same objects in the box. Four hours later, mice behavior was evaluated for 5 minutes with a novel (N) object in place of one of the familiar (F) objects in the box. Data analysis we performed using Any-maze Software (v. 7.5, Wood Dale, IL) and conducted after the completion of testing. Hippocampus size in 12 month old offspring was lower in Ecig compared to control offspring (Ecig 1.73±0.07 mm³ vs Air 2.35±0.12 mm³, p<0.05). **Results:** At 6-months, offspring with maternal Ecig exposure had 2.85 times fewer investigations of N (vs F) object compared to controls (i.e. Ecig F=7.2±1.6 vs N=11.6±1.4 vs control F=3.9±1.0 vs N=10.7±1.8; mean ±SE p<0.05). Also, the % total time for Ecig offspring with the N object (vs F object) was 2.1 times lower compared to controls (i.e. Ecig F=36.7±4.8% vs N=63.3±4.8%, p<0.05; and control F=28.1±4.2% vs N=71.9±4.1%; p<0.05). At 12-months, neither control nor Ecig offspring show significant preference for N vs F objects when evaluating the number of investigations or % total time with the N object. Hippocampus size in 12 month old offspring was lower in Ecig compared to control offspring (Ecig 1.73±0.07 mm³ vs Air 2.35±0.12 mm³, p<0.05). **Conclusions:** Offspring with a history of perinatal exposure to Ecig show earlier declines in hippocampal-dependent memory tasks compared to controls, and have reduced hippocampus size with advanced age, suggesting an accelerated loss for the ability to consolidate (or form long-term) memory associated with *in utero* Ecig exposure. **Funding Support:** NIH R56 ES035719-01, P20GM121322, U54GM104942, WV-INBRE NIH Grant P20GM103434 and WVU Stroke CoBRE P20 GM109098.

PS 4061 C-reactive protein levels during pregnancy and their association with tobacco product exposure- evidence from the NHANES dataset

B. Gebremariam¹, C. Igwe¹, E. Parker¹, S. Dickinson¹, R. Pepin¹, H. Lin², W. Su³, A. Noë⁴, P. Silveyra¹, and S. Commodore¹. ¹Indiana University, Bloomington, IN; ²San Diego State University, San Diego, CA; ³Baylor University, Waco, TX; and ⁴Louisiana State University, Baton Rouge, LA.

Background and Purpose: C-reactive protein (CRP) is a commonly used marker of low-grade systemic inflammation. It is one of the most sensitive, though non-specific, indicators of inflammation. CRP levels in blood increase as a part of normal physiologic change of pregnancy in addition to both infectious and noninfectious environmental substances, including tobacco smoke. During critical periods such as pregnancy, CRP-linked low-grade inflammation has been associated with adverse events such as vascular dysfunction, preterm birth, preeclampsia, and increased

long-term health risks for both mothers and their offspring. The goal of the current study is to assess whether CRP levels are modified by both active and passive tobacco product exposures during pregnancy, using the U.S. National Health and Nutrition Examination Survey (NHANES) dataset. This work aims to improve the understanding of how low-grade chronic inflammation in pregnancies can be influenced by tobacco product exposures. **Methods:** We aimed to answer the question: Is there a relationship between CRP in maternal serum and tobacco product exposure? We hypothesized that there would be a positive association between CRP levels and tobacco product exposures. This cross-sectional research study of 9,015 participants utilized data from the 2021-2023 NHANES database. Participants were grouped by pregnancy status and tobacco exposure: (a) pregnant and exposed to cigarettes, (b) pregnant and exposed to e-cigarettes, (c) non-pregnant and exposed, and (d) non-pregnant and unexposed. Measurements of high-sensitivity C-reactive protein (hs-CRP), in mg/L, were obtained from the serum of the NHANES participants with 0.15 mg/L as the lower limit of detection. Pregnancy status was verified when there was a positive urine pregnancy test result for a participant [Icon 25 hCG test kit (Beckman Coulter)]. Tobacco product exposure data were obtained from positive answers to cigarette use, household smokers, and recent tobacco use questionnaires. We used Fisher's exact tests, Wilcoxon rank sum test, and/or Pearson's Chi-squared test to assess any potential associations, with significance set at $p < 0.05$. **Results:** Over the 2021 - 2023 period, 41 of the total 9,015 participants had evidence of positive pregnancy test results. Pregnant women who were exposed to either cigarettes or e-cigarettes based on the tobacco product use and household smoker variables, had sample sizes of ten and one, respectively. Overall, mean ($\pm$ standard deviation) CRP levels among the 9,015 participants in this cross-sectional study were 3.6 ± 7.4 mg/L. Pregnant women who were exposed to tobacco products had higher mean CRP levels (5.2 ± 5.4 mg/L, $n=10$) compared to those who were not pregnant and had not been exposed to tobacco products (3.6 ± 7.4 mg/L, $n=6500$), and this was statistically significant ($p=0.036$). Median concentrations (Q1, Q3) for the pregnant and exposed women and nonpregnant and unexposed women were 3.7 (2.6, 5.7) and 1.6 (0.7, 3.9) mg/L, respectively. While there was no statistically significant difference between pregnant and unexposed women ($n=31$) compared to pregnant and exposed women ($n=10$), the minimum and maximum values of CRP were higher for the latter group (0.2, 17.9 mg/L) vs (0.7, 19.6 mg/L). An assessment of volatile organic compounds (VOCs) and trihalomethanes in whole blood revealed that only one VOC, ethyl acetate, was significantly higher ($p < 0.001$) in the blood of participants who were confirmed pregnant (0.9 ± 2.8 ng/mL, $n=14$) compared to nonpregnant participants (0.3 ± 2.1 ng/mL, $n=2783$). However, this effect was not observed when tobacco product exposure was considered due to small sample sizes for the available blood sample data. **Conclusions:** This cross-sectional study utilized data from NHANES to provide evidence of potential associations between tobacco product exposure during pregnancy and increased levels of CRP. Future work will assess specific populations and include more individuals from the continuous NHANES dataset. Our findings suggest that tobacco exposure during pregnancy may contribute to systemic inflammation, underscoring the need for targeted interventions to reduce maternal and fetal health risks.

PS 4062 Perinatal E-cigarette Exposure Disrupts Lung Function and Germ Cell Development in Offspring

D. Hatai¹, C. Liu¹, Y. Wang², J. Liu², C. Yu², S. Deme¹, S. Silas¹, G. Chandan², S. Madrigal¹, P. Allard¹, and V. Rehan². ¹University of California, Los Angeles, Los Angeles, CA; and ²The Lundquist Institute, Torrance, CA.

Background and Purpose: Recent reports indicate that about 7% of women have used e-cigarettes during their pregnancy, exposing the fetus to harmful toxicants during critical developmental periods. We have previously shown that perinatal nicotine exposure in rodents led to a transgenerational asthma phenotype until the F3 generation. Here, we tested the hypothesis that perinatal e-cigarette exposure alters lung and germ cell transcriptomes in F1 offspring. **Methods:** Pregnant Sprague Dawley rats were exposed daily to e-cigarette vapor from embryonic day 6 (E6) to postnatal day 21 (PND21), achieving serum cotinine levels comparable to those of habitual human smokers. At PND21, F1 pups were subjected to pulmonary function testing and lungs were collected for RNA sequencing. To assess potential germline mechanisms underlying multigenerational effects, we also collected testes and ovaries from F1 pups for single-nucleus RNA + ATAC sequencing. **Results:** F1 offspring exposed to perinatal e-cigarette vapor exhibited increased total airway resistance and decreased lung compliance ($N=6-10$; $p < 0.05$), consistent with an asthma-like phenotype. RNA sequencing in e-cigarette treated lungs ($N=4$) revealed that male pups (461 total DEGs, $FC > 1.5$, $\text{padj} < 0.05$) had a higher number of differentially expressed genes (DEGs) than females (84 total DEGs) compared to controls. Notably, differentially expressed genes were associated with cilia assembly and organization in both sexes. Single nucleus RNA sequencing of F1 pup ovaries and testes ($N=3$) captured all major cell types. E-cigarette exposed testes displayed markedly more DEGs ($q < 0.05$) than ovaries, with early spermatogenic populations (spermatogonia and spermatocytes) showing the highest DEG burden compared with later-stage spermatids. **Conclusions:** Perinatal e-cigarette exposure in rats is associated with sex specific responses in the lungs and gonads of F1 pups. Male lungs displayed a much larger transcriptional response than female lungs, with shared enrichment in cilia-related pathways. In the germline, early-stage male germ cells were particularly sensitive to exposure, exhibiting robust transcriptomic alterations. These data provide molecular evidence that perinatal vaping perturbs both pulmonary develop-

ment and germ cell development, supporting potential mechanisms for multigenerational transmission of vaping-related disease risk. **Grant Support:** HL151769, T32 ES015457 (NIH); T32IP5044, T32IR5048, T32IR5365, T291R0737, T34IR8406 (Tobacco Related Disease Research Program); and EDUC4-12837 (CIRM)

PS 4063 A preliminary investigation of the maternal and perinatal health effects of electronic cigarette use during pregnancy

S. Stowe, R. Vilcassim, V. Reddy, A. Subramaniam, and R. Sinkey. The University of Alabama at Birmingham, Birmingham, AL.

Background and Purpose: Electronic cigarette (e-cigarette) use during pregnancy has been increasing in recent years, prompting growing concern about its potential impact on both maternal and fetal health. Many pregnant women may be susceptible to initiating or continuing e-cigarette use (vaping) because e-cigarettes are available in a wide variety of appealing flavors that may appeal to their pregnancy-related cravings, and because these products are often marketed or perceived as safer alternatives to traditional cigarettes. However, the unique hormonal, metabolic, and physiological changes that occur during pregnancy may heighten women's sensitivity to nicotine and the numerous chemical constituents found in e-cigarette aerosols and increase the risk of adverse health outcomes. Despite this scientific research examining the prevalence, patterns of use, and health effects associated with vaping remains limited. **Methods:** This study investigates the prevalence and health effects of vaping during pregnancy in a cohort of patients receiving prenatal care at the University of Alabama at Birmingham (UAB). Participants are recruited from prenatal clinics to complete a smartphone-based survey on their tobacco use. Upon completion of the survey participants are given the option to provide their contact information to be contacted about participation in the in-person part of this study. Those who provide their contact information are invited to fill out the consent form for this study before being invited to participate. In Aim 1 participants ($n=100$) are invited to perform an exhaled carbon monoxide test and urinary cotinine test to biologically validate their self-reported tobacco. In Aim 2, two groups of pregnant vapers ($n=40$) and pregnant non-users ($n=40$) will be invited to provide blood and urine samples which will then be analyzed for biomarkers of exposure and inflammation and compared between the groups to evaluate whether vaping results in increased exposures and inflammation. In Aim 3, a subset of 20 participants from the vaper and non-user groups in Aim 2 will be invited to provide umbilical cord blood samples which will then be analyzed for exposure and inflammatory biomarkers to assess whether vaping-related chemicals can reach fetal circulation. **Results:** To date, 597 participants have participated in our survey and of those 487 have answered our questions about their tobacco use. Among those, 25 (5.1%) reported that they are exclusively vaping during their pregnancy and an additional 4 reported vaping along with using other tobacco products. The mean age of the overall sample population is 29.24 years old with a standard deviation of 6.46 years. The sample is predominantly White (50.2%) followed by Black (38.01%) and mixed race (4.27%) while vapers were disproportionately White (60%). Additionally, 7.39% of the sample is Hispanic. Among those who reported vaping during their pregnancy most reported vaping daily, using disposable e-cigarettes/vapes, using flavored e-liquids, and that they switched from using cigarettes to vaping. Then Vapers were split between taking 1-10 puffs per day and taking more than 50 puffs per day on a typical day of use. Notably, vapers had significantly lower educational attainment compared to participants reporting no tobacco use ($p = 0.0012$). Finally, of the 23 participants whose tobacco use has been biologically validated so far, 21 matched their self-reported use, while 2 who denied tobacco use tested positive for urinary cotinine and negative for exhaled carbon monoxide use which is indicative of vaping or other smokeless tobacco use. **Conclusions:** These preliminary findings underscore the importance of continuing to investigate the effects of vaping during pregnancy, particularly given its growing prevalence and the unique vulnerabilities of pregnant individuals and their developing fetuses. Our ongoing biomarker analyses will directly measure maternal exposure to nicotine and other chemicals in e-cigarette aerosols and assess whether this results in increased inflammation compared to non-users the extent to which these substances cross the placenta and reach fetal circulation. Ultimately, the evidence generated from this study will be essential for guiding healthcare providers, informing clinical counseling, and shaping public health recommendations and policy aimed at reducing harm and supporting healthier pregnancies.

PS 4064 Secondhand E-cigarette exposure induces sex and region-specific lung collagen deposition

A. Martinez-Santos, J. Bautista, D. A. Herman, M. T. Kleinman, A. Jimenez-Chávez, and A. De Vizcaya Ruiz. Department of Environmental and Occupational Health, Joe C Wen School of Public Health, University of California, Irvine, Irvine, CA.

Background and Purpose: Electronic cigarettes are offered as a "safer" alternative to traditional combustible cigarettes, a perception that has driven their widespread use, and consequently, increased secondhand aerosols and vapors exposure. These aerosols contain particulate matter, volatile organic compounds, polycyclic aromatic hydrocarbons, and metals that remain airborne. Along with nicotine, carrier solvents like propylene glycol and glycerin, and metals released from atomizer components, contribute to airway irritation and impaired lung function, raising concern for chronic

respiratory injury in bystanders. In tissue fibrosis, dysregulated proliferation of fibroblasts leads to abnormal collagen buildup in lung tissue, making collagen a key indicator of fibrotic progression. Research has shown inflammatory and oxidative responses to aerosolized organic compounds and metals, both of which are associated with fibrotic lung injury. This study aimed to assess lung collagen deposition in female and male mice after subchronic and chronic exposure to secondhand e-cigarette vapor, with and without the metallic atomizer component, as a marker of fibrotic injury linked to early development of pulmonary fibrosis. **Methods:** Wildtype C57BL/6J mice (7 weeks old; n=5/sex per group) were exposed nose-only to secondhand e-cigarette vapor (eCig) for 2 hours/day, 4 days/week, for either 3 (subchronic) or 6 months (chronic). Exposure groups included purified air (control), eCig generated with a metallic atomizer, or vaporized metal-free e-liquid (E-liq). Aerosol was produced using a MOD device equipped with a nickel-chromium coil (3-s puff every 30s) at an average particle concentration of $15 \pm 3 \text{ mg/m}^3$. Following exposure, the left lung lobes were fixed, sectioned, and stained with Masson's Trichrome to visualize collagen. Whole-lung and region-specific (perivascular, peribronchial, alveolar) images were captured using automated bright-field microscopy, and collagen area was quantified with ImageJ software. **Results:** After 3 months of exposure, male mice in both the eCig and E-liq groups showed greater lung collagen deposition compared to controls, whereas females showed increases only in the eCig group. At 6 months, eCig-exposed males exhibited significantly higher collagen levels than both controls and E-liq males. In contrast, females in the eCig and E-liq groups displayed higher collagen after 3 months than after 6 months, suggesting a transient fibrotic response. Region-specific analysis revealed that the perivascular region was the primary site of collagen deposition in females across both exposure conditions, whereas males exhibited more diffuse patterns. **Conclusions:** Our results suggest that exposure to secondhand e-cigarette vapor with nicotine induces sex-specific lung collagen deposition, a hallmark of fibrotic injury. Differences observed in the extent and localization of collagen deposition between males and females, particularly within the perivascular, alveolar, and peribronchial regions, suggest a sex-specific susceptibility to fibrotic remodeling. Notably, increased collagen deposition was also observed in animals exposed to vaporized e-liquid, indicating that organic constituents and their thermal byproducts, independent of metal emissions, can promote fibrotic changes. These findings underscore the need to evaluate both e-liquid formulations and heating components when assessing e-cigarette use health risks. Future studies should investigate the sex-specific molecular mechanisms underlying fibrotic responses to organic versus metal components to inform targeted prevention and regulation.

PS 4065 Sex-Specific Transcriptomic Responses to Acute and Subchronic E-cigarette Exposure

A. N. Perryman¹, J. A. Masso-Silva¹, W. Gu², L. Sullivan¹, J. McDermott¹, S. Gaboyan¹, N. Kasaraneni¹, H. Chang¹, D. Oliva¹, S. Perra¹, C. Truong¹, H. Sidhu¹, A. Frounjan¹, I. Advani¹, J. Pham¹, B. Ma¹, A. Castaldi¹, and L. E. Crotty Alexander¹. ¹University of California, San Diego, La Jolla, CA; and ²University of California, San Francisco, San Francisco, CA.

Background and Purpose: Electronic cigarette (e-cigarette) use has rapidly risen in popularity, particularly among youth and young adult populations. Despite widespread use, there is currently limited longitudinal data on health outcomes related to vaping. The purpose of this study was to compare the responses of mice to acute and subchronic e-cigarette exposures. **Methods:** For this study, we exposed male and female C57BL/6 mice (n = 6-8, 6-8 weeks old) to e-cigarette aerosols containing humectants (30% propylene glycol/70% glycerin) with and without free-base nicotine (6 mg/mL) produced from third-generation box mods for 1 hour a day for 1 week or 3 months using the whole-body InExpose system. Following the final exposure, RNA was isolated from lungs and bulk RNAseq was conducted. Differentially expressed gene (DEG) analysis was performed using EnrichR with false discovery rate correction. Pathway enrichment analysis was performed using PathfindR. **Results:** We found the most genes (n=30) to be differentially expressed in mice exposed to e-cigarette aerosol containing nicotine for 1 week. At 3 months, there were no significant differences in either exposure group. However, stratification of the exposed mice by sex demonstrated a differential response. At 1 week, DEGs were driven by female mice with no significant differences in male mice for either exposure. At 3 months, there was only 1 significant DEG in female mice exposed to humectants only whereas male mice exhibited DEGs in response to e-cigarette aerosols with (n = 14) and without nicotine (n = 10). The top enriched pathways for female mice were associated with cilium movement and response to xenobiotic stress. For male mice, the top pathways were cell-substrate adhesion, chemotaxis, and endothelium development. **Conclusions:** Our data indicate that male and female mice have divergent responses to nicotine-containing and nicotine-free e-cigarette aerosols from third-generation devices. Further, humectants alone may be drivers of these transcriptomic changes and potential cellular dysfunction with chronic exposure. Future work is focused on identifying the impacts at the cellular and molecular level, as these changes may be insightful for the potential consequences of chronic daily e-cigarette use.

PS 4066 Sex differences in regional brain volume changes in adult offspring with *in utero* electronic cigarette exposure

A. Hurley, D. Lakhani, A. Stewart, N. Day, C. Alkire, P. Chantler, and I. Olfert. West Virginia University, Morgantown, WV.

Background and Purpose: Electronic cigarette (Ecig) use has increased rapidly and has been promoted as a safer alternative to smoking to pregnant women. Yet, Ecig use is known to increase oxidative stress and the long-term neurobiological effects to the maternal-fetal dyad remain poorly understood. Given that the brain is particularly vulnerable to perinatal environmental exposure, the use of magnetic resonance imaging (MRI) provides a non-invasive approach to assess structural alterations in during the course of life in progeny. The purpose of this study was to evaluate potential changes in brain volumes in offspring with history of maternal use of Ecigs during pregnancy. We tested the hypothesis that *in utero* Ecig exposure would produce significant changes in either whole brain and/or regional brain volumes compared to controls (i.e. air only exposure). **Methods:** We used 1T Bruker MRI system to examine whole brain volume and regional brain volumes (i.e. forebrain, hindbrain, olfactory and ventricles) in adult offspring at both 9- and 12-months of age with history of either *in utero* exposure to Ecig or Air. Time-mated C57BL/6J female mice were exposed from gestational day 7-21 to either Air (control, n=14 dams) or Ecig aerosol using 50:50 VG:PG, no flavor or nicotine (n=13 dams). MRI parameters for 9-month old male and female offspring were T₂-weighted, 160μm sagittal view. MRI parameters for 12-month old male and female offspring were T₁-weighted, 220μm sagittal and axial view. Regional brain volumes are reported normalized to whole brain volume (e.g. regional/WBV). **Results:** Overall ANOVA analysis revealed significant decrease in olfactory size with both exposure and time effects in Ecig offspring compared to air controls. However, whole and regional brain volumes effects were also found to have sex-specific effects. In males, with both 9- and 12-month-old offspring with history of *in utero* Ecig exposure, had an average of 3.0% smaller whole brain volume (WBV, p=0.003) compared to controls; as well as 2.7% decrease in WBV with advancing age (9- vs 12-month old, p=0.011) compared to controls (at 1.7%). Significant time-based changes were also seen with brain parenchymal fraction (BPF, p<0.001). And, WBV normalized forebrain (p=0.006) and hindbrain (p=0.0051) volumes show significant interaction effect for exposure x time. No significant changes were observed in WBV normalized olfactory bulb volumes. Absolute ventricular volume was lower with age in males (p<.001), but not with exposure. In females, WBV and normalized forebrain volume did not differ by exposure or time effects. Normalized hindbrain volume (p=0.022) and BPF (p<0.001) exhibited significant time (but not exposure) effects. WBV normalized olfactory bulb volume showed smaller time-based change in Ecig offspring compared to controls (4.6% vs 13.3%, respectively; p<0.001). Absolute ventricular volume was also lower with age in females (p<.001), but not with exposure. **Conclusions:** These findings are consistent with emerging evidence of adverse neurobiological health in offspring which experience *in utero* exposure to harmful or potentially harmful constituents (HPHCs) from Ecigs. Future studies need to provide longitudinal MRI assessment and behavior testing in offspring throughout its life course. Funding Support: NIH R56 ES035719-01, P20GM121322, U54GM104942 and WV-INBRE NIH Grant P20GM103434.

PS 4067 Investigating the Sex-Specific Impacts of E-Cigarettes on Humoral Immunity *In Vitro*

V. Jagoo^{1,2}, V. Caruana^{1,2}, N. Kukolj^{1,2}, and K. K. Mann^{1,2}. ¹Department of Pharmacology & Therapeutics, McGill University, Montréal, QC, Canada; and ²Lady Davis Institute, Montréal, QC, Canada.

Background and Purpose: E-cigarettes, initially designed to aid the cessation of traditional cigarettes, have become increasingly popular among young adults. Despite this notable increase in use, the health effects of e-cigarette exposure remain uncertain, especially regarding the immune system. B lymphocytes represent a key part of adaptive immunity because of their ability to generate specific long-term memory to pathogens. B lymphocytes originate in the bone marrow from a common lymphoid progenitor, and then develop from pro-B cells to mature B cells that can migrate to secondary lymphoid organs and secrete antibodies. Preliminary findings indicate that a two-week *in vivo* e-cigarette exposure decreases B lymphocyte populations in the bone marrow, with significant effects only seen in females. We aim to develop a model to interrogate these findings *in vitro*. **Methods:** Primary murine bone marrow from female and male C57BL/6 was isolated and utilized in Whitlock-Witte cultures for 7 days. These cultures were then treated with extracts from e-cigarettes or their component parts: propylene glycol and vegetable glycerin (PG/VG), ethanol, nicotine salts, tobacco-flavouring, STLTH extract, and Vuse extract. Cultures were treated for three days. B lymphocytes were analyzed using spectral flow cytometry to investigate cell death along with the Hardy fractions, representing the B cell populations during the different stages of B cell development. **Results:** Three-day *in vitro* treatment reduced the frequency of B220+ stained B lymphocytes, without a change in viability. Cultures from male mice were more sensitive than cultures from female mice. Cultures responded similarly to extracts from e-cigarette components. **Conclusions:** Our results suggest that B cell differentiation could be impaired following e-cigarette exposure while cell viability is preserved. Additionally, these preliminary findings suggest that the male primary B cell populations seem to be more sensitive to e-cigarette exposure *in vitro*. This suggests that primary B cell cultures are suitable *in vitro* models to investigate the molecular mechanisms of action of e-cigarettes.

H. B. Wilker, A. Dias, A. Vargas, S. Sabnis, G. Kelly, S. Serna-Pemberthy, P. Sarathy, T. Jennings, R. Amini, J. Oakes, and C. Bellini. Northeastern University, Boston, MA.

Background and Purpose: Cardiovascular disease (CVD) is the global leading cause of mortality for both sexes, but there is a feminine advantage in both lower prevalence and later onset. Yet despite this increased protection, females experience a greater acceleration in CVD risk around the menopausal transition compared to age matched males. Additionally, sex differences in CV risk factors reveal disproportionate vulnerability among women. Comorbidities such as diabetes and hypertension confer twice the risk of heart failure in women compared to men with the same conditions. A similar pattern is observed for the leading modifiable risk factor for myocardial infarction (MI): cigarette smoking. Although women smoke at lower rates and generally exhibit lower baseline CVD incidence, female smokers experience a 25% higher risk of developing coronary artery disease than male smokers and a 3x higher risk for MI. Yet, despite this clear mechanistic difference, preclinical CVD research in animal models is overwhelmingly biased, over 70% of studies solely use male mice. Furthermore, <1% of CVD preclinical studies use a human-like menopausal phenotype. Accounting for menopause is crucial when evaluating the cardiovascular impact of environmental stressors that span a significant portion of life. To address these limitations and create a translationally relevant model, we superimposed cigarette smoke exposure on a preclinical model of menopause. **Methods:** We replicated the human transition from perimenopause to menopause in female C57BL/6 mice by administering 4-vinylcyclohexene diepoxide (VCD), a selectively ovotoxic molecule that induces follicular atresia, resulting in a gradual decline and cessation of non-androgenic endocrine production. Following persistent diestrus, mice were exposed to cigarette smoke or air for 1 hour/day, 5 days/week, for 20 weeks. Our study thus included 4 groups, labelled as: VCD-Cig, VCD-Air, Estrous-Cig, and Estrous-Air. Functional changes to the descending thoracic aorta were quantified via vasoactive biaxial testing using phenylephrine for vasoconstriction and acetylcholine (ACh) for vasodilation. Vasodilation is largely mediated by the production of nitric oxide (NO) by endothelial nitric oxide synthase (eNOS), which then diffuses to vascular smooth muscle cells, triggering relaxation. A second ACh challenge following eNOS inhibition by L-NAME determined the contribution of eNOS to endothelial function. The difference between the two challenges acted as a proxy for NO bioavailability. Passive inflation-extension testing was used to determine changes in biaxial stiffness, stress, and cyclic distensibility. **Results:** The menopausal aorta phenotype exhibited two main features, increased contractility and impaired vasodilation in response to adrenergic and cholinergic stimuli, respectively, both of which were exacerbated by cigarette smoking. VCD and cigarette smoking increased contractility by 2.1x and 1.3x respectively, but VCD-Cig aortas showed 3x contractility compared to Estrous-Air controls. Endothelial function was significantly impaired by oxidative stress, VCD-Cig aortas only recovering to 57% relaxation compared to VCD-Air (59%), Estrous-Cig (72%), Estrous-Air (98%). VCD-Cig aortas exhibited the greatest increase in tissue stiffness, which in turn elevated pressure-induced circumferential wall stress, indicating that vascular cells may be unable to sustain normal physiological loading conditions. **Conclusions:** Overall, these results confirm that the menopausal transition presents a turning point for endothelial function and further suggests that the menopausal endocrine shift primes the vasculature for dysfunction when combined with exogenous sources of oxidative stress. Endothelial dysfunction is the primum movens of CVD, triggering a cascade of events resulting in hypertension, arterial stiffening, and heart disease. Ultimately, accounting for menopausal transition and menopause is necessary for translational relevance when studying aging-related disease in preclinical models. By excluding these effects, specific risks facing half of the aging populations may be overlooked. Utilizing menopause models in environmental exposure studies will advance understanding of the mechanisms that underly sex-dependent disease and risk disparities.

PS 4069 Electronic Cigarette Use During Pregnancy Impairs Uteroplacental Structure and Function

Z. A. Olverson, R. A. Miller, and M. W. Gorr. The Ohio State University, Columbus, OH.

Background and Purpose: Electronic cigarette (e-cig) use has increased among adults and pregnant individuals, with 1-15% reporting use during pregnancy. Although marketed as "safe", e-cigs contain nicotine, propylene glycol, vegetable glycerin, heavy metals, and flavorings that may adversely affect the uterine environment and compromise maternal and fetal health. We previously found that gestational e-cig exposure reduces maternal diastolic function, uterine artery blood flow, fetal heart rate, fetal growth, and placental efficiency, yet the underlying mechanisms remain unclear. We hypothesize e-cig use during pregnancy impairs placental development and function by reducing trophoblast differentiation and regulated cell death. Defining how e-cig aerosols alter trophoblast biology is essential for understanding their impact on uteroplacental structure and function for maternal and fetal health outcome prediction. **Methods:** Pregnant FVB/J mice were exposed to e-cig aerosols without nicotine (50:50 propylene glycol and vegetable glycerin, PV), or with 2% nicotine (PVN) for 5 days per week. At E17.5, dams underwent cesarean collection of fetal, placental and uterine artery tissues for fixation, H&E staining, or immunohistochemistry for morphometric analysis. **Results:** At E17.5, PV placentas showed reduced trophoblast giant cell density in the junctional zone ($P<0.05$, one-way

ANOVA), increased CD335/NKp46+ immune cell density in the decidua ($P<0.05$, one-way ANOVA) and decreased cleaved caspase-3 staining within the decidua ($P<0.05$, one-way ANOVA) compared to filtered air (FA) controls. Uterine arteries from exposed dams displayed reduced lumen area ($P<0.05$, one-way ANOVA). CD31 and α -SMA staining were unchanged between groups ($P>0.05$), indicating preserved endothelial and smooth muscle layers despite lumen narrowing. **Conclusions:** Gestational e-cig exposure, even in the absence of nicotine, disrupts trophoblast differentiation, regulated cell death, and uteroplacental vascular structure, contributing to impaired placental development and reduced placental efficiency. Together, these findings challenge the perception of e-cig use during pregnancy as "harmless" and highlight the need to reevaluate their safety for maternal and fetal health.

PS 4070 Combined Toxicity of E-Cigarette Flavoring Chemicals and Metals in Human Lung Epithelial Cells

E. Kabir, and T. Muthumalage. Purdue University, West Lafayette, IN.

Background and Purpose: Menthol- and tobacco-flavored electronic cigarettes (e-cigarettes) are widely marketed as safer alternatives to combustible cigarettes. E-cigarette aerosols contain both flavoring chemicals, such as aldehydes, and metals, including nickel. The combined toxicity of these chemical-metal mixtures remains poorly understood. We hypothesized that e-cigarette-derived chemicals and metals exert synergistic toxicity on lung epithelial cells. **Methods:** Human bronchial epithelial cells (BEAS-2B) were exposed to common flavoring chemicals (vanillin, ethyl vanillin, p-anisaldehyde, and WS23) at 10 μ M-1000 μ M to assess dose-responses, individually and in mixtures (1:1-1:49), with or without nickel oxide (10 - 50 μ g/cm²). Twenty-four hours post-treatment, cytotoxicity was determined by MTT assay and AO/PI assays, and the elicited inflammatory response was assessed by quantifying IL-6 and IL-8 cytokine levels using ELISA in conditioned media. **Results:** Aldehydes induced differential toxicity thresholds (LOAELs: vanillin, 200 μ M; ethyl vanillin, 300 μ M; p-anisaldehyde, 100 μ M; WS23, 50 μ M). Mixture toxicity of vanillin and WS23 induced synergistic cytotoxicity, whereas ethyl vanillin and p-anisaldehyde showed antagonism. Ethyl vanillin and nickel oxide induced significant cytotoxicity and augmented IL-6 and IL-8 responses compared to either component alone. **Conclusions:** E-cigarette flavoring aldehydes interact with each other and with metal constituents to drive augmented epithelial injury and inflammation. Our data underscore the importance of mixture toxicity analysis in evaluating e-cigarette safety and suggest that regulatory policies should account for combined chemical-metal exposures rather than single-agent effects. This study was supported by the National Institutes of Health R00ES033835.

PS 4071 Intracellular cannabidiol induces translational repression and stress granules through eIF2alpha phosphorylation in human pulmonary cells

S. Kanno¹, J. M. Otaki¹, S. Hirano², M. Kanie¹, K. Igarashi¹, H. Kato¹, Y. Nakamura¹, and T. Oshima¹. ¹Nagoya City University Graduate School of Medical Sciences, Nagoya, Japan; and ²National Institute for Environmental Studies, Tsukuba, Japan.

Background and Purpose: Cannabidiol (CBD) is a compound extracted from Cannabis. Because CBD does not cause hallucinations, it is used for health purposes, and so on. Stress granules (SGs) are phase-separated and membrane-less intracellular organelles composed of proteins and RNA and play a cytoprotective role. The assembly of SGs is formed transiently in response to various stress stimuli to ensure cell survival. However, the stress responses including formation of SGs against inhaled CBD have not been extensively studied. In this study, we examined the effects of CBD on SG formation and translational repression using pulmonary cells to assess the toxicity of inhaled CBD. **Methods:** To examine time-dependent cellular uptake of CBD, the cells were exposed to 25 μ M CBD for 0-6 hrs. The cellular CBD concentrations were analyzed by LC-MS/MS. GFP-tagged G3BP1 expressing CHO-K1 cells (G3BP1-CHO) and human pulmonary cell lines, A549 and BEAS-2B (Beas), were exposed to 0-50 μ M CBD for 1 hr. The SG formation in G3BP1-CHO cells was observed using fluorescent microscope. A549 and Beas cells were immunostained with anti-G3BP1 and a fluorescence-tagged secondary antibodies to observe SG formation. A549 and Beas cells were lysed in RIPA buffer, and phosphorylated eIF2 α and total eIF2 α levels were examined by western blotting. To investigate whether reactive oxygen species (ROS) are involved in SG formation, CHO-K1 cells expressing Antioxidant Response Element (ARE)-Luciferase were exposed to 0-5 μ M CBD, and a reporter gene assay was performed. Translational repression was examined by puromycin-based SUNSET assay in CBD-exposed A549 and Beas cells. **Results:** LC-MS/MS analysis revealed that intracellular CBD rapidly increased after CBD exposure and accumulated in a time-dependent manner. In response to the intracellular CBD following exposure to 25-50 μ M CBD, G3BP1-CHO, A549 and Beas cells formed discrete SG assemblies after exposure to CBD. The levels of phosphorylation of eIF2 α increased by CBD in both A549 and Beas cells, suggesting that CBD induced canonical SG formation. In reporter gene assay, CBD significantly increased ARE activity. Puromycin-labeled newly synthesized proteins were robustly reduced in CBD-exposed A549 and Beas cells. **Conclusions:** These results suggest that pulmonary cells generate SGs in response to exposure to CBD via a canonical pathway to reduce the adverse effects. Furthermore, ROS might contribute to this process.

PS 4072 **Induction of Cytotoxicity in A549 Human Lung Carcinoma Cells by Illicit Flavored Disposable E-cigarette Products in the US Market**

M. J. Mulcahy, S. E. Davidson, P. A. Jackson, and N. Ivanov. Juul Labs Inc., Mountain View, CA.

Background and Purpose: To date, the U.S. Food and Drug Administration (FDA) has authorized only tobacco and menthol flavored electronic nicotine delivery systems (ENDS). Despite this, illicit flavored disposable ENDS have become widely accessible in the United States (US). Recent data show that illicit flavored disposables represent approximately 80% of the US ENDS market. With the prevalent use of illicit flavored ENDS devices in the United States, consumers and regulatory bodies require a better understanding of the potential hazards associated with the use of these products. The purpose of this study was to screen a variety of e-liquids extracted from illicit ENDS available in the US market and assess the ability of those products to induce cytotoxicity in A549 cells. **Methods:** To assess the cytotoxicity of illicit product e-liquids we utilized the Neutral Red Uptake "NRU" assay with A549 cells, a human lung carcinoma cell line. The NRU assay is a robust assay which measures the ability of healthy cells to take up the dye neutral red. All NRU testing was conducted following OECD 129 and ICCVAM 07-4519 guidance modified to perform the test in A549 cells. Unflavored 1.5% nicotine and 5% nicotine strength e-liquids were prepared with equimolar benzoic acid and used as negative controls. As part of a broader market study to examine the chemical composition of e-liquids from 74 illicit ENDS products, 16 products were selected for further *in vitro* toxicology testing. E-liquids were diluted 1:1 with DMSO and then serially diluted into assay media to treat cells. All products were evaluated with 8 separate concentrations. Final DMSO concentration did not exceed 0.5% (v/v). Products that caused $\geq 30\%$ decrease in cell viability were considered cytotoxic (ISO 10993-5). Osmolality and pH were measured for assay media, vehicle control (VC), and the top two concentrations of test article. Product testing was separated into 2 waves with 5 to 10 products tested per wave. In this study, 16 disposable e-vapor products from the United States market were selected for cytotoxicity testing. **Results:** Sodium lauryl sulfate positive controls performed consistently with results from previously published interlaboratory studies (Coresta 2024) for A549. No impacts on pH or osmolality were observed with inclusion of test article as compared to VC. We found that all illicit flavored disposable e-liquids tested caused cytotoxicity in A549 after 48-hour treatments. Cell viabilities ranged from 67.1% to 10.8%. In comparison, negative control e-liquids did not elicit cytotoxicity in A549. Future studies will explore which aspect(s) of illicit products may drive cytotoxicity and expand to other prevalent cytotoxicity models such as Balb/c 3T3 clone a31. **Conclusions:** All illicit disposable ENDS products assessed in this study failed the NRU assay as described while our negative control e-liquids, 1.5% and 5% nicotine strength unflavored e-liquids, were found to be not cytotoxic. These findings highlight the need for better understanding of what factors drive cytotoxicity in these illicit flavored products and the importance of rigorous regulatory review of ENDS products.

PS 4073 **Enhanced Cytotoxic and Oxidative Stress Responses Induced by 6-Methyl and 4-Methyl Nicotine in Human Bronchial Epithelial Cells**

Y. Liu^{1,2}, X. Li^{1,2}, H. Wang^{1,2}, Y. Tian^{1,2}, S. Han^{1,2}, L. Cui^{1,2}, Z. Song^{1,2}, H. Chen^{2,1}, and H. Hou^{2,1}. ¹China National Tobacco Quality Supervision & Test Center, Zhengzhou, China; and ²Beijing Life Science Academy, Beijing, China. Sponsor: S. Jia

Background and Purpose: 6-Methylnicotine (6MN) is an emerging synthetic nicotine analog identified in e-cigarette and oral pouch products, often marketed outside current FDA regulatory frameworks. 4-Methylnicotine (4MN), a positional isomer and synthesis byproduct, not currently used in commercial products, was included to explore structure-activity relationships. Systematic toxicological data for both analogs are lacking. This study compared the cytotoxicity and Oxidative stress-induced effects of 6MN and 4MN with nicotine in human bronchial epithelial cells (BEAS-2B). **Methods:** BEAS-2B cells were exposed to serial concentrations of NIC, 6MN, or 4MN for 24 hours. Assessments included cell viability (CKK-8), membrane integrity (LDH release), apoptosis (Caspase-3/7), proliferation (EdU assay), DNA damage (γ H2A.X foci), mitochondrial membrane potential (MMP), reactive oxygen species (ROS), glutathione (GSH) content, and expression of Nrf2-mediated antioxidant pathway genes. **Results:** Both 6MN and 4MN exhibited significantly greater cytotoxicity than nicotine, as reflected by lower IC₅₀ values and substantially higher LDH release. The methylated analogs also induced stronger anti-proliferative and genotoxic effects, along with more pronounced mitochondrial dysfunction, indicated by reduced MMP. Furthermore, 6MN and 4MN provoked a heightened oxidative stress response, characterized by increased ROS and GSH levels, and upregulation of Nrf2 target genes, suggesting an activated adaptive antioxidant response. **Conclusions:** 6MN and 4MN induce more severe cytotoxicity and oxidative stress in human bronchial epithelial cells than nicotine. These findings indicate that pyridine ring methylation enhances the toxic potential of nicotine, highlighting the need for comprehensive toxicological evaluation and regulatory scrutiny of these emerging synthetic analogs.

PS 4074 **Electronic Cigarette Aerosols Redirect Human Airway Epithelial Fate Toward Squamous Metaplasia with Partial Reversal After Exposure Cessation**

R. Phandthong, E. Rolon, B. Ramirez, M. Kudsi, A. Choi, A. Tahmasbi, Y. Hassan, T. Martinez, and P. Talbot. University of California, Riverside, Riverside, CA.

Background and Purpose: Electronic cigarette (EC) aerosols contain chemicals capable of altering airway epithelial physiology, yet their toxicological effects remain inadequately characterized. Squamous metaplasia (SM) is a well-recognized consequence of smoking, but its induction by electronic cigarette (EC) aerosols has not been evaluated. SM involves replacement of the normal pseudostratified epithelium with squamous cells. This remodeling compromises mucociliary clearance, disrupts epithelial homeostasis, and increases the risk of chronic lung disease, such as squamous cells carcinoma; however, SM is recognized to reverse when the underlying cause is removed. This study used a 3D human tracheobronchial epithelial tissue (hTET) model derived from airway basal stem cells to determine whether EC aerosols induce SM, characterize dose- and time-dependent responses, assess donor-specific susceptibility, and evaluate the potential for reversibility following exposure cessation. **Methods:** Airway basal stem cells from deceased human donors were expanded and differentiated at the air-liquid interface for 28 days to generate mucociliary hTETs. To first establish a temporal and dose-dependent exposure protocol, hTETs were exposed daily to aerosols from the NJOY ACE EC for three weeks at 1 puff/day or 5 puffs/day, with clean air as a control. Morphometric endpoints and markers of mucin (MUC5AC), cilia (acetylated α -tubulin), and squamous differentiation (involucrin) were quantified after week 1, 2, and 3 using immunolabeling, image-based analyses, and Western blotting. After the exposure protocol was defined, the same exposure was applied to aerosols generated from NJOY ACE and two popular brand devices (Vuse Alto and JUUL) using hTETs derived from six human donors. Following the 3-week exposure period, tissues were subjected to an additional two-week aerosol-free recovery period. SM severity (mild, moderate, severe) and reversibility were quantified by a min-max rescaling approach integrating all measured endpoints. **Results:** NJOY ACE exposure demonstrated that MUC5AC increased through week 1, peaked at week 2, and declined by week 3 under 5-puffs conditions. Early SM indicators, including ciliary loss and involucrin elevation, emerged by week 1 and amplified with increasing puff number. By week 2, tissues exhibited pronounced ciliary loss, reduced epithelial thickness, horizontal nuclear reorientation, and elevated involucrin. By week 3, squamous metaplasia phenotype was evident in both dose groups. Quantitative analyses demonstrated involucrin levels plateaued by week 3, at which point the 1-puff group reached concentrations comparable to those observed in the 5-puff group. Applying the established exposure protocol to multiple EC products and donors demonstrated both device- and donor-dependent variability. Vuse Alto induced the most severe remodeling, followed by JUUL and NJOY ACE. All donors exposed to Vuse Alto developed moderate-to-severe SM, whereas JUUL and NJOY ACE produced a wider range of responses, with four donors showing severe remodeling, one moderate, and one minimal. Recovery depended strongly on the initial severity of remodeling, with mildly affected tissues showing near-complete reversal and severely remodeled tissues exhibiting only partial restoration evidenced by limited ciliogenesis, reduced involucrin, and incomplete epithelial reorganization. Full mucociliary recovery was not observed. **Conclusions:** These findings demonstrate that EC aerosols from widely used products can reprogram human airway epithelium toward a squamous fate in a dose- and time-dependent manner, and that severe remodeling shows limited capacity for repair. The substantial variability across devices and donors emphasizes the complexity of EC-associated airway injury and reveals the limitations of relying on traditional toxicology screening assays. Together, these observations highlight the need for more product assessment and strengthened surveillance as EC device designs and formulations continue to evolve.

PS 4075 **Macrophages Synergistically Enhance the Airway Epithelial Cell Response to E-cigarette Exposure**

O. H. Rice¹, T. Sukale¹, M. Trezza¹, and L. A. Miller^{1,2}. ¹California National Primate Research Center, University of California Davis, Davis, CA; and ²Department of Anatomy, Physiology, and Cell Biology, School of Veterinary Medicine, University of California Davis, Davis, CA.

Background and Purpose: The US Centers for Disease Control and Prevention estimates that approximately 6.5% of adults in the United States are current electronic cigarette (e-cigarette) users. E-cigarettes are drug delivery devices that produce aerosols by heating and aerosolizing e-liquids containing primarily propylene glycol, glycerol, nicotine, and flavorants. Clinical reports indicate detrimental health impacts of e-cigarettes in adult users, yet there is still a common perception that e-cigarettes are safer to use than conventional tobacco cigarettes. *In vivo* investigations using rodents have shown increased oxidative stress and inflammation in the lungs following aerosol exposure to e-cigarettes. However, *in vitro* studies using lung epithelial cell lines and primary cultures have reported inconsistent outcomes using comparable modalities for exposure to e-cigarettes. Because the alveolar macrophage is a significant cellular contributor to mucosal immunity in the lung, we hypothesized that macrophage and lung epithelial cells may function synergistically when exposed to e-cigarettes. To test this hypothesis, we used established human cell lines for macrophages and lung epithelial cells to investigate whether cocultures modulate the inflammatory response to e-cigarettes, using the neutrophilic chemokine IL-8 as

an outcome measure. **Methods:** The human promyelocytic leukemia HL-60 cell line was used to model a macrophage phenotype. The human bronchial epithelial cell line BEAS-2B and human adenocarcinoma alveolar epithelial cell line A549 were used to model conducting airway and alveolar epithelium, respectively. HL-60 cells were differentiated into macrophages by culturing with phorbol 12-myristate 13-acetate for 48 hours. BEAS-2B or A549 cells were directly cultured on the basal membrane surface of Transwell inserts until confluent. Differentiated HL-60, BEAS-2B and A549 cells were separately treated with 3% tobacco-flavored JUUL diluted in media, 3% propylene glycol and glycerin vehicle (PGVG) diluted in media, or media control for 6 hours. After treatment, all cells were washed with phosphate buffered saline, then combined as cocultures for 24 hours. Media from the basolateral Transwell compartment (apical surface of epithelium) were collected and evaluated for IL-8 protein using ELISA. **Results:** In monocultures of HL60, BEAS-2B and A549 cells, 3% JUUL exposure did not result in a significant increase in IL-8 secretion relative to unexposed controls. JUUL-exposed BEAS-2B cells significantly decreased IL-8 secretion when cocultured with JUUL-exposed HL-60 cells, relative to unexposed control HL-60 cells. In contrast, JUUL-exposed A549 cells showed a significant increase in IL-8 secretion when cocultured with HL-60 cells, independent of prior JUUL exposure. Additionally, there was a modest, but significant increase in IL-8 secretion when comparing JUUL-exposed A549 cells with JUUL-exposed HL-60 cells, relative to control HL-60 cells. To assess for synergistic interactions, we compared expected IL-8 concentrations derived from monocultures relative to coculture outcomes for all exposure groups. For both BEAS-2B and A549 cells, there was a significant difference between expected and actual IL-8 concentration resulting from cocultures, primarily in conjunction with JUUL treatment. In BEAS-2B cocultures, we observed 2-fold increase in IL-8 secretion with HL-60 cells relative to expected concentrations, despite the attenuated response with JUUL treatment relative to controls. In A549 cocultures, we also found an approximate 2-fold increase in IL-8 secretion relative to expected concentrations. **Conclusions:** Taken together, our findings support a synergistic relationship between macrophages and lung epithelium that modulates the innate immune response following exposure to e-cigarette liquids. Differential outcomes between conducting airway and alveolar epithelium may reflect regionally distinct inflammatory pathways. Future studies will incorporate *in vitro* aerosol exposures to validate e-cigarette liquid findings, as well as the use of primary alveolar macrophage and airway epithelial cell cultures.

PS 4076 Tobacco Harm Reduction: *In Vitro* Toxicological Assessment of Next Generation Tobacco and Nicotine Products versus Combustible Cigarettes and Smokeless Tobacco

R. Leverette, B. M. Keyser, and B. Ganesh. RAI Services Company, Winston-Salem, NC.

Background and Purpose: Next generation tobacco and nicotine (NGP) products, which include Electronic Nicotine Delivery Systems (ENDS), Heated Tobacco Products (HP), and Nicotine Pouch (NP) products, provide alternative, potentially less harmful, nicotine products to adult smokers and nicotine consumers wanting to transition from combustible and other tobacco containing products. NGPs must undergo the premarket tobacco product application (PMTA) process and obtain a marketing granted order (MGO) from FDA Center of Tobacco Products (CTP) to become authorized for marketing. Currently, FDA-CTP PMTA submissions require comprehensive listings of product ingredients and components, harmful and potentially harmful constituents (HPHC), product stability and information on potential health risks including risk assessments, *in vitro* toxicological, and clinical testing to establish a Weight of Evidence (WoE) to determine if the marketing of an NGP is appropriate for the protection of the public health (APPH). **Methods:** This assessment will examine the *in vitro* toxicological testing of representative ENDS, HP and NP products (all menthol or mint flavor varieties) through a series of three standard genotoxicity and cytotoxicity assays and compared to combustible cigarettes (CC) and traditional smokeless tobacco (ST). The three standard regulatory toxicology assays utilized include the Ames (mutagenicity), *in vitro* micronucleus (iVMN: genotoxicity), and neutral red uptake (NRU: cytotoxicity) following respective OECD guidelines. Test samples from CC, HP, and ENDS included pad-collected total particulate matter (TPM: CC & HP) or aerosol collected material (ACM: ENDS), all combined with their respective gas vapor phase (GVP) preparations as well as combustible cigarette whole smoke (WS) and whole aerosol (WA) from ENDS and HP (NRU). NP products with either tobacco-derived (TDN) or synthetic (SYN) nicotine and ST (snus) were tested using complete artificial saliva (CAS) extracts in all three assays. The Ames assay utilized a recommended battery of five *Salmonella* tester strains (TA98, TA100, TA102, TA1535 & TA1537) with and without metabolic activation ($\pm$ S9). The three standard exposure schedules were performed in the iVMN, with an additional long-term exposure schedule (24-hr, -S9, with 24-hr recovery) previously shown to increase sensitivity of these test items in the iVMN assay. Cytotoxicity of CC, ENDS and HP was determined by exposing mammalian cells at the air-liquid interface (ALI) to freshly generated WS (CC) or WA (ENDS, HP) while NP and ST samples utilized CAS extracts. For all assays, nicotine content of the test samples was determined to allow testing to be based on nicotine equivalents and allow comparison across NGP categories. **Results:** CC TPM+GVP was genotoxic in both the Ames (TA98; $\pm$ S9: TA100; $\pm$ S9 TA1537; +S9) and iVMN (all exposure schedules) assays while ENDS and NP tested negative in both the Ames (all strains, $\pm$ S9) and iVMN (all exposure schedules). The HP was non-mutagenic in the Ames but genotoxic in the iVMN (short-term, -S9; long-term with recovery), albeit less toxic when comparing the slopes of the CC

and HP response curves ($p < 0.0001$) at $\sim 10\times$ higher delivered nicotine equivalent concentrations compared to CC. CC WS was cytotoxic ($IC_{50} \sim 2.0 - 2.4 \mu\text{g}$ nicotine equivalents) while an IC_{50} could not be determined for ENDS up to maximum delivered dose ($\sim 3 \text{ mg}$ nicotine equivalents). An IC_{50} was determined for HP WA ($\sim 70 \mu\text{g}$ nicotine equivalents) that was statistically significantly higher (less cytotoxic) than CC WS ($p < 0.0001$). CAS extracts of NP (TDN and SYN) and ST (snus) were found to be non-mutagenic (all strains, $\pm$ S9), non-genotoxic (all exposure schedules) and non-cytotoxic (NRU) at the tested doses. **Conclusions:** Overall, the results from this series of studies found ENDS and NP to be non-genotoxic and non-cytotoxic and HP with decreased genotoxicity and cytotoxicity when compared to CC and provides important data to the WoE necessary to determine if an NGP is APPH. Additionally, the *in vitro* data supports the possible role these NGPs have in the tobacco harm reduction paradigm.

PS 4077 Development of the combined oxidative stress and cytotoxicity model in MucilAir tissues for the exposure of cigarette smoke and Heated Tobacco Product aerosols

I. Crooks¹, E. L. Bishop¹, M. Hollings², R. Bedford², and D. Breheny¹. ¹B.A.T. (Investments) Ltd, Southampton, United Kingdom; and ²Labcorp, Harrogate, United Kingdom. Sponsor: R. Leverette

Background and Purpose: Oxidative stress plays an important role in the progression of some diseases, such as cardiovascular disease and various inflammatory conditions such as chronic obstructive pulmonary disease (COPD). Several clinical markers of oxidative stress exist including Nrf2 transcription factor and 8-isoprostane (8-IP), a stable downstream marker following Nrf2 activation. Cigarette smoking induces oxidative stress in the lungs of smokers due to the abundance of chemical toxicants in cigarette smoke. Heated Tobacco Products (HTP) are postulated as a potentially reduced risk product compared to cigarettes, and HTP aerosols show lower biological activity in *in vitro* and clinical studies as compared to cigarette smoke. We exposed the 3D lung model, MucilAir, to cigarette smoke and a HTP aerosol to measure 8-IP as a biomarker for oxidative stress and combine this with a measure of cytotoxicity using MTT reduction. Doses were carefully selected to ensure an appropriate number of doses within the non-cytotoxic range ($>70\%$ cytotoxicity) for 8-IP measurements. **Methods:** Eight 1R6F cigarettes were smoked under ISO 20778 (55mL puff volume, taken over 2 seconds, every 30 seconds, with vents 100% blocked) on a Vitrocell® VC 10® and MucilAir tissues were exposed to the whole resulting aerosol for approximately 30 minutes. Seven diluting airflows ranging from 10L/min to 0.5 L/min were used. An HTP aerosol was generated using the Vitrocell VC 1/7 under ISO 5501-1 (55mL puff volume, taken over 2 seconds, every 30 seconds, with vents unblocked). 24 sticks were puffed over 120 minutes, using 7 diluting airflows ranging from 4L/min to 0 L/min. Positive controls Phorbol 12-myristate 13-acetate (PMA), ionomycin and tert-butyl hydroperoxide (tBHP) were included. Following exposure, a sample of the culture media was collected from the exposure module media and the recovery media, and analysed for 8-IP using ELISA kits. Cytotoxicity was assessed using the MTT reduction assay. Nicotine was also measured in a blank Transwell for each dose of aerosol delivered as a dosimetry metric. **Results:** PMA, ionomycin and t-BHP induced 8-IP responses that were typically >10 fold and >3 -fold the vehicle control, respectively. 1R6F smoke induced dose related increases in 8-IP release that typically exceeded ~ 3 fold compared to the concurrent air control at non-cytotoxic doses. In addition, dose related decreases in tissue survival was observed at aerosol dilutions ranging between 4 and 0.5 L/min, and IC_{50} values could be derived. The HTP aerosol also induced dose related increases in 8-isoprostane that typically reached 2 to 3-fold the concurrent air controls at non-cytotoxic concentrations, and dose related decreases in tissue survival were observed at diluting airflows between 2 and 0 L/min. These responses were only achieved when a more concentrated aerosol and longer exposure duration was used. To account for the differences in the exposure duration and aerosol concentration between the 1R6F and HTP exposures, the deposited nicotine was used as a dose descriptor. At the lowest diluting airflows (highest aerosol concentration), 1R6F deposited a mean nicotine concentration of $25.3 \mu\text{g/mL}$, whereas the HTP deposited $150.7 \mu\text{g/mL}$. There is a clear differentiation between cigarettes and HTPs for both 8-IP release and cytotoxicity, with 1R6F clearly inducing higher levels at significantly lower levels of delivered nicotine compared to HTPs. **Conclusions:** A combined model to determine both 8-IP release as a surrogate for oxidative stress and cytotoxicity in the same *in vitro* tissue culture has been developed. The positive controls induced significant increases in 8-IP release at different levels of induction, demonstrating the potential of the assay to detect low and high responses to tested aerosols. Exposure to whole aerosol from 1R6F and HTP showed dose related increases in 8-IP release at non-cytotoxic doses, and complete cytotoxicity as measured by MTT reduction. However, 1R6F induced higher levels of 8-IP, and significantly longer exposure duration and more concentrated aerosol concentrations were required to induce responses from the HTP, adding to the weight of evidence that HTPs offer potentially reduced risks as compared to traditional cigarettes and can thereby contribute to tobacco harm reduction.

S. Umphres, H. Ali, A. Alarabi, F. Z. Alshbool, and F. T. Khasawneh. Texas A&M University, Kingsville, TX.

Background and Purpose: It was recently shown that e-cigarette (EC) use during pregnancy increases the risk of cardiovascular disease (CVD) in the offspring. While EC usage has been on the rise among pregnant women, this is not the only means by which innocent fetuses get exposed. Indeed, there is evidence that ECs are also a source of thirdhand exposure (THEC), which is formed from toxicants "produced" by vapor that accumulates on materials including carpets, clothing, furniture etc. In this connection, we have recently shown that *in utero* thirdhand smoke increases the risk of thrombosis. However, whether *in utero* THEC exposure poses any health effects on the offspring remains unknown. Our objective was to characterize the impact of maternal THEC on platelet functional responses and thrombotic CVD, and gain mechanistic insight into platelet transcriptomic changes in the exposed adult offspring that could mediate thrombogenicity triggered by maternal THEC exposure. **Methods:** Mice were housed with EC-exposed or clean air (CA) material for one week prior to mating and throughout the pregnancy to mimic real-life exposure scenarios. To assess the phenotype, platelet functional assays were performed. Blood was collected from twenty mice in each exposure group, and platelets were depleted of leukocytes and red blood cells. Additionally, RNA sequencing was utilized to identify differentially expressed platelet expression profiles between maternal THEC and CA exposed mice. All data was collected on the adult offspring at 10-12 weeks of age, and in a sex dependent manner. **Results:** Our results indicate that maternal THEC exposed mice exhibit shortened bleeding and occlusion times in comparison to clean air. Platelet function assays revealed platelet aggregation and dense & alpha granule secretion were potentiated in the maternal THEC exposed mice upon agonist stimulation. Additionally, integrin activation and phosphatidylserine exposure, separate platelet functional responses, were also enhanced. Notably, no detectable differences were observed in platelet number, and maternal THEC exposure did not impact the weight of the offspring. Furthermore, our platelet transcriptomic data highlighted 257 dysregulated pathways in females primarily associated with platelet activation and aggregation, including activated P2Y purinergic receptor, thrombin, and GP6 signaling pathways. In contrast, males had 175 dysregulated pathways mainly associated with inflammation and oxidative stress, suggesting an indirect effect on platelet function, including but not limited to NIK noncanonical NF-KB signaling and KEAP1-NFE2L2 pathway. Moreover, eNOS signaling was dysregulated in both males and females suggesting that the integrity of the vascular wall was compromised as a result of THEC exposure. Differentially expressed (DE) platelet patterns displayed 121 and 17 clustered genes in males and females, respectively. Integrated analysis of DE genes and dysregulated pathways designated several interactions to be associated with platelet signaling pathways, inflammation and oxidative stress, or impaired vascular wall integrity. Notably, there were some sex differences observed in specific aspects of the phenotype, which is consistent with the transcriptomic data. **Conclusions:** It is evidenced by our data, and demonstrated for the first time, that the observed prothrombotic phenotype is a multifactorial process involving a combination of direct and indirect platelet function alterations that are programmed during fetal development, which highlights it as an underestimated risk factor for CVD in the offspring. These findings could inform cessation efforts and guide policy development to prevent humans from being subjected to any known and unknown health risks associated with THEC; especially in vulnerable populations such as pregnant females.

PS 4079 Serum Surfactant Protein-D is Not Elevated in E-Cigarette Users:
Divergent Alveolar Responses Compared to Cigarette Smoking or
Too Early To Tell?

L. S. Meijer¹, E. Mitchell², A. Perryman², N. Kasaraneni², K. Nicola², J. Masso-Silva^{2,3}, A. Kumar³, S. Karandashova², and L. E. Crotty Alexander^{2,3}. ¹Utrecht University, Utrecht, Netherlands; ²University of California San Diego, La Jolla, CA; and ³VA San Diego Healthcare System, La Jolla, CA.

Background and Purpose: Alveolar type II (ATII) cells synthesize surfactant protein D (SP-D) and secrete this into the alveolar lumen. In the setting of lung injury, SP-D is translocated into the circulatory system, resulting in increased serum SP-D. These processes seem to be driven by ATII cell stress and alveolar leakage as opposed to increased synthesis systemically. While elevations in serum SP-D have been documented in combustible cigarette smokers, the effect of e-cigarette vaping on the release of SP-D into the circulation has not been studied. Here we utilized our cohort of young, healthy, chronic e-cigarette vapers to determine whether 1. circulating SP-D is elevated in the setting of vaping, and 2. serum SP-D concentrations correlate with recent vaping, using self-reported time since last vape as well as a cotinine concentration, a serum biomarker of nicotine exposure. **Methods:** A cross-sectional observational study was performed in healthy young adults aged 18-35 years. Participants were grouped based on their history of inhalant use: non-smoking non-vaping controls (n=23), nicotine vapers (n=12), and all other inhalant users (cannabis vapers, cannabis smokers, tobacco smokers and mixed inhalant users; n=73). Blood was drawn from all subjects, serum isolated, and SP-D quantified via ELISA (R&D

Systems). Data were analyzed using ANOVA, Welch's t-tests, and linear regression. *SFTPD* gene expression was measured in human lung epithelial cells (H441), after exposure to Air, Nicotine control, Vehicle control and JUULTM Mint, Mango, Menthol and Virginia Tobacco flavored aerosols *in vitro*, via droplet digital polymerase chain reaction (ddPCR). **Results:** Serum SP-D concentrations did not vary between nicotine vapers (60.6 ng/mL) and controls (51.0 ng/mL; Welch's t (18.6) = 0.61, p=0.55, $\eta^2=0.02$). Likewise, when all inhalant users were compared to controls, no difference was observed (62.0 vs. 51.0 ng/mL, respectively; t(92.8)= 0.78, p=0.44, $\eta^2=0.006$). Inhalant users did have greater variance in serum SP-D levels compared to controls (F=6.82, p<0.0001). In nicotine vapers, serum SP-D did not vary by self-reported time since last vape (ANOVA: F = 1.24, p=0.30, R²=0.05) or by their serum cotinine level (linear regression: F(1,70)=0.0029, p=0.96, R²<0.001; β = -0.00014 [95% CI -0.0055 to 0.0052]). Expression of *SFTPD* in human epithelial cells exposed *in vitro* did not vary between different JUULTM flavored aerosols and air controls 24 hours after exposure (ANOVA: F = 0.30, p=0.922, R²=0.11). **Conclusions:** No association between elevated serum SP-D levels and chronic e-cigarette vaping was detected in human subjects, nor was a correlation to nicotine exposure identified. No change in expression of *SFTPD* in human epithelial cells exposed *in vitro* was found between JUULTM flavored aerosols and air control. These findings suggest that e-cigarette vaping does not cause the same acute ATII cell injury seen in patients using combustible cigarettes, which drives increased SP-D levels in the circulation. Alternatively, serum SP-D might not be related to chemical exposure but rather to lung diseases such as COPD, which develop over time. This may suggest that the effect of vaping on alveolar damage is minimal or that systemic SP-D only rises after decades of chronic exposure. Unfortunately in this study we were unable to include subjects who only smoke combustible tobacco, because it is a rare pattern of inhalant use in this age group. Future studies will follow subjects longitudinally to assess for trends in serum SP-D over time, as has been previously described in cigarette smoking.

PS 4080 Characterization of breath biomarkers in vapers, smokers, and non-users via a novel breath biopsy method

R. Vilcassim, S. Stowe, A. Chadha, and J. Wickliffe. University of Alabama at Birmingham, Birmingham, AL.

Background and Purpose: E-cigarette use (vaping) continues to rise across the world, particularly among young adults. While e-cigarettes are considered less harmful than combustible cigarettes, heating of e-liquids generates volatile organic compounds (VOCs) and other toxicants with potential respiratory, cardiovascular, and immune-related effects. A key challenge in vaping-toxicity research has been the difficulty of distinguishing vaping-associated biomarkers from those of smoking and other tobacco product use, with current assessment methods being mostly invasive. Breath biopsy offers a non-invasive approach to assess both exogenous exposures and endogenous biomarkers linked to inhaled toxicants. Therefore, this pilot study aimed to explore the potential of 'breath biopsy' - a non-invasive and highly sensitive technique - to identify unique biomarkers associated with vaping. **Methods:** We conducted a single-site, cross-sectional observational study of 24 healthy males (aged 21-35) that included cigarette smokers (n=8), exclusive e-cigarette users (n=8), and those who did not use any tobacco products (n=8). Breath samples were collected from all groups, with an additional abstinence condition in vapers: samples were taken at baseline and after 24 hours without vaping. Owlstone Medical's (UK) ReCIVA breath sampler with their breath biopsy platform was used to capture and analyze exhaled VOCs. **Results:** Vapers and smokers exhibited clearly distinct VOC biomarker clusters, underscoring the ability of breath biopsy to identify and differentiate inhalation exposures from e-cigarette and combustible cigarette aerosols. Overall, VOC biomarkers associated with health risks were elevated in smokers and vapers compared to controls. A 24-hour abstinence period in vapers demonstrated decreased VOC levels, suggesting that some vaping-related biomarkers are transient and that the method is sensitive to recent use. Further analysis of VOCs in the breath demonstrated that the gut microbiome and nutrient uptake can be negatively impacted in vapers and smokers. Despite the modest sample size, the tightly controlled design and exclusive user groups lent robustness to the findings. **Conclusions:** This exploratory study demonstrates the feasibility of using breath biopsy to distinguish between smokers and vapers based on VOC profiles. VOC biomarkers may provide early insights into physiological changes from vaping, including selenium depletion and microbiome alterations. These findings support larger longitudinal studies to better define vaping-related health risks.

PS 4081 Stability of Combustible Cigarettes Gas Vapour Phase Extracts For In Vitro Testing

I. Crooks¹, E. Bishop¹, M. Hollings², S. Martin², and D. Breheny¹. ¹B.A.T. (Investments) Ltd, Southampton, United Kingdom; and ²Labcorp, Harrogate, United Kingdom. Sponsor: R. Leverette

Background and Purpose: The *in vitro* testing of cigarettes often involves the fractionating of the aerosol produced by the product, by using automated smoking robots. The particulate matter is captured on Cambridge filter pads (Total Particulate Matter; TPM), and the gas-vapour phase (GVP) that passes through the pad is collected in an impinger solution. The impingers often contain aqueous or organic solvents that act

as a gas wash to trap volatile and semi-volatile substances, such as carbonyls. The TPM and GVP are often combined into one test article and tested *in vitro*. TPM has been well characterised and much is known about its long term stability. However, less is known about the GVP stability. Because of its assumed instability due to the presence of volatile and semi-volatile compounds, scientific literature often states that GVP should be used within 1 hour, or at least on the same day of generation. Furthermore, no studies have investigated the potential for long-term storage of the GVP for the same period and conditions as the TPM. This study was designed to address four key questions: Is PBS or ethanol more efficient at trapping carbonyls; at what point does the GVP become saturated; at what timepoint does the GVP begin to deteriorate on the day of generation; and what is the long-term stability of GVP under frozen conditions? **Methods:** 1R6F cigarettes were smoked on a Korber RM200 smoking robot, and the TPM trapped on Cambridge filter pads. The GVP that passed through the pad was trapped in two impingers in series into a fixed volume of either PBS or ethanol - the second impinger was used to quantify any blow off from the first impinger. The following methods were then applied to address each question: An incremental number of cigarettes were smoked to determine the point of saturation for both solvents. A fixed number of cigarettes was then puffed and the GVP captured in impingers containing PBS. Immediately after the completion of the smoking run, the GVP was then aliquoted into glass vials with minimal headspace and refrigerated. 14 timepoints spanning immediately after aliquotting and up to 6 hours storage were analysed for carbonyls. Aliquots of GVP were stored at -80°C and analysed at specified timepoints for up to 7 months storage. **Results:** The data demonstrated that no saturation of carbonyls occurred, when up to 12 cigarettes were puffed into PBS or ethanol. A linear trend in increasing levels of carbonyls was observed with the increasing number of cigarettes. The secondary impinger to determine any blow off that occurred from the initial trapping there was approximately 20-30% capture when compared to the initial values for PBS. For ethanol, similar values were seen at lower number of cigarettes; however at higher concentrations this increased to approximately 50%, suggesting that PBS was more efficient at trapping carbonyls compared to ethanol. Both the PBS and ethanol samples were stable for up to 6-hour storage, when kept under refrigerated conditions with minimal headspace. The long-term stability phase demonstrated that the GVP was stable for up to 4 months storage; however after this timepoint, some deterioration of some carbonyls were observed. **Conclusions:** This study has demonstrated that PBS has a higher efficiency for trapping carbonyls than ethanol and no saturation was observed when up to 12 cigarettes were smoked. When the GVP was stored refrigerated for up to 6 hours, no deterioration in any carbonyls were observed and the long-term stability demonstrated that GVP can be stored for up to 4 months without a significant loss of carbonyls.

PS 4082 Preliminary investigation of the chemistry and respiratory toxicology of vaping

X. Zheng^{1,2}, C. Billington¹, J. Powell¹, and M. Glass^{1,2}. ¹PHF Science, Christchurch, New Zealand; and ²University of Otago, Dunedin, New Zealand. Sponsor: M. Howes

Background and Purpose: Vape liquids, typically composed of propylene glycol (PG), vegetable glycerine (VG), nicotine, and ethanol, undergo heating and aerosolisation during use, generating additional toxic by-products. Understanding the health risks of vaping requires a dual approach: chemical characterisation of aerosols and biological assessment of their effects on lung tissue. Lung-on-a-chip technology offers a biomimetic model bridging *in vitro* studies and clinical relevance. The newly released Emulate Chip-A1, optimised for aerosol studies, motivated our investigation into vaping-related respiratory risks. Here, we present 2D cell culture data and outline an experimental framework for aerosol analysis and chip-based testing. **Methods:** Human alveolar epithelial cells (NCI-H441), cultured in 96- and 24-well plates, were exposed to various vape liquid components, PG/VG, nicotine (3-36 mg/ml) and ethanol (1-30% v/v) for 24 hours. Cell supernatants were collected and analysed for evidence of cytotoxicity (lactate dehydrogenase, LDH) and cytokines (IL-8 and IL-10). **Results:** Vape aerosols are highly diluted in the airways, exposing alveoli to ~1% of the original vape liquid. To model this, NCI-H441 cells were treated with varying PG and VG dilutions. At 10%, PG induced greater cytotoxicity than VG, and nicotine increased this effect dose-dependently, while ethanol showed no toxicity. Thus, 10% solutions were used for cytotoxicity assays and 1% for non-cytotoxic inflammatory responses. At 1%, PG and nicotine significantly elevated IL-8 without affecting IL-10, ethanol remained non-toxic. We adapted a vaping machine to generate aerosols under controlled puffing regimes for chemical analysis and exposure within a lung-on-a-chip system. **Conclusions:** Preliminary data suggest that vape liquids may impair immune responses in alveolar epithelial cells by increasing pro-inflammatory IL-8 while not affecting anti-inflammatory IL-10. Although ethanol alone had no effect in 2D cell culture, its volatility and -OH group could alter aerosol composition and chemical interactions during heating. We will next use our vaping machine to collect whole aerosols for analysis of PG, VG, nicotine, ethanol, carbonyls, and metal content, and for controlled exposure of human cells in the 3D lung-on-a-chip system. This approach will extend our 2D culture findings, modelling aerosol exposure in a more physiologically relevant system. A key focus will be measuring the impact of increasing power wattage, which raises aerosolisation temperature and may enhance the formation of harmful compounds. As the first group in New Zealand applying lung-on-a-chip technology to vaping research, we aim to provide mechanistic insights into the respiratory effects of vape aerosols. Our findings will have regulatory relevance and may support evidence-based harm reduction strategies and public health policy.

PS 4083 Developing a multi-task quantitative structure-activity relationship (QSAR) model for the prediction of e-cigarette emissions toxicity

A. Canchola¹, K. Chen¹, M. Rahman², L. Tran¹, W. Woo¹, L. Tian¹, Y. Lin¹, and W. Chou¹. ¹University of California, Riverside, Riverside, CA; and ²University of Minnesota, Duluth, Duluth, MN.

Background and Purpose: Electronic cigarette (e-cigarette) products and emissions contain a complex mixture of active ingredients, solvents, flavors, thermal degradation products, and contaminants. Despite recent efforts, evaluating the toxicity of each organic constituent through experimental methods alone is infeasible due to the large volume and variability of compounds, posing a significant challenge for effective hazard assessment. To address this gap, we developed interpretable deep neural network (DNN)-based quantitative structure-activity relationship (QSAR) models to predict e-cigarette toxicity for multiple endpoints: eye irritation, skin irritation and sensitization, carcinogenicity, and genotoxicity. **Methods:** The dataset of over 980 diverse e-cigarette chemicals was curated from existing literature and toxicological databases (e.g., CompTox Chemicals Dashboard) and included labeled data for each endpoint ("1": Toxic, "0": Non-Toxic). A total of seven DNN-QSAR models were developed using PyTorch: five single-task models to independently predict related endpoints, and 2 multi-task models to simultaneously predict related endpoints. For the multi-task models, eye irritation, skin irritation, and skin sensitization were grouped into one model, and carcinogenicity and genotoxicity were grouped together into a second model. All models used nested cross validation with Bayesian optimization to optimize hyperparameter tuning and reduce the risk of overfitting. The best-performing model was tested on a holdout set for final evaluation, and metrics were computed across endpoints. Finally, applicability domain analysis was conducted to define the chemical space reliably covered by the model and SHapley Additive explanation (SHAP) to identify important chemical features that most significantly impacted model performance. **Results:** The optimized DNN-QSAR models demonstrated good predictive performance for all endpoints (all AUC ≥ 0.66, all Accuracy ≥ 61%). Compared to the best performing single-task models, certain endpoints, such as eye irritation, saw substantial performance improvement (AUC +13 %, Accuracy +20%), while others, like carcinogenicity saw reduced performance (AUC -13 %, Accuracy -5%). Feature importance analysis revealed that nitrogen-containing groups (e.g., amines and amides) were influential predictors of eye and skin toxicity, whereas cancer-related endpoints were highly dependent on the electrostatic and electronegative properties of compounds. These results highlight the importance of carefully selecting tasks that share high degrees of structural feature overlap, sample sizes, and class distributions for efficient multi-task models. **Conclusions:** This study presents novel single- and multi-task QSAR models capable of predicting important toxicity endpoints for e-cigarette emission constituents that currently lack detailed toxicity data. These models can help address current data gaps and support more comprehensive, high-throughput hazard evaluations of e-cigarette products, potentially informing regulatory decision-making and supporting safer product formulation. Future work will focus on expanding the model's chemical coverage and validating predictions with experimental data to further strengthen its application in toxicity risk assessment.

PS 4084 Emissions characterization and modelled dosimetry estimates from ultrasonic Ecig and IQOS devices

L. Shouldis, I. Olfert, and A. Ranpara. West Virginia University, Morgantown, WV.

Background and Purpose: E-cigarette (Ecig) that vaporize liquid has been undergoing advancements to attract users. SURGE, a modern device, aerosolizes e-liquid via ultrasonic vibrations (~3 million hits/sec) to generate emissions. IQOS is a heated tobacco product (HTP) that warms a tobacco-laced cigarette without burning it to generate its emissions. Particle and chemical constituents in these emissions may be different based on the composition of the materials (e.g., e-liquid vs tobacco leaves), puff topography (i.e., volume, heating power-wattages), or the differences in underlying heating technology. Comparison of particles and chemicals between technologically varying vape devices are still poorly characterized and their toxic potentials on health outcomes after long-term exposures remain great concerns. The purpose of the study was to: 1) characterize and compare particles and chemicals emitted from Ecig (i.e., JoyeTech), IQOS, and SURGE at two puff volumes, and 2) evaluate dosimetric estimates for lung depositions among primary users. **Methods:** Emissions were generated by an automated syringe set up at 55- and 100-mL puff volumes within 5 sec duration and 30 sec intervals from JoyeTech at 9W, IQOS, and Surge. Total particle mass and mass-based particle size distribution (PSD) were determined off-line using a cascade impactor, MiniMOUDI™. PSD was reported using median aerodynamic diameters (MMAD) ± geometric standard deviation (GSD). Estimate for modelled dosimetric depositions in head, tracheobronchial (TB), and alveolar regions was calculated using multiple path particle dosimetry model (MPPD v 3.04). Real-time measurements of speciated chemicals were considered using Fourier Transform Infrared spectroscopy (FTIR). For brevity, measurements for total of 13 volatile carbonyl compounds (VCC) and 31 other toxicant chemicals (OTC) are presented in parts per millions (PPM). Data acquisition (for at-least three trials) was conducted for particle and chemical assays using JMP® Pro 16.0.0. Average and standard deviations (SD) were considered for total mass (mg/puff) and MMAD (µm) aerosol generated with 55-, and 100- mL puff volumes. Significant differences (p <

0.05) between MMADs, and total aerosol masses were determined using an ANOVA and Tukey's test for multiple comparisons. Average of total and maximum (in PPM) of VCC and OTC are presented for both puff volumes. **Results:** Higher aerosol mass (mg/puff) were emitted at 100- than 55- mL puff volume: JoyeTech (10.19 vs 8.39) > Surge (4.73 vs 4.38) > IQOS (0.79 vs 0.59). Further, higher puff volume 100 mL vs 55 mL emitted smaller size of particles: MMAD of IQOS (0.53 μ m vs 0.60 μ m) that were also resulted into significantly different ($p < 0.05$) than JoyeTech (1.25 μ m vs 1.55 μ m) and Surge (0.96 μ m vs 1.25 μ m). In general, all emissions resulted in polydisperse PSD with GSD ranged 1.4-1.6. Modelled dosimetry estimated similar regional respiratory deposition in head (~39%), TB (~21%), and alveolar (~40%) for all the emissions. Real-time measurements with FTIR resulted into higher VCC and OTC for 100- than 55-mL for Surge, IQOS, and Joyetech. Maximum values of VCC for 55 mL vs 100 mL constituted Pentenal (PPM: 59 vs 70) and Acetaldehyde (PPM: 132 vs 172), respectively for Surge and IQOS. Glycerol (PPM: 200.71-1780.49) was the maximum out of all the OTCs for both Surge and IQOS at 55- and 100-mL. JoyeTech also emitted VCC: Isobutyraldehyde (PPM: 72 vs 52) and OTC: Nitrobenzene (PPM: 2197 vs 2116) at 100 mL vs 55 mL puff volume. According to IARC, Acetaldehyde and Nitrobenzene are group 2B: possibly carcinogenic to humans. **Conclusions:** We conclude that: 1) statistical difference in MMADs do not imply practically for regional respiratory deposits, 2) real-time speciation of chemicals reveals previously unreported chemicals, 3) maximum concentrations of chemicals outweigh traditionally reported averages that could undervalue exposure assessment and thereby biological impacts, and 4) though quantitatively lesser, cumulative burden of smaller sized particles and chemicals from Surge and IQOS devices do not suggest safer emissions compared to other Ecig devices. Although, characterization of Ecig emissions is a complex dynamic, it important to evaluate PSDs with as less fortification as possible for accurate evaluation of their deposition dose and thereby, to understanding biological insults. Future study will include animal exposure to better address inferences of such emissions.

PS 4085 Substantially Equivalent and Equally Addictive: The Case of Cool Non-menthol Cigarettes in California

A. Adeniji¹, S. Atai¹, S. V. Jabba², B. Henderson³, T. L. Wagener¹, M. C. Brinkman¹, A. P. Tackett¹, and A. El Hellani¹. ¹The Ohio State University, Columbus, OH; ²Duke University, Durham, NC; and ³Marshall University, Huntington, WV.

Background and Purpose: In 2022, California banned flavors in tobacco products, including menthol in cigarettes. In response, a big tobacco company (RJ Reynolds) introduced "non-menthol" cigarettes in the state after securing a substantially equivalent (SE) report from the FDA, stating that these new cigarettes do not raise different questions of public health. We interpreted this SE designation as the new cigarettes are equally addictive and toxic as menthol cigarettes, and wanted to verify this chemically. **Methods:** We purchased non-menthol cigarettes in California (Camel and Newport), brand-matched unflavored regular and menthol cigarettes in Ohio and Georgia, cigarettes from another manufacturer with brand names emphasizing cooling sensations in Ohio (Marlboro), and filtered little cigars for comparison. We tested for nicotine, menthol, and synthetic cooling agents (Wilkinson Sword (WS)-3 and WS-23) in the cigarette rod and mainstream smoke, generated using smoking machines with total particulate matter (TPM) collected on filters and measured gravimetrically. We extracted the four chemicals using liquid-liquid extraction and quantified them on gas chromatography-mass spectrometry (GC-MS). We assessed the transfer of the chemicals from the rod to the smoke and compared the cooling strength across products. **Results:** The only cooling agent detected in non-menthol Newport and Camel cigarettes was WS-3 (0.88-1.93 mg/cigarette). Like menthol in the mentholated counterparts (0.59-1.40 mg/cigarette), the level of WS-3 was 10% of that of nicotine (9.3-15.52 mg/cigarette). All cigarettes emitted the same level of TPM (~33 mg/cigarette). Although the transfer of menthol was higher for Newport menthol (22-27%) compared to non-menthol cigarettes (13-16%), the calculated cooling strength was the same. The newly introduced Marlboro brands had much higher menthol (0.93-3.78 mg/cigarette) and were comparable to filtered little cigars (5.19-6.71 mg/cigar). **Conclusions:** Non-menthol cigarettes introduced in California have the same cooling strength as the banned menthol cigarettes. Our work confirms the SE interpretation that these cigarettes are equally harmful to public health as menthol cigarettes and have the potential to undermine local, state, or federal bans on menthol cigarettes.

PS 4086 Applicability of USP-1664, ICH-Q3E and ISO 10993-17 Standards to the Toxicological Risk Assessment of Leachables from Illicit ENDS Product: A Case Study

V. Kannappan. Juul Labs, Washington, DC. Sponsor: V. Kannappan, Society of Environmental Toxicology and Chemistry

Background and Purpose: To date, the U.S. Food and Drug Administration (FDA) has authorized only tobacco and menthol flavored electronic nicotine delivery systems (ENDS). Despite this, illicit flavored disposable ENDS have become widely accessible in the United States. Contemporary disposable vapes are often illicit flavored disposable ENDS that are made of larger tank leading to high puff counts. Tank and containers of e-cigarettes and vaping products can be made from various plastic

materials. A deconstructing study of contemporary disposable vapes has identified various polymeric plastic materials such as poly(n-butyl methacrylate) (PBMA), polycarbonate (PC), polydimethylsiloxane (PDMS), polyethylene (PE) etc. Polyvinyl chloride (PVC) can be used in combination with these polymers (e.g., PBMA, PC, PDMS, PE etc.) to create new plastic materials with enhanced properties, such as rigidity, flexibility, thermal stability, durability and cost-effectiveness. The FDA's final Premarket Tobacco Product Application rule for ENDS indicates that the container closure system could, intentionally or unintentionally, leach ingredients from the packaging into the product. Leachable substances are chemical components that can migrate from a contact surface of a product into the surrounding media or its contents or process stream under intended use conditions. A case study was developed using pharmaceutical grade PVC in a hypothetical ENDS product and toxicologically evaluating reported leachable compounds using three different standards: USP-1664; ICH-Q3E and ISO 10993-17. **Methods:** Leachable levels of 24 different chemicals in pharmaceutical products stored in PVC containers was extrapolated to a hypothetical ENDS product that uses a PVC tank. ElfBar was chosen as a hypothetical ENDS product because it is an illicit flavored ENDS product. In addition, study findings published (2024) in the "The Journal of Medical Internet Research" concluded that there was an increasing trend in Google searches for Elf Bar, which indicated that there was a rising interest in this brand in the United States. The leachable chemicals were evaluated for their potential risks based on the use and exposure scenario of the ElfBar illicit E-Cigarette (tank volume of 13 mL, e-liquid density of 1.16 g/mL, consumption of 0.06 pod per day). Toxicological risk assessment was carried out by estimating the daily consumer exposure level of leachable chemicals to the selected toxicity thresholds established by three different standards: USP-1664 (Qualification Threshold-QT & Safety Concern Threshold-SCT); ICH-Q3E (Safety Concern Threshold-SCT); and ISO 10993-17 (Toxicological Screening Limit-TSL). **Results:** Margin of exposure assessment of leachable chemicals showed one chemical exceeded the SCT of 0.15 μ g/day and was considered to pose a toxicity risk, requiring further assessment for both carcinogenic and genotoxic effects. All the 24 leachable chemicals were below the QT of 5 μ g/day and the TSL of 600 μ g/day and was considered to have negligible toxicological risk for both systemic and local toxicity. **Conclusions:** This case study of a hypothetical ENDS product illustrated use of different standards (USP-1664 -QT & SCT, ICH-Q3E - SCT), and ISO 10993-17 - TSL) for toxicological analysis of leachable compounds from pharmaceutical grade PVC. It also highlighted that even if pharmaceutical grade PVC is used in ENDS device construction, chemicals may potentially leach into the product, which would require further toxicological evaluation.

PS 4087 Pesticide exposure and placental circadian phase using transcriptomics

Y. Wang¹, D. Wallace¹, P. Panuwet², N. Fiedler³, T. Prapamontol⁴, P. Suttiwan⁵, W. Naksen⁴, D. Barr¹, C. Lesseur⁶, J. Chen⁶, and C. Marsit¹. ¹Emory University, Atlanta, GA; ²Massachusetts Department of Environmental Protection, Worcester, MA; ³Rutgers University School of Public Health, Piscataway, NJ; ⁴Chiang Mai University, Chiang Mai, Thailand; ⁵Chulalongkorn University, Bangkok, Thailand; and ⁶Icahn School of Medicine at Mount Sinai, New York, NY.

Background and Purpose: Circadian timing is integral to placental physiology and fetal development. Environmental toxicants may act as chronodisruptors, yet human evidence of the impact of prenatal exposures on genes that demonstrate circadian rhythmicity in the placenta is limited. In a cohort of Thai farmworking women, we tested whether prenatal exposure to mixtures of organophosphate (OP) and pyrethroid (PY) pesticides, or a combined OP-PY mixture (MIX), were associated with differences in the amplitude or phase of peak expression of circadian rhythmic genes in the placenta. **Methods:** Placental transcriptomes were obtained by RNA-seq from the SAWASDEE cohort (n=252). Gene-level rhythmicity was modeled with DiscoRhythm and LimoRhyde, yielding per-gene amplitudes and times of peak expression (0-24 h). These were applied to a z-scored expression matrix to compute two sample-level circadian indices: (1) acrophase (ϕ), representing the average peak timing across rhythmic genes, and (2) amplitude ($\hat{A}$), the mean strength of rhythmic expression. These indices were tested for association with total-pregnancy and trimester-specific exposures — OP, PY, and MIX—using quantile g-computation (q=4), applying the same covariate adjustment across all models (gestational age, maternal age, BMI, infant sex, and estimated placental cell-type proportions). Sensitivity analyses tested subsets of daytime and vaginal deliveries. **Results:** PY exposure was associated with a delayed shift in the average circadian phase (ϕ) of rhythmic placental genes, with the strongest trimester-specific effect in the third trimester (q = 0.066). PY was also modestly associated with increased rhythm strength ($\hat{A}$) in daytime deliveries (q = 0.057). Metabolite-specific associations showed that 3-phenoxybenzoic acid (3-PBA, a PY metabolite) and total dialkyl phosphate (DAP, OP markers) were linked to delayed phase and reduced amplitude. In contrast, diethylphosphate (DEP), dimethylphosphate (DMP), and trans-DCCA (tDCCA) showed the opposite pattern, contributing to earlier phase and increased amplitude. Decomposition of the sample-level circadian phase (ϕ) into its sine and cosine components revealed a net phase displacement of approximately 4.6 hours (magnitude of the phase shift $|\phi| = 0.074$, p = 0.345), primarily driven by the sine component ($\phi_{\sin}$). This component captures vertical variation in rhythmic phase positioning and was most influenced by 3-PBA and DEP/DMP. In contrast, total DAP attenuated both phase components, leading to a muted shift. **Conclusions:** Prenatal exposure to pesticide mixtures—particularly PY in late gestation—is associated with gene-level altered circadian phase and rhythm

strength in the placenta. Metabolite-specific effects show opposing influences on circadian timing and amplitude, suggesting complex, component-specific mechanisms of disruption. These findings highlight the placenta as a sensitive target of circadian misalignment following environmental exposures and underscore the need for replication and mechanistic studies.

PS 4088 Phenotypically Anchored Transcriptomics Across Diverse Agrichemicals Reveals Conserved Pathways and Unique Gene Expression Signatures in Zebrafish

L. St. Mary. Exponent, Natick, MA.

Background and Purpose: Agrichemicals such as herbicides, fungicides, insecticides, and biocides represent some of the most structurally and biologically diverse chemical classes in wide-scale use. This diversity, coupled with overlapping adverse outcomes, make them powerful tools for developing and testing new approaches to hazard assessment. Although many agrichemicals are represented in high-throughput *in vitro* programs such as the U.S. EPA's ToxCast program, systematic *in vivo* evaluation using transcriptomic profiling—a method that can reveal both chemical-specific signatures and shared toxicity pathways—remains limited. **Methods:** We evaluated a structurally diverse subset of agrichemicals from the U.S. EPA's ToxCast Phase I and II libraries by statically exposing early life stage zebrafish from 6 hours post fertilization (hpf) to 120 hpf at concentrations ranging from 0.25–100 μ M. Morphological outcomes were assessed at 120 hpf across 10 endpoints, including yolk sac edema, craniofacial malformations, and axis abnormalities. Chemicals that produced robust concentration-response relationships were selected for transcriptomic profiling. For transcriptomic analysis, zebrafish were statically exposed to each chemical and sampled at 48 hpf, prior to the onset of morphological effects observed at 120 hpf. **Results:** Differential expression analysis identified between 0 and 4,538 differentially expressed genes (DEGs) per chemical, with no clear correlation to morphological severity. Both DEG and co-expression network analyses revealed chemical-specific expression patterns that converged on shared biological pathways, including neurodevelopment and cytoskeletal organization. Key regulatory genes such as *mylpfa* and *krt4* were identified within co-expression modules, suggesting their potential role in conserved toxicity mechanisms. Semantic similarity analysis of enriched gene ontology (GO) terms, when compared to existing datasets, highlighted gaps in the annotation of neurodevelopmental processes, indicating that some *in vivo* effects may not be fully captured by current curated resources. **Conclusions:** This study highlights the value of integrating transcriptomic profiling with assessments of adverse morphological outcomes in a vertebrate model. Rather than relying on transcriptomic profiling alone, we demonstrate how its use as a complement to traditional morphological endpoints can capture early molecular disruptions, thereby providing deeper insight into the mechanisms of toxicity. Agrichemicals offer a uniquely challenging and informative chemical space for assessing the robustness of transcriptomics to predict and contextualize toxicological outcomes across diverse chemical structures and biological targets. By integrating these molecular responses in a vertebrate model, we outline a broadly applicable framework for advancing transcriptomics as a core component of next-generation hazard assessment.

PS 4089 Exploring the Toxicological Effects of Commonly Sold Pesticides on Non-Target Organisms and Human Health

C. Grayson, L. Alford, and A. Chaudhuri. Stillman College, Tuscaloosa, AL.

Background and Purpose: Global pesticide usage has increased by nearly 94% since 1990, reaching about 3.7 million metric tons annually. The World Health Organization reports nearly one million unintentional pesticide poisonings each year, resulting in approximately 20,000 deaths. In the United States, more than one billion pounds of pesticides are applied annually. Although pesticides are designed to protect crops, their persistence and bio-accumulative nature pose serious risks to non-target species—such as pollinators, birds, aquatic life, and humans. Chronic exposure has been linked to oxidative stress, neurodegeneration, and diseases including cancer, Parkinson's, and Alzheimer's. This study investigates the types of pesticides commonly sold by major retail outlets and identifies their active chemical constituents to assess their potential toxicological hazards. We hypothesize that while not all ingredients are acutely toxic, several may cause significant harm to non-targeted organisms and human health through environmental contamination and bioaccumulation. **Methods:** A survey of major retail stores (e.g., Walmart, Home Depot, Lowe's, Dollar Tree, Dollar General and Tractor Supply) was conducted to document widely sold pesticide formulations and their active ingredients. Laboratory analyses using *Drosophila melanogaster* were performed to examine the neurotoxic and oxidative effects of selected compounds such as paraquat, glyphosate, and atrazine. Use GraphPad Prism 5 software to analyze the data wherever necessary. **Results:** Survey data indicated that Roundup, Spectracide, and Ortho were among the most frequently purchased products. Behavioral and molecular assays in *Drosophila* revealed that exposure to these formulations induced oxidative stress, dopaminergic neuronal loss, and circadian rhythm disruption. Some compounds also affected cell-cycle and cellular integrity. **Conclusions:** Findings indicate that certain active ingredients in commonly marketed pesticides may contribute to oxidative damage and neurodegenerative outcomes. These findings highlight the urgent need to strengthen regula-

tory measures, consumer awareness, and further molecular investigations into their mechanisms of toxicity. Ongoing studies will employ genomic and proteomic analyses in *Drosophila* to identify gene and protein targets affected by pesticide exposure, enhancing understanding of their molecular toxicity pathways.

PS 4090 Toxicological Assessment of BCS-BT38895: A Novel Aniline Metabolite of Diflufenican

M. McCool¹, D. Geter¹, and A. Hueser². ¹Bayer CropScience, Chesterfield, MO; and ²Bayer Aktiengesellschaft, Monheim, Germany.

Background and Purpose: Diflufenican is a selective herbicide of the phenoxy-nicotinamide class, registered in Europe and several countries in Asia, Africa, and South America, and recently accepted for registration in Canada and the USA for pre-emergent use on soybean and corn. During soybean field trials supporting the North American registration, a malonic acid conjugate of the known 2,4-difluoroaniline metabolite of diflufenican, named BCS-BT38895, was detected above the limit of quantitation in 4 out of 22 trials. This metabolite has not been observed in any plant, rat or livestock metabolism studies. In agreement with the U.S. Environmental Protection Agency (EPA) and the Canadian Pest Management Regulatory Agency (PMRA), a hazard characterization was conducted through an *in silico* analysis, a literature review, and a suite of toxicity studies. **Methods:** SciFinder (CAS) was used to search Cplus and MEDLINE databases using the CAS number for each molecule, with no time restrictions. Each identified study was downloaded and reviewed in a rapid assessment analysis. Studies with supplemental or supportive information for a human health risk assessment were reviewed in detail. Toxicity studies included an acute oral toxicity study in rats (tested up to 2,000 mg/kg bodyweight), *in vitro* mutagenicity assays (Ames test, hypoxanthine phosphoribosyl transferase (HPRT) mutation test, and a micronucleus test), and a 28-day repeat-dose dietary study in Wistar rats. In this study, three dose groups (6 males and 6 females each) received BCS-BT38895 at 0 (control), 50, 300, or 1500 ppm (resulting in overall achieved dosages of 4.68, 28.2 and 139 mg/kg/day in males and 3.97, 25.0 and 124 mg/kg/day in females, respectively). Observations included clinical signs, sensory reactivity, motor activity, hematology (including methemoglobin and Heinz body analysis), blood chemistry, organ weights, and histopathology. **Results:** The *in silico* analysis identified structural alerts for methemoglobinemia, hepatotoxicity, and nephrotoxicity, but none for carcinogenicity. The literature review did not identify any studies or publications relevant to a human health risk assessment. The acute oral toxicity study established an LD₅₀ > 2000 mg/kg bodyweight, indicating low acute toxicity. The genotoxicity assays showed no gene mutations or micronuclei, confirming non-mutagenic potential. In the 28-day repeat-dose study, BCS-BT38895 induced classic aniline toxicity hallmarks: methemoglobinemia, spleen congestion, and increased spleen weight at 300 and 1500 ppm; however, no Heinz bodies were observed in any dose level. Findings at 50 ppm were minor and considered non-adverse. The NOAEL was therefore 3.97 mg/kg/day. **Conclusions:** BCS-BT38895, found exclusively in soybean seeds, exhibited no acute toxicity and was non-mutagenic *in vitro*. No literature findings were supportive for use in a human health risk assessment. The 28-day study showed treatment was well-tolerated, with methemoglobinemia and spleen effects observed only at higher doses. A robust NOAEL was therefore established at the low dose. According to the US EPA Human Health Risk Assessment, anticipated exposure (5×10^{-6} mg/kg/day) is orders of magnitude below the chronic population adjusted dose of 4×10^{-3} mg/kg/day from the 28-day oral rat study NOAEL and a 1000x uncertainty factor applied. Given its specificity to soybean seed, low exposure potential, and a well-understood mechanism of toxicity for aniline, further long-term *in vivo* studies are unwarranted and inconsistent with animal use reduction principles.

PS 4091 The limitations of alternative approaches for predicting irritation and sensitization hazards of solid agrochemical formulations

J. Henriquez¹, P. Santos¹, P. Deford¹, R. Dee¹, V. Kumar², and E. Bianchi¹. ¹Corteva Agriscience, Zionsville, IN; and ²Corteva Agriscience, Hyderabad, India.

Background and Purpose: Pesticides are one of the most heavily regulated and toxicologically evaluated classes of molecules on the market. In addition to the extensive testing required by global regulatory agencies on the pesticidal active ingredient, each new formulated product must be evaluated for acute mammalian toxicity endpoints in a data package colloquially referred to as the "Acute Tox 6-Pack". According to a public statement in 2016, the USEPA reviews 500 pesticide product registrations every year. With an average of ~50 animals per acute tox package, this level of review potentially represents average annual testing on ~ 25,000 animals for new products submissions. As a result, efforts across both industry and regulatory agencies have been made to reduce animal testing by adhering to the 3Rs of responsible animal research. Consequently, there is interest in utilization of alternatives for the evaluation of irritation and sensitization potential, yet the *in vivo* irritation and sensitization studies remain the gold standard. The purpose of this project was to retroactively evaluate predictive accuracy of alternative approaches for evaluation of irritation and sensitization potential for solid agrochemical formulations. **Methods:** Solid formulations with alternative assessments for eye, skin, and sensitization potential (i.e., GHS calculation and/or *in vitro* methods) were selected from

the Corteva products (current and historical). Appropriate *in vivo* studies were those performed for regulatory submissions either under OECD/OPPTS guidelines for skin, eye, and sensitization potential. Appropriate *in vitro* studies were those performed for regulatory submissions or for internal screening either under OECD 492 (EpiOcular)/OECD 437(BCOP) (or similar) or OECD 439/431 (EpiSkin™) (or similar) guidelines for eye and skin irritation, and OECD 442 respectively. GHS Calculations for hazard predictions were also included for all formulations. Evaluation of predictivity was determined by confusion matrix and calculation of sensitivity, specificity, and false positive/negative rates. **Results:** Thirteen formulations were determined as having the appropriate data available for evaluation or irritation, though not all formulations had both irritation and corrosion tests available. Of those formulations there were 8 herbicides, 3 insecticides, and 2 fungicides representing Water dispersible granules (WG, 8), wettable powder (WP, 2), granule (GR, 2), and bait formulation (1) types. All the formulations were considered “non-irritating” according to *in vivo* studies. The *In vitro* skin irritation study (OECD 439) correctly predicted 9/10 formulations as non-irritating. The Eye irritation study (OECD 492) correctly predicted only 3/9 formulations as non-irritating and while all three of the eye corrosion assays (OECD 437) correctly identified the tested formulations as non-irritating, the limited number of OECD 437 studies available (N=3) inhibits further interpretation from the corrosion assay. For sensitization, 12 formulations had *in vivo* data, and all were negative. *In vitro* predictions varied, with DPRA had *in vitro* data available. Of those four formulations, Keratinosens (KE2) accurately predicted non-sensitizer for all 4, while GARD had 3 false positives, and DPRA could only be run for 1 formulation due to solubility limitations. In all cases. For GHS Calculations, lack of skin irritation hazard was accurately captured 90% of the time while eye irritation and skin sensitization was over predicted 67% of the time. **Conclusions:** While useful in the context of evaluation for liquid formulations, there is a tendency to over predict hazard potential with solid formulations. These results suggest that negative predictions for irritation of solid formulations are likely representative of the true lack of irritancy potential and could be used for regulatory classification in the absence of animal testing. Further, these results suggest that current ‘default’ testing procedures may not be appropriate for solid formulations and encourage refinement of approaches more suitable for testing solid formulations. However, robustness of these interpretations are limited by the small data set which can be expanded through industry collaboration.

PS 4092 Modulation of Organophosphate Metabolism and Toxicity via NRF2 Signaling

S. Preston, M. Garcia-Mares, A. Bartman, D. Martin, and J. Doorn. University of Iowa, Iowa City, IA.

Background and Purpose: Human exposure to organophosphate (OP) pesticides such as chlorpyrifos (CPF) occurs in agricultural, occupational and military settings worldwide. OP pesticides, such as CPF, can lead to cholinergic crisis via acetylcholinesterase (AChE) inhibition and accumulation of the neurotransmitter acetylcholine. Downstream effects of OP intoxication include seizures and production of reactive oxygen species (ROS), likely due to glutamate (Glu) excitotoxicity. Furthermore, there is evidence that CPF exposure correlates with additional adverse outcomes, including depression and neurodegenerative diseases. Molecular mechanisms for such conditions are elusive and may involve targets other than AChE. Metabolism of CPF is critical to cholinergic toxicity as it can yield either bioactivation to the toxic chlorpyrifos-oxon (CPO) or detoxication via glutathione (GSH)/glutathione-S-transferase (GST; dechlorination) or hydrolysis of CPO via the esterases, paraoxonase 1 (PON1) and carboxylesterase 1 and 2 (CES), with CES serving as a “sink” to protect AChE. Interestingly, several of the enzymes critical to the metabolism of CPF are under the control of the transcription factor NRF2, including: GSH/GST, PON1 and CES. Activation of NRF2 is known to induce expression of numerous antioxidant enzymes to mitigate aberrant ROS production. The goal of our work is to explore the role of NRF2 modulation in mitigating risk of toxicity and adverse effects to CPF/OP agents and the therapeutic potential to target this pathway to mitigate CPF/OP toxicity. **Methods:** qPCR, Esterase Activity Assays, CellROX imaging, MTT assays **Results:** Preliminary work found that pretreatment of PC12 cells with potent activators of NRF2 provides protection against acute CPF/CPO treatment at sub-micromolar concentrations. In addition, we have shown that NRF2 activators induce the expression of both CES and PON1 in HepG2 cells (liver). We found that NRF2 activation increases esterase activity in HepG2 cells. Protection against the organophosphates CPF and Paraoxon in HepG2 cells was also observed. **Conclusions:** These data indicate the potential for NRF2 as a target to mitigate short- and long-term OP/CPF toxicity, and that through activation of liver NRF2, soluble serum esterases could provide systemic protection against OP poisoning.

PS 4093 Reconsidering the use of repeat dose dermal toxicity study for agrochemical risk assessment

A. Elizalde Velazquez, A. Goetz, A. Karmaus, C. Schlosser, B. Jackson, and J. Yan. Syngenta Crop Protection, LLC, Greensboro, NC.

Background and Purpose: As part of standard toxicology packages for regulatory submissions of agrochemicals in North America, repeat dose dermal toxicity (RDDT) studies (28/21-day exposure) are required to assess dermal exposure. However,

often RDDT studies are not ultimately used as points of departure (PODs) for final risk assessments. To evaluate RDDT utility, we conducted a retrospective analysis of publicly available Human Health Risk Assessment (HHRA) documents from United States Environmental Protection Agency (US EPA) and Health Canada Pest Management Regulatory Agency (PMRA) for multiple agrochemical active ingredients registered in North America. **Methods:** In this study, 52 HHRA documents from the US EPA and 41 publicly available pesticide registration documents from PMRA were evaluated. Critical information was manually extracted in standardized format to generate a robust dataset. For each active ingredient molecule, we collected pesticidal class, dermal POD and derivation study, and dermal absorption factor (DAF). To represent risk assessment without RDDT, surrogate dermal PODs were selected and dermal equivalent doses (DEDs) calculated by dividing surrogate POD by DAF. DEDs were compared against the limit dose; when DEDs were at or near the limit dose, no dermal risk was concluded, aligning with US EPA practice. **Results:** Our analysis indicates that US EPA often cites RDDT studies 30/52 (58%) for dermal risk assessment. However, only 6/30 were used to set dermal PODs and which were based on systemic effects. For the remaining 24/30 the conclusion was no dermal risk (as NOAEL at or above the limit dose). For these 30 molecules, 22/30, had DEDs at or above the limit dose. Oral studies were used to conduct dermal risk assessments on 22/52 (42%) molecules. In 19/22 this was due to developmental, reproductive, or functional effects not assessed in dermal studies. Overall, the US EPA could have completed the dermal risk assessment for 41/52 (79%) molecules without a RDDT study. In contrast, PMRA relies more often on oral studies to set dermal POD: 27/41 (66%). The majority (23/27) fell outside the scope of RDDT experimental design due to endpoints associated with susceptibility of the young or developmental effects. For the remaining molecules 14/41 (34%) RDDT studies were cited for dermal risk assessment: 8/14 the dermal PODs were based on systemic effects; 3/14 no dermal risk concluded; 3/14 the dermal POD was set at the limit dose. For those 14 molecules using RDDT studies, 8/14, had DEDs at or above the limit dose. Overall, PMRA dermal risk assessment for 31/41 (78%) molecules could have been conducted without a RDDT study **Conclusions:** Regardless of region in North America, RDDT studies were generally not useful for risk assessment in >78% of cases and could have been waived. Primary waiver rationales include: (1) RDDT studies did not assess critical toxic effects observed in oral studies (young susceptibility, developmental effects, neurotoxicity), or (2) calculated DED at or near the limit dose. Based on these results, we developed a decision tree to guide RDDT necessity for risk assessment that could align with both PMRA and US EPA processes. This work demonstrates limited RDDT utility and suggests a practical decision tree could refine North American dermal toxicity testing and risk assessment.

PS 4094 90-day dog study for crop protection active substance toxicity testing program

T. Syeda, D. Anderson, J. Henriquez, K. Stebbins, and M. DeLorme. Corteva Agriscience, Indianapolis, IN.

Background and Purpose: Crop protection active substances are among the most extensively evaluated chemical substances for toxicological effects. For a new crop protection active substance registration, repeated dose oral toxicity studies in both rodent and non-rodent species are required as part of a standard battery of tests to support human health risk assessment in many geographies. Dogs historically have been recommended as the non-rodent species and have been widely accepted by global regulatory agencies. The 90-day guideline study for non-rodent species (i.e., OECD No. 409) requires a minimum of 32 dogs with additional dogs needed for range finding (phase I) and 28 day studies (phase II). The phase I and II studies provide data for dose-setting and target organ identification for a subsequent 90-day study (phase III). Thus, a typical new crop protection active substance requires approximately 48-58 dogs for the completion of the testing program. There are concerted directives from regulatory agencies and efforts from the agrochemical sector to reduce, replace, or refine vertebrate animal testing for animal welfare. To reduce the number of dogs used in a toxicity testing program and meet the data requirements for a crop protection active substance, we use scientifically driven approaches such as: 1) Using the same animals for both a preliminary dose range-finding (Phase I), followed by a wash out period, and the 28 day repeat dosing (Phase II) study; 2) Using the minimum number of dogs/sex/group and not using a control group in the Phase I and Phase II studies; and 3) when the toxicity profile is favorable, using the limit dose approach with testing only at 1000 mg/kg in the Phase III 90-day study. **Methods:** In our approach, a crop protection active substance was used to evaluate toxicity and determine the toxicokinetics when administered orally via capsules to Beagles once daily for 90 days with preliminary dose range finding (Phase I) and repeat dosing (Phase II) studies conducted prior to the 90-day study. During the Phase I study, two dogs/sex were dosed at 250 mg/kg (Group 1) on Days 1 through 3. A second group of two dogs/sex were dosed with 500 mg/kg on Days 8 through 10. Following a wash out period of 12 days, Group 1 dogs were dosed again on Days 15 through 17 with 750 mg/kg and Group 2 dogs dosed with 1000 mg/kg on Days 22 through 24. Dose levels for Phase I were adjusted depending on study findings following the previous dose. A washout period of at least 2 weeks occurred between the completion of Phase I and the start of the subsequent Phase II 28-day repeat dose study. During Phase II doses of 500 mg/kg (Group 1, n=2 dogs/sex) and 1000 mg/kg (Group 2, n=2 dogs/sex) were administered by oral capsule daily for 28 consecutive days, excluding the day of necropsy. All animals survived to their scheduled necropsy. No adverse test-article related changes were noted in clinical observations, body weight,

food consumption, clinical pathology, gross necropsy evaluation, or microscopic histopathology observations. Based on these results, the no observed adverse effect level of crop protection active substance administered via capsule was 1000 mg/kg/day in male and female Beagle dogs. Based upon the findings in Phase I and II studies, the Phase III 90-day study utilized only the limit dose level of 1000 mg/kg and a control group, thus further reducing the number of animals used with four dogs/sex/group. In this study, all animals survived to their scheduled necropsy and no test article related changes in clinical observations, body weight, or food consumption were noted. **Results:** This strategy only required the use of 8 dogs for the Phase I dose range finding and Phase II 28-day studies and a total of 16 dogs for phase III. **Conclusions:** Thus, for a crop protection active substance testing program, a total of 24 dogs were used for the entire canine testing program which represents a 50% - 60% reduction in animal use. A favorable toxicological profile, and the lack of sensitivity across species made this approach for the crop protection active substance testing program possible. This approach may not be viable when canines show a higher level of sensitivity; however, even in cases where the limit dose approach cannot be used for the 90-day study, the number of dogs used for a crop protection active substance testing program can be reduced to 40 animals from the normally used 48 - 58. Overall, using this strategy has established a theoretical minimum requirement to help drive our animal reduction goals.

PS 4095 Utilizing Toxicogenomics to Identify a Mechanistic Hypothesis for Species Differences in Toxicity Studies

A. H. Hofstra¹, D. E. Cowie², R. A. Currie², A. Kende², M. Yin², and C. C. Lord³.
¹Syngenta Canada Inc, Guelph, ON, Canada; ²Syngenta, Bracknell, United Kingdom; and ³Syngenta Crop Protection LLC, Greensboro, NC.

Background and Purpose: Hyperlipidemia (significant increases in total plasma cholesterol, high- and low-density lipoprotein cholesterol, and triglycerides) was observed in dogs but not in rodents following repeat dose administration of a novel agrochemical. No evidence of liver toxicity or steatosis was observed in any species. The species differences in hyperlipidemia and potential relevance to human safety were investigated using toxicogenomics to identify a verifiable mechanistic hypothesis. **Methods:** Transcriptomic analysis of dog liver and metabolomic analysis of dog liver and plasma clearly identified liver X receptor (LXR) activation as the mechanistic hypothesis for the hyperlipidemia observed in dogs. This hypothesis was then tested by assessing direct agonist activity of the novel agrochemical in human, dog and rat LXRA and LXRB transactivation assays. Further context was provided by comparing plasma concentrations of the novel agrochemical across species. **Results:** Toxicogenomic assessments reflected the increase in plasma cholesterol and triglycerides. Transcriptomic assessment of dog liver identified significant up-regulation of LXR target genes, including sterol regulatory element binding transcription factor 1 (SREBF1), stearyl-CoA desaturase (SCD), ATP binding cassette subfamily G member 1 (ABCG1) and inducible degrader of the LDL receptor (IDOL or MYLIP). Metabolomic assessment of liver and plasma also supported an LXR activation hypothesis. The novel agrochemical displayed dose-dependent direct agonist activity in LXR assays from human, dog, and rat, with similar potency in all species. However, plasma concentrations sufficient to reach the EC50 were only noted in dogs, which had ten-fold higher plasma concentrations than rats at similar externally administered doses of the novel agrochemical. **Conclusions:** Toxicogenomics successfully identified a verifiable mechanistic hypothesis for the hyperlipidemia observed in dogs, enabling an assessment of the relevance for human safety. The hypothesis of direct LXR activation was tested and supported using *in vitro* transactivation assays in rat, dog and human LXR. The species differences in hyperlipidemia effects were attributable to a large difference in systemic exposure demonstrated using traditional pharmacokinetic assessments and pharmacokinetic modelling. This approach confirmed that LXR activation resulted in hyperlipidemia in dogs and established lack of human safety relevance, as predicted human exposure falls well below concentrations required for LXR activation.

PS 4096 Quantifying Military and Non-Military Pesticide Exposure is US Veterans Using a Cumulative Exposure Index (CEI)

A. Doepker¹, N. Rattray², E. Zaubner³, J. Cannon¹, and E. Wells¹. ¹Purdue University, West Lafayette, IN; ²Richard L. Roudebush Veterans' Administration, Indianapolis, IN; and ³Indiana University School of Medicine, Indianapolis, IN.

Background and Purpose: There is a lack of literature addressing various exposures faced by those who have served in the armed forces. We created a cumulative exposure index (CEI) to quantify military and non-military exposure to pesticides in United States veterans with Parkinson's disease (PD). **Methods:** Participants were recruited nationally and mailed a questionnaire that detailed exposure, residentially, and employment history. The participants were also asked to provide a saliva sample to check for genetic polymorphisms. The CEI was generated by incorporating questions that measured exposure, and answers to all exposure questions were given a rank (low/medium/high exposure). These ranks were multiplied by exposure, frequency, and duration. All ranks were added together, resulting in the total potential exposure. An industrial hygienist with military background reviewed the construction of the CEI. Two additional CEIs were created to estimate potential military exposure

and potential non-military exposure. **Results:** The data was abnormally distributed, with one major outlier in non-military exposure and one major outlier in the military exposure category. The military CEI had a shorter duration of exposure but higher intensity, while the non-military CEI had a longer duration with a lower intensity. Of the 155 veterans surveyed for this study, N=14 (9%) reported applying pesticides as a part of their military service, N=95 (61%) reported applying skin creams to repel pests while in the military, and N=54 (34%) reported personally mixing or applying pesticides. A significant negative correlation was identified between age and military-related pesticide exposure reported (Spearman's ρ : -0.22, $p=0.02$), but no other significant correlations were found. **Conclusions:** Our next steps are to evaluate potential gene-environment interactions using the participant saliva samples and create CEIs for specific groups of pesticides. The overarching goal of this research is to utilize the CEI created to evaluate military exposure to pesticides and the relationship to PD in cases versus controls.

PS 4097 Rabbit Developmental Toxicity Studies: Are They Needed for Agrochemical Pesticides?

E. L. House¹, J. Henriquez², and E. Shipp³. ¹Corteva Agriscience, Newark, DE; ²Corteva Agriscience, Indianapolis, IN; and ³Ramboll, London, United Kingdom.

Background and Purpose: Agrochemical pesticide active substances (A.S.) are heavily regulated and subject to rigorous testing guidelines to gain approval for commercial use. To identify potential hazards relevant to human health risk assessment, toxicity evaluations are conducted in rodent and non-rodent species. Meeting the stringent data requirements to develop global data packages for agrochemical pesticides necessitates a high animal burden. One such data requirement is the evaluation of developmental toxicity end points in two species: the rodent and the rabbit. Guidelines requiring the rabbit for developmental toxicity studies were developed following the post-market identification of fetal abnormalities associated with maternal use of thalidomide. More recently, the research community has taken part in an effort to reduce, refine, and replace animals in testing. Due to this initiative, recent work has focused on evaluating the utility of rabbit-based endpoints in risk assessment and exploring the use of *in silico* models to potentially reduce *in vivo* requirements in the future. The goal of this work aimed to determine the frequency of risk assessment endpoint derivation from rabbit studies, and whether developmental toxicity can be predicted by commercial software packages. **Methods:** The EU Pesticides database was filtered for registered substances which are commercialized, industrially synthesized, and currently registered in Europe. Classification for each substance was confirmed using the ECHA Classification and Labelling Inventory, considering only classification for developmental toxicity. Endpoints for risk assessment for each substance were obtained from the most recent review report or EFSA conclusion. SMILES codes were utilized for *in silico* modeling to predict developmental toxicology or teratogenicity. Risk assessment endpoints, classification status, and *in silico* predictions were then compared to evaluate how frequently the rabbit is relied upon for developmental toxicity classification, as well as to evaluate the reliability of *in silico* predictions from readily available modeling systems. **Results:** Of the 194 active substances evaluated, 63 have at least one risk assessment endpoint based on the rabbit developmental toxicity study. However, nearly all these 63 were driven by maternal, rather than fetal, endpoints. 27 of the AS are classified for developmental toxicity. 14 of the 27 classifications were based, at least in part, on rabbit developmental toxicity endpoints. Of the 63 AS with rabbit-based risk assessment endpoints, only 9 are classified by ECHA-RAC. Available *in silico* modeling systems provided inconsistent results. Derek Nexus predicted only 8 substances for potential developmental toxicity, none of which are classified for developmental toxicity based on available *in vivo* data. VEGA/CESAR predicted 127 developmentally toxic AS, while only 10 of those were classified based on the rabbit. And finally, 59 substances triggered alerts in the OECD QSAR toolbox, with only 6 classified on the basis of the rabbit study. **Conclusions:** Frequently, the use of rabbit derived endpoints to drive risk assessment reflects maternal, rather than fetal, toxicity of the test item. Further, as the rabbit is often the lowest overall NOAEL, it is commonly used as the default endpoint for risk assessment, which may cause over reliance on the species in testing. However, of the 14 AS with both developmental toxicity classification and risk assessment endpoints in the rabbit, 5 had a lower fetal NOAEL in the rabbit than in the rat and showed fetal observations in the rabbit that were absent in the rat, suggesting the use of the rabbit is not redundant in all cases. In addition, *in silico* predictive models did not prove to be sufficiently powerful to substitute rabbit developmental toxicity studies in pesticide AS development. Thus, A tiered approach to *in vivo* testing, and further refinement of available *in silico* models are necessary to reduce animal use in testing, while ensuring the safety of new pesticidal AS.

PS 4098 Application of short-term transcriptomic point of departure to inform human health risk assessments in replacement of chronic studies: A case study with a novel insecticide

J. LaRocca, K. Johnston, P. Deford, and C. Beevers. Corteva Agriscience, Indianapolis, IN.

Background and Purpose: Studies required for new plant protection product registration are resource intensive and take many years to develop due to extensive safety testing requirements. For human health, this typically involves a comprehensive testing program largely focused on rodent testing, ranging from acute to chronic exposures, which require thousands of animals. Fulfilling the 3R (Refinement, Reduction, and Replacement) principles and supporting animal welfare regulation (e.g., Directive 2010/63/EU), new approach methodologies (NAMs) such as toxicogenomics are critical tools for future refinement of new product testing programs. Prior evidence suggests that short term toxicogenomic points of departure (tPODs) can closely approximate chronic traditional apical points of departure (PODs). **Methods:** A toxicology testing program for a novel insecticide active ingredient, (N-4-chloro-2-(pyridin-3-yl)thiazol-5-yl)-N-ethyl-3-(methanesulfonyl)propanamide, was leveraged to compare chronic PODs with short-term tPODs. CD-1 mice were exposed via the diet to three dose levels of insecticide and control for 28 days (liver tPOD and apical endpoints collected), 90 days (liver tPOD and apical endpoints collected), and 18 months (apical endpoints collected). Wistar rats were exposed via the diet to three dose levels of insecticide and control for 28 days, 90 days, and one year, and both liver tPODs and standard apical endpoint data were collected. To compare apical PODs with a short-term tPOD, a customized 7-day study was performed in male and female Wistar rats. Male rats were exposed to insecticide at doses of 0, 44, 221, and 525 mg/kg/day (n=5/group) and female rats were exposed at doses of 0, 49, 240, and 563 mg/kg/day (n=5/group) for seven days and whole genome sequencing was performed on liver to generate a tPOD via benchmark dose analysis. **Results:** The liver was the main target organ identified in all repeat dose studies in both mice and rats, and no treatment-related liver tumors were identified in any study. The tPODs in mice were similar across sexes and timepoints (39 and 44 mg/kg/day tPOD in males and females, respectively, in 28-day study, 56 and 25 mg/kg/day tPOD in males and females, respectively in 90-day study). The apical PODs from the mouse cancer bioassay NOAEL were 88 mg/kg/day for male mice and 315 mg/kg/day for female mice, indicating that short-term tPODs were more conservative compared to traditional chronic apical PODs. The tPODs in rats were also similar across sexes and timepoints (116 and 120 mg/kg/day tPOD in males and females, respectively in 28-day study, 160 and 220 mg/kg/day tPOD in males and females, respectively in 90-day study, and 212 and 235 mg/kg/day tPOD in males and females, respectively in the one-year chronic study). The 28-day rat no observed adverse effect levels (NOAELs) were 232 and 423 mg/kg/day in male and female rats, respectively. The 90-day rat NOAELs were 40 and 226 mg/kg/day in male and female rats, respectively, indicating close approximation to the tPODs. For the 7-day transcriptomic study in rats, BMD-derived tPODs from liver samples were determined to be 150 mg/kg/day for males and 178 mg/kg/day for females. **Conclusions:** Following exposure to the active ingredient (N-4-chloro-2-(pyridin-3-yl)thiazol-5-yl)-N-ethyl-3-(methanesulfonyl)propanamide, both rat and mouse short-term tPODs were either more conservative or closely approximated long-term PODs. This adds to the weight of evidence that short-term tPODs, potentially combined with uncertainty factors to apply for short-term to long-term exposure periods, can be a conservative method to inform risk assessments without the need for additional animal testing while still protecting human health.

PS 4099 Probabilistic Dietary Exposure Analysis of Imidacloprid Residues in Food and Drinking Water: Use of Federal and State Pesticide Residue Monitoring Data for Refining Exposure

S. Tiscione, P. Dodmane, A. Kalashnikova, S. Koshlukova, and S. DuTeaux. California Environmental Protection Agency, Sacramento, CA.

Background and Purpose: Imidacloprid is a neonicotinoid insecticide that acts by blocking the nicotinic acetylcholine receptors in the insect nervous system. In mammals, signs of toxicity include incoordination, tremors, decreased activity, reduced body temperature, and at sufficiently high doses, death. Imidacloprid is widely used on a variety of crops and the U.S. Environmental Protection Agency (US EPA) has established tolerances (maximum allowable residues) on more than 100 commodities or commodity groups for the combined residues of the parent imidacloprid and its metabolites containing the 6-chloropyridinyl moiety. However, established tolerances do not consider a comprehensive dietary exposure from consumption of all these commodities. In this evaluation, dietary exposure to imidacloprid residues in food and drinking water from legal uses was calculated for multiple populations, including sensitive subpopulations. Accurate exposure estimation is essential for realistic risk assessment and protection of public health; therefore, DPR conducted a highly refined probabilistic approach to calculate acute dietary exposure to imidacloprid. **Methods:** DPR's dietary exposure guidance and the U.S. EPA's DEEM (Dietary Exposure Evaluation Model) software were used to estimate exposure from residues on all commodities with established tolerances and drinking water for imidacloprid for the US population and sensitive subpopulations including infants, children aged 1-2, and women of childbearing age (13-49 years old). The food consumption data were from 2005-2010 National Health and Nutrition Examination

Survey. Residue inputs included either tolerance values or measured residues of imidacloprid and its degradates and metabolites (desnitro-imidacloprid, imidacloprid urea and olefinic imidacloprid) from federal and state monitoring programs (USDA's Pesticide Data Program, DPR, or FDA). DPR's tiered approach includes a) Tier 1: Deterministic assessment, using tolerance values for all commodities; b) Tier 2: Deterministic assessment, using the highest detected residue values from monitoring data; and c) Tier 3: Probabilistic assessment, using residue distributions from monitoring data adjusted for the percent of the crop treated, combined with food consumption distributions via Monte Carlo simulation to generate exposure distributions. **Results:** A total of 478 food forms were analyzed. Of these, 210 were assigned residue distributions from monitoring databases, while the remaining 268 were assigned point estimates: either tolerance values, maximum measured residues on the food or on an appropriate surrogate, or one-half the limit of detection, as appropriate. Residues were further refined using percent crop treated and hydration/processing factors. Monte Carlo simulations were used to generate exposure distributions, and the 99.9th percentile of exposure was calculated for multiple subpopulations. Estimated acute dietary exposure to imidacloprid ranged from 2.52 to 7.22 µg/kg/day across all subpopulations. The non-Hispanic-other population group had the highest calculated exposure. Major contributors to infant and child exposure included corn (field) syrup in baby food, drinking water, grapes, cassava in baby food, apple juice, and bananas. For women of childbearing age, Hispanic, and non-Hispanic-other subpopulations, key contributors included hops, corn (field) syrup, artichokes, Belgian endive, grape wine, and sherry. **Conclusions:** DPR conducted a highly refined Tier 3 acute probabilistic dietary exposure analysis using the extensive imidacloprid residue data from national and state food and drinking water monitoring programs. Compared to deterministic methods where the tolerance or highest measured residue is assumed, it provides more realistic exposure and health risks estimates, while remaining highly health protective. The refined exposure estimates support more accurate risk assessments for diverse subpopulations.

PS 4100 Predictive Power of the GHS Mixtures Equation for Determining the Acute Oral Toxicity (LD50) of Spray Adjuvants

N. Bhowmik, P. Le, X. Cheng, V. Singh, N. Verma, and S. DuTeaux. California Department of Pesticide Regulation, Sacramento, CA.

Background and Purpose: Spray adjuvants are products used in conjunction with pesticides to enhance their application or effectiveness. While exempt from federal pesticide registration by the US Environmental Protection Agency (US EPA), California law requires their registration as pesticides before sale or use. An evaluation was conducted to assess the suitability and acceptability of the United Nations Globally Harmonized System (GHS) Mixtures Equation for predicting the acute oral toxicity of spray adjuvants. The objective was to determine whether the GHS Mixtures Equation could serve as an acceptable alternative to *in vivo* animal testing, thereby supporting efforts to reduce animal use in the registration of spray adjuvants. **Methods:** The GHS Mixtures Equation estimates the acute oral toxicity (LD50) of a mixture by mathematically integrating the LD50 values of its individual components. In this study, the GHS Mixtures Equation was applied to all spray adjuvant mixtures registered in California (n=51). The LD50 values of all the individual components in these mixtures were sourced and validated in two phases using multiple publicly available toxicological databases. After calculating the estimated LD50 value for each mixture using the GHS Mixtures Equation, the resulting acute oral toxicity categories were directly compared against those obtained from *in vivo* acute toxicity studies for the same spray adjuvant formulation. **Results:** In Phase I, acute oral LD50 values were identified for only 175 of 237 relevant ingredients using the Integrated Chemical Environment (ICE) database. This limitation allowed the GHS Mixtures Equation to be applied to only 67% of the dataset (n=34 mixtures). To improve data completeness, the search was expanded in Phase II to include additional public databases (e.g., CompTox, ECHA) and peer-reviewed literature. This broader search yielded LD50 values for 35 of the 62 previously unassessed chemicals, increasing the equation's predictive power to 96% of the dataset (n=49 mixtures). When the GHS Mixtures Equation-derived toxicity categories were compared to those assigned using the US EPA classification system, 82% concordance was observed. Discrepancies included 6% of mixtures being over-classified and 12% under-classified by one toxicity category. In comparison with the US Occupational Safety and Health Administration's GHS (OSHA GHS) classification system, the equation achieved 88% concordance, with 12% of mixtures over-classified by one toxicity category and no instances of under-classification (n=49). **Conclusions:** Although the study's small sample size was a notable limitation, the findings indicate that the GHS Mixtures Equation may serve as a viable alternative to animal testing for predicting the acute oral toxicity of low-toxicity spray adjuvant formulations (i.e., those with LD50 values > 2000 mg/kg body weight), provided that LD50 values for the individual components in the mixture are available from vetted and validated sources.

A. B. Riaño, T. Workman, W. C. Griffith, J. Marsillach, and E. M. Faustman. University of Washington, Seattle, WA.

Background and Purpose: Studies from the University of Washington - Center for Child Environmental Health Risks Research (CHC) on the agricultural children's cohort, located in the lower Yakima Valley in Washington State, have analyzed levels of pesticides in biological and environmental samples of both farmworkers and non-farmworkers. An agricultural exposome was characterized by determining levels of over 47 pesticides in house dust. These pesticides were examined as potential neurodevelopmental toxicants based on EPA Registration Eligibility Decisions (REDs). Organophosphate exposures were significantly increased in farmworker versus non-farmworker households, and these increases were dependent upon season and agricultural activities. Biomarkers of response were also evaluated in these CHC studies, including miRNA urinary profiles, and we observed an upregulation of 6 miRNAs miR-223, -518d-3p, -597, -517b, -133b, and -28-5p associated with organophosphate exposure patterns. Current literature suggests miRNAs are of importance for pyrethroid impacts and may correlate with neurotoxicity potential. Pyrethroid (PT) levels in dust were stratified by occupational group, year and agricultural season. PTs are of interest in our cohort as EPA recommended their use as substitutes for OPs as their uses are phased out. **Methods:** Analysis compared total pyrethroid levels per sample in 2005 to samples taken in 2011, to determine differences between farmworkers and non-farmworkers as well as variances across seasons. This variability was analyzed using a Bayesian mixed effects model and brms package in R studio. Pyrethroids identified as developmental neurotoxicant potency were characterized using EPA REDs documents and included cyphenothrin, deltamethrin, etofenprox, imiprothrin, permethrin and s-bio allethrin. Preliminary analysis of pyrethroid levels in house dust showed higher levels in farmworker households than non-farmworker households in both years. **Results:** Total pyrethroid levels are the lowest in the non-spray season for both years as well, which is associated with agricultural activities and regulatory changes. Although the levels of pyrethroids in non-farmworker house dust are lower overall, the pyrethroid levels increased during the thinning and harvest seasons in both years, showing pesticide use correlated with exposure of non-pome fruit workers. **Conclusions:** The new PT results allow us to relate miRNAs with both OP and PT exposure. Further analysis will be done to test our hypothesis that miRNAs are of interest in this cohort by using KEGG pathway annotations to see if these relate with pesticide neurodevelopmental toxicity potential.

PS 4102 Weight of Evidence (WoE) Approach Based Assessment of Skin Irritation from Antimicrobial Cleaning Products Using the Phenion Full-Thickness Human Skin Model

N. Bhowmik, N. Verma, and S. Deteaux. California Environmental Protection Agency, Sacramento, CA.

Background and Purpose: Skin irritation, i.e., reversible damage to the skin, is one of the key endpoints assessed in the acute toxicity tests required as a part of pesticide registration, informally known as the acute "six-pack." This testing battery is used globally by regulatory bodies to determine hazards of pesticide formulations. Until the recent advancement of *in vitro* alternatives to animal testing, governmental agencies had relied on *in vivo* tests using rabbits to assess potential skin irritation hazards. In the present study, DPR has independently compared a novel model called Phenion® Full-Thickness (FT) Skin model for its utility and predictability, compared to other *in vitro* methods and previously DPR-reviewed *in vivo* data, in determining skin irritation potential of antimicrobial cleaning products (ACPs). This model is comprised of a fully stratified epidermis that includes a multilayered stratum corneum and dermis and is considered more physiologically accurate. The aim of the present study is an independent evaluation to determine the skin irritation hazard of an ACP using a Weight-of-Evidence (WoE) approach which incorporates results from an *in vitro* skin irritation study using the Phenion® (FT) test system along with results from a historical *in vivo* test to determine skin irritation potential. **Methods:** As part of the WoE approach, an *in vitro* skin irritation study was conducted on an ACP formulation (ACP 1) using the Phenion™ FT human tissue model. The study protocol is based on a modified *in vitro* human keratinocyte model of the OECD Test Guideline 439. A volume of 60 µL each of the undiluted test substance was topically applied directly to the Phenion skin tissue for an exposure duration of 15 ± 1 minutes at room temperature. Following this, the tissue was incubated for 42 ± 1 hours at 32°C. Cytotoxicity (irritancy) was measured using a 3-(4,5-Dimethylthiazol-2-yl)-2,5-diphenyltetrazolium bromide (MTT) assay. For this modified OECD method, a tissue viability greater than 70% (mean of three tissue replicates) was selected as the cut-off threshold for discriminating non-irritants (US EPA Toxicity Category IV). Conversely, a tissue viability of 70% or less will result in classification of the chemical as an irritant necessitating further analysis to determine if it falls under US EPA Toxicity Category I, II or III. Results from a previously conducted *in vivo* rabbit test on a substantially similar ACP (ACP 2) were included in the WoE approach. The *in vivo* test was performed according to the standard guidelines on six New Zealand White rabbits, with 0.5 mL test substance applied to each site for a single, 4-hour dermal exposure. The results from both studies were used by DPR as a WoE approach to determine skin irritation hazard. **Results:** In the Phenion assay, the relative mean

tissue viability obtained after exposure to ACP 1 compared to the negative control tissues was 72%. Since the mean relative tissue viability for the test material was above 70% after a treatment duration of 15 ± 0.5 minutes, the test material is classified as a non-irritant (US EPA Toxicity Category IV). In the rabbit *in vivo* test, grade 2 erythema was observed in all 6 animals one hour after unwrapping, while at 24 hours, grade 1 erythema was noted for one animal and grade 2 for 5 animals. At 72 hours, grade 1 erythema was observed in all 6 animals, and on days 4 and 5, it was seen in 5 out of 6 animals, which persisted in 2 out of 6 animals up to days 6 and 7. The Draize rabbit *in vivo* skin irritation test resulted in a combined PDI score of 1.4, and ACP 2 was assigned US EPA Toxicity Category IV for primary dermal irritation hazards. **Conclusions:** DPR's analysis of results from the Phenion FT *in vitro* and historical *in vivo* studies, used in the proposed WoE approach, showed concordance in detecting non-irritancy or US EPA Category IV hazard classification. The use of the Phenion model could widen the applicability domain of other *in vitro* tests in determining skin irritation hazard. Overall, this WoE approach provides greater confidence in determining non-irritancy (US EPA Toxicity Category IV). Moreover, results support that additional *in vivo* data are not required to determine skin irritation potential of ACPs identified as US EPA Toxicity Category IV, thus supporting the reduction in use of animals in toxicity testing.

PS 4103 Sex-Specific Disruption of Gut Microbial Communities Link with Altered Liver Gene Expression in Acute Exposure to Azoxystrobin

L. Duan, and C. A. Gaulke. UIUC, Urbana, IL. Sponsor: J. Flaws

Background and Purpose: Azoxystrobin (AZO) is a widely used fungicide linked to reproductive, neurological, and developmental defects. While this chemical disrupts gut microbial communities, it remains unclear if these microbial perturbations contribute to the host harms associated with AZO exposure. Our objective was to investigate the effects of acute exposure to environmentally relevant concentrations (5-500 mg/kg) of AZO on the host and gut microbiota in zebrafish. **Methods:** Adult zebrafish (N=60) were fed AZO-contaminated food (0, 5, 50, 500 mg/kg) for 14 days. Fecal samples (Days 0, 7, 14) were profiled using 16S rRNA and shotgun metagenomic sequencing. Livers (Day 14) were analyzed via RNA-seq and H&E staining. Microbial data were processed using DADA2 (16S) and HUMAnN3 (metagenomics). Host (DESeq2) and microbial (PERMANOVA, GLMMs) data were then statistically analyzed to identify significant alterations and associations. **Results:** AZO exposure resulted in significant alterations in microbiome composition (PERMANOVA, $R^2 = 0.333$, $P = 2 \times 10^{-4}$) and functional potential in a dose- and sex-dependent manner. Microbial communities of exposed animals showed increased pathways associated with xenobiotic metabolism (e.g., atrazine degradation, $P = 1.18 \times 10^{-2}$) and decreased pathways for bacterial motility (e.g., flagellar assembly, $P = 4.20 \times 10^{-2}$) and lipopolysaccharide biosynthesis ($P = 2.14 \times 10^{-2}$). Liver injury and transcriptional reprogramming were also noted, with 143 DEGs identified ($FDR < 0.1$). These were characterized by increased expression of genes involved in oxidative stress (e.g., xdh, mt2) and enrichment of downregulated genes in pathways like lipid metabolic process (GO, $FDR = 8.09 \times 10^{-5}$), also in a sex-specific manner. Importantly, changes in host gene expression were linked with alterations in the abundance of specific microbial taxa (2,431 unique associations), such as *Pseudomonas* abundance positively correlating with xdh and mt2 expression ($FDR < 0.15$). **Conclusions:** Our findings demonstrate that acute AZO exposure is associated with both gut microbial disruption and altered hepatic gene expression related to oxidative stress and lipid metabolism. These results identify the microbiome as a key target of AZO toxicity. The strong, sex-specific associations between microbial taxa and host gene expression suggest a potential gut-liver interplay that warrants mechanistic evaluation. Our ongoing work aims to evaluate the mechanisms that underpin these associations.

PS 4104 Assessing Impacts of Aldicarb Exposure on Gut Microbial Communities

J. Wanyama, and C. A. Gaulke. University of Illinois at Urbana-Champaign, Urbana, IL. Sponsor: J. Flaws

Background and Purpose: Aldicarb is a highly toxic restricted use pesticide with neurotoxic effects and links to cancer. While the impacts of aldicarb on the brain, liver, and other organs have been well described, the effects of exposure on host associated microbial communities is poorly understood. Gut microbial communities are both sensitive to xenobiotic exposures and highly capable of transforming these compounds and their impacts on the host. Here we aimed to define the impacts of aldicarb on gut microbial communities, isolate microbes that exhibited differential sensitivity and resistance to exposure, and to identify potential mechanisms that underpin these differences. **Methods:** To evaluate the acute impacts of aldicarb on gut microbial communities we exposed 60 adult tropical 5D zebrafish to one of three diets containing aldicarb (0.5, 5, and 50µg/kg) or a control diet with no aldicarb. Fecal samples were collected from individually housed animals at day 0, 7, and 14 of exposure. The V4 region of the 16S rRNA gene was amplified from fecal DNA using barcoded 515F and 806R universal primers and amplicon libraries sequenced on an Illumina MiSeq instrument. Shifts in microbial diversity and composition were quantified with DADA2 and custom R scripts. Potential mechanisms of resistance of differentially abundant taxa were identified by searching protein sequences of aldicarb-de-

grading genes encoded by environmental microbes against a zebrafish microbial protein catalog using DIAMOND. Resistance profiles of these taxa were further characterized by analyzing isolate growth kinetics in mineral salts media contain increasing concentrations of aldicarb (0.01-1.0mg/ml). **Results:** Acute exposure was associated with moderate disruption of the gut microbiome. Interestingly, responses to aldicarb were delayed in males and were only apparent at day 14 (PERMANOVA, $R^2 = 0.23$, $p = 0.005$), while female disruption began at day 7 (PERMANOVA, $R^2 = 0.23$, $p = 0.01$). Exposure was associated with increased abundance of several genera whose members can metabolize aldicarb, including *Arsenibacter*, *Pseudomonas*, *Rhizobium*, *Mycoplana* and *Methyloversatilis*. A homology search of aldicarb degrading genes in a zebrafish gut microbial gene catalog confirmed the presence homologs of these genes in common zebrafish gut microbes. To further evaluate if increasing taxa may utilize aldicarb degradation we isolated dozens of *Pseudomonas*, *Rhizobium* and *Mycoplana* strains from *ex vivo* culture of zebrafish fecal microbial communities in selective aldicarb-containing media. Several of these isolated taxa were capable of minimally disrupted growth even at 1mg/ml concentrations of aldicarb. Of note, *Pseudomonas* isolates varied substantially in their ability to grow in aldicarb suggesting differential sensitivity of this genus to aldicarb exposure. **Conclusions:** Our results suggest that zebrafish gut microbiota are sensitive to acute exposure to aldicarb and taxa that increase during exposure may possess machinery to metabolize aldicarb. Ongoing work seeks to identify the mechanistic underpinnings of resistance to aldicarb in specific taxa. We hope to leverage this knowledge to identify microbes that may encode similar functions in humans and to design resilient microbial communities capable of mitigating aldicarb impacts on the host.

PS 4106 Knockout of TNIP1 Protein in HaCaT Human Keratinocytes Provides a NAM Platform for Gene-Environment Interactions in Psoriasis

M. L. Samulevich¹, L. E. Carman¹, J. Harney², A. K. Kopec², and B. J. Aneskievich¹.
¹University of Connecticut, Department of Pharmaceutical Sciences, Storrs, CT; and
²Pfizer Inc., Investigative Toxicology, Drug Safety Research & Development, Groton, CT.

Background and Purpose: Psoriasis has experienced a 73% increase in global health burden as represented by Disability-Adjusted Life Years (from 1990-2017). While there is a genetic predisposition associated with psoriasis, environmental toxicants are known to trigger the disease in susceptible individuals. Developing new approach methodologies (NAMs) mimicking psoriasis provides advanced, human-relevant methods to study the complex gene-environment interactions involved in the disease. TNF α -induced protein 3 Interacting Protein 1 (TNIP1) acts to repress inflammatory signaling. GWAS and protein deficiencies in affected patient tissues link TNIP1 protein and chronic hyper-inflammatory diseases. While psoriasis is a complex disease state with multiple genetic factors, we hypothesize that TNIP1 deficiency sensitizes keratinocytes to toxicant-induced inflammation. Herein, we developed and characterized a TNIP1-null line of keratinocytes as a NAM for studying psoriasis. **Methods:** A TNIP1-null line of HaCaT spontaneously immortalized human keratinocytes was developed using gene editing with knockout confirmed by Sanger sequencing and western blotting. Bulk RNA-seq identified differentially expressed genes (DEGs) between parental and TNIP1-KO cells. The resulting data was processed with DESeq2 and analyzed via gene correlation plots comparing the TNIP1-KO DEGs to those of clinical psoriatic samples and functional pathway enrichment analysis. For both cell lines, levels of key inflammatory and keratinocyte differentiation protein markers were detected and quantified using a Jess Automated Western Blot system. To analyze late differentiation keratinocyte markers, organotypic keratinocyte models were developed by growing HaCaT cells on a fibroblast-containing collagen raft. Confluent rafts were raised to the air-liquid interface (ALI) to induce differentiation. Tissue structure and stratified differentiation markers were analyzed via histology and immunohistochemistry (IHC). **Results:** Sanger sequencing confirmed an exon 3 frameshift mutation in the TNIP1 gene, which was corroborated by absence of protein in western blotting. RNA-seq of the parental and TNIP1-KO cell lines revealed DEGs positively correlated with tissue from psoriasis patients. Additionally, of the top 20 DEGs by fold change, the majority of genes are highly associated with a psoriatic phenotype (e.g., those encoding inflammation proteins IFIT3 and PI3, structural protein IVL, and ECM remodeling proteins MMP1 and MMP10). Pathway analysis corroborated these findings with most terms directly related to the psoriatic phenotype (e.g., decreased cornified envelope formation and cell-cell adhesion) or the underlying mechanisms (e.g., increased IFN signaling). Western blotting confirmed changes in key psoriatic biomarkers: inflammation-associated proteins (TNFAIP3, KRT6A) and the psoriasis hallmark S100A7/psoriasin were increased, while the structural protein IVL was decreased. Finally, H&E staining of organotypic models showed decreased cell layers and increased collagen protrusion. IHC analysis of basal cell proliferation (Ki67) and suprabasal differentiation (KRT10, IVL) biomarkers showed retention of biomarker compartmentalization by the TNIP1-KO cells. **Conclusions:** The TNIP1-KO HaCaT line recapitulates key features of the psoriatic phenotype at both the transcriptomic and proteomic levels. This is evidenced by the positive correlation with clinical psoriatic DEGs, the upregulation of key inflammatory and psoriasis-associated markers (e.g., S100A7, KRT6A), and the downregulation of structural proteins (e.g., IVL). Furthermore, the 3D organotypic model displayed significant structural alterations. Appropriate protein marker compartmentalization occurred across the KO strata despite a reduction in cell layers suggesting the model represents a psoriatic phenotype of impaired tissue integrity and barrier function, rather than simple

hyperproliferation. This model serves as a promising, human-relevant NAM platform for investigating how environmental toxicants trigger or exacerbate psoriatic inflammation in genetically susceptible individuals.

PS 4107 New Approach Methodologies for Photoallergy: Results of a Set of Reference Photoallergens in the Photo-DPRA, Photo-Keratinosens, and Photo h-CLAT

G. Ritacco¹, A. Hilberer², A. Islas-Robles², K. Bouchard², J. Philips², C. Deodhar¹, D. Botelho¹, and A. Api¹. ¹Research Institute for Fragrance Materials, Mahwah, NJ; and ²Institute for In Vitro Sciences, Gaithersburg, MD.

Background and Purpose: The Research Institute for Fragrance Materials (RIFM) evaluates fragrance ingredients for both photoirritation and photoallergenicity. Photoallergy evaluation that avoids testing in animals is challenging due to a lack of validated *in chemico* or *in vitro* methods. RIFM has focused its photosafety research program on new approach methodologies (NAMs) for photoallergy. The test methods investigated are modifications of existing skin sensitization assays under OECD TG 442C, 442D, and 442E with inclusion of an irradiation exposure. To determine the suitability of these assays, we evaluated a set of reference photoallergens. Herein we describe the results of testing in the photo-direct peptide reactivity assay (photo-DPRA), the photo-Keratinosens assay, and the photo-human cell line activation test (photo h-CLAT). **Methods:** 3,3',4',5-Tetrachlorosalicylanilide, Musk ambrette, 6-Methylcoumarin, Fenticlor, Lomeflaxacin, Sulfanilamide, Chlorpromazine, 4-Methyl-7-ethoxycoumarin, 7-Methoxycoumarin, and Bithionol were chosen based on compelling evidence in the literature to support that classification with a focus on clinical relevance. In the photo-DPRA the percent depletion of a cysteine-containing peptide was evaluated immediately after 5 J/cm² of UVA exposure (herein referred to as irradiation), and then again after 24 hours of exposure to a test material. The peptide depletion was determined by HPLC. The photoreactivity was measured by comparing the peptide depletion in the presence and absence of irradiation. The photo-Keratinosens assay evaluated the potential of a test material to activate antioxidant response element (ARE) dependent genes in keratinocytes, as measured by the induction of luciferase in the KeratinoSens™ cells, a reporter cell line which contains an ARE and a luciferase gene. Photoallergy potential was evaluated by comparing the luciferase induction after exposure to the test material in the presence and absence of irradiation. The photo h-CLAT identifies changes in the expression of cell surface markers CD54 and CD86, which are associated with dendritic cell activation in the human leukemia cell line, THP-1, following exposure to a test substance and irradiation. The cell surface marker expression is measured by flow cytometry following cell staining with fluorescently labelled antibodies for CD54 and CD86, and photoallergy potential was evaluated by comparing the expression of CD54 and CD86 after exposure to the test material in the presence and absence of irradiation. **Results:** Nine materials demonstrated increased depletion of a cysteine containing peptide >13.89% in the presence of irradiation and were considered photoreactive in the photo-DPRA. One material resulted in co-elution and could not be evaluated. In the photo-Keratinosens assay, 3 materials produced a luciferase induction in the presence of irradiation at least 1.5 times greater than the induction in the absence of irradiation at corresponding concentrations, indicating activation of ARE-dependent genes. Six materials failed to induce a fold induction ratio >1.5-fold in the presence of irradiation compared to the absence of irradiation. One reference material, 6-Methylcoumarin, is used as the positive control in the assay; for the purposes of this analysis, the results from this material are not included herein. In the photo h-CLAT, 9 materials were found to have the potential to activate dendritic cells, as indicated by the ratio of relative fluorescence intensity for the irradiated cells compared to non-irradiated cells; 1 material did not. **Conclusions:** Currently, there are no validated NAMs for the assessment of photoallergy. Data from these preliminary studies are promising. In particular, the photo-DPRA and the photo h-CLAT showed a high level of accuracy. Results from the photo-Keratinosens assay were unexpected for many of the reference photoallergens. More studies are needed to evaluate the suitability of these assays to evaluate photoallergy, with reference chemicals that include photoirritants, skin sensitizers, and skin irritants. That work is currently underway.

PS 4108 Use of New Approach Methodology to Assess Inhalation Toxicity Risk from Three Ingredients in Pesticide Products

T. G. Osmitz¹, R. Corley², S. Constant³, G. Arib³, and W. Droege¹. ¹Science Strategies, LLC, Salt Lake City, UT; ²Greek Creek Toxicokinetics Consulting, LLC, Boise, ID; and ³Epithelix Sàrl, Plan-les-Ouates, Switzerland.

Background and Purpose: N-Octyl bicycloheptene dicarboximide (MGK-264) and piperonyl butoxide (PBO) function as synergists when formulated with insecticides such as pyrethrins. Collectively referred to as the Trio actives, these three compounds are commonly used in combination in pesticide product formulations. Although these compounds exhibit low acute toxicity (EPA Category IV), EPA guideline subchronic inhalation studies in rats have reported laryngeal and nasal epithelial hyperplasia and squamous metaplasia at comparatively low exposure levels, prompting regulatory concern. Project Trio was established to develop a next-generation, human tissue-based inhalation risk assessment framework integrating new approach methodologies (NAMs) with quantitative dosimetry to assess the risk of these effects

to humans. The hypothesis is that *in vitro* human airway models combined with target-tissue dose modeling provide a more relevant estimate of human risk than direct extrapolation of rat lowest-observed-adverse-effect-concentrations (LOAECs) from subchronic inhalation studies. **Methods:** Realistic consumer exposure scenarios were evaluated for a water-based aerosol, an ultra-low-volume (ULV) fogger, and a pet care powder. Chamber studies measured time-weighted average airborne concentrations of sentinel compound PBO and particle-size distributions associated with product use. Computational Fluid-Particle Dynamics (CFPD) and Multiple-Path Particle Dosimetry (MPPD) models were used to translate these concentrations into deposited and retained doses (mg/cm²) in both rats and humans. **Results:** Chamber monitoring studies following product use showed transient exposures that declined rapidly post-application. Subsequent concentration-response studies conducted in the human tissue assays identified clear no-observed-adverse-effect-concentrations (NOAECs) and LOAECs for all three actives. For human risk characterization, *in vitro* human tissue NOAECs were used as Points of Departure (PODs) combined with modeled retained human doses to derive Margins of Exposure (MOEs). Across all product types and airway regions (nasal, bronchial and bronchiolar regions), MOEs exceeded regulatory thresholds by large margins, demonstrating negligible respiratory risk. **Conclusions:** The integration of human *in vitro* airway models, realistic exposure data, and quantitative dosimetry provides a scientifically robust NAM-based framework that enhances human relevance, reduces reliance on animal testing, and confirms that the Trio actives do not pose a respiratory hazard or risk when used in the products evaluated.

PS 4109 hTERT/SV40Tag-immortalized human hepatocytes preserves functional and transcriptomic integrity for molecular toxicology applications

S. Bera¹, B. L. Pierce², and D. V. Griendl¹. ¹University of Illinois at Chicago, Chicago, IL; and ²University of Chicago, Chicago, IL. Sponsor: G. Prins

Background and Purpose: Primary human hepatocytes are indispensable for modeling xenobiotic metabolism and hepatotoxic mechanisms, yet their limited proliferative capacity and rapid loss of function in culture restrict long-term molecular investigations. Immortalized non-tumor hepatic lines such as THLE-2 and THLE-3, generated using SV40 large T antigen alone, offer practical alternatives but lack telomerase activation, leading to progressive telomere shortening, phenotypic drift, and limited culture stability. In contrast, tumor-derived lines such as HepG2 and Huh7, while metabolically active, harbor oncogenic mutations and dysregulated signaling pathways that compromise physiological relevance. To overcome these constraints, we developed a defined dual-component immortalization strategy using hTERT and SV40Tag, designed to extend proliferative lifespan while preserving hepatocyte identity, metabolic competence and transcriptomic integrity for mechanistic toxicology research. **Methods:** Primary hepatocytes were transduced with lentiviral vectors expressing hTERT and SV40Tag. Immortalization efficiency and growth kinetics were assessed by IncuCyte live-cell imaging and proliferation curves. Functional assays included albumin and urea secretion, CYP450 expression, and Seahorse-based mitochondrial and glycolytic profiling. RNA-seq was performed to characterize transcriptional reprogramming during immortalization, followed by GSEA, GO, and KEGG enrichment analysis to identify pathway-level changes. Expression of hepatocyte, telomerase, cell-cycle, and senescence-related gene signatures were examined by hierarchical clustering and ssGSEA scoring. **Results:** The immortalized lines exhibited stable, non-tumor morphology and sustained proliferation beyond 30 passages while maintaining albumin and urea synthesis, and demonstrated active CYP450 expression and energy metabolism. Principal component analysis of global transcriptomes distinguished primary, immortalized, and tumor-derived hepatocytes, confirming defined but controlled reprogramming. Immortalization induced cell-cycle and extracellular matrix pathways while preserving hepatic metabolic and xenobiotic gene networks. Signature enrichment confirmed active hTERT and SV40Tag programs with repression of senescence-associated genes. Importantly, ADME/Tox and CYP450-related pathways remained functionally intact and comparable to HepG2 and THLE2. **Conclusions:** This study establishes a scalable, dual-component, and reproducible method for hepatocyte immortalization that maintains molecular integrity and functional metabolism. The resulting hTERT/SV40Tag lines provide physiologically relevant, genomically defined platforms for molecular toxicology and xenobiotic metabolism research, offering a validated alternative to existing hepatic models.

PS 4110 An In Vitro Self-Renewing Human Intestinal Epithelium for Evaluation of Gut Toxicity and Repair

M. Bunger, A. Spreen, L. Boone, and L. Boazak. Altis Biosystems, Durham, NC.

Background and Purpose: Damage to the intestinal epithelium and disruption of crypt-villus homeostasis underlie many forms of gut toxicity, inflammation, and disease. A major challenge in evaluating intestinal safety and recovery *in vitro* is the lack of models that recapitulate the cellular organization, renewal capacity, and repair dynamics of the *in vivo* human gut. We developed a self-renewing two-dimensional intestinal epithelial model that mimics the architecture and function of the crypt compartment, enabling assessment of epithelial injury, regeneration, and long-

term responses to cytokines, chemicals, and drugs. **Methods:** Non-permeable cell culture inserts were engineered with 91 laser-drilled microholes to generate localized gradients of growth factors from the basal compartment through an overlaid hydrogel scaffold. Primary human intestinal stem cells cultured on these inserts formed organized epithelial tissues with spatially distinct proliferative (Edu⁺), secretory (MUC2⁺), and absorptive (ALP⁺) zones that were maintained for at least 14 days. The resulting polarized tissue was pulsed for 24 hours with proinflammatory cytokines to induce damage in the presence or absence of preventative agents and allowed to recover over 7 days. **Results:** Exposure to the cytokine IL-22 increased proliferative Edu⁺ cells, an effect that reversed after a 7-day washout, demonstrating the model's ability to capture epithelial repair. A 24-hour exposure to an inflammatory cytokine cocktail (TNF α , IFN γ , and IL-1 β) induced LDH release and loss of epithelial confluence, reflecting acute barrier disruption. Co-treatment with anti-inflammatory drugs adalimumab or tofacitinib mitigated these effects. Upon cytokine removal and return to normal media, epithelial confluence and lineage allocation recovered over the subsequent 7 days, confirming the model's sensitivity to inflammatory injury, therapeutic modulation, and repair dynamics. **Conclusions:** This physiologically relevant crypt-mimetic platform, henceforth called RepliGut® Crypt, enables quantification of both epithelial toxicity and regenerative capacity in response to diverse chemical and biological stressors. By capturing self-renewal and recovery processes that are absent in conventional monolayer systems, the model provides a human-relevant assay for evaluating epithelial resilience and compound safety. Applications span the chemical, food ingredient, and pharmaceutical industries, supporting preclinical toxicity assessment, mechanism-of-injury studies, and discovery of agents that promote intestinal protection and repair.

PS 4111 Microengineered 3D Vascular Injury Model for Immune-Mediated Drug Toxicity Assessment

E. Wang^{1,2}, C. Kamperschroer¹, K. Adkins¹, Q. Smith², P. Bajaj¹, and D. Soni¹. ¹Global Investigative Toxicology, Preclinical Safety, Sanofi, Cambridge, MA; and ²University of California, Irvine, Irvine, CA.

Background and Purpose: Drug-induced vascular injury (DIVI), which refers to blood vessel (endothelial cells and/or smooth muscle cells) damage caused by pharmaceuticals, is a challenge in drug development. DIVI can result from various classes of drugs, including both small molecules and biologics, with many compounds inducing vascular injury via activation of immune pathways, known as immune-mediated DIVI (iDIVI). This involves the release of proinflammatory cytokines and subsequent vascular disruption. Early identification of these candidates could thus help mitigate unintended toxicity, reduce delays, and lower costs in drug discovery and development. In preclinical settings, screening for iDIVI-inducing compounds traditionally involves a combination of *in vitro* and *in vivo* models to try and predict clinical outcomes. However, standard *in vitro* models have often lacked the physiological cues and diversity in cell types necessary to accurately predict iDIVI, while *in vivo* models pose challenges regarding interspecies translatability and ethical considerations. The U.S. FDA Modernization Act 3.0 supports complementing animal models in preclinical studies with new approach methodologies (NAMs). This has encouraged the development of more translatable *in vitro* models for screening drug candidates. **Methods:** In this study, a vascular coculture model was developed using OrganoPlate® 3-Lane 64 and compared against traditional Transwell® setup, combining human umbilical vein derived endothelial cells (HUVECs) and peripheral blood mononuclear cells (PBMCs) as an *in vitro* NAM to detect iDIVI. HUVECs were seeded against a collagen matrix to form endothelial tubules under gravity-driven flow. After seven days, PBMCs were introduced to the endothelial tubules along with test compounds [e.g. LPS (a toll-like receptor (TLR) 4 agonist) and Resiquimod (R848; a TLR7/8 agonist, or commercial drugs associated with vasculitis adverse events)] for 24 hours. To detect changes in endothelial function, trans-endothelial electrical resistance (TEER), morphological analysis, immunostaining, and proinflammatory cytokine (TNF- α , IFN- γ , IL-1 β , and IL-6) measurement were performed. Additionally, to confirm the involvement of inflammatory pathways for barrier damage, a one-hour pretreatment of cells with a pharmacological inhibitor for MAPKKK (aka TAK1; nodal kinase in proinflammatory pathways) was employed prior to stimulation with drugs. **Results:** Both OrganoPlate® and Transwell® coculture models demonstrated iDIVI responses, identified by disruption of the endothelial barrier when stimulated with immunomodulators only in the presence of PBMCs. However, OrganoPlate® model showed R848-induced responses at 10x lower concentrations compared to Transwell®, which were captured by real-time TEER measurement, high-content microscopy-enabled direct visualization of cell morphology, and increased expression of ICAM-1 as well as proinflammatory cytokines. When screening commercial drugs (daclizumab, docetaxel, etc.) that have been reported to cause vasculitis as a rare adverse event, several showed varying degrees of vascular damage. Notably, daclizumab (now off-market) exhibited concentration-dependent iDIVI responses starting at 1 μ g/mL [clinical C_{max} (30 μ g/mL)]. Importantly, inhibition of proinflammatory signaling using a TAK1 inhibitor effectively rescued the iDIVI phenotype induced by LPS and daclizumab. This protective effect was evidenced by blockade of TEER and junctional VE-cadherin loss, suppression of ICAM-1 upregulation, reduction in proinflammatory cytokine release (IL-1 β and IL-6), and decreased leukocyte adherence to the HUVECs. **Conclusions:** OrganoPlate® provided a robust model for characterizing the role of immune cells in DIVI by mimicking immune-endothelial interactions in a microfluidic *in vitro* model. Multiple classes of drugs including small molecules and monoclonal antibodies showed iDIVI in this model, and perturbation

with a pharmacological inhibitor allowed for proof of applicability for mechanistic studies. Thus, Organoplate® iDIVI model is expected to have broad utility for understanding the iDIVI risk for different classes of drugs, reducing the need for animal use in early screening, and ultimately helping to facilitate development of clinically safer drugs.

PS 4112 Assessment of Endothelial Network Formation and Immune-Endothelial Cell Interactions Using Different Commercially-Available Microphysiological Vascular Devices

H. Jesse¹, C. Sakolish¹, R. Villenave², P. Hewitt³, and I. Rusyn¹. ¹Texas A&M University, College Station, TX; ²Roche Pharma Research and Early Development, Basel, Switzerland; and ³Merck KGaA, Darmstadt, Germany.

Background and Purpose: Perfusable, immune-competent *in vitro* models of human vasculature can serve as powerful decision-making tools to assess the effects of novel therapeutics and chemicals on the vasculature as a whole and also on the leukocyte-endothelium interactions. This study aimed at evaluating robustness and reproducibility of the methods for establishment of perfusable vascular networks and induction of inflammatory response. For this, we used two commercially available human-vasculature microphysiological systems (MPS): the IdentTX-40 (AimBiotech), based on vascular self-assembly process, and the Mimetas' Organoplate®, relying on endothelial cells forming a tubule in a hollow channel. Specifically, we evaluated how endothelial cell type, cell culture medium composition, stromal cell support, and pro-inflammatory stimuli may shape vascular architecture and immune-endothelial cell interactions. **Methods:** In IdentTX MPS, endothelial progenitor cells (EPCs) and human umbilical vein endothelial cells (HUVECs) were seeded in a fibrin-thrombin gel with either a manufacturer's recommended medium or a supplemented medium with or without primary lung fibroblasts. Vascular network morphology and pro-inflammatory signaling were assessed. In parallel, we also evaluated the 2-lane 96 Organoplate® for immune cell adhesion following LPS stimulus. This MPS does not rely on vascular self-assembly and a single, perfusable tube can be formed using endothelial cells, allowing for increased control of the vascular architecture. Fluorescently tagged THP-1 monocytes and M0/M1 macrophages were perfused through the endothelial channels, and cell adhesion and ICAM-1 expression were evaluated. Building on this, a 3-lane Organoplate® model, incorporating EPCs exposed to TNF- α and chemokine gradients (CCL2 or CXCL12), was also tested to investigate immune cell extravasation. We quantified monocyte migration toward the chemokine channel as an indicator of directional immune trafficking across an inflamed endothelium. **Results:** As expected, fibroblasts markedly improved HUVEC vessel stability and reduced ICAM-1 expression. Interestingly, EPCs formed robust, perfusable networks regardless of the presence of fibroblasts. EPCs cultured in the highly supplemented medium exhibited the highest ICAM-1 levels, suggesting that nutrient-rich formulations used to induce vessel formation may also increase undesirable baseline inflammation. Fluorescent imaging demonstrated immune cell migration toward the chemokine channel within 24-48 hours, suggesting functional modeling of directional immune trafficking across an inflamed endothelium. **Conclusions:** Together, these studies highlight differences in biology and functionality between different vasculature MPS and support a cross-platform comparison approach to leverage the strength of individual experimental tools depending on the context of use. By utilizing the benefits of IdentTX for reliable self-assembly vessel formation and Organoplate® for precise control over immune cell dynamics and signaling, we present examples for customizable MPS for studies of endothelial barrier, inflammatory activation, and immune trafficking. This integrated approach supports the development of more physiologically-relevant vascular MPS for disease modeling and studies of hazardous chemicals and drugs.

PS 4113 Bridging the Gap Between *In Vitro* Models and Human Physiology: The Advantages of HUB's Intestinal Patient-Derived Organoids in Toxicology

A. Merenda, M. Derksen, J. Frias Aldeguez, Y. Hendriksen, M. Statia, F. Pourfarzad, R. G. Vries, S. Boj, and S. Rittchen. HUB Organoids B.V., Utrecht, Netherlands. Sponsor: S. Boj, American Association for Cancer Research

Background and Purpose: Gastrointestinal toxicity (GIT) is among the most frequently observed drug-induced adverse effects, occurring both in clinical trials and after market approval. Although generally non-life-threatening, GIT often requires dose adjustments or co-medication, which can compromise therapeutic efficacy and patient quality of life. Preclinical safety assessments for predicting drug-induced toxicity typically rely on animal models, two-dimensional (2D) cell cultures, or primary tissues. However, animal models exhibit limited clinical translatability (e.g., in rodents) or are constrained by ethical and cost considerations (e.g., in non-rodents). Among *in vitro* systems, CaCo-2 cell lines are widely used but represent only a single absorptive enterocyte-like phenotype, lacking the cellular diversity, tissue architecture, and physiological relevance of the human intestinal epithelium. Consequently, these limitations hinder the accurate prediction of human gastrointestinal responses to drug exposure. In contrast, intestinal organoids provide a three-dimensional, multicellular, and physiologically relevant model that more closely mimics native human intestinal tissue, offering a promising alternative for improv-

ing the translational value of preclinical toxicology studies. **Methods:** To overcome these limitations, we established a human-relevant *in vitro* platform based on Patient-Derived Organoids (PDOs). PDOs are generated from adult intestinal stem cells and retain the genetic, phenotypic, and functional properties of native intestinal tissue. They can be derived from different regions of the gastrointestinal tract, enabling the study of region-specific responses, and can be differentiated into various intestinal cell types, including enterocytes. In addition, the 3D organoid format is compatible with high-throughput screening, enabling efficient, reproducible testing of large compound libraries for toxicity profiling. **Results:** To assess the suitability of our intestinal organoid platform for evaluating drug-induced GIT, ten compounds with known *in vivo* outcomes—five inducing GIT (e.g., *Gefitinib*) and five non-inducing (e.g., *Flecainide*)—were tested. Compound effects were evaluated in 3D organoids cultured in either expansion medium (enriched in stem and transit-amplifying cells) or enterocyte differentiation medium (enriching for enterocytes) by measuring cell viability via an ATP-based assay. Additionally, 2D organoid-derived enterocyte-enriched monolayers were treated with the same compounds, and both cell viability (ATP-based) and epithelial barrier integrity (transepithelial electrical resistance, TEER) were assessed. In the 3D assay, all ten compounds were correctly classified, achieving 100% sensitivity and specificity. In contrast, in the 2D monolayer assay, only the non-GIT-inducing compounds behaved as expected (100% specificity), whereas half of the GIT-inducing compounds did not reduce viability or TEER values, suggesting that alternative or complementary readouts may be required to detect GIT toxicity in 2D systems. **Conclusions:** These findings demonstrate that HUB's intestinal Patient-Derived Organoids offer a robust, physiologically relevant, and predictive platform for assessing drug-induced GIT. This system provides superior sensitivity and specificity compared with conventional 2D assays, making it a valuable tool for preclinical safety evaluation and drug development and helping bridge the gap between *in vitro* models and human physiology.

PS 4114 Comparative Toxicity of Alkylated and Parent Polycyclic Aromatic Hydrocarbons in Primary Human Bronchial Epithelial Cells

M. Allison^{1,2}, J. M. Pennington¹, R. M. Valdez^{1,2}, V. C. Colvin^{1,2}, D. J. Degnan³, B. N. Rivera^{1,2}, K. M. Waters^{3,1,2}, D. Rohlman^{1,2}, and S. C. Tilton^{1,2}. ¹Oregon State University, Corvallis, OR; ²Superfund Research Program, Corvallis, OR; and ³Pacific Northwest National Laboratory, Richland, WA.

Background and Purpose: Polycyclic aromatic hydrocarbons (PAHs) constitute a broad class of structurally diverse environmental contaminants primarily derived from incomplete combustion of organic materials and petroleum products. Current understanding of PAH-related health effects is largely based on studies of unsubstituted or parent PAHs. However, alkyl-substituted PAHs are among the most abundant PAHs found near contaminated sites, occurring in both vapor and particle phases in the air. Despite their abundance, little is known about the respiratory toxicity of alkyl-PAHs after inhalation exposure. Moreover, alkylated PAHs are typically excluded from routine measurements and risk assessments, raising concerns that overall health risks associated with PAH exposure may be underestimated. To address this gap, we investigated the toxicity of a range of 2-5-ring alkylated PAHs in primary human bronchial epithelial cells (HBEC) *in vitro* across multiple endpoints of toxicity compared to parent PAHs. **Methods:** Normal primary human bronchial cells were expanded and seeded in 96-well plates and maintained until they reached 95% confluency. Cells were then exposed to four increasing doses of each chemical (ranging from 0 - 400 μ M) in a 0.5-1% DMSO (assay dependent) solution for 24 hours. Nine parent PAHs, anthracene, benz(a)anthracene, benzo(a)pyrene, benzo(c)phenanthrene, chrysene, dibenz(a,h)anthracene, naphthalene, phenanthrene, and pyrene, and 52 alkylated PAHs were tested in HBEC across dose-response for endpoints of cytotoxicity, mitochondrial membrane potential, oxidative stress, and DNA damage. Based on preliminary data in other test systems, we hypothesize that alkylated PAHs will exhibit equivalent or higher toxicity compared to the parent form. **Results:** Overall, the results showed that across parent groups, many alkylated products had equal or higher toxicity than their parent compound, depending on the endpoint that was being tested. The Benz(a)anthracene family is the largest in this screening, with 15 alkyl forms tested. Of those 15, 13 caused significant cytotoxicity, and nine caused significant mitochondrial membrane damage, at a concentration equal to or less than the parent form. We see similar results in the other chemical families. In addition, we observed that alkylated PAHs may cause toxicity through unique mechanisms compared to their parent forms, potentially involving genotoxic effects. These data are being used to model the dose-response relationship and quantify the relative potency between the parent and alkylated forms using benchmark dose modeling. **Conclusions:** Overall, these data indicate that current risk assessments may underestimate PAH risk from inhalation exposure due to a lack of data for alkylated forms. Additional research is required to close the data gap on the toxicity of alkylated polycyclic aromatic hydrocarbons.

PS 4115 A New Approach Methodology (NAM) Emphasizes hypothesis-driven Experimental Timing for Air-liquid Interface Studies: A Proof-of-Concept Investigation Using Human Primary Bronchial Basal Stem Cells

F. Effah, Y. Sun, R. Raghu, G. Kaur, and I. Rahman. University of Rochester Medical Center, Rochester, NY.

Background and Purpose: Several studies have been conducted on air-liquid interface (ALI)-cultured human bronchial basal cells (HBBCs) at different time points. Traditionally, experimental applications in ALI cultures are typically performed after day 21, assuming complete epithelial differentiation. Nonetheless, gene expression dynamics may vary across differentiation stages, and a fixed time point may not always be optimal for studying specific biological processes. **Methods:** To determine this, we conducted a targeted screening of key markers involved in DNA damage responses (*DDIT3*, *TP53*) and inflammatory pathways (*TNF-α*, *IL-10*, *IL-8*), alongside the gene expression markers of differentiation for basal cells (*ITGA6*, *KRT5*, *TRP63*), goblet cells (*MUC5AC* and *MUC5B*), ciliated cells (*FOXJ1*) and Club cells (*SCGB1A1*) at multiple time points (Day 0, 7, 14 and 21). In addition, we measured the TEER as a proxy for tight junction formation and pro-inflammatory mediators IL-8, IL-6, TNF-α, and IL-1β. **Results:** We show a distinctive pattern of gene expression and protein levels across three stages: proliferative, differentiation, and maturation. This shows that at each stage of epithelial development, different genes are at play. **Conclusions:** This novel approach may enhance the reproducibility and accuracy of airway disease modelling and drug testing, ensuring that studies are conducted at the most functionally relevant stage of differentiation. To the best of our knowledge, this is the first time such an experimental approach has been proposed. Our findings do not challenge the conventional 21-day approach for ALI studies but suggest a data-driven strategy to determine the optimal experimental window based on pathway-specific gene expression.

PS 4116 Comprehensive In Vitro Safety Assessment of Acorus calamus Rhizome Oil Using OECD Compliant New Approach Methods

K. R. Desai¹, R. M. Nagane¹, J. R. Ranade¹, M. V. Patel¹, C. S. Roper², A. D. Deshpande¹, and G. Babu K³. ¹Jai Research Foundation, Vapi, Gujarat, India; ²Roper Toxicology Consulting Limited, Edinburgh, United Kingdom; and ³Parul University of Applied Sciences, Vadodara, Gujarat, India.

Background and Purpose: *Acorus calamus* (sweet flag) is widely used in traditional medicine, yet its dermal safety profile remains insufficiently defined under modern regulatory standards. The objective of this study was to comprehensively evaluate the skin irritation, corrosion, and sensitisation potential of *A. calamus* rhizome oil using new approach methodologies (NAMs) test battery under GLP conditions. **Methods:** Hydro-distilled *A. calamus* oil's chemical characterization was performed via HPLC and LC-MS/MS to detect and quantify α, β, and γ asarone content. The oil was evaluated for skin irritation/corrosion potential using SkinEthic™ reconstructed human epidermis skin irritation test (OECD TG No. 439) and corrosion test (TG No. 431). Furthermore, the oil was also evaluated for skin sensitisation potential using Direct Peptide Reactivity Assay (OECD TG No. 442C), KeratinoSens™ transcriptional activation assay (OECD TG No. 442D), and human Cell Line Activation Test (OECD TG No. 442E). The risk assessment was conducted using the SARA-ICE Extended Model and SCCS default exposure parameters. **Results:** The *A. calamus* rhizome oil was predicted as a Category 2 skin irritant, non-corrosive, and GHS Category 1B skin sensitizer. Chemical analysis revealed β-asarone as the major constituent (~40.75%). The reconstructed human epidermis models established reversible irritation without corrosion. Mechanistic concordance across the Direct Peptide Reactivity Assay, KeratinoSens™, and human Cell Line Activation Test showed activation of the three key events of the skin sensitisation adverse outcome pathway. Using the "2-out-of-3" Defined Approach with the KE3/1 sequential strategy allowed the hazard classification into GHS Category 1B. Quantitative risk modelling using SARA-ICE models and SCCS parameters yielded conservative safe-use concentrations ranging from 0.13-0.78% (w/w) for leave-on products and up to 7.46% (w/w) for rinse-off formulations. **Conclusions:** The combined evidence from the NAM-based assays showed that *A. calamus* rhizome oil is a moderate sensitizer and irritant but not corrosive, providing critical data for risk assessment and regulatory decision-making, which was previously unknown. The SARA-ICE PoD-derived safe-use concentrations provide guidance for cosmetic formulators to ensure consumer safety, particularly in leave-on applications such as face and hand creams, where sensitisation risk is highest. This study demonstrates the utility of NAMs for botanical safety assessment and regulatory decision-making.

PS 4117 Predicting gastrointestinal toxicity using the assay-ready, primary-derived OrganoReady® Colon Organoid model

S. Shafiei, B. Duggan, M. Cuijpers, K. Liu, M. Morelli, I. Joore, M. Haarmans, K. Kosim, L. van den Broek, P. Hombrink, and S. Trietsch. MIMETAS B.V., Oegstgeest, Netherlands. Sponsor: S. Kundu

Background and Purpose: Gastrointestinal (GI) toxicity is among the most common adverse effects observed in clinical trials and after drug approval, often resulting in treatment delays, reduced patient quality of life, or even therapy discontinuation. Accurately predicting GI toxicity for novel drugs remains challenging, as many existing intestinal models fail to capture the full complexity of the gut epithelium. **Methods:** To address this limitation, we developed the OrganoReady® Colon Organoid model, which employs automated seeding and tubule formation of primary-derived colon organoids. Our platform integrates 64 microfluidic chips within a single plate, each supporting fluid flow and providing access to both apical and basolateral compartments, thereby enabling high-throughput screening of small- and large-molecule therapeutics. Staining analyses confirmed effective polarization of the gut tubules and the presence of key differentiated colon cell types. Functional assays demonstrated that the OrganoReady Colon Organoid tubules recapitulate essential intestinal functions, including drug transport, metabolism, and barrier integrity. **Results:** We exposed the OrganoReady Colon Organoid model with a representative panel of GI-toxicity-inducing compounds. After 72 hours, we assessed both viability and barrier integrity using Trans-Epithelial Electrical Resistance (TEER) measurements. The Colon Organoid tubules displayed greater sensitivity than conventional Caco-2 models. To evaluate reproducibility, we quantified intra- and inter-plate variability. Results showed minimal variation between chips within a single plate ($Z' \geq 0.5$) and strong reproducibility between plates. Additionally, the model remained stable during shipment under controlled temperature conditions, allowing end users to perform large-scale compound screening following a short recovery period. **Conclusions:** Together, the OrganoReady Colon Organoid represents a robust and highly predictive platform for GI toxicity testing, offering multiple functional readouts to support safety-related decision-making. Furthermore, this platform lays the groundwork for future GI toxicity studies incorporating donor diversity.

PS 4118 A Ready-to-Use 3D Human Blood Vessel model for Scalable Assessment of Endothelial Toxicity and Immune Activation

G. Rabussier, K. Liu, C. Clavijo, J. Heijmans, I. Joore, B. Kramer, L. Gijzen, and P. Hombrink. MIMETAS B.V., Oegstgeest, Netherlands. Sponsor: S. Kundu

Background and Purpose: The vascular endothelium is essential for maintaining homeostasis, controlling permeability, and regulating immune cell trafficking, processes often disrupted by pharmacological compounds. Conventional *in vitro* models lack the dynamic barrier function and immune responsiveness required for accurate prediction of vascular toxicity and inflammation, emphasizing the increasing demand for physiologically relevant and scalable models. Microphysiological systems (MPS) offer improved translational value by bridging the gap between static cultures and *in vivo* studies. Previous studies have demonstrated the utility of endothelial models in the OrganoPlate® platform for vascular and immunological applications. **Methods:** In this study, we present the OrganoReady Blood Vessel HUVEC model, a ready-to-use, membrane-free, high-throughput platform that forms a robust and modulatable endothelial barrier suitable for compound screening. The model was established in the OrganoPlate® 3-lane platform, which supports parallel culture of 40 to 64 endothelial vessels. Under gravity-driven flow, each chip enables the self-organization of HUVECs against an extracellular matrix to form a perfused, tubule-like endothelial structure. **Results:** Barrier integrity, assessed using the OrganoTEER® system, confirmed the formation of tight endothelial tubules with trans-endothelial electrical resistance (TEER). The model responded sensitively to inflammatory stimuli such as TNF-α and IFN-γ, showing reduced barrier function and morphological changes indicative of endothelial stress. High-content imaging confirmed ICAM-1 upregulation and altered morphology upon cytokine exposure, demonstrating vascular inflammation and supporting ICAM-1 as a marker for endothelial activation. Building on this inflammatory response, immune-endothelial interactions were evaluated using a PBMC adhesion assay. Following 16-hour stimulation with TNF-α and IL-1β, VE-cadherin disruption and a marked increase in immune cell adhesion were observed compared to non-inflamed controls. The model showed high reproducibility across experiments, confirming its robustness for screening applications. **Conclusions:** Together, these results validate the OrganoReady Blood Vessel HUVEC model as a reliable and scalable platform for high-throughput assessment of vascular toxicity, inflammation, and immune-endothelial interactions, addressing key needs in pharmaceutical compound evaluation.

R. A. Currie, S. Payvandi, Y. Adeleye, J. Feltham, and K. Rudd. Syngenta, Bracknell, Berkshire, United Kingdom.

Background and Purpose: Modern toxicological assessments increasingly rely on *in vitro* assays for chemical prioritization, often using potency-based ranking. While nominal concentrations have traditionally been used, more biologically relevant exposure metrics useful. Mass balance modeling supports this by predicting compound bioavailability, accounting for non-specific binding, partitioning, and intracellular distribution, typically under steady-state assumptions. This study explores the impact of selecting dose metrics when applying mass balance modeling, using case examples where transcriptomic points of departure (tPoDs) were derived from *in vitro* screening assays to inform prioritisation in new active ingredient research projects. **Methods:** High-throughput transcriptomic profiling was performed using six commercially available human cell lines (HepRG, HEK293, SHSY-5Y, U2OS, iCell cardiomyocytes, H295R) via the DRUG-seq methodology. Cells were exposed to 20 research agrochemical active ingredients for 24 hours across an 8-point dose-response curve (maximum 100 μ M; half-log dilutions; 5 replicates). Benchmark dose (BMD) modeling was conducted using BMDExpress3. Gene-level BMDs were calculated from modeled concentrations using a Williams Trend Test prefilter (FDR < 0.05; fold change > 1.5), followed by BMD estimation using polynomial, exponential, and Hill models (benchmark response > 1 SD). Compound-level tPoDs were defined as the median BMD of the lowest significantly enriched GO Biological Process term (FDR < 0.05; gene sets of 5-100 genes; BMDL/BMDU ratio < 40). Compound distribution within the assay system was predicted using the mass balance model described by Armitage et al. (2014, 2021). BMDs calculations were performed by adjusting BMDs calculated on nominal concentrations and also by mass balance adjustment prior to BMD calculation. Compounds were ranked by potency in each compartment in the mass balance model. **Results:** Chemical ranking by BMD potency was different and depended on the choice of dose metric. The basis of these differences were driven by divergent physicochemical properties (log P, solubility, and pKa/pKb) within the selected compounds. High log P increased non-specific binding (reducing free concentrations) but also enhanced cellular uptake. Low solubility reduced both free and intracellular concentrations due to precipitation. pKa/pKb influences cellular localization and uptake, as ionic form and compartmental pH affect membrane interactions and organelle distribution. The consequence of this was (1) reinterpretation of low potency responses after accounting for insufficient bioavailable concentrations at cellular targets; (2) divergent ranking outcomes when correcting nominal BMDs post hoc versus adjusting full concentration-response curves prior to BMD modelling; and (3) divergent compound ranking within chemical series when using free or intracellular concentrations instead of nominal media concentrations. **Conclusions:** Dose metric selection critically influences tPoD derivation and potency-based compound ranking. While distribution modeling is a powerful tool for predicting compound behaviour *in vitro*, careful consideration of metric choice and associated uncertainties is essential for robust AI screening and toxicological decision-making. The relevant dose metric should ideally be related to the sub-cellular location of the molecular initiating event.

PS 4120 Unidirectional, pumpless, scalable: Perfusable vascular networks with long-term stability using a gravity driven microfluidic system.

A. Rodrigues, S. de Ruiter, C. Clavijo, T. Olivier, A. Dalaid, W. Allen, I. Schilt, S. Trietsch, L. van den Broek, and T. Burton. MIMETAS B.V., Oegstgeest, Netherlands. Sponsor: S. Kundu

Background and Purpose: This study introduces a novel microphysiological system designed to enhance both physiological relevance and throughput in vascularized tissue models. Traditional *in vitro* models often lack the complexity and physiological relevance, whilst many microphysiological systems rely on pumps, valves, and a network of tubing to create recirculation setups for unidirectional flow, which can limit scalability and increase complexity. **Methods:** The OrganoPlate Graft 32 UniFlow (UF), our newly developed microphysiological system addresses these limitations by enabling pumpless, unidirectional perfusion of a vascular plexus cultured within a fibrin gel. The ability to create long-term stable vascular beds is the basis for more complex tissue building and can facilitate development of lung, skin, gut, liver or tumour models of greater physiological relevance. The system comprises a custom design based on the 384-well titre plate format with 32 microfluidic chips per plate, each engineered to support vascular network formation and unidirectional perfusion. The microfluidic device uses #1 coverslip thickness glass sheets, allowing for optimal compatibility with automated imaging equipment. Each chip consists of a vascular network region which is flanked by a supporting tube, and a bypass channel; a pressure drop has been designed across the vascular network region to allow for unidirectional perfusion. By leveraging a gravity-driven mechanism, the system generates flow through passive levelling, during the one-minute active phase a height difference is used to create a pressure gradient that drives unidirectional flow across the vascular network region and through the supporting tubule; changing the rocking orientation allows the system to reset through a bypass channel in a 15 second reload phase. This design utilised an open well format with access to the vascular bed via a hole above, it eliminates the need for external pumps, and reduces complex-

ity while significantly increasing throughput. Up to 16 plates (512 chips) can be accommodated on a single rocking unit, enhancing scalability for medium-throughput applications. **Results:** In experimental setups, the system demonstrated consistent formation of vascular beds within a fibrin gel and maintained perfusable vessels. Vessels within the network were seen to mature over time, and first becoming perfusable between days 6 and 9. Once perfusable, vessels are seen to widen and remain stable for 8 weeks. This was consistent for multiple users, cell lots and plates. The vascular networks exhibited stable, unidirectional perfusion, allowing for the flow of beads and immune cells across the vascular network at both an early and late stage of culture. The ability to create long term stable vasculature opens the door for modelling the interaction of vasculature with a multitude of tissues and assess both acute and chronic toxicity. **Conclusions:** In summary, the OrganoPlate Graft 32 UF, our pumpless unidirectional microphysiological system provides a versatile platform for the study of vascularized tissue models with increased longevity. Increasing the stability of vascular beds and tissues over time creates opportunities for more physiologically relevant disease triggers and repeat dosing of drugs, which can contribute to the development of new therapeutic strategies.

PS 4121 Integration of Incucyte analytics and multi-organ toxplate (kidney, Small intestine, and Liver) for NAMS-based hazard and risk assessment of compounds

S. Ayeahunie¹, J. Finelli¹, M. Mayo¹, P. Keselman², S. Letasiova³, and A. Armento¹. ¹MatTek Now Part of Sartorius, Ashland, MA; ²Sartorius Stedim North America, Ann Arbor, MI; and ³MatTek Europe, Bratislava, Slovakia.

Background and Purpose: Advanced cell models are key components of NAMS for hazard and risk assessment of chemicals and pharmaceuticals. To overcome the limitations of traditional single-organ systems in predicting human responses, we developed a 3D human Multi-Organ ToxPlate (MOTP) that integrates small intestine, liver, and kidney tissues in a 96-well plate format. This platform was adjusted to be compatible with Sartorius's IncuCyte® system for high-throughput automated live-cell imaging allowing to study the effect of single or multiple drugs across three organ systems simultaneously. By combining conventional toxicological endpoints such as TEER for barrier integrity, MTT for viability, and H&E staining for histology with IncuCyte® analytics, the ToxPlate delivers comprehensive outcome measurements of pharmacokinetics and pharmacodynamics. This approach improves prediction accuracy, supports early detection of off-target effects, and contributes to reduction in late-stage clinical failures. This integrated platform enables evaluation of therapeutic toxicity, metabolism, and clearance in a physiologically relevant specific context of use. **Methods:** Primary human cells representing three organ systems (liver, kidney, and intestine) were seeded into a 96-well ToxPlate, with each organ system allocated 32 wells. Cultures were maintained under submerged conditions for 1-3 days, followed by air-liquid interface (ALI) conditions for 12 days to achieve proper differentiation and stratification. To validate the workflow, we first reconstructed a single-organ plate of the 3D human kidney model and dosed it with Cisplatin (known nephrotoxicant) and Oxaliplatin (non-toxicant) at various concentrations. Cell death was monitored using IncuCyte® Cytotox Green reagent (Sartorius, Ann Arbor, MI) dosed with the test compound. Next, we developed a 96-well multi-organ ToxPlate (MOTP) incorporating 3D tissues of intestine, liver, and kidney. Drug-exposed tissues were incubated at 37°C and imaged in an IncuCyte® S3 Live-Cell Analysis System housed within the incubator. Green fluorescence images were acquired at 10x magnification every 4 hours for 48 hours. Global mean fluorescence values were calculated using the Basic Analyzer module of the IncuCyte® software, where higher fluorescence indicates greater cell death. Since IncuCyte® imaging and analysis is non-invasive, TEER, MTT viability, and histological measurements were performed after IncuCyte® data collection. **Results:** The study demonstrated a dose-dependent decrease in TEER following Cisplatin treatment of the 3D kidney tissue model. IncuCyte® live-cell analysis revealed EC50 values for Cisplatin ranging from 11 to 25 μ M, consistent with previously reported manual measurements. No drug-induced acute kidney injury was observed in Oxaliplatin-treated tissues at the tested concentrations. We then expanded the study by testing three drugs Cisplatin, Fialuridine, and Troglitazone. Post-treatment incucyte analysis and TEER measurements indicated that Cisplatin was toxic to all three tissue models at higher doses. Fialuridine, liver toxicant, exhibited selective hepatotoxicity without affecting kidney or intestinal tissues. Troglitazone showed toxicity toward liver and kidney at higher concentrations. Finally, a 48-hour, seven-dose range finding study was performed using Cisplatin and Oxaliplatin on ToxPlate containing kidney and intestinal tissues integrated with the IncuCyte® workflow. Cisplatin exposure resulted in a clear dose-dependent reduction in TEER and MTT viability. IncuCyte® analytics also revealed a difference in drug response for Cisplatin (17 μ M) compared to Oxaliplatin (88 μ M) in 3D kidney tissue model. Post-IncuCyte® analysis showed that Oxaliplatin, however, TEER values exhibited a dose-dependent decrease, suggesting TEER may be a more sensitive endpoint for this compound. **Conclusions:** The integrated MOTP-IncuCyte® workflow provides a robust and economical platform for drug toxicity testing. This trio-tox assay system accelerates *in vitro* toxicity predictions, enhances physiological relevance, and supports early detection of organ-specific and off-target effects and reduces animal experimentation.

A. Maerten¹, E. Callewaert¹, J. Sanz Serrano¹, L. Devisscher², and M. Vinken¹. ¹Vrije Universiteit Brussel, Brussels, Belgium; and ²Universiteit Gent, Gent, Belgium.

Background and Purpose: Per- and polyfluoroalkyl substances (PFAS) are abundantly used in a plethora of products with applications in daily life. As a result, PFAS are widely distributed in the environment, raising concerns regarding accumulation in humans. Recent data show impairment of bile acid metabolism by legacy PFAS, yet the potential of short-chain and alternative PFAS as well as the mechanistic basis of these cholestatic effects remain elusive. The present study relied on an *in vitro* test battery mechanistically anchored in an adverse outcome pathway network to assess the cholestatic potential of legacy, short-chain and alternative PFAS. Focus was put on the effects of PFAS on molecular initiating events, in particular transporter changes and bile canaliculi dynamics. **Methods:** Cultures of human HepaRG liver cells were exposed to 8 types of PFAS in 3 concentrations. Fluorescently labeled probes were used to investigate effects on the functionality of bile acid transporters. Effects at the transcriptional level were studied by means of quantitative reverse transcriptase polymerase chain reaction analysis. Bile canaliculi dynamics were monitored *via in situ* immunostaining and phase-contrast imaging. An integrated weight-of-evidence approach was applied to process the results of the *in vitro* test battery. **Results:** PFAS inhibit the expression and activity of various bile acid transporters, including organic anion transporting polypeptides and multidrug resistance-associated proteins. Some PFAS inflicted morphological disruption of bile canaliculi. The highest overall cholestatic scores were observed for perfluorooctane sulfonic acid, perfluorobutanoic acid and perfluorobutanoic acid, while C6 PFAS exhibited low cholestatic potential. **Conclusions:** This study shows the power of *in vitro* testing to elucidate mechanisms underlying hepatotoxicity induced by PFAS and, simultaneously, to quantify the cholestatic potential of these ubiquitous “forever chemicals”.

PS 4123 A real-time, multiplexed assay for evaluating compound-induced disruption of barrier integrity

X. Zhang, and J. Zhang. Agilent Technologies, La Jolla, CA. Sponsor: L. Zhao

Background and Purpose: Cell barriers, such as epithelial and endothelial layers, act as protective interfaces that tightly regulate the passage of ions, molecules, and pathogens between compartments. When these barriers are compromised, exposure to toxins increases, contributing to disease development. Assessing barrier integrity is therefore critical for understanding compound-induced toxicity, including cytotoxicity and changes in permeability. **Methods:** In this study, we introduce an assay that simultaneously evaluates barrier permeability through real-time impedance measurements and live-cell imaging. EA.hy926, an immortalized human endothelial cell line, was used to model endothelial barrier function. Cells were seeded at 5,000 cells per well on a biosensor plate and monitored continuously for approximately seven days using the xCELLigence RTCA eSight system. Barrier formation was indicated by a plateau in impedance, reported as the Cell Index. **Results:** Thrombin, a well-established barrier disruptor, was applied to increase permeability. Its addition caused a dose-dependent, reversible decline in Cell Index, followed by recovery. Live-cell imaging of the same monolayer revealed normal morphology with sparse open areas, confirming that the Cell Index drop reflected increased permeability rather than reduced viability. Pretreatment with Argatroban, a direct thrombin inhibitor, completely prevented the thrombin-induced decline in Cell Index, demonstrating its protective effect on barrier integrity. This impedance- and imaging-based assay was further validated by a conventional FITC-Dextran permeability assay and immunofluorescence staining of the tight junction protein Zonula occludens-1 (ZO-1). **Conclusions:** This integrated approach enables early detection of adverse effects of pharmaceuticals, environmental chemicals, and consumer products on barrier permeability.

PS 4124 Cynomolgus iPSC-Derived Neural Models as a Translational NHP In Vitro Platform for Preclinical Neurotoxicity Testing and NAM Alignment

S. Dwyer¹, L. Ramirez², K. Kotok^{2,3}, M. Nandi², F. Suchy^{2,4}, N. Rapicavoli², C. Hinckley¹, and M. Roodgar^{2,4}. ¹Biogen, Cambridge, MA; ²Exir Bio, Menlo Park, CA; ³San José State University, San Jose, CA; and ⁴Stanford University, School of Medicine, Stanford, CA.

Background and Purpose: Nonhuman primates (NHPs) remain an essential model for assessing neurotoxicity and neuropharmacology in CNS drug development due to NHPs close genetic and physiological similarity to humans. However, *in vivo* NHP studies are costly, time-consuming, and ethically challenging. Current regulatory frameworks advance drug candidates from human *in vitro* (i.e., neurons) directly to *in vivo* NHP studies; changing both model type (*in vitro* to *in vivo*) and species (human to NHP), which weakens translational reliability. Drug candidates often fail late in the drug development process at the preclinical safety step when candidates are tested in *in vivo* NHP animal models. Exir Bio has developed cynomolgus macaque iPSC-de-

rived neural models that enable *in vitro* NHP testing alongside human systems to better anticipate *in vivo* outcomes, and refine and reduce animal dependence. These models support post-study mechanistic investigations when neurotoxicity is observed *in vivo*. **Methods:** Cynomolgus macaque (cyno) iPSCs were differentiated into NGN2 neurons, astrocytes, and oligodendrocytes via transfection with respective doxycycline-inducible vectors. Motor neurons (MN) were differentiated by generating via embryoid-body formation followed by terminal differentiation by supplementing with small molecules. **Results:** Cyno NGN2 and MN populations expressed canonical terminal differentiation markers by qPCR and immunocytochemistry: MAP2, ISL1, TUJ1 for NGN2 neurons and MAP2, ISL1, and HOX6 for MN, respectively. Multielectrode array (MEA) demonstrated that the cyno NGN2 and motor neurons had comparable firing rates to human iPSC-derived neurons. Co-culture with human astrocytes supported synaptic connectivity and neurite outgrowth. **Conclusions:** Exir Bio's cyno iPSC-derived *in vitro* models fill a key gap in the ability to examine *in vitro* to *in vivo* translatability between NHPs and animal models in four cell types from the neural progenitor cell lineages including NGN2 cells and motor neurons. These cells express the functional markers of their respective terminally differentiated neurons, confirmed via qPCR and immunocytochemistry staining, and perform equivalently in functional assays. These models provide translational NHP *in vitro* platforms for neurotoxicity and preclinical drug testing that embody the 3Rs of modern drug development.

PS 4125 Modeling repeated ENDS exposure response trajectories in adolescents using a co-culture model of the bronchial epithelium

E. A. Huber, H. Kellner, N. McNabb-Kelada, A. Clayton, R. Chartier, and S. D. McCullough. RTI International, Durham, NC.

Background and Purpose: The use of primary *in vitro* models for inhaled chemical testing often relies on single cell models, specifically, differentiated primary human bronchial epithelial cell (dpHBEC) cultures. While dpHBECs hold physiological relevance based on their ability to form cilia, tight junctions, and mucus production, they are only one of many cell types in the bronchial epithelium. Incorporating multiple cell types increases biological complexity of *in vitro* models while also providing added context of interactions occurring *in vivo* to better predict human health outcomes. Additionally, primary *in vitro* models from human donors may capture heterogeneous responses to toxicant exposures, including response trajectories in susceptible populations. The rapid popularity of Electronic Nicotine Delivery Systems (ENDS) in adolescents had led to a knowledge gap in understanding the cumulative and long-term health impacts in humans. The effects and underlying mechanisms of inhaled test articles, such as ENDS aerosols, are often modeled using acute exposures and only one cell type commonly from human immortalized cell lines. In realistic exposures, ENDS usage typically involves repeated exposures over time and interaction of numerous cell types in the bronchial epithelium. Therefore, to increase physiological relevance of ENDS exposures in adolescents, we conducted repeated exposures to ENDS aerosols using a co-culture model containing dpHBEC air-liquid interface (ALI) cultures and donor-matched primary human lung fibroblasts (pHLFs) from adolescent donors, known as the trans-epithelial exposure model (TEEM). **Methods:** We assessed the impact of repeated ENDS exposures in the TEEM using 6 sex-balanced adolescent donors with no known health issues or history of smoking. Cultures were exposed to either vehicle control containing propylene glycol: vegetable glycerin (PG:VG) or ENDS aerosol containing benzaldehyde and nicotine for 1 (1X) or 5 (5X) days in CelTox units while maintaining ALI conditions. Exposure groups were compared against a matched ALI control. Total aerosol mass from *in vitro* exposures was compared with the *in vivo* peak modeled deposition in humans using Multiple-Path Particle Dosimetry (MPPD) model. Following repeated exposures, we evaluated impacts on common *in vivo*-relevant endpoints, such as ciliary beat frequency (CBF), trans-epithelial electrical resistance (TEER), cytotoxicity, MUC5AC secretion, and pro-inflammatory cytokine secretion: interleukin 1 α (IL-1 α), IL-6, and IL-8. We assessed transcriptional changes in epithelial and fibroblast cell types using RNA sequencing. **Results:** Aerosol mass per cm² in CelTox units was slightly decreased compared to the MPPD modeled predictive *in vivo* peak deposition in humans. ENDS aerosol exposure for 5-days led to increased cytotoxicity among all donors when compared against controls. TEER was not impacted by exposures. CBF and MUC5AC showed a robust increase in response following 5-days of exposure. Donor specific sensitivities were seen in cytokine secretion with 4 donors classified as responders to ENDS aerosol effects. RNA-seq revealed cell type dictated variation with the greatest difference in gene expression between dpHBECs and pHLFs. Additionally, pHLFs showed distinct gene expression patterns between 1 and 5-day exposures with greater induction of oxidative stress, DNA damage, fibrosis, and lung cancer pathways following 5X exposures. Gene expression patterns showed minimal upregulation in dpHBECs with a similar pattern amongst control and exposure groups. RNA-seq data indicated that model complexity can drive experimental outcomes. **Conclusions:** This study demonstrates the need to characterize primary *in vitro* systems through understanding cell type-specificity and inter-individual variability in outcomes by including susceptible population groups and increased donor numbers in toxicological studies to capture response trajectories that represent the human population. Utilization of the TEEM and repeated exposures to ENDS aerosols was able to capture complex and cumulative biological responses that single-cell or single-exposure models may miss, which better predicts adverse health outcomes in humans.

T. Nguyen-Jones¹, J. McKenna², W. Chen², K. K. Wolf³, T. Stone³, E. Bianchi², J. R. LaRocca², J. Chen¹, E. LeCluyse³, J. Klein¹, and E. Rogers¹. ¹LifeNet Health LifeSciences, Virginia Beach, VA; ²Corteva Agriscience, Indianapolis, IN; and ³LifeNet Health LifeSciences, Research Triangle Park, NC.

Background and Purpose: There is a regulatory need within the U.S. EPA's Endocrine Disruptor Screening Program (EDSP) to develop new approach methodologies (NAMs) for identifying and evaluating chemicals that may interfere with the thyroid endocrine system in human. To address this need, an integrated tiered testing strategy has been established for assessing thyroid hormone (TH) disruption. Tier 1 assays typically employ cell lysates, rat or human thyroid microsomes, immortalized cell lines (e.g., FRTL-5, Nthy-ori 3-1), and engineered cells (e.g., HEK293, HeLa) over-expressing thyroid-related target genes such as thyroid peroxidase (TPO), sodium iodide symporter (NIS), and iodothyronine deiodinase-1 (DIO1). These assays focus on single molecular initiating events (MIEs) but lack thyroid-specific phenotype and the capacity for TH synthesis. Tier 2 assays incorporate organ-on-a-chip and organoid models that provide enhanced physiological relevance. This study evaluated the applicability of cryopreserved primary human thyrocytes as a 3D physiologically relevant *in vitro* model for multi-pathway screening of thyroid-disrupting chemicals (TDCs), using both T₄ and T₃ synthesis as an endpoint quantified by both ELISA and LC-MS/MS. **Methods:** Primary human thyroid epithelial cells (passage 1) obtained from healthy adult donors (≤55 years old; BMI ≤35) were cryopreserved in a serum-free bio-preservation medium. Cells from individual donors (n=3) were thawed in human thyrocyte plating medium (HTPM) and seeded on Matrigel-coated 96-well plates at 7,500 cells per well. Beginning on Day 2, cultures were maintained in an h7H-based medium supplemented with 1 mIU/mL bovine thyroid-stimulating hormone (hTSH). The effects of two reference TDCs, methimazole (MMI) and potassium hexafluorophosphate (KPF₆), known to decrease the T4 level in plasma by decreasing the TH synthesis in human were assessed using a 3D thyroid microtissue model in 96-well format. After a 6-day exposure (Days 8-14), medium samples were collected at day 14 for TH quantification via LC-MS/MS or ELISA. The limit of detection (LOD) for T₄ and T₃ by LC-MS/MS was 0.1 ng/mL and 0.05 ng/mL, respectively, while the ELISA sensitivity for T₄ was 0.33 ng/mL. **Results:** All three thyrocyte lots met quality criteria for TDC applications, forming uniform microtissues on Matrigel and synthesizing >1.0 ng/mL T₄ by Day 14. The cryopreserved thyrocytes maintained follicular morphology and T₄:T₃ ratios of >2.5. Both MMI and KPF₆ inhibited T₄ and T₃ synthesis in a dose-dependent manner. The average IC₅₀ values for T₄ were 0.16 μM and 1.49 μM, and for T₃ were 0.29 μM and 3.68 μM, respectively. IC₅₀ values for T₄ were consistent across LC-MS/MS and ELISA, demonstrating assay reliability. **Conclusions:** In summary, the primary human thyrocyte 3D microtissue assay using either ELISA or LC-MS/MS analytical approaches represents a promising strategy for evaluating and prioritizing potential TDCs in human health risk assessment. Moreover, the model enables the identification of compounds acting directly on the thyroid and supports simultaneous evaluation of multiple MIEs (e.g., TPO, NIS) for small-molecule screening in both agriscience and therapeutic research.

PS 4127 Bridging Physiological Accuracy and Reproducibility: The EpiVaginal Model Integrated with Simulated Vaginal Fluid

E. Marquesdosreis¹, J. Markus¹, K. Forro², M. Klausner³, T. Landry³, K. Coen³, S. Letasiova¹, K. Kejlova⁴, M. Dvorakova⁴, E. Pácalová⁴, and S. Ayeunnie³. ¹MatTek Europe, Bratislava, Slovakia; ²Comenius University, Bratislava, Slovakia; ³MatTek Now Part of Sartorius, Ashland, MA; and ⁴National Institute of Public Health, Prague, Czech Republic.

Background and Purpose: The EpiVaginal model (MatTek), a 3D vaginal tissue based on a normal human ectocervical epithelial cells, has been developed as an *in vitro* alternative to the Rabbit Vaginal Irritation (RVI) assay to evaluate the safety of vaginal products. This highly differentiated 3D tissue model mimics the structural, physiological, and functional features of native vaginal mucosa and has been successfully applied in studies of vaginal irritation, inflammation, drug delivery, and microbicides. EpiVaginal aligns with the goals of New Approach Methodologies (NAMs) by providing a physiologically relevant, reliable, and reproducible assay for specific context of use for hazard and risk assessment of feminine products such as lubricants, hygiene products, microbicides, spermicides, and medical devices. While commercially available in the U.S. for years, the model was only recently introduced in Europe. In this study, we assessed reproducibility and robustness of manufacturing the tissue model by comparing ET-50 values, the exposure time required to reduce tissue viability by 50%, across two production sites (U.S. and Europe). ET-50 values serve as a standardized metric for batch-to-batch and site-to-site comparisons was used to evaluate the model's reliability and reproducibility. To further evaluate discriminatory power, we tested a panel of widely used vaginal ingredients, including exposures with Simulated Vaginal Fluid (SVF) to enhance physiological relevance. **Methods:** EpiVaginal tissues were produced simultaneously by MatTek in the U.S. and Europe (Bratislava). Tissues were produced from normal human vaginal ectocervical (VEC) cells obtained from healthy donors undergoing hysterectomy for benign conditions. Cells were cultured on 0.6 cm² inserts in serum-free medium for ~2 weeks, forming multilayered, highly differentiated 3D models that recapitulate native vaginal epithelial

structure. Each batch underwent QC testing via topical exposure to 1% Triton X-100 (positive control) for 0.5, 1, and 2 h to determine ET-50 values. Ultrapure water exposure for 1 h served as a negative control. ET-50 values between 0.70-1.70 h were used as acceptance criteria. We evaluated batch reproducibility for lots produced in 2024 in the U.S. (n=20) and 2024-2025 in Slovakia (n=31). Additionally, tissues produced at MatTek Europe were exposed to 100 μL of two concentrations of five feminine care ingredients for 24 h at both MatTek Europe and the National Institute of Public Health (Prague). Endpoints included MTT viability and TEER for barrier integrity. For selected test articles, ET-50 assays were conducted following 1, 4, and 18 h exposures, comparing cytotoxicity profiles with and without SVF. Irritation potential was evaluated based on MTT, TEER, and histology. **Results:** Across 51 lots (U.S. n=20; Slovakia n=31), all ET-50 values for 1% Triton X-100 met QC criteria (0.70 < ET-50 < 1.70 h). Following 24 h exposure to feminine care ingredients, the average difference in %MTT viability across eight test articles was 7.2%, with only two exceeding 10%. The average difference in %TEER was 6.4%, with two exceeding 10%. Toxicity profiles of Boric acid (6%), benzalkonium chloride (0.06%), and benzocaine (5%) showed ET-50 >18 h with minor SVF-related shifts (e.g., BZK: early TEER dip with partial recovery; BEN: gradual TEER decline). Miconazole (2%) exhibited a modest ET-50 right-shift (~17.0 → ~17.8 h). Nonoxonyl-9 (2%) caused early, severe loss of MTT/TEER regardless of SVF, whereas lactic acid (2%) seems protected by SVF (ET-50 >18 h vs <1 h) with higher MTT and partial TEER rescue. Overall, SVF buffered acidity-driven effects but not surfactant-type injury. **Conclusions:** ET-50-based QC criteria were reproducible across two laboratories in 51 production lots, confirming lot-to-lot and site-to-site consistency. Furthermore, SVF improved physiological relevance by mitigating acidity effects (e.g., lactic acid), highlighting its importance in irritation testing. The findings support EpiVaginal as a reliable non-animal alternative for screening feminine care products.

PS 4128 A Mechanistic Add-On to Human DNT NAMs for Detecting Endocrine Disruption via RAR and GR Signaling in Neural Progenitors

K. Schlüppmann¹, L. M. Stark¹, S. Hüsken¹, E. Zühr¹, A. Dönmez^{2,1}, E. Fritzsche^{2,1,3,4}, and K. Koch^{2,1}. ¹IUF - Leibniz Research Institute for Environmental Medicine, Düsseldorf, Germany; ²DNTOX GmbH, Düsseldorf, Germany; ³SCAHT - Swiss Center for Applied Human Toxicology, Basel, Switzerland; and ⁴Department of Pharmaceutical Sciences, University of Basel, Basel, Switzerland.

Background and Purpose: Endocrine-disrupting chemicals (EDCs) pose a significant risk to the developing human brain, yet current regulatory frameworks lack tools to detect endocrine disruption-mediated developmental neurotoxicity (ED-DNT), particularly via non-EATS pathways such as retinoic acid receptor (RAR) and glucocorticoid receptor (GR) signaling. Both pathways reduce neural progenitor cell (NPC) proliferation, a key neurodevelopmental process, to enable terminal differentiation. While the human Neurosphere Assay, an established and scientifically validated component of the DNT *in vitro* battery (DNT-IVB), captures NPC proliferation, it cannot determine whether effects are hormone receptor-mediated or detect RAR/GR antagonism in the absence of physiological ligands. Here, we developed the NPC1_RAR_GR assay as a hormone receptor-specific add-on to the DNT-IVB, extending the NPC proliferation endpoint with mechanistic confirmation of hormone receptor involvement. **Methods:** The NPC1_RAR_GR assay uses a two-tiered design anchored in the DNT-IVB Neurosphere Assay methodology. Tier 1 quantifies NPC proliferation after single-compound exposure. Tier 2 determines whether Tier 1 effects are mediated through RAR or GR, and detects receptor antagonism that cannot be observed in Tier 1. To test agonism, compounds are co-exposed with selective antagonists for both receptors (AGN193109 for RAR, mifepristone for GR). A right-shift of the concentration-response curve indicates receptor-mediated agonism. To test antagonism, compounds are co-exposed with both receptor agonists (all-trans retinoic acid, dexamethasone). Antagonism is defined as a rescue of the anti-proliferative effects of the hormones above a predefined threshold. Seventeen environmental chemicals and a human biomonitoring-based prenatal mixture (MIX N) of seven urinary biomarkers were tested. Fetal brain concentrations for MIX N components were estimated using a human gestational PBTK model. **Results:** Model RAR and GR agonists and antagonists were reliably detected, confirming assay specificity. Among the 17 environmental chemicals, several organochlorine pesticides (DDT, aldrin, dieldrin) showed clear RAR/GR antagonism, a mode-of-action not detectable in the classical DNT IVB assay. Our results are confirmed by ToxCast RAR/GR receptor-level activity, however, for DDT at significantly higher benchmark concentrations compared to our cellular assay. Interestingly, the metabolite DDE showed only weak partial activity. Other DNT-IVB positives (e.g. cadmium chloride, tributyltin chloride, valproic acid) reduced NPC proliferation in tier 1 but were not rescued by co-exposure to antagonists, indicating non-RAR/GR mechanisms. The prenatal exposure mixture MIX N (BPA, BPF, MEP, MBzP, DPHP, TCP, and 3- PBA), tested at modeled fetal brain concentrations and up to 10 000× higher, produced no effects in tier 1 or tier 2. Consistently, all mixture components were inactive in ToxCast RAR/GR receptor-level assays except for weak activity of BPA and MBzP, neither of which translated into cellular responses. **Conclusions:** The NPC1_RAR_GR assay provides a mechanistically anchored, receptor-specific extension to the DNT *in vitro* battery, enabling differentiation between receptor-mediated and receptor-independent effects and detecting receptor antagonism, a mode-of-action not captured by standard DNT-IVB assays. Strong alignment with ToxCast RAR/GR receptor binding activity for OCP effects and absence of effects for a human biomonitoring-based prenatal mixture,

demonstrates both specificity and translational relevance. These findings support the NPC1_RAR_GR assay as a promising NAM for integration into regulatory ED-DNT assessment frameworks.

PS 4129 RosetteArray® Platform for Quantitative High-Throughput Screening of Human Developmental Neurotoxicity and Modeling of Neurodevelopmental Disorders

B. Lundin^{1,2}, G. Knight^{3,1,2}, F. Seipel^{1,2}, N. Fedorchak^{3,1,2}, K. Krucki³, M. Birtele⁴, N. Iyer^{1,2}, J. Robinson⁵, B. Iskandar¹, G. Quadrato⁴, R. Willett^{6,3}, and R. S. Ashton^{1,3,2}.

¹University of Wisconsin-Madison, Madison, WI; ²Wisconsin Institute for Discovery, Madison, WI; ³Neurosetta, Madison, WI; ⁴University of Southern California, Los Angeles, CA; ⁵University of California, San Francisco, San Francisco, CA; and ⁶University of Chicago, Chicago, IL.

Background and Purpose: Human pluripotent stem cell (hPSC)-derived neural organoids (hNOs) are prominent *in vitro* models of human central nervous system (CNS) development. Formed through spontaneous self-organization of neurally differentiating cell aggregates, hNOs recapitulate extensive aspects of CNS tissue morphogenesis. As such, they are excellent tools for toxicological screening, disease modeling, and drug discovery. Yet, emergence of their 3D structure and morphology is variable limiting their reproducible use as a scalable screening platform. Here, we present the RosetteArray® platform which enables scalable derivation of nascent forebrain (198.9 ± 11.6 per well) and spinal (793.6 ± 125.7 per well) hNOs with reproducible single-rosette structure in 96-well plate formats. Coupled with semi-automated confocal imaging and RosetteDetect™ software for artificial intelligence-based image analysis, the RosetteArray platform enables hNO-based quantitative high-throughput screening (qHTS) for assessing the risk of chemicals/drugs to cause human developmental neurotoxicity (DNT) or neurodevelopmental disorders. **Methods:** We present use of micropatterned culture substrates to standardize formation of 3D, nascent forebrain and spinal cord hNOs with consistent single-rosette structure (Knight et al. *ELife* 2018). 96-, 24-, and 6-well RosetteArray plates can be manufactured with micropatterned culture substrates as the plate bottom. Then, the plates can be used to standardize derivation of 100's-1000's of single-rosette hNOs per well from direct seeding of cryopreserved hPSCs or hPSC-derived neuromesodermal progenitors (NMPs, Lippman et al. *Stem Cell Rep.* 2015). After 8 (forebrain) or 5 (spinal) days of culture, RosetteArray assays are analyzed via standard fixation, immunostaining, and confocal imaging steps followed by image analysis using artificial intelligence-based RosetteDetect software to quantify salient metrics: # of DAPI+ cells per tissue; % of PAX6+ neural stem cells per tissue; % of tissues per well displaying a singularly polarized neural rosette structure. **Results:** To assess reproducibility and scalability, WA09 hPSCs seeded into 96-well forebrain RosetteArray plates, either manually or via a liquid handler, generated arrays with 95.46% ± 5.81 and 91.46% ± 5.81 (manual) or 91.83% ± 5.80 and 86.67% ± 6.84 (liquid handler) single rosette emergence efficiency under control conditions. Also, WA09-derived, cervical and lumbosacral spinal NMPs seeded into 96-well spinal RosetteArray plates generated 80.63 ± 8.00 or 94.38 ± 6.57 single neural rosette emergence efficiency, respectively, under control conditions. Second to assess suitability for DNT, dose-response assays were conducted with glycolic acid as a negative control and methotrexate, valproic acid, novobiocin, and benomyl, i.e., well-known Spina Bifida risk factors, as positive controls. Sensitive detection of toxicity was observed with differential profiles both across RosetteArray metrics and regions (forebrain vs. spinal). This was followed by screening a 30 compound library of pharmaceuticals and pesticides using forebrain RosetteArrays. The screen yielded 0.96 sensitivity and 1.0 specificity values with several chemicals demonstrating differential toxicity levels depending on whether they were pre-digested with S9-pooled liver fraction to simulate human metabolism. Lastly, the RosetteArray platform was used to model Spina Bifida risk caused by both chemical and genetic disruption of folate metabolism (Lundin et al. *BioRxiv* 2024, <https://doi.org/10.1101/2024.04.01.587605>) and Autism Spectrum Disorder risk caused by a SYNGAP1 genetic mutation (Birtele et al. *Nat. Neurosci.* 2023). **Conclusions:** Collectively, these results support the RosetteArray® platform's utility for qHTS of chemical DNT and modeling risk factors that cause neurodevelopmental disorders such as Spina Bifida and Autism Spectrum Disorder. Moreover, they motivate its inclusion in OECD's DNT *In Vitro* Testing Battery.

PS 4130 Innovative Assays for the Characterization of Seizure Liabilities

J. Price, C. Garrison, A. Singanamalli, S. Zhu, X. Li, S. Moore, and K. Augustine. Bristol Myers Squibb, Princeton, NJ.

Background and Purpose: A BMS program lead BMS-X caused unexpected, seizure-like adverse effects in toxicity studies in both mouse and dog. To identify alternate leads devoid of this liability, we have implemented multiple new approach methodologies (NAMs). The purpose is to leverage these assays to identify compounds with reduced risk for CNS Tox potential. **Methods:** A human-relevant *in vitro* multielectrode array (MEA) assay was established using stem cell-derived glutamatergic neurons. This assay captures key parameters of neural synchrony which are predictive of seizurogenic potential *in vivo*, and its implementation facilitates rapid program compound screen. Additionally, we have qualified and applied zebrafish larvae, a known neurotoxicity model, to assess compound toxicity in a whole organism with

an intact blood-brain barrier. Behavioral changes were recorded in parallel across the wells of a 96-well plate using Ramona's Multi-Camera Array Microscope, with videos captured at 90 fps. AI-based methods were then used to quantify behavioral endpoints such as distance traveled, speed, orientation, and tail position. **Results:** Leveraging both the MEA and zebrafish larvae assays, we have identified several internal program compounds that are non-excitatory at concentrations of up to 100 µM with *in-vivo* correlation. **Conclusions:** We have shown that these NAMs have greatly accelerated triage of program compounds prior to resource-intensive rodent studies without requiring compound scale-up, or program compounds.

PS 4131 Evaluating luminal-basal cellular plasticity using a dual transduced reporter MCF10A cell line

A. Tapaswi¹, J. Wotring¹, P. Yang², J. Sexton¹, X. Zhou², and J. A. Colacino¹.

¹University of Michigan, Ann Arbor, MI; and ²Yale University, New Haven, CT.

Background and Purpose: The human breast epithelium is comprised of various cell types, with 2 major defining cell types being luminal and basal cells. These cells express cytokeratin intermediate filaments in a cell type-specific manner. Luminal cells are characterized by the expression of keratin 8 (KRT8) and basal cells are defined by keratin 14 (KRT14). Onset and progression of cancer is marked by loss of cellular identity and cellular plasticity, now an established hallmark of cancer. This cellular plasticity could be further accentuated by exposure to common environmental chemicals. We developed a lentivirus-based reporter cell line in non-tumorigenic MCF10A human breast epithelial cells where the KRT8 promoter drives GFP expression and the KRT14 promoter drives RFP expression. We treated these cells with common environmental toxicants to study their effect on cellular plasticity. Morphological and cell state perturbations could point towards potential mode-of-action for chemicals with undetermined mechanisms. **Methods:** MCF10A cells were plated in 6-well plate at 30% confluency. Cells were sequentially transduced with KRT8-GFP lentivirus and positive cells were selected with puromycin. KRT14-RFP lentivirus was added to puromycin selected cells, and positive cells were selected using hygromycin. Dual fluorescent cells were cultured and sorted using flow cytometry and bulk RNA-seq was done to confirm KRT8+ and KRT8+/KRT14+ expression. To study the perturbation in cellular populations, cells were dosed with TGFβ-1, a known EMT inducer, at 24, 48, 72 and 96 hours with doses ranging from 3.9pM to 2µM. To study the effect of some common environmental chemicals, cells were dosed with cadmium chloride, copper chloride, p,p-DDE, lead acetate and PFOS with doses ranging from 0.03µM to 99µM for 96 hours. Cells were fixed and stained with Hoechst33342, a nuclear stain imaged on a CX5 or CV8000 high content imaging microscopes. A cell segmentation and feature extraction pipeline was setup in Cellprofiler 4.2.1. Raw data was imported in R and was normalized using the Cytominer package. Cells were classified as KRT8+, KRT14+, KRT8-/KRT14- and KRT8+/KRT14+. Generalized linear models were used to compare KRT8 and KRT14 intensities for all chemicals across concentrations. **Results:** Flow cytometry data revealed that the reporter cell line contained ~93% cells in the KRT8+/KRT14+ state. 6% cells were KRT8+ and ~1% cells were KRT14+. After TGFβ-1 treatment, an increase in KRT14+ and KRT8+/KRT14+ populations was observed at 24 and 48h. KRT14+ only population showed an increase at 72h, with a decrease in KRT8+/KRT14+ cells. At 96h, an increase in KRT8-/KRT14- population was seen. When dosed with cadmium chloride, a decrease in KRT8-GFP intensity at doses above 160nM and an increase in KRT14-RFP intensity was observed at doses above 2.56µM. Copper chloride exposure at 2.6µM and 6.4µM showed a decrease in KRT8-GFP intensity and an increase in KRT14-RFP intensity. At 1.04µM p,p-DDE, we observed an increase in both KRT8-GFP and KRT14-RFP intensities. Interestingly, lead acetate showed a decrease in KRT8-GFP intensity at concentrations tested, and an increase in KRT14-RFP intensity at 2.56µM and doses at and above 16µM. Cells exposed to PFOS concentrations from 80 to 400nM exhibited an increase in both KRT8-GFP and KRT14-RFP intensity. **Conclusions:** A stable dual transduced luminal-basal cell line was generated to study cellular plasticity in non-tumorigenic MCF10A cells. An increase in a KRT14+ population and the loss of KRT8+ cells with TGFβ1 treatment for a shorter duration demonstrated TGFβ1's effect on modulating cytokeratin filaments and the responsiveness of this line to this signaling molecule. We found that common environmental toxicants like cadmium chloride, lead, p,p-DDE and PFOS can modulate luminal-basal cellular plasticity. An in-depth analysis of other parameters like cell morphology, fluorescence is ongoing to differentiate between the established cell population categories and understand functional impacts of toxicant-induced changes in expression of markers of cell state.

PS 4132 Assessment of a complex PAH-mixture from wildfires in a 3D respiratory model for asthma

R. M. Valdez^{1,2}, V. C. Colvin^{1,2}, J. M. Pennington¹, R. S. McClure³, K. M. Waters^{3,1,2}, and S. C. Tilton^{1,2}. ¹Oregon State University, Corvallis, OR; ²OSU/PNNL Superfund Research Program, Corvallis, OR; and ³Pacific Northwest National Laboratory, Richland, WA.

Background and Purpose: There exists a significant knowledge gap in understanding how non-chemical stressors, such as inflammation associated with pre-existing disease, interacts with chemical exposures to elicit distinct or exacerbated adverse

health outcomes compared to healthy populations. Prior studies employing a 3D respiratory model of type 2 allergic inflammation demonstrated unique functional changes and transcriptional alterations following exposure to a single polycyclic aromatic hydrocarbon (PAH), benzo[a]pyrene, indicative of altered susceptibility to chemical-induced toxicity under inflammatory conditions. This study will be among the first to evaluate the toxicological effects of an environmentally relevant wild-fire-creosote mixture of PAHs (ToxMix) using a 3D respiratory model for asthmatic inflammation. **Methods:** To compare mechanisms of toxicity between normal and asthmatic phenotypes, primary human bronchial epithelial cells (HBEC) were cultured in 3D at the air-liquid interface (ALI) in the presence or absence of 10 ng/mL interleukin-13 (IL-13) to induce the asthmatic phenotype. Fully differentiated cells at the ALI (25 days) were treated with 0 - 275 μ M ToxMix for 24 hours and collected for analysis of cytotoxicity, barrier integrity and global gene expression by RNA-seq. Expression of mRNAs after ToxMix exposure were normalized to their phenotypic controls and significantly differentially expressed genes (DEGs; q -value<0.05) were identified in order to begin investigating how different processes were affected by ToxMix in each phenotype. **Results:** While no increase in cytotoxicity was observed with treatment in the asthmatic phenotype, barrier integrity was significantly decreased (p -value<0.05) with ToxMix treatment across all concentrations in the IL-13 induced asthmatic phenotype. In the normal phenotype, ToxMix treatment had no significant impact on cytotoxicity or barrier integrity. With regard to global gene expression, more DEGs were identified after ToxMix exposure in the IL-13 induced asthmatic phenotype compared to ToxMix exposure in the normal phenotype. Across three concentrations (11 μ M, 55 μ M, and 275 μ M) of ToxMix exposure, 2,615 DEGs were identified in the IL-13 induced asthmatic phenotype compared to only 88 DEGs in the normal phenotype. Similar trends were observed when evaluating biological processes regulated within each phenotype. The most dysregulated pathways in the IL-13 induced asthmatic phenotype included cell adhesion processes and regulation of the epithelial-to-mesenchymal transition. **Conclusions:** Overall, these data are among the first to provide insight into how exposure to environmentally relevant PAH mixtures may elicit different responses between normal and asthma-like phenotypes.

PS 4133 Development of *in-vitro*-to-*in-vivo* extrapolation (IVIVE) approaches for PFOA and PFHpA

H. M. Bolstad¹, S. Majid², S. Coffin², and A. Soshilov². ¹Office of Environmental Health Hazard Assessment (OEHH), California EPA, Oakland, CA; and ²Office of Environmental Health Hazard Assessment (OEHH), California EPA, Sacramento, CA.

Background and Purpose: Perfluoroheptanoic acid (PFHpA) was detected in approximately 20% of public water systems in California, including sites near airports and landfills. Due to limited animal toxicity studies, we used *in vitro* transcriptomic and *in-vitro*-to-*in-vivo* extrapolation (IVIVE) approaches to derive a transcriptomic point of departure (tPOD_{IVIVE}) for PFHpA and compared it to animal toxicity PODs. As a control, the same analysis was first applied to well-characterized perfluorooctanoic acid (PFOA). Mass-balance modeling was incorporated to refine the IVIVE. **Methods:** The Reardon *et al.* (2021) primary human hepatic spheroid transcriptomic dataset was analyzed for gene- and pathway-level responses, with raw counts normalized and processed using BMDExpress to derive benchmark concentrations (BMCs) and tPODs. Two *in vitro* mass balance models (IV-MBMs) - EQP v2.0 (Armitage *et al.*, 2021) and Qin *et al.* (2024) - were evaluated to translate nominal concentrations to free or cellular metrics; model performance was validated using PFAS concentration data from HepaRG cells. The best-performing IV-MBM was used to adjust tPODs for the estimated fraction unbound. Five IVIVE approaches were then tested (using PFOA as a test chemical) to convert tPODs to plasma-equivalent concentrations: assuming free *in vitro* PFOA concentration equals (1) free or (2) total plasma concentration, (3) estimated PFOA cellular concentration equals PFOA liver concentration, (4) estimated cellular protein-bound PFOA concentration equals liver protein-bound PFOA concentration, and (5) a novel extrapolation method based on estimated binding to fatty acid binding protein 1 (FABP1). Resulting tPOD_{IVIVE} values were compared to available human and animal toxicity PODs, and the best-performing approach was applied to PFHpA. **Results:** Seventy-eight and 123 genes passed BMC filters at 1 and 10 days of exposure to PFHpA, respectively, with median BMC 95% lower bound values (BMCLs) of 3.2 and 0.8 μ M. GO_BP and Reactome pathway analyses identified xenobiotic response as the most sensitive pathway at 10 days (BMCL = 0.5 μ M). The EQP v2.0 (Armitage *et al.*, 2021) model exhibited the lowest bias (-0.83 vs 3.91 nmol/mg protein) and predicted that 99% of PFHpA was free in media. Applying the five IVIVE approaches to the PFOA pathway BMCL produced tPOD_{IVIVE} values spanning three orders of magnitude, with approach 2 yielding values closest to available serum-based human and animal PODs - a human POD for alanine aminotransferase and an animal POD for relative liver weight. Approach 5 was the next most consistent. Application of approach 2 to PFHpA yielded gene- and pathway-based tPOD_{IVIVE} values of 0.8 and 0.5 μ M, respectively, which were one to three orders of magnitude below mouse serum-based PODs for relative liver weight and hepatocellular hypertrophy. **Conclusions:** Selection of IVIVE approach has a profound impact on the magnitude of tPOD_{IVIVE}. Approach 2 - commonly used in the literature - produced values most consistent with *in vivo* PODs. The next most consistent was approach 5, which incorporates binding to FABP1. Considering additional binding proteins, such as bile acid sequestering proteins, may further align tPOD_{IVIVE} values with *in vivo* PODs.

PS 4134 Automated Generation of 3D iPSC-Based Cardiac Microtissues for High-Throughput Calcium Transient Screening

T. Smith, S. Schwengberg, and S. Jain. NCardia, Leiden, Netherlands.

Background and Purpose: Transition towards *in vitro* compound screening for safety and efficacy in preclinical drug development needs physiologically relevant test systems reflecting complex biology while allowing for higher throughput applications. While iPSC technology integrates human biology, standard 2D high-throughput assays are often lacking complexity, whereas most 3D models are not allowing sufficient throughput. We have developed a physiologically relevant 3D iPSC-based cardiac microtissue (MT) model that is assembled and maintained by a robotic system and can be used for high-throughput measurement of calcium transients. **Methods:** MTs were assembled in 384w plates using a Tecan Fluent robot by combining 70% ventricular cardiomyocytes, 15% endothelial cells, and 15% cardiac fibroblasts differentiated from either a control iPSC line, or an iPSC line harboring a RyR2 mutation recapitulating a phenotype of catecholaminergic polymorphic ventricular tachycardia (CPVT). MT formation, media changes, and addition of reagents were performed by a Tecan Fluent robotic system. After 14 days of culture, MTs were loaded with FLIPR6 calcium dye and transferred to a FDSS μ Cell imager for subsequent compound addition and recording of calcium transients. **Results:** Automated formation of MTs resulted in inter-well variability of MT volume <5%, with an increase in diameter (305-375 μ m) from d1-d7 after formation. Calcium transient amplitude and peak width was comparable in several batches of MTs at day 14 after formation with an intra-well variability <10%. 0.1 μ M nifedipine reduced calcium transient peak amplitude by 42.2 $\pm$ 17.22 %, and peak rate by 11.9 $\pm$ 50.3%. 1 μ M BayK8644 induced an increase in peak amplitude of 43.4 $\pm$ 46.6%, and a decrease in peak rate by 4.5 $\pm$ 6.9%. 1 μ M Isoproterenol induced both a positive chronotropic (67.3 $\pm$ 11.1% increase in peak rate) and inotropic (45.7 $\pm$ 7.7% increase in peak amplitude) effect. To demonstrate the suitability of the system for pharmacological screening in a disease model, MTs generated from the CPVT line were treated with 2000 compounds from the Specs Repurposing Library. The screen revealed several hits with known mode-of-action against the disease phenotype, as well as compounds whose therapeutic role is currently under investigation. The average Z' factor across the screen was 0.6. **Conclusions:** Our 3D cardiac microtissue model can be assembled and maintained at scale in an automated process, displays robust calcium handling properties and is suitable for high-throughput screening in safety / tox studies. Microtissues generated from a CPVT iPSC line recapitulated the phenotype, which could be rescued using clinically relevant compounds, demonstrating that the platform can be leveraged to advance cardiac drug screening.

PS 4135 Evaluation of Isogenic Human iPSC-Derived 3D Cardiac Spheroid Co-culture Model for Predictive High-Throughput Cardiotoxicity Assessment

B. Anson, N. Beardsley, N. Meyer, R. Fiene, C. Carlson, and R. Vaidyanathan. FUJIFILM Cellular Dynamics Inc., Madison, WI.

Background and Purpose: The adult human heart is a complex organ providing highly regulated processes of pumping blood throughout the body. Heart tissue contains various types of cells, including (but not limited to) cardiomyocytes, endothelial cells, smooth muscle cells, and fibroblasts. Although cardiomyocytes may occupy about 75% of the total volume, they only constitute 40-50% of the total cell count. Recent publications show that 3D cardiac spheroids (aka, microtissues or "cardiospheres") enhance the maturation and functional activity of the cardiomyocytes compared to 2D cultures, thus more closely mimicking actual heart physiology. In this study, we developed a tri-culture spheroid model by mixing human iPSC-derived cardiomyocytes, cardiac fibroblasts, and endothelial cells from the same donor to generate 3D cardiac spheroids, aka, "cardiospheres". **Methods:** All human iPSC-derived cell types and optimized media formulations were from FUJIFILM Cellular Dynamics, Inc. Individual cell types were thawed and combined in defined ratios (65:15:20 of CM:CF:EN) and cultured in ultra-low attachment (ULA) plates. Typically, 5-10K cells per well were used in 96- or 384-well format and spheroids formed within 48 h. The structures started to contract spontaneously and regularly after 4-5 days. Spheroid formation (size and morphology) was tracked over time using live cell imaging in cultures maintained under serum-containing and serum-free conditions. Additionally, different cell types in the tri-culture system were immunostained using antibodies for Troponin T (cardiomyocytes, CM), COL1A1 (cardiac fibroblasts, CF), and VE-Cadherin (endothelial cells, EN). Spontaneous beat rate activity of 3D cardiospheres was investigated by recording the calcium oscillations on a high-throughput kinetic screening instrument (i.e., FLIPR Penta or FDSS/ μ Cell). Pharmacological modulation was performed by exposing the cells to a set of known small molecule inotropes, including isoproterenol (1-500 nM), dobutamine (0.01-10 μ M), epinephrine (1-300 nM), and Bay-K 8644 (0.01-0.3 μ M). Cell viability was also assessed following treatment with a panel of compounds with known cardiotoxicity, including doxorubicin, sunitinib, staurosporine, and others. **Results:** Importantly, we observed significant increases (approx. 2-fold) in the oscillation rate or peak count (positive chronotropic response) and increased the peak amplitude 1.2-1.5-fold (positive inotropic response) with compounds like isoproterenol. Other cardioactive drugs, including HERG blockers E-4031 (1-100 nM) and dofetilide (0.1-30 nM) and ion channel blockers nifedipine (10-300 nM) and mexiletine (0.550 μ M) demonstrated changes in the calcium oscillation patterns consistent with expected mode of action. Compounds

with previously demonstrated cardiotoxicity resulted in decreased cell viability, albeit with some differences compared to 2D format or 3D mono-culture. **Conclusions:** The work demonstrates the value and biological relevance of using human iPSC-derived cell types assembled into 3D cardiac spheroids compared to traditional 2D cardiomyocytes cultures. The 3D model represents a promising *in-vitro* model for drug discovery screens and preclinical screening, enabling high-throughput assessment of human cardiac microtissues

PS 4136 Human Liver-on-a-Chip Systems for Enhanced Mechanism-Based Toxicity Screening

C. Moon, F. Ventura, and C. Lucchesi. ATCC, Gaithersburg, MD.

Background and Purpose: High-quality hepatocytes are essential for *in vitro* toxicology studies because they recapitulate critical liver functions, including metabolism, detoxification, and drug response. Their integration into advanced model systems improves prediction of drug-induced liver injury (DILI), reduces reliance on animal models, and enables early identification of hepatotoxic compounds. This study evaluated cryopreserved HepatoXcell™ Pro hepatocytes within a liver-on-a-chip platform under dynamic, physiologically relevant conditions, aiming to establish a robust system for predictive toxicology and pharmacokinetic assessment. **Methods:** Primary human hepatocytes (HepatoXcell™ Pro) were incorporated into a liver-on-a-chip system featuring 3-D liver tissue architecture within a dynamic fluidic environment. The platform was optimized for hepatocyte viability and function, enabling measurement of liver-specific markers, toxicity-related enzymes, and pharmacokinetic parameters. Standardized protocols were developed to assess drug-induced cytotoxicity via viability assays and enzyme activity profiling. System performance was benchmarked against qualification guidelines for preclinical toxicology models. **Results:** The liver-on-a-chip platform maintained hepatocyte morphology and function under dynamic flow conditions. HepatoXcell™ Pro exhibited stable expression of liver-specific markers and metabolic enzymes, supporting accurate assessment of hepatotoxicity. Toxicity testing with therapeutic compounds revealed dose-dependent cytotoxicity and changes in enzyme activity consistent with known DILI profiles. The platform demonstrated reproducibility across multiple runs, meeting qualification criteria for predictive toxicology applications. **Conclusions:** Integrating HepatoXcell™ Pro into a liver-on-a-chip system enhances predictive accuracy for DILI and supports mechanism-based toxicity screening in human-relevant models. This approach reduces reliance on animal testing and strengthens early-stage safety assessment, facilitating the development of safer therapeutic agents. Broad adoption of this technology could significantly advance translational toxicology and risk assessment in drug development.

PS 4137 Predicting PARP Inhibitor-Induced Bone Marrow Toxicity Using a Multi-Lineage *in vitro* Platform

J. Terc¹, M. Stahl¹, C. Kim¹, A. Mak¹, A. Dhanda¹, D. Leung¹, K. Tse¹, R. K. Conder¹, A. C. Eaves¹,², and S. A. Louis¹. ¹STEMCELL Technologies Inc, Vancouver, BC, Canada; and ²Terry Fox Laboratory, BC Cancer Agency, Vancouver, BC, Canada.

Background and Purpose: Poly(ADP-ribose) polymerase (PARP) inhibitors (PARPi) are vital therapeutics, but their use is often limited by dose-dependent toxicities, most notably neutropenia (hematotoxicity) and gastrointestinal (GI) adverse events. To better predict these risks early in drug development, we established a comprehensive, human-relevant *in vitro* platform to evaluate the toxicity profiles of various clinical agents, such as talazoparib, olaparib, and veliparib. **Methods:** Compound toxicity was assessed over relevant concentration ranges, using three human cell-based models. Granulocyte/macrophage and erythroid toxicity was quantified using human progenitor cells in both the gold-standard colony-forming unit (CFU) assay and a high-throughput HemaTox™ assay. Effects on GI liability were evaluated using a human intestinal organoid monolayer assay to measure cell viability and barrier function. **Results:** All tested PARPi demonstrated dose-dependent toxicity across the hematopoietic models. Both the CFU and the HemaTox™ assays produced a consistent hierarchy of toxicity: talazoparib > olaparib > veliparib. This *in vitro* ranking strongly validated the platform, as it accurately mirrored the reported differential clinical incidence and severity of neutropenia for these agents. The IC₅₀ values from the Erythroid and Myeloid HemaTox™ assay ranged from 0.0041 - 0.0066 µM for talazoparib, 0.61 - 1.44 µM for olaparib, and 2.1 - 9.5 µM for veliparib. Collectively, these results demonstrated the platform's suitability for comprehensive assessment of drug toxicity. **Conclusions:** The predictive capacity demonstrated in the hematopoietic models successfully correlates with the clinically observed hierarchy of PARPi-induced myelosuppression. These *in vitro* models provide a rapid, translational, and robust collection of tools for evaluating the differential multi-organ toxicity risk of novel therapeutics.

PS 4138 In-Vitro cytotoxicity assays using RTgill-W1 cells for Toxicity Identification and Reduction Evaluation (TIE/TRE) Strategies for Wastewater and Ambient Water Analysis

L. P. Butler^{1,2}, J. Scott^{2,3}, and M. Minghetti¹. ¹Oklahoma State University, Stillwater, OK; ²Cove Environmental, Stillwater, OK; and ³Oklahoma State University, Stillwater Oklahoma, OK.

Background and Purpose: Current fish toxicity testing methods are vital for the chemical registration and aquatic toxicity of pollutants dissolved in water. However, advancements with *in vitro* ecotoxicity techniques have continued to be highlighted for their ethical alternatives and more informative approach, such as providing insight into the Mode of Toxic Action (MoA). Specifically, these cell-based systems directly address the key aspects of the 3 R's (replacement, reduction, refinement), offering a screening tool that significantly decreases the reliance on live vertebrate toxicity tests. The rainbow trout (*Oncorhynchus mykiss*) gill cell line, RTgill-W1, has shown promise for incorporation into Whole Effluent Toxicity (WET) regulatory testing techniques. Moreover, while these New Approach Methods (NAMs) offer a promising animal alternative component, their primary strength lies in the utility of better understanding MoAs essential to Toxicity Identification/Reduction Evaluation (TIE/TRE) strategies, an aspect where current *in-vivo* assays are often deficient. **Methods:** The RTgill-W1 cells were maintained and cultured in Leibovitz's L-15 medium and utilized for cytotoxicity testing (Scott et al., 2023). For the assays, cells were seeded at a density of 79,000 cells per cm² in 24 multi-well plates. Cell viability was measured following a 24-hour exposure to effluent samples using the Multiple Endpoint Viability Assay, which was performed with sample adjustment (ISO 2019). This assay simultaneously measured three key endpoints: alamar Blue for Metabolic Activity, CFDA-AM for Membrane Integrity, and Neutral Red for Lysosomal Integrity. To evaluate the predictive capacity of the *in vitro* system, results were compared against traditional Fathead Minnow (FHM) larvae assays, which measured mortality at 96 hours and determined the lethal concentration 50% (LC50). The resulting cell effect concentration of 50% (EC50) values were directly compared to the LC50 values. Furthermore, various TIE treatments were systematically performed on the effluent samples to identify and remove toxicants, with cytotoxicity assays subsequently used to confirm the success of the removal process. **Results:** The RTgill-W1 cell line has been utilized to predict the mortality of acutely toxic effluents to fish larvae, covering a broad range of wastewater facility types, operations, and sample sources (i.e. pulp and paper production, agriculture, chemical production, food and beverage, and superfund sites). In this capacity, RTgill-W1 cell viability successfully predicted all toxic effluent samples, with six of these samples exhibiting greater sensitivity than the Fathead Minnow (FHM) larvae assays. Furthermore, studies have demonstrated the efficacy of TIE treatments (i.e., chemical addition, mechanical filtration and sample adjustments) in removing toxic effects to both fish and cells, and the TIE treatments were successfully applied and shown to remove toxicants from the tested effluents. This removal was subsequently confirmed through cytotoxicity assays which demonstrated a corresponding decrease in toxic effects when comparing measured subcellular endpoints before and after the TIE process. Additionally, RTgill-W1 cytotoxicity assays were able to highlight specific MoAs of wastewater samples, distinguishing between specific classes of toxicants based on sample type and subcellular endpoints. Ongoing research also indicates the promise of these cells for modeling key chronic exposure endpoints. **Conclusions:** Our results underscore the substantial utility of RTgill-W1 cells, highlighting their ability to effectively identify toxicants of concern relating to WET failures. This demonstrates that the cell line can be used for routine TRE treatments similar to established fish larvae tests, offering a fast, ethical, and mechanistically informative tool for environmental monitoring and regulatory compliance.

PS 4139 A New Approach Methodology for Hepatocyte Proliferation: EdU-Based High-Content Imaging in Human and Rodent Primary Cells

J. Olson¹, W. Chen², S. Al Janabi¹, A. Raza¹, Y. Gu², R. Settivari¹, and S. Catalano¹. ¹Corteva, Newark, DE; and ²Corteva, Indianapolis, IN.

Background and Purpose: Hepatocyte proliferation is a critical key event (KE) leading to adverse outcome (AO) to liver tumorigenesis, particularly in the context of chemical exposure in rodent. The mode of action (MOA) provides a mechanistic framework linking molecular initiating events (nuclear receptor activation) to downstream biological KEs that culminate in tumors. Determining human relevance of xenobiotic induced hepatocyte proliferation is essential for agrochemical risk assessment. Currently, there is no *in vitro* test guideline to address this KE. Building on prior applications of 5-ethynyl-2'-deoxyuridine (EdU) incorporation for assessing proliferative responses (e.g. Yamada et al., 2015), this work advances new approach methodologies (NAMs) by evaluating donor variability, time course and pregnenolone-16α-carbonitrile (PCN) as rodent-specific nuclear receptor control (to demonstrate specificity). This study aims to qualify rat and human hepatocytes and optimize *in vitro* method in hepatic proliferation following nuclear receptor activation using high-content imaging (HCI) for analysis. **Methods:** Cryopreserved primary human hepatocytes and pooled Wistar Han rat lots were plated on collagen-coated 4 chamber glass slides (3 well/slide). Dimethyl sulfoxide (DMSO) was the vehicle control (VC). Time-course comparison at 24 and 48 hours (h) used 2 rat lots and 2 human donors (1 slide/lot/donor/time point) with 200ng/mL HGF or PCN (5 or 20µM) as a pretest to assess onset of proliferation and select optimal timepoint. For main study, 4 human

donors (2 male; M and 2 female; F) and 6 rat lots (3M and 3F) were exposed to 2 doses of HGF (25 or 200ng/mL) or PCN (5 or 20μM) for 48 h (2 slides/lot/donor). Treatment began 6 h post-plating, repeated every 24 h, with 10μM EdU in final dose. After exposure slides were stained with 5μg/mL Hoechst. Images were captured using Opera Phenix Plus high content screening system with Harmony® v5.1 (Revvity, Waltham, MA). Percent EdU-positive nuclei were calculated as number EdU-positive cell divided by total Hoechst-positive/field. Data were expressed as fold-change (FC) relative to VC and evaluated with SAS Software. Data was transformed to meet the assumptions of statistical tests. The mixed-effects model used to provide estimates FC and confidence. Unpaired t-tests used to assess whether observed FC was significant than a threshold. Qualification was based on post thaw viability, morphology, and proliferation responses. **Results:** All 6 rat lots and 4 human donors had acceptable viability (>70%) and normal morphology. Average cell counts of 13382.6 per rat lot and 19824.3 per human donor were quantified, an order of magnitude higher to historical manual scoring standard 1000 cells typically used in EdU studies providing improved assay sensitivity. At 24 h (time course), treated hepatocytes did not demonstrate significant responses. In human, response was less than 2 FC for both HGF and PCN, while in rats the response was 1/2 donor achieved greater than 2 FC after HGF while both less than 1.5 FC after PCN exposure. At 48 h, human and rat showed greater than 2 FC increase in response to HGF. In contrast, PCN induced greater than 1.5 FC in rats but not in humans, as expected. Therefore 48 h (2 doses) was selected for main study. In the main study, analysis showed donor variability however, no sex-based differences were observed. Reproducible response greater than 2 FC following HGF exposure was seen in 5/6 rat lots and all 4 human donors. PCN response was greater or equal than 1.5 FC in 5/6 rat lots, whereas no human donors exhibited a response greater than 1.5 FC. Overall, these studies showed consistent donor variability without sex-based differences, with strong HGF-induced proliferation in rat and human cells and selective PCN response in rats. **Conclusions:** This work demonstrates the development of a quantitative, EdU-based primary hepatocyte proliferation assay. Confirmed donor variability and time point improving assay reliability. Incorporated PCN as alternative rodent specific nuclear receptor control supporting broader use in mechanistic liver toxicity assessments. The assay provides a foundation for screening reference chemicals to expand species comparability and support human relevance determinations. The results support development of human-relevant, non-animal methods for regulatory toxicology and risk assessment.

PS 4140 ATCC's Human-Relevant Cancer Models for Mechanism-Based Toxicity and Drug Response Profiling

A. Andar, A. Singh, M. Changsuk, S. Friend, M. Graziano, R. E. Thamert, F. Ventura, U. Sharma, J. Jacobs, and C. Lucchesi. ATCC, Gaithersburg, MD.

Background and Purpose: The Human Cancer Models Initiative (HCMI) is a global collaboration led by the National Cancer Institute (NCI) that aims to advance translational oncology by developing patient-derived cancer models. Traditional cell lines often fail to capture the complexity of human tumors, which limits their utility in drug discovery and precision medicine. HCMI addresses this gap by generating biologically relevant 2-D and 3-D models derived directly from patient samples, ensuring high genomic fidelity and clinical relevance. ATCC contributes to the initiative by developing, manufacturing, and distributing these models worldwide. The HCMI portfolio includes over 300 models spanning 28 tissue types, including colorectal, pancreatic, brain, and esophageal cancers, as well as rare malignancies such as Wilms tumor and Ewing's sarcoma. These models reflect diverse clinical diagnoses, stages, age ranges, and racial backgrounds, providing researchers with tools to study tumor heterogeneity and health disparities. Comparative analyses show strong concordance with The Cancer Genome Atlas (TCGA), retaining over 80% of oncogenic drivers and preserving transcriptional and epigenetic landscapes. The purpose of this work is to provide researchers with clinically relevant models that improve preclinical testing, support biomarker discovery, and enable precision oncology strategies. **Methods:** Organoids were cultured in 3-D extracellular matrix conditions using ATCC Organoid Growth Kits and passaged to form uniform structures prior to drug screening. Models were seeded into 96-well plates and treated with a panel of chemotherapeutic and targeted compounds using 12-point or 8-point dilution curves. Drug response was assessed via ATP-based luminescent viability assays and live-cell fluorescence imaging. Genomic characterization was performed using whole-exome or targeted sequencing, and data were compared to matched patient tumors and TCGA datasets to confirm model fidelity. Z' factor scores were calculated to validate assay robustness, enabling correlation of genomic alterations with drug sensitivity. **Results:** ATCC has expanded the HCMI portfolio to include 91 colorectal and over 54 pancreatic cancer organoids, each annotated with clinical, genomic, and drug-response data. Colorectal models, primarily adenocarcinomas, mirror TCGA mutation profiles and exhibit genotype-dependent drug sensitivity across 24 compounds. Pancreatic models similarly reflect key driver mutations (KRAS, TP53, SMAD4) and exhibit differential responses to targeted agents, including KRAS inhibitors. High-throughput assays demonstrated strong reproducibility (Z' >0.7), and models preserved patient tumor morphology and molecular features. Sequencing and clinical metadata are publicly available via the HCMI portal. **Conclusions:** The HCMI portfolio, distributed by ATCC, represents a next-generation resource for oncology research and toxicology. These patient-derived models enable mechanism-based toxicity screening in human-relevant systems, improving prediction of drug-induced cytotoxicity, off-target effects, and population-level variability. Their

genomic fidelity and 3-D architecture provide a robust platform for safety pharmacology and risk assessment. Ongoing expansion to include breast, glioblastoma, and ovarian cancer models will further strengthen translational toxicology and precision medicine efforts.

PS 4141 Primate NAMS : Development of Human and Cynomolgus Macaque iPSC-based Assay for *in vitro* Developmental Toxicity Evaluation of Protein Degraders

K. Kotok^{1,2}, F. Suchy^{1,3}, L. Brückner⁴, L. Ramirez^{1,3}, M. Nandi¹, N. Rapicavoli¹, P. Hewitt⁴, and M. Roodgar^{1,3}. ¹Exir Bio, Menlo Park, CA; ²San José State University, San Jose, CA; ³Stanford University, School of Medicine, Stanford, CA; and ⁴Merck Healthcare KGaA, Darmstadt, Germany.

Background and Purpose: Targeted Protein Degraders (TPDs), including Proteolysis Targeting Chimeras (PROTACs), represent a promising drug class capable of targeting otherwise "undruggable" proteins in cancer and other diseases. Despite their promise, developmental toxicity, including off-target toxicity remain key challenges, particularly degradation of critical developmental transcription factors such as SALL4, implicated in teratogenic outcomes associated with thalidomide analogs. Because of their close physiological and developmental homology to humans, nonhuman primates (NHPs) remain an essential animal model for evaluating developmental and drug safety profiles of TPDs. However, traditional *in vivo* NHP studies—particularly those involving pregnancy—pose significant ethical, temporal and financial barriers. To address this gap, we developed a New Approach Methodology (NAM) using Cynomolgus macaque (cyno) pluripotent stem cell model and a human pluripotent stem cell model to evaluate SALL4 degradation *in vitro*. These cross species, reporter based systems enable quantifiable, high content assessment of developmental toxicity prior to *in vivo* testing. **Methods:** Cyno and human pluripotent stem cells (PSCs) were first validated for SALL4 expression using immunocytochemistry and Western blot. We then generated SALL4-TdTomato reporter lines via AAV-mediated tagging of the SALL4 3' exon, enabling non-destructive, longitudinal tracking of protein degradation. Cells were exposed to known degraders (Thalidomide, Lenalidomide, and Pomalidomide) at varying concentrations. Degradation kinetics and EC₅₀ values were quantified via fluorescence imaging and proteomic validation using Data-Independent Acquisition (DIA) mass spectrometry. **Results:** SALL4 expression was robust and comparable across cyno and human PSCs. Both Western blot and reporter-based imaging confirmed dose-dependent SALL4 degradation following Thalidomide and Thalidomide analog exposure, with consistent EC₅₀ trends between species. Proteomic profiling verified SALL4 loss and revealed overlapping degradation signatures in cyno and human cells, supporting translational relevance of the model. Importantly, we observed that cell density influenced degradation efficiency, underscoring the value of dynamic, live-cell reporter assays over endpoint-based methods. **Conclusions:** This study establishes a scalable, ethically sustainable, cross-species NAM platform for evaluating developmental toxicity of TPDs. By integrating reporter-based readouts with global proteomics, our human-cynomolgus PSC system enables *in vitro* prediction of *in vivo* teratogenic risk, offering regulators and sponsors a translational bridge between human safety assessment and NHP data. The platform supports the 3Rs principles (Replacement, Reduction, Refinement) and provides a powerful preclinical tool for ranking compound safety prior to animal testing, further accelerating safer drug development of next-generation protein degraders.

PS 4142 The Utilization of *In Vitro*, Human on a Chip Cortical Networks to Assess Neurocognitive Impairment for Drug Safety and Efficacy

R. Brighton, and C. McAleer. Hesperos, Orlando, FL. Sponsor: J. Hickman

Background and Purpose: Currently, the methods for assessing disease pathology to improve the prediction of compound efficacy and safety for neurodegenerative disorders are limited to animal sources. In an effort to minimize the need for animals and improve biological accuracy of drug effects, there has been an impetus for developing *in vitro*, human-based models, particularly for modeling difficult-to-source, complex neural networks. The development and validation of human-based functional platforms would not only lead to accelerated timelines for preclinical drug assessment at a fraction of the cost of developing and testing animal models, but also emphasize the importance of employing functional readouts relevant to clinical diagnoses cases that can be supplemented with biomarker assessment. To achieve this, long-term potentiation (LTP), a widely accepted *in vitro* correlate for memory and learning, was employed as the main readout of synaptic function in this study. Utilizing microelectrode array (MEA) and human, induced-pluripotent stem cell (hiPSC) technology, this study sought to validate the use of hiPSC-cortical LTP for drug efficacy and safety studies of anticholinergic cognitive burden (ACB). ACB is currently diagnosed through amalgamated categories 0-3 on the ACB scale, which possesses gaps in its reflection of the complexity of ACB-induced dementia, and does not consider attributions of co-occurring network dysfunction, such as mild-cognitive impairment (MCI). **Methods:** LTP was evaluated as synapse-dependent, persistent enhanced activity following high-frequency electrical stimulation. To assess functional neurotoxicity, anticholinergics, drugs classified into subcategories for severity of ACB induction, were tested at five concentrations to generate dose-ef-

fect curves for LTP. Anticholinergics from all classes of severity were administered directly onto a central nervous system (CNS) MEA comprised of cortical neurons and astrocytes. To determine the potential of synergistic impairment of ACB and an MCI phenotype, the systems were acutely co-exposed to exogenous amyloid-beta42 (Aβ42) oligomers and anticholinergics at nominal concentrations. **Results:** Dose-response curves for ACB-induced neurocognitive detriment were established between ACB drug concentration and acute LTP maintenance. Concentrations of ACB drugs spanning 2 log scales produced sigmoidal curves when plotted using the Hill equation. Co-exposure of nominal concentrations of anticholinergics and Aβ42 oligomers confirmed the combination induced a significant exacerbation of cognitive impairment. **Conclusions:** Drugs from various groups, classified as inducing no, low, moderate, or severe ACB on the 0-3 ACB scale, respectively, were assessed independently to provide insight to potential inconsistencies with the current clinical scale. Parameters from the Hill equation and dose-response curves provided more granularity in quantifying cognitive deficits, suggesting the need for reevaluation of the current diagnostic scale. Additionally, evaluating the synergistic contributions of ACB and MCI, co-occurring implications to cognitive preservation, underscored the need for smaller-scale platforms to not only assess the complexity of neural network health, but also that could operate at a fraction of the cost and timeframe for evaluating drug efficacy and potential functional toxicity.

PS 4143 Energy Healing Dampens PFOA-Induced Stress Responses in Lung Alveolar Epithelial Cells

M. Thakur, and A. Amoliga. Southern University and A&M College, Baton Rouge, LA.

Background and Purpose: Perfluorooctanoic acid (PFOA), a persistent environmental pollutant, induces inflammatory and epigenetic alterations contributing to respiratory disorders. Reiki is widely practiced as a non-invasive complementary therapy to promote stress reduction and overall well-being, although robust experimental evidence for anti-inflammatory or epigenetic effects is limited in biomedical literature. This study investigates the effects of Reiki healing on PFOA-induced inflammatory responses. **Methods:** Human lung alveolar epithelial cells (A549) were divided into three groups: control, Sham Reiki (mock Reiki), and Reiki healing. Each group included a DMSO (control) and 100 nM PFOA (24h)-exposed sets. The Reiki healing group received four healing sessions (one in-person and three distant sessions of 10 min each) from a certified practitioner, while the Sham Reiki group underwent mock sessions mimicking the real Reiki, but without actual intent. The in-person sessions were observed and incorporated hand placements and symbolic practices. While the distant healing was performed remotely in three sessions, each separated by six hours. Inflammatory markers (e.g., NF-κB, STAT3, IL-17, NLRP3), epigenetic regulators (Polycomb Repressive Complex components), membraneless organelle markers (G3BP1, TIA1, DCP1A), cytokines and chemokine levels (IL-6, IL-8, CCL-2, CCL-5) were assessed using qPCR and ELISA. **Results:** PFOA treatment significantly elevated the studied inflammatory mediators and cytokine and chemokine production compared to the DMSO-treated group, in control and Sham Reiki groups. In contrast, PFOA exposure was unable to mount the expression of any inflammatory mediator, and cytokine/chemokine production in the Reiki healing group. **Conclusions:** Reiki healing demonstrably rescues PFOA-induced activation of inflammatory signaling, stress granule marker expression and altered epigenetic signatures in lung epithelial cells. These findings provide strong support for Reiki as a viable complementary strategy to reduce environmental pollutant-related lung inflammation/toxicity and highlight the need for further translational and clinical validation.

PS 4144 High Throughput Assessment of Barrier Function Using Human iPSC-Derived Brain Microvascular Endothelial Cells

R. Vaidyanathan, C. A. Savic, M. E. Donegan, D. J. Majewski, R. Fiene, J. Liu, and C. Carlson. FUJIFILM Cellular Dynamics Inc., Madison, WI.

Background and Purpose: The blood-brain barrier (BBB) is composed of specialized brain microvascular endothelial cells (BMEC) that serve to regulate the flow of substances into and out of the brain. BMEC have physical, transport, and metabolic properties that are regulated by other vascular, immune, and neural cells to create a tightly controlled microenvironment of the central nervous system. Understanding how BMECs work alone and in concert with these other cell types is essential to understand how the brain functions during health and disease. One of the key functional features of BMEC is barrier formation, and the strength and integrity of this barrier can be evaluated via measurement of the electrical resistance across the cell layer. In this study, the barrier function properties of human iPSC-derived BMEC were measured using different platform technologies, such as impedance and trans-endothelial electrical resistance (TEER). **Methods:** Human iPSC-derived brain microvascular endothelial cells (iCell® Brain Microvascular Endothelial Cells) and all media with supplements were from FUJIFILM Cellular Dynamics. These cells were differentiated similar to previously published protocols from an apparently healthy normal (AHN) male donor 01279. Development of TEER assays to measure the barrier function of BMEC were performed using 24-well or 96-well cell culture inserts (Corning) coated with Collagen-IV and Fibronectin (Sigma). Lucifer Yellow was used to measure permeability in these cell culture inserts. To increase the throughput of TEER measurements, iCell Brain Microvascular Endothelial Cells

were also plated on CytoView-Z plates and signal was recorded using the Maestro Z (Axion Biosystems). This technology monitors cell coverage (or confluence) as a resistance at high frequency (41.5 kHz) and a very sensitive TEER at a low frequency (1 kHz). These properties were monitored continuously over the course of 10 days. **Results:** Data from culture inserts demonstrated consistent TEER >1500 Ω·cm² measured using standard 96-well STX HTS EVOM™ Electrode. They also demonstrated low permeability to Lucifer Yellow on day 5 in culture. Culturing iCell Brain Microvascular Endothelial Cells on the CytoView Z plates enables measuring real-time traces of impedance over time and demonstrated lot-to-lot consistency of iCell Brain Microvascular Endothelial Cells with uncorrected TEER resistance values of ~3500 Ω at 140 hours. This assay was used to profile compounds in 384-well format (n=4 wells; 8-point dose-response curve) that are known to disrupt the barrier and decrease TEER after exposure to the cells, including bupropion, mannitol, prazosin, VEGF, and verapamil. **Conclusions:** Characterization of and testing with the individual cellular components that make up the blood-brain barrier (BBB) provides added insight to the functional aspects of this complex system. Human iPSC-derived BMEC offer a robust and reliable source of cells to interrogate the multiple properties of this specialized cell type.

PS 4145 Acute Polyamide Micro- and Nanoplastic Aerosol Exposure Alters Ciliary Motility in Primary Human Bronchial Epithelial Cells

M. Pavlovic, D. Lee, X. Jing, L. K. Gautam, S. Murthy, A. Adamcakova-Dodd, A. L. Ryan, and J. Kim. University of Iowa, Iowa City, IA.

Background and Purpose: Micro- and nanoplastics (MNPs, <5 μm), such as polyamides (PA), are increasingly detected in ambient air and human lung tissues, often carrying co-contaminants like lead (Pb). At the same time, an increasing incidence of chronic respiratory diseases was observed worldwide. However, MNP effects on mucociliary function remain poorly understood. We examined the acute effects of PA-12 and Pb-bound PA-12 aerosols on mucociliary integrity and function in primary human bronchial epithelial cells (HBECs) differentiated at the air-liquid interface (ALI). **Methods:** HBECs from three non-smoking female donors (mean age: 52 ± 24 years) were differentiated for 21 days at ALI, and exposed for 4 h to filtered air (FA), PA-12 aerosols (11.6 ± 0.5 mg/m³; geometric mean diameters-GMD: 0.3 μm and 3.7 μm), or Pb-bound PA-12 aerosols (11.4 ± 1.3 mg/m³; GMD: 0.3 μm and 3.7 μm). Following exposure, cells were incubated for an additional 40 h before assessment (post-aerosol exposure). Endpoints included cell viability, lactate dehydrogenase (LDH) release, mucus secretion (MUC5AC), ciliary beat frequency (CBF), ciliary length, and gene expression related to ciliogenesis (*FOXJ1*, *DNAH5*), epithelial signaling (*EGFR*), inflammation (*CXCL8*, *NFKB*), oxidative stress (*NFE2L2*), and mucus production (*MUC5AC*). **Results:** Neither PA-12 nor Pb-bound PA-12 aerosols significantly affected HBEC viability, LDH release, or MUC5AC secretion at 40 h post-aerosol exposure, indicating an absence of acute toxicity or mucus hypersecretion. In contrast, CBF exhibited a transient, statistically significant increase at 20 h post-exposure ($p < 0.05$) before returning to baseline at 40 h ($p < 0.001$). Cilia length remained stable ($7.1 \pm 0.8 \mu\text{m}$ at 40 h) and no statistically significant effect on gene expression were observed. **Conclusions:** Acute PA-12 aerosol exposure transiently enhances ciliary motility without inducing significant epithelial damage. This data suggests functional modulation of mucociliary clearance as a key early defense mechanism to acute exposure to inhaled MNPs. Further studies examining the effects of repeated exposures are necessary to elucidate long-term effects of MNP aerosol exposures on human airways.

PS 4146 Is there something simpler than EASZY for zebrafish estrogenicity detection?

A. M. Martini¹, R. Mirchandani², G. Jones³, E. Bianchi³, and M. B. Bondesson².

¹Corteva Agriscience, Newark, DE; ²Indiana University, Bloomington, IN; and ³Corteva Agriscience, Indianapolis, IN.

Background and Purpose: Early identification of estrogenic activity is essential in chemical development to prevent the advancement of endocrine-disrupting compounds and ensure regulatory compliance. While the OECD test guideline 250 (EASZY assay) provides a validated embryo-based screen for estrogen receptor (ER) agonists, it has limitations related to imaging complexity and tissue specificity. This project aims to develop a high-throughput transgenic zebrafish assay, using the transgenic 5XERE:GFP line to detect both ER agonists and antagonists. This approach enhances screening efficiency and provides mechanistic insights into estrogenic activity. **Methods:** Embryos from the Tg(5XERE:GFP) zebrafish line were exposed to five concentrations of each compound—17α-ethinyl estradiol, 17β-estradiol, 17α-estradiol, diethylstilbestrol, bisphenol A, flutamide, dexamethasone, dibutyl phthalate, pentachlorophenol, norethindrone, 4-tert-octylphenol, tributylchlorostannane, octamethylcyclotetrasiloxane—repeatedly at 3 and 4 dpf. At 5 dpf, the fluorescence of anesthetized larvae in 96-well plates was measured using a plate reader (Ex: 480 nm, Em: 509 nm), and data was used to determine the lowest concentration inducing GFP expression (lowest effect level; LEL). In addition, an estrogenic index was calculated as the ratio of the effective concentration causing 25% embryo mortality or malformation (EC25) to the LEL. **Results:** Estrogenic activity of the tested compounds was quantified using an estrogenic index, defined as the ratio

of the effective concentration (EC25) to the lowest concentration inducing estrogen receptor (ER) activation. Preliminary results showed strong concordance with established ToxCast ER model scores. Specifically, compounds such as TBTC, dexamethasone, dibutyl phthalate, flutamide, D4, and pentachlorophenol exhibited no ER activation. Bisphenol A and 4-tert-octylphenol showed intermediate activation, while potent ER activation was observed for 17 β -estradiol, 17 α -ethinyl estradiol, 17 α -estradiol, and diethylstilbestrol. **Conclusions:** Based on preliminary findings, the 5XERE:GFP zebrafish assay represents a compelling alternative to established estrogen receptor activity screening methods. It offers reduced hands-on time and accelerated data acquisition while maintaining high levels of accuracy and sensitivity. These attributes position the assay as a valuable tool for efficient and reliable endocrine activity assessment in early-stage safety evaluations.

PS 4147 High-Precision Neurotoxicity and Neuropharmacology Assessment in CNS Models Using Field Potential Imaging

N. Matsuda, N. Nagafuku, H. Kurashiki, B. Noda, and I. Suzuki. Tohoku Institute of Technology, Sendai, Japan.

Background and Purpose: A detailed understanding of neural circuit dynamics is essential for advancing drug discovery, neuropharmacology, and toxicity assessment. Recent advances in microelectrode array (MEA) technology, particularly the emergence of ultra-high-density CMOS-MEAs, now enable simultaneous recording of large-scale neuronal activity with single-cell resolution. This study aimed to establish a multiscale field potential imaging platform for central nervous system (CNS) models using a CMOS-MEA containing 236,880 electrodes. **Methods:** Human iPSC-derived cortical neurons, primary cultured rat hippocampal neurons, and acute rat brain slices (hippocampus and neocortex) were prepared on the CMOS-MEA. Electrophysiological activity was recorded before and after compound administration. Network-level and single-neuron parameters were quantified in iPSC-derived neurons. In rat primary neuronal cultures, network organization was further assessed using a graph theory-based connectivity analysis. In hippocampal-cortical slices, large-area recordings enabled mapping of region-specific activity propagation. **Results:** In human iPSC-derived cortical neurons, integrated analyses revealed previously inaccessible features of compound responsiveness, including modulation of synaptic strength and alterations in network bursting characteristics. In primary cultured rat hippocampal neurons, connectivity analysis demonstrated that pharmacological perturbation with picrotoxin and muscimol induced distinct reconfigurations of functional connectivity, accompanied by clear changes in firing patterns and propagation dynamics. These connectivity-based signatures identified shifts in excitatory-inhibitory balance that were not detectable through firing-rate-based metrics alone. In acute hippocampal-cortical slices, carbachol administration enhanced beta-band oscillatory power in hippocampal circuits and induced coordinated activity transitions in neocortical regions, demonstrating the system's ability to resolve drug-dependent changes in oscillatory activity and propagation dynamics *ex vivo*. **Conclusions:** Ultra-high-density CMOS-MEA-based field potential imaging enables multiscale characterization of CNS neural circuits across human iPSC-derived neurons, primary rodent neurons, and brain slices. Integrating high-resolution recordings with propagation-based and connectivity-based analyses provides a powerful framework for detecting subtle compound effects, dissecting neural circuit mechanisms, and supporting high-precision neurotoxicity evaluation.

PS 4148 Repeated daily exposure to acetic acid attenuates of the induction of *in vivo*-relevant *in vitro* markers of respiratory irritation in a donor-dependent manner.

E. A. Huber¹, H. Kellner¹, N. McNabb-Kelada¹, V. Vasukuttan¹, J. White¹, N. Sadekar², and S. D. McCullough¹. ¹RTI International, Durham, NC; and ²Research Institute for Fragrance Materials, Mahwah, NJ.

Background and Purpose: In addition to a range of industrial, commercial, and household applications, acetic acid is commonly found in personal care products where it is typically used to support fragrance stability, solubility, and pH control. It is also an essential component in the manufacturing of many floral and fruit scents used in fragranced products. Fragrance-related exposures to acetic acid via the inhalation route of exposure can occur during both the manufacturing of fragrances as well as the use of the finished product. In either case, exposures can occur daily. Here, we sought to define the effects of repeated daily exposures to a range of acetic acid concentrations across a battery of *in vivo*-relevant *in vitro* endpoints using a biologically complex air-liquid interface (ALI) model of the human nasal epithelium. **Methods:** Donor-matched differentiated primary human nasal epithelial cell (dphNEC)/primary human nasal fibroblast (pHNF) co-cultures (Epithelix MucilAir-HF Nasal) from five individual donors were exposed to a range of acetic acid concentrations daily for two hours for three or five days. The effects of exposures were evaluated for cytotoxicity, epithelial barrier integrity by trans-epithelial electrical integrity (TEER), ciliary beat frequency (CBF), percent active ciliated surface area (PACSA), apical release of mucin 5AC (MUC5AC), and basolateral secretion of the pro-inflammatory cytokines interleukin (IL)-8, IL-6, and tumor necrosis factor alpha (TNF α) over five daily exposures. **Results:** Acetic acid exposures resulted in mild cytotoxicity at 120 ug/cm² that peaked after the first exposure and was progressively attenuated

following repeated exposures. Epithelial barrier integrity was significantly increased following both Day 3 and Day 5 of exposures at 120 ug/cm² with greater TEER following Day 5 than Day 3. While CBF was not affected, PACSA was significantly reduced following treatment with 120 ug/cm² following both Day 3 and Day 5 exposures. Apical secretion of MUC5AC decreased following Day 3 and Day 5 exposures to 120 ug/cm² acetic acid. Secretion of IL-8, IL-6, and TNF α increased following the Day 3 exposure to 120 ug/cm². IL-8 and TNF α were increased to a lesser extent following Day 5 exposure and IL-6 was not significantly altered. While acetic acid exposures typically resulted in statistically significant contributions to observed variation in endpoint measurements, inter-individual differences also significantly impacted variation across all endpoints. TEER, CBF, MUC5AC secretion, and IL-6 release were affected more by inter-donor differences than acetic acid concentration. **Conclusions:** Considered together, the observations reported here indicate that repeated exposures cause an adaptive effect that results in the attenuation of induction of *in vitro* indicators of respiratory irritation such that the magnitude of exposure-induced changes following five exposures is lower than following three exposures. Thus, an increase in the number of exposures progressively reduced the ability of the tissue to respond to irritant insult, resulting in outcomes similar to those observed following repeated exposures to the respiratory irritant ozone in humans and animal models. These observations may also indicate that repeated acetic acid exposures result in tissue-level adaptation that involves loss of ciliated and goblet cells and remodeling of the epithelium in a manner that reduces its susceptibility to the cytotoxic and pro-inflammatory effects of repeated acetic acid exposures. This can be confirmed with histopathological analyses of the tissues. Further, the observation that contribution of inter-individual differences to the observed variation in endpoint data often exceeds that of a known irritant highlights the importance of improving our understanding of the role of donor variation in *in vitro* exposure outcomes. Accomplishing this will support the rigor of study designs, define key variables in the test system, and facilitate a more relevant understanding of how to extrapolate the outcomes of *in vitro* studies to the variable human population. Ultimately, gaining this understanding will support their safe and effective integration into product safety evaluation and regulatory applications.

PS 4149 Impacts of Exposure Method and Cell Type on Transcriptomic Concentration-Response Curves during Toxicological Screening of Respiratory Irritants

T. W. Jackson¹, M. Muraski^{1,2}, J. Herwick^{1,3}, J. Lewis^{1,3}, A. Ogunda^{1,3}, and J. R. Murray¹. ¹US EPA, Research Triangle Park, NC; ²ORISE, Oak Ridge, TN; and ³ORAU, Oak Ridge, TN.

Background and Purpose: There is a critical need to develop new approach methodologies (NAMs) to assess the health effects of inhalable substances. Proposed NAMs include several 2D or 3D lung cell culture systems at the air-liquid interface (ALI) exposed to chemical via direct liquid application (DLA) or via aerosol delivery with ALI exposure systems. *In vitro* inhalation NAMs have the potential to provide relevant, rapid toxicity data and points of departure (PODs) to be used in hazard assessments, but it is important to understand how the selected cell types, time points, or exposure methods may influence study outcomes. Assessment of gene expression changes using transcriptomics is a well-characterized tool for comparing activation of biological pathways across species and can be used to determine whether differential exposure methods of ALI airway cultures impact transcriptional concentration-response curves. Here, the effects of exposure on gene expression and biological pathways, transcriptomic biological pathway-altering concentration (BPACs), and transcriptomic PODs were evaluated following exposure to a compound known to cause respiratory irritation at the ALI and via DLA in organotypic and immortalized HBEC cell culture systems at multiple time points to characterize best practices. **Methods:** Organotypic (MatTek EpiAirway; differentiated primary human bronchial epithelial cells (dphBEC)) and immortalized human bronchial epithelial (16HBE) cells were exposed to multiple concentrations of an irritant case study chemical using both ALI and DLA approaches. ALI exposures were conducted with the VITROCELL Cloud α 12, and multiple apical volumes (10, 30, 50 μ L) were assessed. Cell lysates were collected at 6 and 24 h following exposures. The BioSpyder Tempo-Seq human whole transcriptome version 2 (hWTV2) assay was utilized and only gene probes with at least one read in at least 10% of samples were included. Differential gene expression was assessed using DESeq2 (absolute fold change $\geq 20\%$, false discovery rate < 0.05). Transcriptional benchmark dose (BMD) values at the probe level were calculated and aggregated to gene set and pathway level using BMDExpress3 (v3.20) software. The BPAC was calculated as median BMD for associated genes/pathways passing all filters in the most sensitive gene sets, with only gene sets containing at least 3 valid genes and 5 % gene set coverage retained in final analyses. **Results:** Exposure resulted in a concentration-responsive increase in number of differentially expressed genes (DEG) for all exposures. The absolute number of DEG varied across exposure system, cell type, and timepoint. Samples exposed at ALI generally had higher numbers of DEG than those exposed at any volume under DLA exposure conditions, but the specific genes and pathways were generally concordant. This study observed similar transcriptional reprogramming of DLA vehicle controls that has been reported previously for dphBEC-fibroblast co-cultures. This reprogramming appears to be volume-dependent and more pronounced in organotypic cultures. The BPACs and PODs identified in each condition varied across exposure systems, cell types, and timepoints, but were quite similar (< 5.5 -fold different). **Conclusions:** NAMs to screen inhalation hazards are a rapidly developing area, and

different exposure methods, cell types, and assessment timepoints are commonly utilized. The presented results characterize how these study variables impact transcriptomic concentration-response curves and demonstrate the need to characterize variables and harmonize study design to facilitate regulatory acceptance. [Abstract does not reflect views or policies of the U.S. EPA. Mention of specific technologies or companies does not represent endorsement by U.S. EPA].

PS 4150 Quantitative High-Throughput Screening Identifies Small-Molecule Inhibitors of Wnt/ β -catenin Signaling

X. Chen, S. Yang, S. Sakamuru, R. Sukhawanit, S. Wood, M. Ooka, R. Huang, and M. Xia. National Center for Advancing Translational Sciences, National Institutes of Health, Rockville, MD.

Background and Purpose: The Wnt/ β -catenin signaling pathway plays a pivotal role in development, cell fate determination, and tissue homeostasis. Aberrant activation of this pathway contributes to a wide range of human diseases, including cancer, fibrosis, and neurodegeneration. However, identifying small-molecule modulators has remained challenging due to pathway complexity and feedback regulation. In this study, we developed and optimized a T-cell factor/lymphoid enhancer-binding factor (TCF/LEF) β -lactamase reporter assay in a 1536-well format suitable for quantitative high-throughput screening (qHTS). **Methods:** A TCF/LEF- β -lactamase reporter HEK293 cell line was optimized to identify inhibitors of canonical Wnt/ β -catenin signaling. The assay, activated by Wnt-3a and R-spondin 2, was validated with known inhibitor imatinib mesylate. The compounds from the Library of Pharmacologically Active Compounds (LOPAC) and the Toxicology in the 21st Century (Tox21) collections were screened across multiple concentrations. Screening data were analyzed for potency and efficacy, and active compounds were confirmed through repeat testing and Western blot analysis of non-phosphorylated (active form) and total β -catenin levels. **Results:** The optimized assay exhibited strong performance with Z' factor of 0.58 ± 0.07 and signal-to-background ratio of 2.9 ± 0.17 . Primary screening against the LOPAC library identified 12 potential inhibitors, including 5 known and 7 previously unreported compounds, all of which were confirmed on retesting. Western blot analysis revealed that 6 of these compounds, including 5 known inhibitors (emetine dihydrochloride hydrate, tyrphostin A9, niclosamide, ouabain, and podophyllotoxin) and 1 unreported compound, reduced levels of non-phosphorylated β -catenin and total β -catenin, confirming inhibition of canonical Wnt signaling. **Conclusions:** This study established a robust qHTS-compatible reporter gene assay for discovering small-molecule inhibitors of Wnt/ β -catenin signaling. The identification of an unreported Wnt antagonist expands the repertoire of chemical tools available for studying pathway regulation and demonstrates the assay's utility for mechanism-based toxicology and drug discovery applications.

PS 4151 Impact of Chemical Quality on High-Throughput *In Vitro* Assays - A Tox21 Study

D. K. Ngan¹, L. Ye¹, J. Hsieh², T. Xu¹, J. Zhao¹, S. Sakamuru¹, D. Tao¹, C. A. LeClair¹, T. Zhao¹, A. Rossoshek¹, D. M. Reif², A. Simeonov¹, M. Xia¹, and R. Huang¹. ¹NIH/NCATS, Bethesda, MD; and ²NIH/NIEHS, Research Triangle Park, NC.

Background and Purpose: The Tox21 10K library has undergone analytical quality control (QC) testing after exposure to room temperature storage for 0 and 4 months (T0 and T4). Each chemical was previously assigned a QC grade based on purity, identity, and concentration. In parallel, the Tox21 10K library has been tested in ~80 *in vitro* assays in qHTS format, generating >120M datapoints to date. These data were used to analyze the correlation between chemical quality and bioassay activity, as well as chemical structure. The chemical characteristics of poor quality and unstable compounds were explored to identify structural features that should be avoided. A high-throughput assay measuring the induction of p53 activity by small molecules was used to test the Tox21 10K library at T0 and T4 to monitor compound stability. This study is the first attempt to systematically evaluate the impact of compound quality and stability on biological activity outcomes based on results from a large and diverse library. **Methods:** The Tox21 10K chemical library is an *in vitro* toxicology toolbox consisting of more than 8,900 unique chemical entities including environmental chemicals and drugs. Chemical structures were processed using the publicly available ToxPrint chemotypes (729-bit) generated within the ChemoType application and the Chemical Developer Kit (CDK) package (29 physicochemical properties) as implemented in KNIME. *In vitro* assay data of ~80 assays with 241 readouts were obtained from the Tox21 database (<https://tripod.nih.gov/pubdata/>). The p53 assay activities at T0 and T4 were compared using log AC₅₀ values. Statistical significance was determined by the Fisher's exact test for chemical features, the Student's t-test for physicochemical properties, and the Wilcoxon rank-sum test for log AC₅₀ value differences between T0 and T4. Machine learning models were built using the Random Forest method and model performance was evaluated by calculating the AUC-ROC. **Results:** The chemical characteristics of poor quality and unstable compounds were explored to identify structural features that should be avoided. In addition, one of the high-throughput assays measuring the induction of p53 activity by small molecules was used to test the Tox21 10K compound library at T0 and T4 due to its robust performance and reproducibility. Approximately 2% of compounds in the library showed a significant change in activity in the p53 assay between T0 and

T4 (active to inactive or vice versa), which also correlated with chemical stability. Here, machine learning models were constructed using bioassay data or chemical structure to predict poor quality (low QC grades at T0) and unstable (grade drop from T0 to T4) chemicals. Chemical structure was found to be highly predictive (0.75) of chemical quality and stability, whereas bioassay data was less predictive (0.66) but still showed better than random performance. **Conclusions:** A cell-based assay was utilized alongside analytical QC efforts to assess the stability of the Tox21 10K library, revealing time-dependent changes in assay activity that aligned with QC grade shifts. Comparative analyses showed that chemical quality has a significant impact on assay activity, and poor quality/degraded chemicals tend to be less active than the chemicals that passed QC. Machine learning models were used to analyze the impact of chemical quality and stability on bioassay activity, demonstrating that chemical structure was a good predictor of chemical quality. Chemical features of poor quality/unstable chemicals were identified, which can be used to guide future chemical selection and handling.

PS 4152 Evaluating Effects of Varying Serum Levels on *In Vitro* Disposition (IVD) and Partitioning of Per- and Polyfluoroalkyl Substances (PFAS) in Human Cell Models

C. P. Sumner¹, J. A. Harrill¹, M. DeVito¹, C. Willis¹, F. Harris², C. H. Christen¹, and B. A. Wetmore¹. ¹Environmental Protection Agency, Durham, NC; and ²Oak Ridge Institute for Science and Education, Oak Ridge, TN.

Background and Purpose: US EPA is developing *in vitro* new approach methods (NAMs) that efficiently evaluate bioactivity across a range of biological pathways and targets. Characterizing *in vitro* disposition (IVD), the distribution and binding of a chemical in microplate systems, is important for interpreting exposure and effects data generated by NAMs and informing *in-vitro-in-vivo* extrapolation (IVIVE). Despite increased acceptance of NAMs for risk prioritization, it is recognized that the nominal concentration is not always the concentration available to elicit an effect. This study explores the IVD and partitioning of 21 per- and polyfluoroalkyl substances (PFAS), selected to capture a range of carbon-fluorine (CF₂) chain lengths (C4-C14) and functional groups, in U-2 OS cells, a human osteosarcoma cell line model used for *in vitro* chemical testing, amenable to culture in varied concentrations of fetal bovine serum (FBS) to evaluate protein binding effects. We analyzed differences in PFAS cell partitioning in media containing 10%, 5%, or 0% FBS to determine its influence on chemical distribution *in vitro*. **Methods:** Three 96-well culture plates were used to assess the compartmental distribution of PFAS compounds after 24 hr of exposure. The media was transferred from two plates and tested for their PFAS concentration separate from the plastic. Therefore, the third plate containing cells was analyzed completely and served as a 100% representation of the PFAS concentration *in vitro*. Each well in the culture plates was spiked to contain a final concentration of 10 μ M of PFAS. Acetonitrile was used to crash the biological material and extract the PFAS from the plastic. Quadruplicate PFAS concentrations were analyzed from each plate using a Waters Xevo TQ-S micro-LC-MS/MS. Cell confluency 24 hours before and after dosing was quantified using an Opera Phenix Plus. Ionomycin served as a reference for cytotoxicity and DMSO as a vehicle control to confirm cell growth was not impacted by the PFAS. **Results:** Our study demonstrated the partitioning behavior of PFAS in *in vitro* microplate test systems across three serum levels depends primarily on CF₂ chain length. As the number of fluorinated carbons increased, the partitioning coefficient increased, attributing to lower concentrations of PFAS in the media compartment *in vitro*. There were no discernable trends nor evidence that functional group influenced PFAS plastic-media partitioning or concentrations in the media. Rather, the main driver seemed to be the CF₂ chain length. Additionally, linear regressions created using physicochemical properties dependent on molecular size all followed the same trends and were consistent throughout each serum level, suggesting that FBS did not have a significant impact on *in vitro* partitioning. However, cell-free media preparations had statistically higher concentrations of longer chain PFAS than media from the cell-based preparations, implying heightened chemical-cell partitioning. This trend was consistent with each serum level analyzed. Insolubility was only observed for the longest chain PFAS (>12 carbons) in serum free media, suggesting FBS allows chemicals to stay in solution. **Conclusions:** Our study provides important information to reduce knowledge gaps on PFAS IVD. Our findings advance understanding of how PFAS structural differences influence their behavior *in vitro*. Longer CF₂ chain lengths impact bioavailable concentrations *in vitro*, affecting NAM and IVIVE analyses. The lack of significance PFAS functional groups have on IVD can provide better insight on the administered equivalent dose (AEDs) for NAMs, since previous studies indicated sulfonated groups to have higher partitioning to membranes or polymers. Overall, there is a scientific knowledge gap on PFAS binding to various components of a cell-based *in vitro* test system in microplate format. Current use of NAMs estimating AEDs for PFAS is a conservative method using the nominal concentration to determine potency. Our study indicates that most PFAS have low partitioning out of the media, possibly reducing the free/bioavailable concentration of the chemical. *This abstract does not represent US EPA policy.*

A. Jurgelewicz^{1,2}, C. M. Willis¹, F. R. Harris^{1,2}, G. Byrd^{1,2}, D. E. Haggard¹, J. L. Bundy¹, L. J. Everett¹, A. Middleton³, S. Cable³, B. A. Wetmore¹, and J. A. Harrill¹. ¹US EPA, RTP, NC; ²ORISE, Oak Ridge, TN; and ³Unilever, Sharnbrook, United Kingdom.

Background and Purpose: Advances in new approach methods (NAMs) have led to more efficient, information rich, and cost-effective strategies for next generation risk assessment (NGRA). Two NAMs-based assays, high-throughput phenotypic profiling (HTPP) with Cell Painting and high-throughput transcriptomics (HTTr) with TempO-Seq, measure changes in cell morphology and gene expression, respectively, to inform hazard assessments. Notably, points of departure (PODs) can be derived from chemical bioactivity data from these assays for use in NGRA. In this study, both assays were conducted in a biologically diverse battery of ten human cell lines and results were evaluated in the context of an example NGRA application: bioactivity:exposure ratio (BER) analysis for chemical prioritization. Here, we assessed how the individual or combined use of both assays and the cell line battery affected the ability to flag chemicals with overlapping bioactivity and predicted human exposure potential. **Methods:** A total of 41 test chemicals found in drugs or consumer products were screened in ten biologically diverse human cell lines (ASC52Telo, CHON-001, CCD-18Co, HBEC3-KT, HepG2, hNP1, Ker-CT, RPTEC/TERT1, TeloHAEC, U-2 OS) using HTPP and HTTr. Each chemical was tested at 8 concentrations and were a priori assigned to a dose range based on available bioactivity data. The dose ranges were designated "HIGH" (0.1 - 300 μ M), "MEDIUM" (0.01 - 30 μ M), "LOW" (0.01 - 3 μ M), and "VERY LOW" (3x10⁻⁶ - 30 μ M). For each cell line x chemical combination, concentration-response modeling was performed to calculate phenotypic altering concentrations (PACs) in HTPP and biological pathway altering concentrations (BPACs) in HTTr. These *in vitro* PODs correspond to the lowest test chemical concentrations where biological perturbations are observed. PACs and BPACs were used as input for *in vitro* to *in vivo* extrapolation (IVIVE) using the htk R package to calculate human administered equivalent doses (AEDs). For BER analysis, AEDs were compared to estimated human exposure levels derived from the systematic empirical evaluation of models (v3) (SEEM3) model. A BER was calculated by taking the difference between an AED and SEEM3 exposure prediction, and chemicals were flagged for prioritization if a BER was less than three or if a negative BER was detected. **Results:** Chemical PODs in both assays varied widely across cell lines in response to drug-like chemicals in the VERY LOW dose band. In some cases, PODs ranged by multiple orders of magnitude across cell lines supporting that biological context (i.e. cell type) influences response to chemicals. While PODs between assays were largely within one order of magnitude of each other for each cell line x chemical combination, there were also cases where active hits were only observed in one assay. Due to the range of PODs and differences between assay observed, analysis was conducted to assess how BER results may be influenced by assay and cell line. Results supported that combined use of HTPP and HTTr provided the greatest level of biological coverage in comparison to only using information from either assay alone. Additionally, BER results using the full cell line battery flagged a greater number of chemicals than using a leave-one-out approach or when considering only one cell line in isolation. Using one cell line alone resulted in large variations in the number of active chemicals and flagged chemicals across the battery. In addition, the identity of the cell line driving the BER varied from chemical to chemical with each cell line being represented at least once. Therefore, BER results were not driven by a single cell line. **Conclusions:** Our results showed that using a cell line battery in addition to screening in both assays was a more comprehensive approach to BER analysis for chemical prioritization as compared to using a single cell type or either technology alone. Furthermore, using a cell line battery in screening can capture how biological responses to chemicals can be influenced by cell context, as observed with our POD comparisons, which may be missed by only screening in one cell line. *This abstract does not reflect the views or policies of the US EPA or Unilever.*

PS 4154 Use of Data Derived Extrapolation Factors to Reduce Uncertainty in Organophosphate Human Health Risk Assessments

J. Leonard, E. Mendez, C. Tan, D. Hoer, R. Loudon, J. Kidwell, J. Nguyen, and M. Perron. US Environmental Protection Agency, Washington DC, DC.

Background and Purpose: When conducting human health risk assessments for pesticides, it is important to recognize that pharmacokinetic (PK) and pharmacodynamic (PD) differences exist between animal models and humans and from person to person. To account for these interspecies and intraspecies differences, uncertainty factors (UFs) are applied to the point of departure; the point of departure is a dose or concentration not expected to lead to the most sensitive effect for a given route of exposure. A default value of 10X is most often given to each UF, which incorporates 3X each for PD and PK considerations, for a total of 100X. Refining these UFs based on robust data results in a more accurate evaluation of real-world risk estimates. The purpose of this study is to apply data derived extrapolation factors (DDEFs) to refine the UFs of organophosphates (OPs), a large group of insecticidal pesticides registered for a wide range of uses, including agriculture and public health pest control. OPs share a well-established mode of action (MOA) involving inhibition of the enzyme acetylcholinesterase (AChE), preventing the breakdown of acetylcholine and leading to neurotoxicity. This universally accepted MOA, along with the extensive

amount of data available for OPs, provides an opportunity to utilize *in vitro* data to generate DDEFs and utilize human relevant data to inform human health risk assessments for OPs. **Methods:** This study incorporates a new approach method (NAM) using animal and human enzyme *in vitro* kinetics data for 15 registered OPs and a positive control (parathion). Red blood cell AChE was collected from Sprague Dawley rats (3 pooled samples of 5 animals/sex) and from 18 human individuals of various age, sex, and ethnicity. Measurements were conducted every minute for 5 minutes at varying concentrations of each OP to determine the bimolecular rate constant. Absorbance for duplicate samples was measured via a spectrophotometric assay, and velocity of each reaction was calculated by determining the slope of plotted absorbance as a function of time. In addition, the longest time point of 5 minutes was used to estimate the concentrations leading to 50% of maximum enzyme activity (i.e., IC₅₀) across the dose-inhibition curve for each OP. Five model options were evaluated using a 3-parameter log-logistic dose-response curve consisting of the IC₅₀, upper limit, and slope of the curve. The most appropriate model was used to determine the species-specific IC₅₀ and the ratio of the rat-to-human IC₅₀ was used to estimate the DDEF and assess the PD differences between species. From the same dose-response curves, interspecies ratios were also calculated for other inhibitory concentrations (IC₁₀, IC₂₅, and IC₇₅) in a similar manner. **Results:** Interspecies PD DDEFs ranged from 0.42 to 1.60. Values could not be calculated for 2 of the tested compounds. While outlier or convergence issues impacted a minority of the analyzed OPs, the central tendency of the interspecies DDEFs was approximately 1. This finding was broadly conserved regardless of inhibitory concentration. For some tested chemicals, the width of the 95% confidence intervals indicates some uncertainty around interspecies ratios at each of the inhibitory concentrations, which could reflect inherent variability in the *in vitro* assays and study design, such as sample size or incubation duration, or interindividual differences. Generally, confidence intervals were narrow around point estimates as inhibitory concentration increased, reflecting lower variability between individuals at high treatment response levels. **Conclusions:** *In vitro* data supports reduction of an interspecies PD UF from 3X to 1X for all but 2 of the 16 tested OPs. This health protective approach considers minor variability observed across the data, the inhibitory concentrations evaluated, and the high degree of species homology in the enzymatic structure of rat and human AChE. Additionally, other data demonstrate that PK differences, such as metabolic clearance, primarily contribute to the differences in AChE activity between rats and humans, rather than PD. Refinement of the interspecies UF through application of NAMs provides opportunity to reflect more realistic human health risk estimates for OPs.

PS 4155 Screening Level Assessment of 1470 ToxCast Chemicals Across Nine Biologically Diverse Human Cell Lines Using the Cell Painting Assay

C. M. Willis¹, A. Jurgelewicz², F. R. Harris², G. Byrd², D. Haggard¹, and J. A. Harrill¹. ¹U.S. EPA, RTP, NC; and ²ORISE, Oak Ridge, TN.

Background and Purpose: New Approach Methods (NAMs) have the capability to support chemical risk assessment by characterizing bioactivity and potential hazards using human cell-based *in vitro* models. There are thousands of chemicals in the environment with insufficient or absent human health hazard data where evaluation with NAMs will be less expensive and more efficient than animal studies. In this study, a set of human cell lines from diverse tissues were screened using High-Throughput Phenotypic Profiling (HTPP) with the Cell Painting assay. High-throughput profiling assays, like HTPP, can characterize chemical bioactivity across a broad range of biological processes and molecular targets. Bioactivity points-of-departure (PODs), the chemical concentration where perturbations in cell morphology are first detected, derived from these data can be compared to human exposure estimates and help inform chemical risk assessment. The ability to run HTPP in combination with other bioactivity assays and computational methods has the potential to accelerate the pace of chemical risk assessments. **Methods:** HTPP is a high-content imaging assay that uses fluorescent labeling of organelles and automated image analysis to quantify changes in cell morphology. The cell line panel screened in this study was selected using a data-driven approach based on differences in baseline gene expression and consists of hTERT-immortalized cell lines (ASC52Telo mesenchymal stem cells, HBEC3-KT bronchial cells, Ker-CT skin keratinocytes, RPTEC/TERT-1 kidney cells, and TeloHAEC vascular cells), normal cell lines (CCD-18Co colon fibroblasts), and cancer cell lines (Huh-1 hepatocellular carcinoma, MCF-7 adenocarcinoma, U-2 OS osteosarcoma). In each cell type, a total of 1,470 unique test chemicals were screened at 8 different concentrations using either a 1/2-log₁₀ dose spacing or full log₁₀ dose space, assigned based on previously collected ToxCast high-throughput screening data. After a 24h exposure period, assay plates were stained, imaged and concentration response modeling was performed using the R package *tcplfit2* to determine phenotypic altering concentrations (PACs) for each chemical x cell line combination. Cell viability was evaluated using normalized cell counts (nCC) and treatments resulting in cytotoxic or cytostatic effects were excluded from downstream analysis. HTPP PAC values were further utilized for *in vitro* to *in vivo* extrapolation (IVIVE) using the R package *httk* to calculate human administered equivalent doses (AEDs). These AEDs were compared to human exposure estimates to determine a bioactivity-exposure ratio (BER) and flag chemicals for prioritization. **Results:** Ker-CT was found to be the most sensitive cell type with 873 total active hits. CCD-18Co were found to be the least sensitive with 486 active hits. In total, 412 chemicals were found to be active across all nine cell types tested

and 300 chemicals were found to be inactive. There were 1,120 chemicals that were found to be active in at least one cell type. A subset of chemicals found to be active in a single cell type exists for all cell types tested. Chemical PAC values were found to be either consistent across all cell types tested (<1 order of magnitude) or highly variable (>5 orders of magnitude), depending on the chemical x cell type combination. The cell types ASC52Telo, CCD-18Co, Huh-1, and U-2 OS were found to have increased sensitivity to glucocorticoid steroids. Evidence of metabolism was found with the Huh-1 liver cell line where both bioactivation of 3'-azido-3'-deoxythymidine (a left shifted PAC >2 orders of magnitude) and inactivation of multiple parabens and phthalates that were active in all cell lines except Huh-1. **Conclusions:** These results indicate that the bioactivity of some chemicals is dependent on the cell type being screened and should be considered during study planning. Molecular targets of cell lines are being examined as potential sources of PAC variability for some chemicals. Subsequent analyses will use HTPP PACs, IVIVE and human exposure estimates to flag chemicals for prioritization and demonstrate the capability of these NAMs for accelerating hazard identification and informing chemical assessments. *This abstract does not reflect the views or policies of the US EPA.*

PS 4156 Evaluating Respiratory Irritants using New Approach Methods: Harmonizing Key Study Design Variables for Air-Liquid Interface and Direct Liquid Application Exposures

J. R. Murray¹, M. Muraski^{1,2}, J. Herwick^{1,3}, J. Lewis^{1,3}, A. Ogunda^{1,3}, and A. M. Jarabek¹. ¹US EPA, Research Triangle Park, NC; ²ORISE, Oak Ridge, TN; and ³ORAU, Oak Ridge, TN.

Background and Purpose: New Approach Methods (NAMs) are increasingly used to assess the toxicity of inhalable substances, highlighting the need to optimize and harmonize exposure methods for airway cell cultures. While air-liquid interface (ALI) exposure systems preserve the physicochemical properties of inhalable chemicals and allow direct cell-toxicant interaction, they are often costly, low-throughput, and require specialized expertise. Direct liquid application (DLA) presents an attractive alternative to screen non-volatile chemicals because many challenges associated with aerosol delivery can be bypassed by directly applying a known amount of chemical in a liquid solution to the apical surface of ALI cell cultures. This study was designed to evaluate *in vitro* exposure parameters in support of building best practices to screen respiratory irritants using organotypic and immortalized human bronchial epithelial cell (HBEC) cultures. **Methods:** In the first phase of this study, MatTek EpiAirway tissues were exposed to a model respiratory irritant at the ALI using the VITROCELL Cloud or across a range of commonly utilized DLA volumes (10, 30, 50 μ L in 6.5 mm ALI inserts) to determine the effect of apical volumes on study outcomes. Exposures were then repeated with the lowest apical volume that maintained cell surface coverage (30 μ L) in differentiated primary human bronchial epithelial cells (dpHBEC) and immortalized 16HBE cell cultures to assess repeatability across multiple human donors and within cost-effective cell culture systems. Trans-epithelial electrical resistance (TEER), viability (ATP production), cytotoxicity (LDH release), and pro-inflammatory cytokine release were assessed at two timepoints (6, 24 h). **Results:** Both ALI and DLA exposures resulted in similar points of departure (PODs) when the most sensitive endpoints were compared. Cytotoxicity measured through LDH release was most impacted by exposure study design variables, especially at the 6 h timepoint. In general, observed differences between ALI and DLA exposures diminished at the 24 h timepoint. Notably, DLA exposures led to vehicle toxicities in a volume-dependent manner which supports the use of the lowest volume that achieves full cell coverage. Mass per surface area (μ g/cm²) is the most appropriate dose metric to report regardless of exposure method to enable *in vitro* to *in vivo* extrapolation. **Conclusions:** This study demonstrated the utility of ALI and DLA exposure methods to evaluate respiratory irritants and identified key study design variables that can be harmonized to increase repeatability of study outcomes. DLA exposures compare most favorably to ALI exposures at the 24 h endpoints compared to the 6 h measurements. Applied apical volume remains an important variable for DLA study designs and should be optimized across 6-, 12-, and 24-well formats. Application of 30 μ L in a 6.5 mm ALI insert was identified as the minimum volume that provided uniform cell coverage, and future studies should explore whether a shortened DLA submersion period reduces vehicle toxicities observed in organotypic ALI cultures (e.g., a 4 h liquid application, removal of applied material, and restoration of ALI conditions until the desired timepoint is achieved). Future studies would also benefit from direct measurements of cellular uptake to further refine dosimetry characterization across *in vitro* exposure methods. *[Abstract does not reflect views or policies of the U.S. EPA. Mention of specific technologies or companies does not represent endorsement by the U.S. EPA].*

PS 4157 Comparative Predictivity of Estrogen-Dependent Cell Proliferation Assays to In Vitro/In Vivo Reference Data

P. Sadrpour¹, S. G. Lynn², R. J. Bever², and S. O. Simmons¹. ¹US EPA, Durham, NC; and ²US EPA, Washington, DC.

Background and Purpose: To modernize and improve the efficiency of the Endocrine Disruption Screening Program (EDSP), computational models using data from high-throughput assays were developed. A key focus has been the estrogen receptor

(ER) agonist model—originally constructed from 16 ToxCast assays— which may be used in lieu of three EDSP Tier 1 assays, including the uterotrophic assay, an *in vivo* assay that assesses estrogen pathway agonism. Subsequent analyses revealed that a predictive ER model could be effectively streamlined to use as few as four assays, focusing on critical events in ER pathway activation: ligand binding, dimerization, transcriptional activation (ERTA), and proliferation. Some of the original ToxCast assays are no longer available or face practical implementation barriers; therefore, alternatives to these assays are being developed with the aim of building a new ER computational model comprised entirely of accessible methods. This study utilized 32 ER reference chemicals to compare five alternative cell proliferation methods to the original ToxCast proliferation assay (ACEA Biosciences), evaluating their ability to predict responses *in vitro* versus *in vivo*. **Methods:** Alamar Blue, CellTiter-Glo®, CyQuant™, and Hoechst quantify the increase in number of T47D cells by measuring cellular reduction, cellular ATP, DNA content, and nuclei counts respectively. BrdU incorporation identifies actively proliferating cells undergoing DNA synthesis. The 32 reference chemicals were tested from 0.1 pM to 100 μ M (final) in five replicate experiments. Responses were scaled 0% to 100% using the vehicle and estradiol control responses, respectively. Data were fit using the tcplfit2 R package constrained to one of three models- Hill, gain-loss, or constant with activity calls and half-maximal concentrations (AC₅₀) derived from the best fitting model. Activity calls and AC₅₀ data for the ACEA_ER_80hr ToxCast assay were retrieved from invitrodb (v4.3). The responses listed in OECD Test Guideline 455 (ERTA) were used for *in vitro* reference activity. *In vivo* reference activity was determined from uterotrophic data using only guideline-like studies with chemicals active in > 70% of studies classified as active, those active in < 30% classified as inactive and all others classified as equivocal. **Results:** For the 32 *in vitro* reference activities, each of the five alternative proliferation methods has lower balanced accuracies (67-81%) than ACEA (89%) due to lower specificities (43-71%) stemming from the misclassification of two chemicals - linuron and spironolactone. Of the 21 chemicals classified as active or inactive based on uterotrophic responses, Hoechst was more predictive than any other method (including ACEA) with a balanced accuracy of 68%. Kepone and methoxychlor were misclassified as inactive by most methods, while daidzein, ethylparaben and kaempferol were misclassified as actives by all methods including ACEA. AC₅₀ values for potent ER agonists like 17 β -estradiol were much lower (20 pM) in the alternative methods than ACEA (2 nM), but similar AC₅₀ values were observed for less potent agonists like bisphenol A. **Conclusions:** ER activation is sufficient to stimulate cell growth in some tissues; however, proliferation is a complex response to many competing factors. Reference chemicals selected based on ERTA activity may not be well predicted by cell proliferation assays if the chemical elicits other anti-growth responses and stimulates cell growth in an ER-independent manner. Reference chemicals selected based on uterotrophic response may not be well predicted in a cell proliferation assay due to the toxicokinetic differences between intact animals and cultured cells. Chemicals like kaempferol and butyl benzyl phthalate have opposing *in vitro* and *in vivo* activities. However, cell proliferation assays serve as a gateway between test methods that focus on ER mechanics (e.g., ERTA) and a complex *in vivo* response and thus are indispensable for any new ER computational model. The disparity in balanced accuracy between the ACEA and the alternative methods largely stems from a small number of false positives compounded by an imbalance in reference chemical composition (actives >> inactives). Of the alternative methods evaluated, Hoechst was the most predictive overall.

PS 4158 Predictivity Assessment of the Human Thyroid Microtissue Assay

K. E. Pereira^{1,2}, B. E. Foley³, M. Feshuk², S. Lynn⁴, and C. Deisenroth³. ¹ORISE, Oak Ridge, TN; ²US EPA/OCSP, Research Triangle Park, NC; ³former US EPA/ORD, Research Triangle Park, NC; and ⁴US EPA/OCSP, Washington, DC.

Background and Purpose: The U.S. Environmental Protection Agency (EPA) aims to evaluate and adopt new approach methods (NAMs) for screening endocrine disruptor chemicals, when appropriate. One NAM-based assay, the human thyroid microtissue (hTMT) assay, utilizes primary human thyrocytes in a 3D culture model to evaluate chemical effects on thyroid hormone synthesis. Previous work characterized the hTMT model, including qualification criteria for human thyrocyte selection, acceptance criteria for assay performance, and reference chemical benchmark doses (BMDs) for proficiency testing. While an interlaboratory validation study assessed the relevance, reliability, and transferability of the assay for a small reference chemical set, expanding the tested chemical space will aid in evaluating the predictive performance of the assay. The objective of this study was to assess the predictive accuracy of the hTMT assay by conducting a within-laboratory assessment with 49 test chemicals. **Methods:** A set of 49 chemicals were tested across six concentrations (0.001 - 100 μ M) in the standardized hTMT assay to evaluate disruptive effects on thyroxine (T4) synthesis. The chemical set comprised four previously established reference chemicals, and 45 chemicals curated by subject matter experts. These included known inhibitors of molecular initiating events (MIEs) within the thyroid adverse outcome pathway network, and inactive chemicals. A priori chemical classifications were established using previously published data on molecular and functional inhibition of thyroid MIEs, gland activity, and hormone composition, classifying 36 as positive (disruptive to T4 synthesis) and 13 as negative (non-disruptive). **Results:** Initial results from two of four experimental replicates demonstrated chemical-induced T4 disruption with BMDs ranging from 0.8 to 75.4 μ M. T4 disruptive activity and potencies of the reference chemical set (methimazole [0.31 μ M], 6-propyl-2-thiouracil [0.24 μ M], sodium perchlorate [0.25 μ M], and methomyl [non-disruptive]) were slightly outside of the range of established proficiency testing thresholds.

Because differences were within an order of magnitude and consistent with previous studies (e.g., interlaboratory validation), reference chemical results are considered to meet acceptance criteria. Assay performance measures for T4, for dynamic range (rS/B, 21.5 ± 11.9), precision (rCV, 4.4 ± 2.6), and screening quality (rZ' factor, 0.9 ± 00.4) also satisfy acceptance criteria. Collectively, these results demonstrate that technical proficiency was achieved and further support the robustness and reliability of the hTMT model. Among test chemicals, 24 of 36 were identified as true positives, where T4-disruptive activity was correctly matched to a priori positive classifications, and 11 of 13 were identified as true negatives, where non-disruptive activity was correctly matched to negative classifications. These outcomes were used to calculate predictive performance metrics: 67% sensitivity (ratio of true positives to all a priori positives), 85% specificity (ratio of true negatives to all a priori negatives), and 76% balanced accuracy (average of sensitivity and specificity, providing an overall measure of predictive performance). These results demonstrate acceptable predictive accuracy of the hTMT assay. **Conclusions:** Given the acceptable predictive accuracy and technical performance, this within-laboratory study supports the continued evaluation and advancement of the hTMT assay towards regulatory adoption and the implementation of NAMs in an improved screening paradigm for thyroid-disruptive chemicals. The views expressed in this presentation do not necessarily reflect the views or policies of the U.S. EPA.

PS 4159 In vitro Cardiac New Approach Methodologies Compared to Nonclinical Animal Studies and Clinical Repolarization Prolongation

N. E. Simpson, T. K. Feaster, K. Blinova, and N. Sadrieh. FDA, Silver Spring, MD.
Sponsor: B. Anson

Background and Purpose: The study evaluated human induced pluripotent stem cell-derived cardiomyocytes (hiPSC-CMs) as a non-animal new approach methodology (NAM) for assessing cardiovascular repolarization risk in drug development. The research compared hiPSC-CM data with traditional methods (hERG assays and animal studies), to determine if hiPSC-CMs could potentially support regulatory decision-making, aligning with FDA Modernization Act 2.0 goals. **Methods:** The study retrospectively analyzed Investigational New Drug (IND) applications submitted to FDA/CDER between 2020 and 2023, comparing hiPSC-CM studies using multielectrode array (MEA) and voltage sensing optical (VSO) platforms with hERG assays and *in vivo* non-rodent QT studies. The analysis focused on concordance between these methods and their ability to predict clinical QT prolongation risk. **Results:** Both hERG and hiPSC-CM assays showed similar concordance with clinical QT outcomes. hiPSC-CMs had accuracy (0.83) and likelihood ratios comparable to *in vivo* non-rodent QT studies (0.74-0.78). Both hERG and hiPSC-CM assays tested effects at higher exposure multiples than animal studies. **Conclusions:** hiPSC-CMs offer a promising alternative to extensive animal testing for cardiovascular risk assessment. However, limitations include small sample size, low prevalence of clinical QT True Positives, early-phase INDs, variability in hiPSC-CM study rigor, and challenges in establishing exposure-response relationships. Despite these limitations, this research provides evidence supporting the application of hiPSC-CMs for cardiovascular regulatory assessments. Further research is needed to establish robust protocols for integrating hiPSC-CM data into regulatory workflows, balancing the promise of reduced animal testing with the need for comprehensive safety assessment. **Disclaimer:** This abstract reflects the views of the author and should not be construed to represent FDA's views or policies.

PS 4160 Electrophysiological Evaluation of Fentanyl-Naloxone Combination using Human Neural New Approach Methodologies (NAMs)

C. Serna III, B. Bhardwaj, K. Blinova, and T. K. Feaster. FDA, Silver Spring, MD.
Sponsor: B. Anson

Background and Purpose: The FDA Modernization Act 2.0 has promoted the adoption of human-relevant models such as those using human induced pluripotent stem cells (hiPSCs) as new approach methodologies (NAMs) to reduce animal testing for pharmacological safety assessment. This study combines multielectrode array (MEA) technology with a neural co-culture derived from hiPSCs to characterize electrophysiological signatures resulting from opioid activation and antagonism as part of efforts to address the ongoing opioid epidemic through nonclinical central nervous system (CNS) drug interaction research. **Methods:** The neural NAM model we present is composed of hiPSC-neurons and hiPSC-astrocytes coupled with MEA which was used to assess the neural electrophysiology. Neural cells were treated with varying concentrations of fentanyl and naloxone following their plating onto the MEA platform. Spontaneous neural electrical activity was then continuously recorded for up to 1 hour using an Axion Maestro Pro to evaluate the functional effects. **Results:** Throughout the experimental window there was a display of robust networked electrical activity within the co-cultured neural population. When exposed to fentanyl and the combination (i.e., fentanyl and naloxone), the assay displayed a concentration-dependent modulation of neural electrophysiological activity relative to the vehicle control. Moreover, the combination mitigated the electrophysiological effects of fentanyl alone. The effects resulting from these drug interactions were

observed across spiking, bursting, and network bursting parameters which were used to characterize the degree and quality of hierarchical communication with the neural population. **Conclusions:** We demonstrate a capacity for this NAM to assess opioid and opioid antagonist interactions on a hiPSC neural population through the characterization of human networked electrical activity at baseline and following exposure to fentanyl, naloxone, and both in combination. Future studies will investigate additional CNS active compounds, polypharmacy, and reversal agents. As a whole, these data support the application of a neural MEA platform as a human *in vitro* model to assess the safety and efficacy of CNS active compounds. **Disclaimer:** This abstract reflects the views of the author and should not be construed to represent FDA's views or policies.

PS 4161 Neurotoxicity and Hepatotoxicity Testing in Organotypic Models as Part of a Tiered Screening Assessment for Force Health Protection

A. J. Keebaugh^{1,2}, L. M. Sweeney^{1,2}, T. Lalonde^{3,2}, T. R. Sterner^{3,2}, S. Hirway^{1,2}, and R. A. Clewell^{A2}. ¹BlueHalo, an AV Company, Dayton, OH; ²Air Force Research Laboratory, Wpaafb, OH; ³HJF, Wright Patterson Air Force Base, OH; and ⁴Eagle Integrated Services, Wright Patterson Air Force Base, OH.

Background and Purpose: Military personnel may be exposed to a variety of substances, many of which have limited data regarding health risks. A tiered screening strategy using new approach methods (NAMs) is being developed to expedite the assessment of health risks from poorly characterized substances. Initial tiers employ *in silico* and high throughput *in vitro* screening to identify potential modes of action. Higher tiers use biologically relevant organotypic models to generate points of departure (PODs) for quantitative risk assessment, with the goal of reducing the need for *in vivo* tests. To assess whether human equivalent doses (HEDs) derived from *in vitro* PODs from organotypic neurotoxicity and hepatotoxicity models are at least as conservative as *in vivo* PODs, nine organophosphates (OPs; chlorpyrifos [CPF], chlorpyrifos oxon [CPF oxon], diazinon, diazoxon, diisopropylfluorophosphate [DFP], malathion, malaoxon, tris (2-chloroethyl) phosphate [TCEP], tris(1,3-dichloro-2-propyl) phosphate [TDCPP]) and three carbamates (aldicarb, carbaryl, methomyl) were tested in a central nervous system organoid model (CNS-3D, 28bio). Six hepatotoxic chemicals (4-chlorobiphenyl [4-CBP], chlorobenzene, diazinon, diazoxon, TCEP, TDCPP) were assessed in liver microtissues (3DInSight, InSphero). **Methods:** In the CNS-3D model, acute and three-week repeat dose-response curves for OP and carbamate administration were generated for acetylcholinesterase (AChE) inhibition, viability, and intracellular calcium (Ca²⁺) flux. In the 3DInSight model, dose-response curves were generated for tissue viability, total glutathione, and triglycerides on day seven after dosing on days 0, 2, and 5. *In vitro* PODs were calculated as the benchmark dose lower confidence limits (BMDLs) for each assay. A high-throughput toxicokinetic (HTTK) model, adapted for the United States Air Force population, was used to predict lower 95th percentile oral HEDs (HED₉₅) from the *in vitro* PODs. In select cases, HEDs were also calculated using bespoke physiologically-based pharmacokinetic models. For each chemical, the lowest *in vitro*-derived HED₉₅ was compared to literature-derived *in vivo* PODs (POD_{Lit}). **Results:** AChE inhibition had the lowest HTTK HED₉₅ for most OPs and carbamates in the CNS-3D model acute testing, with values ranging from 0.0011 mg/kg for methomyl to 307 mg/kg for malathion. Sensitive acute dose-dependent responses were obtained for Ca²⁺ flux assays for carbaryl, DFP, CPF, and CPF oxon, with the lowest HED₉₅s (ranging from 0.001 mg/kg for CPF oxon to 0.038 mg/kg for carbaryl) derived from excitatory or inhibitory effects on the Ca²⁺ flux activity. More pronounced effects on Ca²⁺ flux burst strength and viability were measured after three-week exposures. Neurotoxicity HTTK HED₉₅s were generally similar to, or more conservative than, the POD_{Lit} values, with the exception of aldicarb (4-fold higher) and malathion (16-fold higher). Some PBPK HED₉₅s were comparable to HTTK HED₉₅s (aldicarb, chlorobenzene; within 2-fold), but others were much higher (diazinon/diazoxon, 50 to 200-fold) or lower (TCEP, 20-fold) than HTTK HED₉₅s. Liver microtissue testing also produced HTTK HED₉₅s that were comparable to *in vivo* values, with reduction in cell viability being the most sensitive effect for 4-CBP and TCEP, and alteration of glutathione levels being the most sensitive effect for diazinon, diazoxon, and TDCPP. **Conclusions:** The testing demonstrates the utility of using organotypic models in the later stages of a tiered approach that will support reasonable predictions of *in vivo* PODs in rapid assessments of novel or data-poor chemicals. HTTK HED₉₅s derived from organoids were at least as conservative as POD_{Lit} values when based on the most sensitive *in vitro* endpoint for each chemical, with exceptions of aldicarb and malathion, although they had HED₉₅s that were comparable to POD_{Lit} values in prior early tier testing. While the findings support that these NAM-based methods show promise for rapid risk assessment, work is continuing on their broader applicability and limitations, and for the diverse exposure scenarios encountered in military risk assessments. **Disclaimer:** No DoD endorsement implied.

PS 4162 Dose-response evaluation of lung injury in human reconstructed lung epithelium *in vitro* models following acute propylene oxide exposure

R. D. Devine¹, R. A. Moyer¹, S. N. Pearson¹, K. C. Hofacre¹, A. Gupta¹, A. J. Keebaugh², and R. A. Clewell^{3,2}. ¹Battelle Memorial Institute, Columbus, OH; ²Air Force Research Laboratory, Wright-Patterson AFB, OH; and ³Eagle Integrated Services, Inc., Wright-Patterson AFB, OH.

Background and Purpose: Assessment of health risks posed by chemical exposures is a fundamental component of force health protection. Novel approaches are needed to support timely, defensible operational decisions, particularly with regard to use of new chemicals/materials or their byproducts in emerging technologies. While *in vitro* and *in silico* methods for chemical testing have advanced tremendously over the last decade, *in vitro* methods for respiratory toxicity are not nearly as well-studied as other portal of entry effects. Here, we tested multiple key events for lung injury in an established reconstructed human airway *in vitro* model and compared the dose-response results to *in vivo* data to evaluate the utility of the *in vitro* model for testing reactive gases in support of health risk assessments for novel chemicals. **Methods:** EpiAirway™ cells were exposed at the air-liquid interface to propylene oxide (PrO) for four hours at concentrations of 0, 354 ± 3.3, 756 ± 4.1, or 1250 ± 7.0 ppm (mean ± standard deviation) in a VITROCELL® 24/48 exposure system. Initial range-finding studies were used to identify the three PrO concentrations used in the definitive study. The vapor generation system used compressed PrO gas metered via a mass flow controller, diluted with temperature/humidity-controlled filtered air (36.2 ± 0.2°C, 86 ± 0% relative humidity) and transported to the VITROCELL® chamber via heated Teflon lines. Exposures were monitored with an on-line Total Hydrocarbon Analyzer with a Flame Ionization Detector that was calibrated to known PrO concentrations. Trans-epithelial electrical resistance (TEER) was measured pre-exposure, immediately following, and 22 ± 2 hours post-exposure. Tissue histology, cytotoxicity (measured by lactate dehydrogenase, LDH, and adenylate kinase, AK), inflammatory cytokines, and the ratio of reduced to oxidized glutathione (oxidative stress marker) were also evaluated post-exposure. **Results:** Two range-finding studies demonstrated dose-dependent increases in markers of cell death (LDH, AK), and morphological changes at 900 ppm. In the definitive exposure studies, 1250 ppm PrO caused a significant decrease in TEER immediately after exposure, which continued to decline 22 hours post-exposure. Increased PrO concentrations were associated with increased cytotoxic protein marker expression; the AK assay demonstrated greater sensitivity than LDH. At 1250 ppm PrO exposure, microscopic signs of barrier stress (mucus production, cell rounding, cilia loss, cell loss) were affected immediately after exposure and worsened after 22 hours. Cytokine analysis revealed increased production of the pro-inflammatory and immune cell recruitment cytokines IL-6, IL-1α, and IL-1β. The reduced to oxidized glutathione ratio also decreased at 1250 ppm, indicating increased oxidative stress at 22 hours post-exposure. In summary, no effects were seen at 350 ppm and only the most sensitive effects were perturbed (e.g., AK-indicated cytotoxicity, cilia loss) at 750 ppm. All endpoints were altered at 1250 ppm PrO. **Conclusions:** This work successfully developed and characterized an *in vitro* air-liquid interface respiratory toxicity testing strategy with PrO. EpiAirway™ tissues exposed to PrO demonstrated a concentration-dependent increase in cytotoxicity, barrier stress, cytokine production and oxidative stress in human bronchial reconstructed airway models. The EpiAirway™ model demonstrated responses that were qualitatively and quantitatively consistent with acute inhalation toxicity studies in animals, which report lethality with marked respiratory effects starting at similar concentrations (1000-4000 ppm). The data collected in this study demonstrates the utility of the EpiAirway™ model to identify acute lung injury from a reactive gas at *in vivo*-relevant doses. This work is part of a larger suite of studies aimed at developing a rapid risk assessment process for novel and poorly tested chemicals, to improve force health protection and warfighter readiness. **Disclaimer:** No DoD endorsement implied.

PS 4163 Accelerating Organoid Adoption as a NAM with New Non-Toxic Dyes that Deliver Comprehensive Insights

F. Lavoie-Perusse¹, M. Bjoras², M. Camara Quilez², J. Ye², and M. Stanon³. ¹Saguaro Biosciences, Quebec, QC, Canada; ²NTNU, Trondheim, Norway; and ³Opal Therapeutics, San Francisco, CA. Sponsor: C. Mitchell

Background and Purpose: The U.S. FDA and NIH are actively promoting New Approach Methodologies (NAMs) like organoids to reduce reliance on animal models, which often fail to predict human-relevant efficacy and toxicity. However, the successful adoption of organoids requires technologies capable of probing these sensitive models in a standardized and reproducible way, but also in their native, unperturbed state for optimal data capture. To address these challenges, we present a live-cell imaging approach with NucleoLIVE™ and MortaLIVE™. This new approach not only allows for real-time assessment of organoid health and response to treatments, but also for reproducible and accurate biological data capture through uniform dye penetration of 3D cultures, and the non-toxic nature of these dyes. **Methods:** NucleoLIVE™ and MortaLIVE™ were used for viability and cytotoxicity assessment in human organoid models. These dyes are two non-toxic dyes, one for nuclear staining and the other for live-dead evaluation, which were applied to heart, retinal, and brain organoids under hypoxic stress, and to endometrial organoids for preclinical toxicology screening of known therapeutics (e.g., Relugolix, Stauroporine, Tamoxifen).

Results: Our imaging studies demonstrate that these non-toxic dyes provide a robust and data-rich solution for viability assessment in 3D models. In hypoxia studies, the dyes successfully detected elevated cell death and stress. In endometrial organoids, the assay effectively distinguished between compounds with high (Stauroporine), moderate (Relugolix), and minimal (Tamoxifen) cytotoxicity. Notably, this live-cell platform was sensitive enough to identify a potential dose-dependent, off-target toxicity from Relugolix, highlighting the assay's sensitivity for detecting specific toxic thresholds. The non-toxic nature of the dyes further allowed deep staining of 3D structures, enabling optimal data capture from these valuable organoid models. **Conclusions:** By providing a reproducible and data-rich assay that's ideally suited for organoid cytotoxicity evaluation, NucleoLIVE™ and MortaLIVE™ non-toxic live-cell dyes are a critical enabling technology platform that promises to accelerate the regulatory adoption of organoids as a NAM.

PS 4164 Quantitative Assessment of Mitochondrial Toxicity in Liver Organoids Using the Seahorse XF Mito Tox Assay and XF Flex Organoid Microplate

Y. Kam, L. Winer, and N. Romero. Agilent Technologies, Inc, Lexington, MA. Sponsor: Y. Kam, American Association for Cancer Research

Background and Purpose: Drug-induced liver injury (DILI) is a major challenge in drug development and safety assessment, and mitochondrial dysfunction is a key mechanism underlying it. Liver organoids—3D structures derived from pluripotent stem cells or primary liver tissue—offer a physiologically relevant model that better recapitulates liver architecture, cellular heterogeneity, and metabolic function compared to traditional 2D hepatocyte cultures or animal models. This study demonstrates the application of the Seahorse XF Mito Tox assay for quantitative evaluation of mitochondrial toxicity in liver organoids using the newly developed XF Flex organoid microplate. **Methods:** The XF Mito Tox assay quantifies mitochondrial toxicity through the Mito Tox Index (MTI), which distinguishes between inhibition and uncoupling of the electron transport chain. MTI is a normalized, unitless metric that enables reproducible comparisons across different culture formats. While previous applications of the XF Mito Tox assay focused on 2D models (e.g., HepG2, primary hepatocytes, HUREL co-cultures), its use in 3D matrix-embedded organoids was limited due to incompatibility with plate formats. The XF Flex organoid microplate overcomes this barrier, supporting matrix-embedded organoid culture and real-time mitochondrial respiration measurements. **Results:** Using mouse hepatic organoids, we evaluated four model hepatotoxic drugs known to impair mitochondrial function. The assay successfully quantified mitochondrial toxicity and demonstrated full compatibility with the organoid format, confirming the utility of the XF Flex organoid microplate for drug safety screening. **Conclusions:** This study introduces the XF Mito Tox assay as a robust and reproducible platform for assessing mitochondrial toxicity in liver organoids. The integration of the XF Flex organoid microplate expands the assay's applicability to 3D culture systems, enhancing its relevance for predictive DILI screening in preclinical drug development.

PS 4165 Evaluation of RNA preparation for Induction Studies in Primary Human Hepatocytes in 2D and 3D Formats

L. Mier. Thermo Fisher Scientific, Austin, TX.

Background and Purpose: Spin-column RNA purification is widely used for hepatocyte CYP450 induction assays but adds handling steps that could affect recovery. We assessed whether an extraction-free direct-lysis approach (TaqMan™ Cells-to-CT™ HepatoExpress™; Thermo Fisher Scientific) produces induction results comparable to spin-column-purified RNA across common hepatocyte culture formats. **Methods:** Primary human hepatocytes were cultured in 24-well and 96-well plates and as 3D spheroids. Induction experiments were performed under standard conditions. For each condition, we collected triplicate biological samples and ran duplicate technical RT-qPCR replicates. RNA was prepared either by direct lysis (Cells-to-CT HepatoExpress) or by spin-column purification. Expression of CYP1A2, CYP2B6, and CYP3A4 was quantified by qRT-PCR; fold-change was calculated relative to matched vehicle controls and normalized to internal reference gene, GAPDH. Method- and format-related differences were compared within each dataset using the 2^{-ΔΔCT} method. **Results:** Across both 96-well and 24-well plating formats, induction measurements obtained from direct-lysis preparations were comparable to those from spin-column RNA for all three genes. A plate-format effect was observed: 24-well cultures displayed slightly greater induction than 96-well cultures under otherwise matched conditions for some of the CYP genes. In primary hepatocyte spheroids, direct-lysis and spin-column preparations yielded comparable expression results. **Conclusions:** Within the conditions tested, a direct-lysis, extraction-free RNA preparation produced RT-qPCR induction readouts comparable to spin-column RNA in primary human hepatocytes, including 3D spheroids. The modest increase in induction observed in 24-well versus 96-well plates indicates that culture format can influence induction magnitude and should be considered when comparing studies.

Background and Purpose: Regulatory agencies are interested in assessing the potential toxicity of surfactants due to their use in consumer products, including household cleaners, personal care items, and pharmaceuticals. Inhalation is one of the routes by which human exposure to these chemicals can happen. To evaluate the respiratory toxicity of these chemicals, a normal human bronchial epithelial cell line (BEAS-2B), and two reconstructed human respiratory epithelium (RHRE) models—a bronchial (MucilAir, Epithelix), and an alveolar model (^hAECS; AlveoliX)—were exposed to two surfactants: oleoyl sarcosine and Triton X-100. **Methods:** The biological systems were treated with the two surfactants by pipetting (30 µL, 100 µL/cm²), either as a single (in BEAS-2B, MucilAir, and ^hAECS) or as repeated exposures (MucilAir only). For single exposures, five concentrations of the two surfactants were tested for 24 hours. Cellular effects were evaluated approximately 24 hours after, and after recovery periods of 3 days (^hAECS) and 7 days (MucilAir). For repeated exposures, MucilAir tissues were exposed to three concentrations of the two surfactants for 4 hours daily (with 20 hours of recovery between exposures) consecutively for 4 days. Cellular effects were assessed each day after exposure (~4 hours) and 7 days after the last exposure. Cellular effects assessed included cytotoxicity (lactate dehydrogenase release) and cell viability (PrestoBlue assay) for all three systems. Secretion of interleukins (IL-6 and -8 (CXCL-8; MSD V-Plex Assay) was assessed for BEAS-2B and MucilAir. Barrier integrity, using transepithelial electrical resistance (TEER), was measured for MucilAir and ^hAECS. Cilia beat frequency (CBF), average active area (AAA), and histology were assessed for MucilAir. **Results:** In BEAS-2B cells, a concentration-dependent decrease in cell viability was observed after single exposure to oleoyl sarcosine and Triton X-100, with higher concentrations of Triton X-100 needed to cause toxicity. A concentration-dependent increase in IL-6 and CXCL-8 was observed for both surfactants. In MucilAir tissues, single exposure to the two surfactants elicited concentration-dependent effects. At the two highest concentrations, both surfactants caused a marked reduction in cell viability and barrier integrity, and increased cytotoxicity, confirmed by histology showing partial to complete cell layer destruction. At the middle concentration, viability remained unaffected, but cytotoxicity increased and TEER dropped markedly for both chemicals. TEER recovered after 7 days, though oleoyl sarcosine still showed slightly reduced viability. In ^hAECS, viability decreased after exposure to either surfactant in a dose-dependent manner, but more prominently for oleoyl sarcosine. Barrier integrity was completely abolished in cells treated with oleoyl sarcosine and showed long-lasting effects. For Triton X-100, there was a concentration-dependent decrease in barrier integrity that recovered over time. In the repeat-dose assessment, both surfactants showed a concentration-dependent decline in MucilAir barrier function after the first exposure. For oleoyl sarcosine, this trend persisted with repeated dosing. For Triton X-100, after a drop on day 1, differences between treated and control groups were less pronounced over time. **Conclusions:** BEAS-2Bs and ^hAECS responded similarly and were generally more sensitive to surfactant exposure than MucilAir tissues, particularly in terms of decreased cell viability and barrier integrity. Except for single exposure in MucilAir, oleoyl sarcosine was typically more toxic than Triton X-100 and caused longer-lasting impairment of barrier integrity in MucilAir and ^hAECS. The results from this work were used to inform a multi-laboratory study, the goal of which is to establish a standardized test method that can be used to help meet regulatory needs related to inhalation toxicity.

PS 4167 **Aerosol Application for Prediction of Respiratory Toxicity using a Human Airway Model**

M. McElroy¹, J. Wallace¹, B. Stobbs¹, A. Marshall¹, J. Baily¹, R. Boni¹, M. Klausner², and S. Ayeahunie². ¹Charles River Laboratories, Tranent, Edinburgh, United Kingdom; and ²MatTek, Ashland, MA. Sponsor: S. Letasiova

Background and Purpose: Traditional *in vivo* inhalation toxicology studies are costly, require large numbers of animals, and often fail to translate effectively to human outcomes due to anatomical and physiological disparities between animal and human respiratory systems. Consequently, there is growing interest in human-relevant *in vitro* models for assessing inhalation toxicity. Human lung organotypic cultures are currently being used to assess direct toxicity of inhaled chemicals in a case-by-case basis. However, the absence of an OECD guideline limits their broader regulatory adoption. Establishing such a guideline would provide a standardized framework and promote regulatory acceptance of these models. The objective of this project is to develop an *in vitro* inhalation toxicity screening protocol for risk-based decision making. We show that an EpiAirway™ protocol has the potential to allow prediction of human hazard classifications for acute inhalation risk by applying chemicals directly to the epithelial surface at the air liquid interface in solution or suspension. We also re-evaluate a subset of chemicals using aerosol exposure to determine whether the mode of application influences the resulting toxicity profiles. **Methods:** A panel of ten chemicals with known inhalation point-of-contact toxicity, spanning a range of toxicities and mechanisms of action, were tested using the 3D

human EpiAirway™ tissue model. Acute exposures were performed by applying the test materials directly to the epithelial surface for 4 h, followed by a 20 h recovery period, according to a harmonized protocol conducted in parallel at Charles River Laboratories (CRL) and MatTek. A subset of 4 chemicals were subsequently tested using aerosol conditions with a Vitrocell 12/12 Continuous Flow Exposure System (CRL only). Flow rates, temperatures and humidity of aerosols were closely regulated and continuously monitored. Barrier integrity (TEER), cell viability (AlamarBlue) and morphology changes (H&E staining) using AI analysis algorithms (Visiopharm) were used as endpoint measurements. The drc package R was used to curve fit data, calculate EC₁₀ values (the dose required to reduce a response by 10%), and compare results from the 2 laboratories. **Results:** Comparable results were obtained between laboratories with p values of >0.05 and <2.5-fold difference denoting no biological relevance of differences. EC₁₀ generated from direct application to EpiAirway™ successfully ranked the chemicals in order of UN GHS inhalation hazard. Compounds producing EC₁₀ < 5 mg/mL for TEER or viability endpoints (e.g., potassium dichromate) corresponded to the highest hazard categories, whereas chemicals with EC₁₀ values exceeding the maximum testable concentration (e.g., lactose) were classified as non-hazardous. Samples exhibiting TEER < 50 Ωcm² generally lacked sufficient structural integrity for histological analysis. For analyzable tissues, concentration-dependent morphological alterations were evident for both labs (quantitative image analysis by Visiopharm). Aerosol application of vehicle (humidified air) did not significantly alter TEER or viability compared to incubator controls (P>0.05: one way ANOVA). Furthermore, when normalized to surface area dose (µg/cm²), the dose-response relationships obtained from aerosol exposures closely aligned with those from direct applications. **Conclusions:** These findings demonstrate that this tiered *in vitro* testing strategy shows strong potential for predicting human acute inhalation hazard classifications. The approach represents a key step toward developing a predictive, risk-based testing framework for aerosolized chemicals. The broader research program aims to establish an integrated *in vitro* protocol capable of supporting regulatory decision-making for inhalation risk assessment. This initiative directly supports the global regulatory objective of replacing animal testing with scientifically robust, translatable, and cost-efficient alternative methods. This work is funded by the American Chemistry Council's Long Range Research Initiative.

PS 4168 **prophECG: An AI-Enabled, Single-Cell, Multiplexed Kinetic Image Cytometry-based Cardiotoxicity Screening NAM for Extracting Actionable Clinical Insights from Human iPSCs in Early Drug Development**

R. C. Basa¹, R. S. Ingemanson¹, F. Catalan-Perez¹, C. Handley¹, L. Harrison¹, J. M. Hilton¹, P. M. McDonough¹, I. Sanchez², R. Serrano², A. Smith¹, A. Wang¹, M. Mercola^{2,3}, and J. H. Price^{1,4}. ¹Vala Sciences, Inc., San Diego, CA; ²Stanford Cardiovascular Institute, Stanford, CA; ³Department of Medicine, Stanford University, Stanford, CA; and ⁴Scintillon Institute, San Diego, CA. Sponsor: R. Basa, American Association for the Advancement of Science

Background and Purpose: Cardiotoxicity (CTox) remains a leading cause of clinical trial failures, post-FDA approval drug withdrawals, and post-market adverse drug reactions. Traditional preclinical CTox studies rely on animals and are costly and laborious, yet still poorly predictive of clinical outcomes. Here, we present the latest iteration of "prophECG": a new approach method (NAM) that leverages multiplexed Kinetic Image Cytometry (KIC) of human iPSC-cardiomyocytes (hiPSC-CMs) to obtain functional readouts (calcium transients [Ca], action potentials/membrane voltage [V], and motion/contraction [Mot]) which are used to calculate margins of safety (MoS=EC₂₀/effective therapeutic "free" concentration [ETPC₁]) for rank-ordering the relative CTox of test compounds. We further use a fully-explainable, white-box AI approach to amplify the utility, scale, and holistic clinical predictivity of our *in vitro* hiPSC-CM KIC model. **Methods:** We loaded hiPSC-CMs with Cal-520 (for Ca), BeRST-1 (for V), TMRM, and Hoechst. After acute drug exposure, we used Vala's IC200-KIC automated microscope to acquire videos of interleaved Ca and V images at 30 Hz/channel (60 Hz overall), along with static images of TMRM and Hoechst. Our proprietary image analysis software, CyteSeer, extracted single-cell waveforms and transient data (Ca & V, separately; and Mot derived from both Ca & V), from which >200 measurements each for Ca (255), V (255), and Mot (233) were obtained. The prophECG platform characterized compound-induced effects in 25 manually-curated measurements empirically correlated with 6 clinical E/ECG classes. Torque clustering (TC) was then employed to classify all >200 measurements from each readout to further augment and expand on our 6 pre-defined classes. **Results:** In a previous validation study, our assay predicted the clinical outcomes of 30 out of the 31 drugs we tested (96.8% predictivity). We also previously compared our *in vitro* results with E/ECG readouts to group 25 kinetic measurements into 6 empirical classifications, corresponding to: 1) heart rate (HR), 2) the QT interval, 3) the QRS complex, 4) TU (early/delayed afterpolarizations [EADs/DADs] and triangulation), 5) rhythm (Rhy, including severe arrhythmias, e.g., alternans and cell-cell asynchrony), and 6) arrest (Arr). In the present study, we added 34 compounds to the validation set (for a total of 65, spanning varying degrees and mechanisms of CTox). We generated a (preliminary) rank-ordering of these 65 compounds according to overall CTox and by subclasses of CTox, along with CTox "fingerprints" illustrating at-a-glance relative CTox risk across the 6 E/ECG categories as a function of the calculated MoS in each class. Unsupervised clustering via TC of all >200 measurements/readout yielded 19-23 classes of measurements. Comparing our 6 empirical classes from 25 curated measurements to the TC-generated classes revealed some expected

overlap, but also implied the existence of “hidden” subclasses and/or unexpected interplay between measurements. We posit that fully comprehending the underlying relationships amongst the measurements and classes will help elucidate causal mechanisms of action/toxicity. **Conclusions:** Our single-cell approach captures cellular heterogeneity that may be obfuscated by other whole-well/-field *in vitro* platforms, leading to higher sensitivity and thus predictivity. By using explainable AI (via TC), we are working towards causal models that exploit the data-richness of prophECG to move far beyond existing single-target cardiosafety paradigms (e.g., CiPA, for *hERG*) to give a more comprehensive view of CTox through a single NAM. We envision further scaling to “Clinical Trials-in-a-Dish” to de-risk drug portfolios early in the development process to subvert the pitfalls of traditional animal testing.

PS 4169 Replacing animal testing in local tolerance assessment of an injection device: Human *ex vivo* HypoSkin model as a New Approach Methodology (NAM)

J. Argenty¹, C. Letzelter¹, C. Marques¹, S. Abadie¹, A. Sanchez¹, C. Gendrin¹, A. Ochando¹, A. Rock², R. Byrne², P. Descargues¹, and N. Bertollo². ¹Genoskin, Toulouse, France; and ²Pharma Latch, Dublin, Ireland. Sponsor: A. Ochando Descargues, EUROTOX

Background and Purpose: Local tolerance testing of medical devices and injectable formulations is critical to ensuring patient safety and regulatory compliance. In line with current regulatory trends promoting New Approach Methodologies (NAMs) for non-animal safety assessment, human-relevant *in vitro* and *ex vivo* platforms are being increasingly adopted to improve translational predictivity. However, conventional preclinical systems often fail to replicate the complex immune and structural features of real human skin, particularly in the context of intradermal delivery. HypoSkin®, an *ex vivo* human skin platform that preserves native immune cell populations and tissue architecture, provides a NAM-aligned solution for assessing local tolerance and immunoreactivity. In this study, HypoSkin® was used to evaluate the impact on tissue and immune response following intradermal injection using an innovative fixed-depth and fixed-angle delivery device, in comparison to a standard 30G syringe and a reference device. **Methods:** A two-phase workflow was established to accommodate the large injection footprint of the Pharma Latch Hollow intradermal delivery device. The device and a reference device were used to either pierce the skin (sham) or inject phosphate-buffered saline (PBS; 100-500 µL) into fresh *ex vivo* human skin obtained from a single donor. In parallel, the Comirnaty® COVID-19 vaccine was administered using the test device. Following treatment, 23-mm skin biopsies were collected from injection sites to generate HypoSkin® models, which were subsequently cultured for three days. For additional comparisons, standard HypoSkin® models were produced and then injected using a conventional 30G syringe (sham, PBS, or vaccine). Local tolerance was assessed by macroscopic imaging, histopathology (H&E staining), and multiplex cytokine profiling (29-plex panel analyzed with Audacy™ bioinformatics). **Results:** Injections performed with the test device, reference device, and 30G syringe were well tolerated across all models. No macroscopic or histopathological alterations were detected compared to untreated controls, regardless of the injected compound or volume. H&E analysis confirmed preservation of epidermal, dermal, and hypodermal structures, supporting the absence of local irritation or tissue injury. PBS injections using the device, the reference device, or the 30G syringe induced only slight and device-dependent cytokine secretion, with no notable overall effects compared to the no injection control. Administration of the Comirnaty® vaccine elicited cytokine responses comparable between the test device and the 30G syringe, while levels remained within physiological ranges. The pro-inflammatory control (LPS + TNF-α) confirmed model responsiveness, exhibiting a marked induction of cytokine release. **Conclusions:** This study demonstrates the robustness and human relevance of HypoSkin® for local tolerance assessment of intradermal injection devices. The customized workflow enabled controlled, intra donor comparison of multiple delivery systems, generating reproducible data aligned with regulatory expectations. The tested device was well tolerated, showing no structural damage or excessive cytokine release, and elicited immune activation comparable to that observed with a standard 30G syringe following vaccine injection. As an *ex vivo* New Approach Methodology (NAM), HypoSkin® provides a valuable non-animal, human-relevant platform that supports regulatory-compliant evaluation of both local tolerance and immunoreactivity of injectable delivery systems, facilitating the translation from preclinical safety testing to humans.

PS 4170 Harnessing Bioconvergence to Advance Organ-on-a-Chip Technology and Help Transform Drug Discovery and Development

S. Kriegel¹, S. K. Tiwari², F. C. Pan², D. Austin², K. Su², L. M. Pfeifer¹, M. Asadian³, X. Song³, L. C. Orellana³, A. Venz³, M. Lucchetti³, J. Lento⁴, S. Roth³, O. Henry³, D. Braeken³, L. Braeuninger-Weimer⁵, P. Hewitt¹, S. Johnston⁵, and V. Chu². ¹Merck Healthcare KGaA, Darmstadt, Germany; ²MilliporeSigma, Temecula, CA; ³imec, Leuven, Belgium; ⁴MilliporeSigma, Burlington, MA; and ⁵Merck KGaA, Darmstadt, Germany.

Background and Purpose: Bioconvergence integrates materials science and microelectronics with organoid biology transforming organ-on-a-chip (OOC) technology for more translational drug discovery. Our bioconvergence program seeks to produce a new generation of *in vitro* and *in silico* platforms by merging human 3D cell cultures with a semiconductor-based sensor-integrated microfluidic silicon chip that simulates interconnected multi-organ physiology at a microscale. We aim to achieve greater clinical translatability compared to existing cell and animal models, while also reducing our reliance on animals. Together with imec we aim to translate our validated organoid models into a scalable platform. The system roadmap includes enzymatic metabolic sensors, Transepithelial electrical resistance (TEER), top-and-bottom live imaging, and photonic sensing for low-volume, longitudinal, CMOS-compatible measurements. **Methods:** Using efficient and reproducible differentiation protocols, we generated human gut- and liver organoids from induced pluripotent stem cells (iPSC) and patient-derived (PDO) sources. Organoids were validated for lineage identity and function by immunofluorescence for key markers, RT-qPCR for gene panels, and functional assays including TEER and enzyme activity. Integration of the validated biology with the semiconductor platform was performed by coupling them to fluidic and electrical interfaces under sterile conditions. Sensor readouts were benchmarked against established commercial reference methods to assess accuracy, sensitivity, dynamic range and temporal resolution. **Results:** iPSC-derived gut organoids demonstrated epithelial architecture and barrier integrity as well as the expression of key transporters and metabolic enzymes (for example, BCRP, MRP3; CYP3A4, UGT1A1), alongside representative lineage markers (enterocyte/brush border [Villin], goblet [MUC2], Paneth [LYZ], enteroendocrine [CHGA], epithelial [E-cadherin]). iPSC-derived mature liver organoids express hepatocyte and cholangiocyte markers (for example, albumin; Sox9, CK7, CK19) and show Phase I/II metabolic competence and relevant drug transporters (for example, CYP3A4, CYP2C9, CYP1A2; GST; MDR1/P-gp, MRP2). These organoid systems, provide a robust foundation for investigating the viability and functionality of the platform. Prototype silicon chips sustain viability and function of Caco-2 cells and colon organoids under perfusion, establishing single-organ feasibility, sensor module characterization and calibration. Planned expansions include small intestine and duodenum PDOs and iPSC-derived liver organoids, followed by modular multi-organ use cases and compound response profiling. **Conclusions:** Converging validated human organoid biology with scalable semiconductor microfluidics yields a microphysiological platform with improved translational relevance for toxicology, DMPK, and disease modeling. By enabling longitudinal, low-volume measurements and modular multi-organ coupling, the platform bridges preclinical and clinical applications and supports the development of safer, more effective therapies while reducing reliance on animal studies.

PS 4171 Evaluation of Cell Health in Microphysiological Systems (MPS) under Different Perfusion Conditions Using Metabolic Monitoring

S. Ishida¹, Y. Araki¹, S. Takebayashi¹, Y. Komizu¹, E. Yamanishi², Y. Shigekawa², N. Sakai³, T. Higuchi³, T. Osada⁴, and T. Matsushita¹. ¹Sojo University, Kumamoto, Japan; ²PHC Corporation, Toon, Japan; ³Mediford Corporation, Kumamoto, Japan; and ⁴Mediford Corporation, Tokyo, Japan. Sponsor: S. Ishida, Japanese Society of Toxicology

Background and Purpose: Microphysiological systems (MPS) are microfluidic devices designed to reproduce key physiological functions of human organs and have attracted attention as alternative approaches to animal testing in drug discovery and toxicological studies. To enhance the reliability of MPS, it is essential to maintain and continuously monitor the physiological health of cultured cells throughout experiments. Our research group focuses on real-time metabolic monitoring as an indicator of cellular health, aiming to establish a quantitative assessment framework for MPS functionality. In this study, we investigated how medium perfusion rates affect cellular viability and metabolism in a hepatocyte-based MPS model and evaluated the usefulness of glucose and lactate as metabolic indicators for cell health monitoring. **Methods:** HepG2 cells were seeded on collagen-coated microfluidic chips (ChipShop GmbH) and perfused with culture medium running at flow rates of 0.5, 2.0, and 4.0 µL/min for 72 hours. Cell viability was evaluated by Hoechst33342 and EthD-1 staining, followed by quantitative image analysis using ImageJ. Effluent medium samples were analyzed for glucose and lactate concentrations using a high-sensitivity electrochemical measurement system developed by PHC Corporation, which enables measurements with less than 1 µL of sample within 15 seconds. To further characterize the effects of lactate accumulation, static cultures were performed with exogenous lactate concentrations ranging from 2 to 15 mM. In addition, cultures were exposed to the anticancer drug doxorubicin (DOX) under different lactate conditions to assess whether metabolic changes could serve

as early indicators of drug-induced cellular effects. These combined experiments were designed to clarify the significance of controlled perfusion and to evaluate the potential of metabolic monitoring for early detection of cellular responses in MPS. **Results:** Under perfusion culture, cell proliferation was suppressed at 0.5 $\mu\text{L}/\text{min}$ but maintained at 2.0 $\mu\text{L}/\text{min}$ and above. Metabolic analysis revealed that perfused cultures maintained glucose concentrations around 5 mM and lactate below 3 mM, while static cultures showed marked glucose consumption and lactate accumulation, exceeding 7 mM. These findings suggest that appropriate medium supply is critical for sustaining metabolic balance and cellular viability in MPS. In static cultures, increasing external lactate concentrations led to reduced glucose consumption and lactate production, accompanied by decreased cell proliferation in high-lactate environments. When DOX was introduced, both glucose consumption and lactate production declined earlier than in control cultures (around 46 hours), indicating that metabolic shifts reflected the onset of growth inhibition. Moreover, in high-lactate conditions, the magnitude of DOX-induced metabolic change was smaller, suggesting that uncontrolled lactate accumulation may lead to over- or underestimation of drug effects. **Conclusions:** This study demonstrates that optimization of perfusion flow rate is essential for maintaining metabolic homeostasis and cell health within MPS. Monitoring glucose and lactate concentrations provides a valuable means to assess culture conditions and detect early cellular responses to drug exposure. These findings highlight the importance of integrating metabolic monitoring into MPS to ensure reproducibility and reliability in toxicity and efficacy testing. Building upon these results, we aim to develop an in-line metabolic monitoring system that enables real-time assessment of cell status, thereby contributing to the advancement of more reliable MPS-based toxicological and pharmacological evaluations.

PS 4172 Placentation Disruption by Perfluorooctanoic Acid and Perfluorooctanesulfonate in Human Trophoblast Organoids

J. Hu. Fudan University, Shanghai, China. Sponsor: J. Hu, Japanese Society of Toxicology

Background and Purpose: Prenatal exposure to perfluorooctanoic acid (PFOA) and perfluorooctanesulfonate (PFOS) is associated with low birth weight, a condition often resulting from placental dysfunction. However, whether and how PFOA and PFOS affect human placentation and placental-specific functions remains unclear. **Methods:** We reconstructed a human trophoblast organoid model, incorporating a near-physiological proportion of extravillous trophoblast (EVT). The organoids were exposed to PFOA or PFOS for 7 days. **Results:** Exposure to PFOA at 10 nM significantly increased the proportion of villous cytotrophoblast (CTB) cells, while reducing the proportion of EVT and syncytiotrophoblast (STB) cells at 10 and 100 nM, respectively. A similar pattern was observed with PFOS, albeit at concentrations 10 times higher than those of PFOA. Mechanistically, both PFOA and PFOS inhibited trophoblast differentiation by antagonizing the transcriptional activity of cAMP response element-binding protein (CREB). This disruption in placentation impaired placental function, as evidenced by significantly decreasing hormone secretion and invasion potential. **Conclusions:** Our investigation provides mechanistic insight into the association of PFOA and PFOS with low birth weight observed in epidemiological studies, with PFOA demonstrating a stronger effect than PFOS. These findings may aid in evaluating the toxicity of emerging PFAS and support the development or selection of safer chemical alternatives.

PS 4173 A NOVEL APPROACH TO EXTRAPOLATE EPIAIRWAY IN VITRO INHALATION TOXICITY DATA TO IN VIVO INHALATION TOXICITY ASSESSMENT

A. Lyubimov, S. Sanchez, and P. Dias. Center for BioMedical Testing, San Diego, CA.

Background and Purpose: *In vitro* inhalation toxicity was assessed to evaluate the potential respiratory toxicity of two test articles of the same organotin chemical class, a known industrial chemical Dimethyltin dichloride (DMTC) and a new organotin chemical of the same class (MBT-1). **Methods:** Two *in vitro* experiments were conducted using reconstructed 3D human airway epithelial tissues (EpiAirway AIR-100, MatTek EpiAirway™). The first experiment tested both chemicals dissolved in vehicle at concentrations recommended by the MatTek protocol (20-200 mg/mL) to determine each chemical's GSH (Globally Harmonized System Classification hazard category, 2003). Then extrapolation of the expected *in vivo* air concentration was made based on the GSH classification levels of *in vivo* toxicity. To assess the relevance of established inhalation toxicity to a real-world exposure scenarios, a second experiment was performed using significantly lower *in vitro* concentrations—0.002–0.02 mg/mL at serial dilutions—representing a 1,000- to 10,000-fold reduction from the toxic *in vitro* doses used in the first Experiment. These concentrations were chosen based on the worst-case predicted exposure levels in the human breathing zone after the possible spillage of these chemicals. **Results:** Both chemicals showed significant cytotoxicity in the first experiment at the tested *in vitro* concentrations, with the cell viability falling well below the 75% threshold, classifying them within GSH Hazard Category 1 or 2. Based on the known acute *in vivo* toxicity of DMTC, this experiment correctly placed this chemical in the GSH classification. No cytotoxic effects were observed at any of *in vitro* lower concentrations range in the second experiment, as all cell viability measurements remained above 75%

relative to vehicle controls. **Conclusions:** These findings indicate that, despite high toxicity of the tested chemicals, the levels of DMTC and MBT-1 expected in occupational settings (similar to what people might be exposed to at work) do not pose a significant risk to human respiratory health. A novel approach to correlate *in vitro* concentration range (in concentrations preprepared in liquid vehicle) to a real *in vivo* air concentration in the working breathing zone was used in this study. Additional studies with the air pollutants of other GSH classes are needed to confirm a validity of this approach.

PS 4174 Novel tox readouts: high-throughput protein profiling captures compound cytotoxicity, immunotoxicity, and distinguishes on- from off-target bioactivity

N. Robichaud¹, A. Rosenbloom¹, K. Edwardson¹, J. Ewald², N. Rashidi¹, and M. Dagher¹. ¹Nomic Bio, Montreal, QC, Canada; and ²EMBL-EBI, Cambridge, United Kingdom.

Background and Purpose: The toxicity landscape is changing, with increasing pressure to develop New Approach Modalities (NAMs), emphasizing *in vitro* models yielding insights that translate to patients. Protein profiling is particularly well-suited to these efforts, capturing ground-truth signals of toxicity and immune responses, but adoption has been limited by the high cost of proteomic platforms. **Methods:** Here, we leverage Nomic's Omni 1000, capable of absolute quantification of 1000 proteins in high-throughput and low cost, to analyze the secretome of 20,000 samples from cell-based models, simultaneously capturing compound MOA and signs of toxicity. To achieve this, supernatants from hepatocytes, cardiomyocytes, and microglia treated for 48 hours with 510 bioactive compounds at three concentrations were analyzed. **Results:** Across all samples, >700 proteins were affected by at least 1 compound. Each cell type presented unique secretory features, though certain phenotypes were shared reflecting toxicity modes of action. For example, cytotoxic compounds such as staurosporine resulted in intracellular proteins leaking out of cells and being detected in the supernatant; TLR agonists such as resiquimod induced the expression of a variety of cytokines, which were inhibited by anti-inflammatory compounds such as corticosteroids. Critically, paradoxical pro-inflammatory effects of corticosteroids such as methylprednisolone were also captured, characterized by the induction of SAA and IL-6, reflecting the observed immunotoxicity of this compound when delivered systemically at high dose in the clinic. We used cosine similarity to identify compounds sharing the cytotoxic phenotype of staurosporine, or the immunotoxic phenotype of methylprednisolone; of 20 compounds with liver exposure in the clinic, 16 (80%) display liver toxicity in patients, highlighting the translatability of secretome analysis as a readout for tox models. Finally, secretome analysis was inherently interpretable, and thus enabled distinctions between on-target bioactivity and off-target toxicities. In the case of cycloheximide, we captured 3 distinct, dose dependent activities: low dose inhibition of protein synthesis, immunotoxicity caused by superinduction of IL-6 at intermediate doses, and high dose cytotoxicity. Furthermore, when comparing a set of 11 mTOR inhibitors, we identified shared biomarkers reflecting on-target immune modulation and a distinct set of biomarkers for compounds with distinct off-target effects. Comparing the doses at which these effects arose enabled the characterization of compound potency and specificity. Finally, we compared the sensitivity of secretome analysis to the ToxCast reference dataset, as well as published reports of image-based toxicity profiling. For 152 compounds shared with the ToxCast database, two thirds showed signs of toxicity at lower doses using Omni 1000 than traditional readouts, whereas 58 of 59 yielded signs of toxicity at lower doses in our assay than by imaging. **Conclusions:** These results highlight that secretome analysis captures toxicity with sensitivities on par with state-of-the-art readouts, while providing critical mechanistic information that translate to clinical outcomes.

PS 4175 Protocol Transfer and Reproducibility of an Electrospun Scaffold-based In Vitro Human Full-thickness Skin Model

P. J. Hayden¹, L. M. Fitzgerald¹, R. K. Hodroj¹, J. Chakravarty¹, J. T. Le Do¹, J. Rangel¹, E. McFadden¹, H. Keng², V. Patel², H. P. Behrsing², N. F. Long¹, and M. Phaneuf¹. ¹BioSurfaces Inc, Ashland, MA; and ²Institute for In Vitro Sciences, Gaithersburg, MD.

Background and Purpose: *In vitro* full-thickness human skin models are important tools for testing cosmetics and chemicals, screening new pharmaceuticals, and human disease research. However, these models commonly use animal-derived collagen as a main structural element of the stromal matrix, resulting in stability and contraction issues, short lifespan and poor reproducibility. Additionally, culture media used to produce these models commonly contain undesirable animal-derived components including fetal bovine serum (FBS) and bovine pituitary extract (BPE). To address these shortcomings, we recently developed a full-thickness human skin model (Bio-Spun™ FT-Skin model) using electrospun scaffolds as the stromal structural component, together with open-source FBS/BPE-free culture media. In the current work, we evaluated protocol transfer and reproducibility of the Bio-Spun™ FT-skin model in a naive laboratory. **Methods:** To test the reproducibility and robustness of the Bio-Spun™ FT-Skin production protocols and Bio-Spun™ scaffold inserts, Bio-Spun™ FT-Skin models were produced by an independent contract research

laboratory (the Institute for *In Vitro* Sciences, IIVS). Tissue morphology and baseline viability were determined by histological analysis and WST-8 metabolism assays, respectively. A time-to-toxicity (ET50) barrier assessment assay that is commonly used as a quality control test for several commonly accepted regulatory assays was also performed. Parallel tissue lots were produced at BioSurfaces (Ashland, MA) and IIVS (Gaithersburg, MD) using identical lots of Bio-Spun™ scaffold inserts, cryopreserved NHDF and HEKn, and FBS/BPE-free culture media. All materials were prepared at BioSurfaces and shipped to IIVS by overnight courier. IIVS staff received ½ day of in-person training at IIVS and further 1 ½ hour training by zoom conference prior to performing the production runs. **Results:** Well-to-well baseline viability was assessed on n = 6 random tissues from 3 independent production runs from both laboratories using the WST-8 assay. Results show a low coefficient of variation (cv) ranging between 5.87-11.64 %, and good concordance between laboratories. ANOVA showed that run #2 was significantly different from runs #s 1 and 3 (p < 0.01). No statistically significant difference was observed between run #s 1 and 3 (p = 0.55). No overall statistically significant difference was observed between laboratories (2-tailed t-test, p = 0.67). The WST-8 assay is non-destructive, allowing histological assessment of the same tissues following the WST-8 viability assay. The morphology of the Bio-Spun™ FT-Skin tissues produced by BioSurfaces and IIVS was virtually indistinguishable. A robust viable epithelium with similar thickness, showing well-developed basal, spinous and granulosum layers was produced by both laboratories. Stratum corneum development between the 2 sets of FT-Skin tissues was also similar. The Triton X-100 (TX-100) ET50 assay was conducted to assess the functional barrier of the Bio-Spun™ FT-Skin tissues produced by the 2 laboratories in 3 independent production runs. The barrier of the tissues was found to be highly reproducible within and between laboratories. The observed average ET50 of 12.51 +/- 0.37 hours (cv = 2.97 %) demonstrated a very robust stratum corneum barrier of the models. No statistically significant differences were found between production runs (1-way ANOVA p = 0.30) or laboratories (2-tailed t-test p = 0.052). **Conclusions:** Bio-Spun™ FT human skin models were produced using animal collagen-free 3D electrospun scaffolds and open-source FBS/BPE-free culture media formulations. The models provide long-term stability without contraction and stromal degradation issues. Excellent reproducibility and robustness of the production protocols, Bio-Spun™ scaffold inserts and Bio-Spun™ FT-Skin models were demonstrated following technology transfer to a naïve laboratory. These next-generation, full-thickness human skin models offer the opportunity for reduced reliance on proprietary commercial models, and show promise for completely animal-product-free testing of cosmetics/chemicals, screening of new pharmaceuticals and more human-relevant disease modeling.

PS 4176 Integrating Inter-Individual Variability and Cellular Interactions: Transcriptomic Responses to Acrolein in a Donor-Matched Lung Co-Culture Model

N. A. McNabb-Kelada¹, E. M. Martin², O. Paul², A. E. Simmons³, J. Foley⁴, and S. D. McCullough¹. ¹Center for Therapeutics, Toxicology, and Devices, RTI International, Durham, NC; ²NIHES, Durham, NC; ³UNC Chapel Hill, Chapel Hill, NC; and ⁴NIHES/NTP, Durham, NC.

Background and Purpose: There is a growing movement toward New Approach Methodologies (NAMs) to improve human relevance in chemical safety assessment. Among these, human-derived *in vitro* models coupled with high-throughput molecular profiling are increasingly important in inhalation toxicology for generating mechanistic data. Currently, many respiratory toxicity studies rely on isogenic cell lines or primary cell-based epithelial monocultures, which lack intercellular communication that occurs *in vivo* and intrinsic inter-individual variability within human populations. Thus, relying solely on these models may not accurately capture human exposure responses. Since airway responses arise from coordinated activity among multiple interacting cell types, we used a donor-matched co-culture model of differentiated primary human bronchial epithelial cells (dHBECs) and primary human lung fibroblasts (pHLFs) from 14 donors to better represent cellular heterogeneity and inter-individual variability. Cells were exposed to acrolein, a reactive aldehyde and major toxicant in cigarette smoke and air pollution, to characterize transcriptomic responses using RNA-seq as a sensitive, unbiased readout of molecular perturbations. We hypothesized that acrolein would induce both shared and cell-type-specific transcriptomic responses, and that incorporating multiple cell types from a range of human donors would reveal mechanisms not captured by conventional monocultures or cell lines. **Methods:** dHBECs at air-liquid interface were co-cultured with donor-matched pHLFs and exposed to 0.6, 1.0, 2.0, or 4.0 ppm acrolein for one hour, with filtered air as the control. RNA was isolated separately from each cell type and sequenced on an Illumina NovaSeq (~150 million paired-end reads/sample). Quality control confirmed high sequencing depth and mapping efficiency. Unsupervised principal component analysis (PCA) was used to examine major sources of variation between and within cell types. Differentially expressed genes (DEGs) were identified using edgeR for each dose versus control (FDR < 0.05, |log₂FC| > 1.5). Enriched pathways and biological themes were identified by over-representation analysis. **Results:** Both cell type and donor identity contributed to variation in transcriptomic response to acrolein. At baseline, fibroblasts exhibited greater inter-donor variability than epithelial cells. Transcriptional responses in epithelial cells were strongly dose-dependent, increasing from 35 DEGs at 0.6 ppm to 870 at 4.0 ppm. Fewer DEGs were detected in fibroblasts (8-490 across doses), with donor effects exceeding dose effects in PCA. Only a small subset of DEGs overlapped between cell types, indicating distinct transcriptional responses, yet both converged on stress- and inflamma-

tion-related pathways. Epithelial cells were enriched for oxidative, proteotoxic, and stress-adaptive responses (p53, reactive oxygen species, unfolded protein response, mTORC1, hypoxia) and pro-inflammatory signaling (TNFα/NFκB, IL6-JAK-STAT3). Fibroblasts were enriched for inflammatory and stress-adaptive pathways (p53, TNFα/NFκB, IL6-JAK-STAT3, hypoxia), reflecting activation of common defense mechanisms despite divergent gene-level responses. **Conclusions:** Acrolein induced distinct cell-type-specific transcriptomic profiles while activating shared stress and inflammatory pathways in epithelial cells and fibroblasts. Inclusion of 14 donors revealed substantial inter-individual variability, particularly among fibroblasts, highlighting the importance of incorporating biological complexity and inter-individual human variability in predictive *in vitro* inhalation models. These findings demonstrate the utility of donor-derived multicellular systems as NAMs for mechanistic toxicology and for integration into risk assessment. These models improve translational relevance of *in vitro* data and provide greater context for understanding how biological complexity and inter-individual variability shape study outcomes, which is critical to ensure these models are predictive of human responses as the field increases reliance on *in vitro* approaches for human health decision making.

PS 4178 Primate *in vitro* NAMs : A Platform to Complement Human *in vitro* NAMs Model for Efficient Drug Safety Evaluation

M. Roodgar^{1,2}, F. Suchy^{1,2}, K. Kotok^{1,3}, L. Brücker⁴, S. Dwyer⁵, L. Ramirez¹, M. Nandi¹, N. Rapicavoli¹, K. Pryde⁶, C. Hinckley⁵, S. Engle⁷, and P. Hewitt⁴. ¹Exir Bio, Menlo Park, CA; ²Stanford University, School of Medicine, Stanford, CA; ³San José State University, San Jose, CA; ⁴Merck Healthcare KGaA, Darmstadt, Germany; ⁵Biogen, Cambridge, MA; ⁶AstraZeneca PLC, Cambridge, United Kingdom; and ⁷Etiome, Cambridge, MA.

Background and Purpose: With the FDA Modernization Acts 2.0 and 3.0 and the April 2025 FDA roadmap to reduce nonhuman primate (NHP) use in drug safety studies, there is growing momentum to adopt human *in vitro* New Approach Methods (NAMs) for early safety testing. However, a persistent challenge in human NAMs is limited *in vitro*-to-*in vivo* translation, as unapproved compounds cannot be tested in human subjects before preclinical safety evaluation in animal models. We propose a primate *in vitro* NAMs platform using induced pluripotent stem cells (iPSCs), autologous immune cells, and primary tissues from cynomolgus macaques (Macaca fascicularis), each linked to personalized genomic data. This platform serves as a comprehensive translational toolbox to bridge the *in vitro*-*in vivo* gap in drug safety evaluation. Three core *in vitro* systems have been developed: (1) NHP iPSC-derived neurons, (2) NHP iPSC-based developmental toxicology assays, and (3) NHP primary tissue-derived gut organoids. Together with matching genomic information, these enable human-NHP side-by-side testing before costly NHP *in vivo* studies and can also support post-*in vivo* investigative toxicology, especially when observed toxicities in NHPs are not reproduced in human *in vitro* models. **Methods:** (1) NHP iPSCs were generated from cynomolgus macaques and differentiated into NGN2 and motor neurons using induction vectors and chemical cues. (2) AAV-based SALL4 reporter cell lines were created from NHP iPSCs to evaluate potential toxicity of Targeted Protein Degraders (TPDs) such as Proteolysis Targeting Chimeras (PROTACs) in parallel with human stem cell lines to determine EC₅₀ and dose-dependent effects. (3) Cynomolgus macaque gut organoids were developed for *in vitro* evaluation of gastrointestinal toxicity observed in NHP *in vivo* studies. **Results:** NHP iPSC-derived neurons showed appropriate lineage markers and electrophysiological activity confirmed by multielectrode array (MEA) recordings. The iPSC-based developmental toxicity assay demonstrated high accuracy, identifying EC₅₀ and dose responses for known degraders (thalidomide, lenalidomide, pomalidomide) and new candidate compounds. NHP gut organoids exhibited molecular and structural features comparable to human gut organoids, providing a robust system for cross-species comparative studies. Collectively, these tools enable Weight of Evidence (WoE)-based preclinical evaluations aligned with the FDA 2025 NAMs roadmap, supporting more informed decisions on when NHP models are appropriate before initiating *in vivo* studies. **Conclusions:** Our findings demonstrate that NHP *in vitro* NAMs complement human *in vitro* systems, bridging the translational gap between *in vitro* and *in vivo* studies. In line with the FDA's April 2025 NAMs roadmap, these NHP models can serve as Weight of Evidence (WoE) in IND submissions, helping determine when NHPs are the appropriate translational models. This approach enhances predictive safety, reduces reliance on live NHP studies, and advances the 3Rs principles in drug development.

PS 4179 Exposure to welding fumes induces systemic inflammation in not only welders but also office workers working in factories

M. Tsuji¹, Y. Ishihara², and C. Koriyama³. ¹University of Occupational and Environmental Health, Kitakyusyu, Japan; ²Hiroshima University, Higashi Hiroshima, Japan; and ³Kagoshima University Graduate School of Medical and Dental Sciences, Kagoshima, Japan.

Background and Purpose: Welding fumes are complex mixtures of airborne particles generated during the welding processes, and primarily consist of metal oxides, including iron, manganese, chromium, and other trace metals. Welding fumes can induce various lung disorders and neurodegenerative diseases. In addition, heavy

metals in welding fumes can induce oxidative stress by increasing the levels of reactive oxygen species (ROS) and altering the expression of antioxidant enzymes. Oxidative damage is recognized by the immune system as a danger signal, leading to activation of inflammatory pathways. Therefore, welding fume exposure is involved in systemic inflammation, which may contribute to the onset and progression of several disorders. Welders are required by law to wear masks in Japan. Welding fumes are airborne, and in factories with offices on the same premises, employees other than welders may also be exposed to welding fumes. However, to our knowledge, no previous studies have investigated the inflammatory status of office workers in welding factories in Japan. In this study, we aimed to estimate the fume exposure risk of welders, office workers in welding factories, and general subjects living in cities far from factories by measuring blood cytokine and chemokine concentrations. **Methods:** The concentrations of cytokines (IL-1 β , IL-6, IL-8, IL-10, IL-12p70, IL-17A, IL-18, IL-23, IL-33, and tumor necrosis factor α (TNF α)), interferon γ (IFN γ), and chemokines (C-C motif chemokine ligand 2 (CCL2), CCL3, CCL4, CCL11, CCL17, CCL20, chemokine C-X-C motif ligand 1 (CXCL1), CXCL5, CXCL9, CXCL10, and CXCL11) in the serum were determined. **Results:** We recruited 105 welders and 129 office workers in the factories from ten welding factories. Thirty people living in Kyusyu far from welding factories (general subjects) participated in the study. The serum concentration of IL-1 β was significantly higher in office workers and welders than that in general subjects. Importantly, the serum concentrations of IL-12p70, IL-17A, IL-33, TNF α , and CCL3 in office workers were significantly higher than those in general subjects, and there was no significant difference in the levels of these inflammatory molecules between welders and general subjects. **Conclusions:** What's particularly novel about this study is that it found that office workers who work in welding factories and are not legally required to wear respiratory protection are at high risk of developing systemic inflammation due to exposure to welding fumes, just like welders. In the future, it is important to closely examine the exposure status and risk management of office workers in factories and welders.

PS 4180 Triangulation of Evidence in Reconstruction of Historical Exposure and Health Risks for Nuclear Workers

J. Tsuji, L. Corey, J. Lin, and M. Garry. Exponent Inc, Bellevue, WA.

Background and Purpose: Worker exposure reconstruction at U.S. nuclear production facilities is particularly challenging because of missing personnel records, long operational histories, multitude of hazardous chemicals, and little recognition of non-radiological hazards until after the mid-1990's. The Hanford Nuclear Reservation produced plutonium from 1942 to about 1989, followed by extensive decommissioning, demolition, waste treatment, and cleanup. Due to the lack of an OSHA-equivalent safety and health program until recently, the large work force has few records on non-radiological exposure and poor documentation of chemical use and disposal practices. Estimating worker exposures, however, is critical for conducting epidemiological studies as well as for government programs on diseases related to workplace exposures. The purpose of this study was to use triangulation to produce surrogate exposure measures or ratings for potential substance exposure by specific job tasks and employment dates for Hanford workers. Exposures were related to health effects based on substance toxicology. Triangulation methods integrate available lines of evidence with differing sources of potential bias and uncertainty. **Methods:** Information on workers and from publicly available documents were triangulated to develop exposure and health risk ratings for diseases: 1) employment dates, job titles, and work location; 2) job task analyses in later years; 3) dosimetry data; 4) historical chemical use and release from site production processes, supporting activities, construction, and demolition/decommissioning; 5) worksite characteristics; 6) time periods for different chemical processes; 7) records of upsets, contamination events by location; 8) substance exposure matrices by job title and location; 9) development of the industrial hygiene program over time; 10) limited epidemiological studies of specific job tasks for a few health endpoints or on radiation exposure and cancer; 11) substance-specific toxicology. Job exposure matrices identify substances associated with over 100 job titles and locations at the site, involving production, construction, maintenance, waste handling/treatment, demolition, and research. The matrices vary in completeness, particularly for exposure timing. Potential exposures depending on job title, work location, and time period involved 1000s of chemicals, including hydrocarbon and chlorinated solvents, aromatic hydrocarbons, aromatic amines, nitrosamines, ammonia, acids, nitrogen and sulfur-containing compounds, metals (beryllium, lead, welding fume, mercury, chromium), diesel exhaust, asbestos and mineral particles/fibers, and radiological materials. Limited worker health studies (e.g., x-ray abnormalities v. lung function decrements) provide insight on substances and relative exposure specific to jobs titles (e.g., asbestos/silica v. other respiratory toxicants). **Results:** Higher exposure and health risk identified by triangulation for rating worker exposures include: 1) aromatic amines (bladder cancer) for nuclear process operator at the Plutonium Finishing Plant, 1955 to 1989; 2) asbestos, silica (lung disease/cancer) for plumber/steam fitter in reactor, process, and tank waste areas, prior to 2000; 3) lead, solvents (neurological and obstructive lung disease) for painters. Lead paint was widely used including to cover radioactive waste spills, prior to 2000. Ratings are upgraded based on longer employment particularly pre-1994, higher radiological dosimetry and internal intake levels, exposure incidents, and frequent overtime. **Conclusions:** Substance exposures and health risks can be reconstructed qualitatively for past nuclear workers. This methodology has broader application for estimates of exposures and health risks for other operations with historically large work forces and complex work histories.

PS 4181 Odor perception versus real-world fragrance exposure via inhalation

P. Dalton¹, and N. Sadekar². ¹Monell, Philadelphia, PA; and ²Research Institute for Fragrance Materials, Mahwah, NJ.

Background and Purpose: Odor thresholds and irritation thresholds from chemicals have broad applications across scientific, regulatory, and industrial domains, including safety assessment, product development and quality control, and environmental air quality monitoring. In the cosmetics, personal care, and household product industries, odor perception is central to fragrance formulation, inhalation safety evaluation, and overall product acceptability. Fragrances are unique organic, semi-volatile substances distinguished by their odorous properties. Upon inhalation, fragrance molecules interact with specialized olfactory receptor neurons in the nasal cavity, generating sensory stimuli perceived as smell. The lowest concentration at which an odor can be detected is referred to as the *odor threshold*. Although odor detection occurs at extremely low concentrations, the perceived intensity can often create the impression of much higher exposure levels. Chemesthesis is the chemical sensation elicited by certain compounds, which occurs when odorant molecules activate the free nerve endings of the trigeminal nerve (cranial nerve V) located in the nose, eyes, and mouth, producing sensations of warming, cooling, tingling, stinging, or burning, depending on concentration. The lowest concentration at which these sensations are perceived is known as the *irritation threshold*, which is typically an order of magnitude higher than the odor threshold. In this study, odor thresholds and irritation thresholds were determined in human volunteers for eight individual fragrance ingredients. **Methods:** 30 healthy, non-smoking males and females, aged 20-38, were recruited to participate. The fragrance materials were phenylethyl alcohol, acetic acid, linalool, eucalyptol, menthol, styrene, terpineol, and cinnamaldehyde. We used a custom-designed air-dilution olfactometer (Olfasense GmbH, Kiel, Germany) to collect both odor and irritation thresholds for eight fragrance materials. The computer-controlled olfactometer presents precise dilutions of the chemical in an air stream at 20 L/minute for odor and 8 L/minutes for irritation. For odor detection, participants were presented with a series of three stimuli, only one of which contained the fragrance, and the others were clean air. The task was to identify the 'odor' presentation. Concentrations were presented in ascending order to avoid sensory adaptation. For irritation detection, Teflon nose plugs were used to present the chemical to one nostril while clean air was simultaneously presented to the other nostril. The concentration that activated the nasal branch of the trigeminal nerve enabled individuals to say which nostril was stimulated and represented the irritation threshold. **Results:** As hypothesized, irritation thresholds were significantly higher than corresponding odor thresholds, in some cases an order of magnitude higher. For phenylethyl alcohol (PEA), no irritation threshold could be obtained, as it was not able to be localized at the highest vapor concentration tested. No sex differences were observed for either threshold. The slope of the psychophysical function for odor and irritation differed across the tested materials, indicating that intensity increases faster for some materials as a function of concentration. **Conclusions:** Nearly all fragrance chemicals have the potential to elicit chemesthesis and result in eye and nose irritation; however, the concentration at which that occurs was significantly higher than what is detectable by odor and what is necessary to be used in fragrance formulations to ensure a positive fragrance experience. Establishing the distance between the odor and irritation thresholds for fragrance materials can guide formulations and avoid unpleasant sensory effects from fragranced product use.

PS 4182 Assessing PFAS Exposure in Donor Human Milk Across Lactation Stages

K. Dinh¹, W. Wang^{1,2}, and N. M. Johnson¹. ¹Texas A&M University, College Station, TX; and ²National Cheng Kung University, Tainan City, Taiwan.

Background and Purpose: Breast milk is widely regarded as the optimal source of nutrition for infants because it delivers essential nutrients, immune support, and bioactive components. When mothers are unable to provide their own milk, donor human milk is often recommended as an alternative due to its nutritional and therapeutic benefits in comparison to infant formula. Although donor milk is screened for pathogenic microorganisms and certain drugs/medications, current milk bank guidelines do not typically address maternal exposure to environmental contaminants. This gap is particularly relevant for per- and polyfluoroalkyl substances (PFAS), a class of persistent chemicals that have been consistently detected in maternal serum and breast milk in studies worldwide. Despite growing concern, U.S.-based biomonitoring efforts remain limited, with relatively few studies evaluating PFAS levels in human breast milk and assessing how these concentrations change over time or vary across geographically diverse populations. Given the widespread detection of PFAS and ongoing gaps in national surveillance, there is a need to characterize PFAS occurrence in donor milk and to better understand the factors that influence exposure during lactation. **Methods:** In collaboration with Mothers' Milk Bank Austin (MMBA), breast milk samples were collected from ten donors, each providing three samples representing different stages of lactation (n=30). Samples were stored at -80°C until analysis and extracted using a QuEChERS-based method with isotope-labeled internal standards. 21 PFAS (8 short-chain, 13-long chain) were quantified via ultraperformance liquid chromatograph tandem mass spectrometry (UPLC-MS/MS) using external calibration and matrix-matched quality controls. Donor socio-demographic information (maternal age, occupation, education level, and race/ethnicity)

was provided by MMBA and multivariate regression models were used to assess associations between PFAS levels and donor characteristics. **Results:** Overall, 11 of 21 PFAS were detected in donors. Short-chain compounds perfluoro-n-heptanoic acid (PFHpA) and perfluoro-n-hexanoic acid (PFHxA) were detected in 93% and 70% of samples with median concentrations of 0.31 and 0.12 ng/mL. Long-chain compounds including perfluoro-n-octanoic acid (PFOA), perfluoro-n-undecanoic acid (PFUnDA), and perfluoro-n-tetradecanoic acid (PFTrDA) were detected in 93%, 80%, and 73% of samples at median concentrations of 0.28, 0.52, and 0.19 ng/mL. Regarding temporal trends, PFAS concentrations were generally stable across the lactation period for most donors, although a few donors exhibited declines in certain PFAS over time. Donor sociodemographic characteristics were not significantly associated with milk PFAS concentrations. **Conclusions:** Several PFAS were detected in donor milk samples, with short-chain PFAS appearing more frequently, consistent with the phase-out of many legacy long-chain compounds. Although concentrations generally remained stable throughout lactation, modest declines in select PFAS for a subset of donors highlight the importance of evaluating individual variability. Incorporating additional covariates such as parity, dietary patterns, and personal care product use may help determine whether these factors influence PFAS transfer into milk. More comprehensive biomonitoring studies with a focus on current-use PFAS and how these chemicals change over the course of lactation are essential for assessing potential risks and estimating infant daily intakes. Such data will help inform evidence-based breastfeeding recommendations and support the development of strategies to minimize PFAS exposure in early life.

PS 4183 Methodological Limits in Assessing Long-term Blood Lead Trends

A. Bailey¹, R. A. Schoof¹, and K. Harvey². ¹Ramboll, Seattle, WA; and ²Butte-Silver Bow Health Department, Butte, MT.

Background and Purpose: More than 20 years of data are available from a blood lead monitoring program in a historical mining district in Butte-Silver Bow County, Montana, USA. Since the late 1980s there has been substantial remediation of mine wastes in Butte. Residential soil and dust lead abatement programs are ongoing. Pursuant to a USEPA order, studies are conducted every five years to assess the effectiveness of these activities in reducing lead exposures in Butte children. The third study will be completed in early 2026. The Butte-Silver Bow Health Department administers the blood lead monitoring program for families participating in the USDA Special Supplemental Nutrition Program for Women, Infants, and Children. A large number of 12 to <60 month old children have been tested each year since 2003 (257 to 464 children per year through 2019). The first Butte study evaluated laboratory-analyzed capillary blood lead data collected from 2003 to 2010 with a detection limit of 1 µg/dL. Since 2012 capillary blood lead testing has been conducted with the LeadCarell device which has a much higher detection limit (3.3 µg/dL). The purpose of this study is to examine the ability to reliably identify trends in blood lead levels (BLLs) using LeadCarell data, as lead exposures have declined over time, considering the high detection limit and false positive rates. **Methods:** After deidentifying individual records, the studies have used regression models to examine differences in BLLs over time and among categories of variables including season, child age, gender, neighborhood, and house age. Neighborhoods include Uptown, characterized by a high percentage of pre-1940 housing located atop historical mine workings, and the Flats with newer housing and less mining influence. Analyses have focused on children aged 12 to <60 months. **Results:** The first study demonstrated substantial declines in geometric mean BLLs from 2003 to 2010 (3.6 to 1.7 µg/dL in Uptown, and 3.4 to 1.4 µg/dL in the Flats). In the second and third studies, very high rates of nondetect results (>75%) have limited analyses to rates of elevated BLLs. From 2003 to 2010, the percentages of 12 to <60-month-old children with BLLs >5 µg/dL declined from 41% to 15% in Uptown and from 31% to 5% in the Flats. Since about 2009, the percentage of BLLs ≥5 µg/dL among 12 to <60-month-old children living in either neighborhood appears to have leveled off, varying within a consistent range (5% - 12%) without apparent trend through the end of 2019. Similar percentages have been observed through 2024, but data limitations (including numerous disruptions in services related to the COVID-19 pandemic) complicate interpretation of more recent data. Significant differences in the likelihood of elevated BLLs were observed between categories of the house age (year built before 1940 or 1940 and later), neighborhood (Uptown/Flats), and age range (12 to <36 and 36 to <60 months) variables, none of which are solely related to historical mining influences. The first two studies found significant differences in blood lead level patterns between seasons, with a greater percentage of elevated BLLs occurring in warmer months when children spend more time playing outside. Consistent seasonal patterns were no longer apparent in the third study. A venous confirmation program begun in June 2022 has identified a high rate of false positives among LeadCarell results, with 33% false positives for results ≥5 µg/dL, and 85% among results in the 3.5 to <5 µg/dL range. The second study had a similar finding (~75% for results ≥5 µg/dL), but with more uncertainty. **Conclusions:** The high false positive rates observed with consistent venous confirmation testing suggest that LeadCarell results may not be reliable to assess trends in elevated BLLs. As the rates of elevated BLLs decline, isolated (rather than community) sources of exposure have greater influence on the observed rates. The lack of seasonal differences observed in the most recent study may indicate a reduction in the influence of soil lead as cleanup has progressed. Follow up with families of Butte children with elevated BLLs seldom identified one clear exposure source for BLLs in the range of 5-10 µg/dL. Higher BLLs were more likely

to have identifiable sources. With small numbers of affected children, such sources may alter community rates of elevated BLLs from year to year. Alternate approaches to screening with LeadCarell may be needed to discern the influence of community lead sources on childhood exposures.

PS 4184 Metal Exposure from Retained Shrapnel Fragments in War-Injured Veterans: Findings from Surveillance Efforts

J. M. Gaitens^{1,2}, T. H. Girmay^{1,2}, B. Charland¹, and M. A. McDiarmid^{1,2}. ¹VA Maryland Health Care System, Baltimore, MD; and ²University of Maryland School of Medicine, Baltimore, MD.

Background and Purpose: Evidence suggests that embedded metal fragments can oxidize *in situ*, thereby releasing metal ions into the systemic circulation permitting adverse target organ effects remote from the injury site. As a result, an on-going medical surveillance program was established to help inform the clinical management of war-injured veterans with embedded fragments. **Methods:** Surveillance-eligible veterans, identified through screening questions incorporated in the Department of Veterans Affairs' (VA) electronic health record system, are asked to complete an exposure questionnaire and provide a urine sample to assess systemic metal exposure. Using inductively coupled-mass spectrometry (ICP-MS), concentrations of 15 different fragment-relevant metals are measured in the urine, creatinine-adjusted, and compared to established reference values and known toxicity thresholds. In addition to considering the fragment as a likely source of a metal elevation, other sources of metal exposure, such as the presence of a metal implant or veteran reporting a metal-related hobby or occupation, are also considered. **Results:** Of almost 2,200 enrolled veterans, most are male (96.7%) and served in the Army (65.5%). The majority (72.4%) reported suffering only a blast injury, 18.5% reported both blast and bullet injuries, and 9.1% reported being injured only by a bullet. The mean self-reported age of participants at time of injury was 28.5 years and urine samples were submitted an average of 10.6 years post-injury. Most veterans (~76%) had no urine metal elevations, suggesting that if metal ions are being released from the fragment, they are not being released in excess, into the systemic circulation. When a metal elevation was observed, in most cases it was below a level of concern for a toxicity threshold. In some cases, metal elevations were significantly associated with non-fragment related sources of exposure. For example, veterans who reported having a joint implant were more likely to have elevated urine cobalt (9.8% versus 0.7%, p<0.001) and chromium levels (11.8% versus 3.9%, p=0.005) compared to those without a joint implant. However, veterans with a bullet injury were more likely to have an elevated lead level compared to those with a blast only injury (3.8% versus 1.1%, p<0.001), suggesting the fragment as the source of the metal elevation. **Conclusions:** Interpretation of urine biomonitoring results is complex; however, in the absence of other known metal exposure sources, elevated levels may indicate the release of metal ions into systemic circulation from embedded fragments. Because surgical morbidity often precludes fragment removal and injuries typically occur at a relatively young age, retained fragments can result in decades of sustained metal exposure. Thus, continued surveillance is crucial to better understand the kinetics of fragment-related metal exposure and the concentrations that may reach thresholds of injury over the long term. *This material is the result of work supported with resources and the use of facilities at the VA Maryland Health Care System, Baltimore, Maryland. The contents do not represent the views of the U.S. Department of Veterans Affairs or the United States Government.*

PS 4185 Characterizing Chemical Exposure in Human Serum Using Ion Mobility Spectrometry-Mass Spectrometry (IMS-MS): Comparison with Traditional Targeted Analytical Techniques

N. Barlow¹, T. McDonald², J. N. Dodds³, E. S. Baker³, and I. Rusyn⁴. ¹Texas A&M University, College Station, TX; ²Texas A&M University School of Public Health, College Station, TX; ³University of North Carolina at Chapel Hill, Chapel Hill, NC; and ⁴Texas A&M University Interdisciplinary Faculty of Toxicology, College Station, TX.

Background and Purpose: Accurately characterizing human exposure to environmental contaminants is essential for evaluating potential health risks. Biomonitoring studies traditionally rely on targeted analytical techniques such as liquid chromatography-tandem mass spectrometry (LC-MS/MS) and gas chromatography-tandem mass spectrometry (GC-MS/MS), which can quantify hundreds of known compounds with high sensitivity. However, in the context of chemical exposomics, these methods often focus on quantification of specific pre-selected analytes and depend on the availability of chemical standards, limiting their utility for the detection of emerging or unknown contaminants. High-resolution mass spectrometry (HRMS) has expanded exposomic analyses through non-targeted workflows, yet gaps remain in the comprehensive chemical characterization of complex biological samples. This study aimed to evaluate the utility of ion mobility spectrometry coupled with quadrupole time-of-flight mass spectrometry (IMS-QTOF-MS) as a hybrid, semi-targeted platform for simultaneous quantitative and non-targeted assessment of persistent organic pollutants (POPs) in human serum. **Methods:** A biphasic protein precipitation extraction was used to preserve a wide range of analyte polarities and reduce matrix effects. Serum samples from 32 individuals were analyzed using IMS-QTOF-MS (with and without liquid chromatography) and compared with LC-MS/MS and GC-MS/MS.

A suite of per- and polyfluoroalkyl substances (PFAS) was used to evaluate quantitative performance. The calibration curves of PFAS ranged from 0.025 to 100 ng/mL and were constructed using a single surrogate internal standard. Method performance was assessed using detection frequency, calibration curve linearity, and accuracy of quality control (QC) samples. **Results:** Both LC-IMS-QTOF-MS and LC-MS/MS consistently detected PFOS, PFHxS, and PFDoA in all serum samples, with comparable concentration trends between methods. LC-MS/MS achieved lower absolute detection limits overall. Calibration curves exhibited strong linearity for both techniques (coefficients of determination > 0.9 for all PFAS), with more than 50% of PFAS analyzed by LC-IMS-QTOF-MS and over 80% by LC-MS/MS achieving coefficients of determination > 0.99. LC-IMS-QTOF-MS demonstrated higher average accuracy and lower variance in QC quantification, suggesting strong reproducibility. Distinct drift time profiles were observed for individual PFAS in LC-IMS-QTOF-MS analyses, indicating enhanced selectivity in complex mixtures. **Conclusions:** LC-IMS-QTOF-MS generated quantitative data comparable to LC-MS/MS for major PFAS while offering the added benefit of ion mobility separation to resolve co-eluting compounds. The strong calibration linearity and improved QC reproducibility demonstrate its potential as a complementary platform for quantitative and semi-targeted biomonitoring. Expanding this workflow to additional chemical classes, such as pesticides and polycyclic aromatic hydrocarbons (PAHs), and including nontargeted analyses may enhance detection coverage and advance the comprehensive characterization of human exposures. This hybrid analytical approach represents a promising step towards improving the accuracy and scope of exposomic assessment in toxicology.

PS 4186 Metabolic Reprogramming in Gut Microbiota Exposed to Lithium

L. Li, X. Liu, S. Cui, C. Ho, D. Hawley, K. Le, and H. Gu. Arizona State University, Phoenix, AZ.

Background and Purpose: Lithium (Li), a key component in rechargeable batteries and industrial products, is increasingly released into the environment due to the rapid expansion of the electric vehicle and energy storage industries. The widespread presence of Li in soil and water raises concerns about its potential toxicological impacts on human health, including homeostasis of the gut microbiome. In this pilot study, we hypothesize that Li exposure will negatively affect gut microbiota composition and function, in which metabolic reprogramming plays an important role. **Methods:** We conducted both *in vitro* and *in vivo* experiments to evaluate the biological effects of Li exposure. Three representative gut bacterial strains—*Escherichia coli* MG1655, Nissle 1917, and *Lactobacillus rhamnosus*—were individually cultured in anaerobic conditions and exposed to various concentrations of lithium chloride (0, 10, 20, 50, 100, and 500 µg/mL). Bacterial growth and viability were assessed, followed by untargeted and targeted metabolomics using liquid chromatography-mass spectrometry (LC-MS). In parallel, C57BL/6 mice were orally exposed to Li via drinking water for 4 weeks. Fecal samples were collected for 16S rRNA sequencing and metabolomic profiling to investigate Li-induced alterations in gut microbial composition, function, and metabolism. **Results:** Li exposure reduced bacterial viability in a dose-dependent manner and induced broad metabolic reprogramming across several key pathways, such as sulfur metabolism, amino acid metabolism, and nucleotide metabolism. In mice, we observed significant shifts in microbial taxa, including a decrease in beneficial *Lactobacillales* and disruption in energy-producing pathways such as glycolysis/gluconeogenesis and the pentose phosphate pathway. **Conclusions:** This study showed that lithium exposure may cause comprehensive alterations in gut microbial metabolism and composition. The results will contribute to understanding the mechanistic basis of Li-induced metabolic disturbances and potential adverse health, offering insight into environmental lithium toxicity at the gut-microbiome interface.

PS 4187 Use of *in vitro* reconstructed intestinal epithelium to study effects of repeated aluminum exposure

G. D. Atanasio¹, G. Allaria¹, L. Dondero¹, F. Rispo¹, F. Tardanico¹, E. Lertora¹, K. Cortese², S. Ferrando¹, F. Soggia³, J. Markus⁴, S. Letasiova⁴, T. Filippini⁵, F. Robino⁶, M. Zanotti Russo⁶, S. Ayehunie⁷, and E. Grasselli^{1,8}. ¹DISTAV University of Genoa, Genova, Italy; ²DIMES, University of Genoa, Genova, Italy; ³DCCI, University of Genoa, Genova, Italy; ⁴MATTEK IVLSL, Bratislava, Slovakia; ⁵CREAGEN, University of Modena and Reggio Emilia, Modena, Italy; ⁶Angel Consulting, Milan, Italy; ⁷MATTEK, Ashland, MA; and ⁸Centro 3R, Interuniversity Centre for the Promotion of 3Rs, Genova, Italy.

Background and Purpose: Aluminum (Al³⁺) is one of the most prevalent elements in the environment and is commonly found in dietary products. The free cation, Al³⁺, is physiologically reactive and thus might affect metabolism when ingested. The gastrointestinal tract plays a pivotal role in its absorption, and it is estimated that approximately 40% of ingested aluminum is retained in the intestinal tissues. The present study aims to evaluate morphological alterations, barrier effects, and gene expression pattern changes after repeated exposure of *in vitro* intestinal tissue models to aluminum. **Methods:** Al³⁺ was applied twice a day for two hours at 5, 20, and 50 ppm for 12 days onto the *in vitro* reconstructed intestinal epithelium EpiIntestinal (MatTek). The tissue integrity was monitored over the course of the experiment using trans-epithelial electric resistance measurement (TEER). At the end of the dosing period the cumulated Al³⁺ absorption was assessed using Inductively Coupled Plasma-Atomic Emission Spectroscopy (ICP-AES) analysis and the morpho-

logical effects were analyzed by standard histological assessment and transmission electron microscopy (TEM). RT-qPCR was used to assess expression of genes associated with oxidative stress. **Results:** Barrier integrity monitoring via TEER did not reveal any significant differences between tissues exposed to Al³⁺ and controls except for the highest concentration. These findings were consistent with observed expression patterns of genes associated with tight junctions and with level of metallothionein genes associated with different amounts of Al³⁺. Histological and TEM analyses revealed that the highest Al³⁺ concentration was associated with vacuolization and microvilli shortening, while no pathological changes were observed in other samples. **Conclusions:** Overall, the results of this study suggest that the repeated exposure to Al³⁺ did not lead to significant detrimental effects of the 3D intestinal tissue model except for the highest concentration used. These findings contribute to our understanding of the safety of Al³⁺ exposure within the context of the gastrointestinal system since physiological concentrations of aluminum in blood stream are very low, typically < 10 µg/L (0.01 ppm). Nonetheless, further research may be needed to explore any potential long-term effects and to understand the possible implications for human health especially for chronic exposure at high concentrations. The observed morphological changes may deserve further attention.

PS 4188 Quantitative Assessment of Microbial Activity in a Veterinary Clinic Environment: Integrating ATP Bioluminescence Surface Assays with Airborne Culture-Based Sampling

O. P. Jegede, D. M. McGee, D. K. Seybold, and A. Adhikari. Georgia Southern University, Statesboro, GA. Sponsor: O. Jegede, Society of Environmental Toxicology and Chemistry

Background and Purpose: Veterinary clinics are complex microenvironments where microorganisms coexist with animal dander, disinfectants, and organic debris. This study quantified microbial activity within a mixed-species veterinary facility to evaluate spatial and temporal variations in bacterial and fungal presence, focusing on potential occupational exposure pathways relevant to toxicology and human health. **Methods:** Sampling was performed across nine functional zones (wash, grooming, wards, treatment, and control areas). Airborne microorganisms were collected using SKC BioStage impactors operating at 28.3 L/min for 3 minutes and plated on Tryptic Soy Agar (bacteria) and Malt Extract Agar (fungi). Plates were incubated for 72 hours at 36 °C for bacteria and 27 °C for mold, and results expressed as CFU/m³. Surface cleanliness was evaluated using ATP bioluminescence (Hygiena SystemsSURE Plus), with swabs taken above and below breathing level (floors, rails, counters, scales, and kennel surfaces). Temperature and relative humidity were concurrently recorded. Morning and afternoon samples were collected to capture operational variability during clinic activity. **Results:** Mean bacterial counts were highest in the grooming (523.9 CFU/m³ in the morning; 348.1 CFU/m³ in the afternoon), wash (2,504.1 CFU/m³ in the morning; 384.9 CFU/m³ in the afternoon), and ward areas (5,223.5 CFU/m³ in the morning; 279.4 CFU/m³ in the afternoon), suggesting persistent microbial loading where animals were bathed, handled, and housed. Fungal (mold) counts were also elevated in these zones, with morning means of 357.2 CFU/m³ (ward) and 279.7 CFU/m³ (grooming), reflecting favorable growth under moist, humid conditions (mean RH 68-74%). Office and control areas exhibited substantially lower microbial loads (bacteria ≈220-379; fungi ≈170-250 CFU/m³). ATP surface activity paralleled these patterns, averaging 523 RLU below breathing level in animal-contact areas versus 119 RLU above. Floors, scales, and kennel surfaces showed the highest readings (up to 1,276 RLU) in morning sessions, suggesting organic residue buildup and potential biofilm initiation. Morning values generally exceeded afternoon levels across CFU assays, indicating cumulative microbial loading associated with daily animal movement, grooming, and cleaning cycles. Bacterial counts consistently surpassed fungal counts, suggesting greater aerosol mobility and persistence of bacteria, whereas mold activity clustered in moist, poorly ventilated zones. Elevated mold levels in the wash, grooming, and ward areas may indicate sustained moisture retention and suboptimal air exchange despite disinfectant use, conditions favorable for fungal sporulation and mycotoxin production. **Conclusions:** Our preliminary data suggest that veterinary clinic environments represent dual biological exposure sources: bacterial aerosols with potential inflammatory and endotoxin activity, and fungal bioaerosols capable of allergenic or mycotoxic effects contributing to respiratory irritation. Compared with other occupational environments, microbial loads in the wash, grooming, and ward zones appear elevated and are more consistent with animal-handling or agricultural settings, implying comparable exposure potential. These trends may indicate that veterinary staff experience measurable bioaerosol exposures requiring targeted ventilation and humidity management. The observed concordance between ATP and viable counts suggests ATP bioluminescence can serve as a practical, real-time indicator of microbial contamination and exposure potential. Our preliminary findings point toward the utility of integrated ATP-culture surveillance for assessing occupational bioaerosol exposure and identifying biomarkers of inflammation or sensitization. Ongoing work aims to extend this dataset through antibiotic-resistance gene profiling and evaluation of sustainable ("green") disinfectants to inform One Health-based risk mitigation strategies.

K. K. Isaacs, N. Charest, J. F. Wambaugh, H. Whitehead, and K. Paul Friedman. UL Research Institutes, Research Triangle Park, NC.

Background and Purpose: Drinking water (DW) is a potential pathway for human exposure to per- and polyfluoroalkyl substances (PFAS), prompting increased monitoring and regulatory attention. To enable accurate exposure assessment and targeted mitigation strategies, research is needed to characterize PFAS sources and quantify their relative contributions to DW contamination. Risk-based approaches should be used to prioritize sources for investigation, ensuring sampling focuses on those most likely to significantly impact DW and human exposure. **Methods:** In this study, monitoring data for 29 PFAS from the Environmental Protection Agency's (EPA) Fifth Unregulated Contaminant Monitoring Rule (UCMR5) program were analyzed to identify potential source-related chemical signatures in finished DW. Non-negative matrix factorization (NMF) was applied to resolve distinct PFAS source profiles and corresponding sample contributions. Samples were clustered by profile contributions; cluster geographic locations and profile signatures were examined to generate source hypotheses. PFAS DW concentrations were converted to estimated steady-state plasma concentrations using high-throughput toxicokinetic (HTTK) approaches and an assumption of an average water intake rate. Distributions of mixture bioactivity-to-exposure (BER) ratios in each cluster were developed by comparing, for each sample, the sum of observed sample PFAS concentrations to median modeled mixture points of departure (PODs) derived using a concentration addition model of mixture bioactivity, the sample PFAS composition (component ratios), and available single-component PFAS PODs (activity concentration at the cutoff threshold concentration, ACC) for a PFAS-relevant endpoint (peroxisome proliferator-activated receptor- α activation) from the ToxCast database, invitrodb (v. 4.3). **Results:** A total of 8564 samples contained at least one PFAS concentration greater than the method reporting limit; 16 PFAS were represented. NMF of concentrations identified 5 source profiles that explained 93.4% of the variance in the data. Samples were grouped into 10 clusters reflecting different patterns of source profile contribution. Source 1 was composed of medium chain-length (C5-C7) perfluorinated carboxylic acids; samples with large contributions from this source were co-located with PFAS manufacturers and importers. Source 2 was dominated by 6:2 fluorotelomer sulfonate, a replacement for PFOS in aqueous film-forming foams (AFFF). Source 3 included contributions from several perfluorinated carboxylic and sulfonic acids including perfluorooctanesulfonic acid (PFOS) and perfluorooctanoic acid (PFOA) and had impacts throughout the U.S.; it may be indicative of historic PFAS contamination. Source 4, dominated by perfluorobutanoic acid and observed in locations along the Mississippi River, may reflect transport of PFAS manufacturing facility emissions. Source 5 contained a high proportion of perfluorobutane sulfonate, a replacement for PFOS in AFFF and other products. ToxCast ACCs and HTTK data were available for 7 PFAS for BER inclusion; 5 other PFAS were inactive for the endpoint. Median BERs for sample clusters ranged from 293 (cluster dominated by Source 2) to 2162 (cluster impacted by Source 1 and Source 4); the 5th percentile of BER in 7 clusters was less than 100. The minimum BER was 5.93, for a sample associated with Source 3 in San Diego County, CA. **Conclusions:** Existing targeted monitoring data from UCMR could be successfully mined for insight into the composition and distribution of PFAS sources in U.S. DW. Future work should aim to further link observed source profiles with available PFAS emission data. Additional work to characterize PFAS contamination with non-targeted analysis can increase the specificity of known source profiles and refine evaluations of risk.

PS 4190 Thinking Zinc: An Intervention study for mitigation of metal toxicity

E. J. Dashner-Titus, K. L. Cooper, K. Torczynski, D. MacKenzie, E. Erdei, and L. G. Hudson. University of New Mexico, Albuquerque, NM.

Background and Purpose: Zinc is an essential micronutrient with various key functions in human health. Experimental models indicate that zinc protects against genotoxicity through multiple mechanisms including its functions in antioxidant defense and DNA damage repair pathways. Numerous environmental metals share underlying mechanisms of toxicity that contribute to adverse human health outcomes. Studies from our laboratory and others demonstrate that multiple metals disrupt zinc finger motifs altering protein function. In these systems, supplemental zinc confers protection against the metals' effects. Based on this evidence, a community and academic partnership developed an intervention trial called *Thinking Zinc*. *Thinking Zinc* is a mechanism-informed intervention study of zinc supplementation to test the potential benefits of zinc in a mixed metal exposed tribal population living in proximity to more than 500 abandoned uranium mines. **Methods:** The study is a single-arm cohort design with longitudinal collection of biospecimens, specifically blood and urine. We investigated three biomarkers of DNA damage previously reported to be zinc responsive: DNA strand break (Comet assay), oxidative DNA damage (8-hydroxy-2-deoxyguanosine, 8-OHdG) and poly(ADP-ribose) polymerase (PARP) activity. **Results:** Urinary metal analysis finds *Thinking Zinc* study participants with elevated levels of multiple environmental metals compared to the general US population, including some that had at least 10% of the participants above the National Health and Nutrition Examination Survey (NHANES) 95th percentile. Metals concentrations showed substantial fluctuations over time, with greater differences detected

in urinary metals than in serum metals. Zinc supplementation did not appreciably impact urinary levels of measured metals nor significantly increase serum zinc in study participants. However, zinc supplementation did modulate DNA damage markers evaluated by comet assay and PARP activity. **Conclusions:** We conclude that zinc is an important determinant of DNA damage in human populations and that DNA damage biomarkers are not equivalent for detecting the impact of zinc on DNA damage.

PS 4191 A community-based participatory research approach to evaluate toxic metals exposure among agricultural, native communities in the Southern Andes

J. K. Lessing¹, S. A. Stratton², A. Zhang³, J. S. Lu¹, C. Portugal⁴, C. L. Doherty², and Z. Rivera-Núñez². ¹Rutgers University, New Brunswick, NJ; ²Rutgers University, Piscataway, NJ; ³Brown University, Providence, RI; and ⁴Cotabambas Province, Tambobamba, Peru.

Background and Purpose: Elevated exposure to toxic metals is a well-documented risk factor for adverse metabolic, cardiovascular, and developmental outcomes. Copper (Cu) mining releases Cu and co-occurring metals such as arsenic (As), cadmium (Cd), and lead (Pb) into surrounding soil and water, potentially creating multiple exposure pathways for nearby populations. In Peru's Cotabambas province, large-scale Cu extraction from the Las Bambas mine overlaps with local water sources and agricultural lands used by rural Quechua-speaking communities, placing them at elevated risk for environmental contamination. This pilot study investigated potential metal exposure in two such communities, establishing preliminary data to assess human and environmental health risks associated with Cu mining. **Methods:** A mixed-methods approach incorporating participatory research tools was used. Following local community approval, residents guided researchers through their land to identify suspected sites of contamination. Soil, water, dust, and potato samples were collected from potentially contaminated sites. Metals were analyzed by inductively coupled plasma mass spectrometry (ICP-MS) to quantify As, Cd, Cu, and Pb concentrations. Additionally, soil samples were analyzed in the field by x-ray fluorescence (PXRF), and resulting maps of metal distributions were reviewed with community members in public assembly. Participant interviews provided contextual data on environmental practices and perceived exposure risks. All procedures were approved by institutional review boards at the Universidad Peruana Cayetano Heredia (Peru) and Rutgers University (USA). **Results:** A total of 37 soil, 54 water, 33 dust, and 16 potato samples were analyzed by ICP-MS. PXRF estimates of Pb concentrations were strongly correlated with ICP-MS measurements ($R^2 = 0.68$) but consistently underestimated absolute values. Soil metal concentrations exceeded international environmental thresholds for Cu in 6 (16%) samples and As in 1 (3%) sample. No potato samples exceeded international agricultural limits. Pb levels in dust exceeded regulatory U.S. limits in 19 (58%) samples, while water samples exceeded U.S. EPA maximum contaminant levels for As in 4 (7%) and Pb in 2 (4%) samples. Maps created with PXRF facilitated community engagement by visualizing potential contamination sources and helped build trust in the research process. **Conclusions:** PXRF is a feasible and informative tool for rapid, community-engaged assessment of toxic metal contamination. Findings indicate that Pb concentrations in dust frequently exceed regulatory limits, suggesting a potential risk for lead exposure that warrants biomonitoring in future studies. Elevated As levels in dust, though lacking formal standards, also raise concern for possible health effects. Continued community-based monitoring is essential to assess and mitigate toxic metal exposures in mining-affected regions.

PS 4192 Advancing Chemical Exposomics: Untargeted and Targeted LC-MS Approaches for Phase II Metabolite Analyses

J. Y. Chen, B. Taylor, T. Krivokhizhina, Z. Xie, P. Lorkiewicz, and S. Srivastava. University of Louisville, Louisville, KY.

Background and Purpose: Humans are exposed to a vast array of chemicals daily, many of which may impact health. Accurate identification and quantification of these chemicals and their metabolites (e.g., phase II conjugation products) in biospecimens are needed for comprehensive exposure assessment and health outcome evaluation. Liquid chromatography-mass spectrometry (LC-MS) is a powerful tool for chemical exposomic research. Yet, most detected features remain unannotated due to limited reference standard materials and incomplete databases. To help overcome this bottleneck, we utilize and develop untargeted (LC-QTOF/MS) and targeted (LC-MS/MS) approaches for discovery and measurement of prominent phase II metabolites - mercapturic acids (MAs), glucuronic acids (GAs), and sulfates (SAs). Previously, we developed an untargeted workflow using an integrated library-guided analysis (ILGA) and annotated 424 metabolites consisting of 146 MAs, 171 GAs, and 107 SAs derived from ~200 parent chemicals in 844 human urine samples. In this study, we aimed to confirm the chemical identities of some of those metabolites by exposing mice to parent chemicals using LC-QTOF/MS. Then, quantify the confirmed metabolites by LC-MS/MS. **Methods:** Adult male C57BL/6J mice were injected intraperitoneally (IP) with 85 parent organic chemicals prepared in 16 different chemical mixture batches. Urine samples were collected after 24hr exposure and kept frozen at -80 °C until analysis. For LC-QTOF/MS experiment, the urine samples (50 μ L) were

mixed with an internal standard mixture (5 μ L) and 0.1% formic acid in water (195 μ L). The prepared samples (5 μ L) were injected and analyzed using Waters Acquity I-Class UPLC system and Synapt XS HDMS with an electrospray ionization source operated in negative mode. The raw data files were uploaded to UNIFI software for peak picking and metabolite profiling, which was facilitated by in-house curated metabolite libraries. **Results:** LC-QTOF/MS analysis of the mice urine samples have characterized 191 phase II metabolites (62 MAs, 68 GAs, and 61 SAs). These metabolites were derived from 85 parent chemicals consisting of aromatics (e.g., o-catechol and cresol), polycyclic aromatic hydrocarbons (e.g., naphthalene and pyrene), dietary phenolics/flavonoids (e.g., caffeic acid and eugenol), and biogenic volatile organic compounds (e.g., geraniol and citronellol). Currently, we are working on developing a quantitative LC-MS/MS method of all detected metabolites in mice urine samples by using LC-QTOF/MS detection results such as retention times, m/z of molecular ions ([M-H]⁻), and signature fragmentation ions. Afterward, we aim to measure these metabolites in human urine samples to examine prevalence of exposure to their parent chemicals. **Conclusions:** IP exposure of 85 organic chemicals in mice facilitated detection of 191 phase II metabolites in urine samples by LC-QTOF/MS. This is an advancement in untargeted field as there is often a lack of authentic standards available for chemical identity confirmation. In addition, the LC-QTOF/MS results can enable us to establish a LC-MS/MS approach for the quantitative analysis of target metabolites, which will help to expand metabolite list for biomonitoring and exposomic research.

PS 4193 The Application of Non-Targeted, Volatile Organic Compound (VOC) Mobile Air Monitoring in Fenceline Communities

E. Vitucci¹, W. Wang², A. Sprague³, T. Mustapha¹, J. Cisneros⁴, M. O'Quinne⁵, C. Roberts⁵, J. Schermbeck⁵, F. Wright⁶, and N. Johnson¹. ¹Texas A&M University, College Station, TX; ²National Cheng Kung University, Tainan, Taiwan; ³Lindenwood University, College Station, MO; ⁴Singleton United/Unidos, Dallas, TX; ⁵Downwinders at Risk, Dallas, TX; and ⁶North Carolina State University, Raleigh, NC.

Background and Purpose: Fenceline communities experience disproportionate exposure to criteria air pollutants, namely PM_{2.5}. However, robust monitoring and assessment of non-criteria air pollutants, such as of the hazardous chemicals, volatile organic compounds (VOCs), is lacking. To investigate if VOCs also contribute to the disproportionate exposure burden in fenceline communities, mobile air monitoring at sites within two fenceline communities and one non-fenceline (background) community in Dallas County, TX was conducted to assess community exposure to VOCs. **Methods:** Mobile air monitoring was carried out using proton transfer reaction mass spectrometry (PTR-MS) using targeted and non-targeted analysis (NTA) to investigate VOC profiles in the community. Statistical clustering analyses of the NTA data assessed the similarity between community VOC profiles, and composite Z-scores of total VOC concentrations within each community were combined with mobile data to visualize the distribution of VOCs within each community. **Results:** Targeted analysis of the VOCs benzene, toluene, and ethylbenzene and/or xylene (BTEX) revealed periodic, significant elevations in their average concentrations in the fenceline communities compared to background. Statistical clustering analyses revealed distinct separation of the communities based on their VOC profiles and identified specific VOCs contributing to these clustering effects. Targeted and NTA revealed that multiple VOCs had periodically large spikes (hotspots) in their concentration throughout the fenceline communities. Notably, hotspots were not detected in the background community. **Conclusions:** Together, our data highlight that VOCs likely contribute to the disproportionate air pollutant exposure burden faced by fenceline communities. These data support the expansion of current fenceline monitoring programs and support the incorporation of VOC monitoring into these programs to protect residential and worker health. Furthermore, our study introduces new strategies for assessing non-targeted VOC datasets that can expand their utilization in ongoing efforts to monitor ambient VOCs and support efforts to regulate and improve air quality.

PS 4194 Air Quality and Respiratory Function among Veterinary Staff: A Pilot Exposure-Response Assessment in Clinical Settings

D. K. Seybold, D. M. McGee, O. P. Jegede, E. Orteiz, and A. Adhikari. Georgia Southern University, Statesboro, GA. Sponsor: D. Seybold, Society of Environmental Toxicology and Chemistry

Background and Purpose: Veterinary professionals are continually exposed to various airborne particulates and chemical disinfectants, which compromise respiratory health. Fine Particulate matter, specifically PM_{2.5}, penetrate deep into airways reducing airflow and causing inflammation. Limited research fails to explore the direct relationship of PM_{2.5} and pulmonary outcomes in conjunction with inflammatory biomarkers within veterinarian settings. This pilot study aims to investigate the exposure relationships among PM_{2.5} and respiratory performance among staff at a veterinary clinic in Southeast Georgia. **Methods:** Veterinary professionals are continually exposed to various airborne particulates and chemical disinfectants, which compromise respiratory health. Fine Particulate matter, specifically PM_{2.5}, penetrate deep into airways reducing airflow and causing inflammation. Limited research fails to explore the direct relationship of PM_{2.5} and pulmonary outcomes in conjunction

with inflammatory biomarkers within veterinarian settings. This pilot study aims to investigate the exposure relationships among PM_{2.5} and respiratory performance among staff at a veterinary clinic in Southeast Georgia. **Results:** Preliminary results performed from the CEM showed higher PM_{2.5} concentrations in animal handling zones compared to reception areas, with peak levels occurring after cleansing and pest decontamination: 1) Morning PM_{2.5} (1060.18 $\pm$ 1915.30 μ g/m³), 2) Afternoon PM_{2.5} (260.40 $\pm$ 317.72 μ g/m³), (insert total mass (microgram by cubic meter symbol). Early lung function testing indicated a mild reduction in FEV₁ (2.91 $\pm$ 1.45L), FVC (4.37 $\pm$ 1.29L), and elevated eNO levels (17.92 $\pm$ 14.86ppb) post-shift, compared to pre-shift FEV₁ (3.01 $\pm$ 1.50L), FVC (4.48 $\pm$ 1.34L), eNO (16.64 $\pm$ 14.39ppb). Individuals in this preliminary study had consistently below the eNO average compared to the normal range for healthy individuals (eNO <25 ppb), but still showed trends of decreasing eNO at the end of the work day (p < 0.05). Similarly, the preliminary study data for FEV₁ and FVC also remain in standard healthy range, (2.5-4.5L) and (3.0-5.5L) but show no statistical difference between morning and afternoon. This suggests that transient airway inflammation associated with chronic workplace exposure may negatively impact lung function overtime, triggering inflammation in the respiratory tract. **Conclusions:** The preliminary data show differences in PM_{2.5} between working and waiting areas, as well as a greater rate of change in lung function among individuals who frequently work in washing, grooming, and exam rooms, compared with those who work in reception areas. Based on this primary data, further research is needed to closely examine the risk relationship and response to higher particulate matter exposure in veterinary clinics compared to those with less frequent exposure, to inform future interventions to mitigate PM_{2.5} respiratory risks among animal care professionals.

PS 4195 Pinpointing the Pervasive: An Exposome Platform for Subtle Environmental Threats

E. Stancliffe, and G. J. Patti. Panome Bio, Saint Louis, MO. Sponsor: G. Patti, American Association for Cancer Research

Background and Purpose: Exposure to environmental and lifestyle factors is increasingly recognized as a significant, yet under-characterized, driver of numerous emerging health trends, including rising incidences of cancer, neurodegenerative diseases, autoimmune disorders, and metabolic syndromes. The totality of these exposures, termed the "exposome", represents a critical gap in our understanding of disease etiology. Panome Bio developed a novel analytical platform for human exposure profiling, specifically designed to unravel these complex connections. **Methods:** First, we compiled and curated a relational database of small molecule exposure chemicals from public sources (CompTox, FoodDB, The Toxic Exposome Database, DrugBank). Second, we developed an optimized LC/MS-based analytical method. Through comparative evaluation and extensive spike-in experiments on human plasma, we developed a targeted method to quantify >200 compounds with >90% quantitative accuracy. Finally, we developed a robust computational platform for large-scale untargeted exposomics. This platform incorporated memory and compute-efficient peak detection and a machine-learning algorithm for batch effect/technical drift correction, demonstrating >90% coverage of spiked-in compounds and a mean coefficient of variation <20% in technical replicates. **Results:** Next, we applied this methodology to a serum cohort of individuals with Alzheimer's Disease (AD) as well as age/sex matched healthy controls. The results of this analysis identified 28 chemical exposures present in at least one of the serum samples. Comparison between healthy and AD patients resulted in four chemical exposures with differential abundance, including insecticides and pesticides with known neurological effects as well as the forever chemical perfluorooctane sulfonate. **Conclusions:** These findings demonstrate the utility of Panome Bio's exposome profiling platform for sensitively detecting and quantifying environmental chemical exposures in human biofluids, providing a powerful new approach for uncovering links between subtle environmental threats and disease.

PS 4196 Does the Dose Make the Poison? Time Will Tell

P. M. Kruse, and K. P. Messier. National Institute of Environmental Health Sciences, Durham, NC.

Background and Purpose: Human exposures to environmental and anthropogenic chemical pollutants arrive through several different pathways and at varying rates. In addition to determining exposure pathways, the location of the exposure and its duration are also of key importance for modeling and risk assessment considerations. The GeoTox framework and R package was introduced to provide source-to-outcome modeling of exposures to chemicals and their downstream effects on different biological mechanisms. Users supply geo-spatially resolved steady-state exposure data and study how this affects a given population through a variety of *in vitro* endpoints. However, users of GeoTox are limited by a reliance on steady-state dose-response data, restricting study to longer timescales and less dynamic exposure scenarios. **Methods:** Here, we develop the GeoTox framework to model non-steady state exposure scenarios. The user supplies a time-series of exposure data and simulates a population of a given size, age, and weight classification through functionality provided by the R package htk. Using new GeoTox functions, this data can be analyzed to determine the impact of these exposure scenarios on biological response using traditional dose-response curves characterized by the Hill

equation. We also considered a time resolved dose-response equation derived from a Hill equation model with a dose- and time-dependent decay factor. We developed functionality to model pre-equilibrium chemical dose-response to determine how time-varying exposures impact different endpoints during the exposure. This framework allows users to simulate the biological response to a time-series of exposure values when the exposure does not fit into the steady-state scenario. Functionality is included to determine the magnitude and duration of a response above user-defined response thresholds. **Results:** We completed numeric simulations of three different exposure scenarios (acute, periodic, and constant) on populations of 500 individuals in ten-year age ranges (20-29, 30-39, 40-49, 50-59, 60-69, 70-79) and in "normal" and "obese" weight classifications for 39 chemicals included in the National Air Toxics Assessment list or in the GeoTox package data. Each exposure scenario produced the same total exposure over the same total time but followed different exposure profiles. An examination of distributions of peak blood plasma concentrations and blood plasma concentration area under the curve (AUC) values showed differentiation among the exposure scenarios that held across the various demographic combinations we simulated, with periodic and constant exposures producing similar distributions, distinct from the acute exposure distribution. We also observed a tradeoff between how close the peak plasma concentrations were and the AUC values across exposure and demographic groups for a given chemical. For instance, for 32 chemicals the mean of the ratio of the acute to periodic max plasma values was greater than 2, and for the 7 chemicals for which this did not hold, the mean of the ratio of acute plasma AUC to periodic AUC was at least 1.2. We analyzed the behavior of the pre-equilibrium dose-response functionality of GeoTox. We observed behavior of time-varying dose-response falling between two limiting behaviors, with a tradeoff between peak response values and total response AUC above set response thresholds. We noted that response behaviors depend heavily on the timescales of the exposure and the orders of magnitude of the exposures, binding association constant and dissociation constant (that define the equilibrium dissociation constant) of the molecule with its target receptor. We also determined a rough heuristic relating a decay term in the dose-response model with the dose-response curve behavior. **Conclusions:** To determine downstream biological effects of environmental exposures, it is important to consider not only geospatially resolved exposure data but also temporally resolved data. Expanding the functionality of GeoTox to handle non-steady state exposure time-series provides users with tools to begin exploring more dynamic exposure scenarios aside from low resolution and long-term exposure profiles. Our simulations demonstrate a need for more time-resolved dose-response experimental data as well as time-dependent dose-response models to study more complex exposure scenarios. This is particularly important for understanding spatially and temporally varying exposures across life-course.

PS 4197 Advancing the Systematic Understanding of Quaternary Ammonium Compounds (QACs): Harmonized Nomenclature and Consumer Product Use Patterns

B. N. Chung¹, K. Balasubramanian¹, L. Huang¹, T. Moradkhan¹, Q. Meng¹, V. Samano², C. N. Lowe³, A. Williams³, N. Pham¹, T. Buck¹, T. A. Bruton¹, and A. Doherty¹. ¹California Safer Consumer Products Program, Department of Toxic Substances Control, Sacramento, CA; ²Senior Environmental Employment Program, U.S. Environmental Protection Agency, Durham, NC; and ³Office of Research and Development, Center for Computational Toxicology and Exposure, U.S. Environmental Protection Agency, Durham, NC.

Background and Purpose: Quaternary ammonium compounds (QACs or quats) are a broad and diverse class of chemicals characterized by at least one positively charged nitrogen bonded to four carbon-based substituents. They are widely used as surfactants and antimicrobial agents in household and personal care products, with significantly increased use during the COVID-19 pandemic, raising concerns about their safety. However, inconsistent nomenclature and limited awareness of the breadth of QAC chemistries and their uses have hindered health and environmental research on this chemical class. As part of an effort to evaluate potential adverse impacts of QACs use in consumer products, we aimed to (1) create a systematic nomenclature for QACs and (2) assess the use of QACs in different consumer product categories. **Methods:** We developed a systematic nomenclature that clearly and concisely describes QACs and applied it to a list of 366 substances on EPA's Distributed Structure-Searchable Toxicity (DSSTox) Database, available through EPA's CompTox Chemicals Dashboard. Using this harmonized list of QACs, we assessed their presence in household and personal care products from the Mintel Global New Products Database (2017-2022), which includes over 140,000 products across 112 categories. **Results:** Using the nomenclature, we accurately categorized structurally diverse QACs by clearly and concisely describing the structure of each QAC or QACs mixture and identified 259 unique QACs in 19,460 consumer products. Of these 259, only 28 belonged to well-studied subclasses such as benzyl alkyl dimethyl ammonium compounds (BACs), alkyl trimethyl ammonium compounds (ATMACs), and dialkyl dimethyl ammonium compounds (DADMACs). The majority were less-studied QACs, including polyquaterniums, cocamidopropyl betaine, betaine, guar gum-derived galactomannans, and organoclays. These compounds were commonly found in hair care, skin care, and soap products, suggesting frequent and potentially chronic human exposure through dermal contact and incidental ingestion. Many of these compounds have little or no environmental fate or hazard data in the peer-reviewed scientific literature, indicating a significant gap between their widespread use and scientific understanding of their safety. These results highlight

the need for hazard testing and human exposure and biomonitoring evaluations for QACs. **Conclusions:** This systematic nomenclature approach strengthens the ability to clearly define, evaluate, and communicate about QACs as a chemical group. Incorporation of this nomenclature into DSSTox facilitates use of this nomenclature by researchers. Further, the incorporation of information from CompTox into other large chemical databases, such as PubChem and ChemSpider will support more widespread adoption of the nomenclature. We demonstrate an example of how this new nomenclature can be used to increase understanding of potential exposure to QACs by characterizing their use in consumer products. Our method of integrating standardized nomenclature with product-use data demonstrates how regulatory science can identify data gaps and inform efforts to design characterize the hazards and potential adverse impacts of chemicals in consumer products.

PS 4198 From Numbers to Mechanisms: A Unified Framework for Interpreting and Predicting Urinary Excretion Fractions

Y. Li, and L. Li. University of Nevada Reno, Reno, NV. Sponsor: D. Li

Background and Purpose: The urinary excretion fraction (FUE), which represents the proportion of an applied chemical dose excreted in urine over time, has been widely used to back-calculate human chemical exposure based on measured chemical or metabolite levels in urine. However, current FUE values suffer from several major limitations. First, FUE can only be obtained through controlled human or animal experiments, and the biological mechanisms underlying measured values are often unclear. This makes it impossible to estimate FUE for most chemicals that have never been tested. Second, even when FUE has been measured, data usually come from very small studies with few participants, meaning that only average values are reported and interindividual variability remains poorly characterized. To overcome these challenges, we developed a mechanism-based, input-parsimonious approach that explains and quantifies how the body processes chemicals and how much appears in urine. This framework provides a scientific basis for interpreting existing FUE measurements and enables prediction of FUE for chemicals lacking human data. In addition, by combining the model with NHANES biomonitoring data, it allows estimation of personalized FUE values rather than relying solely on population averages. **Methods:** We developed a mechanistic model describing the biological processes that govern FUE. The model considers hierarchical and branching metabolism of a parent compounds to 1st-, 2nd-, 3rd-, ... orders of metabolites. It requires only five key parameters: the fraction absorbed into blood (fabs), the fraction metabolized at each metabolic order (M), the fraction undergoing Phase II conjugation (C), the relative yield of each metabolite (Y), and the fraction excreted unchanged in urine (U). Three of these parameters (fabs, M, U) can be estimated directly from chemical properties using the "human exposure and toxicokinetic module" in the PROTEX model (or other similar toxicokinetic models supporting calculating absorption and elimination processes), which has been validated against biokinetic data for over 1,200 chemicals. The remaining parameters, C and Y, can be obtained from experimental data measured in either *in vivo* or *in vitro* observations. Using nicotine biomonitoring data from 1,801 NHANES participants, we further identified how metabolism (M) and urinary elimination (U) vary across individuals. These population patterns allow the model to generate personalized FUE estimates for chemicals that share similar metabolic pathways. **Results:** The mechanistic model showed strong agreement with empirical data for 105 chemicals, with 93 of them exhibiting less than one log-unit difference between predicted and observed FUE values. This level of performance demonstrates that the model successfully captures the essential biological processes that determine FUE. A key insight is that chemicals can have similar overall FUE values but for entirely different biological reasons. For example, the literature reported measured FUE values of ~70% for both monoethyl phthalate (MEP) and monobenzyl phthalate (MBzP). At first glance, this may be interpreted in a counterintuitive manner that humans have a similar urinary excretion capacity for both compounds, despite their markedly different hydrophobicity levels. However, our mechanistic approach reveals that 61.2% of MEHP is eliminated in the unchanged form, whereas only 0.1% of MBzP follows this pathway, with the remaining fraction requiring conjugation before excretion. NHANES data further revealed large interindividual differences in metabolism and urinary elimination, with an approximately 40-fold range in M and a 10-fold range in U. When incorporated into the model, these differences produced nearly a 30-fold variation in personalized FUE for nicotine across the population, highlighting the importance of accounting for individual variability rather than relying on a single average value. **Conclusions:** This study establishes a mechanistic foundation for understanding and predicting FUE. The framework explains why chemicals differ in their FUE values, resolves inconsistencies that arise from small experimental studies, and enables FUE predictions for chemicals without human data. By incorporating population biomonitoring information, the model also provides person specific FUE estimates, supporting more accurate exposure assessment, toxicokinetic modeling, and chemical risk prioritization.

K. M. Salerno¹, D. R. Nachman¹, J. M. Kalter¹, T. J. Buckley¹, K. E. Klarup¹, T. R. Sterner^{2,3}, and R. A. Clewell^{2,4}. ¹Johns Hopkins University Applied Physics Laboratory, Laurel, MD; ²Air Force Research Laboratory (711HPW/RHBAF), Wright Patterson AFB, OH; ³Henry M. Jackson Foundation for the Advancement of Military Medicine, Inc., Wright Patterson AFB, OH; and ⁴Eagle Integrated Sciences, Inc., Wright Patterson AFB, OH.

Background and Purpose: Military personnel are subject to varied and complex chemical exposures with potential to adversely affect health and mission readiness. A common concern for warfighter health is uncharacterized mixtures, such as those produced from thermal degradation during fires, explosions, and jet exhaust. This collaborative effort between the Air Force Research Laboratory and the Johns Hopkins University Applied Physics Laboratory leveraged predictive chemistry models, large language models (LLMs), and targeted burn studies to develop an artificial intelligence (AI)-enabled model for predicting emissions from combustion and pyrolysis at varying conditions. **Methods:** A chemical burn test chamber utilizing a tube furnace was developed to allow precise and automated fuel, air and temperature control. The thermal degradation byproducts were measured with Fourier Transform Infrared (FTIR) spectroscopy and Gas Chromatography/Mass Spectrometry (GC/MS) for direct comparison to the models. The predictive chemistry model was built on a foundation of chemistry and physics, incorporating three modern AI tools to augment chemical kinetics models. The REXGEN AI reaction prediction tool generated candidate products. An LLM-driven literature search workflow was used to identify relevant chemicals, thermochemistry data, and reaction parameters in the literature. The Reaction Mechanism Generator (RMG) software integrated standardized, high-quality thermochemistry and reaction-kinetics databases with custom, literature-derived databases to automatically build chemical kinetics mechanisms. These reaction mechanisms were then used in Cantera model calculations tailored to the experimental conditions in the burn chamber. Results from generated reaction mechanisms were compared with experimental results and published literature. A case study was performed with 1,1,2-trichloroethane (1,1,2-TCA) to demonstrate the utility of this integrated workflow. **Results:** The LLM significantly improved search efficiency with a 10-fold reduction in time compared to manual searches. The REXGEN model accurately predicted relevant decomposition products ~75% of the time on the training dataset. To evaluate to utility of the computational workflow, model predictions were compared to pyrolysis and combustion data for 1,1,2-TCA. The most abundant pyrolysis byproduct was predicted to be hydrogen chloride (HCl), followed by isomers of dichloroethylene (DCE), which were confirmed experimentally. As the parent compound was completely broken down near 650° Celsius, DCE was further degraded to acetylene, chloroethyne and additional HCl. Adding oxygen at 500° C produced carbon dioxide, phosgene and likely carbon tetrachloride, in addition to HCl. There was strong agreement between laboratory and modeling results for 1,1,2-TCA thermal degradation. Modeling and experiments conducted for dichloromethane, cyclohexane and toluene also showed strong agreement between the model and collected data. Success with this process has provided a framework to apply to additional relevant chemistries. **Conclusions:** Together with predictive toxicology models, these thermal degradation models demonstrate a computational approach to identifying, predicting, and mitigating risk from the complex toxic exposures associated with high temperature processes. The project demonstrated a computational workflow for effectively predicting the byproducts of chemical combustion and pyrolysis under varying conditions with experimental validation. The example of 1,1,2-TCA demonstrated how specific byproducts and their relative concentrations can indicate the original parent compound and thermal history. This is a key step in identifying the source of airborne contaminants, prioritizing chemical sensor target development, and estimating health risks associated with operational exposures. Further, this research furthers the goal of creating user-friendly decision aids to ensure a healthy and ready force.

PS 4200 USEtox Modeling of Children's Exposures to Potential Endocrine Disruptors in Personal Care Products

L. Nakayama Wong¹, L. Huang¹, M. Romero Franco¹, B. Chung², X. Zhou¹, Q. Meng¹, O. Joliet³, and N. Pham¹. ¹California Department of Toxic Substances Control, Sacramento, CA; ²California Department of Toxic Substances Control, Cypress, CA; and ³Technical University Denmark, Lyngby, Denmark.

Background and Purpose: Endocrine disrupting chemicals (EDCs) in personal care products (PCPs) are an important source of exposure, especially for children, who are exposed daily to mixtures of known and potential EDCs through various routes including dermal, oral, and inhalation. Parabens are widely used preservatives found in products marketed to infants and children. Better understanding of children's aggregate and cumulative exposures to different parabens and potential EDCs in children is needed. **Methods:** We applied the USEtox 3.0 tool to systematically evaluate children's aggregate and cumulative exposures to parabens and potential EDCs. To assess the aggregate exposure to parabens, we focused on 6 parabens: methyl- (MeP), ethyl- (EtP), N-propyl- (NPrP), isopropyl- (IPrP), N-butyl- (NBuP), and isobutylparaben (IBuP). We identified 28 PCP categories containing at least one paraben commonly used by children, and collected ingredient list informa-

tion using the Mintel Global New Product database and Clearya. Each PCP category was assigned to appropriate age group(s) of children according to the product's target users and child behaviors, where a total of 8 age groups for children from birth to 11 years old (birth to <1 month, 1 to <3 month, 3 to <6 month, 6 to <12 month, 1 to <2 years, 2 to <3 years, 3 to <6 years, and 6 to <11 years) were considered. The weight fractions of parabens in each PCP category were gathered from the Pharos (Habitable) and the Interstate Chemicals Clearinghouse (IC2) databases. To assess the cumulative exposure to parabens and potential EDCs, we conducted a case study on newborn's (birth to <1 month) body lotions (n=5) and diaper cream (n=1) products. The ingredients of these products were queried in the U.S. EPA's Cheminformatics hazard module to identify potential EDCs other than parabens based on a high hazard score for endocrine disruption. The U.S. EPA's Chemical Product Database was then used to estimate weight fractions of the identified EDCs in these products. **Results: Aggregate exposures to parabens.** Direct dermal exposure contributes to >99% of children's aggregate exposure to parabens. MeP and NPrP result in the highest aggregate exposure doses across all eight age groups, primarily due to their presence in all PCP categories considered. The highest aggregate exposure dose for NPrP was estimated to be 1.57 mg/kg/d in children 3 to <6 years, and for MeP 1.54 mg/kg/d in children 6 to <11 years. The 8 age groups can be divided into three categories: birth to <6 months, 6 months to <3 years, and 3 to <11 years. Paraben exposure is dominated by different products within each category: baby wash (birth to <6 months), sunscreen (6 months to <3 years), body lotion, body wash, and hand cream (3 to <11 years). Within each category, the product use is similar, but the body weight increases with age, so the aggregate exposure dose tends to decrease as the age increases. The paraben exposure estimates are dependent on the model estimated product intake fraction (PiF), the paraben's mass fraction in the product, and the product mass applied. Overall, the paraben's weight fraction displays the largest variation between products, making it the most important factor in determining the exposure. **Cumulative exposure to parabens and potential EDCs.** We identified 6 potential EDCs other than parabens in newborn body lotion and diaper creams that can be modeled by USEtox, including benzoic acid, bronopol, liliol, propylene glycol, stearic acid, and triethanolamine. Parabens found in these products included MeP, EtP, and NPrP. The cumulative exposure doses range from 6.5 to 28 mg/kg/d across the six products. Of the six products studied, one body lotion product resulted in the highest cumulative exposure dose, which was dominated by stearic acid and triethanolamine. The second highest cumulative exposure dose was from the diaper cream product, which was dominated by propylene glycol, MeP, and NPrP. **Conclusions:** This study demonstrates the feasibility of USEtox modeling to assess children's aggregate and cumulative exposures to known and potential EDCs in PCPs. Policymakers can leverage these findings to prioritize chemicals in products for regulation and protect public health.

PS 4201 Oxidative stress, PGE2 and NGF/TrkA/P75^{NTR} dysregulation and neurodegeneration induced by thyroid signaling disruption following PFOS single and repeated treatment

P. Moyano¹, A. Flores¹, J. Sanjuan¹, J. C. Plaza¹, L. Guerra-Menéndez², L. Abascal¹, O. Mateo¹, and J. Del Pino¹. ¹Complutense University of Madrid, Madrid, Spain; and ²San Pablo CEU University, Madrid, Spain.

Background and Purpose: Perfluorooctane sulfonic acid (PFOS), a persistent industrial chemical, has been associated with impairments in cognition. While several studies have attempted to identify the underlying mechanisms, the precise pathways mediating these cognitive deficits remain incompletely understood. PFOS induces cell death in basal forebrain cholinergic neurons (BFCNs), a population critically involved in maintaining cognitive function, through disruption of thyroid hormone (TH) signaling. These neurotoxic effects could be mediated through multiple interconnected pathways, including the generation of oxidative stress, dysregulation of prostaglandin E2 (PGE2) signaling, and disruption of nerve growth factor (NGF) homeostasis, all of which have been independently linked to BFCN degeneration and cognitive dysfunction, and were reported to be induced after PFOS exposure. **Methods:** To systematically evaluate PFOS-induced neurodegeneration in BFCNs, we employed the SN56 cholinergic cell line derived from the basal forebrain. Cells were exposed to PFOS across a concentration range (0.1-40 µM) in combination with various pharmacological agents: thyroxine (T3; 15 nM), recombinant NGF (20 µM), MF-63 (1 µM), and N-acetyl cysteine (1 mM). **Results:** Our experimental results show that PFOS exposure (both single 1-day and repeated 14-day treatments) triggers oxidative stress through reactive oxygen species accumulation coupled with diminished NRF2 pathway activity. Furthermore, PFOS disrupts both PGE2 signaling and the NGF/TrkA/P75^{NTR} neurotrophic pathways, ultimately leading to BFCN cell death. These neurotoxic effects appear to be fundamentally mediated through PFOS-induced interference with TH signaling pathways. **Conclusions:** These findings provide valuable mechanistic insights into PFOS-induced BFCN neurodegeneration and the consequent cognitive decline, while simultaneously suggesting potential therapeutic strategies to counteract these detrimental effects.

PS 4202 **Impact of Developmental Atrazine Exposure on Antioxidant Activity and AD-Related Pathways in Wild-Type and *sorl1* Mutant Zebrafish Embryos**

K. S. Chelladurai, and J. L. Freeman. Purdue University, West Lafayette, IN.

Background and Purpose: Dementia is a growing global health concern, affecting around 55.2 million people worldwide. Alzheimer's disease (AD) is the leading cause, responsible for 70-80% of all dementia cases. Despite extensive research, the exact causes of AD remain unclear due to its complex and multifactorial nature. Along with amyloid- β and tau, factors like neuroinflammation, oxidative stress, and mitochondrial dysfunction play major roles in its progression. The recently identified genetic risk factor SORL1 affects APP processing, tau seeding, and interacts with multiple brain metabolites. Lifestyle, environmental, psychosocial factors, and comorbidities can further increase AD risk, although research on gene-environment interactions remains limited. We chose to investigate atrazine (ATZ), which is one of the most widely used herbicides globally. Recent studies reported ATZ disrupts the neuroendocrine and neurotransmitter systems, causes neuronal inflammation, and accelerates brain aging. The purpose of this study was to examine the neurotoxic AD-related outcomes of ATZ exposure on antioxidant enzymes, glutamate and glutamine levels, and the amyloid pathway and tau in wild-type and *sorl1* mutant early development zebrafish model. We investigated the hypothesis that ATZ exposure will induce oxidative stress, disturb the glutamate-glutamine cycle, and interfere with amyloid and tau pathways. In addition, interaction with the *sorl1* mutation is expected to further increase AD-like pathophysiological changes. **Methods:** In this study, experiments were first conducted using wild-type zebrafish (*Danio rerio*). Wild-type fish were bred and embryos were collected 40 minutes post-fertilization. After rinsing, embryos were randomly distributed into Petri dishes in groups of 50. Within 1 hour post-fertilization (hpf), fish were exposed to 20 mL of ATZ at concentrations of 0, 0.3, 3, or 30 ppb ($\mu\text{g/L}$) at 28°C for 1 to 72 hpf, covering the full embryogenesis period. The same experimental setup was applied to the *sorl1* mutants but also included a wild-type control. Each treatment group was replicated at least six times. Antioxidant enzyme activities were determined using colorimetric assays. Glutamine and glutamate concentrations were then measured. Gene expression related to the amyloid and tau pathways was analyzed using qPCR, while amyloid- β peptide and tau protein levels were quantified using ELISA. Data were analyzed in SAS using ANOVA, followed by a post hoc least significant difference (LSD) test when significant differences were detected among treatments ($\alpha = 0.05$). **Results:** Results revealed that in wild-type fish, there were no significant changes in lipid peroxidation in any of the ATZ exposure groups. Similarly, there were no significant alterations in the antioxidant enzyme activity for CAT, CuZnSOD, MnSOD, GST, and GSH. In addition, no differences were observed in the glutamate and glutamine levels in response to ATZ exposure when compared to the negative control group (0 ppb) ($p > 0.05$). In the amyloid pathway, *bace1* gene expression was significantly downregulated in the 0.3 and 30 ppb ATZ-exposed groups ($p < 0.05$), but no significant changes were observed in *sorl1*, *apoea*, *apoeb*, *appa*, *apbb*, *psen1*, and *psen2* gene expression. Likewise, no significant changes were observed in BRI2 protein which is an upstream regulator of *bace1*. On the other hand, the *mapta* and *maptb* gene and the tau protein expression exhibited significant alterations in response to ATZ exposure ($p < 0.05$). *sorl1* mutant embryos also had no significant changes in lipid peroxidation, CAT, and GST activity in any of the exposed groups. However, CuZnSOD, MnSOD, and GSH activity were significantly increased ($p < 0.05$) in all the exposed groups when compared to the wild-type negative control. **Conclusions:** This study suggests ATZ exposure does not increase oxidative stress, does not alter antioxidant enzymes, and resulted in no changes in the glutamate or glutamine levels in the wild-type fish. Alternatively, ATZ exposure did influence expression of specific genes in the amyloid and tau pathways. Furthermore, the *sorl1* mutants showed an elevated antioxidant response, which confirms that the *sorl1* gene and its interaction with ATZ induce oxidative stress in early development, which may have a significant influence on other AD-related mechanisms. However, other AD-related outcomes are yet to be studied.

PS 4203 **Chronic non-cytotoxic manganese exposure disrupts glutamate homeostasis and pathways involved in the integrated stress response in Alzheimer's disease**

H. Kim¹, A. M. Tukker¹, M. M. Strom¹, M. L. Simmel¹, F. E. Harrison², and A. B. Bowman¹. ¹Purdue University, West Lafayette, IN; and ²Vanderbilt University Medical Center, Nashville, TN.

Background and Purpose: Some evidence supports a connection between manganese (Mn) overexposure and Alzheimer's disease (AD). A key pathology shared by Mn neurotoxicity and AD is altered glutamate neurobiology. Neuronal hyperexcitability has been reported in AD patients and studies showed that acute exposure to supraphysiological Mn inhibits synaptic glutamate uptake. Moreover, glutamate is the brain's most abundant excitatory neurotransmitter and free amino acid involved in transcription, translation, and metabolism. How chronic Mn neurotoxicity contributes to AD is unclear. We hypothesized that chronic exposure to pathophysiological Mn levels disrupts glutamate homeostasis as a function of AD genetic risk. **Methods:** Human induced pluripotent stem cells (hiPSCs) derived from neurotypical individuals and AD patients (familial/sporadic) were induced to a neuroectodermal fate via dual SMAD inhibition. Cortical progenitors were maintained for ≈ 100 days to promote neuronal maturation and astrogliogenesis and then exposed to Mn

(0, 0.5 or 5.0 μM) for 4-6 weeks. Following exposure, ¹⁴C-glutamate uptake assay, single cell RNA-sequencing (scRNA-seq), pathway analysis, immunocytochemistry (ICC), and quantitative reverse-transcription PCR (RT-qPCR) were performed. Wild-type (WT) and APP/PSEN1 mice were fed 10 months control (70 ppm) or high Mn diet (2400 ppm) beginning at 3 months of age and were maintained throughout the study period. Liquid chromatography high-resolution mass spectrometry metabolomics was employed to investigate cortical metabolomic profiles. Brain tissue samples from the same animals used for metabolomics analysis were utilized for ribosome profiling (ribo-seq). **Results:** Chronic Mn exposure significantly decreased net glutamate uptake in AD patient-derived cortical cultures compared to neurotypical controls. ICC and RT-qPCR analyses indicated an absence of reactive astrocytes as confirmed by cytoplasmic localization of nuclear factor kappa B/p65, lack of hypertrophic morphology, and unchanged expression of pan-reactive genes. scRNA-seq cluster annotation identified major cortical cell types including glutamatergic and GABAergic neurons, astrocytes, intermediate progenitors, and other cycling progenitors. Qiagen Ingenuity Pathway Analysis and gene ontology (GO) analysis showed, besides alterations in pathways involved in glutamate neurobiology, the most significant enrichment in pathways and GO terms related to translation, mitochondria, and amino acid metabolism, in particular EIF2 signaling, suggesting involvement of the integrated stress response (ISR). *In vivo* metabolomics and ribo-seq showed that WT and AD mice respond differently to Mn as exemplified by clear segregation on PCA plots by treatment/genotype. Pathway analysis via EnrichR using differential translation efficiency genes enriched for similar pathways identified in our hiPSC model. **Conclusions:** Chronic Mn exposure induced alterations in glutamate homeostasis at the functional and transcriptional level, the effect of which seems to be dictated by an individual's genetic risk for AD. This suggests that polygenic AD risk genotypes, at least in some individuals predisposed to AD, confer susceptibility to dysregulated glutamate homeostasis. Absence of astrocyte reactivity suggests that the impaired glutamate uptake phenotype, at least in our model, is likely driven by mechanisms independent of neuroinflammation. Enrichment of biochemical pathways and GO terms associated with translation, cellular energy, and amino acid metabolism suggest dysregulated ISR. Intriguingly, our *in vivo* metabolomics and ribo-seq data suggest presence of a genotype-driven metabolic rewiring and translational response to chronic Mn exposure. Our next experiments will investigate the presence of genotype-dependent susceptibility to chronic Mn by interrogating differentially translated genes and evaluate levels of eIF2 α phosphorylation as a surrogate marker of ISR activation to explore differential chronic ISR activation driven by AD genotype. This work was supported by NIH R01 ES031401 (FEH ABB) and R01 ES035518 (FEH ABB). Acknowledgements: Center for Innovative Technology, Vanderbilt Univ. and TB-Seq, Inc., San Francisco, CA.

PS 4204 **Toxic effects of the obesogenic microbiome metabolite delta-valerobetaine on cognitive function**

D. P. Jones, G. Lim, H. Lee, J. Jeon, Z. R. Jarrell, and Y. Go. Emory University School of Medicine, Atlanta, GA.

Background and Purpose: Environmental Alzheimer's disease (AD) arises from the interaction of genetic susceptibility with modifiable low-dose toxicities that evolve across the lifespan, with underlying mechanisms associated with mitochondrial dysfunction, oxidative stress, and inflammation. We recently found that the intestinal microbiome produces a metabolite, δ -valerobetaine (VB), that causes obesity in mice and is associated with the abundance of visceral and subcutaneous fat in humans. Epidemiologic data underscore the importance of obesity in heightening the risk of developing dementia and AD. Because VB causes obesity and inhibits mitochondrial fatty acid oxidation, we investigated whether VB causes neurotoxicity measured by a decline in spatial working memory in aged mice. **Methods:** 20-month-old male and female C57BL/6J mice from the National Institute of Aging (NIA) were fed standard mouse food *ad libitum* and water with 1.62 mM VB or without VB (Cont) *ad libitum* for 12 weeks. Body weight and water intake were measured weekly. Prior to the initiation of treatment and after 12 weeks of VB treatment, cognitive function was measured using a Y-maze. At the end of the treatment period, mice were euthanized, and brain tissues were collected. Histological analysis was conducted in the dentate gyrus (DG) and cornu ammonis 1 (CA1) regions of the hippocampus, and brain metabolomics was analyzed using high-resolution mass spectrometry. Human neuroblastoma cells (SH-SY5Y) were used to assess VB's impact on neuronal mitochondrial function. Protocols were approved by Emory University Institutional Animal Care and Use Committee (IACUC). **Results:** Brain VB concentration increased with oral VB intake and showed three to five times higher concentrations in brains from VB-treated mice than control mice, with no apparent differences between sexes. No baseline differences in % alternation during Y-maze were detected for either male or female mice. Following VB exposure, however, VB-treated aged male mice exhibited lower % spontaneous alternation ($58 \pm 3\%$) compared to the controls ($67 \pm 2\%$), indicating an impaired spatial working memory ($p < 0.05$). No effect of VB on cognitive decline was observed in aged female mice, suggesting a male-specific vulnerability to VB-induced cognitive dysfunction. No significant differences in the number of arm entries were observed between groups at baseline or after the treatment period. The hippocampus is critical for spatial learning, navigation, and memory, and histological analysis of the hippocampus revealed marked neuronal degeneration in the DG and CA1 regions of VB-treated aged males. In contrast, only mild neuronal degeneration was observed in VB-treated females, consistent with the behavioral results. Metabolomics results in both males and females showed impact on acyl-carni-

tines, indicating effects on mitochondrial energy metabolism. Mitochondrial effects were further studied in dose-response studies in SH-SY5Y cells. In undifferentiated cells, VB concentrations of 10, 20, and 50 μM significantly decreased MTT reduction compared with untreated controls, whereas 5 μM had no discernible change in MTT reduction. In differentiated SH-SY5Y cells, VB induced a clear dose-dependent decrease in mitochondrial respiration beginning at 5 μM and progressing through 50 μM . These findings reinforce prior findings that VB impairs mitochondrial activities and further show that VB exposure accelerates hippocampal neurodegeneration in aged male mice. **Conclusions:** VB concentration is increased in the mouse brain in response to increased bioavailability through diet. Increased VB in the brain causes a decline in spatial working memory in aging male mice but not in aging female mice, suggesting that VB toxicity contributes to sex-dependent cognitive deficits in aging. VB also had dose-dependent toxic effects on mitochondrial respiratory activity, indicating that VB-induced neurotoxicity parallels VB-induced obesity and is mechanistically linked to mitochondrial dysfunction.

PS 4206 Perfluorooctane Sulfonate (PFOS)-Induced Mitochondrial Dysfunction and Dopaminergic Neurotoxicity: Implications for Parkinson's Disease

N. Boonpraman, D. Kim, N. Kuhn, and S. R. Sammi. Michigan State University, Grand Rapids, MI.

Background and Purpose: Parkinson's disease (PD) is a progressive neurodegenerative disorder characterized by dopaminergic (DA) neuron loss and the abnormal accumulation of α -synuclein. While most PD cases are sporadic with multifactorial etiologies, mitochondrial dysfunction and oxidative stress are strongly implicated in its pathogenesis. Environmental factors have gained increasing attention for their potential roles in exacerbating neurodegenerative processes. Beyond intrinsic causes, environmental toxicants with long biological half-lives, such as perfluorooctane sulfonate (PFOS), are likely contributors to both disease initiation and progression. PFOS, one of the most widely used per- and polyfluoroalkyl substances (PFAS), is recognized for its extreme environmental persistence, high bioaccumulation potential, and emerging neurotoxic effects. This study aimed to elucidate how PFOS exposure disrupts neuronal systems, focusing on its impact on mitochondrial function and mechanisms underlying neurodegeneration across multiple experimental models. **Methods:** We employed *Caenorhabditis elegans*, a mouse model, and human iPSC-derived dopaminergic (DA) neurons to investigate PFOS-induced neurotoxicity. In *C. elegans* were exposed to PFOS (0-75 ppm) to assess DA neurodegeneration, α -synuclein aggregation, mitochondrial viability using MitoTracker staining, and total reactive oxygen species (ROS) levels using H_2DCFDA fluorescence. In mice, both acute (15 min, 0-75 ppm) and subchronic (0.2, 2, or 10 mg/kg body weight for 1 month via *ad libitum* exposure) PFOS treatments were conducted to evaluate mitochondrial Complex I-IV activities in brain and liver. Western blotting of cortical tissues examined oxidative phosphorylation (OXPHOS) protein expression, while PFOS accumulation in plasma and cortex was quantified by liquid chromatography-tandem mass spectrometry (LC-MS/MS). Additionally, human iPSC-derived DA neurons (day 26 of differentiation) were exposed to 0-6.25 ppm PFOS for 24 hours and analyzed by immunofluorescence for tyrosine hydroxylase (TH) and beta III-tubulin expression. **Results:** In *C. elegans*, PFOS exposure induced dose-dependent increases in α -synuclein levels, DA neuron loss, decrease in mitochondrial viability, and ROS generation. PFOS exposure resulted in a dose-dependent reduction in DA neurons, while MitoTracker staining showed decreased mitochondrial viability, which correlated with elevated ROS levels. Relative mitochondrial DNA content remained unchanged across PFOS concentrations, suggesting that PFOS primarily impairs mitochondrial function rather than reducing mitochondrial content. Acute mitochondrial exposure assays showed significant inhibition of Complex III and IV activities in mitochondria isolated from liver and brain, whereas subchronic exposure (10 mg/kg BW for 1 month) decreased activities of all mitochondrial complexes (I-IV) in liver mitochondria. Cortical OXPHOS protein analysis revealed significant reductions in Complex III and V subunits. LC-MS/MS confirmed dose-dependent PFOS accumulation in plasma and cortex, indicating systemic bioaccumulation and blood-brain barrier penetration. In human iPSC-derived DA neurons, PFOS exposure caused dose-dependent reductions in TH and beta III-tubulin immunoreactivity, indicating dopaminergic vulnerability. **Conclusions:** Our findings suggest that PFOS exposure is associated with mitochondrial dysfunction and oxidative stress, α -synuclein accumulation, and dopaminergic vulnerability, associating PFOS as a potential health risk relevant to neurodegenerative diseases, particularly PD pathology. This work emphasizes the importance of elucidating PFOS-induced neurotoxicity to better understand its underlying molecular mechanisms. Ongoing studies aim to characterize the dose-dependent effects of subchronic PFOS exposure (0.2 and 2 mg/kg) in brain pathology associated with neurodegenerative disorders.

PS 4207 In Utero Exposure to Ultrafine Particulate Matter Impairs Cognitive Function in APP-KI Mice

N. Hida, J. Kilian, H. Hsu, D. Herman, I. Hasen, D. Sanghavi, V. Gaxiola, M. Kleinman, and M. Kitazawa. University of California Irvine, Irvine, CA.

Background and Purpose: Prenatal exposure to particulate matter (PM) has been increasingly recognized as an environmental risk factor for neurodevelopmental and neurodegenerative disorders, including Alzheimer's disease (AD). Epidemiological and experimental studies suggest that maternal PM exposure may alter brain development and long-term cognitive function in offspring. However, the underlying neuropathological mechanisms remain poorly understood. In this study, we investigated whether *in utero* exposure to ultrafine PM affects cognitive performance and AD-related pathology in APP knock-in (APP-KI) mice. We focused on evaluating behavioral outcomes together with amyloid plaque burden and glial activation in the hippocampus and cortex, which are key regions involved in memory processing. **Methods:** Pregnant APP-KI dams were exposed to ultrafine PM or filtered air (Air) during gestation. Adult offspring at 12 months of age were subjected to behavioral testing using the Object Location Memory (OLM) and Object Recognition Memory (ORM) tasks to assess spatial and recognition memory, respectively. Brain tissues were collected and analyzed by ELISA to quantify total Abeta40 or Abeta42 expression levels in hippocampus and cortex. Immunofluorescence staining was performed to visualize amyloid plaques and activated glial cells, including microglia (Iba1, Clec7a) and astrocytes (GFAP, C3). Image analysis was conducted using Fiji/ImageJ for region-based quantification to compare the relative abundance of plaques and activated glia between PM and Air groups. Ongoing analyses are being applied to spatially assess microglial and astrocytic distributions surrounding plaques, as well as synaptic markers, Bassoon and Homer1, to examine potential effects on neuronal connectivity. **Results:** PM-exposed APP-KI offspring exhibited significant impairments in both OLM and ORM performance compared to Air controls, indicating deficits in spatial and recognition memory following prenatal exposure. However, ELISA quantification revealed no significant differences in total Abeta40 or Abeta42 expression in the hippocampus or cortex between the PM and Air groups. Similarly, immunofluorescence analyses showed no significant differences in the total number or area of amyloid plaques, nor in the abundance of activated microglia or astrocytes, in either brain region. These results suggest that the observed cognitive impairments occur independently of gross changes in amyloid deposition or gliosis. **Conclusions:** *In utero* exposure to ultrafine PM resulted in measurable cognitive deficits in APP-KI offspring, as indicated by impaired performance in OLM and ORM tasks. No significant differences were detected in amyloid plaque burden or in the number of activated microglia and astrocytes in the hippocampus or cortex. These findings suggest that prenatal PM exposure may influence neural function through mechanisms not directly reflected by amyloid pathology or glial activation levels. Further ongoing analyses using spatial imaging approaches will help determine whether alterations in plaque-associated gliosis or synaptic abnormality contribute to PM-induced cognitive impairment.

PS 4208 Investigating the Effects of Traffic-Related Air Pollution on Alzheimer's Disease Neuropathology in the Olfactory Bulbs of Transgenic Rat Model of Alzheimer's Disease

A. Bhusal, H. Park, M. Cheng, A. E. Valenzuela, K. J. Bein, A. Wexler, and P. J. Lein. University of California, Davis, Davis, CA.

Background and Purpose: Alzheimer's disease (AD) is increasingly recognized to arise via complex gene $\times$ environment interactions, and traffic-related air pollution (TRAP) has emerged as an environmental risk factor for AD. Olfactory dysfunction (hyposmia/anosmia) is one of the earliest clinical indicators of neurodegenerative diseases, including AD, and the olfactory bulb (OB) is the only part of the brain that directly interfaces with the external environment. Ultrafine particulate matter (<100 nm) from TRAP has been shown to reach the brain via the olfactory nerves in both humans and animal models. Together, these observations suggest that the OB may be a particularly vulnerable region for TRAP-induced AD pathology. However, it remains unclear whether chronic TRAP exposure exacerbates AD-related neuropathology and neuroinflammation in the OB. **Methods:** To model near-roadway exposures experienced by humans, we leveraged a unique exposure facility in which animals were housed in a vivarium adjacent to a heavily trafficked tunnel in Northern California and exposed to TRAP collected from the tunnel in real-time and delivered unchanged to the exposure chambers. Control animals were housed in the same facility and exposed to filtered air (FA). AD-relevant pathology and neuroinflammation were quantified in the OB of TgF344-AD rats, which express two human AD susceptibility genes encoding mutant amyloid precursor protein (APP_{sw}) and presenilin 1 (PS1 ΔE9). Male and female TgF344-AD rats were transported to the tunnel at 1 month of age and randomly assigned to either TRAP or FA groups until 15 months of age. Following exposure cessation, animals were euthanized, and the OB were collected for histological analyses. Amyloid- β fibrils were assessed by quantitative immunohistochemical (qIHC) analyses using the OC antibody, which specifically recognizes amyloid- β fibrils. qIHC analyses of Iba1 and GFAP were used to quantify the abundance of microglia and astrocytes, respectively. **Results:** TRAP had sex-specific effects on AD-relevant endpoints in the OB. In females, TRAP increased amyloid- β deposition, as indicated by increased area of OC immunoreactivity compared to FA controls. In contrast, there were no differences in amyloid- β depo-

sition between TRAP-exposed and FA males. TRAP induced microgliosis in males, evidenced as increased area of Iba1+ immunoreactivity, but had no effect on this endpoint in females. TRAP significantly reduced GFAP immunoreactivity in females, but not males. **Conclusions:** These findings indicate that chronic TRAP exposure causes sex-dependent changes in AD-relevant pathology in the OB, with females showing greater amyloid- β accumulation and males showing increased microglial activation. This supports the OB as a brain region vulnerable to TRAP and highlights sex as a key biological variable. Moving forward, darkfield and hyperspectral imaging with the CytoViva system will be used to visualize and quantify ultrafine particulate matter deposition in the OB and compare this to the spatiotemporal patterns of amyloid pathology and neuroinflammation. This work was supported by the NIH (grants RF1 AG074709 to P.J.L. and K.J.B.; T32 GM135741 predoctoral fellowship to A.B.; and T32 HL007013 predoctoral fellowship to H.H.P.).

PS 4209 Developmental MeHg exposure causes persistent changes in hiPSC-derived cortical models reflecting a neurodegenerative disease risk state

A. M. Tukker¹, H. Kim¹, M. M. Strom¹, B. Han¹, M. Aschner², and A. B. Bowman¹.
¹Purdue University, West Lafayette, IN; and ²Albert Einstein College of Medicine, the Bronx, NY.

Background and Purpose: The Developmental Origins of Health and Disease (DOHaD) hypothesis posits that developmental exposures can have long-term consequences, increasing the risk for later-life disease. Methylmercury (MeHg) is known to preferentially cross the placental barrier affecting the developing brain, especially glutamatergic (GLUergic) neurons. To understand the mechanisms involved in persistently altered GLUergic function as well as potential increased susceptibility for later-life disease, this study utilized a human induced pluripotent stem cell (hiPSC)-derived cortical model. We hypothesized that developmental MeHg exposure causes persistent transcriptomic changes visible long after cessation of exposure. We further hypothesized that these changes could reflect an age-related neurodegenerative disease risk state. **Methods:** Human iPSCs derived from male and female neurotypical control individuals were differentiated into cortical cultures using dual-SMAD inhibition. Cultures were continuously exposed to *in vivo* environmentally relevant (0.1 or 1 μ M) MeHg concentrations during days *in vitro* (DIV) 4-10 of development, a stage where the main cell types present are neuroepithelial cells and radial glia (RG). To assess transcriptomic effects of exposure, single cell RNA sequencing (scRNA-seq) experiments were performed at DIV 40, 150 and 280. Alterations in pathways were studied using Qiagen Ingenuity Pathway Analysis (IPA) and prediction of upstream chemicals was done with iPathwayguide (Advaita). **Results:** Cluster analysis of scRNA-seq data showed that all major cortical cell types were present with some differences in population size across days, but no notable changes across exposure levels. For both concentrations, significant pathway alterations ($p < 0.05$) were observed across all sampling days indicating a strong persistency of the effects of developmental exposure. In line with clinical observations, no clear concentration dependency was found. Many pathways in the top 25 altered pathways relate to healthy aging (e.g. eIF2, sirtuin, mTOR) and energy metabolism (e.g. oxidative phosphorylation, mitochondrial dysfunction). We then identified "core persistency genes" (CPG): genes that are significantly altered across all 3 time points and in 3 out of 4 main cell types (GLUergic neurons, proliferating or quiescent RG, and intermediate progenitor cells). KEGG analysis on these CPG revealed strong enrichment for neurodegenerative diseases, including Alzheimer's disease (AD). To further explore the connection between developmental MeHg exposure and risk for AD, we utilized scRNA-seq data obtained from a study done in our lab comprising of DIV 150 hiPSC-derived cortical cultures (from neurotypical control and AD patients). We found that all CPG were present in differentially expressed genes (DEGs) derived from this data. Bootstrap analysis revealed significant enrichment of these genes beyond chance. We then searched for predicted upstream chemicals in our AD DEGs. Though these cultures have never been exposed to MeHg, MeHg compounds were predicted ($p < 0.0001$) to be in the top 20 upstream chemicals. **Conclusions:** Effects of developmental MeHg exposure are still present 270 days following cessation of exposure. Cluster annotation of UMAPs derived from scRNA-seq revealed that cells matured as expected, with cell population size changing according to culture maturation stage. No clear effect of exposure on cell population was observed. We identified persistent changes in pathways and gene expression. CPG from this data set showed a link with AD. Interestingly, CPG are statistically enriched in our AD data. Next, our AD vs Control DEG list was enriched for MeHg-like changes despite never being exposed. Overall, these data show that developmental MeHg exposure causes persistent transcriptomic changes. Additionally, we showed a potential link between developmental MeHg exposure and later-life AD risk state. This research was supported by NIH [R01 ES07331 (ABB/MA), R01 ES031401 (ABB), and K99 ES036290 (AMT)].

PS 4210 Investigating the potential impact of FUS phosphorylation-dephosphorylation dynamics on subcellular localization in response to DNA Damage

H. L. Gottesman, M. Punjani, and M. A. Johnson. Oberlin College, Oberlin, OH.
 Sponsor: G. Kwakye

Background and Purpose: Frontotemporal dementia (FTD) is a devastating neurodegenerative disease characterized by changes in behavior and language production due to the progressive loss of neurons and glia in frontal and temporal cortical regions. While the neuronal death has been well characterized, the molecular mechanisms driving the initial cellular dysfunction remain poorly understood. Neuropathology from post-mortem tissue suggests that cellular dysfunction may be due to key RNA-binding proteins misfolding, resulting in changes in RNA homeostasis and the accumulation of protein aggregates in affected tissue. Approximately 10% of FTD cases contain cytoplasmic protein aggregates that are positive for the RNA/DNA binding protein fused in sarcoma (FUS). FUS performs various functions, including regulating DNA transcription, mRNA splicing, stress granule formation, and DNA damage repair. While typically localized to the nucleus, FUS can shuttle between the nucleus and the cytoplasm to accomplish its various functions. However, in FTD with FUS pathology, the protein misfolds and mislocalizes into the cytoplasm, exhibiting both toxic gain-of-function and loss-of-function effects. While FUS mutations are the best-characterized case of cytoplasmic aggregation, the majority of FTD patients do not have genetic mutations, suggesting that FTD-FUS may be caused by an environmental trigger. Indeed, double-strand DNA damage can be induced by various environmental triggers, including ultraviolet exposure and oxidative stress. Thus, studying the mechanistic basis for DNA damage may be the key to understanding the pathology of idiopathic FTD. FTD patients show increased γ -H2AX, a marker of double-strand DNA damage. Furthermore, previous work found that double-strand DNA damage induced via calicheamicin γ 1 (CLM) triggers DNA-PK-mediated phosphorylation of FUS (p-FUS) at 12 N-terminal sites. The resulting p-FUS then accumulated in the cytoplasm. However, there are discrepancies in previous findings regarding whether p-FUS becomes mislocalized in response to DNA damage, suggesting context-dependent results and a lack of reproducibility. In this study, we aim to investigate whether phosphorylation-dephosphorylation dynamics regulate the subcellular localization of FUS, and through what mechanisms. By investigating past discrepancies in conjunction with novel variables, we aim to elucidate the mechanisms underlying the molecular basis of FUS FTD pathology. **Methods:** Past reports on p-FUS primarily utilized fixed cell staining and subcellular fractionation to characterize the localization of p-FUS. Even so, each report performed each technique differently. As such, we set out to systematically compare each method used in the various reports. HEK293T or U2OS cells were treated with CLM to induce double-strand DNA damage. Using fixed cell staining, subcellular fractionation, and western blots, we characterized and quantified the amount of FUS in either the nucleus or cytoplasm observed between methods. Lastly, we utilized time-point assays and live-cell imaging to observe the kinetics of FUS phosphorylation and its potential role in FUS localization. **Results:** Overall, we report significant differences in the visualized observation of FUS localization between the tested methods. Namely, we directly compared the three different but previously utilized permeabilization techniques (Methanol, Triton-X-100 and Tween-20) and three different FUS polyclonal antibodies for fixed cell staining. We found that the observed localization of total FUS and p-FUS differed based on the permeabilization and the antibody used. **Conclusions:** Our results demonstrate that visualizing FUS localization is both technique-specific and regulated by phosphorylation states that dynamically respond to environmental and cellular stressors. We find that DNA damage, specifically double-strand breaks, can promote mislocalization. Our findings suggest that FUS phosphorylation may act as a molecular regulator of subcellular distribution and that persistent DNA damage drives a pathogenic shift toward abnormal accumulation. Understanding this modification will not only help elucidate the molecular mechanisms of FUS-related neurodegeneration but also provide insight into therapeutic strategies to restore protein function.

PS 4211 ENVIRONMENTAL CONTRIBUTION AND NEUROANTIBODIES (NAb) BIOMARKERS IN NEONATAL HYPOXIC-ISCHEMIC ENCEPHALOPATHY (HIE)

M. L. Monaco-Brown¹, M. J. Horgan¹, and H. A. El-Fawal². ¹Albany Medical College, Albany, NY; and ²American Health and Diagnostics Institute (AHAD), Troy, NY.

Background and Purpose: To date, the etiology of HIE remains equivocal, as does the availability of diagnostic and prognostic biomarkers. We have proposed the use of autoantibodies against nervous system (NS) proteins (i.e., NAb) as potential biomarkers. In addition, the role of heavy metals, with their ability to induce neurotoxic damage and oxidative stress were investigated for their association with clinical outcome measures (e.g., apgar and MRI at 7d). **Methods:** Following IRB approval and parent consent, blood serum of reference at birth and 1d (total serum n=22) and HIE neonates selected for hypothermia therapy at birth, 1, 2 and 7d (total serum n=35) were analyzed by ELISA for serum NAb, IgM and IgG, against neurofilament triplet (NF), glial fibrillary acidic protein (GFAP) and myelin basic protein (MBP), as well as levels of heavy metals (μ g/dl) Al, Cd, Cr, Cu, Fe, Mn, Ni and Pb measured by ICP in 1d samples. Apgar scoring occurred at birth, EEG conducted between 3-4d of birth and MRI at 7d were also measured. **Results:** HIE neonates (n=14) had signifi-

cantly ($p=0.04$) higher levels of Al, Cu and Mn compared to reference neonates ($n=5$). However, Spearman correlation indicated that 1 and 5 min apgar scores inversely ($r=-0.49$ to -0.71) and significantly ($p=0.001-0.04$) associated with levels of Al, Cd and Cu. Prevalence of NAb IgM against NF triplet proteins, GFAP and MBP was consistently higher in HIE neonates ($>50-88\%$ vs $13-35\%$ for reference) based on 6 and 24hr sera, with odds ratios (OD) of 4-9; $95\%CI$ 1-38; $p<0.001-0.01$). For anti-GFAP IgG, prevalence was 70% vs 35% , respectively; $OD=4$; $95\%CI=1.0806$ to 16.3246 . Furthermore, levels of anti-NF triplet were significantly higher in HIE ($p<0.003-0.04$) compared to reference at all time points, as were the GFAP IgG:IgM ratios at 6hr. The latter suggestive of possible maternal contribution, as IgG crosses the placenta. The cumulative and white matter MRI scores directly correlated ($r=0.48-72$; $p<0.00001-0.003$) with levels of Cd, Cu and Al ($n=33$ across all days), strongly suggesting a role of these metals in HIE pathology. Multiple variable regression ($R^2=0.42-0.68$) modeling indicated that low apgar, high MRI scores and heavy metals, including high Al, Cd, Cu, Mn, Ni, Pb and Fe, were major determinants of specific NAb titers. In addition, several metals were determinants of negative outcomes in apgar and MRI scores ($R^2=0.52-0.75$). This included Cd, Cr, Cu and Al. **Conclusions:** This study strongly suggests environmental toxic contribution in the pathogenesis of neonatal HIE. Heavy metals, particularly Cd, Cu, Mn and Al are recognized as risk factors in neurodegenerative conditions. The high prevalence and elevated NAb titers, particularly IgM, in HIE and their association with clinical presentation suggests their potential as biomarkers in HIE. This pilot provides a promising avenue for research into the complexity of HIE and other pediatric neurological conditions and the importance of external and internal environmental considerations, including maternal roles, in the pathogenesis and biomarker validation.

PS 4212 Cannabidiol and Trazadone suppress Amyloid Beta Pathological features in *Caenorhabditis elegans*

J. Amralo, A. Alsulami, A. Holzer, V. Gilberto, M. Linfoot, S. Alkhudaydi, S. McGrath, and J. Moreno. Colorado State University, Fort Collins, CO.

Background and Purpose: Alzheimer's disease (AD) is the most common neurodegenerative disease, which causes shortened lifespan, motor decline, and progressive cognitive impairment. It is characterized by the extracellular accumulation of misfolded proteins, specifically the amyloid beta ($A\beta_{1-42}$) protein. Current treatments available provide limited therapeutic benefit, highlighting the urgent need for new therapeutic interventions. Cannabidiol (CBD) and Trazadone (TRA) have individually demonstrated neuroprotective effects in previous studies through transcriptional regulation of synaptic and inflammatory genes. However, their individual and combined effect to reduce $A\beta_{1-42}$ aggregation at the protein level have not been investigated. This raises the critical question: Will CBD and TRA treatment provide additive or synergistic protection against Alzheimer's disease? The study aimed to evaluate the neuroprotective effect of CBD and TRA, individually and in combination, in a *Caenorhabditis elegans* (*C. elegans*) model expressing human $A\beta_{1-42}$. **Methods:** Synchronized CL4176 worms expressing muscle-specific human $A\beta_{1-42}$ were treated with concentrations of CBD ($1\mu M$, $10\mu M$, $50\mu M$ and $100\mu M$) and trazadone ($1\mu M$, $10\mu M$, $50\mu M$ and $100\mu M$). The $A\beta$ expression was induced by temperature upshift, and paralysis assay were performed. Protein extracts were fractionated into soluble and insoluble fractions and analyzed via Western blot to assess $A\beta$ aggregation profiles. **Results:** CBD ($\chi^2 = 232$, $df = 4$, $p < 2 \times 10^{-16}$) and TRA ($\chi^2 = 34.5$, $df = 4$, $p = 6 \times 10^{-7}$) independently ameliorated the effect of $A\beta$ toxicity, delayed paralysis, and showed improvement in behavior. Notably, CBD significantly delayed paralysis in a dose-dependent manner, with 10 to $100\mu M$ producing strong protective effects, whilst pairwise comparisons between individual TRA concentrations and vehicle reveal no significance. Western blot analysis showed a reduction of $A\beta_{1-42}$ oligomers for the CBD treatments with maximal effects at $50\mu M$ and $100\mu M$. **Conclusions:** In conclusion, these findings suggest CBD's neuroprotective effect against $A\beta$ induced paralysis in *C. elegans*, and TRA's potential to modulate disease progression overall. We predict that the combined treatments will provide synergistic effect against $A\beta$ toxicity. Further studies need to evaluate higher concentrations of trazadone ($>100\mu M$) to determine its full neuroprotective potential and determine the mechanisms underlying this neuroprotection.

PS 4213 Developmental Phthalate Exposure Increases Alzheimer's Disease-Relevant Neuropathological Outcomes

S. Aktuna, M. Graham, E. Liss, M. M. Mahoney, and H. J. Gritton. University of Illinois at Urbana-Champaign, Urbana, IL.

Background and Purpose: Phthalates are ubiquitous plasticizers present in personal care products, food packaging, and medical devices, resulting in widespread human exposure, including during gestation. This is a significant concern as the developing organism is extremely sensitive to environmental insults. Prenatal phthalate exposure disrupts endocrine signaling, reduces estradiol, accelerates premature ovarian failure and alters steroid receptor activity. Phthalate exposure also increases neuroinflammation and promotes cognitive deficits, effects also seen in Alzheimer's disease (AD) patients and AD mouse models. This led to our hypothesis that developmental exposure to phthalates increases vulnerability to AD by accelerating neuroinflammation that could augment neural hallmarks of the disease later in life.

Methods: Pregnant 3xTg-AD mice, which carry APPSwe, PSEN1, and tauP301L mutations, and B6129SF2/J controls were orally dosed from gestational day 0 through birth with vehicle (oil) or a phthalate mixture at $20\mu g/kg/day$ (environmentally relevant exposure) or $200\mu g/kg/day$ (occupational exposure). The mixture was derived from urinary metabolite concentrations of pregnant women in Illinois and consisted of 35% diethyl phthalate (DEP), 21% di(2-ethylhexyl) phthalate (DEHP), 15% dibutyl phthalate (DBP), 15% diisononyl phthalate (DiNP), 8% diisobutyl phthalate (DiBP), and 5% benzyl butyl phthalate (BzBP). Offspring were aged to 3, 5, and 11 months, then assessed on a battery of cognitive tasks before brain collection. A subset of females underwent ovariectomy at 2 months of age to examine whether estradiol depletion, coupled with developmental phthalate exposure, exacerbates AD pathology compared to intact females and males. The collected tissue underwent immunohistochemistry for Iba-1, a marker of microglia/macrophage neuroinflammation. **Results:** Our initial analysis from 11-month-old animals revealed that the percentage of area occupied by Iba-1 staining in the entorhinal cortex, a cognition relevant region vulnerable to AD pathology, is elevated in males (genotype x treatment interaction: $p < 0.001$). Male 3xTg mice prenatally exposed to both $20\mu g/kg/day$ ($p = 0.05$) and $200\mu g/kg/day$ ($p < 0.001$) had significantly more area covered by Iba-1 staining than control mice exposed to the same phthalate dose. In ovary-intact females, there was a main effect of phthalate treatment at the same 11-month timepoint ($p < 0.05$). Post-hoc analyses show that the $20\mu g/kg/day$ 3xTg animals had a higher percentage of area covered by Iba-1 staining compared to controls exposed to the same dose ($p < 0.05$). Interestingly, ovary-intact 3xTg females exposed to phthalates did not differ from controls, suggesting a potential protective effect of ovarian steroids. Ovariectomized females differed from ovary-intact females and males, as only strain had a significant effect ($p < 0.001$). The wildtype mice exposed to phthalates did not have a significant increase in Iba-1 staining. **Conclusions:** Together these initial results suggest that 3xTg males may be more sensitive to phthalates than females, and phthalate exposure on an AD background may accelerate the onset of pathological changes. We will quantify the markers for amyloid beta, phosphorylated tau, and Iba-1 in earlier timepoints to determine the onset of changes. We will also interrogate additional brain areas relevant to AD. Together, this will provide mechanistic insight into how developmental endocrine disruption interacts with sex hormones and aging to influence AD risk. This work will highlight how prenatal environmental exposures may have lifelong consequences for neurodegenerative disease susceptibility.

PS 4214 Investigating Nanoplastic Effects on Amyloid-Beta Fibril Formation and Neurotoxicity

S. C. Stradtman, S. I. Thrall, K. DeSantis, and B. L. Pearson. Oregon State University, Corvallis, OR.

Background and Purpose: Plastic pollution has emerged as a global concern, with growing attention to the potential health impacts of nanoplastics. While environmental distribution is well documented, their neurotoxic potential and possible role in neurodegenerative processes remain poorly understood. In particular, links between nanoplastic exposure and Alzheimer's disease pathology have yet to be clarified. This work investigates how nanoplastics influence amyloid- β ($A\beta$) fibrillization kinetics and neuronal health. **Methods:** A cell-free *in vitro* assay was utilized to examine polymer-specific effects of 50 nm polystyrene (PS) and poly(methyl methacrylate) (PMMA) nanoparticles on $A\beta$ aggregation. Increasing concentrations of both polymers shifted the fibrillization profile, altering the time to fibril formation. These findings guided subsequent studies in primary cortical neurons isolated from embryonic day 15.5 mice. Cultures were exposed on *in vitro* day 7 to a nine-point concentration range ($0.8-0.003125\mu g/\mu L$) of PS or PMMA nanoparticles for 24 or 120 hours. Neurotoxicity was assessed via fluorescence-based live/dead cell assays and reactive oxygen species (ROS) detection. **Results:** Exposure to both PS and PMMA does not induce significant changes in percentage of dead cells or ROS at multiple concentrations when compared to the control. Neurons were also co-exposed to synthetic $A\beta$ (1-42) at concentrations of 2.5 or 1.25 μM together with 50 nm polystyrene (PS) nanoplastic particles at 0.05 or 0.00625 $\mu g/\mu L$ for 120 hours, in an effort to reproduce the fibrillization phenomenon observed in the cell-free assay within primary neuronal cultures. The results showed a significant decrease in fluorescent signal labeling $A\beta$ peptide and fibrils in the co-exposure group of 2.5 μM peptide with 0.05 $\mu g/\mu L$ PS when compared to the control. **Conclusions:** These findings suggest that the current *in vitro* neuronal model and endpoints used in this study may not be optimal for detecting subtle or delayed neurotoxic effects of nanoplastics. Further optimization of the $A\beta$ co-exposure model, including refinement of exposure conditions, time windows, and analytical endpoints, will be necessary to more effectively evaluate how nanoplastics may contribute to neurodegenerative disease processes *in vitro*.

PS 4215 Pre-Adsorption of Pesticides onto Nanoplastics Alters Neurotoxic Responses in Primary Cortical Neurons

S. Thrall, S. Stradtman, A. Rust, K. DeSantis, and B. Pearson. Oregon State University, Corvallis, OR.

Background and Purpose: Nanoplastics are present in virtually all human tissues evaluated. Due to their ability to cross the blood-brain barrier, there is growing concern about neurotoxicity and contributions to neurodegenerative diseases. Importantly, nanoplastics entering the human body are associated with a complex exposome, including chemicals that adsorb to plastic particles. **Methods:** We examined the potential of polystyrene (PS) nanoplastics to modulate the neurotoxic effects of Parkinson's-linked pesticides. We hypothesized that pre-adsorbing polystyrene nanoplastics with fenpyroximate, rotenone, paraquat, or endothal yields varying neurotoxicity, with nanoplastic-induced alterations in the bioavailability of the pesticides based on their relative hydrophobicity. Primary mouse cortical neurons were isolated on embryonic day 15.5 and cultured in 96-well plates. Each of the aforementioned pesticides were incubated for 72-hours with 50 nm PS beads. Two control conditions were incubated for the same 72-hour time period for comparison: 50 nm PS with lab-grade water, and pesticide with lab-grade water. After the 72-hour incubation, each condition was dialyzed against cell culture feeding media for 48 hours using a Slide-A-Lyzer at 37 degrees Celsius. At seven days *in vitro*, neurons were exposed for 24 hours to a five-point concentration range of each PS-pesticide or control condition, based on the post-dialysis PS concentrations (0.78 - 200 µg/ml) or to a four-point dilution series of the corresponding dialysate (12.5%-100% v/v) in cell culture media. Cell viability was assessed using a fluorescent live/dead cell assay and data was normalized to the control. **Results:** Polystyrene nanoparticles were not cytotoxic. However, the pre-adsorption of rotenone or fenpyroximate with PS 50 nm increased neurotoxicity when compared to the pesticide only condition. The dialysate caused cytotoxicity at the highest concentration, suggesting that free pesticide is crossing the dialysis membrane. This toxicity was minimal, which may be due to tendency of rotenone and fenpyroximate to adsorb to the plastic dialysis tubing. The combination of PS 50 nm with paraquat, a pesticide with lower LogP, did not produce significant exacerbation of neurotoxicity. However, the corresponding dialysate exhibited cytotoxicity, suggesting that the amount of paraquat crossing the dialysis membrane is independent of the presence of polystyrene. Results concerning the pesticide endothal are pending. **Conclusions:** Our results suggest that pre-adsorption of highly lipophilic pesticides onto PS 50 nm, followed by dialysis, increased the amount of pesticide available to cells, thereby enhancing overall toxicity. Our work is currently evaluating other endpoints, such as RNA-seq, to better recapitulate human neurological disease processes. Taken together, the regulation and risk assessment of environmental chemicals and plastics must consider additive and increased bioavailability potential to protect human neurological health.

PS 4216 Intranasal infection with Western Equine Encephalitis Virus induces temporally and spatially distinct patterns of gliosis and neurodegeneration in the hippocampus of C57Bl/6 mice

A. Briggs, A. Schuller, O. Yanouri, M. Hager, S. Rocha, and R. Tjalkens. Colorado State University, Fort Collins, CO.

Background and Purpose: Encephalitic alphaviruses, such as Western Equine Encephalitis Virus (WEEV), are increasingly associated with morbidity and mortality driven by acute viremia and post-encephalitic neurologic dysfunction, including age-related neurodegeneration. Globally, an increase in temperature and annual rainfall has expanded mosquito-occupied territories, increasing infectious risk for previously invulnerable groups and presenting the possibility for large-scale outbreaks capable of drastically altering the health of these populations. Encephalitic alphaviruses have been characterized to possess neurotropic capacity, associated with longitudinal central nervous system dysfunction. Following viral-induced encephalitis, lingering effects such as chronic neuroinflammation and glial-mediated immune modulation are strongly correlated with the onset and progression of neurodegenerative disorders, including Parkinson's disease and related dementias. Our lab has previously demonstrated that sub-lethal infection with WEEV induces robust astrogliosis associated with gait aberrancies, nigrostriatal dopaminergic neurodegeneration, and pathologic protein aggregation in murine models. However, the temporal sequence of glial activation and subsequent neurodegeneration in brain regions relevant to dementia and cognitive decline have yet to be investigated, despite marked neurotropism in these parenchymal structures long after peripheral clearance. Together, this motivated the temporal assessment of glial dynamics, pathologic protein aggregation, and neurodegeneration in the hippocampus of WEEV-infected mice. **Methods:** Six-week-old C57Bl/6 mice were anesthetized and intranasally infected with 20 µL of 1×10^4 PFU/mL McMillan WEEV and subsequently sacrificed at 1-, 2-, and 4-week timepoints. Passive immunotherapy was administered to control the extent of viral replication. Brains were dissected and coronally sectioned for downstream analysis via high-content immunofluorescent microscopy, deep learning-based image analysis, histological examination, and population-level cellular phenotyping. **Results:** We interrogated the complex temporal relationship between gliosis and neuronal loss across time, infection status, and hippocampal subregion. By 4 days post infection, the virus had localized to the brain and was identified within hippocampal neurons. Hematoxylin and eosin staining revealed a sharp increase in neuronal pyknosis at 1-week post-infection (WPI) in the CA1 and CA3 regions of the hippocampus that

was associated with fibrotic-like pathology and confirmed via Masson's trichrome staining. We explored this phenomenon using fluorescence microscopy, reporting a substantial viral-mediated increase in GFAP⁺ and IBA1⁺ cells that peaked at 2 weeks post-infection. Interestingly, this corresponded with the formation of glial-occupied lesions, exclusive to WEEV-infected brains, which inversely correlated with neuronal density and appeared in fibrotic regions. We further investigated the role of these glial inclusions in WEEV-induced neuropathology by querying the proximity to amyloid-B aggregates via nearest-neighbor analysis, observing peak protein aggregation at 1-week post-infection near highly reactive IBA1⁺ cells. Furthermore, we integrated this data with automated rendering of microglial cells to assess morphometric parameters including cellular area, branch length, dendritic arborization, terminal endpoints, and nuclear morphology. This phenomic analysis revealed time- and infection-dependent clustering of cells based on activation status. **Conclusions:** Together, these data highlight robust involvement of glial reactivity in misfolded protein accumulation and neurotoxicity in the pathogenesis of WEEV-induced hippocampal degeneration. Future work will aim to distinguish if modulating glial-mediated inflammatory signaling can protect against these disease-associated molecular sequelae.

PS 4217 Exposure to manganese in juvenile mice primes the hippocampus to glial inflammatory responses and neuronal stress following systemic infection with Influenza A virus subtype H1N1

M. R. Hager, O. R. Yanouri, A. J. Schuller, and R. B. Tjalkens. Colorado State University, Fort Collins, CO.

Background and Purpose: Neurodegenerative disorders (NDDs) are the fastest-growing cause of disability among older adults. Although the etiology of NDDs is poorly understood, pro-inflammatory immune signaling is implicated in the pathogenesis of these conditions. Additionally, exposure to environmental toxins can increase the risk of developing NDDs. Manganese (Mn) is an essential trace mineral that is a cofactor for numerous enzymes in the body and has immune signaling functions. Excess accumulation of Mn in the basal midbrain can lead to manganism, a neurologic disorder leading to parkinsonian-like symptoms and cognitive impairment. Recent epidemiological studies implicate lifetime systemic viral infection with the risk of developing NDDs. Specifically, infection with RNA viruses can lead to long-lasting neurological sequelae, including cognitive impairment and motor dysfunction. Following the 1918 Spanish Influenza pandemic, there was a marked increase in encephalitis lethargica, but it is not known why only select patients surviving H1N1 infection developed post-encephalitic parkinsonism. **Methods:** Previously, our lab demonstrated that Mn exposure in juvenile C57Bl/6 mice increases glial inflammatory responses in the substantia nigra following infection with H1N1 Influenza virus. In the present study, we employed a dual-hit neurotoxin-pathogen model to investigate how juvenile exposure to Mn alters H1N1-induced pathology in the hippocampus. Mice were given MnCl₂ at 50 mg/kg/day in water at P21 for 30 days, then regular water for a month. Mice were then infected by intranasal administration of phosphate-buffered saline with 10^3 TCID₅₀ A/California/04/2009 H1N1 when the mice were 8 weeks old, and animals were terminated at 21 dpi. Coronal brain sections encompassing the hippocampus were immunostained against IBA1, allowing for assessment of the number and morphology of microglia and invading macrophages across hippocampal subregions. Hematoxylin and eosin (H&E) staining was performed to identify the number of healthy and pyknotic neurons within the dentate gyrus. **Results:** Whole hippocampal analysis reveals a main effect of Mn on IBA1+ microglia number, as seen in the increase of IBA1+ cells in the CA3 subregion. Mn exposure increases the total area occupied by IBA1+ processes in the hippocampus. H&E analysis of the dentate gyrus revealed an increase in pyknotic neurons per mm², as well as the ratio of pyknotic to healthy neurons, with no notable change in healthy neurons per mm². Morphometric profiling of individual microglia was accomplished by measuring the length of IBA1+ processes, the area occupied by IBA1+ cells, the number of branch points, and the number of endpoints. Preliminary morphological characterization of IBA1+ cells reveals that Mn treatment did not result in a more amoeboid cellular phenotype. Rather, IBA1+ cells from Mn-treated animals displayed greater cell volume, process length, number of branching points, and number of end points. **Conclusions:** We conclude that these characteristics represent a novel phenotypic state that we refer to as hyperarborized. These findings highlight the capacity of juvenile Mn exposure to trigger immune priming in the brain that induces a pronounced inflammatory phenotype in hippocampal microglia upon viral infections during adulthood. Such toxin-pathogen interactions may impact the later development of NDDs.

PS 4218 Neuropathological features of Alzheimer's Disease like pathology in aging canines

A. Alsulami¹, P. Shirely¹, S. McGrath¹, C. S. Latimer², and J. Moreno¹. ¹Colorado State University, Fort Collins, CO; and ²University of Washington, Seattle, WA.

Background and Purpose: Alzheimer's disease (AD) is a progressive neurodegenerative disorder and a major global health crisis affecting more than 55 million people worldwide. AD is pathologically defined by the accumulation of amyloid-beta (Aβ) plaques, neurofibrillary tangles (NFTs), and neuronal loss, yet effective disease

modifying therapies remain elusive. While transgenic rodent models have provided valuable mechanistic insights, they fail to replicate show the naturally occurring, age-related progression characteristic of human AD. In contrast, the companion develops spontaneous cognitive decline and neuropathological changes that closely mirrors those seen in humans. Dogs exhibit progressive A β and tau pathology, brain atrophy, and behavioral impairments measurable by the validated cognitive scale, Canine Social and Learned Behavior (CSLB). Despite these parallels, a systematic application of human neuropathological criteria to canine brains remains limited. **Methods:** Postmortem brain tissues from 24 client-owned aged dogs were assessed using Thal, Braak and CERAD criteria. We integrated these assessments alongside antemortem cognitive assessments and plasma biomarkers to evaluate relationship between pathology, owner assessment cognition, and biofluid markers. **Results:** Aged dogs show A β progression consistent with early to intermediate Thal stages, tau pathology following Braak staging, and an absence of neuritic plaques. Quantitative analysis revealed higher A β burden in cognitively impaired dogs, and significant association with age and cognitive scores. **Conclusions:** Aging dogs show progressive A β and tau pathology mirroring early to intermediate AD but lack neuritic plaques. These findings strengthen the role of dogs as a natural aging model for AD, offering a translational bridge for investigating early disease mechanisms and evaluating therapeutic interventions in a naturally aging model.

PS 4219 Clinicopathological Profiles From Aging Canine Cohorts Reveal Changes Associated With Cognitive Dysfunction

K. Kawai Puua^{1,2}, I. Harter¹, S. McGrath³, and J. A. Moreno^{1,2}. ¹Department of Environmental and Radiological Health Sciences, College of Veterinary Medicine and Biomedical Sciences, Colorado State University, Fort Collins, CO; ²Brain Research Center, Colorado State University, Fort Collins, CO; and ³Department of Clinical Sciences, College of Veterinary Medicine and Biomedical Sciences, Colorado State University, Fort Collins, CO.

Background and Purpose: Canine cognitive dysfunction (CCD) is a complex, age-associated neurodegenerative syndrome that shares similarities to Alzheimer's disease and related dementias (AD/ADRD) in humans. As canines age, they serve as a naturally occurring model for these diseases, offering valuable insight into disease progression. Because companion dogs age alongside humans and share environmental exposures, they provide a translational model for understanding how systemic aging biology relates to brain health. Our objective was to identify routine systemic clinicopathological biomarkers that may be associated with cognitive status by pairing population-scale clinical data from the Dog Aging Project (DAP) with clinical data from Colorado State University's (CSU) Brain Health Study: Biomarker Research in Aging Dogs (BIORAD), which included matched clinical labs with additional cerebral spinal fluid (CSF) analyses. **Methods:** We performed a cross-sectional analysis of routine clinical biomarkers from dogs enrolled in the DAP and CSU BIORAD cohorts stratified by cognitive status. DAP data included 214 dogs aged ≥ 8 years with hematology and chemistry values aligned to cognitive status using the Canine Social and Learned Behavior survey (CSLB; CCD score: ≥ 50 ; normal cognitive score: ≤ 40). CSU data included 50 dogs aged ≥ 8 years with hematology and chemistry values aligned to cognitive status using the Canine Dementia Scale (CADES; CCD score: ≥ 8 ; normal cognitive score: ≤ 7). Biomarker differences were assessed using Welch's t-tests with FDR correction, including sex-stratified analyses. CSF glucose and CSF protein from the CSU cohort were evaluated using Wilcoxon rank-sum tests. **Results:** Across the DAP cohort, female dogs with CCD showed reduced hematocrit and hemoglobin ($p < 0.01$), higher platelet counts with reduced mean platelet volume ($p < 0.001$), and both sexes showed elevated potassium and serum:potassium ratios. The CSU cohort showed several similar systemic shifts. Dogs with CCD had higher potassium ($p = 0.0148$), higher platelet counts ($p = 0.0396$), higher blood urea nitrogen levels ($p = 0.0343$), and increased anion gap measurements, consistent with metabolic and electrolyte changes also observed in the DAP cohort. Additional changes, although not statistically significant, such as modest increases in alanine transferase values and neutrophil counts, suggest broader systemic metabolic and inflammatory involvement associated with CCD. Unique to the CSU brain health study is the inclusion of CSF biomarkers. CSF glucose was higher in dogs with CCD (87.3 vs 76.9 mg/dL, Wilcoxon $p = 0.027$), indicating dysregulated glucose within the central nervous system. CSF protein was also lower on average in dogs with CCD but was highly variable across groups and not statistically different (Wilcoxon $p = 0.39$). **Conclusions:** Across both independent cohorts, dogs with CCD showed similar systemic hematological and metabolic shifts that include platelet activation, electrolyte imbalance, and metabolic stress. Within the CSU cohort, a central metabolic change reflected by elevated CSF glucose also supports physiological changes related to cognitive decline. Together, these findings support the idea that routine clinical biomarkers, alongside CSF analysis, may capture physiological changes related to neurodegeneration in aging canines. Further work should investigate longitudinal changes in inflammatory and metabolic biomarkers over time in larger cohorts to better understand how biological aging and metabolic dysfunction contribute to neurodegeneration.

PS 4220 Age and Sex Have Significant Impact on Microglia Morphology: Modulation by Acute LPS Challenge

J. K. Wilson, L. Veltmaat, H. D. Ludwig, J. Carpenter, R. Dockman, B. Hudson, and N. Filipov. University of Georgia, Athens, GA.

Background and Purpose: Microglia are the resident innate immune cell of the central nervous system and exhibit functional as well as morphological changes that are influenced by various factors such as age, sex, and inflammatory stimuli. Functionally, microglia can be characterized into three separate states, one unreactive (M0) and two reactive: a pro-inflammatory M1, and an anti-inflammatory M2 state. These functional states are associated with changes in morphology, namely in parameters such as branch length, arborization, density, and soma size. The role that age and sex play in microglia function has been investigated to some extent, functionally, and associated morphological changes have either been evaluated within males (effect of age), or in adults (effects of sex); detailed comparisons between the sexes at different ages are yet to be done. Additionally, morphological responses of microglia to an acute inflammatory challenge have not been investigated. **Methods:** Adult (4-5 months old), middle-aged (14-15 months old), and aged (20-21 months old), C57BL/6J male and mice with GFP-tagged microglia were challenged with LPS (*Escherichia coli* 0111: B4, Sigma Aldrich; 0.3 mg/kg, i.p.) or saline vehicle. Four h post, mice underwent open field behavioral testing; 6 h post brains and plasma were harvested. Brains were fixed, sectioned, and processed for image analyses of hippocampal GFP+ microglia morphology by detailed Sholl, fractal analyses and appropriate statistics. Additionally, selected plasma cytokines were analyzed from a subset of samples from the various age groups; such analysis, together with the open field testing, was also done with "Super-Aged" (25-32-month-old) mice. **Results:** Overall, age exerted strong influence on microglia morphology, with measured reductions in branch complexity and length, soma circularity, and the density of the cell, accompanied by increases to soma size. Adult female microglia also exhibited more complex branches, than adult male microglia; they were also more responsive to LPS, marked by a decrease in these measured areas only in adult females. In the middle-age, branch length was longer in females, though they had less overall intersections and ramifications. Beginning in middle age, microglia of both sexes exhibited age-dependent decreases in overall cell and branch complexity. Soma area, in contrast, was only increased in the aged mice, while cell density was lowest in middle age. Behaviorally, LPS elicited sickness behavior (decreased horizontal and, especially, vertical activity) at all ages; the effects were progressively stronger with age and, females, adults in particular, were affected more than their male counterparts. Super-aged mice exhibited most profound sickness behavior post LPS. In terms of peripheral cytokine levels, in the absence of LPS challenge, there was no observed significance, though there was a nonsignificant age-related increase in pro-inflammatory IL-2. Post LPS, age was a significant factor in the increase of all measured cytokines, including many pro- and some anti-inflammatory. Female response to LPS, in terms of plasma cytokines was greater than the males at all ages. With age, this effect became more exaggerated. Furthermore, there was a non-significant decrease in certain cytokines, namely IL-10 and IL-1B, in Super-Aged mice in comparison to the aged mice, though most other cytokines, saw a numerical increase. **Conclusions:** Collectively, these findings demonstrate that microglia morphology is affected not only by age, but by sex as well, with the middle-age representing a critical transition period. The morphological differences found herein suggest that microglia contribution to brain health and pathology is skewed to pathology by aging, starting at middle age, as characterized by age related loss and retraction of branches and increased soma size. These morphological changes due to age occur with corresponding increases in peripheral cytokine and behavioral responses to acute inflammatory challenge. Additionally, acute inflammatory stimuli might be more consequential in females, especially adults, in terms of microglia morphology, and to all ages in terms of peripheral cytokines. The lack of marked morphological changes post LPS except in adults suggests that at least the early behavioral responses to LPS are driven by peripheral cytokines while central microglia response is not fully engaged at this time.

PS 4221 Neurological Phenotypes and PTSD-Linked Neuroinflammatory Pathways in World Trade Center Responders

R. N. Marquez¹, L. Pitta¹, N. Borisenko¹, S. A. Clouston², and R. G. Lucchini¹. ¹Florida International University, Miami, FL; and ²Stony Brook University, Stony Brook, NY.

Background and Purpose: World Trade Center (WTC) responders are at heightened risk for neurological impairment due to combined exposure to neurotoxic dust, heavy metals, combustion products, PM_{2.5} and severe psychological trauma. Post-Traumatic Stress Disorder (PTSD) and systemic inflammation have been proposed as shared pathways linking WTC environmental exposures to later-life neurobiological vulnerability, consistent with prior cohort findings of neuroimmune activation, altered neuronal signaling, cortical changes, and early biomarker alterations. However, peripheral neurological patterns, often detectable earlier in the clinical course, have not been systematically examined to determine whether distinct sensory-motor phenotypes may capture early manifestations of these exposure- and trauma-related processes in WTC responders. **Methods:** Standardized neurological examination data from 13,016 visits across 2,671 unique responders were analyzed across five domains: cranial nerves, upper and lower light touch, reflex change (categorized as "normal" vs. "abnormal"), and an overall functioning measure. Neurological findings

were aggregated at the participant level and coded as “ever abnormal” to represent cumulative neurological burden; prospective time-to-event analyses are planned to investigate onset patterns. Participants missing all neurological data were excluded. Partial within-domain missingness was retained, with conservative imputation (Not Available [NA] = 0) applied exclusively for clustering analyses to preserve phenotype structure. Hierarchical clustering (Ward’s D²) identified six sensory-motor phenotypes. Clusters were compared by PTSD status using chi-square tests, and standardized stress-burden z-scores were derived from Mental Health Diagnostic Interview Schedule responses. **Results:** Six neurological phenotypes emerged, ranging from low-abnormality to diffuse cranial-sensory-motor involvement. PTSD prevalence differed significantly across clusters ($\chi^2=17.1$, $p=0.004$), with the highest burden observed in diffuse cranial-sensory phenotypes compared to the low-abnormality group. Stress-burden scores showed no significant group differences ($p=0.33$; $\epsilon^2=0.0003$). Exploratory patterns suggested that reflex asymmetry, reduced strength, and sensory abnormalities were more common in diffuse clusters, indicating broader sensory-motor involvement. **Conclusions:** Distinct neurological phenotypes among WTC responders reveal early, clinically accessible sensory-motor patterns that vary by PTSD prevalence and may align with previously reported exposure-related neurobiological signatures in this cohort. These sensory-motor phenotypes may reflect early downstream effects of previously reported WTC-related toxicant pathways, including microglial activation, axonal injury (NFL), and tau-related alterations. Diffuse cranial-sensory involvement with elevated PTSD burden may represent a potential endophenotype relevant to trauma- and exposure-linked pathways. Integration with ongoing biomarker, neuroimmune, and neuroimaging research is warranted to clarify mechanistic links and advance early detection strategies in disaster-exposed populations.

PS 4222 Systemic murine infection with Western Equine Encephalitis Virus results in age-related Parkinson’s disease-like motor dysfunction *in vivo* and astrocyte-mediated neurodegeneration *in vitro*

A. J. Schuller, A. M. Briggs, and R. B. Tjalkens. Colorado State University, Fort Collins, CO.

Background and Purpose: Encephalitic arboviruses, such as Western equine encephalitis virus (WEEV), are rapidly emerging in human and animal populations across the globe due to expansion of vector-occupied territories as a result of rising temperatures and increased rainfall. Viral neurotropism, resulting in acute viremia and post-encephalitic neuroinflammation, is a long-understood mechanism of alpha-virus-induced neurodegeneration. Prior epidemiologic work has posited advanced age as a significant risk factor for severity of viral insult and subsequent risk of neurologic dysfunction; however, the consequences of senescence on glial involvement and neuroimmune modulation as contributors to age-related neurodegeneration remain elusive. Our lab has previously demonstrated that intranasal infection with WEEV is sufficient to elicit a robust male-specific astrocyte-mediated complement response associated with disordered movement, dopaminergic neurodegeneration, and nigrostriatal alpha-synuclein aggregation. We have further shown the ability of footpad-administered WEEV to undergo neuroinvasion and result in parenchymal replication. Still, the ability of this arthropod-relevant mode of transmission to induce neurodegenerative sequelae has not been explored. Together, these data motivated the assessment of footpad-delivered WEEV on motor function and dopaminergic neurodegeneration in young vs. old mice, as well as tandem interrogation of astrocytic infection *in vitro* to tease apart molecular consequences on neuronal populations. **Methods:** Ten-week-old or ten-month-old male C57Bl/6 mice ($n = 4-8$ animals/group) were anesthetized and administered saline vehicle or 5×10^3 PFU McMillan WEEV via footpad injection. Baseline behavioral data was collected prior to viral insult and subsequently compared to weekly timepoints assessing all-paw grip strength, pole test descent time, and hindlimb clasping scores. Four weeks post-infection (WPI) all mice were sacrificed and brains were removed and sagittally hemisected. One hemisphere was utilized for downstream striatal neurochemical profiling, basal midbrain bulk RNA-sequencing, and cortical plaque assay. The other hemisphere was post-fixed and sectioned for assessment via robotic multiplex immunofluorescent labeling, high-content microscopy, and deep learning-based image analysis pipelines. We applied spatial phenomics to characterize nigrostriatal reactive gliosis and dopaminergic neurodegeneration in the context of age-related WEEV infection. Murine neonates were simultaneously sacrificed to establish primary neuronal and astrocyte-enriched glial cultures. Subsequent assessment of cell viability, transcriptomic patterns, and inflammatory signaling occurred in low vs. high passage number cells. **Results:** We observed 50% lethality in young group mice in the first two weeks post-infection, despite no old group mice exhibiting signs of moribundity. Interestingly, advanced age mice demonstrated substantial progressive motor dysfunction following WEEV infection. Histopathologic analysis revealed substantial glial reactivity in all viral-infected mice, concurrent with vulnerability of the nigrostriatal projection. To further investigate mechanistic glial involvement underlying the dystonic phenotype, cell viability was assessed across half-log viral titers spanning 0.01 to 10 PFU/cell which revealed that low passage glia are far more susceptible to WEEV-induced cytotoxicity than high passage cells. We additionally examined the effect of WEEV infection on canonical inflammatory signaling by establishing primary glial cultures from NF-kB-GFP reporter mice, which revealed an age- and dose-dependent activation. Glial conditioned media derived from low or high passage cells at viral titers spanning the multiplicity of infection in glia were applied to primary neuronal cultures, which revealed an age- and dose-dependent effect on

neuronal death. Glial-mediated neurotoxicity was blunted by pharmacologic NF-kB inhibition. **Conclusions:** Together, these data highlight the role that age may play in the susceptibility to Parkinsonism secondary to viral neurotropism. Future work will aim to investigate the impact of modulating glial immune signaling *in vivo* on the progression of this pathologic milieu.

PS 4223 A High-Content Neurotoxicity Assay using multiple Neurotransmitter and Synaptogenesis Markers in *C. elegans*

S. Mondal¹, A. Laing², A. Shen², A. Medewar², J. Brown², and A. Ben-Yakar^{2,3}. ¹vivoVerse, Inc., Austin, TX; ²vivoVerse, LLC, Austin, TX; and ³The University of Texas at Austin, Austin, TX.

Background and Purpose: Neurodevelopmental disorders in children are increasing with one important factor being the exposure to potentially neurotoxic chemicals at a young age. Despite widespread human exposure, many chemicals remain untested for developmental toxicity (DNT) endpoints. Conventional DNT studies are performed in rodents, which face growing regulatory restrictions and are slow, costly, and low throughput to address the urgent need for hazard assessment. New approach methodologies (NAMs) including *in silico* tools, *in vitro* methods, and small model organisms are emerging as alternatives for DNT. While *in vitro* models have been instrumental for drug discovery and are being evaluated for DNT test batteries, they suffer with several technical challenges such as inconsistent network formation, high costs for long-duration studies, dependence on serum, and limited ability to measure systemic or behavioral outcomes. To bridge these gaps, we propose using the small model organism *Caenorhabditis elegans* to complement existing *in vitro* assays and support scalable DNT testing. **Methods:** We established a liquid-culture protocol enabling synchronized growth of 80 worms per well in a 24-well plate, using HB101 as a food source and exposing animals to multiple concentrations of reference chemicals for 3-7 days. Adult worms were immobilized in a high-throughput microfluidic device capable of imaging 960 individuals per chip (40 worms $\times$ 24 conditions). Two reporter strains expressing *dat-1::GFP* and *unc-47::mCherry* were used to visualize dopaminergic and GABAergic neurons, respectively. To evaluate synaptic defects, we generated a dual-color strain co-expressing *syd-2::GFP* in the GABAergic model. Using an automated imaging platform, we acquired multi-color z-stack datasets and quantified multiple morphological and synaptic endpoints using semi-automated and machine-learning-assisted pipelines. **Results:** Assay performance was evaluated using methylmercury (MeHg), a well-established DNT reference toxicant. Dopaminergic neurodegeneration was assessed by quantifying blebbing and dendritic breaks in CEP neurons, while GABAergic toxicity was evaluated based on changes in cell-body size, fluorescence intensity, and synaptic morphology (size, localization, and intensity). Both MeHg and bisphenol A (BPA) induced concentration-dependent increases in neuronal damage and aberrant synaptogenesis. All parameters demonstrated strong repeatability, with coefficients of variance ranging from 3-24%. **Conclusions:** We developed a robust and reproducible *C. elegans*-based DNT assay capable of multiplexed imaging and quantitative analysis across two neurotransmitter systems. Validation with two well-characterized neurotoxins confirms the platform’s sensitivity and scalability. Future efforts will expand to additional chemicals and neurotransmitter models to enable more comprehensive, neuron-specific DNT profiling.

PS 4224 Evaluating the protective role of nicotine in pesticide induced Dopaminergic neuron degeneration through mechanosensation, behavioral, and fluorescent assays

C. Lane¹, S. McDermott¹, A. Svetlik^{1,2}, K. Neubert¹, R. Frye^{1,3}, V. Fitsanakis^{1,4}, and K. Vaughan¹. ¹King University, Bristol, TN; ²Texas A&M, College Station, TX; ³University of Virginia, Charlottesville, VA; and ⁴Robson Forensics, Lancaster, PA.

Background and Purpose: Parkinson’s Disease (PD), a prevalent neurodegenerative disorder is characterized by tremors, bradykinesia, and impaired coordination and balance. PD results from the degeneration of the dopaminergic (DA) neurons in the substantia nigra. The complex etiology of PD is understood to be an interaction of genes and the environment, especially pesticide and heavy metal exposure. Mancozeb (MZ), a common fungicide (active ingredient manzate or Mn/Zn ethylene-bis-dithiocarbamate), is known to disrupt neurotransmission and increase oxidative stress. Previous research in our lab has indicated that the fungicide Mancozeb induces PD-like dopaminergic (DAergic) degeneration in the model organism *C. elegans* by inhibiting complex I of the mitochondrial electron transport chain. Increased oxidative stress and mitochondrial dysfunction are hallmarks of the known pathology of PD development. There is no cure for PD and the few available treatments lose efficacy overtime, therefore there is a need to understand the mechanisms leading to PD. Epidemiological studies have shown that PD is less frequent in tobacco users, although the protective effect and potential mechanism are unknown. While there are several potential components of tobacco that may be driving this inverse association, nicotine has a high binding affinity to the nAChRs (nicotinic Acetyl-Choline Receptors) in DAergic neurons and has been shown to modulate DAergic signaling. Nicotine has also been shown to modulate mitochondrial activity and decrease oxidative stress. It is therefore important to investigate the protective effects of nicotine as well as the potential interaction with mitochon-

drial function associated with DAergic degeneration. **Methods:** To investigate the role of nicotine in pesticide-induced DAergic degeneration, N2 (wild type *C. elegans*) and BY250 (GFP tagged dopamine transporter) were treated with either nicotine or MZ individually, a dual treatment of nicotine followed by MZ and control. DAergic neuron function was monitored by two behavioral based assays. A mechanosensation assay was performed, with the nose touch assay targeting DAergic neurons, soft touch targeting Touch Receptor Neurons (TRNs) and harsh touch serving as a general response control. The DAergic system also controls movement and feeding behavior. The basal slowing response was observed to monitor their locomotion with and without the food source (*E.coli*). The BY250 fluorescence of the GFP-dat-1 was measured as an indicator of DA function. Mitochondrial function was monitored with the MitoToxGlo assay kit to measure membrane integrity and ATP production. **Results:** A significantly decreased response was only observed in the nose touch response for MZ treated worms (p-value <0.5) in both the N2 and BY250 nematodes, indicating that MZ induces DA degeneration and nicotine provides protection on behavioral assays. Neither the harsh or soft touch showed any deviation from control, indicating the DAergic neurons were targeted. The basal slowing response showed a significantly decreased locomotion rate after exposure to food for all treatment groups except MZ, demonstrating an inability to adapt to their surroundings, indicating DAergic degeneration. Supporting previous work, preliminary fluorescent data indicate a decrease in mitochondrial function from both BY250 and MitoToxGlo assays following exposure to MZ. The investigation of the effect of nicotine and nicotine pre-treatment on mitochondrial function is ongoing. **Conclusions:** Taken together, the combination of these assays provides important insight into the protective effect and potential mechanism of nicotine on pesticide induced DAergic neuron degeneration, leading to a better understanding of how nicotine may decrease the risk of developing PD and open potential avenues for understanding underlying mechanisms and finding new treatments.

PS 4225 Methanol Enhances Vascular K_{ATP} Channel Activity: A Potential Mechanism for Methanol-Induced Hypotension

C. Simon, V. Nagaraj, and C. McClenaghan. Center for Advanced Biotechnology and Medicine, and Departments of Pharmacology and Medicine, Robert Wood Johnson Medical School, Rutgers the State University of New Jersey, Piscataway, NJ. Sponsor: C. Simon, Society of Environmental Toxicology and Chemistry

Background and Purpose: Methanol poisoning causes severe metabolic acidosis, visual impairment, and often fatal cardiovascular collapse. Profound hypotension is a frequent but poorly understood complication. Vascular ATP-sensitive potassium (K_{ATP}) channels (Kir6.1/SUR2B) regulate vascular tone through smooth muscle hyperpolarization and vasodilation when activated. Because hypotension and hyperglycemia - both common in methanol toxicity - are expected consequences of K_{ATP} channel activation, we hypothesized that methanol enhances vascular K_{ATP} channel activity, thereby contributing to its toxic cardiovascular effects. **Methods:** Fluorescence-based thallium (Tl^+) flux assays were performed in HEK293 cell lines stably expressing vascular Kir6.1/SUR2B channels. Channel activity was measured under basal conditions and following pharmacological activation with the K_{ATP} opener pinacidil (0.1-300 μ M), in the absence or presence of methanol at concentrations consistent with toxic exposures (1 M and 5% v/v). Glibenclamide (10 μ M) was used to confirm K_{ATP} -specific effects. Flux rates were extracted from fluorescence traces using exponential fitting, and statistical significance was assessed by ANOVA with appropriate post-hoc testing. **Results:** Methanol significantly enhanced Kir6.1/SUR2B activity when preactivated by pinacidil. At 1 M methanol, augmentation was observed across multiple concentrations of pinacidil, with the most robust effect at 100 μ M ($p < 0.001$); these effects were fully reversed by glibenclamide. At 5% methanol, channel activity was enhanced at both 30 μ M ($p < 0.01$) and 100 μ M pinacidil ($p < 0.001$). In a small pilot dataset, 5% methanol alone increased basal activity ($p < 0.01$), suggesting possible direct activation. **Conclusions:** These findings provide the first direct electrophysiological evidence that methanol enhances vascular K_{ATP} channel activity at toxicologically relevant concentrations and might suggest a plausible mechanism for the profound hypotension seen in methanol poisoning. Given pancreatic K_{ATP} channels inhibit insulin secretion when activated, similar effects on Kir6.2/SUR1 channels could explain the associated hyperglycemia. Notably, during methanol toxicity, severe metabolic derangements and ATP depletion may leave K_{ATP} channels in preactivated states, amplifying methanol's potentiating effects. Ongoing studies aim to assess the effects of methanol on these processes. Collectively, these data promise to advance mechanistic understanding of methanol toxicity.

PS 4226 The Effects of Carbon Nanodots on Ultrasonic Vocalizations and Other Behaviors of C57BL/6J and LDLr^{-/-} mice.

D. Cardenas Vasquez, K. M. Erikson, I. Pack, S. Fordahl, C. Tang, K. El-Khoury, T. Philbrook, R. Petric, and Z. Jia. University of North Carolina at Greensboro, Greensboro, NC.

Background and Purpose: Carbon nanodots (CNDs) are new nanomaterials widely used in biomedicine for their cost-effectiveness and low toxicity compared with other nanomaterials and applications such as bioimaging and drug delivery. While multiple *in-vitro* and *in-vivo* studies elucidated the low toxicity of CNDs during a short

period of time (7 days or less), limited information exists regarding their long-term effects on *in-vivo* models. Specifically, we do not understand the potential toxicity of CNDs on the observable appearance, development, and behavior of an individual. **Methods:** We hypothesized that long-term administration of CNDs alters behavior and physiology in laboratory mice. We tested our hypothesis using C57BL/6J mice and LDLr^{-/-} mice and evaluated behavioral and physiological responses to 2.5 mg/kg CNDs over 8 weeks. Specifically, we focused on evaluating the effects of CNDs on Ultrasonic Vocalizations (USVs) as a measure of communicative behavior. We also utilized two standardized behavioral tests, the Open Field Test and the Elevated Plus Maze Test, to analyze alterations in specific behavioral patterns induced by CNDs. Finally, we examined the influence of CNDs on the force strength of mice through a neuromuscular test. **Results:** We found that CND-treated C57BL/6J mice produced fewer USVs than control mice and that CND-treated mice produced USVs with lower-end frequency and maximum frequencies. However, in LDLr^{-/-} mice, we found no difference in calling rate between treatment groups, but CNDs treated mice produced vocalizations with different spectral characteristics. Furthermore, CNDs treated LDLr^{-/-} mice produced calls with lower end frequency, maximum frequency, start frequency, the frequency at maximum amplitude, and minimum frequency. CNDs increased the total floor velocity in the Open Field Test in C57BL/6J mice. We found no differences between treatment groups using the open-field or Neuromuscular tests. **Conclusions:** Together, these results suggest that the difference in behavioral tests, especially in calling rate and changes in spectral characteristics of USVs, may reveal that CNDs induce a potential stress response to C57BL/6J mice and LDLr^{-/-} mice.

PS 4227 The Influence of Isoflurane on the Gut Microbiome in a Rat Model of Diet-Induced Hypertension

A. N. Arce Rodriguez¹, B. Christian², and A. Lauver². ¹Inter American University of Puerto Rico, Aguadilla Campus, Aguadilla, PR; and ²Michigan State University, East Lansing, MI.

Background and Purpose: Dysbiosis can elicit systemic inflammation and disrupt intestinal mechanotransduction, a process involved in blood pressure regulation. Isoflurane, a commonly used anesthetic agent for maintaining general anesthesia, has known effects on BP regulation. Isoflurane may also alter the gut microbiome, which can lead to systemic inflammation and metabolic changes that contribute to hypertension. In this study, we evaluate the effects of diet and repeated isoflurane exposure on the gut microbiome and associated BP changes. **Methods:** 36 Dahl salt-sensitive (SS) rats were used and divided into two cohorts (n=18): control diet (CD; 10% kcal from fat) and high fat diet (60% kcal from fat). Additionally, half of the rats (n=18) were exposed to isoflurane every two weeks for ultrasound imaging procedures, resulting in 12 isoflurane exposures per rat. Arterial BP was measured continuously by implanted radiotelemetry or tail cuff plethysmography. Fecal pellets were collected and analyzed by shallow shotgun whole genome sequencing using the Transnetyx microbiome sequencing service. Fecal pellet collection took place at baseline, and 10, 17, and 24 weeks on diet. **Results:** Our findings will demonstrate that diet plays a role in driving changes in the gut microbiome, which is associated with the development of hypertension. Rats fed a HFD will exhibit altered microbial composition and diversity compared to a CD, associated with elevated BP. Repeated exposure to isoflurane is expected to modulate the diet-associated microbiome changes and potentially the hypertensive response. **Conclusions:** Understanding the impact of diet on the microbiome is crucial for hypertension research. Diet-induced changes in microbial composition can directly impact BP regulation, and repeated exposure to isoflurane can alter the gut microbiome, influencing the development of hypertension. This data could shift how we approach the management of hypertensive patients by encouraging more personalized dietary interventions and reconsidering the type or frequency of anesthetic use in individuals at risk.

PS 4228 Metabolic Remodeling and Mitochondrial Impairment in HFpEF: Insights from a Murine Model

A. Aryal, L. Bishop, P. Mobasher, S. Chatterjee, S. R. Jennings, J. Adamec, H. Xia, E. D. Lazartigues, and Q. Yang. Louisiana State University Health Science Center-New Orleans, New Orleans, LA. Sponsor: Q. Yang, American Physiological Society

Background and Purpose: Heart failure (HF) is a highly morbid condition affecting over 60 million people worldwide. Importantly, heart failure with preserved ejection fraction (HFpEF) accounts for approximately 50% of all HF cases, and continues to rise, especially in young and aging populations. Despite recent advances, the pathophysiology of HFpEF remains incompletely understood, hindering early diagnosis and effective treatments. Emerging evidence highlights metabolic remodeling and mitochondrial dysfunction of the heart as central pathophysiological processes in HFpEF development. However, the mechanistic link between altered cardiac metabolism and mitochondrial impairment remains poorly defined. **Methods:** In this study, we investigated the role of cardiac metabolic remodeling in regulating mitochondrial function during HFpEF progression, using an established angiotensin-II (AngII)/phenylephrine (PE) infusion murine HFpEF model without the confounding effects of multi-stressors, such as obesity and aging. HFpEF was induced in 8-10-week-old mice by implanting osmotic pumps subcutaneously to infuse AngII (1.5 μ g/g/day) and PE

(50 µg/g/day) for 28 days, while Control mice received saline infusion only. **Results:** Mice infused with AngII/PE exhibited key HFpEF characteristics, including preserved ejection fraction, elevated E/E' ratio, prolonged isovolumetric contraction time, and increased myocardial performance index. Compared to Control, AngII/PE-infused mice showed significantly reduced mitochondrial respiration, diminished complex II protein, and impaired mitochondrial supercomplexes formation. Furthermore, AngII/PE-infused mice demonstrated decreased mitochondrial calcium retention capacity compared to Saline. Metabolomic analysis of mitochondria revealed increased metabolites of alternative glucose utilization pathways, and reduced fatty acid metabolites, suggesting a metabolic shift from fatty acid oxidation toward reliance on alternative glucose metabolism pathways. Methylglyoxal, a biomarker of dicarbonyl stress, was elevated in the heart, whereas advanced glycation end products (AGEs), biomarkers of glycation stress, were elevated in both heart homogenates and mitochondria of AngII/PE-infused mice compared to Saline control, suggesting increased glucose metabolite-adducts. Proteomic analysis of mitochondrial proteins co-immunoprecipitated using an anti-AGEs antibody revealed glycation of mitochondrial proteins essential for maintaining electron transport chain integrity. **Conclusions:** Collectively, our findings suggest that metabolic remodeling critically contributes to the increase of dicarbonyl/glycation stress, impairing mitochondrial supercomplexes formation and respiration, as well as mitochondrial calcium retention capacity in the HFpEF heart. The present findings yield novel insights into future promising therapies targeting anti-dicarbonyl/glycation stress and mitochondrial function to improve disease prognosis in HFpEF patients.

PS 4230 Transcriptomic Profiling Reveals Enhanced Cardiomyocyte Maturation in 3D Culture with Fibroblast Co-culture

M. Rao¹, I. Mahfouz², F. Tariq², E. Vermersch², C. Pernici³, E. Ferrari³, P. Occhetta³, R. Visone⁴, and A. Garry². ¹Sanofi Pharmaceuticals, Cambridge, MA; ²Sanofi Pharmaceuticals, Vitry, France; ³BiomimX Srl, Milano, Italy; and ⁴BiomimX Srl, Vitry, Italy.

Background and Purpose: Cardiomyocyte (CM) maturation is essential for modeling adult heart physiology and ensuring cardiac safety during drug development. While human induced pluripotent stem cell-derived CMs (hiPSC-CMs) offer a promising tool, they often remain immature *in vitro*. **Methods:** To identify conditions that enhance maturation, we evaluated the effects of culture format (2D vs. 3D), mechanical environment (static vs mechanical stimulation) and cellular composition (100% CMs vs. 75% CMs + 25% fibroblasts). **Results:** Principal component analysis of RNA-Seq data revealed distinct clustering based on culture format and cell composition. 2D monocultures showed tight clustering over time, indicating minimal transcriptomic divergence, while 3D co-cultures occupied unique PCA space, reflecting intermediate transcriptional profiles and enhanced biological activity. These patterns suggest that both physical environment and cellular diversity drive transcriptional variance and maturation. Differential gene expression analysis showed that 3D co-culture significantly upregulated maturation markers (e.g., MYH6, MLC2v, RYR2, SERCA2, PPARα, PGC1α, TFAM) and downregulated immature markers (e.g., MYH7, MLC2a, HCN4). Pathway enrichment analysis revealed that 3D cultures activated oxidative phosphorylation, calcium signaling, and cardiac conduction pathways, while 2D cultures enriched cholesterol biosynthesis and inflammatory signaling. Mechanical stimulation in 3D cultures further promoted sarcomeric organization and functional responsiveness to inotropic agents. **Conclusions:** These findings demonstrate that optimized 3D co-culture systems provide a more physiologically relevant model for CM maturation. This platform may improve early-stage drug screening and cardiovascular safety evaluation by generating preclinical cardiac models better recapitulating human adult myocardium.

PS 4231 Comparative Assessment of Inhalation Exposure to Military Burn Pit and Wildland Urban Interface Fire Emissions on Systemic Microvascular Function

V. Nguyen¹, A. Ranpara¹, W. T. Goldsmith¹, T. Batchelor¹, H. D. Leonard¹, R. Burns¹, S. Hussain¹, D. Harper², J. Hoyer¹, and T. R. Nurkiewicz¹. ¹West Virginia University, Morgantown, WV; and ²University of Tennessee, Knoxville, Knoxville, TN.

Background and Purpose: Globally, air pollution is the second greatest mortality risk. Complex combustion emissions are some of many contributing factors to air pollution. Military burn pits (BP) and wildland urban interface (WUI) fires are examples of open-air burning that result in complex combustion emissions and lead to worsening air quality. Over 3.5 million military Veterans have been exposed to BP emissions, with many reporting chronic multisymptom illness following deployment. WUI fire and wildfire emissions have been linked to adverse pulmonary outcomes, cardiovascular health, and increased hospitalizations during periods of increased wildfire prevalence. To date, the systemic microcirculation has not been studied after these complex combustion emission exposures. This project's purpose is to assess and compare systemic microvascular function after BP and WUI fire emission inhalation exposures. **Methods:** A computer-controlled modified pellet stove served as a surrogate combustion emissions generator for these experiments. Burn pit pellets composed of 80% wood, 10% plastic, and 10% rubber burned with the presence of jet fuel with additives (JAA) in the modified pellet stove. Alternatively, WUI pellets were

composed of 55% pine, 25% oriented strand board, 17% vinyl, 3% green foam board, and burned without JAA. 7-8 week-old male Sprague Dawley rats were exposed in a whole-body inhalation exposure chamber for a minimum of 4 hours for 2-6 days. 24 hours following exposure, the spinotrapezius muscle was surgically prepared for intravital microscopy. The spinotrapezius muscle was superfused with acetylcholine (ACh, 10⁻⁶-10⁻⁴ M) to assess endothelium-dependent arteriolar vasodilation. Vasoconstriction was evaluated with either phenylephrine (PE, 10⁻⁵-10⁻³ M) or angiotensin II (ANG II, 10⁻⁶-10⁻⁴ M) superfusion. **Results:** Following the whole-body inhalation exposure to BP emissions, there were no impairments to percent change from control in endothelium-dependent vasodilation from the sham control group (-3.92 - 128.67 ± 22.35%) to the 2-day exposed group (-5.24 - 63.49 ± 14.18%). There were no impairments to percent change from control in vasoconstriction from the sham control group (-19.76 - -70.33 ± 5.03%) to the 2-day exposed group (-7.85 - -31.11 ± 8.01%). Compared to the sham control group, significant impairment in endothelium-dependent vasodilation was observed in the 3-day exposure group (1.27 - 24.02 ± 9.80%) and 6-day exposure group (2.69 - 8.42 ± 7.91%). Likewise, vasoconstriction was significantly impaired in the 3-day exposure group (-14.99 - -42.26 ± 8.38%) and 6-day exposure group (-20.01 - -48.73 ± 9.17%). **Conclusions:** This is the first study to conduct a direct comparison of microvascular function between sham control, BP exposed, and WUI exposed rats. Significant microvascular dysfunction was observed through the minimal response in endothelium-dependent vasodilation and vasoconstriction. Future experiments will expose rats to WUI fire emissions by burning WUI pellets in the surrogate combustion emissions generator and making comparisons of the health effects from BP exposures compared to WUI exposed animals. **Support:** UL Research Institutes, NIH P20-GM103434 (WVINBRE), U54-GM104942 (WVCTSI), R21-ES034942 (TRN), T32 ES032920 (TRN, VTN)

PS 4232 High-content phenotypic profiling of human aortic endothelial cells reveals class-specific lipid and organelle perturbations by environmental chemicals

A. T. Szafran¹, M. G. Mancini¹, D. Z. Suske¹, M. J. Bolt¹, M. A. Mancini¹, N. Gokce², and J. J. Schlezinger³. ¹Baylor College of Medicine, Houston, TX; ²Boston University School of Medicine, Boston, MA; and ³Boston University School of Public Health, Boston, MA.

Background and Purpose: Environmental exposures have been associated with cardiovascular disease risk, the leading cause of death worldwide. Endothelial cells are critical sentinels of vascular health and may serve as sensitive targets for toxicant-induced cardio-metabolic stress. To investigate class-specific effects of environmentally relevant compounds, we applied a high-content phenotypic profiling strategy using primary human aortic endothelial cells (HAECs). **Methods:** HAECs were exposed for 72 hours to vehicle (DMSO) or a curated library of 48 compounds consisting of phthalate, bisphenol, pesticide, flame-retardant, liquid crystal monomer (LCM), and per- and polyfluoroalkyl substance (PFAS) classes across a 50 nM-100 µM range. Following exposure, cells were stained using Cell Painting (CPA) and a metabolic CPA (mCPA) variant and imaged on an automated confocal platform. The SPACe image analysis pipeline extracted region-specific metrics encompassing nuclear, endoplasmic reticulum (ER), lipid, and mitochondrial features. Phenotypic distance from DMSO controls and unsupervised UMAP clustering were used to assess concentration- and class-dependent responses. **Results:** Most compounds induced measurable, concentration-dependent morphological phenotypes. Pyrethroid pesticides and LCM emerged as the most active classes, strongly altering lipid-related features by increasing total BODIPY intensity per cell with altered lipid droplet number and size. Flame retardants and phthalates produced weaker, more variable responses, whereas PFAS primarily induced nuclear and ER-localized phenotypes. UMAP-based clustering demonstrated a reproducible progression from inactive to intermediate and strong phenotype states as concentration increased, capturing both potency and mechanistic diversity across chemical classes. **Conclusions:** High-content morphological profiling of endothelial cells can sensitively resolve compound-class-specific activity patterns and identify early indicators of lipid and organelle stress relevant to cardiovascular toxicity. Ongoing work is focused on defining the functional impact of these phenotypic changes, including effects on lipid uptake, activation of pro-inflammatory pathways, atherosclerotic potential, and regulation of endothelial nitric oxide synthase (eNOS)-dependent vascular physiology including vasomotor function and angiogenesis

PS 4233 Loss of PPARα in Murine Hearts Alters Female Sex-Specific Cardioprotection to Doxorubicin

A. Mills, and S. George. University of Pittsburgh School of Medicine, Pittsburgh, PA.

Background and Purpose: Doxorubicin (DOX), a chemotherapeutic agent, causes severe cardiotoxicity, oxidative stress, and mitochondrial dysfunction specifically in FA metabolism. PPARα (Peroxisome Proliferator Activated Receptor alpha) is essential for cardiac FA uptake and mitochondrial β-oxidation. The literature shows that loss of PPARα has no effect on DOX-induced cardiotoxicity or is even cardioprotective, however, these studies are not investigating sex differences and only report male data. Thus, we tested the hypothesis that loss of PPARα would eliminate sex-specific cardioprotection in females during DOX treatment. **Methods:** To test this, we used

quadruple-parametric optical mapping to simultaneously image transmembrane potential (V_m), calcium handling (Ca), NADH, and FAD intensity in male and female murine hearts. Male and female mice were randomly assigned to three groups; 1. Wild type (WT) (n=6) 2. WT+DOX (n=6) and 3. PPAR α KO+DOX (n=3-6). DOX (20mg/kg) was intraperitoneally injected 5 days before echocardiography, electrocardiography and optical mapping were performed in each mouse. **Results:** DOX therapy alone increased ejection fraction (62.37 ± 4.98 vs 54.83 ± 3.32) and fractional shortening (33.02 ± 3.55 , vs 28.03 ± 2.14) in female WT mice but not males, $p < 0.05$. On the other hand, in PPAR α KO+DOX mice vs WT, reduced stroke volume (Male: 24.48 ± 4.599 vs 43.95 ± 7.20 , Female: 23.94 ± 6.96 vs 36.60 ± 4.20) and cardiac output (Male: 12.03 ± 2.93 vs 18.66 ± 4.35 , Female: 10.13 ± 4.40 vs 16.28 ± 2.57) were observed in both sexes, $p < 0.05$. ECG analysis revealed that QTc interval was reduced in both male and female PPAR α KO+DOX mice vs WT (Male: 17.50 ± 2.93 vs 36.22 ± 2.67 , Female: 24.31 ± 3.30 vs 33.61 ± 1.05) and this was associated with increased arrhythmia incidences (Male: 3.52 ± 0.89 vs 0.54 ± 1.17 , Female: 5.45 ± 1.78 vs 1.68 ± 0.94) in these mice. Lastly, optical mapping studies revealed that, in male WT+DOX mice increased V_m rise-time (7.33 ± 0.59 , vs. 5.19 ± 0.64), Ca rise time (10.39 ± 1.43 , vs. 7.16 ± 0.76), and shortened V_m -Ca delay (-3.55 ± 2.56 , vs. -10.59 ± 4.13) were observed. Interestingly, in the male PPAR α KO+DOX mice, these depolarization/calcium release parameters were restored back to control levels contrary to the repolarization parameters recorded from the ECG. No significant electrical remodeling was observed in female WT+DOX or PPAR α KO+DOX mice. There were also no significant changes in NADH, FAD, or redox ratio (FAD/NADH). **Conclusions:** DOX treatment in WT mice, altered female mechanical function and male electrophysiology. On the other hand, DOX treatment in PPAR α ablated mice impaired mechanical and electrical function in both males and females and increased arrhythmia incidences. Notably, DOX-induced arrhythmogenic remodeling in cardiac depolarization observed in WT males was prevented in the PPAR α ablated mice. These findings suggest that 1. PPAR α is cardioprotective during DOX therapy and 2. females have different compensatory mechanisms than males with DOX exposure. This preliminary data adds to the long-term goal of developing sex-specific cardioprotective strategies for patients undergoing cancer chemotherapy.

PS 4234 Comparing Predictability of Drug-Induced Proarrhythmia Using hiPSC-Cardiomyocytes, Ion Channel Inhibition, and APD Simulation

H. Miyoshi¹, N. Mochizuki², M. Tateshita³, Y. Hikida³, and A. Inomata¹. ¹FUJIFILM Corporation, Bio Science & Engineering Laboratories, Ashigara-kami, Kanagawa, Japan; ²FUJIFILM Toyama Chemical Co., Ltd., Toyama, Toyama, Japan; and ³FUJIFILM Corporation, Imaging & Informatics Laboratories, Minato-ku, Tokyo, Japan.

Background and Purpose: Cardiotoxicity, particularly proarrhythmia, is a leading cause of attrition in drug development. Therefore, early assessment of a drug compound's proarrhythmic potential is critical to mitigate the risk of encountering such issues in later stages. Proarrhythmic potential is typically evaluated by screening drug-induced inhibition of key ion channels, including hERG, NaV, and CaV, followed by phenotypic assays using hiPSC-derived cardiomyocytes. However, limited data exist comparing the predictive accuracy of these different methods in identifying proarrhythmic risk. In this study, we developed a phenotypic assay using hiPSC-derived cardiomyocytes combined with a multi-electrode array (MEA) system to evaluate the proarrhythmic potential of compounds. The assay outcomes were compared against predictions based on hERG inhibition and computational simulations of action potential duration incorporating effects on hERG, NaV, and CaV channels. **Methods:** iCell® Cardiomyocytes2 (FUJIFILM Cellular Dynamics, Inc.) were cultured in 96-well Cytoview MEA plates (Axion Biosystems, Inc.). A dose-escalation protocol was established to assess dose-response effects across up to four concentration levels. Extracellular field potentials were recorded at each dose, and field potential duration (FPD) was analyzed. We evaluated 27 compounds with known proarrhythmic risk, assessing predictability by identifying compounds that prolonged FPD or induced proarrhythmic events at concentrations up to 30-fold the clinical C_{max}. Ion channel inhibition data were obtained from published literature, and computational simulations of action potential duration were performed using the ORD model as described in prior studies. The same 30-fold C_{max} threshold was applied to evaluate proarrhythmia predictability across methods. **Results:** The hiPSC-cardiomyocyte assay detected 15 true positives and 9 true negatives among the 27 compounds. False negatives (terfenadine) and false positives (ranolazine and mexiletine) were consistent with previous reports. The same misclassifications were observed in assessments based on hERG inhibition and computational simulation. Compounds that inhibit hERG channels are not always associated with a high proarrhythmic risk due to compensatory effects from multi-channel inhibition. Notably, the hiPSC-CM assay effectively predicts risk by capturing this balance, whereas hERG inhibition assays and computational simulations alone may be insufficient for fully accurate risk prediction, as seen with compounds such as clozapine and verapamil. **Conclusions:** In conclusion, we have established a robust *in vitro* proarrhythmia assay using hiPSC-derived cardiomyocytes combined with an MEA system. This assay demonstrated higher predictive accuracy for identifying the proarrhythmic potential of drug compounds compared to the conventional ion channel inhibition assays and computational simulations of action potential duration.

PS 4235 Ready-to-use Human Cardiac Organoids for Chronic Contractility-Based Toxicity Profiling of Small Molecules and Biologics

B. Lickiss¹, J. Hunker¹, S. I. Wang², D. Woo², A. Kim², E. Kim², E. Dragicevic³, S. Stoelzle-Feix³, P. Linder¹, and M. Gossmann¹. ¹innoVibro GmbH, Juelich, Germany; ²NEXEL Co., Ltd., Seoul, Korea, Republic of; and ³Nanion Technologies, Munich, Germany.

Background and Purpose: Human cardiac organoids (hCOs) serve as a human-based alternative for functional cardiotoxicity evaluation, offering complex three-dimensional tissue architecture that mirrors native cardiac cellular composition and cell-cell communication. Their ready-to-use availability enables steady workflow integration, supporting rapid assay initiation and improved experimental consistency. Here, we present a detailed functional characterization of hCOs using a high-throughput label-free system designed to assess cardiac contractility over time. **Methods:** Cryopreserved, ready-to-use cardiac organoids were plated onto flexible membranes resembling human heart mechanical conditions in a 96-well assay format (FLEXcyte 96). Contractile function was monitored using non-invasive capacitive distance sensing analysis. Contraction force was continuously monitored to determine the establishment of a functional steady state. Subsequently, organoids were exposed chronically to cardiotoxic agents doxorubicin (small-molecule) and trastuzumab (monoclonal antibody). Contraction force was measured for three days to evaluate concentration-dependent changes over time. **Results:** Cardiac organoid contraction force increased steadily during pre-culture and reached a stable functional plateau after approximately 14 days, indicating successful establishment of a mature contractile phenotype. Subsequent chronic exposure to 500 nM doxorubicin or 687 nM trastuzumab led to a pronounced reduction in contractile force to 55% and 70% of baseline, respectively. Combined treatment resulted in an additional decline to 50%, consistent with the recognized cardiotoxic profiles of these agents. **Conclusions:** This proof-of-concept study demonstrates that cryopreserved human cardiac organoids plated on flexible membranes provide a sensitive and scalable system for chronic functional cardiotoxicity assessment of both small molecules and monoclonal antibodies. These findings support broader adoption of human-relevant 3D *in vitro* models in cardiovascular safety and toxicology, aligning with the growing regulatory momentum towards acceptance of NAMs in preclinical drug development.

PS 4236 Non-invasive assessment of electromechanical coupling in the study of cardiomyocytes

J. Netzeband, A. Godino, C. Scandellaria, J. Alvarez, G. Bruno, M. Dipalo, and M. Girand. Harvard Bioscience, Holliston, MA. Sponsor: M. Girand, Safety Pharmacology Society

Background and Purpose: Quantitatively assessing cardiomyocyte contractility, in combination with electrophysiological measures, is crucial for understanding cardiac function, cardiovascular diseases, and pharmacological responses. Drug-induced cardiotoxicity remains a significant concern, contributing to nearly one-third of drug failures in late-stage development and causing approximately 10% of global drug withdrawals. Many compounds affect both ion channel activity and mechanical contraction, highlighting the need for integrated, non-invasive approaches to evaluate electromechanical behavior *in vitro*. **Methods:** This poster presents an innovative approach based on the use of the IntraCell system, developed by Foresee Biosystems, to simultaneously monitor the mechanical contractility at a high frame rate (150 frames per second) and electrical activity of human iPSC-derived cardiomyocytes *in vitro* by integrating non-invasive optical and electrophysiological techniques. Contractility and displacement dynamics were quantified using Farneback's dense optical flow applied to high-resolution videos acquired through an integrated camera. In parallel, intracellular action potentials (APs) were recorded using a micro-electrode array (MEA) system combined with laser-based optoporation technology, which preserves cell integrity and viability. A tailored trigger allowed precise synchronization of mechanical and electrical signals. **Results:** We compared control and dofetilide-treated cells, highlighting drug-induced AP prolongation and its effects on the electromechanical behavior of cardiomyocytes. Specifically, dofetilide treatment led to a slower repolarization phase and delayed relaxation, confirming the platform's ability to detect and correlate pharmacologically induced changes in both electrical and mechanical cardiac function. The system successfully recorded high-quality, intracellular-like action potentials using an entirely non-invasive technique, capturing hallmark features such as early afterdepolarizations (EADs) induced by dofetilide. Moreover, the proposed methodology enabled precise tracking of the time evolution of these signals across contraction-relaxation cycles in both control and treated cells, demonstrating its reliability for dynamic, long-term analysis. **Conclusions:** In conclusion, this methodology enables both acute and long-term monitoring, offering significant potential for drug screening and evaluation of cardiotoxicity. The ability to correlate electrical and mechanical signals offers an innovative perspective on the electromechanical coupling of cardiomyocytes, thereby enhancing the understanding of their physiological and pathological dynamics and filling a critical gap in cardiac research.

PS 4237 **Lead (Pb) Exposure During Differentiation Induces Cell Line-Specific Transcriptional and Functional Alterations in Human iPSC-Derived Ventricular Cardiomyocytes**

K. E. Sala-Hamrick¹, A. Tapaswi¹, E. K. Shah¹, T. Ishikawa¹, I. R. Melis¹, A. Monteiro Da Rocha², D. C. Dolinoy¹, and L. K. Svoboda¹. ¹University of Michigan School of Public Health, Ann Arbor, MI; and ²University of Michigan Medical School, Ann Arbor, MI.

Background and Purpose: Cardiovascular disease (CVD) etiology is known to be strongly influenced by lead (Pb) exposure and highly sexually dimorphic, but the underlying sex specific molecular and functional mechanisms are unclear. Further, the dose-response effects of Pb exposure during heart development are yet to be fully understood. Using human induced pluripotent stem cell (iPSC) derived ventricular cardiomyocytes from one male and one female donor, we characterized how Pb exposure during cardiomyocyte differentiation impacts transcriptional as well as voltage and calcium dynamics. **Methods:** We used an established small molecule protocol that temporally modulates Wnt signaling to differentiate iPSCs from one male and one female donor into ventricular cardiomyocytes. During the first 8 days of differentiation, we treated with 0.5 or 5 μ M Pb acetate. We collected samples on days 0-15, extracted RNA, conducted RNA-Seq using a plexwell protocol for library preparation in the female-derived line, and did benchmark dose modeling using BMDExpress 3 on this data. Between days 10-20 of differentiation, the male and female derived iPSC-cardiomyocytes were purified using a magnetic bead protocol to selectively deplete non-cardiomyocyte populations, and after recovery of purified samples, optical mapping of action potentials and calcium (Ca) transients was conducted using a Nautilus instrument and fluorescent dyes (FluoVolt for action potentials and Calbryte for Ca transients). **Results:** RNA-Seq of the Pb-exposed female-derived cell line revealed significant changes in expression of genes throughout differentiation (p -adj < 0.05) and dysregulation of pathways related to heart development and function throughout differentiation in response to Pb, including epigenetic and mitochondrial machinery (FDR < 0.05). Upon benchmark dose modeling of this data, we found unique dose-response gene expression changes induced by Pb on different days of differentiation. While the expression changes were unique, they corresponded to a similar median benchmark concentration of 0.2 μ M for all days assessed. Gene ontology analysis of benchmark modeled genes showed changes in pathways related to heart development (Fisher's exact two-tailed p -value < 0.05). Further, we characterized functional changes in female- and male-derived iPSC-cardiomyocytes exposed to Pb during differentiation using optical mapping of Ca transients and action potentials. We found cell line-specific effects of Pb, including an increase in beating rate in both cell lines with Pb exposure (p -values < 0.0001 for both cell lines at 5 μ M Pb), and a decrease in the change in fluorescence and upstroke slope in the male cell line (p -values < 0.0001 and = 0.0001 for 5 μ M Pb, respectively). Interestingly, in the male cell line, median conduction velocity decreased when measuring voltage and increased when measuring Ca dynamics (p -values 0.0087 for 0.5 μ M Pb and < 0.0001 for 5 μ M Pb, respectively). **Conclusions:** We characterized the transcriptional and electrophysiological changes induced by Pb in ventricular cardiomyocytes derived from iPSCs. Transcriptional changes assessed in the female-derived line showed a dose-response effect correlating to human-relevant exposure ranges. Optical mapping iPSC-cardiomyocytes from the female and male patient donors revealed Pb-induced changes in beat characteristics in both cell lines and disruption of voltage and Ca coupling in the male cell line. Importantly, these changes were present 9-17 days after cessation of exposure to Pb. A limitation of this work is the use of only one cell line for transcriptional studies and two for optical mapping; further transcriptomic and functional studies should use a representative sample of numerous male and female donors to draw conclusions about potential sex differences. Through a combination of transcriptomic and functional analyses, we found that Pb exposure during cardiomyocyte differentiation induces changes related to the development of cardiac pathology, opening the door to future mechanistic studies examining how Pb exposure during differentiation may impact heart function.

PS 4238 **A comprehensive assessment of *in vitro* heart safety evaluation for Tyrosine kinase inhibitors**

X. Guo, S. Zheng, T. Zhao, C. Ren, M. Lin, L. Chen, K. Wu, X. Zhang, T. Bing, and Y. Li. ICE Bioscience, Beijing, China. Sponsor: T. Bing, American Association for Cancer Research

Background and Purpose: Tyrosine kinase inhibitors (TKIs) and other small-molecule anticancer drugs have significantly improved the treatment and prognosis of various cancer types. However, unpredicted cardiac toxicity has been observed in patients undergoing these therapies. This toxicity can manifest as arrhythmias, heart failure, or myocardial infarction, posing severe risks to patient safety. The current study aims to reassess the cardiac safety of anticancer drugs by evaluating their effects on isolated heart electrocardiograph, cardiac action potential, related ion channels, and cytotoxicity. This approach seeks to establish an early cardiac safety assessment method for anticancer drugs, facilitating the safe development of new therapeutic agents. **Methods:** *In vitro* heart perfusion assay was conducted on healthy male New Zealand White rabbits. The hearts were extracted and perfused using the Langendorff system, with Sunitinib (0.3, 3, 10 μ M/L), Crizotinib (0.3, 1, 3 μ M/L), and Doxorubicin (1, 30 μ M/L) administered sequentially for 120 minutes. A control group without drug perfusion was also included for comparison. ECG parameters

and left ventricular pressure were recorded. Additionally, manual patch clamping was used to assess the effects of these drugs on ion channel currents (hERG, Nav1.5, and Cav1.2) and action potentials in human-induced pluripotent stem cell-derived cardiomyocytes (hiPSC-CMs). Cell viability was evaluated by measuring ATP levels using the CellTiter-Glo luminescent cell viability assay. **Results:** *In vitro* heart perfusion experiments revealed that Sunitinib and Crizotinib at concentrations ≥ 3 μ M/L significantly decreased heart rate (P < 0.01), prolonged QT/QTc intervals (P < 0.01), and reduced left ventricular pressure compared to the control group. Manual patch clamping demonstrated that Sunitinib and Crizotinib at 3 μ M/L inhibited the activities of hERG, Nav1.5 and Cav1.2 channels and significantly prolonged the duration of action potential (P < 0.01). Furthermore, Sunitinib, Doxorubicin, and Crizotinib significantly reduced ATP levels and cell viability in hiPSC-CMs at their respective IC50 values (Sunitinib: IC50 = 4.64 μ M/L; Doxorubicin: IC50 = 4.21 μ M/L; Crizotinib: IC50 = 2.87 μ M/L; P < 0.01). **Conclusions:** This study successfully established an early cardiac safety assessment method for anticancer drugs, incorporating *in vitro* heart perfusion assay and electrophysiological patch clamping technique. The results indicate that Sunitinib, Crizotinib, and Doxorubicin exhibit concentration-dependent cardiac toxicity, affecting ECG parameters, ion channel function, and cardiomyocyte viability. This comprehensive evaluation approach provides valuable insights into the cardiac safety of anticancer drugs and supports the safe development of new therapeutic agents. Future studies should further validate this method in larger animal models and clinical trials to ensure its applicability and reliability in predicting cardiac toxicity in humans.

PS 4239 **Complementary cardiotoxicity screening pipeline from 2D hiPSC-cardiomyocytes towards complex 3D cardiac organoids and living myocardial slices**

E. Mohr^{1,2,3}, M. Jordan^{1,2}, N. Hoffmann¹, I. Riedel^{1,3}, A. Gietz³, S. Chatterjee^{1,2,3}, K. Schmidt¹, F. Schmieder⁴, A. Stucki-Koch¹, C. Polk⁴, C. Hansen¹, J. Philipp⁴, S. Behrens⁴, T. Nicke⁵, R. Ramm⁶, F. Sonntag⁴, C. Bär^{1,2,3}, and J. Fiedler^{1,2}. ¹Fraunhofer Institute for Toxicology and Experimental Medicine ITEM, Hannover, Germany; ²Fraunhofer Cluster of Excellence for Immune Mediated Diseases, Hannover, Germany; ³Hannover Medical School, Hannover, Germany; ⁴Fraunhofer Institute for Material and Beam Technology IWS, Dresden, Germany; ⁵Fraunhofer Institute for Digital Medicine MEVIS, Bremen, Germany; and ⁶Department of Cardiac, Thoracic, Transplantation and Vascular Surgery, Hannover Medical School, Hannover, Germany. Sponsor: S. Escher

Background and Purpose: Cardiotoxic side events represent one of the major concerns within pharmaceutical drug development and remain one of the leading causes for market withdrawal. The prevailing preclinical testing strategies rely on the use of cell lines (e.g. transfected HEK293, CHO) that express hERG artificially or iPSC-derived cardiomyocytes. However, these models lack the structural and functional complexity when compared to 3D mature myocardium and intrinsic cardiomyocyte action potentials. To circumvent these experimental limitations, we established a screening pipeline of diverse cardiac models, namely 2D hiPSC-derived cardiomyocytes, multicellular cardiac organoids and a microphysiological system (MPS) for 3D *ex vivo* living myocardial slice (LMS) cultivation. The complementary usage of these platforms enables a multifaceted screening for cardiotoxic events *in vitro* and *ex vivo*. **Methods:** First, dose-dependent effects of known cardiotoxic compounds were investigated using multi electrode array (MEA) measurements of hiPSC-derived cardiomyocytes in adherent cultivation. Second, multicellular cardiac organoids (consistent of cardiomyocytes, fibroblasts, endothelial cells and mesenchymal cells) were utilized for contractility assessment and global characterization of compound effects. Lastly, MPS was applied by combining left ventricular porcine LMS (300 μ m) on a heart-on-chip approach. Here, slices were paced using a dual (S1S2) pacing protocol to monitor action potential duration in functional cardiac tissue upon compound stimulation. **Results:** Initially, adherent hiPSC-cardiomyocytes were treated with known cardiotoxic compounds to perform dose-finding studies. Tolerable concentrations were further investigated in MEA analysis of cardiac beating behavior, revealing altered contractility for fenoterol and bosentan administration, respectively. Cisapride, a known hERG channel blocker, did not display clear impacts on contractile function within this model system. However, reevaluation of these compounds in the multicellular cardiac organoid platform displayed concentration-dependent impairment of contractility, especially with regard to beating frequency and relaxation time for all three mentioned compounds. Lastly, cisapride and the specific hERG channel blocker dofetilide were confirmed to prolong the action potential duration of 3D porcine myocardium within the MPS system in a dose dependent manner. Importantly, these observations were detectable within minutes after drug administration. **Conclusions:** The combination of well-established adherent hiPSC-cardiomyocytes with the complex multicellular organoid and 3D LMS heart-on-a-chip model, presents a complementary approach for the evaluation of drug cardiotoxicity. By integration of a diverse cellular environment and usage of mature porcine cardiac tissue, translatability of drug safety was enhanced complying the need for more reliable testing platforms to reduce animal studies. The herein described approach can be universally applied in pre-clinical drug development to screen for potential cardiac off-target effects.

F. Nakane, T. Nakabayashi, H. Saito, A. Maeda, T. Kubota, Y. Tate, K. Kitta, T. Kadota, and A. Fujiwara. CMIC Bioresearch Center, CMIC Pharma Science Co., Ltd., Hokuto-shi, Yamanashi, Japan.

Background and Purpose: Minoxidil, a potent arteriolar vasodilator, is known to induce reflex tachycardia and conduction abnormalities. However, noninvasive techniques for monitoring vascular toxicity in repeated-dose toxicity studies remain limited. This study aimed to evaluate an integrated approach combining vascular ultrasound and ambulatory electrocardiography under isoflurane anesthesia to characterize cardiovascular toxicity profile in beagle dogs following repeated oral administration of minoxidil for 15 days. **Methods:** Three male beagle dogs received minoxidil (3 mg/kg/day) via oral capsule for 15 consecutive days. Evaluations included clinical observations, body weight, hematology, blood chemistry, 24-hour ambulatory ECG (pre-dose and at multiple timepoints on Day 1 and 14), and vascular ultrasound of the abdominal aorta and renal arteries (Day -10, 2, and 15). Cardiac ultrasound was performed on Day -10, 2, and 15. Histopathological examination of the heart and kidneys was conducted at study termination. Data were compared to individual pre-dose baselines. **Results:** Minoxidil was generally well tolerated, with transient gastrointestinal signs and body weight gain. ECG revealed marked tachycardia shortly after dosing, with shortened PR and QT intervals shortening. Mild atrioventricular block (AV block) and premature ventricular contraction were intermittently observed. Vascular ultrasound showed increased aortic flow velocity and shear stress early in the dosing period, with partial normalization by Day 15. Renal blood flow and resistive indices increased, indicating altered regional hemodynamics. Cardiac ultrasound showed increased cardiac output and transient improvement in myocardial performance, with preserved ejection fraction. Mild valvular regurgitation and pericardial effusion were noted in individual animals. Histopathological examination revealed mild hemorrhage and degeneration in the right atrial wall and papillary muscles of the heart, consistent with previously reported minoxidil-induced cardiac lesions. In the kidneys, minimal tubular dilation and congestion were observed, without overt nephrotoxicity. Hematology revealed increased reticulocyte counts, while coagulation parameters remained stable. Blood chemistry showed decreased lipid levels and transient electrolyte changes; liver enzymes remained within expected variability. These findings are consistent with previous reports indicating that minoxidil-induced cardiac output elevation and atrial overstimulation may contribute to right atrial hemorrhagic lesions and papillary muscle necrosis in dogs. The observed hemodynamic shifts and arrhythmogenic potential align with established mechanisms of minoxidil cardiotoxicity. **Conclusions:** Oral administration of minoxidil for 15 days induced acute hyperdynamic circulation and reflex cardiac changes in beagle dogs. Vascular ultrasound sensitively detected systemic and regional hemodynamic shifts, while ambulatory ECG captured conduction changes and arrhythmias. Histopathological findings supported the functional observations, confirming mild cardiac lesions and minimal renal changes. This combined noninvasive platform offers translational value for detecting vascular toxicity in repeated-dose toxicity studies of vasodilators. Further studies with larger cohorts and controls are warranted to refine thresholds and mechanistic interpretation.

Background and Purpose: The myocardium enables powerful contractions essential for circulation and oxygen delivery. Cardiac contractility is a critical parameter for diagnosing cardiac conditions and guiding therapeutic development. Engineered Heart Tissues (EHTs) derived from human induced pluripotent stem cells (iPSCs) have become indispensable for cardiac research, yet most platforms remain low-throughput, costly, and lack reproducibility. **Methods:** We present a high-throughput 96-well EHT platform featuring a PDMS-free, bioinert consumable manufactured via high-resolution 3D printing, ensuring reproducible pharmacological testing and reduced cell requirements. **Results:** The EHTs displayed spontaneous contractions for approximately 30 days in culture. Over this period, they responded to electrical pacing and exhibited progressive functional maturation, evidenced by increased contraction amplitude and the development of a positive force-frequency relationship. Electrical pacing enhanced contractile strength while simultaneously reducing the spontaneous beating rate, suggesting adaptive remodeling of the tissue. Pharmacological profiling confirmed physiological responsiveness: Isoproterenol induced positive inotropic and chronotropic effects; Nifedipine caused negative inotropy; E4031 prolonged beating pulse width without affecting force; Cisapride slowed relaxation and extended contraction duration. **Conclusions:** These results validate the platform's ability to replicate clinically relevant drug effects and cardiac physiology *in vitro*, offering a scalable, cost-efficient solution for preclinical cardiotoxicity screening and drug discovery.

M. Gossmann¹, A. Monteiro da Rocha², S. R. Zhao³, J. C. Krzykwa⁴, C. A. Mitchell⁴, J. C. Wu³, and P. Linder¹. ¹innoVITro GmbH, Jülich, Germany; ²University of Michigan Medicine, Ann Arbor, MI; ³Stanford University, Stanford, CA; and ⁴HESI Global, Washington, DC. Sponsor: M. Gossmann, Safety Pharmacology Society

Background and Purpose: Natural products, including botanical dietary supplements, are widely used but have variable chemical compositions due to cultivation, extraction, and processing factors. Ensuring their safety is critical, yet no routine *in vitro* methods exist for testing these complex mixtures. Consequently, safety data are limited, and animal studies remain the primary source despite translatability and animal welfare concerns and high costs for routine use. An international effort led by the US Food and Drug Administration (FDA), National Institute of Environmental Health Sciences (NIEHS), and Health and Environmental Sciences Institute (HESI) is evaluating New Approach Methodologies (NAMs) for their applicability to botanical mixtures. **Methods:** For the safety endpoints, a battery of well-established cardiotoxicity assays for single chemicals was selected to evaluate their suitability for botanical mixtures. The assay parameters included contraction force, beat rate, duration, upstroke/downstroke slopes, and arrhythmic events, complemented by metabolic and calcium transient analyses. The assays were performed in human iPSC-derived cardiomyocytes (hiPSC-CMs) cultured in a 96-well microphysiological system mimicking native heart tissues and its vasculature, enabling physiologically relevant contractile measurements. **Results:** Botanicals with known cardiotoxicity were chemically profiled and tested, while milk thistle and Asian ginseng served as negative controls. Among 16 botanicals, aconite, oleander, goldenseal, and yohimbe showed significant effects on contraction force, beat rate, and duration, aligning with their arrhythmogenic potential. Ashwagandha, kratom, comfrey, and thunder god vine had minimal or no impact. Ephedra transiently increased the beat rate by ~40%, resolving within 24 hours. Decaffeinated green tea showed dose-dependent effects after 24 hours, possibly due to higher concentrations than typical consumption levels. The findings were substantiated by calcium transient and metabolic analyses. The botanicals with high cardiotoxic risk showed significant impact on the calcium handling of hiPSC-CMs both under acute and chronic administration, while chronic oxygen consumption analysis revealed impact of a broad range of botanicals, indicating the need for refinement of the concentration ranges and other assay parameters. **Conclusions:** The results from these assays based on hiPSC-CMs show that microphysiological systems are useful for assessing potential for cardiotoxicity of botanical mixtures.

P. Walker¹, C. Bruhn², S. Llewellyn¹, J. Eakins¹, B. Park¹, M. Fernandes dos Reis², and R. Rex². ¹Cypotex Discovery Ltd, Alderley Park, Cheshire, United Kingdom; and ²Evotec International GmbH, Göttingen, Germany. Sponsor: C. Struck

Background and Purpose: Cardiotoxicity remains a leading cause of drug attrition, highlighting the need for predictive non-clinical models. We developed a cardiac safety database of 163 reference compounds, including the CiPA panel, spanning diverse mechanisms of action. This work validates a multi-endpoint strategy incorporating New Approach Methodologies (NAMs) for early cardiotoxicity risk assessment. **Methods:** Human induced pluripotent stem cell-derived cardiomyocytes (hiPSC-CMs) as monocultures or as 3D microtissues in co-culture with fibroblasts and endothelial cells. Our integrated NAM-based approach combined high-content imaging (HCI), calcium transient kinetics (CaT), lactate dehydrogenase (LDH) release, and whole-genome transcriptomics (ScreenSeq™). A cardiotox framework of predictive and mechanistic gene signatures was constructed. Differential gene expression, pathway enrichment, and benchmark dose modeling (BMD Express 2) of gene expression and cardiotox signature regulation were performed. Cardiotoxicity prediction metrics were derived from minimal effective concentrations (MEC) relative to clinical Cmax. AI/ML models were applied to transcriptomic profiles for enhanced prediction. **Results:** Cardiotoxants elicited responses at lower concentrations than non-cardiotoxants. Combined HCI, CaT, and transcriptomics provided the strongest predictive performance in 2D hiPSC-CM monocultures, with sensitivity, specificity, and accuracy of 83.5%, 84.1%, and 83.7%, respectively; AI/ML models improved these to 86.7%, 84.1%, and 85.9%. Dose-response analysis of cardiotoxicity signatures confirmed lower points of departure for cardiotoxants. Clustering and transcriptional signatures revealed mechanistic insights, distinguishing target-related and off-target effects across key cardiotoxicity characteristics. 3D microtissues extended the spectrum of detectable cardiotox characteristics by fibroblast- and endothelial-specific responses. **Conclusions:** This NAM-based, multi-endpoint approach enables robust detection and prediction of diverse cardiotoxicity mechanisms, offering mechanistic insight and early de-risking of new chemical entities in drug discovery.

PS 4244 Developmental exposure to Trifluoroacetic Acid cause vascular toxicity via lactate dehydrogenase-dependent glycolytic disturbance

Y. Wei, S. Huang, Y. Hao, P. Yang, Z. Zhang, and J. Chen. Sun Yat-sen University, Guangzhou, China.

Background and Purpose: Per- and polyfluoroalkyl substances (PFAS) are globally persistent contaminants, yet ultrashort-chain PFAS have been inadequately investigated in current research. Trifluoroacetic acid (TFA), a two-carbon (C2) PFAS, is a terminal degradation product frequently detected in the environmental matrices. This study sought to determine the vascular effects and the underlying mechanism by developmental exposure to environmentally relevant concentrations of TFA. **Methods:** Zebrafish larvae [Tg(fli1a:EGFP)] were exposed to TFA (800 ng/L-2 mg/L) from 2hpf to 72hpf. High-resolution images of the vasculature were obtained using a high-content imaging platform for morphological phenomics. Human Umbilical Vein Endothelial Cells (HUVEC) were treated with TFA and the viability, tube formation, migration, and F-actin assays were measured at 72h. Larvae samples were collected for the RNA-seq and analyze the transcriptome. Glycolytic function was quantified by lactate, pyruvate, ATP production. Lactate dehydrogenase (LDH) inhibition was validated by Lineweaver-Burk kinetics and molecular docking. **Results:** TFA exposure induced a dose-dependent developmental toxicity in zebrafish, increasing malformation rates and reducing body length, while hatching and survival remained largely unaffected. The morphological phenomics exhibited a pronounced impairment of the subintestinal vein plexus (SIVP) as compared to the alteration of intersegmental vessels (ISV), common cardinal vein (CCV), and posterior cardinal vein (PCV). *In vitro* study showed a reduction in cell viability, tube formation capacity, migration, and F-actin disruption. RNA-seq analysis identified the gene expression pattern related to the suppressed glycolysis and the impaired angiogenesis. Consistent with transcriptomic signatures, TFA suppressed glycolytic metabolism, decreasing lactate and ATP while elevating pyruvate levels in a dose-response fashion. Enzyme kinetics demonstrated a competitive inhibition pattern on LDH. Molecular docking confirmed interactions of TFA within the LDH catalytic site. **Conclusions:** Our findings revealed that developmental exposure to environmentally relevant concentrations of TFA impairs vascular growth by disturbing LDH-dependent glycolytic process. This study deepens current understanding of the ultrashort-chain PFAS' toxicity and help establishes a mechanistic framework for identifying sensitive biomarkers of early exposure.

PS 4245 Chemical, Drug, and Stress induced Cardiovascular Dysfunctions: A Comprehensive Bioinformatics and Bench Studies in Gulf War Illness

N. Shree, L. R. Gladwell, K. A. Kunz, M. Kodali, A. K. Shetty, and M. Choudhury. Texas A&M University, College Station, TX.

Background and Purpose: Cardiovascular diseases (CVD) are an emerging problem amongst the different health issues underlying Gulf War Illness (GWI), a multi-symptom illness affecting the Gulf War veterans. Despite emerging evidence suggesting significant impacts of GWI on the cardiovascular systems, research in these areas remain limited. While the exact causes of these symptoms are unknown, they are thought to be a consequence of exposures to multiple chemicals, drug the veterans consumed, and the stress they endured during the war. In this project, we investigated the cardiovascular connection linked to GWI using computational analysis in clinical cohort of healthy and GWI along with well-established GWI rat model *in vivo* and cardiomyoblast cell *in vitro*. **Methods:** We carried out a multi-level computational analysis using transcriptome data from GWI and healthy human cohort's blood samples at baseline (T0) and maximal exertion (T1) timepoints. Core analysis was performed using Ingenuity Pathway Analysis (IPA) to understand the disease end point due to chemical exposure in Gulf War Veterans. To investigate the effect of GWI chemicals *in vivo*, eight-week-old male Sprague Dawley rats were dosed with an acetylcholinesterase inhibitor pyridostigmine bromide (PB), orally daily; N,N-diethyl-m-toluamide (DEET) and Permethrin (PER) dermally, and 15-min restraint stress for four weeks as per our established GWI model. Naïve control rats were maintained in parallel to GWI rats, which were not subjected to chemical or stress exposure. Serum was collected at 7 months and 13 months post-exposure from both naïve as well as GWI groups. To examine the effect of GWI serum on cardiac health, H9C2 (rat cardiomyoblast cell line) was treated with naïve and GWI serum for 48h. Additionally, to confirm the effect of GWI chemicals on cardiotoxicity, H9C2 was treated with PB, DEET and PER individually or in combination at low, medium, and high concentrations. We then investigated a series of inflammation markers, apoptosis markers, and oxidative stress markers in both serum as well as chemical treated cells. **Results:** In GWI veterans, gene ontology analyses showed dysregulation of several processes involving cardiac muscle cell repolarization, action potential, as well as anatomy and physiology compared to healthy controls. For example, ZDHHC12, involved in regulating cardiac function, stability, and responses to injury; was differentially regulated in male and female under stress condition (T0 vs T1). In addition, tox function analysis using IPA revealed the association of molecular alterations in GWI patients to cardiotoxicity such as, cardiac death/ necrosis, cardiac enlargement, and cardiac dilation compared to the healthy ones. Furthermore, IPA also indicated that GWI chemicals can induce apoptosis and mitochondrial dysfunction via various intermediate pro-inflammatory molecules. Serum treatment on H9C2

showed increased Namp1 expression and interleukin-6 (IL-6) in GWI-serum treated group compared to the naïve group indicating inflammatory milieu due to GWI serum components. In addition, we observed a significant increase in apoptosis markers, Caspase-3 and Caspase-8 in both GWI-serum treated timepoints. Furthermore, we observed a significant increase in Sod1 and Gpx which are the key regulators of oxidative stress and known to be induced by inflammation and apoptosis which can further induce mitochondrial dysfunction which is the key contributor to the cardiometabolic disease. Chemical treated cardiomyoblast showed a decreasing trend in mitochondrial marker, Nrf1 across all the treatment groups and an increasing trend of Caspase-3 under all the treatment groups, which is a crucial protein that executes the apoptosis pathway. **Conclusions:** In a nutshell, we showed sex-specific differences in cardiovascular dysfunction of GWI veterans. Our *in vitro* and *in vivo* analysis confirmed dysregulation of functional end points which are the hallmark of CVD. Future work will investigate in-depth *in vivo* characterization at both whole-body and tissue-specific levels in male and female GWI rat model.

PS 4246 Sensitivity of Latin Square and Ascending Dose Design for Cardiovascular Safety Pharmacology Studies in Telemetry Implanted dogs

S. An. Wuxi Apptec (Suzhou) Co., Ltd., Jiangsu, China. Sponsor: R. Zhang

Background and Purpose: The latest ICH E14/S7B Q&As permit the inclusion of high-quality nonclinical QTc data in integrated risk assessments to support waivers for Thorough QT (TQT) studies, provided that rigorous validation criteria are met. Given that Latin Square and ascending dose designs are widely utilized in cardiovascular safety pharmacology studies, we conducted a systematic statistical power analysis of the standard cardiovascular safety study models routinely employed at our facility. This analysis aimed to ensure the generation of high-quality preclinical data and to demonstrate that these models are capable of producing data that meet regulatory requirements. **Methods:** We retrospectively analyzed telemetry data from Latin Square cardiovascular safety pharmacology studies in beagle dogs (n=308) to evaluate the statistical power of these experimental models. The studies typically employed a 4x4 Latin Square crossover design or an ascending dose design with N=3 or 4 dogs. Data were collected over approximately 24 hours, and results from the pre-dose and each subsequent 1-hour interval were analyzed using ANOVA and mixed models, respectively. Minimum detectable differences (MDDs) with 80% statistical power were calculated for standard parameters, such as heart rate (HR) and ECG intervals. **Results:** For the Latin Square crossover design (N=4 or 8), the MDDs were: QRS interval (3.3 ms in males, 3.1 ms in females), PR interval (7.6 ms in males, 7.7 ms in females), and QTc interval (10.1 ms in males, 10.3 ms in females). For the ascending dose design (N=3 or 6), the MDDs were: QRS interval (4.8 ms in males, 3.7 ms in females), PR interval (7.3 ms in males, 7.4 ms in females), and QTc interval (10.5 ms in males, 11.5 ms in females). In addition, we report reference intervals for the root mean square error (RMSE) and its 2.5th and 97.5th percentiles as measures of variability within the studies. **Conclusions:** These findings demonstrate that the Latin Square cardiovascular safety pharmacology model in beagle dogs provides high statistical power and is capable of detecting subtle changes in electrocardiogram parameters, thereby offering a robust experimental foundation for cardiovascular safety evaluation of drug candidates. Nonrodent cardiovascular models are sensitive tools for early detection of cardiovascular risk. Furthermore, the results confirm the assay sensitivity of functional endpoints and support the use of these data within the framework of the ICH E14/S7B Q&As.

PS 4247 Sex Matters: Differences in Cardiac Phenotype and Responses to Inhaled Nano-TiO₂

S. Adams, X. Wang, D. Adler, E. Yurkow, and P. A. Stapleton. Rutgers University, Piscataway, NJ.

Background and Purpose: Epidemiological studies identify particulate matter (PM) exposure as a risk factor for adverse cardiovascular events. There is growing evidence demonstrating sex-dependent effects in cardiac pathophysiological responses to airborne toxicants in humans. Despite this, few studies have assessed sex-specific mechanical and structural outcomes associated with PM inhalation. Therefore, the purpose of this study was to evaluate differences in cardiac responses to inhaled nano-TiO₂ between male and female rats. **Methods:** Age matched male (n=6) and female (n=6) Sprague-Dawley rats were exposed to nano titanium dioxide (nano-TiO₂) aerosols, a surrogate for fine and ultrafine PM, for an average of 9.2 ± 0.04 mg/m³ per day. Animals were exposed in a whole body inhalation chamber 4 hours a day, 5 days a weeks for 2 weeks. Naïve, unexposed rats (n=6/sex) served as controls. Twenty-four hours post final exposure, cardiac ultrasound was conducted, followed by mean arterial pressure (MAP) measurement, sacrifice, and tissue collection. Histopathological and morphometric analyses were conducted on cardiac samples collected at time of euthanasia. **Results:** Data analysis revealed significant exposure/sex interactions, indicating that sex modifies cardiac responses to inhaled nano-TiO₂. Notably, LV mass and volume, key markers of adverse remodeling, exhibited sex-dependent outcomes. Exposure in females resulted in an 11% elevation in LV mass, while males exhibited a 15% loss. Similarly, LV volume was increased by 3% in females and reduced by 11% in males after nano-TiO₂ inhalation. Stroke volume also

presented sexually dimorphic responses, with a 7% increase in females and an 11% decrease in males after exposure. However, nano-TiO₂ increased MAP regardless of sex. Histopathological and morphometric outcomes are pending. **Conclusions:** These findings demonstrate that nano-TiO₂ disrupts cardiac anatomy and function differentially in males and females, which may contribute to sex-dependent pathophysiological responses to PM exposure. Future work will investigate mechanisms underlying these sexually dimorphic responses. Supported by: R01-ES-031285, P30-ES-005022, T32-ES-007148, Grover Foundation, and BMS fellowship

PS 4248 Organ-on-a-chip for cardio- and neurotoxicity studies on spheroids

C. Hoebart, M. Lux, S. Beyl, and S. Hering. Chanpharm, Vienna, Austria.

Background and Purpose: Human cardiac and neuronal stem cell-derived spheroids or organoids are emerging models for drug discovery and drug safety studies. Investigations of their electrical properties are frequently carried out by means of multielectrode arrays (MEAs). The round shape of these 3D models restricts, however, electrode contacts with planar MEAs. Contractions of cardiac 3D models and movement artefacts during the application of test solutions can interfere with the measurements. Here we propose an organ-on-a-chip that attaches free floating spherical cell models such as cardiospheres and neurospheres to conventional planar MEAs. The integrated microfluidics device stabilizes the surface contacts with the spherical cell models, reduces motion artifacts and permits complete solution exchange in pharmacological studies. **Methods:** Cardio- and neurospheres were generated according to the manufacturers instructions. Using the organ-on-a-chip the spheroids could be recorded on planar MEA electrodes. By fixing the spheroids on the electrodes motion artefacts could be reduced throughout the experiment, including fluid exchange for compound application. In addition, this system enables simultaneous recordings of field potentials with MEA and action potentials or calcium signals using fluorescent probes. As proof-of-concept cardiac reference compounds E4031 and dofetilide were cumulatively applied in increasing concentrations every 5 minutes. For neurospheres epilepsy-like bursting was induced using 4-aminopyridine and blocked by ML213. **Results:** The chip was successfully used for field potential measurements and simultaneous imaging using fluorescent probes on small cardio- and neurospheres (diameter 300 to 500 µm). We observed concentration-dependent prolongation of action- and field potentials of cardiospheres by the potassium channel (Kv1.11) inhibitors E4031 and dofetilide. In neurospheres application of the potassium channel (Kv7.2/7.3) activator ML213 reduced spiking and bursting. **Conclusions:** In summary, we present a novel organ-on-a-chip with microfluidics that enables field potential measurements on cardio- and neurospheres using conventional planar MEAs and simultaneous imaging studies. Proof-of-concept studies demonstrate that this technology is suitable for drug testing and toxicity studies.

PS 4249 Investigation of adverse effects of long-term exposure to e-cigarette compounds in human cardiomyocytes

C. E. Brown¹, X. Li¹, Y. Shen², and Q. Liu¹. ¹Clemson University, Clemson, SC; and ²Henan Normal University, Xinxiang, China.

Background and Purpose: Electronic cigarettes (e-cigarettes) have garnered popularity as a “healthy” alternative to traditional cigarette smoking, though evidence suggests that e-cigarettes pose their own unique risks to the cardiovascular system. As one of the major compounds in e-cigarettes, nicotine has been shown to induce oxidative stress, impair mitochondria, and promote apoptosis, all of which contribute to the pathology of cardiovascular diseases. However, there remains a knowledge gap in the understanding of e-cigarette toxicity in cardiomyocytes (CMs) due to methodological shortcomings in the existing literature that do not reflect real-world e-cigarette use. Notable deficiencies include the use of supraphysiological chemical concentrations, unrealistic and unrepresentative chemical compositions, short-term exposure regimes, and non-human models. This study aimed to address these shortcomings by investigating the individual and synergistic cardiotoxic effects of mainstream e-cigarette chemicals on human stem cell-derived CMs under clinically relevant exposure conditions. Human embryonic (hESCs) and induced pluripotent stem cells (hiPSCs) provide a robust platform for disease modeling and chemical screening, and they can be considered as a new approach methodology (NAM) for predictive toxicology. **Methods:** The hESC-derived CMs (hESC-CMs) were exposed to physiologically relevant combinations and concentrations of the most prevalent chemical constituents found in modern e-cigarettes, including freebase nicotine (L-nicotine), salt nicotine (nicotine benzoate), and propylene glycol (PG). After 2 weeks of exposure, mitochondrial and cardiac functions were evaluated, and genome-wide transcriptome was analyzed in the CMs. **Results:** We found that nicotine-derivative or PG treatment alone did not induce obvious adverse effects, however, when CMs were exposed to nicotine and PG in combination, they exhibited more adverse effects on both mitochondrial and cardiac functions, including lower ATP production, decreased oxidative phosphorylation (OXPHOS) and mitochondrial network branching, altered contractility, and sarcomere disorganization. In addition, salt nicotine exhibited more cardiotoxic effects than freebase nicotine, and the mixture of nicotine salt and PG induced the greatest dysfunction of all treatment groups. **Conclusions:** Modern-era, pod-based e-cigarettes formulated with nicotine salts and PG induce greater cellular

dysfunction in CMs than tank-based electronic smoking devices formulated with freebase nicotine and PG. Ultimately, this work addresses a critical gap in the literature by employing clinically relevant exposure conditions and human cell models, providing evidence that the combined effects of modern e-cigarette constituents pose a cardiotoxic risk.

PS 4250 Effects of Titanium Dioxide Nanoparticles on Human Red Blood Integrity and Function: Implications for Anemia and Occupational Health

X. Lin, M. T. Kleinman, and A. De Vizcaya Ruiz. University of California, Irvine, Irvine, CA.

Background and Purpose: Over the past decade, concern has grown about occupational inhalation of titanium dioxide nanoparticles (TiO₂ NPs) and their potential systemic health effects. While research has focused on pulmonary and inflammatory responses, red blood cells (RBCs) have received little attention despite being the first and most abundant cell type that TiO₂ NPs encounter in circulation. Workers in industries such as pigment manufacturing, coatings, and additive production may experience repeated low-level exposures to TiO₂ NPs, underscoring the need to understand systemic targets beyond the lung. RBCs are essential for oxygen transport and maintaining cardiovascular and metabolic homeostasis, and their dysfunction has been linked to anemia, thrombosis, and cardiovascular disease. This study investigates the effects of TiO₂ NP exposure on RBC integrity, premature cell death (eryptosis), and hemoglobin function. We hypothesize that occupationally relevant TiO₂ NP compromise RBC membrane stability and oxygen-carrying capacity, leading to functional impairment and increased vulnerability to secondary stressors. **Methods:** Deidentified human RBCs from healthy donors were exposed *in vitro* to rutile TiO₂ NPs (15-20 nm; MSE Supplies LLC; 5-200 µg/mL) for up to 24 h. Eryptosis, a programmed form of RBC death characterized by cell shrinkage, membrane blebbing and phosphatidylserine (PS) externalization was assessed by Annexin V-FITC staining and RBC size and membrane complexity (blebbing) quantified by forward and side scatter (FSC/SSC) both on a BD Fortessa flow cytometer. Ionomycin (1 µM) served as a positive control, and donor-matched non-exposed RBCs provided baseline signals. Hemolysis was quantified by free hemoglobin absorbance at 415 nm on a Tecan microplate reader and normalized to 0.5% Triton X-100 (100% lysis). Osmotic fragility was tested by incubating post-exposure RBCs in graded NaCl solutions (0.0-0.9%) for 30 min, followed by hemoglobin release measurement. All endpoints were normalized to paired non-exposed RBCs to account for interindividual variability. Flow cytometry data were analyzed using FlowJo, and statistical and dose-response analyses using GraphPad Prism. **Results:** Exposure to TiO₂ NPs induced dose-dependent eryptosis (scored by PS Annexin V-FITC staining) increase in RBCs relative to donor-matched controls, 6.3%, 15.7%, 20.6%, 44.4% and 68.3% at 5, 10, 20, 50 and 200 µg/mL respectively (mean of five donors). Dose-response modeling (4-parameter logistic regression) yielded an inhibitory concentration 50 (IC50) of 34.7 µg/mL (95% CI 19.1-526.9) with a Hill slope of 1.65 (0.61-3.85). Side scatter, reflecting membrane blebbing, increased by 14.9%, 29.2%, 67.3%, 143.9% and 354.4% at the same dose range of 5-200 µg/mL. Linear regression suggested a strong correlation between TiO₂ dose and SSC increase (Y = 1.78X+15.33, R² = 0.90, slope P < 0.0001). Low doses 5-50 µg/mL caused minor cell shrinkage (-0.57% to -2.74%), whereas 200 µg/mL produced slight size gain (+2.78%), suggesting nanoparticle attachment or osmotic effects. TiO₂ exposure induced concentration-dependent hemolysis, 5.2%, 5.5%, 9.0%, 12.5% and 16.6% at 5-200 µg/mL, respectively, confirmed by medium and particle controls. Osmotic fragility assays showed 35.1-60.2% greater hemoglobin release in RBCs exposed to 200 µg/mL TiO₂, indicating compromised membrane integrity after 24 h. **Conclusions:** Our results showed 24 h exposure to TiO₂ NP induces dose-dependent eryptosis, hemolysis, and increased osmotic fragility in human RBCs. Such RBC dysfunction may contribute to systemic effects including anemia, thrombosis and inflammation, and increase the physiological burden on RBC clearance organs (spleen, liver and bone marrow). These findings highlight the need to support further studies to establish occupational exposure thresholds (e.g. LOAEL) to better inform health risk assessment for TiO₂ nanoparticles.

PS 4251 Divergent functional responses in 2D and 3D human iPSC-derived cardiomyocytes to doxorubicin-induced cardiotoxicity and prevention

M. C. Daley^{1,2}, R. Basnet², D. Heikal², A. Szarnicki², U. Mende³, B. Choi³, and K. L. Coulombe². ¹Department of Chemical and Biomolecular Engineering, Lafayette College, Easton, PA; ²Institute for Biology, Engineering and Medicine, Brown University, Providence, RI; and ³Cardiovascular Research Center, Rhode Island Hospital and Warren Alpert Medical School of Brown University, Providence, RI.

Background and Purpose: Despite major improvements in anticancer treatment, chemotherapy-induced cardiotoxicity continues to present an ongoing challenge. Anthracyclines are a commonly prescribed class of anti-cancer drugs with a dose-dependent risk of heart failure after treatment. As a result, there is substantial interest in developing strategies for mitigating anthracycline-induced cardiotoxicity, especially through cardioprotective cotreatments. Human induced pluripotent stem cell-derived cardiomyocytes (hiPSC-CMs) can serve as human-specific preclinical

models of cardiotoxicity, but the effects of culture parameters on toxicity metrics are still not fully understood. In this study, we investigated the interplay of culture format (2D vs. 3D) and media composition (standard vs. maturation medium) in ventricular hiPSC-CM-based models of chronic doxorubicin (DOX) toxicity and cardioprotection from the iron chelator and topoisomerase II β inhibitor dexrazoxane (DEX). **Methods:** Ventricular hiPSC-CMs were generated using established protocols before being seeded into 2D monolayers or formed into 3D microtissues with 5% human cardiac fibroblasts. HiPSC-CMs were treated with DOX alone, DOX with DEX, or vehicle control (DMSO). Concentration and exposure time are noted with corresponding results. DOX toxicity was assessed by measuring concentration-dependent changes in cell viability via the metabolic MTT assay, functional contractile changes via video tracking, electrophysiological changes via high-speed optical mapping, and metabolic shifts via Seahorse Assay. The influence of medium-based maturation on both toxicity and cardioprotection was assessed by culturing hiPSC-CMs in a low-glucose, high-fatty acid, high-calcium maturation medium for one week prior to DOX and DEX treatment and downstream analysis. **Results:** As expected, 2D hiPSC-CMs showed multi-functional changes reflecting concentration- and time-dependent DOX toxicity. Loss of relative cell viability was strongly associated with treatment time (1 μ M DOX: 45.0 $\pm$ 4.7% after 72 hours vs. 86.0 $\pm$ 4.8% after 24 hours, p < 0.05). After treatment with 1 μ M DOX for 72 hours, hiPSC-CMs also showed functional declines in basal respiration compared to vehicle controls (2.4 $\pm$ 0.4 vs. 62.4 $\pm$ 5.7 pmol/min/10,000 cells, p < 0.05). Similarly, in 3D microtissues, there was substantial shortening in action potential duration (332.8 $\pm$ 17.8 vs. 498.8 $\pm$ 30.4 ms, p < 0.05) and reduction in contractility (0.6 $\pm$ 0.5 μ m vs. 4.5 $\pm$ 2.3 μ m, p < 0.05) compared to vehicle controls. Cotreatment with DEX was used to examine the ability of hiPSC-CM models to detect cardioprotection *in vitro* and the effects of culture format. In 2D, cotreatment with up to 30 μ M DEX for 72 hours did not affect viability of hiPSC-CMs treated with 1 μ M DOX (control: 62.3 $\pm$ 19.0% vs. 30 μ M DEX: 62.4 $\pm$ 12.9%). Similarly, in 3D microtissues, treatment with 10 μ M DEX and 1 μ M DOX did not significantly alter DEAD stain intensity (0.092 $\pm$ 0.022 AU) compared 1 μ M DOX alone (0.110 $\pm$ 0.33 AU), suggesting no cardioprotection in standard culture media. With an additional week in maturation medium prior to 1 μ M DOX treatment, 2D hiPSC-CMs did not show significant differences in viability. In contrast, maturation media-treated 3D cardiac microtissues showed 2.1-fold higher DEAD stain intensities (p < 0.05) in response to 1 μ M DOX compared to standard medium. However, we did not observe a significant difference in matured tissues cotreated with DEX and DOX compared to DOX alone, suggesting minimal or no rescue of viability by DEX even with culture in maturation media. **Conclusions:** Together, these data highlight the critical interplay of culture conditions on DOX toxicity in hiPSC-CM with a combination of 3D culture and maturation media driving an increase in observed DOX toxicity, but no DEX cardioprotection. Moreover, they suggest a broader role for 3D systems to represent adult cardiac function as mature culture platforms, especially with supplemental medium-based maturation.

PS 4252 Heart to Heart. Maternal and fetal cardiovascular consequences of gestational nano-titanium dioxide exposure

R. P. Hunter, T. Gluth, S. Keeley, K. Seman, and E. Bowdridge. West Virginia University, Morgantown, WV.

Background and Purpose: Nano-titanium dioxide (nano-TiO₂) is an established vascular toxicant and is also known to impair fetal growth and development when exposed *in-utero*. Deficits in placental and fetal growth and development due to exposure occur in a sex-dependent manner, however these responses remain poorly characterized. Utilizing longitudinal echocardiography, both maternal and fetal cardiac function was tracked through a gestational model of nano-TiO₂ inhalation. **Methods:** Timed-pregnant dams received six nonconsecutive days of whole-body aerosol inhalation after gestational day (GD) 10 at a targeted concentration of 12mg/m³ nano-TiO₂ or sham air (25 mL/m) as controls. Particulate aerosolization was accomplished with an acoustic generator, with concentrations being held constant with the aid of a dataRAM™ aerosol monitor. Immediately following exposure on GD 13,15,17, and 20, animals were assessed for cardiovascular function via ultrasound assessment on a Vevo F2 preclinical ultrasound system using a 29MHz transducer. Motion analysis was used for maternal and fetal cardiac function, with brightness mode acquisitions supplementing maternal cardiac function and speckle-tracking analysis for assessment of cardiac strain. Uterine artery flow data was also assessed using doppler assessment. Additionally, the placental vascular network was assessed via placental explant perfusion with silicone vascular contrast perfusion and imaged via micro-computed tomography. Placentae of the proximal uterine horn were removed immediately following euthanasia of the dam, and the umbilical artery and vein surgically separated. The umbilical artery was cannulated and perfused with heparinized PBS (~500 μ l) immediately followed by Vascupaint® contrast media (~800 μ l) until perfusate exited the umbilical vein indicating complete perfusion throughout the placental vasculature. Male and female placentae (n = 3-4 per group) from exposed and control dams were analyzed with Imaris imaging software to assess total area, vascular length and diameter, as well as branch hierarchy within the placental vasculature. **Results:** Exposed dams presented with significantly decreased cardiac output (62.05 $\pm$ 3.79 mL/min vs. 75.36 $\pm$ 6.37 mL/min controls) beginning at GD 17 and further declining (49.64 $\pm$ 4.50 mL/min vs. 70.92 $\pm$ 2.52 mL/min) near term at GD 20. Fetal cardiac output in exposed animals (3.69 $\pm$ 0.42 mL/min) was also decreased at GD 20 when compared to sham air controls (4.73 $\pm$ 0.32 mL/min). Uterine artery resistance index was significantly decreased in exposed (0.54 $\pm$ 0.02 RI) versus control (0.67 $\pm$ 0.10 RI) dams at GD 20. **Conclusions:** The ability to monitor cardiovascular

adaptations of pregnancy during maternal toxicological stress, through the placenta and into the developing fetus provides a powerful tool that may be advantageous for limiting inter-subject variability within cardiovascular health during gestation and beyond.

PS 4253 β -Adrenergic Inhibition Prevents Gestational E-cig Exposure-Induced Sympathetic Dominance and Ventricular Arrhythmias throughout Pregnancy and Postpartum

B. R. Reynolds^{1,2}, L. Watson³, H. E. Collins², and A. P. Carll^{1,2}. ¹Department of Physiology, University of Louisville School of Medicine, Louisville, KY; ²Center for Cardiometabolic Science, Christina Lee Brown Envirome Institute, University of Louisville School of Medicine, Louisville, KY; and ³Department of Biology, Vassar University, Poughkeepsie, NY.

Background and Purpose: Perceptions that e-cigarettes (e-cigs) are safer than traditional cigarettes may contribute to the popularity of vaping during pregnancy among smokers and ex-smokers. Pregnancy is inherently associated with increased risk for arrhythmias, and the prevalence of pregnancy-associated arrhythmias has recently surged. We previously reported that e-cig exposure accentuates pregnancy-induced sympathetic dominance while evoking ventricular premature beats (VPBs, a predominant arrhythmia in pregnancy), persisting weeks after exposure cessation and labor. Sympathetic activation can evoke VPBs; however, the role of sympathetic dominance in the persistent arrhythmogenesis induced by gestational e-cig exposures remains unknown. Thus, we assessed the role of β -adrenoceptor activation in the arrhythmogenicity of gestational e-cig exposure by administering the non-selective β -adrenergic blocker, propranolol. **Methods:** Pregnant 11-week-old C57BL/6J mice received normal drinking water (n =4-7/group) or propranolol (0.5 g/L; n =4/group), and were exposed to e-cig aerosols or air daily throughout gestation, with exposures ceasing upon parturition. Electrocardiogram (ECG)-derived heart rate (HR) and VPBs were compared between normal water and propranolol groups matched by inhalation exposure. Home-cage ECGs were collected for 21 hours during labor and for 48 hours at 3 weeks postpartum. Propranolol was gradually withdrawn by halving concentrations weekly over the first two weeks postpartum. **Results:** E-cig exposure alone increased maternal HR on gestational day (GD) 1-15 (p <0.05 vs. Air) and depressed maternal RMSSD on GD 1-5 (p <0.05 vs. Air), suggesting sympathetic dominance. Concurrently, e-cig alone also increased the incidence rate of VPBs (p <0.05 vs. Air). Gestational β -adrenergic inhibition opposed these effects, decreasing HR on GD 1-15, increasing SDNN and RMSSD on GD 1-18, and, importantly, abolishing the arrhythmogenic effects of e-cigs (all p <0.05 vs. e-cig alone). During 21-h overnight monitoring of the parturition phase, gestational exposure to e-cig alone increased HR and depressed SDNN and RMSSD for 1 h each (p <0.05 vs. Air) while also increasing VPB incidence rate (p <0.05 vs. Air). In contrast, β -adrenergic inhibition in e-cig-exposed dams opposed these effects over the 21-h parturition phase, reducing HR for 4 h, increasing SDNN for 6 h, increasing RMSSD for 9 h, and abolishing VPBs relative to e-cig alone (all p <0.05). Three weeks after parturition and cessation of e-cig exposures (one week after discontinuing propranolol), there were no group differences in HR or HRV. However, gestational e-cig exposure alone increased VPBs (p <0.05 vs. Air), and prior β -adrenergic inhibition continued to abolish this effect (p <0.05 vs. e-cig alone) despite the discontinuation of propranolol. **Conclusions:** Gestational exposure to e-cigarette aerosols induces maternal sympathetic dominance and ventricular arrhythmias that persist well after parturition and exposures. β -adrenergic inhibition during gestation abolishes the immediate and persistent arrhythmogenic effects of gestational e-cigarette exposures. Thus, vaping during pregnancy may persistently induce arrhythmias and increase maternal peripartum cardiac risk through gestational sympathetic dominance.

PS 4254 Chronic E-Cigarette Exposure Induces Pulmonary Artery Remodeling in Apoe^{-/-} mice

A. Slepchenkova, J. M. Oakes, and C. Bellini. Northeastern University, Boston, MA.

Background and Purpose: Electronic cigarettes (e-cigarettes) have gained popularity during the recent decade and are often considered to be a safer alternative compared to traditional combustible cigarettes. However, the chronic impact of e-cigarette vapor on cardiopulmonary structure and function remains poorly understood. The pulmonary arteries are a critical site of vascular regulation, and their structural remodeling is known to elevate pulmonary pressures, impair hemodynamics, and contribute to pulmonary hypertension. In pulmonary arterial hypertension (PAH), arterial stiffening worsens vascular remodeling and elevates pressure within the pulmonary circulation by placing strain on the right ventricle, which may lead to heart failure (PMID: 30073166). Increased arterial collagen content, particularly Type I collagen, has been shown to contribute to pulmonary artery stiffening (PMID: 21538012). This study aims to investigate the long-term effects of e-cigarette use on pulmonary artery remodeling, fibrosis, and changes in extracellular matrix (ECM) composition. **Methods:** Adult female Apoe^{-/-} mice (8 $\pm$ 1 weeks of age) were randomly assigned to either the e-cigarette aerosol or the air control exposure groups. The mice were exposed for 95 minutes/day, 5 days/week, over 24 weeks through a nose-only aerosol delivery (SCIREQ). Aerosol originated from virginia tobacco flavored JUUL pods containing 3% (35 mg/mL) nicotine and delivered at a rate of 2 puffs/

min, a puff volume of 55 mL/puff (DOI: 10.1093/ntr/ntaf084). Histology samples were collected at the 8 week, 16 week, and 24 week time points. Lung sections were stained using Picro-Sirius Red (PSR) and MOVAT Pentachrome, and imaged under polarized light or brightfield microscopy, respectively. Polarized light images were segmented and analyzed using ImageJ to determine the percentage area of mature (Type I, orange-red birefringence) and immature (Type III, green-yellow birefringence) collagen fibers in the adventitia layer of the pulmonary artery. MOVAT Pentachrome stained samples were used to quantify elastin and fibrin content, as well as artery thickness. Immunofluorescent and chromogenic histology staining (for CD31, vWF, VEGFR3, Fibrinogen, and CCL21 markers) was utilized to investigate fibrosis of pulmonary arteries and infiltration of immune cells into the arterial tissue. **Results:** Polarized light imaging revealed a time-dependent shift toward collagen maturation in the e-cigarette exposed pulmonary arteries exhibited by a gradual increase of Type I collagen relative to Type III collagen in the adventitia (8 week $p = 0.4697$; 12 week $p = 0.0923$; 24 week $p = 0.0002$). Elevated levels of Type I collagen ($p = 0.0235$) and decreased levels of Type III collagen ($p = 0.0490$) were observed in the e-cigarette arteries at the 24 week time point. Collagen maturation relative to controls indicates early fibrotic remodeling of the pulmonary artery wall. Preliminary analysis of MOVAT images showed increased arterial thickness in the e-cigarette exposed samples. Immunostaining analyses characterize the molecular basis of these structural changes, including changes in endothelial and lymphatic markers mentioned above. **Conclusions:** Arterial stiffening, fibrosis, and inflammation in response to chronic e-cigarette exposure suggest potential impairment of pulmonary artery function. This study highlights a correlation between chronic e-cigarette use and arterial remodeling that may predispose users to PAH and other heart diseases. Future research must explore the long-lasting effects of e-cigarettes on the structural remodeling of the pulmonary artery.

PS 4255 Immune Dysregulation in E-Cigarette Users: Contribution of Volatile Organic Compounds and Nicotine

M. V. Malovichko, M. Etemadi, T. Malik, T. V. Krivokhizhina, M. Kulkarni, R. J. Keith, P. K. Lorkiewicz, A. Bhatnagar, D. Riggs, and S. Srivastava. University of Louisville, Louisville, KY.

Background and Purpose: Electronic cigarette (e-cig) use is increasing rapidly, particularly among adolescents and young adults, yet its systemic immunological consequences remain poorly understood. We employed high-dimensional mass cytometry for deep phenotyping of peripheral blood and the functional profiling of peripheral blood mononuclear cells and examined their association with the urinary metabolites of volatile organic compounds (VOCs) and nicotine. **Methods:** We recruited 62 healthy young adults (18-30 years old), including 37 non-users and 25 e-cig users. Circulating immune cell populations were characterized by complete blood counts (CBCs) and high-dimensional mass cytometry (CyTOF). Immune cell activation and intracellular cytokines were assessed *ex vivo* by CyTOF following stimulation of peripheral blood mononuclear cells with lipopolysaccharides and phytohaemagglutinin. Urinary metabolites of VOCs and nicotine were analyzed by liquid chromatography-tandem mass spectrometry (LC-MS/MS). Multivariate analysis was used to evaluate associations between biomarkers of exposure and immune cell phenotypes and functions. **Results:** We observed that nicotine and its metabolites were positively associated with basophils, memory B cells, and plasmacytoid dendritic cells; and has inverse association with CD3⁺, CD4⁺ effector memory (EM), and total CD8⁺ T cells. Functionally, nicotine suppressed CD8⁺ T cell activation (TNF α , PD-1, CD69) but increased CD69, PD-1, and TNF α expression in early, late, and total NK cells. Epoxide metabolites, such as propylene glycol and glycerol showed divergent effects: glycidol was associated with reduced naive and effector T cells and decreased CD69, IL-6, and TNF α responses, whereas propylene oxide increased monocyte activation (CD40, IL-1 β , IL-6, IL-10, GM-CSF) and enhanced PD-1 and CD69 expression in NK and CD8⁺ T cells. Aldehydes and α,β -unsaturated carbonyls (acrolein, crotonaldehyde) were strongly associated with myeloid activation, including increased dendritic cells, multiple monocyte subsets, eosinophils, and basophils. Acrolein showed negative associations with naive T cells and positive associations with terminal effector and central memory (CM) and Th17-like T cells. Functionally, acrolein suppressed monocyte cytokines (IL-1 β , IL-6, IL-10, GM-CSF) while enhancing CD69, PD-1, and TNF α in CD8⁺ T cells. Acrylamide metabolites (AAMA, GAMA) were linked to higher dendritic cells, monocytes, NK cells, and basophils, but showed broad functional suppression across T and B cell activation markers (CD69, PD-1, CD80, TNF α). Alkenes metabolites, such as 1,3-butadiene (DHBMA, MHBMA3) and isoprene (IPM1) were associated with increased monocytes, dendritic cells, effector T cells, memory B cells, and eosinophils and reduced $\gamma\delta$ T cells and neutrophils. Functionally, both compounds enhanced CD69, PD-1, and TNF α in effector T cells while suppressing monocyte cytokine responses. Aromatic hydrocarbons metabolites such as benzene (PPMA), toluene (BMA), ethylbenzene (PGA), styrene (PGA, MA), and xylenes (2MHA, 34MHA) exhibited strong innate activation (monocytes, dendritic cells, NK cells, basophils, plasmablasts) with reduced naive T and B cell activation. Functionally, they increased IL-10, IL-1 β , and GM-CSF in monocytes but suppressed B cell activation markers. Metabolites of nitriles and halogenated VOCs Acrylonitrile (CYMA), 1-Bromopropane (BPMA) displayed mixed effects. Acrylonitrile increased dendritic cells, monocytes, NK cells, memory B cells, and CD8⁺ CM T cells and elevated monocyte cytokines, whereas 1-bromopropane reduced monocyte cytokines and B-cell activation but increased PD-1 and CD69 on CD4⁺ and CD8⁺ TE/CM T cells and decreased neutrophils and MAIT/NKT cells. **Conclusions:** These find-

ings demonstrate that e-cig derived VOCs and nicotine metabolites are associated with phenotypic and functional immune dysregulation across multiple innate and adaptive cell types.

PS 4256 Mice Exposed to Chronic Cadmium Display Pulmonary Arterial Hypertension-like Pathogenesis

D. D. Cathey, X. Hui, Y. Tan, J. Cai, L. Cai, and J. Huang. University of Louisville, Louisville, KY.

Background and Purpose: Pulmonary arterial hypertension (PAH) is a disease wherein chronic high pulmonary arterial pressure causes right ventricular (RV) dysfunction, resulting in global heart failure, eventually leading to patient mortality. Our previous clinical studies demonstrated that patients diagnosed with PAH had increased blood and urine cadmium (Cd) concentrations compared to non-PAH controls. Therefore, we hypothesized that chronic environmental exposure to Cd may novelly contribute to PAH pathogenesis. **Methods:** Recently, we published two articles where we observed the pathological features of PAH in a PAH-induced mouse model through the combination of Semaxinib (SU5416) and hypoxia (SuHx). Right ventricle (RV) diastolic and systolic function, systolic pressure, cardiomyocyte size, collagen deposition, and prominent fibrotic markers were significantly altered within this model. Additionally, pulmonary collagen deposition, arterial remodeling, and fibrotic markers were accentuated as well. Based on these previous studies, we focused on the role chronic Cd-exposure plays in fibrosis, cardiac hypertrophy, and arterial remodeling, to see whether it may contribute to PAH pathogenesis. Twenty male C57BL/6J mice were split into two groups; a control group (CTRL, $n = 10$) who received tap water, and a Cd group (Cd, $n = 10$) who received 5ppm Cd CdCl₂ in their drinking water. The mice were exposed to this experimental design for a total of 12 weeks (wks). To analyze cardiac function, transthoracic echocardiography (echo) was performed on the left and right ventricles (LV and RV) for all mice after 12 wks of Cd-exposure. Then, three mice per group underwent right ventricular catheterization, measuring their diastolic, systolic, and atrial pressures, respectively. At the end of the exposure duration, the mice were euthanized wherein plasma, heart, and lung tissue were collected to undergo: (1) Heavy metal analyses with Inductively Coupled Plasma Mass Spectrometry (ICP-MS), (2) Immunohistochemistry (IHC) staining and western blotting for specific target protein abundance and location, and (3) Reverse transcriptase quantitative polymerase chain reactions (RT-qPCR) of target gene expression. GraphPad Prism 10 software was used regarding statistical analysis. After normality was established, either the parametric or nonparametric equivalence of the student's t-test or TWO-WAY ANOVA was used; with a p -value < 0.05 being considered significant. **Results:** After 12 wks, the mice who underwent chronic Cd-exposure showed significant alterations in both RV diastolic and systolic function, reflected by the increased E/E' ratios and decreased tricuspid annulus plane systolic excursion (TAPSE) values. Exposure to Cd for 12 wks significantly increased heart and lung Cd levels, although this was not the case in plasma. Mice body weight and lung weights were significantly increased after 12 wks of Cd-exposure, which was not seen when comparing heart weights. Pathological examination determined increased lung and RV collagen deposition, alongside LV cardiomyocyte size when compared to the CTRL mice. Additionally, the number of abnormal pulmonary arteries, pulmonary arterial medial thickness, and wall area were all significantly increased when compared to the CTRL mice. These results indicate significant RV dysfunction, alongside pulmonary vascular and cardiac ventricular remodeling. Furthermore, western blot and RT-qPCR analysis on lung tissue determined that 12 wks of Cd-exposure alone significantly upregulated genes and proteins involved in pulmonary arterial remodeling including alpha smooth muscle actin and elastin, further confirming our histological results, all which were seen in the mice with PAH induced by SuHx in our recent published work. **Conclusions:** This concept-proof study confirms our hypothesis: chronic Cd-exposure via 5 ppm drinking water for 12 wks indeed induced a PAH-like phenotype, with further studies currently being conducted to investigate its underlying mechanism. This work is supported by the National Institute of Environmental Health Sciences (T32-ES011564), the American Heart Association (25DIVSUP1477259), and the Kentucky Pediatric Cancer Research Trust Fund (PON2 728 2300001625).

PS 4257 Cardiac Transcriptomics Uncovers Safety Markers for Potentially Cardiotoxic Kinase Inhibitors

D. Dragovic¹, T. Krsmanovic¹, K. Jankovic¹, A. Surla¹, P. Stojakovic¹, S. Lantsman¹, G. Apic¹, and R. B. Russell². ¹Metisox, Cambridge, United Kingdom; and ²Heidelberg University, Heidelberg, Germany.

Background and Purpose: Tyrosine kinase inhibitor drugs (TKIs) are highly effective anti-cancer drugs, yet many TKIs are associated with various forms of cardiotoxicity. The mechanisms underlying these drug-induced adverse events remain poorly understood. The analysis of gene expression profiles could help identify potential mechanisms of toxicity. The aim of the study was to identify safety markers that might be indicative of TKI-induced cardiotoxicity. We analyzed transcriptional profiles of 6 different human induced pluripotent stem cells (hiPSCs)-derived cardiomyocyte cell lines treated for 48h in quadruplicate with one of 8 TKIs exhibiting cardiotoxic potential (dabrafenib, lapatinib, pazopanib, ponatinib, sorafenib, sunitinib, trametinib

and vandetanib) (GSE217421). We identified their effects on subcellular pathways and processes. **Methods:** We used our proprietary database and software for data interpretation and visualization, generated to include internally curated and various publicly available data on proteins, biologically-active chemicals, their interactions, pathways and pathologies. Over 30 million references were catalogued, supporting each database entry. Molecule interactions were hyperlinked to appropriate PubMed articles as support, whereas proteins were hyperlinked to corresponding NCBI gene and UniProt protein pages, and chemicals to corresponding PubChem pages. In order to support data integration and capture different levels of histopathological observations, we developed toxicology ontology with over 9,000 disease and 800 pathology endpoints. The system is also supported by 6.5 million interactions between genes/proteins, chemicals, diseases, pathologies, Gene ontology (GO) clusters and Signaling and metabolic pathways. **Results:** The analysis of gene expression data following each of 8 TKI treatments, using the cut off criteria of log2 fold change $\geq \pm 1$, and $\text{padj} < 0.05$, identified 181 - 909 differentially expressed genes (DEGs). Our system recognized 73-87% of DEGs. We analyzed each set of DEGs and used the compare analysis results function within our system to identify common pathways and pathologies to all 8 TKI treatments. We identified GO processes that indicated potential mechanism behind cardiotoxicity (extracellular matrix organization, collagen fibril organization, Wnt signaling pathway, regulation of blood pressure, response to hypoxia, regulation of heart contraction, and blood coagulation). In addition, enriched Signaling and metabolic pathways were identified providing further explanation of cardiotoxicity potential of these TKIs (platelet aggregation, cell surface interaction at the vascular wall and VEGFR2 mediated vascular permeability). We identified enriched Organ and tissue pathologies that also imply potential cardiovascular pathologies (fibrosis, vascular smooth muscle hyperplasia and vascular endothelial cell apoptosis). In order to find gene expression signatures common to all 8 TKI treatments, we used the compare search results function within our system and identified 13 DEGs (upregulated: SLC6A9, ALDH1L2, NUPR1, CRISPLD2, GLT8D2, FIBIN, SERPINF1, BMP4, CHST2, RSPO3, NHERF1, COL8A2, and downregulated: APLN) common to all 8 TKI treatments. Analysis of these genes showed association with angiogenesis, regulation of heart contraction, and regulation of systemic arterial blood pressure GO processes within our system, indicating indeed involvement in cardiovascular relevant biological pathways. To verify the obtained cardiotoxicity gene expression signature, we analyzed the gene expression data sets from hiPSCs-derived cardiomyocyte cell lines treated with cabozantinib (TKI that induces cardiotoxicity as a recognized adverse effect with potentially reversible outcomes) as well as afatinib (TKI with no evidence of direct primary cardiovascular toxicity). Indeed, all 13 genes were found among the DEGs from cabozantinib treated cells, whereas only 10 out of 13 genes were identified among DEGs from afatinib treated cells. **Conclusions:** By interrogating our proprietary database and software we showed their potential in identifying dysregulated pathways, pathologies and gene signatures of drug cardiotoxicity.

PS 4258 Toxicity of evaluation of R-1132(E) using human cardiomyocytes

R. Takeda¹, N. Mori¹, R. Kobayashi¹, T. Nakaue², S. Tokuno², Z. Guo², and Y. S. Kida¹. ¹National Institute of Advanced Industrial Science and Technology (AIST), Tsukuba, Japan; and ²Daikin Industries, Ltd., Kita, Japan. Sponsor: T. Fukuyama

Background and Purpose: R-1132(E), trans-1,2-Difluoroethylene, is an Hydrofluorolefin (HFO) refrigerant with a global warming potential of 1 or less, very low environmental impact, and excellent energy efficiency. R-1132(E) belongs to a chemical family, called haloalkenes, which also includes R-1234yf (2,3,3,3-Tetrafluoropropene) and HFO-1123 (1,1,2-Trifluoroethene). Both R-1234yf and HFO-1123 have shown cardiac effects following inhalation exposure in rabbit studies. Exposure to R-1132(E) also induced similar cardiac effects in the rabbit, but not in the rat and dog. However, R-1132(E) cardiac effects on humans remain unclear. Therefore, this study evaluated the cardiotoxicity of R-1132(E) using human cardiomyocytes. **Methods:** We seeded iCell Cardiomyocytes 2.0 onto 0.1% gelatin-coated plastic plates and fibronectin-coated Microelectrode array (MEA) plates. Seven days after cell seeding, culture plates were exposed to either 0 ppm or 15,000 ppm of R-1132(E) in Tedlar bags. These bags are gas sampling bags made from polyvinyl fluoride, which provides excellent chemical resistance and low adsorption properties. Five days after exposure, we evaluated cell viability using the CCK-8 assay and recorded the beat rate using MEA (Maestro Edge, Axion Biosystems, Atlanta, GA). Furthermore, we assessed the predictivity of proarrhythmic risk potential based on changes in field potential duration with Fridericia's correction (FPDcF). FPDcF, an indicator used to predict arrhythmia risk when fluctuations exceed 10%, was calculated from the FPD and Inter-spike interval obtained from MEA measurement of human iPS-derived cardiomyocytes. **Results:** CCK-8 levels were significantly elevated in the 15,000 ppm R-1132(E) exposure group (0 ppm: 0.1239 ± 0.0013 , 15,000 ppm: 0.1334 ± 0.0022 , $p < 0.001$). In contrast, heart rate showed no significant change due to R-1132(E) exposure (0 ppm: 33.2 ± 2.0 , 15,000 ppm: 34.5 ± 1.1 , $p = 0.595$). Similarly, the relative FPDcF value showed no change more than 10% in the 15,000 ppm R-1132(E) exposure group (0 ppm: 1.00 ± 0.02 , 15,000 ppm: 1.02 ± 0.01 , $p = 0.403$). **Conclusions:** These results suggest that R-1132(E) may not directly induce cell death and arrhythmia risk in human cardiomyocytes.

PS 4259 Integrating qHTS and QSAR Models to Identify Safe GPCR-targeted Compounds: A Focus on hERG-dependent Cardiotoxicity

X. Luo¹, J. Zhao¹, S. Sakamuru¹, M. Xia¹, T. Xu¹, J. Travers¹, H. Zhu¹, M. Hall¹, S. Ferguson², D. Reif², and R. Huang¹. ¹NCATS/NIH, Rockville, MD; and ²NIEHS/NIH, Research Triangle Park, SC.

Background and Purpose: G protein-coupled receptors (GPCRs) are a diverse family of seven-transmembrane domain receptors that play pivotal roles in various physiological and neurological processes by mediating extracellular signals through G proteins. Notable GPCRs such as ADRB2, CHRM1, DRD2, and HTR2A are important therapeutic targets, linked to conditions ranging from asthma to schizophrenia. The human ether-a-go-go-related gene (hERG), encoding the Kv11.1 potassium channel, is critical for cardiac repolarization, the inhibition of which can lead to prolonged QT intervals and increased risk of arrhythmias. Consequently, assessing hERG-GPCR interactions is essential during drug development to enhance safety and ensure regulatory compliance. **Methods:** In this study, we utilized quantitative high-throughput screening (qHTS) to identify GPCR agonists and inhibitors in the Tox21 10K compound library. We applied machine learning (ML)-based quantitative structure-activity relationship (QSAR) models to predict selective GPCR-targeting compounds with reduced hERG liability, employing different data processing sequences. Our models trained on the Tox21 10K library screening data were subsequently validated using the Library of Pharmacologically Active Compounds (LOPAC). Furthermore, the models were applied to virtually screen approximately 360K diverse compounds with the top predictions experimentally validated. **Results:** Validated compounds revealed new GPCR modulators with minimal hERG liability. **Conclusions:** The findings provide efficient strategies for the development of lead compounds targeting GPCRs while minimizing cardiac risks associated with hERG inhibition.

PS 4260 Impact of Ephedra on vascular function

T. L. van Neel, D. Kuo, and D. Gerhold. NIH/NCATS, Rockville, MD.

Background and Purpose: Cardiovascular disease (CV/CVD) remains the leading cause of death worldwide, accounting for a third of global deaths in 2021. Central to cardiovascular health are the endothelial cells (ECs) that line the inside of all vasculature. Adverse effects of air pollution, smoking, or harmful drugs often result in endothelial dysfunction which can result in CVD such as thrombosis or hypertension, leading to heart attack or stroke. The continued use of over-the-counter supplements containing Ephedra or ephedrine alkaloids, are of particular concern due to their documented history of toxicity. While Ephedra's ability to cause tachycardia is well established, the specific effects of Ephedra on ECs remain unknown. **Methods:** Supernatant samples from primary human umbilical vein endothelial cells (HUVEC) cultures treated with or without 100 $\mu\text{g/mL}$ Ephedra were first analyzed using a large immunoassay panel (42 cytokines). Subsequent cytokine analysis of supernatant samples was performed using a smaller, targeted panel informed by the larger panel. Thrombin assays on HUVEC cultures were performed using platelet-rich plasma (PRP) pre-treated with 10% CaCl₂ and 20 μM ADP; a fluorogenic substrate was then added and thrombin formation was measured in 30 seconds intervals for 1 hour. Fibrinolysis assays were conducted by adding biopsy-punched fibrin discs onto HUVEC cultures for 1 hour and measuring supernatant samples with an immunoassay. These assays were conducted using both cell media and PRP samples. In some cases, a plasminogen activator inhibitor-1 (PAI-1) inhibitor (Tiplaxtinin or TM5441) was added to isolate the coagulation pathway impacted by Ephedra. **Results:** Cytokine analysis of HUVEC treated with ephedra showed a significant decrease in tissue plasminogen activator (tPA) which is important in regulating coagulation. Additionally, increased thrombin activity was observed when HUVEC were treated with Ephedra. This would suggest a higher rate of clot formation via fibrinogen conversion, although additional studies are needed. Last, preliminary results from the fibrinolysis assays showed a decrease in D-dimer when HUVEC were treated with Ephedra. D-dimer is a byproduct of the clot breakdown process, meaning Ephedra is also slowing down clot breakdown which could result in thrombosis. **Conclusions:** Endothelial cells maintain vascular homeostasis by regulating blood flow via blood vessel contractility, delivering oxygen and nutrients to supporting cells, and monitoring immune responses. Additionally, ECs contribute significantly to hemostasis by secreting coagulation factors, coagulation inhibitors, and clot dissolution mediators. Because clinical coagulation assays use whole blood without ECs, it is important to examine effects of xenobiotics on ECs and to develop coagulation models that include ECs. Further investigation will clarify whether Ephedra-containing supplements disrupt hemostasis and contribute to CV adverse effects. These results may improve our understanding of how such supplements affect CVD.

PS 4261 Paradoxical Effects of an Anti-Inflammatory Drug, Anakinra, on Endothelial Cells

D. L. Gerhold, D. Kuo, and T. van Neel. NIH - NCATS, Rockville, MD.

Background and Purpose: Anakinra is an anti-inflammatory drug used to treat a variety of autoimmune and inflammatory diseases. Anakinra is comprised of a recombinant form of the endogenous IL1 Receptor Antagonist (IL1RA). By blocking IL1beta binding to IL1 Receptor 1, anakinra suppresses production of inflamma-

tory cytokines by macrophages, T-cells, neutrophils and epithelial cells. **Methods:** Primary human endothelial cells were cultured from umbilical, aortic, and microvascular beds and treated with anakinra or etanercept for 15 minutes or 24 hours. Cytokines were quantified in the media using Luminex bead-based kits representing 42 secreted proteins, or by RNA sequencing of poly-adenylated mRNA. **Results:** Surprisingly, cultured HUVEC endothelial cells responded to anakinra by secreting a variety of predominantly pro-inflammatory cytokines including TNF, IL1beta, LIF, MIP1alpha, IL4, IL5, IL10, IL12, IL13, IL15, IL16, IL17A, IL20, IL21, IFN-alpha, IFN-gamma, GM-CSF, Eotaxin, P-selectin, OPG, and TSLP. Human Aortic endothelial cells (HAEC), or Human Microvascular Endothelial Cells (HMVEC), as well as HUVEC cells from other subjects, also responded by secreting the same inflammatory cytokines. Thus, this proinflammatory response to anakinra is likely a general feature of human Endothelial Cells (ECs). Puzzlingly, a similar profile of cytokine secretion was observed following treatment of HUVEC with etanercept, an anti-inflammatory recombinant peptide drug that blocks TNF from binding its receptors. However, we observed that etanercept caused secretion of the endogenous cytokine IL1RA by ECs, suggesting the similar profile of cytokine secretion by ECs in response to etanercept is redundant with the response of ECs to the recombinant IL1RA, anakinra. Mechanistic studies showed that cytokine mRNAs did not increase upon anakinra or etanercept treatment, and release of cytokines by ECs occurred within 15 minutes of anakinra treatment, indicating that cytokines were released from storage rather than *de novo* transcribed and translated. **Conclusions:** Anakinra and etanercept caused a rapid release of stored proinflammatory cytokines by cultured primary ECs, with etanercept acting indirectly via release of IL1RA. Recognition that anakinra or etanercept exert a proinflammatory response from ECs seems paradoxical, but does not contradict clinical successes treating a variety of inflammatory diseases. Instead, understanding these responses should help to explain which diseases are likely to respond to anakinra or etanercept.

PS 4262 Toxicological Agents in Self Poisoning Cases at Mzuzu Central Hospital: Trends and Treatment Approaches

V. Mithi¹, B. Dewey², B. Kachingwe¹, and S. Lockwood³. ¹Kamuzu University of Health Sciences, Blantyre, Malawi; ²University of Nottingham, Nottingham, United Kingdom; and ³Bayer Crop Science, Chesterfield, MO. Sponsor: *W. Rumbelha*

Background and Purpose: There is a dearth of knowledge around mechanisms of self-poisoning, prevalence or patterns, the toxicological agents involved and their concentrations, in Malawi. Thus this study aimed to characterize the trends around toxicological agents in self-poisoning cases and their treatment approaches at Mzuzu Central Hospital. **Methods:** This study employed a quantitative retrospective chart review of registered self-poisoning cases managed between January 2022 and December 2023 at the emergency department of Mzuzu Central Hospital using purposive sampling. STATA version 17 was used to analyze the data, create descriptive analysis tables and figures, and to run a multinomial logistic regression. **Results:** Self-poisoning cases (n=313) were higher in males (n=265, 84.66%) than females (n=48, 15.34%). Unintentional self-poisoning (77.96%) was reported in 211 (67.41%) males and 33 (10.54%) females. Intentional self-poisoning (20.77%) was recorded in 50 (15.97%) males and 15 (4.79%) females. Self-harm poisoning was reported in 4 (1.28%) males. The common toxicological agents involved in intentional self-poisoning were pesticides (10% in 2022 vs 8.28% in 2023), prescription medications (8.13% in 2022 vs 4.14% in 2023), alcohol (3.13% in 2022 vs 2.96% in 2023), and acids (1.25% in 2022 vs 1.18% in 2023). Unintentional self-poisoning agents involved alcohol (56.80% in 2023 vs 47.50% in 2022), foods (15.00% in 2022 vs 1.18% in 2023), snake bites (8.28% in 2023 vs 8.13% in 2022), unknown agents (1.88% in 2022 vs 1.78% in 2023), pesticides (1.78% in 2023 vs 0.63% in 2022), prescription medications (1.25% in 2022 vs 1.18% in 2023), and traditional herbs (1.78% in 2023). Where pharmacological treatment was administered, this comprised: ceftriaxone (11.82%), metronidazole (11.35%), paracetamol (8.85%), thiamine (7.75%), intravenous fluids (5.87%), ringers lactate (5.41%), dextrose (5.09%), vitamin b complex (4.93%), diazepam (3.52%), diclofenac (3.37%), omeprazole (3.21%), normal saline (2.82%), atropine (2.35%), ciprofloxacin (2.19%), tramadol (1.41%), activated charcoal (1.17%), and tetanus vaccination (0.86%). Non-pharmacological treatments comprised: respiratory support (supplemental oxygen, non-invasive ventilation, intubation) (33.05%), catheterization (20.91%), nasogastric tube (12.45%), oral rehydration solution (10.42%), limb elevation (6.11%), suction (5.79%), surgery (2.66%), milk (1.25%), chest physiotherapy (1.17%), and water (1.17%). Psychological interventions recorded comprised: dialectical behavioural therapy (34.94%), cognitive behavioural therapy for suicide prevention (5.37%), and improving mood-promoting access to collaborative treatment (0.78%). Regarding outcomes: 276 (88.18%) were discharged with approval of a physician, 24 (7.67%) cases ended in mortality, 10 (3.19%) absconded, and 3 (0.96%) were referred to another tertiary hospital. Exposed individuals that died were at (Relative Risk Ratio: 0.795435) 80% greater risk of dying without molecular toxicological laboratory analysis (p=0.01). **Conclusions:** Self-poisoning is prevalent among males, though often unintentional/accidental. Pesticides, prescription medications, and alcohols are the most common toxicological agents involved. This study demonstrates the need to characterize concentrations of toxicological agents involved, clinical outcomes, and molecular toxicology units to minimize the risk of treatment or death and reduce the burden of poison treatment and management in hospitals. This knowledge is essential in expanding and improving prehospital toxicological and pharmacological treatment measures.

PS 4263 The Importance of Monitoring Indoor Air Quality

S. Kiroglu, and K. A. Swanik. Neumann University, Aston, PA.

Background and Purpose: The importance of indoor air quality (IAQ) is often trivialized in the human health equation. Many pollutants cannot be seen and people are not always aware of the risks. This study focuses on using simple air quality sensors as an education tool to make invisible pollutants visible. The main purpose is to increase environmental health literacy and help people understand toxic exposures in their homes. **Methods:** This research was completed as an independent study project with faculty guidance. I reviewed scientific literature, technical reports, and public health resources. I examined evidence about the health effects of common indoor pollutants and analyzed how real-time sensor feedback can shape behaviors. I interpreted all findings in the context of health education. **Results:** The literature shows that using low-cost indoor air quality (IAQ) sensors as educational tools can increase public awareness and make invisible environmental risks visible. Scientific evidence demonstrates that IAQ pollutants have measurable health effects and the role of real-time feedback from sensors in shaping behaviors. This approach combines environmental health and toxicology with community-based education strategies by making them understandable for the public. The central hypothesis is actually that through sensor feedback, environmental health literacy can be increased, public knowledge about pollutants in the air can be improved, and people can be motivated to take protective actions such as avoiding products that release pollutants. **Conclusions:** This work suggests that using IAQ sensors as an educational tool can support toxicology and environmental health. Making invisible pollutants visible can increase public knowledge, support informed choices, and help communities reduce toxic exposures.

PS 4264 Eucalyptus Oil Ingestion: A Retrospective Descriptive Analysis of Exposures Reported to a Poison Information Helpline in South Africa over five years.

C. van Pletzen, A. Du Plessis, and C. Marks. Stellenbosch University, Cape Town, South Africa. Sponsor: *M. Gulumian*

Background and Purpose: Eucalyptus Oil is a widely available household product in South Africa, often used for its perceived therapeutic benefits in managing respiratory symptoms. However, ingestion of Eucalyptus Oil can result in significant toxicity including seizures, respiratory depression and even death (Ittyachen et al, 2019). Despite its potential for harm, there is limited local epidemiological data available. This study aims to describe the incidence and characteristics of eucalyptus oil exposures reported to a Poison Information Helpline, South Africa. **Methods:** A retrospective, descriptive analysis was conducted using data from the Poison Information Helpline, Western Cape (PIHWC) encompassing all cases of Eucalyptus Oil exposures reported from 2018 to 2023. Non-patient-related and animal enquiries were excluded. Data was analysed descriptively to summarize demographic variables, exposure circumstances, clinical severity using the Poison Severity Score (PSS) and seasonal trends. Basic statistical comparisons were made to evaluate differences in clinical presentation and severity. **Results:** A total of 510 cases of *Eucalyptus Oil* exposures were identified over the five-year period. Most calls were received from the public (287, 56.3%) involving 261 females (51%) and 247 males (49%). Overall, most of the exposures were accidental (371; 72.8%), including 156 (30.6%) in the 1-3 year age group. Intentional self-harm exposures (7, 1.4%) were most common among adults ages >19. A Therapeutic error was recorded in (128; 25.1%) of the exposures. At the time of the call, most patients were asymptomatic, PSS 0 (268; 52.5%) or experienced mild symptoms, PSS1 (204; 40.0%). Only 0.2% presented with severe symptoms, (PSS 3) and no deaths were recorded. While no seasonal trend was observed, a spike in cases occurred in 2021 (286, 56.1%) in comparison to the other years. Most exposures involved liquid formulations (94.7%). Only two of the patients presented with seizures over the 5-year period. **Conclusions:** Eucalyptus oil ingestion remains a frequent cause for Poison Information Helpline consultation, though most cases are of low severity. Young children, especially those <3 years are most vulnerable and highlight the need for targeted caregiver education on safe storage and use, improved product labelling and continued surveillance. The study reinforces the role of Poison Information Helpline in identifying preventable toxic exposures, their respective presentations and outcomes.

PS 4265 Cannabis Abuse, Intoxication, and Vomiting in Mayo Clinic Patients in Arizona, Florida, and Minnesota Between 2017 and 2024

K. D. Conrow¹, M. Go², H. Ha³, S. T. Griffith³, N. Oblizajek⁴, M. Meier⁵, R. W. Kirchoff⁶, and M. C. Leung¹. ¹Arizona State University, Glendale, AZ; ²University of Pennsylvania, Philadelphia, PA; ³Arizona State University, Phoenix, AZ; ⁴Mayo Clinic, Rochester, MN; ⁵Arizona State University, Tempe, AZ; and ⁶Mayo Clinic, Scottsdale, AZ.

Background and Purpose: As more states legalize medical and recreational cannabis in the U.S., there is an increase in emergency room reports of cannabis hyperemesis syndrome (CHS), which is marked by recurring vomiting, nausea, and abdominal

pain in patients with prolonged use of cannabis. The symptoms can be alleviated with hot water baths and abate with prolonged cessation of cannabis use. The occurrence of CHS have been hypothesized to link to genetic and environmental factors, such as differences in individual metabolism and contaminants in cannabis products (e.g., *Fusarium* mycotoxins). **Methods:** This study aims to characterize adult CHS patients from 2017 to 2024 in the Mayo Clinic patient populations in three states with legalized medical cannabis programs - Arizona, Florida, and Minnesota - using the Informatics for Integrating Biology and the Bedside (I2B2) tool, which allows queries of patient population size using different inclusion and exclusion criteria and anonymized electronic health records (EHRs). While no code in the International Classification of Diseases, Tenth Revision, Clinical Modification (ICD-10-CM) specifically indicates CHS, the co-occurrence of cannabis use, abuse, or dependence (ICD-10-CM codes F12.*) or cannabis intoxication (T40.7) with a vomiting syndrome (ICD-10-CM codes G43.A or R11.1) was used as a proxy to estimate the size of the patient populations with CHS. The aggregate data for patient population sizes with cannabis abuse, intoxication, and vomiting was pulled from I2B2, including the yearly breakdown in each state. Two of the states (Arizona and Minnesota) legalized recreational cannabis during the 2017 - 2024 period. **Results:** From January 1, 2017 to December 31, 2024, Mayo Clinic had a total of 2,204,590 adult patients, with 465,851 in Arizona, 497,353 in Florida, and 1,336,253 in Minnesota. The number of patients with cannabis abuse or intoxication for each state in that time was 6,079 in Arizona (1.31%), 3,530 in Florida (0.71%), and 15,796 in Minnesota (1.18%). The time-series of cannabis abuse or intoxication rates in Arizona for each year show increasing rates, while Minnesota rates have generally decreased from 2017. The vomiting syndrome was reported in 33,696 patients (1.5% of the total patient population) and at a higher percentage (3.7%; 949 patients) in patients with cannabis abuse or intoxication. **Conclusions:** This study highlights the number of patients that were affected by cannabis abuse, intoxication, and vomiting. Since only a portion of patients using cannabis were annotated with ICD-10-CM codes F12.*, the number reported here was not representative of patients who could be affected by CHS. Further studies using large language models and other information from EHRs can provide a more accurate estimate of the prevalence of patients affected by CHS.

PS 4266 Integrating wastewater-derived fentanyl consumption rates and public health data: A triangulation approach for community surveillance

M. Garzon-Ramirez¹, J. H. Bisesi², E. Coker³, C. Delcher⁴, J. Bowden², N. Winn², S. E. Bisesi², F. Paneque², S. Tabora-Sarmiento², and T. Sabo-Attwood¹. ¹University of South Carolina, Columbia, SC; ²University of Florida, Gainesville, FL; ³British Columbia Centre for Disease Control, Vancouver, BC, Canada; and ⁴University of Kentucky, Lexington, KY.

Background and Purpose: Drug-involved overdoses have caused nearly one million deaths in the United States over the past two decades, with synthetic opioids—especially illicit fentanyl—driving the increase since the mid-2010s. Although recent reports show that fentanyl-related deaths appeared to decline for the first time in ten years, tracking these trends remains difficult due to long reporting delays. Wastewater-based epidemiology (WBE) offers a promising complementary surveillance tool by detecting community-level drug use patterns in near real time. Despite growing WBE reports on opioids, few studies have compared these findings with public health outcomes across multiple regions. This study tracked wastewater-derived fentanyl consumption rates (FCR) across several states in the US and assessed whether it was associated with multiple indicators of opioid burden, including fentanyl-related deaths and emergency medical services data, at both the state and county levels. **Methods:** Between March 2024 and April 2025, weekly 24-hour composite wastewater samples were collected from eight catchments across four anonymized U.S. cities. The samples were processed using solid-phase extraction, and norfentanyl concentrations (ng/L) were measured via liquid chromatography-tandem mass spectrometry (LC-MS/MS). Fentanyl consumption rates (FCR, mg/day/1,000 people) were then estimated from the excretion rates by applying the urinary excretion fraction of fentanyl, adjusted for the molecular weight ratio of fentanyl to norfentanyl and then normalized to flow rate and population. FCR were compared with CDC-reported synthetic opioid deaths, and EMS-reported overdose cases and naloxone administrations. Monthly FCR medians from three anonymized cities—West, Midwest 1, and Midwest 2—were merged for comparison at the multi-state level; Southeast was excluded due to suppressed data. County-level FCR were compared individually with monthly naloxone administrations. Spearman rank correlation (ρ) tested monotonic associations. Trend and change-point detection methods, including Mann-Kendall, Theil-Sen slope, and Pettitt tests, characterized temporal changes ($p < 0.05$). **Results:** At the multi-state level, FCR showed moderate-to-strong positive correlations with all opioid burden indicators ($\rho \approx 0.68$ - 0.71 , $p < 0.001$), indicating that higher FCR coincided with increased overdose and mortality indicators. Overdose outcomes were highly intercorrelated ($\rho > 0.93$). At the county level, strong positive associations appeared in Midwest 1 and West ($\rho \approx 0.78$ - 0.80 , $p \approx 0.002$), while Midwest 2 showed weaker, non-significant trends ($\rho \approx 0.39$, $p = 0.26$), and Southeast showed none ($\rho \approx -0.04$, $p = 0.89$). Trend analyses indicated gradual upward drift in Southeast, decline then renewed increase in West, and significant change-points ($p < 0.05$) marking declines followed by stabilization in Midwest 1 and 2 during mid to late 2024. **Conclusions:** FCR showed meaningful alignment with indicators of opioid burden, particularly overdose and mortality, at both state and county levels. Strong correlations were seen in West and Midwest 1, while weaker, non-significant patterns

appeared in Midwest 2 and Southeast, likely due to limited data. Temporal analyses identified regime shifts in fentanyl consumption during 2024 in both Midwest and West. However, these results show associations, not causation, and limitations such as small sample size, unaccounted confounders, and lack of lag analysis must be acknowledged. Overall, the findings support WBE as a timely, complementary surveillance tool for monitoring fentanyl consumption and overdose risk. Expanding datasets, extending time coverage, and including lag/confounder analyses are key next steps. This project was supported by a supplement from the National Institutes of Health, NIDA, to the parent award U01DA051126, the National Drug Early Warning System (NDEWS). We also thank our many partners and stakeholders who helped with this project.

PS 4267 An Epidemiologic Evaluation of Inorganic Arsenic Exposure and Teratogenic Effects

K. J. Colonna, and S. R. Boomhower. Gradient, Boston, MA.

Background and Purpose: Inorganic arsenic is considered a developmental toxicant but its potential for teratogenicity in humans remains uncertain. In its 2024 review, the European Food Safety Authority (EFSA) stated that maternal exposure to inorganic arsenic is associated with congenital heart defects. In contrast, the US EPA determined that the available evidence was insufficient to support dose-response analyses for teratogenic outcomes in its 2025 Integrated Risk Information System (IRIS) toxicological review of inorganic arsenic. This divergence in scientific interpretation underscores the importance of critically evaluating the evidence base on inorganic arsenic exposure and potential human teratogenicity. The present work describes a review and quality assessment of epidemiologic studies to determine whether inorganic arsenic exposure during pregnancy is causally linked to teratogenic outcomes in humans. **Methods:** We conducted a targeted review, drawing on major agency assessments (ATSDR, 2007, 2016; EFSA, 2024; US EPA, 2025) and an independent search of the peer-reviewed literature on epidemiologic studies of maternal inorganic arsenic exposure and birth defects. Literature searches were conducted in PubMed and Scopus using combinations of terms related to inorganic arsenic, pregnancy, and birth defects. After summarizing results for each identified study, all studies were evaluated for methodological quality based on (but not limited to) the following: (1) study design and sample size; (2) exposure assessment methods; (3) outcome ascertainment methods; (4) consideration and control of potential confounders (e.g., folate status, alcohol use, maternal age); and (5) temporal alignment between exposure and critical developmental windows. Studies with poor quality were considered of limited utility for causal inference. **Results:** We identified over 14 epidemiology studies of inorganic arsenic exposure and birth defects. Epidemiologic studies generally reported inconsistent associations between inorganic arsenic exposure and endpoints, including neural tube defects, orofacial clefts, spina bifida, congenital heart disease, and “any” birth defects. Several studies reported null findings, while others suggested inconsistent exposure-response associations. Across the studies, common limitations included exposure misclassification (e.g., biomarker measurements post-diagnosis, reliance on total arsenic rather than speciated inorganic arsenic), small sample sizes, and inadequate adjustment for key confounders (e.g., folate, alcohol intake). Notably, studies cited by EFSA (e.g., Richter *et al.*, 2022; Rudnai *et al.*, 2014) that suggested associations with congenital heart anomalies contained several limitations (e.g., exposure assessment and covariate control), undermining their interpretability. **Conclusions:** The current body of evidence does not provide reliable or consistent evidence for a causal association between inorganic arsenic exposure and teratogenic effects in humans. Methodological limitations - particularly in the form of small sample sizes, exposure misclassification, and inadequate adjustment for key confounders - introduced uncertainty into reported associations from individual studies. Future research on inorganic arsenic exposure and teratogenicity should strive to address the study limitations discussed above to better inform agency hazard assessments.

PS 4268 Age and Sex Specific Associations of Arsenic Exposure with Hypertension and Elevated Blood Pressure Measures in African-Caribbean Adults

N. Jahan¹, N. F. Price¹, R. K. Cvejkus¹, V. Wheeler², P. J. Parsons^{3,4}, E. J. Mullin³, A. A. Roberts³, J. M. Zmuda¹, A. L. Kuipers⁵, A. P. Sanders¹, I. Miljkovic¹, and A. Barchowsky¹. ¹University of Pittsburgh, Pittsburgh, PA; ²Scarborough General Hospital, , Tobago, Scarborough, Trinidad and Tobago; ³Wadsworth Center, New York State Department of Health, Albany, NY; ⁴College of Integrated Health Sciences, University at Albany, Albany, NY; and ⁵Michigan State University, Grand Rapids, MI.

Background and Purpose: Arsenic (As) is among the most important environmental toxicants that contribute to the global prevalence of cardiovascular diseases and hypertension, although the impacts of arsenic vary with populations and geographical location. Notably, there is a greater burden of hypertension and cardiovascular diseases among people of African ancestry including in the Caribbean, yet the etiology for this increased burden is largely unexplored. **Hypothesis:** We investigated the hypothesis that environmental factors, such as arsenic exposure, are associated with a greater risk of hypertension and high blood pressures among a cohort of Afro-Caribbean men and women enrolled in the Tobago Health Study (n= 965,

age 40-87). **Methods:** Arsenic exposure was measured as the sum of inorganic and methylated As (Σ As = inorganic As + dimethylarsinic acid + monomethylarsonic acid) in spot urine samples using Liquid Chromatography - Inductively Coupled Plasma Mass Spectrometry. We used multiple linear regression to examine cross-sectional associations of urine Σ As with systolic blood pressure (SBP), diastolic blood pressure (DBP), pulse pressure (PP) & mean arterial pressure (MAP). We used logistic regression to examine odds of hypertension (HTN) defined as systolic BP $\geq$ 140 mmHg, diastolic BP $\geq$ 90 mmHg, or use of antihypertensive medication. The models were adjusted for age, sex, waist circumference, urinary creatinine, physical activity, smoking. In secondary analyses, we additionally adjusted the blood pressure models for antihypertensive medication use. We conducted sex-stratified analyses separately alongside the total cohort. In separate analyses, we further stratified men and women by median age (58 years). We tested for effect measure modification (EMM) by sex across all outcomes and calculated p-values for interactions with likelihood ratio tests to observe whether the associations between arsenic exposure and these outcomes differ significantly by sex. **Results:** Each unit (ug/L) increase in Σ As was associated with 2% higher odds of HTN (OR: 1.02, 95% CI: 1.01-1.04, p: 0.008) in the total cohort and 4% higher odds (OR: 1.04, 95% CI: 1.01- 1.08, p: 0.027) among women. Sex-stratified analyses indicated that higher urinary Σ As was associated with elevated DBP (β = 0.08, 95% CI: 0.001-0.15, p = 0.048) and MAP (β = 0.08, 95% CI: 0.01-0.15, p = 0.029) among men whereas women trended towards higher PP (β = 0.087, 95% CI: -0.003-0.177, p = 0.057). The association of higher Σ As and HTN among women was significant in younger (OR = 1.05, 95% CI: 1.01-1.09, p = 0.017), but not older women, alone. Similarly, the association of higher Σ As with higher MAP among men was significant in younger (β = 0.10, 95% CI: 0.01-0.20, p = 0.037), but not older men, alone. The data suggest evidence of effect modification by sex for the relationship between Σ As and MAP (p-interaction = 0.048) with men having higher MAP, including adjustment for medication effect. **Conclusions:** These findings suggest that exposure to inorganic arsenic is cross-sectionally associated with age and sex specific patterns of greater burden of hypertension and high blood pressures among Afro-Caribbean adults in Tobago. The results may suggest different sex-dependent mechanisms for arsenic effects on blood pressure and response to anti-hypertensive medication. *Supported by NIH grants R01ES033519-01, R01AG074956, R01HL143793, R01-AR049747, R01-DK097084 and U2CES026542.*

PS 4269 An Evaluation of the Epidemiologic and Experimental Animal Evidence of Oral Cadmium Exposure and Teratogenic Effects

P. M. Andrew, J. Chien, K. J. Colonna, and S. R. Boomhower. Gradient, Boston, MA.

Background and Purpose: For the non-smoking general population, the primary source of cadmium exposure is through the diet. In 2012, the Agency for Toxic Substances and Disease Registry (ATSDR) stated in its "Toxicological Profile for Cadmium" that it is not known whether cadmium can cause birth defects in people. Since that review, additional studies have been published regarding the relationship between exposure to cadmium and teratogenic effects. We performed an updated review, quality assessment, and integration of epidemiologic and toxicologic studies to determine whether oral exposure to cadmium during pregnancy is causally associated with human teratogenicity. **Methods:** We searched for epidemiologic and experimental animal studies from government agency reviews (e.g., ATSDR, United States Environmental Protection Agency [US EPA], California Office of Environmental Health Hazard Assessment [CalOEHHA]) and performed an independent literature search in PubMed and Scopus for relevant studies published since ATSDR's 2012 review. For epidemiologic studies, study quality was evaluated based on, but not limited to, the following: (1) study design and sample size; (2) exposure assessment methods; (3) outcome ascertainment methods; (4) consideration and control of potential confounders (e.g., alcohol use, maternal age); and (5) temporal alignment between exposure and critical developmental windows. For animal studies, we focused on studies conducted in mammals that used oral exposures (e.g., food, water, oral gavage), as these exposures are the most relevant to typical human exposures. Study quality in animal studies was evaluated based on several considerations, including but not limited to: (1) study design and sample size; (2) number of dose levels, such that a dose-response curve could be detected; (3) and consideration of maternal toxicity. Studies with poor quality were considered of limited utility for causal inference. **Results:** We identified over 20 epidemiologic studies of cadmium and birth defects. Overall, epidemiologic studies of birth defects reported inconsistent associations with cadmium exposure. In addition, most studies had several limitations, such as cross-sectional study design, potential confounding bias, and unreliable measures of cadmium exposure, which made reported associations uncertain. With respect to animal studies, we identified over 23 studies of oral cadmium exposure in mammals that evaluated potential malformations. Across these studies, exposure to cadmium generally was not associated with an increased incidence of malformations even, in some cases, at levels associated with maternal toxicity (e.g., maternal weight loss). **Conclusions:** Overall, integration of the evidence from studies in humans and experimental animals does not support a causal association between oral cadmium exposure and teratogenicity. In general, epidemiologic studies had several methodological limitations that should be addressed in future research. Evidence from experimental animal studies supports the conclusion that human-relevant oral exposures to cadmium do not result in teratogenic effects.

PS 4270 Disparities in Arsenic Exposure: Evidence from Public Water Systems and Human Biomonitoring

Z. A. Kobs, and T. Roh. Texas A&M University School of Public Health, College Station, TX.

Background and Purpose: Arsenic is a naturally occurring element found in groundwater and a recognized human toxicant linked to various adverse health outcomes. While regulatory efforts have reduced arsenic levels in drinking water, it is unclear whether these improvements have equitably reduced human body burden across populations. This study integrates environmental monitoring data from Texas public water systems (PWS) and biomonitoring data from the U.S. population to assess temporal trends and disparities in arsenic exposure from source to body. **Methods:** Arsenic concentration data from 4,681 residential public water systems in Texas from 2007 to 2023 were obtained from the Texas Commission on Environmental Quality. Descriptive statistics, geospatial mapping, and logistic regression were applied to assess temporal changes and disparities based on system size, water source, rurality, and Social Vulnerability Index (SVI). Separately, urinary inorganic arsenic concentrations in U.S. women aged 20 to 44 years were evaluated using six cycles of the National Health and Nutrition Examination Survey from 2007 to 2020. Survey-weighted linear regression estimated adjusted geometric means (aGMs) and percent change per cycle while adjusting for sociodemographic, dietary, and behavioral factors, including urinary creatinine and serum cotinine. **Results:** In Texas, arsenic violations declined from 9.04% of PWS in 2007-2011 to 2.76% in 2020-2023, with mean arsenic concentrations decreasing from 3.20 μ g/L to 1.75 μ g/L. However, violations remained concentrated in small, groundwater-reliant, and high-SVI systems, with increasing odds ratios for non-metro (OR = 2.15) and high-SVI (OR = 4.82) areas. In NHANES, urinary inorganic arsenic declined by approximately 3% per cycle overall. Yet, Mexican American women and low-income groups exhibited smaller reductions (2.36% and 1.78%, respectively) compared to their higher-SES counterparts. Consumers of arsenic-associated foods had higher aGMs and slower declines than non-consumers. Community water users saw modest reductions, while trends among private well users were variable. **Conclusions:** Despite regulatory progress, environmental and biomonitoring data reveal persistent disparities in arsenic exposure from source to body. Vulnerable populations, particularly those in rural, socioeconomically disadvantaged, and high-SVI areas, continue to bear disproportionate exposure burdens. These findings support the need for enhanced environmental surveillance, targeted exposure reduction efforts, and equitable policy interventions to address the structural determinants of arsenic-related health risk.

PS 4271 Determinants of Placental OATP2A1 and OATP2B1 Transporter Protein Concentrations within the UPSIDE Birth Cohort

C. Jiang¹, K. Getz¹, R. Zhang¹, J. K. Fallon², R. J. Qasem², J. B. Tiley², P. C. Smith², J. Brunner³, R. K. Miller³, T. G. O'Connor³, N. P. Illsley^{1,4}, P. Ohman-Strickland¹, Z. Rivera-Núñez¹, E. S. Barrett¹, and L. M. Aleksunes¹. ¹Rutgers University, Piscataway, NJ; ²University of North Carolina, Chapel Hill, NC; ³University of Rochester Medical Center, Rochester, NY; and ⁴Placental Research Group, Maplewood, NJ.

Background and Purpose: Organic anion transporting polypeptides (SLCO gene, OATP) mediate the uptake of a wide range of anionic substrates into human placentas. OATP2A1, a transporter with high affinity to prostaglandins, is primarily found on the maternal-facing side of the blood-placental barrier. On the other hand, OATP2B1 is primarily found on the fetal side and has a broader substrate profile of xenobiotics and endogenous chemicals. By utilizing the Understanding Pregnancy Signals and Infant Development (UPSIDE) cohort (NY, USA), we sought to evaluate how maternal factors, gestational and infant factors, and prenatal environmental toxicant exposures influence concentrations of OATP2A1 and OATP2B1 proteins in healthy term placentas. **Methods:** Villous placenta tissue (N=255) was homogenized and membrane fractions isolated for quantitative targeted absolute proteomic analysis of OATP2A1 and 2B1 using liquid chromatography mass spectrometry. Extant data were used to evaluate bivariate associations between OATP2A1 and 2B1 concentrations and 1) maternal factors: maternal age, gestational age, pre-pregnancy BMI, gestational weight gain, parity, delivery mode, complications (PE, GDM, smoking during pregnancy) and 2) infant factors: birth weight, race, sex. Mutually adjusted models were built including predictors with p<0.2 in bivariate analyses. Extended models also considered exposure to environmental toxicants including PFAS (2nd trimester serum), cadmium (placenta), and mycoestrogens (placenta). **Results:** OATP2A1 and 2B1 protein concentrations in term placentas were modestly correlated (r=0.34, p<0.05). Median OATP2A1 and 2B1 transporter enrichment from UPSIDE was 0.49 pmol/mg protein (IQR: 0.34 - 0.67) and 0.27 pmol/mg protein (IQR: 0.18 - 0.37), respectively. In bivariate analyses, OATP2A1 levels were associated with pregnancy complications, infant weight, gestational weight gain, serum PFHxS, and placental cadmium levels. In extended models fit for each toxicant, a one log-unit increase in circulating PFHxS was associated with a 6.2% (95% CI: 0.00, 13.9) increase in OATP2A1 levels, while a one log-unit increase in placental cadmium levels was associated with a 4.1% (95% CI: 1.0, 8.3) increase. By comparison, in bivariate analyses, OATP2B1 levels were associated with gestational age, parity, serum PFHxS, and placental mycoestrogen levels. In mutually adjusted models, only parity was associated with a 6.18% (95%CI: 2.02, 9.42) increase in OATP2B1 levels. **Conclusions:** To our knowledge, this is the first study to explore predictors of placental OATPs in a human cohort. OATP2B1 was higher in multiparous preg-

nancies similar to other xenobiotic transporters which may indicate a maternal adaptation during subsequent pregnancies. By comparison, OATP2A1 protein levels were positively correlated with cadmium and PFHxS. We speculate that induction of OATP2A1 following toxicant exposure influences overall uteroplacental prostaglandin handling, an important mechanism that regulates induction of labor and rupture of the fetal membranes. Supported by T32ES007148, R01ES029275, R01HD083369, UG3OD023349, UH3OD023349, P30ES005022, UL1TR003017, S10RR024595, and UC2HD113039.

PS 4272 Integrating Toxicological and Economic Evidence to Optimize Repurposing Strategies for Rare Diseases

M. Mohsenin¹, D. Thomas², and S. Winter³. ¹Elsevier, Pompton Lakes, NJ; ²Elsevier, San Diego, CA; and ³Elsevier, Amsterdam, Netherlands. Sponsor: D. Thomas, International Society for the Study of Xenobiotics

Background and Purpose: Rare diseases pose major challenges for drug development due to small patient populations, phenotypic variability, and limited commercial incentives. These barriers hinder conventional efficacy and safety studies, slowing therapeutic progress despite increasing biological insight. Drug repurposing—identifying new indications for existing compounds—offers a practical route to accelerate therapy development by leveraging known pharmacological and toxicological data. However, most repurposing initiatives emphasize biological plausibility while neglecting comprehensive safety or outcomes evidence. Toxicological data defining exposure limits and organ-specific liabilities are seldom examined alongside health economic and outcomes research (HEOR) data describing treatment burden and healthcare utilization. Integrating these domains early in the repurposing process may improve candidate selection, inform dose optimization, and strengthen regulatory justification. This study developed and applied a structured framework that synthesizes toxicological, mechanistic, and economic evidence to support early decision-making in rare disease repurposing. Pirfenidone, an anti-fibrotic agent approved for idiopathic pulmonary fibrosis (IPF), was evaluated for potential use in systemic sclerosis-associated interstitial lung disease (SSc-ILD), a rare fibrotic disorder with high morbidity and limited therapeutic options. **Methods:** A cross-database evidence synthesis integrated toxicological, mechanistic, and translational data across four major resources: **PharmaPendium - Regulatory Toxicology and Clinical Exposure Data:** Extracted exposure-response relationships, no-observed-adverse-effect levels (NOAELs), and organ-specific findings from preclinical and regulatory submissions, normalized using MeDRA taxonomy. Cross-species comparisons established exposure thresholds and dose-limiting toxicities relevant to chronic oral dosing. **Embase - Clinical and Post-Marketing Safety Evidence:** Aggregated safety data from clinical trials, pharmacovigilance reports, and post-marketing studies. Adverse events were standardized via Emtree to enable system organ class-level comparison and longitudinal analysis of chronic antifibrotic therapy. **Embiology - Mechanistic and Pathway Mapping:** Mapped pirfenidone's molecular targets and pathway-level interactions to assess mechanistic overlap between IPF and SSc-ILD, emphasizing TGF- β and PDGF signaling convergence. **Scopus - Bibliometric and Translational Landscape Analysis:** Characterized research maturity, collaboration networks, and topic clustering in fibrosis and rare disease repurposing, highlighting evidence gaps and translational readiness. Findings were synthesized into a qualitative matrix linking toxicological risk domains, mechanistic plausibility, and economic dimensions, including toxicity-related burden and healthcare resource implications. **Results:** Integrated analysis produced a cross-domain safety-mechanistic-economic profile of pirfenidone for rare disease repurposing. Regulatory data defined exposure-dependent toxicities relevant to chronic antifibrotic use. Clinical and pharmacovigilance evidence confirmed reproducible safety patterns across populations. Mechanistic mapping revealed substantial biological overlap between pirfenidone's targets and SSc-ILD fibrotic pathways. Bibliometric analysis identified an active but fragmented translational landscape, underscoring the need for integrative data frameworks. Together, these analyses demonstrated the feasibility and value of harmonizing toxicological, mechanistic, and economic evidence for early repurposing evaluation. **Conclusions:** This study presents a reproducible framework for integrating regulatory toxicology, clinical safety, mechanistic, and translational evidence to inform rare disease repurposing. Applied to the pirfenidone-SSc-ILD case, the approach enhances transparency, reproducibility, and scientific rigor in candidate evaluation. Future extensions will incorporate quantitative modeling of toxicity-value relationships to support prioritization across rare therapeutic areas.

PS 4273 Prenatal mycoestrogen exposure in relation to maternal cortisol during pregnancy

A. R. Juenke¹, C. Kinkade¹, A. Brinker¹, B. Buckley¹, J. Brunner², R. Miller², L. M. Aleksunes¹, T. G. O'Connor², Z. Rivera-Núñez¹, and E. S. Barrett¹. ¹Rutgers University, Piscataway, NJ; and ²University of Rochester, Rochester, NY.

Background and Purpose: Zearalenone (ZEN) is a highly prevalent mycotoxin contaminating much of the global food supply. ZEN and its metabolites have been designated as 'mycoestrogens' based on the similarity of their structure to estrogens. Our ongoing work in a U.S. pregnancy cohort suggests that over 90% of participants have detectable ZEN concentrations and that levels are linked to

disruptions in sex steroids as well as in placental corticotropin releasing hormone (CRH), a key hormone in the hypothalamus-pituitary-adrenal (HPA) axis. We have additionally linked early gestational ZEN exposure to altered infant cognition and executive function. Here, we continue that line of research examining maternal ZEN exposure in relation to maternal cortisol, an HPA axis hormone that plays a key role in maternal stress as well as fetal growth and neurodevelopment. **Methods:** In a US pregnancy cohort (UPSIDE; Rochester, NY; n=206), we explored associations between ZEN and its metabolites and maternal cortisol across pregnancy. LC-MS was used to measure ZEN in urine samples collected in each trimester. In each trimester, saliva samples were collected at wake, 45 minutes post-wake, 2.5 hours, 8 hours, and 12 hours post-wake using a take-home collection kit. Salivary cortisol was quantified via immunoassay and diurnal area under the curve (AUC) was calculated as a measure of the total daily cortisol production. In preliminary analyses, we examined Pearson correlations between ZEN and its metabolites (ZEN, alpha-zearalenol (AZOL), and the sum of ZEN and its metabolites (SUM)) and cortisol AUC. **Results:** 95% of participants with cortisol AUC measures had detectable urinary concentrations of ZEN or its metabolites during pregnancy. Cortisol AUC increased across trimesters (median = 49.7, 75.6, and 87.7 nmol/L*hour). ZEN was weakly negatively correlated with maternal cortisol AUC in late pregnancy ($r = -0.13$), while correlations earlier in pregnancy and with other metabolites were null. **Conclusions:** Our results suggest that mycoestrogen exposure is likely not associated with maternal daily cortisol load, but further modeling with adjustment for confounders is underway. Furthermore, cortisol follows a diurnal rhythm, thus additional modeling examining the relationship between mycoestrogen exposure and cortisol dynamics, such as awakening response or diurnal slope, is warranted. Supported by P30ES005022, UG3OD035527, T32E5007148, R01ES029275-02S1, R01HD083369, R21ES032047, UG3/UH3OD0223349, T32ES019854, F31ES034269.

PS 4274 An early pregnancy maternal PFAS mixture is associated with decreased gestational age at birth in a prospective birth cohort

K. A. Campbell¹, A. Morris², S. M. Eick¹, K. Shankar³, K. J. Pearson⁴, A. Andres⁵, and T. M. Everson¹. ¹Emory University Rollins School of Public Health, Atlanta, GA; ²Central Arkansas Veterans Affairs Healthcare System and University of Arkansas for Medical Sciences, Little Rock, AR; ³USDA Agricultural Research Services, Responsive Agricultural Food Systems Research Unit, College Station, TX; ⁴University of Kentucky College of Medicine, Lexington, KY; and ⁵University of Arkansas for Medical Sciences, Little Rock, AR.

Background and Purpose: Per- and polyfluoroalkyl substances (PFAS) are a synthetic class of persistent chemicals to which pregnant individuals are routinely exposed. However, associations with gestational age have been inconsistent, possibly due to factors related to PFAS congener, timing of exposure, and differences in underlying biologic mechanisms. **Methods:** Maternal serum PFAS levels, demographic, and gestational age at birth came from the Growing prospective birth cohort (case complete n=217). Seventeen PFAS were measured in maternal serum collected around week 10 gestation with liquid chromatography-tandem mass spectrometry. We analyzed 5 PFAS (PFOS, PFOA, PFHxS, PFNA, and PFDA) with limit-of-detection (LOD) rates >70% that also had approximately normal distributions following log2-transformation. Below LOD measures were imputed to LOD/sqrt(2) with an LOD of 0.1 ng/mL. All models were adjusted for maternal age, education, body mass index, and fetal sex. Multivariate linear regression tested the association between each PFAS and gestational age separately. Quantile g-computation and Bayesian kernel machine regression (BKMR) tested the association between a joint mixture of all five PFAS and gestational age. Statistical significance was assessed at a p-value < 0.05 cutoff. **Results:** Mean gestational age was 39.3 $\pm$ 1.1 weeks, or 275.0 $\pm$ 7.4 days. Mean maternal age was 29.5 $\pm$ 3.5 years old. Each doubling in maternal serum PFOS or PFHxS alone was associated with a -1.4 [-2.6, -0.2] day or -0.7 [-1.4, -0.01] day decrease in gestational age, respectively. A quartile increase in all 5 PFAS was associated with a -1.5 [-2.8, -0.2] day decrease in gestational age. This mixture estimate was primarily driven by PFOS accounting for 32.8%, PFDA at 27.3%, and PFNA at 27.2% of the effect. In the nonlinear BKMR model, compared to each mixture PFAS at its median, setting each PFAS to the 65th percentile was associated with a -1.0 [2.0, -0.01] day decrease in gestational age. This inverse trend was similar from the 60th to 75th (p=0.05). **Conclusions:** In an otherwise uncomplicated cohort of pregnant women, maternal serum PFOS alone and PFHxS alone in the first trimester were inversely associated with gestational age in linear models. Mixture approaches quantile g-computation and BKMR similarly identified an inverse association between gestational age and a mixture of PFOS, PFDA, PFNA, PFHxS, and PFOA. These results are consistent with prior findings that PFAS can adversely affect gestational age. However, this analysis provides evidence that exposure to a complex mixture early in pregnancy of commonly experienced PFAS can jointly affect gestational age, an important sentinel of broader perinatal health even with effect sizes on the scale of days.

R. B. Tanghal¹, Z. Li¹, A. Paik¹, H. Wang¹, S. Han¹, S. Andra², R. O. Wright², J. A. Goodrich¹, A. C. Maretta-Mira¹, L. Golden-Mason¹, D. V. Conti¹, V. Setiawan¹, and L. Chatzi¹. ¹University of Southern California, Los Angeles, CA; and ²Icahn School of Medicine at Mount Sinai, New York, NY.

Background and Purpose: Per- and polyfluoroalkyl substances (PFAS) are ubiquitous chemicals linked to adverse health outcomes. While diet has been identified as one of the major sources of PFAS exposure, how dietary differences translate into variation in PFAS body burden remains poorly understood. The Planetary Health Diet (PHD), proposed by the EAT-Lancet Commission, is a new dietary framework aimed to reduce chronic disease incidence and environmental degradation by promoting higher consumption of plant-based foods and lower consumption of animal-based foods. We hypothesized that higher adherence to the Planetary Health Diet and specific food components of the dietary framework was associated with lower plasma PFAS concentrations in the Multiethnic Cohort (MEC), a prospective cohort with over 200,000 participants from California and Hawaii. **Methods:** In a subsample of the MEC (N=2,783), plasma PFAS levels were measured in samples collected between 1994 and 2004 using liquid chromatography-mass spectrometry (LC-MS). Planetary Health Diet Index (PHDI) scores were derived from baseline (1993-96) validated food frequency questionnaires and categorized into quintiles. We conducted multivariate linear regression analyses to assess the association between PHDI quintiles and PFAS concentrations. Analyses were adjusted for age at blood draw, sex, race and ethnicity, study area, time between baseline entry and blood draw, body mass index and alcohol intake. Additional models evaluated associations between specific food groups and PFAS concentrations. **Results:** Participants were 56% female with a mean age of 65 years; 56% were Japanese American. PHDI scores ranged from 33 to 120, with higher values reflecting greater adherence. Higher PHD adherence was associated with lower plasma concentrations of sum perfluoro-sulfonic acids (PFSA) (Q5 versus Q1 β : -3.31, 95% CI: -5.55, -1.07; trend $P=0.005$) and sum perfluorocarboxylic acids (PFCAs) (Q5 versus Q1 β : -0.47, 95% CI: -1.00, 0.06; trend $P=0.066$). This association may be explained by reduced intake of PFAS-contaminated animal products and increased consumption of plant-based foods with higher PHDI scores. By food group, each standard deviation (SD) increase in whole fruit intake was associated with 3.36% lower Σ PFSA concentrations (β : -0.034), whereas each SD increase in eggs intake was associated with 4.40% higher Σ PFSA concentrations (β : 0.043). **Conclusions:** Higher adherence to the PHD is associated with lower PFAS concentrations, particularly PFSA. These findings suggest that plant-based diets aligned with the PHD may help reduce PFAS exposure and mitigate associated health risks.

D. Van Deventer¹, B. Ritz¹, J. E. Heck^{2,1}, and M. Cockburn¹. ¹University of California, Los Angeles, Los Angeles, CA; and ²University of North Texas, Denton, TX. Sponsor: O. Hankinson

Background and Purpose: Previous studies investigating neuroblastoma risk and parental pesticide exposure have had mixed findings, with some evidence linking maternal occupational or residential exposure to increased risk. However, most assessed pesticides broadly rather than evaluating specific compounds. To our knowledge, no studies have examined ambient residential exposure to individual pesticides and neuroblastoma risk. The purpose of this study is to evaluate associations between childhood neuroblastoma and prenatal exposure to specific pesticides through residential proximity to agricultural applications. **Methods:** We identified neuroblastoma cases from the California Cancer Registry and cancer-free controls from birth certificates. Analyses were restricted to children born 1998-2016 whose mothers lived within 4,000 meters of an agricultural pesticide application during pregnancy (199 cases, 202,796 controls). Probable and possible carcinogens were selected based on U.S. EPA classifications and pesticide use was collected from the California Pesticide Use Reporting system linked to land-use surveys. Exposures were assessed using a 4,000m buffer around geocoded residential addresses at birth. We used a distance decay model and considered pregnancies exposed when the poundage per acre applied exceeded the pesticide-specific median. We analyzed 68 pesticides with at least 5 exposed cases using unconditional logistic regression and hierarchical models co-adjusted for all pesticides. **Results:** In hierarchical models, we observed elevated risks of neuroblastoma with prenatal exposure to flonicamid (aOR: 1.33; 95% CI: 1.02-1.73), benomyl (aOR: 1.53; 95% CI: 0.98-2.38), cypermethrin (aOR: 1.24; 95% CI: 0.96-1.60), and permethrin (aOR: 1.20; 95% CI: 0.96-1.50). **Conclusions:** Our findings suggest that ambient exposure to certain pesticides during pregnancy may increase the risk of neuroblastoma.

A. Orr, C. Leary, and E. Landguth. University of Montana, Missoula, MT.

Background and Purpose: Quantifying and communicating the health risks of environmental exposures remain central challenges in toxicology and risk assessment. Air pollutants such as fine particulate matter (PM_{2.5}), volatile organic compounds, and wildfire-related air toxics are well-known contributors to respiratory and cardiovascular disease, yet the data used to assess these risks are often siloed, technical, and inaccessible to the public. To address this gap, we developed the Montana Healthy Places Dashboard, an interactive, public-facing platform that integrates environmental and public health data to support transparent, community-level risk assessment. **Methods:** The dashboard links datasets on air pollution (e.g., PM_{2.5}, wildfire smoke, and air toxics), meteorology, and social determinants with state level health outcomes such as asthma, premature death, and other exposure-related conditions. Data are displayed through interactive maps, trend visualizations, and downloadable summaries that enable users to explore exposure response relationships, temporal patterns, and geographic disparities. **Results:** Importantly, the platform was designed for diverse stakeholders, state health departments, county and local public health agencies, state legislators and policy representatives, environmental and toxicological researchers, educators, and community organizations. Each group can use the Dashboard to support their unique objectives: public health officials can identify local environmental risk hotspots; policymakers can evaluate data to inform evidence-based legislation; and scientists can access curated datasets for exposure modeling and hypothesis generation. By grounding data visualization in toxicological principles such as cumulative exposure, and population susceptibility, the platform enhances both scientific and public understanding of environmental health risks. **Conclusions:** This work demonstrates how integrating toxicology-based data interpretation with open-access design can advance environmental justice, promote informed policy, and empower local communities to engage in evidence-based decision-making. The Montana Healthy Places Dashboard serves as a model for how risk assessment can move beyond the laboratory making the science of toxicity visible, usable, and actionable for all stakeholders.

M. Salim Saker Santos Lima¹, S. Doherty-Lyons¹, G. Meltzer², J. T. Zelikoff¹, K. Lynch³, and V. Mann⁴. ¹NYU Langone Health, New York, NY; ²American University, Washington, DC; ³NYU School of Global Public Health, New York, NY; and ⁴Ramapough Lunape Turtle Clan Nation, Ringwood, NJ.

Background and Purpose: Native Americans face disproportionate exposure to environmental contamination that affects their physical and mental health, food sovereignty, and culture. The Ramapough Turtle Clan, residing on the Ringwood Mines Superfund Site in Ringwood, New Jersey, has been the intentional target of toxic dumping for over a decade. This qualitative interview study revealed in-depth information to explore and understand concepts, opinions, and experiences related to dealing with and facing environmental pollution on a daily basis. **Methods:** In-depth, semi-structured interviews were conducted with ten members of the Ramapough Lenape Turtle Clan. Participants were asked about their sense of place, perceptions of risk associated with Superfund sites, the impacts of the Ringwood Superfund site on their health, food availability, nutrition, and access to healthcare. Interviews were transcribed and analyzed using Dedoose for a thematic analysis. Codes were developed to identify frequent themes related to food sovereignty, loss of cultural traditions, and physical and mental health. **Results:** Thematic analysis revealed five major themes out of 64 codes in total: (1) Loss of cultural traditions such as fishing, hunting, and gardening due to contamination; (2) Food sovereignty, including restricted access to safe and culturally significant food sources; (3) Health disorders and disparity, highlighting disproportionate self-reported personal health issues and/or those identified among interviewees' family and friends (e.g., cancer and type-2 diabetes); (4) Mental Health aspects associated with historical contamination and cultural loss; and (5) Intersection of contamination and specific diseases, reflecting the community's thoughts on the connection between their health issues and the dumping. Participants generally described how their lives had changed since the contamination, including the burden of uncertainty about whether their ancestral land and homes were still contaminated, the authorities' neglect, and their desire for meaningful and effective remediation efforts. **Conclusions:** The findings from this study highlight the importance of culturally and community-driven approaches in environmental health research, which focus on the impacts of toxic waste dumping on Indigenous communities and acknowledge the interconnection between land, culture, and health. Moreover, such research contributes to protecting public health by addressing structural inequalities and prioritizing environmental justice (in this case) through the voices of the Ramapough Lenape Turtle Clan members. Qualitative data are essential for designing equitable interventions/preventions that sustain both environmental and cultural balance.

¹ToxStrategies, A BlueRidge Life Sciences Company, Asheville, NC; and ²Kenvue Medical Clinical and Safety Sciences, Summit, NJ.

Background and Purpose: Observational epidemiological evidence, including case-control and cohort studies, are increasingly used to support decision making, however these studies have inherent design limitations that introduce uncertainty. Qualitative risk of bias (RoB) approaches assist in identification of potential biases from population selection, confounding, exposure misclassification, and/or outcome misclassification in epidemiological studies. However, RoB judgments are subjective and cannot inform on the magnitude of bias and whether it is sufficiently large to impact study conclusions. Quantitative bias assessments (QBA) include post-hoc methods that can quantify the direction and impact of such systemic biases on results and therefore can be used to inform certainty (or uncertainty) in individual studies as well as a body of evidence. The objective of this study was to conduct QBA and evaluate the impact of exposure misclassification and confounding biases in observational studies assessing acetaminophen use and liver cancer.

Methods: Literature that evaluates associations between acetaminophen use and liver cancer incidence was systematically identified. Qualitative RoB assessments were conducted using the National Toxicology Program (NTP) Office of Health Assessment and Translation (OHAT) RoB tool with topic-specific refinements. Key bias areas were evaluated using QBA techniques that augment reported information through probabilistic simulation of marginal tables that include unmeasured confounding and/or exposure misclassification information while maintaining fidelity to the marginal data counts. Bayes' rule was used to determine probabilities of unobserved counts based on assumptions, such as the expected magnitude of confounding or sensitivity and specificity of exposure classification. Misclassification of exposure and unobserved interactions between alcohol and acetaminophen use and their impacts on observed liver cancer incidence were evaluated both independently and in a joint model that considers multiple systemic biases. The impact of unmeasured confounding was evaluated using both an additive and an interactive model. **Results:** Identified studies ($n = 4$) included retrospective and prospective cohorts and nested case-control designs that evaluated the risk of liver cancer incidence associated with acetaminophen use across three distinct populations. Each of the identified studies were qualitatively judged to have a high RoB due to uncertainties in exposure characterization and limited adjustment for confounding factors, including protopathic bias (i.e., use of acetaminophen for cancer-related pain), channeling biases (i.e., preferential use of acetaminophen due to underlying health conditions that contraindicate use of NSAIDs), or interactions between concurrent alcohol and acetaminophen use. QBA for exposure misclassification, alone, showed marginal changes in the observed risks. Models evaluating the impact of unmeasured confounding, alone, shifted relative risks toward null findings, with a greater impact in the interactive model (0 to 88.4% of models identifying significant effects across simulations, depending on study) as compared to the additive models (0.2 to 100% of the simulated models, depending on study). Joint evaluation of exposure misclassification and unmeasured confounding shifted reported relative risks further towards the null indicating a synergism; here, only 0-19.2% of simulated models were significant when an interaction model was included. **Conclusions:** The QBA shows that unmeasured confounding attributable to interactions between alcohol use and acetaminophen intake has a substantial impact on observed liver cancer risks. QBA tools enable informed judgment making on the potential impact of residual or unmeasured confounding and/or biases in observational epidemiological evidence. Incorporation of these methods in hazard and risk characterizations supports uncertainty analysis and quantitative assessments of the strength and confidence in underlying epidemiological evidence.

PS 4280 Nicotinamide shows evidence of protection against breast cancer in prospective pregnancy cohort

P. M. Cirillo¹, X. Hu², N. Y. Krigbaum¹, B. Minasenko², S. Teeny², Y. Go², D. P. Jones², and B. A. Cohn¹. ¹Public Health Institute, Oakland, CA; and ²Emory University, Atlanta, GA.

Background and Purpose: Previously we found that maternal floor infarction (MFI) of the placenta, a pathology characterized by fibrin deposition on the maternal surface, protected against breast cancer in mothers and daughters in the Child Health and Development Studies (CHDS). We conducted a Metabolome Wide Association Study (MWAS) in trimester 3 (T3) serum comparing MFI pregnancies with controls to discover breast cancer protective pathways and metabolites. **Methods:** The study is based on an 8% random case-cohort sample of CHDS women with available placental information, pregnancy serum and cancer diagnoses through 1997: $N = 566$ in T3 with 43 MFI pathologies and 153 breast cancer cases. Untargeted pathway and metabolite analyses were performed using Rodin (<https://github.com/BM-Boris/rodin.git>). HLIC ESI+ feature intensities were quantile normalized, log2 transformed and tested using one-way ANOVA to discover MFI-enriched pathways ($p < 0.05$). Identified MFI-related metabolites were then tested in proportional hazards models, fitted to a case-cohort study design, to directly determine whether they were associated with risk of subsequent maternal breast cancer. Interactions between metabolites and MFI were tested by adding a product term between MFI and the metabo-

lite. **Results:** MFI-enriched T3 pathways included serine, aspartate and asparagine, phytanic acid oxidation and Vitamin B3 metabolism. Notable, within the Vitamin B3 metabolic pathway, nicotinamide was identified as a significant down-regulated metabolite ($p = 0.02$). When tested in a proportional hazards model, nicotinamide was associated with a 30% protection against future breast cancer (Relative Hazard = 0.7; 95% Confidence Limit = 0.5 to 1.0), that was independent of MFI. **Conclusions:** Nicotinamide in T3 was down-regulated in MFI pregnancies and lower levels were associated with decreased risk of subsequent breast cancer, consistent with MFI protection against breast cancer, but independent of the protective benefit of MFI suggesting multiple pathways to breast cancer development. Nicotinamide is a vitamin B3 precursor of NAD+ (nicotinamide adenine dinucleotide) which is essential for cellular energy regulation, and can directly impact DNA repair, cell senescence and immune processes. NAD+ has been implicated in tumor initiation through dysregulation of DNA repair and cell death and in promoting tumor progression via cellular energy alterations to satisfy the extensive energy demands required for rapidly proliferating cancer cells. Our findings support current efforts targeting NAD+ metabolism for potential therapeutic strategies. Next steps are feature confirmation and targeted examination of breast cancer associations for the intermediary and terminal metabolic features in the metabolism of NAD+ to explore interactions between NAD+, its precursor metabolites and breast cancer risk.

PS 4281 Vibration of effects analysis on cancer mortality for robust discovery of environmental toxicants of aggressive cancers

V. K. Nguyen¹, S. Zimmerman², L. Middleton¹, R. Rudel³, M. B. Terry³, C. Patel⁴, and J. Colacino¹. ¹University of Michigan, Ann Arbor, MI; ²The Broad Institute of MIT and Harvard, Cambridge, MA; ³Silent Spring Institute, Newton, MA; and ⁴Harvard Medical School, Boston, MA.

Background and Purpose: Chemical exposures have been linked to cellular processes making cancer cells more aggressive. Epidemiological studies have examined the associations between chemical exposures and cancer mortality, which is a population-level surrogate of cancer aggressiveness. But their findings differ due to variations in model specifications, such as covariate selection and linear vs. non-linear assumptions. These differences reflect how multiple analytical choices can lead to divergent conclusions about which chemicals are associated with increased risk for cancer mortality. A vibration of effects (VoE) approach systematically quantifies how such modeling decisions influence the estimated associations, thereby enabling the identification of associations between chemical exposures and cancer mortality that are most robust across model specifications. Such insights can guide prevention measures and improve patient outcomes. **Methods:** Using biomonitoring data from 34,100 US women in the National Health and Nutrition Examination Study (NHANES) 1999-2018, we assessed which of 259 chemical biomarkers are consistently associated with cancer mortality across model adjustments (1,639 deaths). First, we selected the following biological or behavioral covariates based on prior literature: age, race/ethnicity, parity, menopause status, current smoking habits through cotinine biomarker levels, poverty income ratio, educational level, hormone replacement therapy, BMI, and survey cycles. Second, we ran Cox proportional hazard models for all possible combinations of these covariates to assess how varying model adjustments influenced estimated risks. We evaluated both linear and non-linear associations. For non-linearity, we discretized the biomarker levels into nine quantiles (novemtiles). Third, we quantified the stability of each chemical's associations by defining a VoE p-value from the 1st and 99th percentiles of its distribution of hazard ratios across all models. Finally, we prioritized chemicals with a VoE p-value ≤ 0.02 , implying that the chemical is consistently associated with cancer mortality risk across multiple specifications. **Results:** We identified 27 chemical biomarkers with levels consistently associated with risk for cancer mortality. Participants with cotinine levels indicative of heavy tobacco exposure (170-478 ng/mL) had a 2.68-fold greater risk of dying from cancer (VoE p-value = 6.1×10^{-9}) compared with those with minimal exposure (0.011-0.018 ng/mL). Elevated levels of cadmium (0.50-3.00 ug/L, HR = 2.29-3.58, VoE p-values = 2.04×10^{-6} - 3.46×10^{-3}), lead (2.30-5.37 ug/dL, HR = 3.27, VoE p-value = 0.003), and potassium (4.30-4.80 mmol/L, HR = 1.85, VoE p-value = 0.001) were each associated with increased risk of cancer mortality. o-Desmethylnangolensin exhibited low dose effects at 0.4-0.9 ng/mL (HR = 2.23, VoE p-value = 0.01), but higher biomarker levels were near null and not consistent. Similarly, levels of mono-3-hydroxy-n-butyl phthalate at 0.50-0.70 ng/mL (HR = 8.52, VoE p-value = 0.008) showed elevated risk compared to the minimal levels, and while higher levels were linked to higher risk of cancer death, the risk was not consistent. In contrast, higher biomarker levels of Vitamin D and carotenoid-related dietary components (α -carotene, α -cryptoxanthin, β -cryptoxanthin, trans-lycopene, and phytofluene) were associated with lower risk. Gamma-tocopherol exhibited a non-linear relationship: levels between 91.7-252 ug/dL were protective, whereas risk increased beyond this range. **Conclusions:** Leveraging a population-based cohort study, we identified chemicals consistently associated with cancer mortality across varying model specifications. While meeting Bradford Hill's criterion of consistency strengthens confidence in these associations and supports their plausibility for causation, it does not by itself establish causality. Experimental validation is still needed to elucidate the mechanisms by which such chemicals influence aggressive cancers. Accordingly, we are planning experiments to examine the chemical effects on cell migration and invasion, which are key processes underlying metastasis.

F. C. Sillé, and T. Hartung. Center for Alternatives to Animal Testing (CAAT), Department of Environmental Health and Engineering, Johns Hopkins Bloomberg School of Public Health, Baltimore, MD.

Background and Purpose: The Human Exposome Project represents the next frontier in precision environmental health—a globally coordinated effort to systematically map, measure, and mitigate the environmental determinants of disease. Approximately 70-90% of chronic diseases have environmental rather than genetic roots, highlighting the critical need to comprehensively map and understand the exposome—the totality of chemical, physical, biological, and psychosocial influences that interact with our biology across the lifespan. Complementing the Human Genome Project, the Human Exposome Project aims to capture the exposure side of disease and translate this understanding into precision prevention and health protection. **Methods:** Utilizing advanced sensors, artificial intelligence (AI), precision analytics, and predictive biological tools, the Human Exposome Project will revolutionize public health by enabling precise interventions based on robust, real-time data rather than relying on retrospective epidemiological analyses. This integration of “Exposome Intelligence”—the convergence of exposomics and AI—will enable the discovery of exposure-disease relationships at unprecedented scale and resolution, transforming how we detect, predict, and mitigate environmental health risks. **Results:** In May 2025, more than 400 global leaders convened in Washington, D.C. for the inaugural Exposome Moonshot Forum, formally launching the Global Exposome Forum (GEF) and signing the Washington D.C. Declaration on the Human Exposome. Building on this foundation, the GEF has begun developing an actionable Roadmap for the Human Exposome Project. The Roadmap defines five foundational pillars: (1) Big Data, AI, and Analytics; (2) Measurement Technologies and Standards; (3) Population and Cohort Integration; (4) Policy, Regulation, and Implementation; and (5) Capacity Building and Workforce Development, supported by cross-cutting themes such as, Global governance and collaboration, Ethics, Legal, and Social Aspects (ELSA), Stakeholder engagement and Communication, FAIR data interoperability, and Economics and Sustainability. The near-term (≤ 2 years) phase focuses on establishing an interim global governance structure, harmonized data standards, and pilot projects linking population cohorts across regions. Mid-term priorities (3-8 years) center on scaling infrastructure, deploying validated measurement technologies, federated data platforms, and AI models that can process heterogeneous exposure data at scale. The long-term horizon (9-16 years) envisions exposome data integration into clinical and regulatory decision-making, the creation of a living Global Exposome Atlas, and measurable reductions in exposure-related disease burden. **Conclusions:** This roadmap transforms exposomics from a conceptual framework into a mission infrastructure—anchored in open science, equitable participation, and human-relevant evidence. By aligning standards, governance, and technology across continents, the Human Exposome Project will enable the transition from reactive medicine to precision prevention, redefining public health for the 21st century.

PS 4283 Accelerating the Adoption of Safer Chemistry in Household and Industrial Cleaners: A Data-Driven Solution for Cleaner and Degreaser Ingredient Optimization

G. Rigutto, H. McKenney, and C. Bartlett. ChemFORWARD, San Francisco, CA.

Background and Purpose: Hazards associated with industrial and household cleaners have previously been underscored by parallel longitudinal studies focusing on household cleaning products, which demonstrate that regular chemical exposure associated with household cleaning is linked to significant lung function decline in women equivalent to smoking 20 cigarettes a day for 20 years (Svanes et al., 2018). Similarly, the extensive use of chemical cleaners and degreasers in electronics (and other consumer goods) assembly presents critical occupational health risks, including, but not limited to, those related to respiratory health. ChemFORWARD is a not-for-profit organization (NGO) that maintains a centralized online platform of comprehensive chemical hazard assessments (CHAs) spanning >20 human and environmental health endpoints designed to support users in selecting safer chemical ingredient alternatives for products across diverse industry sectors, including cosmetics, food packaging, plastic additives, and industrial and household cleaners. **Methods:** To mitigate the risks posed by hazardous ingredients, we collaborated with brands, NGOs and certification programs working to scale the availability and accelerate the adoption of safer cleaners that protect workers and the environment. This presentation will demonstrate how the tool enables users to identify chemicals of high hazard and provide a framework for identifying safer, functional alternatives to high hazard chemicals used in cleaners by leveraging known functional data (e.g. solvent, surfactant) as well as similarity calculations with regard to key characteristics: solubility, molecular structure, and physical/chemical properties. **Results:** The ChemWorks collaboration launched a dedicated, free, web-based Cleaners and Degreasers Ingredient Optimization Tool Application (Chemworks.org) designed to support the transition to safer cleaners, including a registry of trade name materials that are accepted by leading frameworks such as GreenScreen Certified™, EPA Safer Choice, and ToxFMD®. Further, we identified certain hazard traits as failing to meet the criteria for safer cleaners, particularly chemicals with respiratory sensitization and inhalation toxicity. In combination, ChemWorks and CHAs provide a roadmap to substituting hazardous with safer functional alternatives, reducing risk

across the value chain from manufacturing to consumer and end-of-life. We will share case studies where chemical selection using these tools supports data-driven chemical management decisions for the development of safer cleaning products. **Conclusions:** By enabling formulators to optimize their product formulations against rigorous criteria, the platform has potential to significantly reduce development cost, accelerate time-to-market, and simplify the pathway to product verification. The adoption of this transparent, data-driven approach removes technical, financial, and informational barriers, thereby institutionalizing safer chemical stewardship across both the industrial and household cleaner supply chain and accelerating the industry-wide transition toward verified safer cleaning solutions.

PS 4284 Exosomal miRNA Profiles Identify Resolving Versus Non-Resolving Pulmonary Inflammation Following Nanoparticle Exposure

A. E. Siddique¹, X. Jing¹, S. Rajaram¹, Z. Hutchins², P. Thorne¹, Y. Wang², J. Cho¹, and A. Adamcakova-Dodd¹. ¹University of Iowa, Iowa City, IA; and ²University of California, Riverside, Riverside, CA.

Background and Purpose: Exosomes, small extracellular vesicles carrying proteins, lipids, and regulatory RNAs, are emerging as key mediators of intercellular signaling, immune regulation, and disease progression. Inhalation of engineered nanoparticles (NPs) has become a significant public health concern due to their widespread use in consumer, industrial, and biomedical applications, as well as unintentional occupational exposures. These particles (<100 nm) can penetrate deep into the lungs, where they interact with epithelial and immune cells, generate reactive oxygen species, and activate pro-inflammatory pathways. While acute inflammation is a protective host response, failure to resolve the inflammation drives chronic disease, including asthma, COPD, pulmonary fibrosis, and cancer. Our previous studies demonstrated that inhaled copper oxide (CuO) NPs produce self-limiting inflammation, whereas cadmium sulfide (CdS) NPs sustain persistent immune activation. This study aimed to determine whether exosomal microRNAs (miRNAs) distinguish resolving from persistent NP-induced inflammation and which miRNAs play a role in these two distinct conditions. **Methods:** Female C57BL/6J mice (4 weeks old) were acutely exposed (4 h, ~3.3 mg/m³) to CuO (40 nm) or CdS (60 nm) aerosols in a nose-only inhalation system. Aerosols were generated by a 6-jet Collision nebulizer, dried, charge-neutralized, and characterized by scanning mobility particle size analysis (geometric means: 33.3 nm CuO, 40.8 nm CdS). Lung dosimetry by ICP-MS confirmed clearance of Cu by day 7, whereas Cd persisted beyond day 7. Bronchoalveolar lavage fluid (BALF) was collected on days 1, 3, and 7. Exosomes were isolated from BALF using ExoRNeasy columns, quantified by Horiba ViewSizer and Qubit assays, and profiled for miRNA cargo using the NanoString nCounter Mouse miRNA Panel. Statistical analyses were performed using GraphPad Prism and R. **Results:** BALF analyses showed neutrophil and total cell counts peaked on day 3 for both NPs. By day 7, CuO-induced inflammation largely resolved, while CdS-exposed mice retained elevated neutrophils, proinflammatory cytokines, and M1 macrophage recruitment. Flow cytometry analyses of lungs confirmed neutrophil infiltration, macrophage polarization, and epithelial injury signatures normalized in CuO lungs but persisted in CdS lungs. Exosome concentrations paralleled these kinetics: CuO-induced transient increases that returned to baseline by day 7, while CdS exposure sustained elevated and larger vesicles. miRNA profiling revealed distinct temporal patterns. CuO triggered early upregulation of miRNAs by day 1, mixed regulation by day 3, and normalization by day 7. In contrast, CdS exposure predominantly induced downregulation of miRNAs at the beginning, followed by a trend toward upregulation at later time points. Both CuO and CdS exposures altered miR-200a, miR-148a, and miR-1224, which are key regulators of epithelial repair, macrophage activation, and neutrophil trafficking, respectively. Distinct signatures also emerged: CuO exposure induced resolution-linked miRNAs (miR-21, miR-146a, miR-223), which promote neutrophil clearance, macrophage M1→M2 transition, and epithelial repair. In contrast, CdS exposure suppressed these protective signals and sustained pro-inflammatory miRNAs (miR-155, miR-31, miR-34a), consistent with chronic immune activation and impaired resolution. Pathway enrichment analyses (GO, KEGG, MSIGDB) demonstrated that CuO-associated miRNAs engaged pro-resolution signaling networks, while CdS diminished immune-suppressive and tissue-repair pathways. **Conclusions:** Exosomal miRNA cargo provides a molecular fingerprint of inflammation trajectory, distinguishing resolving (CuO) from persistent (CdS) pulmonary responses. These findings fill a critical knowledge gap by linking immune cell behavior, nanoparticle properties, and exosome signaling to the fate of lung inflammation. Exosomal miRNAs emerge as both biomarkers of exposure effects and potential therapeutic targets. By elucidating how nanoparticles influence inflammatory resolution, this work lays a foundation for exosome-based diagnostics and therapeutics to mitigate environmentally induced chronic lung disease.

PS 4286 Delta-8-Tetrahydrocannabinol Attenuates Colitis in Mice by Modulating Innate Immune Cell Polarization Involving Epigenetic Alterations

J. I. Garcia-Sanchez, M. Nagarkatti, and P. Nagarkatti. University of South Carolina School of Medicine, Columbia, SC.

Background and Purpose: Colitis is an inflammatory bowel disease characterized by persistent autoinflammation in the colon. While Delta-9-tetrahydrocannabinol (Δ^9 -THC) is known to exhibit anti-inflammatory effects and reduce hyperinflammation in colitis, this study specifically investigated the impact of Δ^8 -THC, a less psychoactive analog on colitis. The research focused on how Δ^8 -THC influences key innate immune cells—macrophages, neutrophils, and dendritic cells—and the specific miRNAs that may mediate these effects. **Methods:** Colitis was induced in C57BL/6 mice using dextran sodium sulfate (DSS). Mice were treated with either a vehicle or 20 mg/kg Δ^8 -THC administered intraperitoneally every other day for nine days. Euthanasia occurred on day 10, three days after DSS administration ceased and colitis was established. **Results:** Macroscopic data indicated that Δ^8 -THC treatment significantly reduced the colitis phenotype, evidenced by less colon shrinkage, decreased weight loss, and improved colonoscopy scores. At a cellular level, Δ^8 -THC treatment resulted in an overall decrease in myeloid cells and a direct shift in macrophage populations: pro-inflammatory M1 phenotype macrophages decreased, while anti-inflammatory M2 macrophages increased. This phenotypic shift was associated with specific miRNA changes identified through sequencing and IPA analysis. Notably, levels of let-7a-5p, a miRNA known to inhibit both CD86 and TLR4 expression, increased significantly. Targets were verified *in silico* alignment and qPCR from *in vivo* colon samples. **Conclusions:** Together, these findings demonstrate that Δ^8 -THC treatment alters miRNA expression that promote an anti-inflammatory phenotype in the colon, suggesting therapeutic potential for inflammatory bowel diseases. Also, because Δ^8 -THC exhibits less psychoactive properties than Δ^9 -THC, it may be better suited for clinical treatment of inflammatory diseases (Supported by NIH grants P20GM103641, P30GM154631, R01ES030144, and R01AI160896 to PSN and MN).

PS 4287 Indole-3-Carbinol, an AhR ligand, Attenuates Colitis by Suppressing miR-92a and miR-7a to Restore Antimicrobial Peptide Expression and Microbial Homeostasis

M. Palrasu, H. Hamida, K. Kakar, S. Thada, A. Marudamuthu, Y. Zhong, P. Nagarkatti, and M. Nagarkatti. University of South Carolina, Columbia, SC.

Background and Purpose: Antimicrobial peptides (AMPs) serve as a primary defense against infections and play a crucial role in maintaining gut microbial and immune balance. An imbalance between pro- and anti-inflammatory cells is a hallmark of ulcerative colitis (UC), but the underlying molecular mechanisms remain unclear. MicroRNAs (miRNAs) are key regulators of inflammatory responses in various diseases, including UC. In this study, we investigated the functional roles of disease-promoting miRNAs in regulating AMPs, which in turn influence immune response, microbial dysbiosis and colitis. **Methods:** AhR-deficient mice and wild-type controls were used to evaluate the effects of Indole-3-carbinol (I3C) in dextran sulfate sodium (DSS)- and anti-CD40-induced models of colitis. Disease severity was assessed by monitoring changes in body weight, measuring colon length, and performing histopathological analysis. To characterize gut microbial composition, 16S rRNA gene sequencing of colonic contents from control and colitic mice was conducted using the MiSeq platform. Molecular analyses, including miRNA sequencing, quantitative PCR, and Western blotting, were performed to examine the expression of relevant microRNAs and antimicrobial peptides. **Results:** In this study, we identified a major disease-promoting role for microRNA-92a-1-5p (miR-92a) and microRNA-7a-5p (miR-7a) in both DSS- and anti-CD40-induced models of colitis. We also observed similar results in murine adenocarcinoma MC38 cells treated with DSS. Elevated levels of miR-92a and miR-7a were associated with reduced expression of antimicrobial peptides (AMPs) Reg3a and Reg3b respectively, accompanied by marked microbial dysbiosis. This dysbiosis was characterized by an increase in disease-promoting Gram-negative bacteria and a decrease in beneficial Gram-positive bacteria, contributing to intestinal inflammation. Treatment with Indole-3-carbinol (I3C), a ligand for AhR, restored microbial and immune homeostasis and significantly attenuated colitis severity. Mechanistically, I3C downregulated the expression of miR-92a and miR-7a, relieving their repression of Reg3a and Reg3b, thereby enhancing AMP expression, improving microbial balance, and mitigating intestinal inflammation in both DSS- and anti-CD40-induced colitis models. **Conclusions:** Our results demonstrate that miR-92a and miR-7a drive intestinal inflammation by reducing antimicrobial peptides and sustaining microbial imbalance, implicating these miRNAs as potential therapeutic targets for colitis. (Supported by NIH grants P20GM103641, P30GM154631, R01ES030144, and R01AI160896).

PS 4288 Potential contribution of sphingosine-1-phosphate to crystalline silica-induced NLRP3 inflammasome activation

J. M. Albright, R. L. Kendall, and A. Holian. The University of Montana, Missoula, MT.

Background and Purpose: Silicosis is a debilitating lung disease caused by respiratory exposure to crystalline silica particles (cSiO₂). It is well known that inhaled cSiO₂ are phagocytosed by alveolar macrophages leading to NLRP3 inflammasome activation and subsequent IL-1 β release resulting in chronic lung inflammation and fibrosis. Furthermore, previous research suggests that sphingomyelin metabolism is activated in alveolar macrophages during silicosis disease pathology. The present study investigated the role of sphingomyelin metabolism in cSiO₂-induced lysosome membrane permeability (LMP) and NLRP3 inflammasome activation. **Methods:** Murine macrophages were pretreated with specific inhibitors of acid sphingomyelinase (aSMase) or sphingosine kinase 2 (SphK2) and exposed to cSiO₂ before measuring LMP, NLRP3 inflammasome activation, and S1P production. LMP was determined based on the detection of lysosomal enzyme activity in cytosol extracts. IL-1 β release from macrophages was used as a proxy measurement of NLRP3 inflammasome activation. S1P levels were measured in cell lysates using ELISA. **Results:** S1P production was elevated in macrophages in response to cSiO₂ exposure. In addition, inhibiting S1P production by inhibiting aSMase or SphK2 enzyme activity, in turn, attenuated cSiO₂-induced LMP and IL-1 β release. **Conclusions:** The results suggest that cSiO₂ uptake by macrophages leads to LMP, which activates the NLRP3 inflammasome through a mechanism that may involve increased S1P production.

PS 4289 HSCs-Macrophage Cross-Talk Mediated by IL-11 Exacerbates Liver Fibrosis.

Y. Zhang^{1,2}, J. Chen^{1,2}, and L. Gong^{1,2}. ¹Center for Drug Safety Evaluation and Research, State Key Laboratory of Drug Research, Shanghai Institute of Materia Medica, Shanghai, China; and ²Zhongshan Institute for Drug Discovery, Shanghai Institute of Materia Medica, Chinese Academy of Sciences, Zhongshan, China.

Background and Purpose: Liver fibrosis is a pivotal stage leading chronic liver diseases toward cirrhosis. It is consensus that the hepatic microenvironment shaped by intricate networks of non-parenchymal cells plays a decisive role during fibrogenesis, among which the communication between hepatic stellate cells (HSCs) and macrophages aroused researcher's attention. Interleukin-11 (IL-11) has been identified as a pro-fibrogenic cytokine, mainly characterized in the context of hepatocyte-HSCs signaling. However, its potential involvement in mediating the interplay between HSCs and macrophages, as well as the underlying molecular mechanisms, remains poorly understood. **Methods:** To explore the function of IL-11 in hepatic fibrosis by overexpressing it in HSCs of CCl₄-administrated mice using AAV6. The underlying mechanisms were probed with RNA sequencing and *in vitro* assays. Additionally, *in vivo* macrophage depletion studies were performed to validate the function of macrophages in IL-11-associated fibrogenesis. Lastly, an anti-IL-11 nanobody was applied to CCl₄-induced fibrotic mice in order to evaluate the therapeutic potential of inhibiting IL-11 signaling. **Results:** HSCs-derived IL-11 aggravated liver fibrosis by driving macrophages into a pro-fibrotic M2 state. *In vitro*, IL-11 acted synergistically with IL-4 to activate PI3K-mTOR pathway, promoting M2 polarization and TGF- β production, while simultaneously to trigger STAT3 pathway to increase the release of chemokine. *In vivo*, overexpressed-IL-11 in HSCs worsened fibrosis, which was diminished by macrophage depletion. Conversely, treating fibrotic mice with an anti-IL-11 nanobody reduced fibrosis and shifted the macrophage profile, highlighting the therapeutic potential of IL-11. **Conclusions:** Our data reveal a self-reinforcing cycle between HSCs and macrophages: HSCs-derived IL-11 reprograms macrophages to become pro-fibrotic, and these macrophages subsequently exacerbate HSCs activation, fueling the progression of liver fibrosis. This pathogenic loop provides strong evidence for targeting IL-11 as an anti-fibrotic strategy.

PS 4290 Extracellular Vesicles Mediate Inflammatory Signaling in Arsenic-Exposed Bronchial Epithelial Cells

A. Svetlik, J. Szule, and N. Johnson. Texas A&M University, College Station, TX.

Background and Purpose: Exposure to arsenic (As) from drinking water is a worldwide public health concern. In the US, 5 million people drink water with As concentrations over the EPA standard limit of 10 μ g/L. Due to its persistence and toxicity, As is a priority contaminant at numerous Superfund sites across the U.S. where cleanup and long-term monitoring remain a challenge. In the state of Texas, over a million residents rely on well water. Since private wells are not routinely tested, millions of people are potentially exposed, especially rural residents living in South Texas. As is a known carcinogen, and recent evidence implicates As exposure with respiratory disease following ingestion. Extracellular vesicles (EVs) are cell-derived structures that represent potential biomarkers of exposure or effect to inform environmentally related diseases. Considering the increased risk of arsenic exposure and the heightened prevalence of asthma in South Texas, developing novel biomarkers is essential to identify susceptible populations and clarify the mechanisms by which EVs contribute to respiratory toxicity. **Methods:** To address these objectives, we exposed human bronchial epithelial (16HBE) cells to 0, 5, or 10 μ M of NaAsO₂ for

24 hours (acute exposure) to establish phenotypic endpoints, including cytotoxicity and inflammation at the gene and protein level. Next, to model sub-chronic exposure levels, 16HBE cells were treated with 0, 0.1, or 0.5 μM of NaAsO_2 for 1 week. To further study the mechanism underlying inflammation, conditioned media saved from the 24-hour NaAsO_2 -exposed 16HBE cells was transferred to naïve (unexposed) 16HBE cells for 24 hours. EVs were then isolated from 16HBE cell culture media and characterized using nanoparticle tracking analysis (NTA), transmission electron microscopy (TEM), and Western blotting of EVs were performed. Isolated EVs were applied to naïve 16HBE cells for 24 hours to assess their functional effects. **Results:** After 24 hours, lactate dehydrogenase activity was slightly elevated, indicating toxicity. Gene expression of the pro-inflammatory cytokine *IL-1 β* was significantly increased by 5 μM ($p < 0.01$) and 10 μM ($p < 0.01$) after 24 hours of exposure to NaAsO_2 . Protein expression of IL-1B was not statistically increased compared to control, but with an increased trend at the 10 μM dose. At 1 week, *IL-1 β* was also slightly elevated as NaAsO_2 exposure increased. *IL-1 β* was noticeably increased by the conditioned media from the low dose and high dose, by 3 and 2-fold, respectively. For the EV exposure, *IL-1 β* was statistically increased at the high dose. **Conclusions:** Collectively, these findings implicate soluble inflammatory mediators and EV signaling in arsenic-induced epithelial toxicity. EVs isolated from exposed bronchial epithelial cells may serve as novel biomarkers of respiratory inflammation. Future work will validate these mechanisms in primary pediatric lung cell models to enhance translational relevance.

PS 4291 Rodent Liver Tumors Produced by Activators of the Constitutive Androstane Receptor (CAR) and the Peroxisome Proliferator-Activated Receptor Alpha (PPAR α) are Not Relevant to Human Cancer Risk

T. Yamada¹, S. M. Cohen², and B. G. Lake³. ¹Labcorp, Tokyo, Japan; ²University of Nebraska Medical Center, Omaha, NE; and ³University of Surrey, Surrey, United Kingdom.

Background and Purpose: The hepatocarcinogenic potential of CAR and PPAR α activators in rodents has been debated for over five decades, particularly regarding relevance to human cancer risk. Although metabolic responses are qualitatively similar across species, hepatocellular proliferation appears specific to rodents. This study aims to clarify species-specific differences in CAR- and PPAR α -mediated liver carcinogenesis, incorporating recent molecular findings. **Methods:** This review examines literature to assess the human relevance of liver carcinogenesis induced by CAR and PPAR α activators in rodents. A comprehensive search was conducted using PubMed, ScienceDirect, and relevant references cited in selected publications. Comparative analyses included *in vitro* proliferation assays in hepatocytes from mice, rats, and humans, and *in vivo* studies using human and rat hepatocytes in chimeric mice. Studies involving nonresponsive species, including Syrian hamsters and guinea pigs, were also examined. Epidemiological data were reviewed to assess cancer risk in humans exposed to CAR or PPAR α activators. Particular attention was given to molecular mechanisms, such as Yes-associated protein (YAP) interactions with CAR or PPAR α , to elucidate species-specific responses. The YAP is an effector protein in the Hippo signalling, which controls cell and organ size. **Results:** Findings confirmed that hepatocellular proliferation occurs in rodents but not in humans, as shown by both *in vitro* and *in vivo* studies. *In vitro* assays revealed marked proliferation in rodent hepatocytes upon CAR activator exposure, while human hepatocytes showed no such response. *In vivo* studies using chimeric mice with humanized livers confirmed that human hepatocytes remained quiescent under conditions inducing proliferation in rodents whereas rat hepatocytes in chimeric mice showed proliferation. Molecular evidence, especially from CAR-YAP interaction analyses, supports the absence of proliferative response in humans and primates. In mice and rats, CAR activation triggers YAP activation, followed by nuclear translocation, promoting transcription of proliferation-related genes. In contrast, human hepatocytes show limited or no YAP activation following CAR stimulation, suggesting a species-specific disconnect in downstream signaling. For PPAR α activators, which increase hepatocyte proliferation in mice and rats, no significant proliferation is observed in cultured human hepatocytes, chimeric mice with humanized livers, or human PPAR α mice treated with these activators. These species differences are attributed to variations in receptor activation mechanisms. In mice, interaction with PPAR α -YAP appears necessary for hepatocyte proliferation, whereas this is not the case in humans, although further experimental validation is needed. Epidemiological data show no increased risk of liver cancer or other cancers in humans exposed to either CAR or PPAR α activators. Therefore, CAR and PPAR α share several common characteristics, and these findings support the conclusion that CAR- and PPAR α -mediated liver carcinogenesis in rodents is not relevant to humans. **Conclusions:** This study provides updated molecular insights into species-specific liver carcinogenic responses, which align with previously accumulated evidence and reinforces the conclusion that these rodent-specific mechanisms are not applicable to humans. Consequently, our position is that when a CAR- and/or PPAR α -dependent mode of action (MOA) is demonstrated in rodent studies and other MOAs are excluded, no further testing is needed to determine the absence of human hazard. However, if regulatory authorities require direct experimental evidence, since proliferative responses in human hepatocytes serve as a critical indicator for hazard potential, further methodological standardization of procedures to assess replicative DNA synthesis in cultured human hepatocytes is essential. This is consistent with the 2024 recommendation by the Joint Research Centre, the European Commission's

science and knowledge service. Such standardization would enhance scientific robustness and facilitate efficient and transparent regulatory evaluations, enabling timely and appropriate decision-making.

PS 4292 1,4-Dioxane Induces Epithelial-Mesenchymal Transition and Carcinogenesis in an Nrf2-Dependent Manner

Z. Wang¹, C. Thakur¹, Z. Bi¹, Y. Qiu¹, W. Zhang¹, H. Ji¹, A. K. Venkatesan², S. Cherukuri¹, K. Liu¹, J. D. Haley¹, X. Mao³, and F. Chen¹. ¹Stony Brook Cancer Center, Stony Brook, NY; ²School of Marine and Atmospheric Sciences, Stony Brook, NY; and ³College of Engineering and Applied Sciences, Stony Brook, NY.

Background and Purpose: Limited animal evidence suggests that Nrf2 mediates carcinogenesis induced by high doses of 1,4-dioxane (1,4-D), but its role in environmentally relevant concentrations remains unclear. The mechanisms driving the genotoxicity and carcinogenicity of 1,4-D are also challenging to elucidate, underscoring the need for further studies to assess its carcinogenic potential in humans. **Methods:** In this study, BEAS-2B cells, with or without CRISPR/Cas9-editing Nrf2 knockout, were treated with 1.25-20 ppm 1,4-D for two months. Malignant transformation was evaluated through colony formation, migration and invasion assays, while tumorigenicity was confirmed by subcutaneous implantation in immunodeficient mice. RNA sequencing, proteomics, and functional analyses were conducted to identify mechanisms underlying 1,4-D-induced carcinogenesis, with a specific focus on Nrf2's tumor-promoting effects. **Results:** Our results demonstrate that continuous exposure to environmentally relevant concentrations of 1.25-20 ppm 1,4-D over 2 months induces malignant transformation in an Nrf2-dependent manner. Transformed cells exhibit enhanced anchorage-independent growth in soft agar, increased migration and invasion, and tumorigenic potential in a xenograft mouse model. Integrated RNA sequencing and proteomics analyses reveal that 1,4-D robustly activates Nrf2 signaling, driving extracellular vesicle (EV) biogenesis and cargo loading with syndecan 4 (SDC4) and other proteins, including COL12A1, CAPG and NNMT, which are associated with epithelial-mesenchymal transition (EMT) and cancer metastasis. Nrf2 knockout reduces SDC4 expression and its incorporation into EVs, leading to decreased EV uptake by recipient cells. Unlike EVs from 1,4-D-transformed WT cells, which enhance the proliferation, migration and invasion of recipient cells, EVs from 1,4-D-transformed Nrf2 KO cells exhibit a diminished capacity to promote these EMT properties. Furthermore, we demonstrate that the Nrf2 target gene SDC4, induced by 1,4-D and enriched in EVs, plays a critical role in EV uptake by recipient cells, thereby facilitating EMT propagation. **Conclusions:** Our study identifies 1,4-D as a potential human carcinogen, with its effects primarily driven by Nrf2-dependent EV biogenesis, and highlights SDC4-enriched EVs as key mediators of EMT and carcinogenesis.

PS 4293 Cadmium exposure promotes colorectal cancer metastasis through the dysregulation of iron metabolism

J. Tolbert, L. Villareal, L. Goodla, and X. Xue. University of New Mexico, Albuquerque, NM.

Background and Purpose: Cadmium (Cd) is a toxic environmental pollutant primarily released through agricultural and industrial activities. Human exposure occurs mainly through the ingestion of contaminated food and water or the inhalation of Cd-containing dust and smoke. Colorectal cancer (CRC) is the third leading cause of cancer-related deaths in the United States with metastasis to the liver and lungs being the primary cause of mortality. Emerging evidence suggests environmental factors such as Cd may contribute to CRC progression and metastasis, potentially by disrupting iron metabolism. Our lab has previously demonstrated the importance of iron in CRC metastasis through proteins such as transferrin receptor (TFRC), ferritin heavy chain (FTH1), and nuclear receptor coactivator (NCOA4) which are important for iron uptake, storage, and recycling. It is hypothesized that exposure to Cd promotes CRC metastasis by dysregulating iron metabolism, particularly through NCOA4. **Methods:** Inductively coupled plasma mass spectrometry (ICP-MS) was used to quantify cadmium concentrations in normal, tumor, and metastatic colorectal tissue samples. Human colorectal cancer (HCT116) cells were subsequently exposed to increasing concentrations of CdCl_2 to assess the cellular effects of cadmium exposure. Cell viability and proliferation were evaluated using MTT assays. Protein expression levels of FTH1 and NCOA4 were analyzed by Western blot following Cd treatment. **Results:** ICP-MS tissue analysis revealed an increase in Cd concentrations from normal and tumor colorectal tissue to metastases, with significantly elevated levels in metastatic sites. These findings suggest Cd involvement in the metastatic process. Further, HCT116 cells were treated with increasing concentrations of CdCl_2 . MTT assays indicated no negative impact on cell proliferation at environmentally relevant doses. Finally, Western blot analysis revealed upregulation of FTH1 and downregulation of NCOA4 following Cd treatment. **Conclusions:** These results support the hypothesis that Cd promotes CRC metastasis by promoting iron overload and activating iron-dependent signaling pathways associated with proliferation and metastasis. This work provides insight into the potential cancer risks of environmental toxicants and emphasizes the need for further investigation into iron metabolism as a therapeutic target for Cd-associated colorectal cancer.

K. K. Venneman, M. Kotulkar, D. Paine-Cabrera, and U. Apte. University of Kansas Medical Center, Department of Pharmacology, Toxicology and Therapeutics, Kansas City, KS.

Background and Purpose: The liver is a common target for injury due to xenobiotic exposure. Xenobiotics such as Endocrine-Disrupting Chemicals (EDCs) impact liver function by mimicking naturally secreted hormones and have been associated with liver-related complications, including intrahepatic cholestasis, sinusoidal dilations, and hepatic adenomas. Estrogen Receptor Alpha (ERα), the primary receptor that mediates estrogenic effects in both male and female livers, is a target of EDCs. Disruption in EDC-induced ERα signaling is associated with obesity, metabolic dysfunction, and hepatocellular carcinoma (HCC). However, the mechanisms behind EDC impact on ERα signaling in the liver are not well understood. The objective of this study was to investigate the mechanisms through which ERα activation mediates EDC-induced liver injury. **Methods:** Male and female Sprague-Dawley WT and ERα KO rats received a 10 mg/kg dose of 17β-estradiol (17β, an endogenous estrogen) or diethylstilbestrol (DES, a known EDC) via oral gavage once daily for five days. Liver and serum samples were collected on the sixth day. Liver to body weight (LW:BW) ratio was measured, and Ki67 immunohistochemistry was performed to analyze proliferation. In addition, RNA-seq was performed to identify transcriptomic changes. Ingenuity Pathway Analysis (IPA) was used to identify impacts on upstream transcription regulators and GSEA analyses were used to identify pathways uniquely enriched in male and female WT rats treated with DES or 17β. **Results:** Both 17β and DES treatments increased hepatic proliferation in WT male and female rats, but not in KO rats. However, only DES-treated WT male and female rats showed hepatomegaly, as evidenced by a significant increase in LW:BW ratio. To determine the transcriptional changes underlying these distinct outcomes, KO RNA-seq data were used to remove effects of ERα deletion and to retain genes uniquely regulated by 17β or DES in WT rats. In males, this approach identified 97 unique, WT-dominant DEGs in DES-treated rats compared to 8 in WT 17β-treated rats. IPA revealed that DES treatment increased activation of several proto-oncogenes, including c-Myc, a transcription factor that is known to be involved in liver carcinogenesis. IPA could not be performed for WT rats treated with 17β due to the small number of unique genes. While GSEA identified similar pathway enrichment for both treatments, there were a few key differences. Most notably up-regulation of p53 and DNA repair pathways in 17β-treated rats. In females, RNA-seq analysis identified 85 unique, WT-dominant DEGs in DES-treated rats compared to 88 in WT 17β-treated rats. Unlike with males, IPA was performed for both DES and 17β-treated rats. In WT DES-treated female rats, IPA identified upregulation of several transcription factors associated with cell growth and oncogenic signaling, including SP1, SOX4, and HNF1β. Female rats treated with 17β were surprisingly similar to DES-treated males and showed increased expression of proto-oncogenes, including c-Myc. GSEA also identified many similar pathways for both treatments in WT females, but again, there were key differences. Most notably, upregulation of p53, DNA repair, and apoptosis pathways in 17β-treated rats. **Conclusions:** These data show that DES, but not 17β, induces significant hepatomegaly, which may be linked to treatment-specific upstream regulators. GSEA analyses indicate that WT 17β-treated rats of both sexes exhibit increased proliferative signaling without hepatomegaly, possibly due to concurrent activation of apoptotic and tumor suppressor pathways, which was not observed in WT DES-treated rats. Together, these results suggest that DES and 17β activate distinct molecular mechanisms in the liver.

PS 4295 **Adipocyte-Derived Kynurenine Enhances 3D Growth of Tamoxifen-Resistant Breast Cancer: A Potential Endogenous Toxicometabolic Mechanism**

S. Musso, R. Gonzalez Pons, and J. Bernard. Michigan State University, East Lansing, MI.

Background and Purpose: Every 13 minutes, a woman dies from breast cancer (BC) in the United States. Among women with estrogen receptor-positive (ER+) BC treated with tamoxifen; epidemiological studies show that women with obesity (BMI ≥ 30) experience significantly worse survival outcomes compared to underweight or lean women (BMI < 25). **However, the exact mechanism by which obesity promotes the growth of aggressive, treatment resistant breast cancer remains unclear.** Using a mass spectrometry analysis, the Bernard lab has demonstrated adipocytes (fat cells) are able to metabolize the amino acid tryptophan into kynurenine, an endogenous ligand of the aryl hydrocarbon receptor. Like epidemiological studies that demonstrate circulating kynurenine levels are elevated in women with obesity, our published *in vivo* research indicates mice fed a high fat diet also have elevated serum kynurenine levels. **Therefore, we hypothesize breast cancer cells can take up kynurenine from the microenvironment to induce growth of aggressive, tamoxifen resistant BC cells.** **Methods:** We treated sensitive and tamoxifen resistant ER+ BC cells with increasing concentrations of kynurenine and performed flow cytometry, soft agar colony formation assays, RNA-sequencing, and qRT-PCR. **Results:** Using a novel flow cytometric monitoring system and the auto fluorescent properties of kynurenine, we demonstrated both sensitive (MCF7) and tamoxifen resistant (TAMR7) BC cells are able to take up kynurenine from the microenvironment overtime. Because both MCF7s and

TAMR7s express very low levels of the tryptophan metabolizing enzyme indoleamine 2,3-dioxygenase, these findings suggest the increase in kynurenine uptake from the microenvironment likely results from increased uptake, rather than increased synthesis of tryptophan into kynurenine directly by the BC cells. Moreover, we have developed a novel *in vitro* system to model three-dimensional growth of tamoxifen resistant cells known as a soft agar colony formation assay. We treated two sensitive (MCF7 and ZR-75-1) and two tamoxifen resistant (TAMR7 and ZR-75-1-T) cell lines with increasing concentrations of kynurenine. Over a 10-day period, we demonstrated kynurenine increases colony size in a concentration dependent manner in all cell lines. To understand potential mechanism of this kynurenine-induced 3D cell growth, RNA-sequencing was completed on MCF7 cells treated with a low and a high concentration of kynurenine. Potential pathways of interest revealed include activation of the aryl hydrocarbon receptor, as exhibited by the increased expression of CYP1A1. **Conclusions:** Given that 90-95% of BC cases are associated with modifiable lifestyle factors such as exposure to environmental chemicals, diet, and obesity, this study underscores the potential of kynurenine as a biomarker for identifying patients at elevated risk of developing aggressive, treatment resistant, obesity-driven breast cancer, enabling earlier and more personalized interventions.

PS 4296 **Berberine Modulates Cell Survival in a Peroxisome Proliferator-Activated Receptor (PPAR)-dependent Manner in a Human Malignant Melanoma Cell Line**

A. W. Faust¹, L. N. Boyer¹, D. S. Milnes¹, E. M. Kehres¹, J. M. Peters², and M. G. Borland¹. ¹Commonwealth University of PA - Bloomsburg, Bloomsburg, PA; and ²Pennsylvania State University, University Park, PA.

Background and Purpose: Low-survival cancers, including malignant melanoma, require innovative new therapeutic interventions. Peroxisome proliferator-activated receptors (PPAR) is a class of nuclear hormone receptors that can inhibit carcinogenicity and potentially be used therapeutically as a target for melanoma. In particular, pharmacological targeting of PPARβ/δ and PPARγ have been shown to reduce tumorigenesis in several human melanoma models. Berberine, is a naturally occurring isoquinoline alkaloid found in the roots and stems of barberry and turmeric, that may be useful for treating cancers. Interestingly, berberine is reported to be a PPAR agonist. Thus, these studies examined the hypothesis that berberine modulates PPAR-dependent anti-cancer effects in human malignant melanoma. **Methods:** The effects of berberine on melanoma tumorigenesis in a melanoma cell line model (UACC903) with stable modulated PPAR over-expression of PPARβ/δ and PPARγ was examined. A dose response (10.0 - 50.0 μM) of berberine was examined in all UACC cell lines to examine cell proliferation, clonal expansion, soft agar transformation, caspase activation, and cellular metabolic activity. **Results:** Cell proliferation was reduced by berberine in a dose-dependent manner in all UACC903 cell lines compared to controls. Cells over-expressing PPARβ/δ or PPARγ were more sensitive to the effect than control cell lines. Clonal expansion was inhibited by berberine in all cell lines; only cells over-expressing PPARβ/δ exhibited increased sensitivity. Berberine also reduced soft agar colony formation in a dose-dependent manner compared to controls. Over-expression of either PPARβ/δ or PPARγ enhanced this response. Berberine was more potent in inducing caspase activity in cells over-expressing PPARβ/δ or PPARγ compared to controls. Similarly, berberine modulated metabolic activity at lower doses in cells over-expressing PPARβ/δ or PPARγ compared to controls. **Conclusions:** These studies demonstrate 1) berberine has anti-melanoma activities and 2) PPARs contribute to the anti-cancer properties associated with berberine. Mechanistic studies are needed to delineate the molecular signaling pathways of how berberine interacts with PPAR for future development of co-therapeutic approaches for melanoma.

PS 4297 **Evaluation of the Hepatotoxic Effects of Various PFAS in a Short-Term Rat Study**

S. Suzuki, M. Fujioka, G. Qi, A. Vachiraarunwong, A. Kakehashi, and M. Gi. Osaka Metropolitan University Graduate School of Medicine, Osaka, Japan.

Background and Purpose: Perfluoroalkyl and polyfluoroalkyl substances (PFAS) have been used in a wide array of products due to their ability to repel oil and water, reduce friction, and withstand temperature fluctuations. However, some PFAS, including perfluorooctanoic acid (PFOA), have been reported to induce toxicity and tumor formation in the liver of rodents. Therefore, the present study aimed to evaluate the hepatotoxicity of various PFAS using a rat short-term study. **Methods:** Six-week-old male SD rats were administered 6 PFAS including PFOA, undecafluoro-2-methyl-3-oxahexanoic acid (GenX), 3-perfluorohexyl-1,2-epoxypropane (PFHEP), 2,2-difluoroethyl trifluoromethanesulfonate (DFEMS), hexafluoroglutaryl chloride (HxFGC) and perfluorohexanoic acid (PFHxA), for 4 weeks. After treatment, rats were euthanized, and livers were collected for histological examination and RNA extraction. Hepatic gene expression profile was obtained using microarray, and compared with controls to identify altered gene expression. These alterations were subsequently evaluated using a non-genotoxic hepatocarcinogens (NGHCs) prediction model. **Results:** Histopathologically, hepatocellular hypertrophy in Zone 3 was observed in the livers of rats treated with PFOA, GenX, and PFHEP. Periportal necrosis was observed in those treated with DFEMS. In contrast, no histological changes

were noted in the livers of rats treated with HxFGC or PFHxA compared to the control group. Using NGHCs prediction model, PFOA and GenX were identified as NGHCs, whereas the others were classified as negative. **Conclusions:** These findings indicate that PFASs exhibit structural diversity and distinct toxicological properties, suggesting that their individual toxicity should be carefully evaluated.

PS 4298 Investigating the Effects of Chronic Arsenic Exposure in Human Keratinocytes Overexpressing hsa-miR-362

J. L. Scott, G. Rodriguez, T. B. Emran, L. Abozaid, and J. C. States. University of Louisville, Louisville, KY.

Background and Purpose: Arsenic is a Group I human carcinogen, a known clastogen that does not directly interact with DNA, but dysregulates DNA repair, chromosomal stability, mRNA alternative splicing, and miRNA (miR) expression. miRs are small non-coding RNAs that can suppress mRNA translation. hsa-miR-362 (miR-362) expression was elevated in arsenic-induced human skin tumors, suggesting a role in arsenic-induced carcinogenesis. **Hypothesis:** miR-362 overexpression will suppress proteins involved in biological pathways known to be dysregulated by arsenic. **Methods:** Ker-CT cells were transduced with lentiviral particles overexpressing either miR-362 or a scrambled miR control (SC-miR). miR-362-5p expression was measured with TaqMan RT-qPCR with hsa-miR-191-5p as control. Four miR-362 or SC-miR clones with similar expression were selected, cultured with +/- 100 nM NaAsO₂, and passaged for several weeks. Predicted miR-362-5p targets were ranked by their combined score from three miRNA - mRNA binding databases: DIANA-MicroT, TargetScan, and miRDP. Expression of target proteins with roles in DNA repair, chromosomal stability, alternative splicing, and their mRNAs were assessed by immunoblot and RT-qPCR. Their downstream protein interactions were determined with STRING. Statistical analyses were completed using unpaired t-tests as well as 2 and 3-way ANOVAs. **Results:** Clonal Ker-CT cell lines transduced with miR-362 and SC-miR lentiviruses were produced. miR-362-5p overexpression was confirmed and ranged between 250- and 2000-fold over basal expression. The 54 miR-362-5p target hits that were found in all three databases were categorized by biological pathway and ranked by combined score. The top results in DNA repair (RMI1), alternative splicing (LUC7L3), and chromosomal stability (RMI1, LUC7L3, and CENPK) were confirmed to be translationally suppressed in miR-362 overexpressing cells. STRING interactions revealed that CENPK primarily interacts with other centromere proteins, RMI1 interacts with members of the Bloom and Fanconi Anemia complexes, and LUC7L3 interacts with several splice factors. Chronic culture assays demonstrated that both miR-362 overexpression and arsenic exposure inhibited cell growth compared to unexposed SC-miR. **Conclusions:** Overexpression of miR-362 was shown to suppress the expression of proteins involved in DNA repair, maintenance of chromosomal stability, and alternative splicing. The resulting dysregulation of these pathways could contribute to arsenic-induced transformation and skin carcinogenesis, but further studies are needed. **Grant support:** R01ES027778, P30ES030283, T35ES014559

PS 4299 Curcumin Analogues Trigger HMOX-1-Mediated Ferroptosis to Halt Endometrial Cancer Growth

X. Wu, K. Leslie, and X. Xue. University of New Mexico, Albuquerque, NM.

Background and Purpose: Advanced endometrial cancer remains challenging to treat due to limited therapeutic options and drug resistance. Ferroptosis, an iron-dependent form of cell death, offers a potential strategy for overcoming resistance. Curcumin analogues with improved bioavailability, such as HO-3867 and AKT-100, exhibit potent anti-cancer activity, but their mechanisms remain underexplored. **Methods:** KLE and Hec50cc endometrial cancer cells were treated with HO-3867 or AKT-100. RNA sequencing, qPCR, and immunoblotting assessed ferroptosis-related gene expression, focusing on HMOX-1. Intracellular iron and ROS were measured via FerroOrange and DCFH-DA staining. Cytotoxicity and colony formation were evaluated using CyQUANT assays, with pharmacological inhibitors (ZnPP, Liproxstatin-1, Z-VAD-FMK) and HMOX-1 siRNA to dissect the roles of ferroptosis and apoptosis. **Results:** Both analogues upregulated multiple ferroptosis genes, prominently HMOX-1. AKT-100 increased intracellular iron and ROS levels. Inhibition of HMOX-1, ferroptosis, or apoptosis partially rescued cell viability, while HMOX-1 knockdown enhanced clonogenic growth, confirming its key role in AKT-100-mediated cytotoxicity. **Conclusions:** HO-3867 and AKT-100 induce HMOX-1-mediated ferroptosis and apoptosis, effectively suppressing endometrial cancer cell growth. These findings support the therapeutic potential of curcumin analogues and provide a foundation for *in vivo* studies targeting HMOX-1 in endometrial cancer.

PS 4300 Ursolic Acid Modulates Cell Survival in a Peroxisome Proliferator-Activated Receptor (PPAR)-dependent Manner in a Human Malignant Melanoma Cell Line

N. C. McKee¹, K. A. Liebersohn¹, H. L. Hudak¹, K. B. Wood¹, E. M. Kehres¹, J. M. Peters², and M. G. Borland¹. ¹Commonwealth University of PA - Bloomsburg, Bloomsburg, PA; and ²Pennsylvania State University, University Park, PA.

Background and Purpose: Low-survival cancers, including malignant melanoma, require innovative new therapeutic interventions. Peroxisome proliferator-activated receptors (PPAR) is a class of nuclear hormone receptors that can inhibit carcinogenicity and potentially be used therapeutically as a target for melanoma. In particular, pharmacological targeting of PPAR β/δ and PPAR γ have been shown to reduce tumorigenesis in several human melanoma models. Ursolic acid, is a naturally occurring triterpene found in apples, cranberries, and peppermint, that may be useful for treating cancers. Interestingly, ursolic acid is reported to be a PPAR agonist. Thus, these studies examined the hypothesis that ursolic acid modulates PPAR-dependent anti-cancer effects in human malignant melanoma. **Methods:** The effects of ursolic acid on melanoma tumorigenesis in a melanoma cell line model (UACC903) with stable modulated PPAR over-expression of PPAR β/δ and PPAR γ was examined. A dose response (10.0 - 40.0 μ M) of ursolic acid was examined in all UACC cell lines to examine cell proliferation, clonal expansion, soft agar transformation, caspase activation, and cellular metabolic activity. **Results:** Cell proliferation was reduced by ursolic acid in a dose-dependent manner in all UACC903 cell lines compared to controls. Cells over-expressing PPAR β/δ or PPAR γ were more sensitive to the effect than control cell lines. Clonal expansion was inhibited by ursolic acid in all cell lines; only cells over-expressing PPAR β/δ exhibited increased sensitivity. Ursolic acid also reduced soft agar colony formation in a dose-dependent manner compared to controls. Over-expression of either PPAR β/δ or PPAR γ enhanced this response. Ursolic acid was more potent in inducing caspase activity in cells over-expressing PPAR β/δ or PPAR γ compared to controls. Similarly, ursolic acid modulated metabolic activity at lower doses in cells over-expressing PPAR β/δ or PPAR γ compared to controls. **Conclusions:** These studies demonstrate 1) ursolic acid has anti-melanoma activities and 2) PPARs contribute to the anti-cancer properties associated with ursolic acid. Mechanistic studies are needed to delineate the molecular signaling pathways of how ursolic acid interacts with PPAR for future development of co-therapeutic approaches for melanoma.

PS 4301 Investigating Cadmium's Adipogenic Effects on Breast Cancer Metastasis in the Bone Niche

S. C. Helewicz, C. M. McVeigh, J. L. Moreno, and A. M. Bolt. University of New Mexico, Albuquerque, NM.

Background and Purpose: Cadmium (Cd), a heavy metal widely used in battery production, electroplating, paints, and metal alloys, is an environmental toxicant with both carcinogenic and obesogenic potential. Human exposure to Cd continues to rise due to occupational hazards in metal industries, inhalation of cigarette smoke, and contamination of water sources through industrial and agricultural pollution. Cd acts as an obesogen and is classified as a Group 1 human carcinogen. Cd exposure has been associated with increased incidence of breast cancer, but its ability to drive tumor progression by enhancing metastasis has not been fully explored. Because Cd has a long biological half-life and accumulates in the bone, which is a frequent site of breast cancer metastasis, it may directly contribute to metastatic progression to the bone niche. We hypothesize that Cd accumulation within bone, combined with its obesogenic effects, serves as a key driver to induced breast cancer metastasis to the bone. **Methods:** An *in vitro* model was established using OP9 mouse bone marrow stromal cells (BMSCs), which are capable of differentiating into adipocytes. Cells were exposed to CdCl₂ at varying concentrations, and cytotoxicity was assessed via MTT assays to determine nontoxic doses. To evaluate Cd-driven adipogenesis, OP9 cells were treated with 0.5, 0.75, and 1 μ M CdCl₂ and 25% serum replacement media. RT-qPCR quantified changes in adipokine and cytokine gene expression, and Oil Red O staining was used to visualize and quantify adipocyte formation. Two *in vivo* models were used to evaluate the effects of Cd on bone marrow adipogenesis and its potential to drive breast cancer metastasis to the bone: a non-tumor mouse model and an orthotopic mouse model. In each model, female BALB/c mice were exposed to either 5ppm Cd or a no Cd control in their drinking water for 8 weeks. In the orthotopic model, mice were orthotopically injected with 4T1 triple-negative breast cancer cells into the mammary fat pad after 4 full weeks of Cd exposure. Fresh Cd-treated water was prepared three times per week, body weights were recorded weekly, and tumor volumes were measured three times per week post-injection. At the terminal endpoint, body, spleen, adipose, and tumor weights were recorded. Femurs were stained for the adipocyte marker Plin1 via immunohistochemical staining, and Cd accumulation in tibias was quantified using ICP-MS. Bone marrow colony assays and H&E staining of lung and liver tissues evaluated metastatic progression. Additional analyses included microCT imaging of femurs, cytokine profiling in plasma, and flow cytometric quantification of myeloid-derived suppressor cells in bone marrow. **Results:** MTT assays revealed that CdCl₂ concentrations above 1 μ M caused significant toxicity in OP9 cells after 48 hours; thus, concentrations $\leq$ 1 μ M were used for subsequent experiments. CdCl₂ exposure is expected to significantly increase adipokine gene expression in OP9 cells and enhance BMSC differentiation into adipocytes, reflected by elevated adipogenic markers and increased Oil Red O staining. *In vivo*,

mice exposed to 5ppm Cd displayed higher adipocyte numbers within bone marrow and had a higher accumulation of Cd within the bone of Cd-exposed non-tumor-bearing mice. Cd exposure did not significantly alter white adipose tissue weight, spleen weight, or overall body weight in non-tumor-bearing mice. In the tumor-bearing mice, Cd exposure is expected to accelerate tumor growth and enhance metastatic markers relative to controls. **Conclusions:** Preliminary data suggest Cd exposure promotes adipogenesis in BMSCs and within the bone marrow of Cd-exposed mice, creating a bone microenvironment favorable for tumor cell colonization and growth. These effects may parallel those of other heavy metals, indicating that environmental metals can remodel the bone niche to promote metastasis. Ongoing studies will further define Cd's role in the metastatic process and microenvironment modulation. Understanding Cd's contribution to breast cancer progression and metastasis could identify it as a modifiable environmental risk factor, with implications for cancer prevention and public health policy.

PS 4302 KEAP1-NRF2 modulation via posttranslational modifications with the nitro-PAH 3-nitrobenzanthrone

C. F. Marques¹, K. El-Bayoumy², and T. M. Penning³. ¹Department of Systems Pharmacology and Translational Therapeutics, University of Pennsylvania Perelman School of Medicine, Philadelphia, PA; ²Department of Molecular and Precision Medicine, Penn State College of Medicine, Pennsylvania State University, Hershey, PA; and ³Center of Excellence in Environmental Toxicology & Department of Systems Pharmacology and Translational Therapeutics, University of Pennsylvania Perelman School of Medicine University of Pennsylvania, Philadelphia, PA.

Background and Purpose: Nitroated polycyclic aromatic hydrocarbons (NO₂-PAHs) are a major component of diesel engine exhaust (DEE) - classified as a Group 1 carcinogen by the International Agency for Research on Cancer (IARC). NO₂-PAHs (including 1-nitropyrene (1-NP) and 3-nitrobenzanthrone (3-NBA)) are formed during the incomplete combustion of PAHs and are adsorbed at the surface of PM_{2.5}. Despite their mutagenic properties, there is insufficient evidence to increase their IARC classification above Group 2A or 2B carcinogens. To become mutagenic, these compounds require metabolic activation through a 6-electron reduction of the nitro-group via a nitroso-, hydroxylamino-, and amine intermediates, which are catalyzed by cytosolic nitroreductases, such as aldo-keto reductases (AKR)1C1-3 and NQO1. The expression of these enzymes is induced by the NRF2-KEAP1 stress response pathway. KEAP1 is part of the cullin 3 (CUL3)-based E2 ubiquitin ligase complex and is responsible for controlling NRF2 stability and activation. The NRF2-KEAP1 pathway is regulated by a "thiol-driven master switch": in the presence of electrophiles and ROS, KEAP1 cysteine residues are modified, which prevents the ubiquitination of NRF2, leading to NRF2 translocation into the nucleus where it induces the expression of genes regulated by the antioxidant response element (ARE). We hypothesized that the reactive nitroso intermediate of 3-NBA can modify KEAP1 cysteine residues, leading to NRF2 activation and consequent induction of enzymes (AKRs and NQO1) responsible for 3-NBA activation increasing its toxicity via a positive feedback loop. **Methods:** The ability of 3-nitrosobenzanthrone (3-NBA) to form covalent bonds with cysteine residues was first assessed using N-acetyl-L-cysteine and glutathione. Recombinant KEAP1 protein was then incubated with 3-NBA. The protein was immunopurified, free cysteine residues were alkylated, and the protein complexes were digested with trypsin. Tryptic peptides were analyzed by nano-LC-MS/MS. Human bronchial epithelial cells HBEC3-KT cells (with wild-type KEAP1) were then exposed to 3-NBA, and the consequent modulation of KEAP1-NRF2 pathway was investigated by measuring post-translational modification (PTM) of KEAP1 by targeted proteomics by nano-LC-MS/MS, nuclear translocation of NRF2 by western-blot analysis, and induction of AKR1C transcripts by RT-qPCR. **Results:** Mass spectrometry analysis of recombinant KEAP1 demonstrated that 3-NBA forms sulfonamide and sulfonamide adducts with multiple key cysteine residues in both the CUL3- and NRF2-binding domains (e.g., Cys151, Cys273, Cys288, Cys319, Cys368, Cys489). Consistent with NRF2 activation, HBEC3-KT cells treated with 3-NBA showed evidence of PTM of KEAP1, NRF2 nuclear translocation, and induction of AKR1C1 gene and protein expression. **Conclusions:** This work demonstrates, for the first time, that a chemical carcinogen can covalently modify KEAP1. This modification activates NRF2, leading to the subsequent activation of ARE genes, such as AKRs, which supports the hypothesis that nitroarenes induce their own toxicity via a positive feedback loop involving KEAP1. These findings provide a novel mechanistic understanding of how NO₂-PAHs may exert their genotoxicity and highlight the NRF2-KEAP1 pathway as a critical molecular target influencing individual susceptibility to the carcinogenic effects of diesel exhaust exposure.

PS 4303 Myricetin and Capsaicin synergistically reduce the proliferation of human hepatoma cells by inhibiting Ki-67, PCNA, and HIF1A expression

J. Whitfield, and X. Cheng. St. John's University, Jamaica, NY.

Background and Purpose: Phytochemicals are naturally occurring compounds that are commonly consumed in foods. Numerous studies have demonstrated that certain phytochemicals possess antitumoral properties, including the inhibition of cell proliferation, angiogenesis, and invasion of cancer cells. Myricetin (Myr), a

flavonoid that is found in berries, nuts, and herbs, shows antioxidant properties and causes cell cycle arrest. Capsaicin (Cap), a pungent-smelling alkaloid found in chili pepper, can decrease cell proliferation by triggering cell apoptosis. **Methods:** Human Hep3B and Huh-7 hepatoma cells, cultured in 96-well plates, were treated with Myr, Cap, Myr + Cap, or DMSO and then processed for MTT analysis to assess cell viability and cell proliferation. In addition, Hep3B and Huh-7 cells were cultured in T-25 flasks and treated with Myr, Cap, Myr + Cap, or DMSO for 48 hours (n = 4/treatment). The harvested cells were processed for RT-qPCR analysis of genes involved in regulating cell proliferation. **Results:** MTT assay showed that both Myr and Cap decreased the cell proliferation and viability in both Hep3B and Huh-7 cells. Co-treatment of Myr and Cap synergistically decreased the cell proliferation and viability in both Hep3B and Huh-7 cells. Additionally, both Myr and Cap decreased the mRNA expression of Ki-67, PCNA, and HIF1A in both Hep3B and Huh-7 cells. Co-treatment of Myr and Cap synergistically decreased the mRNA expression of Ki-67, PCNA, and HIF1A in both Hep3B and Huh-7 cells. **Conclusions:** The combination therapy of Myr and Cap may enhance their antitumoral properties.

PS 4304 Genetic Toxicology Studies on trans-1,2-difluoroethene (R-1132-E)

Z. Guo, T. Nakaue, and S. Tokuno. Daikin Industries, Ltd., Osaka, Japan. Sponsor: T. Fukuyama

Background and Purpose: A novel refrigerant gas, identified as R-1132-(E), trans-1,2-difluoroethene, has been extensively evaluated for its genotoxicity potential. A series of *in vitro* and *in vivo* assays have been used for this purpose. A significant mutagenic activity was observed in the bacterial mutagenicity test (Ames studies/OECD471), particularly in the absence of mammalian metabolic enzymes. In the presence of mammalian enzymes the activity in bacteria was markedly attenuated, especially at the exposure level lower than 50%. **Methods:** The potential for genotoxic activity was further investigated in a series of mammalian cell assays *in vitro* (Chromosome aberration test /OECD473, Micronucleus test/OECD487) and also in *in vivo* studies (Micronucleus test in the bone marrow of the rat/OECD474, The activity observed in bacteria and in the Comet study was investigated using the Big Blue® transgenic assay. The Big Blue® assay is a transgenic rodent (TGR) mutation assay, as described in Organization for Economic Co-Operation and Development (OECD) Test Guideline (TG) 488 (OECD 2022). **Results:** Comet assay in 4 tissues of the rat/OECD489). In all of these assays, R-1132-(E) was shown to be not genotoxic, i.e., not clastogenic, not aneugenic, and not mutagenic. R-1132-(E) was observed to induce an apparent increase in DNA damage in lung, kidney, bladder, and liver tissues, but only at dose levels that greatly exceeded the limit dose for the assay. In addition, the DNA damage was only seen in association with an increase in 'hedgheg cells', which were not observed in the tissues of the positive control group. The increase in DNA damage was concluded to be secondary to a separate mode of action (likely excessive cytotoxicity) and not due to direct DNA damage. Since the dose levels of TKN1 used in the comet study were excessively high (up to 8% of the atmosphere breathed by the animals), the possibility that anoxia may have contributed to the response is also considered possible. The purpose of the TGR gene mutation assay is to identify substances that cause mutations due to DNA damage in the tissue being analyzed. The three tissues (lung, kidney, and liver), which showed some evidence of apparent DNA damage in the Comet assay, and bone marrow were analyzed for mutations, and there was no increase in the mutation rate in any of the tissues. It was concluded that the apparent DNA damage in the Comet assay was not caused by a direct interaction with DNA and did not result in mutations. **Conclusions:** The set of genotoxicity data demonstrated that R-1132(E) is not mutagenic.

PS 4305 The Metabolo-Epigenetic Role of AS3MT in Arsenic Exposure

S. G. Avila-Barnard, S. Deme, H. Jiang, Y. Kang, and P. Allard. University of California, Los Angeles, Los Angeles, CA.

Background and Purpose: Trivalent inorganic arsenic (iAs^{III}) is a complex epigenetic toxicant and the mechanism underlying its signature of genome-wide DNA hypomethylation remains poorly understood. We previously found that exposure to iAs^{III} within mESCs increased both total and nuclear levels of AS3MT (an arsenic methyltransferase). While AS3MT has been identified as a cytosolic protein, evidence suggests it may also localize to the nucleus and play functional roles in DNA cytosine methylation and histone modification. This project investigates the genomic distribution and mechanistic role of AS3MT within mESCs and human cancer cell lines by testing the hypothesis that nuclear AS3MT is a key mediator of iAs^{III} epigenetic and carcinogenic activity. **Methods:** We exposed human liver, skin, and lung cells to NaAsO₂ at the LOAEL (1 μM) for 48-h with media replenishment at 24-h to assess epigenetic alterations. Additionally, in a separate experiment, we exposed the same cell types to iAs^{III} and then allowed cells to recover for seven days post-exposure, after which samples were counted and collected for RNA sequencing. Trypan blue staining was used to measure cell proliferation across cell types. RNA-seq analysis revealed differentially expressed gene signatures. **Results:** iAs^{III} exposure resulted in significantly decreased cell proliferation without affecting cell viability after 48-h exposure across all cell types. iAs^{III} exposure resulted in distinct genetic signatures of DNA replication and repair machinery in the recovered samples across all cell types. **Conclusions:** This research demonstrates that although AS3MT was

not differentially expressed across all three cell types, DNA replication and repair machinery may be a critical pathway for exploration and future direction in elucidating the mechanistic role of iAs¹¹. Understanding the functional roles of critically impacted replication machinery may help elucidate how environmental toxicant exposures lead to epigenome signatures that perturb transcriptional processes, gene function, and carcinogenicity.

PS 4306 Reconsidering False Positive Rates for a Portfolio of Carcinogenicity Studies in Rats and Mice

K. S. Konrad¹, L. Betz¹, S. Harris¹, H. Cunney², and K. Shockley³. ¹DLH LLC, Bethesda, MD; ²Division of Translational Toxicology, National Institute of Environmental Health Sciences, Research Triangle Park, NC; and ³Division of Intramural Research, National Institute of Environmental Health Sciences, Research Triangle Park, NC.

Background and Purpose: Hundreds of chemicals have been evaluated for their potential carcinogenicity via two-year rodent studies conducted by the Division of Translational Toxicology within The National Institute of Environmental Health Sciences. Each study includes two rodent species, two sexes, three or more dose groups, and over 40 tumor types. These tumor data are binary, with tumors being either present or absent. Trend and pairwise tests are used to test for the effect of a given chemical's dose on tumor formation. 485 dose-related tests are conducted per study, leading to potentially inflated false positive rates (FPR), or the likelihood that a statistical test would count a true negative as positive. While statistical significance is not the only consideration for declaring the carcinogenicity of a chemical, it is an important contributing factor. Previous work has examined FPRs in two-year rodent studies, but tumor background rates have shifted over time, and there are now scenarios where more sophisticated statistical models that correct for differential survival are utilized. **Methods:** We built statistical simulations to assess a study's FPR using the Poly-3 test, an extension of the Cochran-Armitage test that includes adjustments for differential survivability among the dose groups. These simulations used the most recent male and female historical control data from 9 chronic mouse studies with 929 unique control animals and 11 chronic rat studies with 1179 unique control animals to assist in computing the FPR of the Poly-3 test for a study. Studies were selected from the 2024 NTP Historical Control Database, with starting dates between 2011 and 2016. Ten thousand simulated datasets were generated per sex and species. Trend and pairwise tests were performed for each tumor type within each simulation dataset, with an alpha level of 0.05 for determining significance. The false positive rate for each species, sex, and tumor type was calculated as the number of significant tests divided by the total number of tests (i.e., 10,000). The expected number of false positive trend and pairwise tests within a study (combining sexes and tumor types) was calculated as the average number of false positives across the simulations. The background tumor rates present in the historical control data were also calculated. Note that there were more tumor types present in rats than mice. **Results:** Across the 10,000 simulations in rats, an average of 1.93 false positive trend tests per study were observed, with 0.85 false positive pairwise tests, ranging from 0 to 12 false positives out of the 260 tumor type and sex combinations tested. Across the 10,000 simulations in mice, an average of 1.57 false positive trend tests per study were observed, with 0.76 false positive pairwise tests, ranging from 0 to 8 false positives out of the 225 tumor type and sex combinations tested. As the background tumor rates increased up to 60%, the FPR increased but remained below the 0.05 level, indicating that the low incidence of tumors controls the FPR. **Conclusions:** This work seeks to emphasize the real-world impact of statistical modeling and enhance confidence in science. In any given carcinogenicity study using the Poly3 test, we would not expect to see more than 2 false positive trend tests or 1 false positive pairwise test. The number of significant tests in some studies has been an order of magnitude greater than these counts, reliably suggesting a true effect compared to the false positive baseline expectations calculated here. This research was supported in part by the NIH, National Institute of Environmental Health Sciences and the Intramural Research Program of the NIH including 75N96022F00055. The contributions of the NIH authors are considered Works of the United States Government. The findings and conclusions presented in this poster are those of the authors and do not necessarily reflect the views of the NIH of the U.S. Department of Health and Human Services.

PS 4307 Getting the big picture of data-rich chemicals: Survey sampling increased efficiency in mapping mechanistic data for polycyclic aromatic hydrocarbons

G. Chappell¹, B. E. Howard², A. Varghese¹, W. Arroyave³, R. M. Lunn⁴, L. Schmidt², J. W. Tracy⁵, R. Silva⁵, H. Cunney⁴, K. Shipkowski⁴, A. A. Rooney⁴, and A. Wang⁴. ¹ICF, Reston, VA; ²Sciome, Durham, NC; ³Inotive, Durham, NC; ⁴NIH/ES/DTT, RTP, NC; and ⁵ICF, Durham, NC.

Background and Purpose: Mechanistic information is critical for human health hazard evaluation. However, systematic organization of diverse mechanistic information can be resource-prohibitive for data-rich chemicals. Our objective was to organize mechanistic information on polycyclic aromatic hydrocarbons (PAHs) by key characteristics of carcinogens (KCCs) into systematic evidence maps (SEMs) to support cancer hazard evaluations, and to develop methods to increase efficiency

while maintaining accuracy. **Methods:** A literature search for cancer mechanistic data for 45 PAHs with cancer data from animal models was conducted in PubMed, Scopus, and Web of Science using the National Toxicology Program's Report on Carcinogens search syntax for mechanism, mainly KCCs. To effectively identify PAHs and categorize KCCs mentioned in the abstract, we first compared text mining with manual identification of PAHs and KCCs categorization. We divided KCC8 receptor-mediated effects into 8a aryl hydrocarbon receptor (AhR)-related and 8b non-AhR-related. To estimate numbers of references for each PAH-KCC pair without screening every single reference found, we used a survey sampling and statistical analysis approach to predict KCC distribution for each PAH. Furthermore, to validate the performance of this approach, we compared the predicted number of references per KCC per PAH with numbers from manual KCC categorization for five PAHs. To develop SEMs of mechanistic information for PAHs that have animal cancer data from human-relevant exposure routes, we identified 14 priority PAHs and applied the best-performing methods from our tests. **Results:** Nearly 44,000 references were returned from searches conducted through October 2025 for 45 PAHs. PAH identification within the references was more accurate by text mining than by manual review, while KCC categorization was more accurate by manual review. We proceeded with text mining PAHs and manual categorization of KCCs for the rest of the project. The survey sampling method validation demonstrated that predictions of the distribution of references across KCCs per PAH (i.e., number of references per PAH) closely aligned with the results of manual categorization, indicating survey sampling can accurately predict the KCC distribution. We then applied survey sampling methods to predict KCC categorization for data-rich PAHs (i.e., those with 500 or more references). For the SEMs of 14 priority PAHs, over 16,000 references were identified by text mining as containing information relevant to one or more the PAHs and we manually screened nearly 7,000 references for KCC categorization. Three PAHs (benzo[a]pyrene, fluoranthene, and naphthalene) had over 500 references each; thus, the number of references with specific KCC data per PAH was predicted based on survey sampling of the manual categorization results. When all 14 priority PAHs are considered, KCCs 1 (electrophilicity, including DNA adducts), 2 (genotoxicity), 8a (AhR-related), and 5 (oxidative stress) had more references per KCC than any other KCCs. The predictions and the manual screening results are shown in detail in an online, interactive SEM (<https://tinyurl.com/cdatrv33>), where users can explore the data (e.g., sort by chemical structure features). **Conclusions:** Evaluating the performance of new methods helps build confidence in approaches that differ from standard procedures. We recommend chemical identification by text mining coupled with manual categorization of mechanistic information, and we recommend survey sampling prediction for large datasets for appreciable time savings. Our development, evaluation, and validation of approaches for literature categorization by PAHs and KCCs demonstrates how text mining and survey sampling in toxicological topic areas with specific characteristics, such as cancer mechanistic data, can expedite the organization of voluminous mechanistic information into an SEM.

PS 4308 Conserved Alternative Splicing Events Underlie Spontaneous and Chemically Induced Hepatocellular Carcinomas in B6C3F1/N mice

K. Kanchi, M. Xu, T. Ton, J. Li, R. C. Sills, and A. R. Pandiri. The National Institute of Environmental Health Sciences, Durham, NC. Sponsor: C. Rider

Background and Purpose: Hepatocellular carcinoma (HCC) is the third leading cause of cancer-related mortality worldwide. In addition to viral etiologies, lifestyle and environmental exposures contribute to hepatocarcinogenesis. In National Toxicology Program (NTP) studies, spontaneous and chemically induced HCCs arise frequently in B6C3F1/N mice and display several morphological and genetic similarities to some human HCCs. Prior genomic analyses indicate that these mouse HCCs share broadly similar mutation profiles. However, the influence of chronic chemical exposure on alternative splicing (AS), a key driver of proteomic diversity, tumor-specific isoform production, and neoantigen formation, in the context of hepatocarcinogenesis remains unclear. Aberrant AS can disrupt apoptosis, cell-cycle control, metabolic homeostasis and stress-response pathways. We hypothesized that AS events may reflect distinct carcinogenic modes of action and reveal molecular features shared across, or unique to, spontaneous and chemically induced HCCs. **Methods:** RNA-seq was performed on HCCs from B6C3F1/N mice arising spontaneously or following one of ten chronic chemical exposures (four genotoxic and six nongenotoxic agents), with age-matched untreated livers serving as controls. Reads were aligned to the mm10 genome using STAR 2.6.0c. Differential AS events were identified using rMATS turbo ($p < 0.05$, $FDR < 0.05$, $|\Delta\text{IncLevel}| > 0.1$) across five event types: skipped exon (SE), mutually exclusive exons (MXE), alternative 5'/3' splice sites (A5SS/A3SS), and retained intron (RI). Visualization and downstream splicing events were performed using rmats2sashimiplot v2.0.2. Enriched RNA-binding protein (RBP) motifs flanking significant AS events were detected using rMATS2 v2.2.0. Differential gene expression was integrated with AS profiles to identify genes undergoing coordinated dysregulation at both levels. Functional implications were assessed using Gene Ontology Biological Processes and Reactome pathway annotations. **Results:** Across treatment groups, tumors exhibited 604-3535 significant AS events (total 13,779 junction + exon counts), demonstrating extensive splicing dysregulation in both spontaneous and chemically induced HCCs. SE and MXE events predominated across all HCCs representing 28-54% and 27-63%, respectively. HCCs from BDCA and DBP exposures showed high MXE proportions, suggesting chemical-specific splice perturbation. Spontaneous HCCs had 39 unique AS-affected genes. Despite this

heterogeneity, a conserved core of 21 SE, 13 MXE, 6 RI and two A5SS/A3SS events (*Arhgap26*, *Dleu2*) events was shared across all HCCs, indicating convergence at the splicing level despite differences in carcinogen class and mode of action. Integration of AS with expression data showed that 11-33% of AS genes were also differentially expressed. Seven genes (*Cep55*, *Dst*, *Ndr2*, *Sgms1*, *Sort1*, *Tnfrsf13*, and *Tpm1*) were consistently dysregulated at both AS and expression levels in every tumor group, highlighting coordinated transcriptional and post-transcriptional remodeling. RBP motif analysis revealed distinct regulatory patterns: SRP20 and RBM proteins in SE events; HuR (ELAVL1) enrichment in MXE events; and HuR, RBM, SRSF, HNRNPCL, and PTBP1 motifs enriched in RI events. Functional analyses showed enrichment of pathways involved in mRNA and nucleic acid metabolism, protein/macromolecule regulation, cellular stress and damage response, and signaling. **Conclusions:** Spontaneous and chemically induced mouse HCCs share a recurrent program of alternative splicing dysregulation, constituting a core molecular hallmark of hepatocarcinogenesis in B6C3F1/N mice. The presence of highly conserved SE and MXE events across all tumors, coupled with consistent dual dysregulation of key genes such as the tumor-suppressor *Ndr2*, suggests that AS influences pathways governing proliferation, cellular stress tolerance, and oncogenic signaling. The AS events in 39 unique genes in spontaneous HCCs may reflect endogenous processes and warrant further validation. Overall, these data suggest that AS may be an important regulatory layer in liver tumor development and support future functional studies to define the mechanistic consequences of specific AS events and their potential value as biomarkers of chemical hepatocarcinogenesis.

PS 4309 Putative lncRNA-miRNA-mRNA Interactions Distinguish Spontaneous and Chemically Induced Mouse Hepatocellular Carcinomas

M. Xu, K. Kanchi, A. Brooks, T. Ton, J. Li, R. Sills, and A. R. Pandiri. The National Institute of Environmental Health Sciences, Durham, NC. Sponsor: C. Rider

Background and Purpose: Hepatocellular carcinomas (HCCs) in B6C3F1/N mice are a frequent endpoint in the National Toxicology Program (NTP) cancer bioassays. Recently, we have shown that HCCs arising due to aging (spontaneously) or due to chronic chemical exposure showed comparable genomic alterations. However, the role of non-coding RNAs (ncRNAs) and competitive endogenous RNA (ceRNA) relationships in shaping etiology-specific tumor biology remains incompletely understood. To address this gap, we have performed RNA-seq and miRNA-seq on B6C3F1/N mouse HCCs arising spontaneously due to age or due to chronic repeated dose exposures to potential human carcinogens. **Methods:** RNA-seq and miRNA-seq were performed on HCCs from B6C3F1/N mice arising spontaneously or due to chronic exposures to one of ten chemicals with diverse modes of action (four genotoxic and six non-genotoxic chemicals), and on age-matched control livers. Differentially expressed lncRNAs, miRNAs, and mRNAs between the untreated control livers and the HCC groups were identified using the DESeq2 R package ($|\log_2FC| > 1$, FDR < 0.05). The miRNA-mRNA functional analyses and pathway enrichment was performed using Qiagen Ingenuity Pathway Analysis (IPA) platform. **Results:** Across chemical-induced HCCs from male mice, 356-1042 lncRNAs, 129-205 miRNAs, and 1622-4060 mRNAs were differentially expressed. In comparison, 731 and 939 lncRNAs, 168 and 205 miRNAs, and 2888 and 3177 mRNAs were differentially expressed respectively in female and male spontaneous HCCs. Two miRNAs (*mmu-miR-879-5p* and *-703*) were upregulated and six miRNAs (*mmu-miR-30c-1-3p*, *-467c-5p*, *-3962*, *-467d-5p*, *-467e-5p*, *-592-5p*) were downregulated across multiple chemical-induced HCCs (n5), mainly BCA, BDCA, GBE, OZ, PCTFT and PM, suggesting chemical-specific miRNA deregulation. Thirty-nine target mRNAs of these DE miRNAs (mainly *mmu-miR-30c-1-3p* and *-212-3p*) were specific to chemically induced HCCs. Despite chemical-specific patterns, 49 miRNAs were upregulated and six miRNAs (*mmu-miR-12195-3p*, *-137-3p*, *-193a-3p*, *-215-5p*, *-455-3p* and *-455-5p*) were downregulated across all HCC groups regardless of exposure. Twenty-two target mRNAs of the DE miRNAs in both spontaneous and chemically induced HCCs were identified. Literature-based analyses identified putative lncRNA-miRNA-mRNA ceRNA relationships, including *NEAT1-mmu-miR-193a-3p-CCND1/MYC/N/TGFB2*, *XIST-mmu-miR-133a-3p-ELF3/PAX7/SOX4*, and *XIST-mmu-miR-137-3p-EPGN*, which were observed in chemically induced but not in spontaneous HCCs. Pathway enrichment suggested that genes within these networks may intersect with AMPK, ERK/MAPK, AKT, Activin/Inhibin, and WNT/ β -catenin signaling pathways, all of which influence hepatocyte growth and metabolic regulation. In contrast, a putative *PVT1-mmu-miR-455-5p-SOX11* axis was detected across all HCCs regardless of the etiology and may signal through the WNT/ β -catenin pathway. **Conclusions:** These findings provide a comprehensive characterization of lncRNA, miRNA, and mRNA dysregulation in spontaneous and chemically induced mouse HCCs, highlighting candidate ceRNA interactions and signaling pathways for further exploration especially for the different exposures examined in this study. The identified ncRNA networks and conserved signaling pathways offer new mechanistic leads and potential biomarkers of chemically induced hepatocarcinogenesis with translational relevance to human disease, and a framework for future validation studies.

PS 4310 Methylation and Transcriptomic Alterations Drive Tumor Promotion Pathways in Chemically Induced Mouse Hepatocellular Carcinomas

A. R. Pandiri, K. Kanchi, M. Xu, T. Ton, A. Brooks, L. Wharey, K. Gerrish, J. Li, and R. C. Sills. The National Institute of Environmental Health Sciences, Durham, NC. Sponsor: C. Rider

Background and Purpose: Hepatocellular carcinoma (HCC), the third leading cause of cancer mortality worldwide, arises from chronic etiologies including HBV/HCV infection, alcohol misuse, aflatoxin B1 exposure, and lifestyle-associated metabolic dysfunction. The B6C3F1/N mouse, widely used in the National Toxicology Program (NTP) carcinogenicity studies, develops HCCs spontaneously with aging and at higher incidences following chronic chemical exposures. Mouse HCCs share important morphologic and genetic features with subsets of human HCC. Prior work demonstrated that spontaneous and chemically induced mouse HCCs display broadly similar genomic alterations. Here, we hypothesized that chemically induced tumors harbor additional transcriptional and epigenetic dysregulation that distinguishes them from spontaneous HCCs. **Methods:** We analyzed HCCs arising spontaneously or following exposure to one of ten chemicals (4 genotoxic and 6 non-genotoxic) with diverse modes of action. DNA methylation profiling was performed using the Infinium MouseMethylation-12 v1.0 BeadChip, enabling high-resolution assessment of CpG methylation across promoter regions, and gene bodies. RNA sequencing of total RNA was conducted using Ribo-Zero depletion to capture both coding and noncoding transcripts. Differential gene expression analysis was carried out using standard pipelines with thresholds of $p < 0.05$ and $|\log_2FC| > 1.5$ to identify robust transcriptional changes. Methylation alterations were quantified in relation to expressed genes, allowing integration of epigenetic and transcriptomic signals. Functional pathway enrichment analyses were performed using gene sets derived from both DEG and methylation profiles. **Results:** Chemical-induced HCCs exhibited 1820-4585 DEGs, whereas spontaneous male HCCs showed 3789 DEGs. Across all tumors, 39-53% of DEGs also demonstrated altered methylation status, predominantly hypomethylation. Common pathways shared across spontaneous and chemically induced HCCs included FAK-mediated signaling via L1CAM interactions, S100 family signaling, RAF-independent MAPK1/3 signaling, and cell cycle regulatory pathways, indicating conserved oncogenic signaling in murine hepatocarcinogenesis. HCCs from chemical exposures displayed additional transcriptional and epigenetic alterations involving HIF1 α signaling, MSP-RON signaling, and cytokine-mediated pathways linked to IL-4, IL-13, IL-17A, and IL-10. These immune-modulatory changes promoted downstream activation of Wnt/ β -catenin and NF- κ B signaling, suggesting remodeling of the tumor immune microenvironment. Methylation profiling revealed epigenetic alterations in genes associated with alterations in receptor-type tyrosine-protein phosphatases, matrix metalloproteases, and RAF-independent MAPK1/3 signaling across HCCs regardless of the etiology. **Conclusions:** Spontaneous and chemically induced HCCs share activation of conserved oncogenic signaling pathways; however, chemical exposures induce additional transcriptional and epigenetic dysregulation involving hypoxia response pathways, cytokine signaling, and immune remodeling. HCCs from chemical exposures show additional transcriptional and epigenetic alterations that reshape the immune landscape to promote carcinogenesis. These integrated molecular profiles highlight convergent and exposure-specific mechanisms of hepatocarcinogenesis in the B6C3F1/N mouse and may support identification of biomarkers useful for evaluating chemical-induced liver cancer risk.

PS 4311 Mode of Action Analysis of the Tumor Triad Induced by DEHP

A. Luz¹, D. Alewell¹, C. Corton¹, J. Allran¹, C. Beachum¹, and A. Lowit². ¹US EPA, Research Triangle Park, NC; and ²US EPA, Washington, DC, DC.

Background and Purpose: The US Environmental Protection Agency's (EPA) Office of Pollution Prevention and Toxics is conducting a risk evaluation for di-ethylhexyl phthalate (DEHP), including a cancer hazard assessment. DEHP is a known activator of peroxisome proliferator-activated receptor alpha (PPAR α). PPAR α activators, including DEHP, are known to induce hepatocellular adenomas and/or carcinomas in rats and mice, as well as pancreatic acinar cell tumors (PACTs) and testicular Leydig cell tumors in rats (often referred to as the "tumor triad" in rats). A postulated mode of action (MOA) for liver tumors involving PPAR α activation has been experimentally supported and discussed by previous existing assessments of DEHP. However, a refined DEHP cancer analysis which also experimentally supports an MOA for PACTs and Leydig cell tumors has not been conducted. Thus, in conducting its DEHP risk evaluation and determining the proper cancer hazard assessment and dose-response approach (i.e., linear low-dose extrapolation vs. threshold approach), EPA performed a cancer MOA analysis of the tumor triad consistent with the 2005 EPA Guidelines for Carcinogenic Risk Assessment. **Methods:** In conducting its MOA analysis of the DEHP tumor triad, EPA considered available epidemiological, animal toxicology, and mechanistic evidence, including published reviews by Corton et al. (2018, 2014) and Klaunig et al. (2003). Further, to address uncertainty in precise mechanisms of DEHP-induced PACTs and Leydig cell tumors with less experimental and direct MOA evidence, EPA considered epidemiological and animal experimental evidence on prototypical PPAR α activators (e.g., WY 14,643) and hypolipidemic drugs (e.g., clofibrate, fenofibrate, gemfibrozil) that mechanistically lower serum lipid levels through activation of PPAR α . Data for these PPAR α activators was used to support inferences for DEHP-induced liver, pancreatic, and testicular tumors that

share postulated mechanistic initiating events. **Results:** Available evidence indicated that DEHP is not directly mutagenic or genotoxic. Experimental studies of mice and rats, as well as mechanistic data, support the conclusion that DEHP-related hepatocellular adenomas and carcinomas in rodents arise through a PPAR α MOA. As a novel approach, EPA included evidence from hypolipidemic drugs and other prototypical PPAR α activators to support inferences. Data for these hypolipidemic drugs and prototypical PPAR α activators demonstrate that these chemicals induce the tumor triad in rats, but not in humans when prescribed at doses several orders of magnitude higher than levels of exposure to DEHP for the general U.S. population based on NHANES biomonitoring data. Based on inferences from hypolipidemic drugs, EPA concluded that PACTs, Leydig cell tumors, and liver tumors are related to PPAR α activation following chronic DEHP exposure. **Conclusions:** Overall, review of available evidence indicated, in addition to hepatocellular tumors, PACTs and Leydig cell tumors in rats are related to PPAR α activation following chronic exposure to DEHP and hypolipidemic drugs. Although some uncertainties remain, there is strong evidence to support the postulated, non-genotoxic, PPAR α MOA inclusive of the tumor triad, indicating a non-linear threshold approach is appropriate in evaluating DEHP cancer risk. Under the EPA Guidelines for Carcinogen Risk Assessment, EPA determined that DEHP is "Not Likely to be Carcinogenic to Humans" at doses below levels that do not result in PPAR α activation. In consideration of this analysis with the overall DEHP human hazard assessment, EPA determined conducting quantitative dose-response assessment of tumor outcomes were not appropriate considering the identified non-cancer point of departure based on effects on the developing male reproductive system consistent with phthalate syndrome is expected to adequately account for all chronic toxicity, including carcinogenicity. The views expressed in this abstract are those of the authors and do not necessarily represent the views or policies of US EPA.

PS 4311a A Multi-Lab Single-Cell and interpretable AI Investigation of Pesticide NGTxC Mechanisms in 3D Lung Models

H. Groux¹, F. Cottrez¹, E. Boitel¹, L. Peyre-Teisseyre¹, G. Vassaux², B. Mari², C. Bonjour², L. Guardini², J. Mille², C. Pasquier³, F. Abou Choucha³, X. Fernandez⁴, C. Dubois⁴, V. Ventos⁵, and J. Darmon⁵. ¹ImmunoSearch, Grasse, France; ²Institut de Pharmacologie Moléculaire et Cellulaire (IPMC) UMR7275 CNRS - Inserm U1323 - Université Côte d'Azur, Sophia Antipolis, France; ³Université Côte d'Azur, CNRS, I3S, Sophia Antipolis, France; ⁴CNRS - Institut de Chimie de Nice Université Côte d'Azur, Nice, France; and ⁵NukkAI, Paris, France. Sponsor: F. Gerberik

Background and Purpose: Non-genotoxic carcinogens (NGTxC) are challenging to identify because they do not induce direct DNA damage but act through progressive alterations in gene regulation, epithelial identity, and tissue homeostasis. The ImmunoSearch-led NewgenTOXiv consortium (3 academic laboratories, ImmunoSearch Labs, and AI partner NukkAI) aims to define early mechanistic signatures capable of distinguishing NGTxC from structurally related non-carcinogens across multiple chemical families. Here, we present the first results obtained on a set of pesticides and highlight the broader applicability of the approach to additional NGTxC compound classes. **Methods:** Human 3D airway tissues (Epithelix MucilAir™) were exposed to three NGTxC pesticides (Aldrin, Dieldrin, p,p'-DDT) and two non-carcinogenic analogs (Endrin, Methoxychlor) using two exposure paradigms: (1) acute, consisting of a single non-cytotoxic topical or systemic dose followed by single-cell transcriptomic analysis at 6 hours; and (2) chronic, involving repeated low-dose exposures for eight weeks with longitudinal sampling. Transcriptomic datasets were analyzed using regulatory network reconstruction and NukkAI's interpretable AI pipeline. Their approach combined an autoencoder to learn low-dimensional latent representations of gene expression, jointly trained with a classifier to separate NGTxC from non-carcinogens. An interpretable classifier was subsequently applied to the latent space to identify the most discriminative regions and extract pathway-level drivers for mechanistic interpretation. **Results:** Across independent analytical strategies, NGTxC pesticides consistently induced a convergent set of pathway-level perturbations absent in structurally related non-carcinogens. Acute exposures triggered disruption of epithelial differentiation, marked loss of ciliary organization, activation of stress-response and pro-inflammatory pathways, and selective engagement of pro-survival and repair programs associated with epithelial plasticity. Chronic exposures amplified these early signatures, revealing progressive activation of regeneration-linked proliferative circuits consistent with early non-genotoxic carcinogenic processes. Importantly, the same analytical pipeline applied to additional NGTxC compound families revealed comparable early mechanistic patterns, demonstrating that the approach is not pesticide-specific but captures cross-chemical NGTxC biology. **Conclusions:** Combining 3D human lung models, single-cell genomics, and interpretable AI provides a robust multi-laboratory strategy for mechanistic discrimination of NGTxC carcinogens. This study offers the first single-cell-resolved, AI-supported map of pesticide-induced NGTxC activity in human airway tissue and demonstrates that the same analytical framework successfully identifies comparable early NGTxC signatures in other chemical classes. These findings support the development of mechanism-based, cross-chemical screening strategies for NGTxC hazard identification in regulatory toxicology.

PS 4312 DNA Damage Evaluation of Benzo[b]Fluoranthene (B[b]F) Using Rat Liver Comet Assay

J. A. Bhalli, B. Yard, S. Philips, and M. Simolin. Frontage Laboratories, Concord, OH.

Background and Purpose: Benzo[b]fluoranthene (B[b]F) is a polycyclic aromatic hydrocarbon (PAH) produced from the incomplete combustion of organic materials, such as fossil fuels and tobacco. While B[b]F has been shown to be genotoxic in various *in vitro* assays (e.g., Ames test), its *in vivo* genotoxicity and carcinogenicity properties are less well characterized compared to other PAHs such as benzo[a]pyrene. **Methods:** In this study, the genotoxic potential of B[b]F was investigated using rat liver Comet assay. Male Sprague-Dawley rats (N=5) were orally administered B[b]F at 0, 50, 100, and 200 mg/kg/day for 3 consecutive days. Ethyl Methanesulfonate at dose level of 150 mg/kg/day was used as positive control. Animals were euthanized 3-4 hours after the 3rd dose and left lateral liver lobe was collected to conduct Comet assay the same day with fresh liver tissues. **Results:** B[b]F did not induce any adverse clinical signs or decreases in body weight or food consumption over 3 days of dosing. Percent tail intensity (%TI) was used as measure of DNA damage by scoring 150 cells (75/slide) per animal. Group and individual median %TI in vehicle control animals was <6%. No increase in the median %TI was observed in the low (4.75%) and mid (4.54%) dose groups. Median %TI (66.95%) in the high dose group was statistically significant compared to the concurrent control. Positive control %TI (64.89%) was statistically significant and within the positive control historical control range. **Conclusions:** The results indicate that the B[b]F has the potential to cause DNA damage at higher but clinically non-toxic dose levels.

PS 4313 Evaluating the Applicability of the ICH M7 Less Than Lifetime Concept to N-Nitrosomorpholine Using Error-Corrected next-generation sequencing

S. Zhang. Pfizer, Groton, CT. Sponsor: S. Zhang, Environmental Mutagenesis and Genomics Society

Background and Purpose: The ICH M7 guideline introduced the "less than lifetime" (LTL) concept for assessing mutagenic impurities, proposing that cumulative exposure over a shorter duration may present a comparable potential cancer risk to lower-dose lifetime exposure. This framework permits higher daily intake limits for mutagenic impurities under short-term exposure scenarios while maintaining equivalent risk levels. Nitrosamines, classified under the "Cohort of Concern" in ICH M7 due to the potent carcinogenicity of certain compounds in animal studies, present a regulatory challenge when applying LTL adjustments. **Methods:** This study investigates the applicability of the LTL approach to nitrosamine using rodents exposed to N-Nitrosomorpholine (NMOR) at various dose levels for 3, 10, or 28 days. Mutagenicity was assessed using two different error-corrected next-generation sequencing (ecNGS) platforms: Duplex Sequencing (DS), a targeted method, and SMM-seq, a non-targeted approach. These technologies enable ultra-accurate detection of endogenous mutations across species. **Results:** The results demonstrated a linear relationship between genotoxicity and total exposure, consistent with Haber's law, suggesting that total exposure may serve as a valid metric for NMOR-induced mutagenicity. Both ecNGS platforms produced comparable mutation profiles, reinforcing the robustness of the analytical methods. **Conclusions:** These findings offer critical insights into the risk assessment of nitrosamines under LTL exposure scenarios and may inform future regulatory considerations regarding the application of the LTL concept to this class of compounds and adoption of ecNGS methods in the genetic toxicology field.

PS 4314 Investigation of the Effects of Dimethyl Sulfoxide on the *in vivo* Micronucleus Test in Rats

H. Ouchi, Y. Ikeuchi, K. Tanioka, M. Shoji, T. Takahashi, and T. Shoda. Toxicology Research Laboratories, Yokohama Research Center, Shionogi & Co., Ltd., Yokohama, Kanagawa, Japan. Sponsor: H. Ouchi, Japanese Society of Toxicology

Background and Purpose: In order to assess the safety of a drug candidate compound under development, a high systemic exposure level corresponding to the maximum tolerated dose in animals is generally required in the non-clinical toxicity studies. However, we often encounter difficulties obtaining higher systemic exposures despite investigating various dosing formulations. Therefore, identifying a vehicle applicable to toxicity studies that has high solubility and is well-tolerated and which could help to obtain high systemic exposures would be of considerable benefit for safety assessment. Dimethyl sulfoxide (DMSO) is widely used as a solvent in *in vitro* toxicity studies, but data on its role as a vehicle in *in vivo* micronucleus tests in rats is limited. The purpose of this study is to investigate whether oral or intravenous administration of dimethyl sulfoxide could be applicable for a rat micronucleus test. **Methods:** DMSO was administered orally at the dose levels of 5 and 10 mL/kg or intravenously at 1 mL/kg to non-fasted male Sprague-Dawley rats (8 weeks of age, 5-9 animals/group) for 2 days. The animals in the negative control group were given saline in the same manner. The animals in the positive control group (5 animals) received a single intraperitoneal injection of 50 mg/kg cyclophosphamide. During the dosing period, clinical observations and measurements of the body weights and

food consumption were conducted. Bone marrow smears were prepared approximately 18 to 24 hours after the last dose. The frequency of micronucleated polychromatic erythrocytes (MNPCEs) in the bone marrow smear was examined under the microscope and the proportions of reticulocyte (RETs) to erythrocytes in the bone marrow smears, a marker of bone marrow toxicity, were also determined. **Results:** The following changes were observed in the group intravenously administered DMSO: decreased locomotor activity immediately after dosing on Day 2 in 1/9 animal, reddish urine in 8/9 animals on Day 1 and 9/9 animals on Day 2. No DMSO treatment-related findings in the clinical observations were observed in the group administered DMSO orally. In both administration route groups, there were no DMSO treatment-related findings in the body weights and food consumption. DMSO did not increase the frequency of MNPCEs and there were no treatment-related changes in the proportion of RETs in both administration route groups when compared with the negative control group. In the positive control group, the frequency of MNPCEs was statistically significantly higher than that in the negative control group. **Conclusions:** DMSO is considered to be a useful vehicle for rat bone marrow micronucleus tests at doses up to 10 mL/kg for oral administration and up to 1 mL/kg for intravenous administration.

PS 4315 Optimization of S9 metabolism protocols for *in vitro* genotoxicity testing

G. Hendriks. Toxys, Leiden, Netherlands.

Background and Purpose: S9 liver fractions (S9) from rat, hamsters or humans are used in *in vitro* assays to mimic the metabolism in the liver. This metabolism can increase or decrease the DNA reactivity of a substance, resulting in different responses in absence and presence of S9. For the bacterial or mammalian cell genotoxicity assays with OECD Test Guidelines, typically cells are exposed for 24-30h in absence of S9 and 3-4h in presence of S9 mix. Cytotoxicity of S9 often limits exposure time and S9 concentration that are tolerated in the *in vitro* assays. New Approach Methodologies (NAMs) that investigate multiple direct and indirect genotoxic modes-of-action, would benefit from tailored S9 metabolism protocols. In addition, some classes of chemical, e.g. N-nitrosamines, required dedicated *in vitro* metabolism protocols to investigate their genotoxicity. Recently an enhanced S9 protocol for the Ames test (EAT) was developed. In this study, we explored various modifications to the standard *in vitro* metabolism protocol based on S9 liver fraction from phenobarbital/ 5,6-benzoflavone-exposed rats and hamster. **Methods:** To investigate optimizations of S9 metabolism protocol, the mammalian cell-based GFP reporter assay ToxTracker was used. This NAM includes six different fluorescent reporter genes for direct DNA damage as well as indirect genotoxicity related to oxidative stress, protein unfolding and cytotoxicity. Differential activation of the reporter genes was assessed using flow cytometry. Different concentrations of S9 extract, different co-factor mixes, exposure times and S9 from different species were explored. To test the optimized S9 metabolism protocols, a selection of 15 reference chemicals, including NDMA, Aflatoxin B1, Cyclophosphamide and Benzo[a]pyrene, was applied to compare different S9 exposure protocols. **Results:** We first determined the maximum concentration of rat S9 mix that would be tolerated by the ToxTracker cells for 4h and 24h exposure. Importantly, the maximum S9 concentration did not induce cytotoxicity nor activated any of the (geno)toxicity reporters in ToxTracker. Decreasing the S9 mix concentration from 1% to 0.4% allowed for 24h continuous exposure. Next, we compared the metabolic effectiveness of the short and long exposure protocol for 15 pro-genotoxic compounds. No significant difference between the two exposure protocols was observed for direct DNA reactive genotoxins. However, indirect genotoxicity related to oxidative stress after S9 metabolism for benzo[a]pyrene was only observed in the 24h 0.4% S9 protocol. For the *in vitro* genotoxicity assessment of N-nitrosamines, S9 mixes from rat and hamster liver extracts were compared. Hamster S9 was more efficient in metabolism of NDMA. To improve metabolic activation, the hamster S9 concentration was increased to 10% and exposure time reduced to 30 minutes, followed by 4 h exposure at 3% S9. The addition of calcium chloride to the hamster S9 mix further improved the metabolic activity. This enhances metabolism protocol was successfully validated with 7 genotoxic N-nitrosamines, including NDMA, NDEA, NDELA and NF. **Conclusions:** By reducing the S9 concentration and extending exposure to 24h, both direct and indirect genotoxic effects of compounds could be detected in ToxTracker. Metabolism of 15 pro-genotoxins was comparable using a 3h and 24h exposure protocol. For genotoxicity assessment of N-nitrosamines, a dedicated hamster S9-based metabolism protocol was developed.

PS 4316 Repair Assisted Damage Detection (RADD), a versatile tool for measuring DNA damage across species and damage types

N. R. Gassman, A. Hernandez, H. Levi, N. Mukherjee, J. Hedlich-Dwyer, and T. Morrison. University of Alabama at Birmingham, Birmingham, AL.

Background and Purpose: Numerous DNA damaging events occur daily from the environments we live in, the lifestyles we lead, and through our normal metabolic processes. Damaging events that directly modify DNA bases have been linked to mutagenesis and carcinogenesis. There is a substantial need to characterize DNA damage events and their repair to understand how they contribute to disease etiol-

ogy. Current methods to characterize and quantify the formation of DNA adducts have significant drawbacks because they often require a substantial amount of biological sample, highly specialized expertise and equipment, and depending on technique, may be limited to the detection and quantification of only a handful of DNA adducts at a time. There is a pressing need for high-throughput, easy-to-use, fluorescence-based methodologies for the measurement of a broad spectrum of DNA lesions across biological samples. We have validated the Repair Assisted Damage Detection (RADD) assay to address this need. **Methods:** RADD utilizes a DNA damage processing repair enzyme cocktail to detect and modify sites of DNA damage for a subsequent gap filling reaction that labels the DNA damage sites. This ability to detect and label a broad spectrum of DNA lesions within cells offers a novel and easy-to-use tool for assessing levels of DNA damage in cells. **Results:** Here, we present several applications of the RADD methodology to map DNA damage at promoter sites, identify DNA lesions from emerging environmental chemicals, examine DNA repair defects, and understand environmental stressors and their impact on genomic stability across different species, i.e., mice, rats, zebra finches, and *Drosophila*. Using RADD, we have identified unique DNA lesion signatures for the e-cigarette component, dihydroxyacetone, and monitored the induction of DNA lesions from acute, sub-acute, and chronic exposures. We also identified fluctuations in DNA damage across a population of zebra finches that experiences different stressors. Finally, we identified novel DNA damage induction and DNA repair changes induced in mice that were fed a high carbohydrate and fat diet. **Conclusions:** These applications demonstrate that RADD offers researchers a unique tool for investigating DNA adducts and DNA repair across biological specimens that may provide new insight into DNA repair defects and DNA damage induction, particularly for non-genotoxic chemicals or complex exposures.

PS 4317 Regulatory-Compliant Genetic Toxicology Assessment for Tides

M. Zhang, L. Gao, M. Chen, X. Li, and R. Zhang. WuXi AppTec (Suzhou) Co., Ltd., Suzhou, China.

Background and Purpose: Peptide and oligonucleotide therapeutics, commonly grouped as TIDES, are two of the fastest-growing and most promising modalities within the pharmaceutical industry. Oligonucleotides (ONs), comprising single or double strands of RNA or DNA, act via mechanisms such as antisense oligonucleotides (ASOs), small interfering RNAs (siRNAs), microRNAs (miRNAs), small activating RNAs (saRNAs), and aptamers. Peptides mean any polymer that are composed of 40 or fewer amino acids. With the unique properties, Tides have emerged as a prominent force in innovative drug development, to better understand the genotoxicity of Tides, we conducted a retrospective analysis of genotox data for both FDA-approved Tides and the Tides previously evaluated in our laboratory. **Methods:** No single assay is able to detect all types of DNA damage, a test battery has been adopted to evaluate the genotoxic liability of novel pharmaceuticals. ICH S2(R1) guidance outlines appropriate *in vitro* and *in vivo* tests. The guidance provides two options for the standard genetic toxicology battery that includes an assessment of mutagenicity in a bacterial reverse mutation assay and genotoxicity evaluation in mammalian cells using *in vitro* and/or *in vivo* tests. Genotoxicity data of Tides that were either approved for marketing by the FDA between 2016 and 2025, or evaluated at WuXi AppTec (Suzhou) Co., Ltd. between 2018 and 2025, were collected for this retrospective analysis. **Results:** Percentage of different classes of novel therapeutics approved by the FDA in the span of 2016-2025 of which Tides attribute for 11.2%. A total of 20 Oligonucleotide drug products that includes 1 aptamer, 11 antisense oligonucleotides (ASOs), 7 small interfering ribonucleic acids (siRNAs), and 1 mixture of single-stranded and double-stranded polydeoxyribonucleotides have been identified. All oligonucleotide drug products were evaluated for genotoxicity and the results are all negative. A total of 33 peptides that includes 9 Peptide-Drug Conjugates (PDCs); 19 oligopeptides (2-9 amino acids); 1 Polypeptide (PP), 32 of them are synthetic. 24/33 (73%) were evaluated for Ames: 1 positive, 2 false positive (due to feeding effect), others are negative. 23/33 (70%) were evaluated *in vitro* mammalian cell test, 16 run for chromosomal aberration assay (CAA), others are for MLA/micronucleus assay (MNT), and they are all negative. 22/33 (67%) were evaluated for *in vivo* micronucleus (12 in rats and 10 in mice), and they are all negative. From 2018 to 2025, there are 19 peptides and 35 oligonucleotides tested in our laboratory. For the 19 peptides, 12/19 (63%) were evaluated for Ames; 15/19 (79%) were evaluated in CAA, and 11/19 (58%) were evaluated for *in vivo* micronucleus, they are all negative. For the 35 oligonucleotides, 35/35 (100%) were evaluated for Ames and CAA, 31/35 (89%) were evaluated for *in vivo* micronucleus, 1 equivocal (WoE was used for evaluating the marginal increase), 2 false positives (one positive is contributed by the excipient, and the other is impacted by the binding between drug product and fluorescent dye), the others are negative. **Conclusions:** Consistent with reports in the literature, the Oligonucleotide Safety Working Group's genotoxicity testing subcommittee believes that therapeutic oligonucleotides are unlikely to be genotoxic and peptides are large with poor membrane permeability and are not expected to reach the cytoplasm or nucleus, thus they would not interact directly with DNA or the mitotic apparatus, and their degradation releases endogenous amino acids which should pose no genotoxic risk. In summary, most Tides have undergone genetic toxicology testing, and the results have generally been negative.

E. Webb¹, D. Farmer¹, and L. Kier². ¹Bayer CropScience, Chesterfield, MO; and ²Private Consultant, Saint Louis, MO.

Background and Purpose: Glyphosate-based herbicide formulations (GBFs) are used world-wide to control unwanted vegetation. Genotoxicity testing is a key part of their safety evaluation, addressing potential for risks of heritable mutations and genotoxic mechanisms of carcinogenesis. Comprehensive science-based regulatory reviews have consistently concluded that approved uses of Bayer GBFs do not present a human health concern. These evaluations include consideration of numerous regulatory and published studies on genotoxicity of diverse GBFs. Many regulatory genotoxicity studies of Bayer GBFs have not previously been published; their experimental details and results are summarized here. **Methods:** Regulatory studies included *in vivo* mammalian (mouse) bone marrow micronucleus, *in vitro* human lymphocyte cytokinesis block micronucleus, and bacterial reverse mutation studies, which were conducted under good laboratory practices (GLPs) and according to international test guidelines that were applicable at the time of the studies. Where there were exceptions to GLPs or test guidelines, they did not affect the integrity or interpretation of the study data or the overall conclusions on genotoxicity. The tested Bayer GBFs included concentrated products, relevant dilutions, and ready-to-use products containing various glyphosate salts (isopropylamine, potassium, and ammonium) of differing concentrations, and various proprietary surfactant blends ranging from 0% to 20%. Twelve *in vivo* micronucleus studies (1998-2016) generally followed OECD Test Guideline 474. Mice received two doses separated by approximately 24 hours, with bone marrow harvested 24 hours after the second dose. Six of the studies used the intraperitoneal route of administration while the other six used the oral (gavage) route of administration. Three dose levels were tested, and generally five males and five females were analyzed for each treatment group. Depending on the study, 1000 to 4000 polychromatic erythrocytes (PCEs) per animal were scored using coded slides. Eighteen *in vitro* micronucleus studies (2016-2023) generally followed OECD Test Guideline 487, using a cytokinesis-block design, and were either dosed the limit dose of 2 mg/mL or the highest dose producing acceptable cytotoxicity. Treatment conditions included 4-hour exposures with and without metabolic activation and an extended exposure without metabolic activation. Two thousand binucleated cells (1000 each from duplicate cultures) per treatment were scored for micronuclei using coded slides. Twenty-seven bacterial reverse mutation studies (1998-2024) generally followed OECD Test Guideline 471, assessing five bacterial strains using both plate incorporation and/or pre-incubation methods at up to nine dose levels, in triplicate, with and without metabolic activation. Plates were incubated (48-72 hours) and scored for the presence of revertant colonies. **Results:** All twelve *in vivo* mammalian micronucleus studies were negative for genotoxicity. All eighteen *in vitro* micronucleus assays in human lymphocytes and all twenty-seven bacterial reverse mutation assays were also negative. **Conclusions:** Across fifty-seven previously unpublished studies - combined with earlier published data - Bayer GBFs consistently showed no evidence of genotoxicity. Results were uniformly negative across *in vivo* mammalian micronucleus, *in vitro* micronucleus, and bacterial reverse mutation studies, covering multiple formulations, concentrations, glyphosate salt forms, and proprietary surfactant blends. These findings substantially expand the genotoxicity database for Bayer GBFs and strengthen the overall weight of evidence that Bayer GBFs are not genotoxic.

PS 4319 **Not all literature-based structural alerts lead to mutagenicity**

L. Gao, D. Li, R. Zhou, J. Wang, X. Ren, S. Jiang, M. Chen, X. Li, and R. Zhang. WuXi AppTec (Suzhou) Co., Ltd., Suzhou, China.

Background and Purpose: DNA-reactive substances are capable of directly damaging DNA even at low concentrations, which can result in mutations and potentially lead to cancer. According to reports, there is a strong correlation between structural alerts indicative of DNA reactivity and mutagenic potential, and structure-based assessments are useful for predicting bacterial mutagenicity outcomes. There are a variety of approaches to conduct this evaluation including a review of the literature-based structural alerts (LBSAs), and/or computational toxicology assessment. The mutagenic potential can be typically identified using bacterial reverse mutation assay. In order to gain a better understanding of the correlation between structural alerts and mutagenic potential, and to facilitate expert review using LBSAs, we conducted a retrospective analysis of bacterial reverse mutation data with structures generated in our laboratory. **Methods:** The bacterial reverse mutation (Ames) assay was performed in compliance with ICH S2(R1) and OECD TG471, some studies are conducted using miniaturized versions of standard assays, such as the mini-Ames assay. The Ames studies conducted at WuXi AppTec (Suzhou) Co., Ltd. from 2018 to 2025 were collected for the retrospective analysis. Only data with available structural information are included, and these mainly pertain to impurities. The structures are classified based on LBSAs, such as those published by Ashby, Tennant and Müller. **Results:** Of the 392 compounds tested in the Ames, 279 (71.2%) were concluded to be negative and 113 (28.8%) were mutagenic. Among these 392 compounds, there are 242 compounds containing LBSAs, and the remaining 150 compounds lack LBSAs. Out of 150 compounds without LBSAs, 14 (9.3%) were mutagenic. For 242 compounds containing LBSAs (totally 15 categories), only 99 (40.9%) were

actually mutagenic in the Ames test, indicating that relying solely on LBSAs without taking mitigating factors into account can result in excessive sensitivity. The highest frequencies of LBSAs found were in three categories that together comprise over 70% of all alerts: aromatic amines and derivatives, alkyl halides and aromatic nitro compounds. The percentage (58.3%) was higher for aromatic nitro compounds, another two classes (aromatic amines and alkyl halides) that were between 40% and 45% Ames positive. The mutagenicity of LBSAs is impacted by physicochemical properties (such as molecular weight), chemical reactivity and metabolic activation and these expertise can be useful in expert reviews of *in silico* predictions. Each alerting structure has its own mutagenic mechanism and can also lead to positive results in specific strains. Two troubleshooting cases are presented here by utilizing these knowledge. Case 1: compound A is a small molecule for metabolic diseases. Compound A with lower purity is positive in TA98/TA100 with S9, but negative in the absence of S9 mix and other strains. Since no LBSAs are identified in compound A, considering the specific positive strains, it is suspected that the positive result is caused by impurities (such as aromatic amines). Aromatic amines are deemed to be specifically acting through the nitrenium ion mechanism of action and generally be positive in TA98/TA100 in the presence of S9 mix. The follow-up studies confirmed the suspicion. Case 2: Invalid Ames due to extreme high revertants even in negative control. Based on the specific positive strains and the alerting structure knowledge, ethylene oxide (EO), a common reagent for sterilization, was suspected (sensitive strains are TA100 and TA1535). The vendor confirmed that EO was used to sterilize the petri dishes. After we switched to petri dishes sterilized by gamma irradiation, everything returned to normal. **Conclusions:** In summary, 392 compounds were tested over an 8-year period in our laboratory, of which 113 (28.8%) were found to be mutagenic in the Ames test. The probability of a positive result for compounds containing LBSAs was 40.9%, compared to only 9.3% for those without LBSAs. LBSAs can be a useful tool in expert reviews of *in silico* predictions and in troubleshooting. However, relying solely on LBSAs without taking mitigating factors into account may lead to a significantly higher rate of false positives.

PS 4320 **Control Charting and Variance Partitioning of Historical Negative Controls: Rat Liver Micronuclei as a Real-World Example**

S. Avlasevich, and S. Dertinger. Litron Laboratories, Rochester, NY.

Background and Purpose: Historical control data (HCD) from negative/vehicle animals can provide valuable context for interpreting genotoxicity assay results, yet recent guidance from the International Workshops on Genotoxicity Testing (IWGT) emphasizes that their use should depend on the data's overall quality and stability. We applied these principles to liver micronucleus (%MNHEP) data from 26 independent rat studies (Crl:CD; 3 male and 3 female vehicle control rats per study; age at time of tissue harvest 5 or 7 weeks). **Methods:** %MNHEP were scored via flow cytometry, and log₁₀-transformed values were evaluated with JMP Pro (v18) software using Individual (I-) charts, Nelson Rules, and Variance Components Analysis (VCA). **Results:** Most %MNHEP values fell within ± 2 -sigma limits, as defined by the I-chart methodology, indicating overall process control. Even so, there was a low-value time interval encompassing studies 16-24 suggesting a temporary yet sustained downward shift. Although the underlying cause of this shift has not been identified, its persistence warrants analytical attention. Including this low-response time interval widened the HCD distribution and increased inter-study variability: the Stability Index (SI) for the full data set was 1.24, improving to 1.14 after excluding studies 16-24. VCA showed total variability estimates as Study = 43.2 %, Sex = 0.6 %, Age at Time of Harvest = 0 %, Vehicle = 0 %, and Inter-animal = 56.3 % when all data were included; after excluding studies 16-24 these values were Study = 24.4 %, Sex = 1.1 %, Age at Time of Harvest = 0 %, Vehicle = 0 %, and Inter-animal = 74.5 %. To use these HCD for "Criterion C" purposes (i.e., comparison of index study results to HCD), we have been experimenting with a compatibility check/requirement. For example: if the concurrent negative-control group mean falls below the 20th percentile of the majority-era HCD distribution of group means, Criterion C is not applied and interpretation relies on concurrent vehicle controls. When instituting this requirement, 2 of 17 majority-era studies and each of 9 low-response studies were deemed ineligible for Criterion C-type comparisons. **Conclusions:** The use of HCD as an aid for interpreting index study results should be highly transparent, and also provide some flexibility given the underlying structure of the data and real-world issues that may be encountered. The approach described herein illustrates how process-control tools can support nuanced, evidence-driven use of HCD in genotoxicity assessment.

PS 4321 **Generalizability of an S9 Metabolic Activation System Optimized for Nitrosamines: *In vitro* MicroFlow and MultiFlow Assay Results**

S. Bryce, S. Avlasevich, J. Bemis, and S. Dertinger. Litron Laboratories, Rochester, NY.

Background and Purpose: Certain N-nitrosamines are DNA-reactive, and this genotoxic activity often requires CYP-mediated metabolic. Although exogenous rodent S9 systems contain relevant CYP isoforms to varying degrees, the genotoxicity of some important N-nitrosamines can be challenging to detect in mammalian cell assays. To address this, an optimized exogenous S9 metabolic activation protocol was developed that combines rat and hamster S9 fractions with CaCl₂-supplemented cofac-

tors according to the report by O'Neill and colleagues [Environmental Mutagenesis 4(1982)7-18]. We report here on the evaluation of set of nitrosamines that have now been extended to include several non-nitrosamines in order to more broadly evaluate the generalizability of the method. **Methods:** Human lymphoblastoid TK6 cells (functional p53) were treated with each of eight nitrosamines (NDMA, NDEA, NNK, NNN, NPIP, NPYR, NMOR, NDELA), three metabolically activated genotoxiciants (cyclophosphamide [CP], benzo[a]pyrene [BaP], and 2-amino-1-methyl-6-phenylimidazo[5-b]pyrene (PhIP)), and two cytotoxicants (Tunicamycin and Curcumin). All chemical treatments occurred for 4-hours in the presence of the optimized S9 mix (1.5% Rat plus 1.5% Hamster liver S9 fractions, a NADPH generating cofactor mix that includes NADP, glucose-6-phosphate, KCl, MgCl₂, and excess CaCl as described by O'Neill et al.). At the 4-hour time point, cells were washed and cells were allowed to recover for 20-hours. At the 4- and 24-hour timepoints, cells were processed with MultiFlow DNA Damage Assay reagents to provide γ -H2AX and p53 activation measurements. At the 24-hour timepoint, cells were processed with *in vitro* MicroFlow (micronucleus, or MN) measurements. All these biomarkers were acquired via flow cytometry. Quantitative benchmark dose (BMD via PROAST v70.0) and area-under-curve (AUC) metrics were complemented by ToxPi visualization and principal component analysis (PCA) to evaluate mechanistic clustering and potency rankings. **Results:** Aggregate biomarker responses revealed that nitrosamines exhibited a wide range of potencies (NNK ~ NNN > NDMA > NDEA > NPIP ~ NPYR > NMOR >> NDELA). Interestingly, temporal γ -H2AX readings revealed what appears to be remarkable repair kinetics of NNN and NNK, whereby robust γ -H2AX signals at the 4hr time point where absent following the washout and 20 hour recovery period. CP, BaP, and PhIP produced strong S9-dependent responses, validating the generalizability of the nitrosamine-optimized metabolic activation system. Tunicamycin and Curcumin were cytotoxic, and curcumin induced what appeared to be an MN response. Even so, MultiFlow's biomarkers were unresponsive to curcumin, which tends to suggest an irrelevant MN response. ToxPi and PCA analyses using BMD and AUC values resulted in clustering of compounds by mechanistic class and potency. **Conclusions:** The optimized exogenous S9 metabolic-activation protocol, featuring a 4-hour exposure and 20-hour recovery design, improves assessment of nitrosamines, while remaining applicable to other classes of pro-genotoxiciants. When combined with MultiFlow and MicroFlow assays, this system represents an economical hazard ID platform that is likely complementary to Ames assays, given the important advantages stemming from its mammalian cell-based nature.

PS 4322 Hemoglobin N-(2-Hydroxyethyl)valine as a Noninvasive Surrogate of Ethylene Oxide Exposure Correlating with DNA Adduct Formation

J. Feng, C. Liu, J. Peng, H. Zhao, X. Wang, and K. Lu. University of North Carolina at Chapel Hill, Chapel Hill, NC.

Background and Purpose: Ethylene oxide (EtO) is a reactive epoxide and a known human carcinogen that alkylates DNA to form mutagenic adducts, including N7-(2-hydroxyethyl)guanine (N7-HEG) and O6-(2-hydroxyethyl)-2'-deoxyguanosine (O6-HEdG). Quantifying genotoxicity induced by EtO remains challenging and invasive because it requires tissue sampling. In contrast, hemoglobin N-(2-hydroxyethyl)valine (HEV) is a blood-based biomarker that can reflect cumulative EtO exposure. This study aimed to determine whether HEV can serve as a surrogate of internal EtO exposure that quantitatively correlates with DNA adduct formation across major tissues. **Methods:** B6C3F1/J mice were exposed to EtO via whole-body inhalation at concentrations ranging from 0.05 to 200 ppm (6 h/day for 28 days). Blood and tissues, including liver, lung, mammary gland, and bone marrow, were collected after exposure. HEV was released from hemoglobin by acid hydrolysis and quantified using a highly sensitive LC-MS/MS method. DNA adducts (N7-HEG and O6-HEdG) were simultaneously quantified in tissues using validated LC-MS/MS assays. Relationships between HEV and DNA adduct levels were evaluated using Pearson correlation analysis. **Results:** HEV levels in hemoglobin increased in a dose-dependent manner with EtO exposure. Parallel dose-dependent increases were observed for both N7-HEG and O6-HEdG across all four tissues. Strong linear correlations ($R^2 = 0.72-0.95$) were found between blood HEV and DNA adduct levels, showing that HEV formation in hemoglobin mirrors tissue DNA alkylation. **Conclusions:** This study establishes hemoglobin N-(2-hydroxyethyl)valine as a noninvasive and mechanistically relevant surrogate biomarker of ethylene oxide exposure. The strong quantitative correlation between HEV and tissue DNA adducts supports its use in translational biomonitoring and in improving risk assessment of EtO-induced genotoxicity.

PS 4323 Optimization of an Exogenous Metabolic Activation System for the Detection of Nitrosamines with Human Cell-Based Genotoxicity Assays

S. Avlasevich, J. Bemis, S. Dertinger, and S. Bryce. Litron Laboratories, Rochester, NY.

Background and Purpose: Nitrosamines such as NDMA, NDEA, NNK, NMOR, NPYR, NNN, and NDELA are established mutagens and carcinogens that require metabolic activation to elicit genotoxic effects. However, standard *in vitro* assays and the exogenous metabolic activation systems applied, i.e. rat S9 fractions, often show

limited sensitivity or inconsistent detection of such compounds. Recent advances such as those utilized in the Enhanced Ames Testing (EAT) protocol show that hamster-derived S9 can at times provide more robust genotoxicity responses. Additionally, O'Neill et al 1982 [Environmental Mutagenesis 4(1982)7-18] reported on enhancement of mutagenicity of nitrosamines following the addition of excess calcium chloride with consequential calcium phosphate precipitation. The current study aimed to optimize the S9 activation system for detecting genotoxic nitrosamines by evaluating species source, concentration, cofactor composition, and exposure duration. **Methods:** TK6 human lymphoblastoid cells were exposed to at least a 10-point concentration range of each nitrosamine under several metabolic activation conditions. A standard continuous low-dose exposure with 0.25% S9 was compared to short-term "NA-optimized" conditions incorporating 3% rat S9, 3% hamster S9, or a 1.5% rat + 1.5% hamster combination. Each system included NADPH-generating cofactors (NADP, glucose-6-phosphate, KCl, MgCl₂). CaCl₂ was introduced into the co-factor mix according to O'Neill et al. 1982. At 4 and 24 hours, cells were evaluated for γ -H2AX, phospho-Histone H3, and p53 using a multiplexed genotoxicity assay (i.e., MultiFlow). Additionally, cells from the 24 hour timepoint were also evaluated for micronucleus induction via the MicroFlow method. The resulting flow cytometry data were evaluated for point of departure using PROAST benchmark dose (BMD) software (v70.0; critical effect size 0.5; model averaging). **Results:** The several 3% S9 CaCl₂-enriched systems produced stronger and more consistent concentration-response relationships compared with the standard 0.25% continuous exposure. Distinct species-related activation patterns were observed. The 3% rat S9 system provided the most robust activation for bulky nitrosamines such as NNK and NNN, producing low BMD values and steep γ -H2AX induction curves. In contrast, the 3% hamster S9 system preferentially activated smaller methylating nitrosamines (NDMA and NDEA), yielding clearer responses and tighter confidence intervals. The combined 1.5% rat + 1.5% hamster S9 condition offered the broadest metabolic coverage, capturing the full spectrum of nitrosamine reactivity within a single exposure system. This dual-species mix improved reproducibility for NMOR and NPYR and minimized false negatives observed when using either species alone.

Conclusions: Systematic optimization of S9 source, concentration, and cofactor composition markedly improved assay sensitivity and reproducibility across several (geno)toxicity biomarkers for the reference nitrosamines studied. The optimized S9 activation system represents an improved hazard identification for nitrosamines, and future work will be directed at evaluating the degree to which resulting *in vitro* biomarker responses correspond to *in vivo* genotoxicity and carcinogenicity.

PS 4324 Elucidation of Mitochondrial Nucleic Acid Signals Under Genotoxic Stress

A. Rios, A. Jana, Y. Chen, and L. Zhao. University of California Riverside, Riverside, CA.

Background and Purpose: Mitochondria are vital organelles in higher eukaryotic cells, playing a crucial role in energy production, cell signaling, and biosynthesis. The mitochondrial DNA (mtDNA) genome, which encodes key components of the oxidative phosphorylation system, is susceptible to damage by endogenous and exogenous chemicals. When compromised, both mtDNA and mitochondrial double-stranded RNA (mt-dsRNA) can be released into the cytosol, where they act as damage-associated molecular patterns (DAMPs), triggering innate immune and inflammatory responses. While their role as signaling molecules is recognized, the relative contributions of mtDNA and mt-dsRNA under different genotoxic chemicals are not well understood. We hypothesize mtDNA and mt-dsRNA molecules contain signaling codes to inform different cellular defense mechanisms. This study aims to quantify the contributions of mtDNA and mt-dsRNA in mitochondrial homeostasis and innate immune response to various genotoxic agents. **Methods:** The initial phase of the project focuses on a mitochondria-targeting chlorambucil derivative developed in my laboratory that selectively alkylates mtDNA without damaging nuclear DNA. We used human bronchial epithelial (BEAS-2B) cells as a model system, which is relevant to inhalation exposures. Quantitative PCR was used to quantify the abundance of mtDNA and mt-dsRNA in the cytoplasm and assess the mtDNA integrity, as well as to determine the effects on the mitochondrial network and activation of an immune response downstream of the sensors cGAS and RIG1. Immunofluorescence using the J2 anti-dsRNA antibody was used to verify the release of mt-dsRNA species. Changes in mitochondrial homeostasis were measured as a function of respiration efficiency using the mitochondrial stress tests by the Seahorse apparatus. **Results:** Our findings revealed that exposure led to a significant increase in mitochondrial copy number and a concomitant decrease in mtDNA integrity. Release of both mtDNA and mt-dsRNA into the cytosol was confirmed, accompanied by changes in mitochondrial and cellular dynamics. We observed the upregulation of both fission and fusion genes, indicative of a shift in mitochondrial dynamics. Furthermore, a significant increase in the transcription of cytosolic sensors and immune response components was observed. Seahorse assays revealed that respiration efficiency was negatively affected after a 24-h exposure. **Conclusions:** Taken together, this research establishes a robust and quantitative platform to assess the distinct contributions of mtDNA and mt-dsRNA in mitochondrial respiration, dynamics, and innate immunity under genotoxic stress. Future work will extend this platform to decode the mitochondrial nucleic acid signals from additional genotoxic chemicals and cell models, particularly at doses relevant to human exposure.

J. S. Kozal¹, and E. Fung². ¹Integral Consulting, San Francisco, CA; and ²Integral Consulting, Los Angeles, CA.

Background and Purpose: Enteric methane emissions from cattle are a major contributor to global greenhouse gas emissions. Use of anti-methanogenic feed additives, including the seaweed *Asparagopsis*, can substantially decrease methane emissions and thus reduce the climate impact of dairy and beef production. Brominata™, a patented strain *A. taxiformis*, is highly effective at reducing methane emissions and has recently been approved as a feed additive in Mexico and some states across the U.S. As part of the feed additive approval process in Europe, the European Food Safety Authority (EFSA) requires two *in vitro* genotoxicity studies and an *in vivo* subchronic oral toxicity test. Depending on the results of these studies, EFSA may recommend follow up studies. Therefore, the objective of this study was to evaluate Brominata™ in the standard set of Organisation for Economic Co-operation and Development (OECD) guideline toxicity tests, including any follow up studies, required by EFSA to assess the safety of a feed additive for the ultimate human consumer. **Methods:** Brominata™ was evaluated in two *in vitro* genotoxicity studies, including the bacterial reverse mutation assay (Ames test) in *Salmonella typhimurium* and *Escherichia coli* (OECD 471) and the mammalian cell micronucleus assay in human lymphocytes (OECD 487). For each *in vitro* assay, two fully independent studies were conducted using different batches of material. A follow up *in vivo* mammalian alkaline comet assay was conducted in Wistar rats (OECD 489). Brominata™ was evaluated in a 28-day dose range finding (DRF) study and a full 90-day oral repeated dose toxicity study (including a 28-day recover period) in Wistar rats (OECD 408). All studies were conducted in compliance with OECD test guidelines and principles of Good Laboratory Practice (GLP) (except the 28-day DRF study). **Results:** In one of the Ames tests, Brominata™ did not cause gene mutations by base pair changes or frameshifts in the genome of any of the five tester strains with or without metabolic activation and was considered to be non-mutagenic. In the second test, Brominata™ was negative in most of the tester strains (TA 98, TA1535, and TA1537) with and without metabolic activation. In TA100, Brominata™ caused an increase in revertant colony numbers without metabolic activation but not with metabolic activation (suggesting the substance would not be mutagenic *in vivo*). Increased revertant colonies were also observed in *E. coli* uvrA (pKM101) in both the presence and absence of metabolic activation; however, the threshold concentration was higher with metabolic activation (suggesting metabolism is detoxifying and limited to no effect would be observed *in vivo*). Based on the results of the Ames tests, a follow up *in vivo* mammalian alkaline comet assay was conducted in Wistar rats (OECD Test No. 489), consistent with EFSA guidance. Brominata™ did not induce biologically relevant DNA-strand breaks in the liver after oral administration of up to 1,200 mg/kg/day on two consecutive days to Wistar rats. Thus, Brominata™ was considered to be non-DNA damaging *in vivo*. In both of the *in vitro* micronucleus assays, Brominata™ did not induce structural and/or numerical chromosomal damage in human lymphocytes in the presence or absence of metabolic activation. Brominata™ was thus considered to be non-mutagenic with respect to clastogenicity and/or aneugenicity. In the DRF study, no adverse test-item related effects were observed at up to 600 mg/kg/day (highest dose tested). In the 90-day study, there were no Brominata™-related effects on clinical signs, functional observation battery, body weight development, food consumption, clinical pathological parameters, organ weight, or gross or microscopic findings related to a systemic effect. The no observed adverse effect level (NOAEL) was 400 mg/kg/day (highest dose tested). **Conclusions:** Based on the results of the genotoxicity and oral repeated dose toxicity studies, Brominata™ was found to be not systemically toxic and non-DNA damaging *in vivo* in rats. Overall, these results support the safety profile of this feed additive. The next step is to conduct a human health risk assessment, using the NOAEL from this study as the safe dose, to evaluate the safety of this feed additive for the ultimate human consumer.

PS 4326 DNA Adductomics to Support the Assessment of Alcohol's Genotoxicity

M. Sausen¹, B. Chavanel², F. Jacobs¹, D. Mckeon¹, M. Korenjak², P. W. Villalta¹, J. Zavidil², and S. Balbo¹. ¹University of Minnesota, Minneapolis, MN; and ²International Agency for Research on Cancer, Lyon, France.

Background and Purpose: Alcohol consumption is a known risk factor for head and neck cancer as one in three cases are associated with drinking. Early detection leads to an increase of over 28% in relative survival rates. However, identification of the early stages of alcohol-related carcinogenesis is difficult as the mechanisms of this process are not well understood. Alcohol may induce a number of different processes leading to cancer initiation, including the induction of DNA damage through its major genotoxic metabolite, acetaldehyde (AA). Individuals who consume alcohol and garner a mutation (rs671) in their ALDH2 gene have a higher risk for developing head and neck cancer. Increased levels of the major AA-derived DNA adduct N²-ethyl-dG have also been found in oral cells of individuals after drinking alcohol. Using a DNA adductomics approach, a mass spectrometric methodology that chemically characterizes DNA damage, we are able to better understand the entire scope of damage that occurs from exposure to AA in the oral cavity. This work aims at better elucidating the genotoxic effects of AA through the genera-

tion of a library of DNA adducts, and provide an example of how DNA adductomics can be used to precisely characterize genotoxicity of chemical exposures. **Methods:** Normal oral keratinocyte (NOK) cells were exposed to AA (0, 4, 8, and 12 mM) for 4 hours, after which DNA was isolated. Enzymatic hydrolysis was performed to isolate modified nucleosides. After samples were processed, DNA adduct analysis was performed using liquid chromatography coupled to high resolution accurate mass (LC-HRAM) mass spectrometry techniques. For targeted analysis of known DNA adducts, a data independent method was used. For screening for unknown DNA adducts, a data dependent approach was utilized that harnesses the instrument's ability to scan for known neutral losses of nucleobases or deoxyribose and further fragment these specific ions. Data for unknown adducts was then uploaded to Compound Discoverer™ to aid in data analysis. **Results:** DNA from exposed NOK cells was evaluated for N²-Et-dG and Cro-dG levels. These adducts showed significant increases after exposure. A dose dependent response was seen for both adducts with levels rising 300 times and 533 times higher in 12 mM vs. 0 mM. In order to identify unknown DNA adducts and form a library that can be used for future studies, an untargeted screening method was performed. Beginning with the 12 mM exposure level, DNA was hydrolyzed and analyzed using a data dependent approach. Data was then uploaded into Compound Discoverer and a list of 36 masses was produced. This list was achieved through the filtering of neutral loss of deoxyribose or one of the nucleobases, obtaining correct fragmentation patterns, and having higher levels in the exposure group compared to controls. This list of 36 masses was then targeted in triplicate analysis to obtain further validation. This yielded 8 masses that were higher in the 12 mM exposure group compared to control. After these findings, a similar process was done comparing the 8 mM exposure group to the control group. A pooled sample of the 8 mM replicates was hydrolyzed and analyzed compared to controls. This data followed the same filtering and validation process as the 12 mM exposure stated above. The filtering yielded a mass list of 45 putative masses that were targeted in triplicate. The triplicate analysis resulted in 7 masses having higher levels in the exposure group compared to control. Comparing the two sets of results together, 4 masses were in common between the groups, leading to an overall library of 11 masses. **Conclusions:** Confirmation of exposure was done by measuring N²-Et-dG and Cro-dG. Screening for unknown DNA adducts led to the putative identification of 11 masses that were confirmed to be associated with AA exposure. This list of adducts can be formed as a library of adducts that can be extended to future studies in animal models or human samples. This library can better explain one of the key events within the carcinogenic process and this experiment shows the value of using DNA adductomics to fill gaps within an AOP of a chemical exposure to cancer formation. Having a library resulting from this *in vitro* analysis shows that DNA adductomics is a viable new approach to address genotoxicity.

PS 4327 Inclusion of structural alerts for the detection of substances from the Cohort of Concern in a combined mutagenicity prediction model

J. Tolosa, M. Palomino-Schätzlein, E. Serrano-Candelas, M. Ruiz, and R. Gozalbos. Faculty of Pharmacy. University of Valencia, Burjassot-Valencia, Spain. Sponsor: A. Anadón

Background and Purpose: Toxicological risk assessment aims to identify safe exposure levels for humans, but some compounds lack sufficient data. Highly carcinogenic substances classified under the Cohort of Concern (CoC), require special regulatory attention according to ICH (International Conference on Harmonization) guidelines [1]. These guidelines focus on assessing DNA-reactive (mutagenic) compounds to evaluate potential genotoxic carcinogens by promoting computational methods (rule-based expert systems (SAR) and statistical models (QSAR)). Thus, this research is focused on the characterization and generation of structural alerts for the identification of the carcinogenic potential and the implementation of a consensus prediction combining these alerts (SAR) with QSAR models for carcinogenicity assessment. **Methods:** A systematic literature review was conducted to retrieve data on the genotoxic and carcinogenic potential of the substances from various scientific databases (Google Scholar, PubMed, Scopus, and Web of Science) by using an in-house developed and an external software. The obtained data were then analysed to identify to find structural patterns characteristic of genotoxic carcinogens versus non-genotoxic carcinogens. To this end, the presence of different functional groups in the carcinogenicity dataset was analyzed for both positive and negative molecules by using the "fragments" module of the Python package rdkit [2]. Finally, the validated substructures were codified as SMARTS (Specific Alert and Response System) and incorporated in python scripts, to automatically screen databases for the identified alerts. **Results:** Our analysis identified 87 relevant molecular substructures, from which a total of 26 functional groups showing relative presence greater in carcinogenic substances than in non-carcinogenic ones were identified. The SMARTS for the 26 functional groups were compiled and compared to compounds for which validated with the retrieved experimental data for diverse toxicological assays evaluating the genotoxic and carcinogenic potential (Ames test, chromosomal aberration assay, COMET assay, micronucleus generation assay, HPRT assay and *in vivo* carcinogenicity assay), showing that the key functional groups present in genotoxic compounds were nNH0, nAniline, nArN and nNitro. To verify the application of these alerts to sets of molecules with a high carcinogenic risk, the presence of the SMARTS for the 26 identified functional groups was analyzed in the IARC database [3] and experimental mycotoxin database that is part of the MICOTOXILICO project (<https://chemopredictionsuite.com/MicotoXilico>) [4]. **Conclusions:** Specific rules or alerts have been

established to detect compounds structurally similar to those included in the CoC and which, therefore, should be considered for their potential carcinogenic and genotoxic effects. The generated SMARTs from the identification of functional groups or substructures responsible for genotoxic carcinogenic potential have been implemented as rule-based expert systems alongside the computational models already included in the ProtolCH tool (https://protopred.protoqsar.com/ProtolCH_info). Thus, the ProtolCH tool is able to detect compounds included in the CoC, as well as other compounds with carcinogenic potential not included in the CoC, thanks to the implementation of a consensus prediction that combines QSAR statistical models and rule-based expert models (SAR). Acknowledgments: This research was funded by MICIU/AEI /10.13039/501100011033/FEDER, UE through the project PID2024-160527OB-I00 and the Generalitat Valenciana CIAEST/2022/035. PS 4328 Implementation of an hOGG1-Enhanced *In Vivo* Comet Assay to Identify Particle-Induced DNA Damage in Rat Lung Tissue Following Instillation

G. Bruer, H. Angelov, H. Brockmeyer, M. Djuari, M. Engelke, C. Müller, J. Wabra, M. Winkler, and C. Ziemann. Fraunhofer Institute for Toxicology and Experimental Medicine (Fh-ITEM), Hannover, Germany. Sponsor: S. Escher

Background and Purpose: The *in vivo* alkaline comet assay according to OECD 489 can detect both DNA-strand breaks and oxidatively damaged DNA upon enzyme modification and is currently an integral part of regulatory genotoxicity testing strategies. While the liver is the primary organ examined for chemicals and pharmaceuticals, the assay is also valuable for genotoxicity testing of particles in the lung after instillation. This study aimed to establish a robust protocol for particle testing in lung tissue. Key challenges included identification of an efficient and reliable cell isolation method that minimizes basal DNA damage, finding appropriate technical positive controls for better adhering to the 3R principles, and implementing an effective enzyme incubation step for detection of oxidatively damaged DNA, relevant for particle-exposed lungs. **Methods:** Initially, we addressed cell isolation from lung tissue by comparing various buffers and mechanical devices (e.g., douncer, scissors, pistils). Optimal tissue dissociation was finally achieved using tissue punches and a grinding step with disposable pistils in tissue buffer-filled reaction cups. Vehicle controls showed low baseline tail intensities (TI) of less than 4% increasing to 9-12% in animals treated with ethyl methanesulfonate (EMS, 300 mg/kg, 3h). But for 3R reasons, also technical *in vitro* positive controls were established. EMS-treated L-929 cells (4.85 mM, 1h), cryopreserved in large batches, served to show appropriate electrophoresis. Both freshly treated and thawed cells (stored up to 11 months) showed consistent TI values of 12-16%. For sensitive detection of oxidatively-damaged DNA, an incubation step $\pm$ human 8-oxoguanine DNA glycosylase 1 (hOGG1) enzyme was chosen. Potassium bromate (KBrO₃)-incubated L5178Y/TK⁺ cells served as technical positive control to ensure hOGG1-functionality. **Results:** A respective incubation protocol with optimized KBrO₃ (5 mM KBrO₃) and hOGG1 concentration (100 μ l of a 2.5 μ g/ml solution of hOGG1) and incubation times (1 h and 15 min, respectively) was finally developed to allow for clear distinction between buffer- and hOGG1-treated KBrO₃ samples. **Conclusions:** In conclusion, the optimized *in vivo* comet assay protocol enables reliable detection of both DNA strand breaks and oxidative DNA damage in rat lung tissue following particle exposure. Future work will focus on enhancing oxidative damage detection by combining hOGG1 with endonuclease IV, which removes AP sites that can inhibit hOGG1 activity.

PS 4329 Mitochondrial Glutathionylated DNA Adducts: Accumulation, Regulation, and Biological Implications

L. Zhao. University of California, Riverside, Riverside, CA. Sponsor: D. Eastmond

Background and Purpose: Mitochondrial DNA (mtDNA) is crucial for cellular energy production, metabolism, and signaling. Its dysfunction is implicated in various diseases, including mitochondrial disorders, neurodegeneration, and diabetes. mtDNA is susceptible to damage by endogenous and environmental factors; however, unlike nuclear DNA (nDNA), mtDNA lesions do not necessarily lead to an increased mutation load in mtDNA. Instead, mtDNA lesions have been implicated in innate immunity and inflammation. Here, we report a novel type of mtDNA damage: glutathionylated DNA (GSH-DNA) adducts. These adducts are formed from abasic (AP) sites, key intermediates in base excision repair, or from alkylation DNA damage. The study aims to establish the importance of GSH-DNA adducts by quantifying their level, clarify their regulation and biological effects. **Methods:** Our study utilized mass spectrometry to directly compare the formation and persistence of GSH-DNA adducts in both nDNA and mtDNA across two distinct human cell lines under various genotoxic stress conditions. To identify the key enzymatic regulators, we quantified adduct levels in DNA repair-deficient cells and characterized the repair efficiency of

candidate enzymes using *in vitro* enzyme kinetic assays. To elucidate the biological effects of adduct accumulation, we performed quantitative proteomics to assess protein level changes and measured cellular glutathione (GSH) levels. Lastly, we determined how GSH-DNA adduct accumulation influences DNA conformational stability and DNA-protein interactions through a combination of molecular dynamics (MD) simulations and *in vitro* binding assays. **Results:** Our data demonstrate that GSH-DNA adducts accumulate in mtDNA of two different human cell lines, with levels one or two orders of magnitude higher than in nDNA. The formation of GSH-DNA adducts is influenced by TFAM and polyamines, and their levels are regulated by repair enzymes AP endonuclease 1 (APE1) and tyrosyl-DNA phosphodiesterase 1 (TDP1). The accumulation of GSH-DNA adducts is associated with the downregulation of several ribosomal and complex I subunit proteins and the upregulation of proteins related to redox balance and mitochondrial dynamics. Their accumulation did not perturb cellular or mitochondrial GSH levels. Molecular dynamics (MD) simulations revealed that the GSH-DNA lesion stabilizes the TFAM-DNA binding, suggesting shielding effects from mtDNA transactions. **Conclusions:** This study provides critical insights into the formation, regulation, and biological effects of GSH-DNA adducts in mtDNA. Our findings underscore the importance of understanding how these lesions may contribute to innate immunity and inflammation.

PS 4330 Benzo[b]fluoranthene induces mutation accumulation and human cancer-relevant mutational signatures in mouse lung alongside steady state levels of chromosome damage in blood.

X. Zhang¹, C. A. Hobbs², M. V. Rivas², A. Diesing², D. P. LeBlanc³, G. Zhou³, J. F. Foley¹, P. A. White³, F. Marchetti³, C. L. Yauk⁴, and S. L. Smith-Roe¹. ¹NIEHS, Durham, NC; ²Inotiv, Research Triangle Park, NC; ³Health Canada, Ottawa, ON, Canada; and ⁴University of Ottawa, Ottawa, ON, Canada.

Background and Purpose: Benzo[b]fluoranthene (BbF) is one of the 16 polycyclic aromatic hydrocarbons (PAHs) prioritized by the US Environmental Protection Agency due to high levels of human exposure, and the known mutagenic and carcinogenic effects of substances in this chemical class. This study examined the effects of increasing exposure durations on the mutagenic effects of BbF. **Methods:** MutaMouse males were exposed to 5 doses of BbF or a vehicle control via repeated oral gavage for 28, 60, 90, 120, or 180 days, with the dose range modified to account for duration of exposure (top doses were 25, 50, or 100 mg/kg/day). To comprehensively assess genotoxicity, mutagenesis was evaluated in lung tissue (n = 4) at 28-, 90- and 180-days via duplex sequencing (DS), a targeted, error-corrected sequencing method; chromosomal damage (n = 8) was evaluated using the peripheral blood micronucleus assay (MN) at all 5 time points. Mutational signature analysis was performed using the SigProfiler suite to fit single-base substitution (SBS) signatures obtained from the Catalogue of Somatic Mutations in Cancer (COSMIC) database. BMD modeling of mutation and MN data was conducted using PROAST 71.1 in the R programming environment. **Results:** Dose-dependent increases in mutation frequency (MF) and C:G > A:T mutations were observed after 28-, 90-, and 180-days of exposure. BbF-induced mutations were lower in genic targets, consistent with transcription-coupled repair of BbF-DNA adducts. As early as 28 days, BbF exposure resulted in enrichment of the cancer-associated mutational signature SBS4, which is linked to tobacco smoking. SBS4 accounted for 72.4% of the reconstructed spectrum at 28 days, which increased to 87.5% at 180 days. Induction of chromosomal damage by BbF was observed at all five time points. Mutations accumulated over time in lung tissue, whereas chromosomal damage in peripheral blood erythrocytes reached a steady state by 28 days. Benchmark dose (BMD) confidence intervals (CIs) for MF became more precise with extended exposure, while BMD CIs for micronucleus frequency remained relatively stable. **Conclusions:** These data demonstrate that BbF is a potent mutagen capable of inducing persistent mutations in lung with cancer-relevant signatures, supporting its potential role in human lung carcinogenesis.

PS 4331 Correlation of Dietary Antioxidant Levels to Incidence and Severity of Oteseconazole-induced Nuclear Opacities in Peri-Postnatal Development (PPND) Studies

T. Degenhardt¹, S. Brand¹, X. Fan², and M. D. Aleo³. ¹Mycovia Pharmaceuticals, Inc., Durham, NC; ²Medical College of Georgia at Augusta University, Augusta, GA; and ³TOXinsights360, LLC, Boiling Springs, PA.

Background and Purpose: Oteseconazole (VIVJOA®) is an antifungal agent approved for recurrent vulvovaginal candidiasis (RVVC); however, its use is restricted to women not of child-bearing potential. This restriction is due to rat PPND studies where a higher incidence of spontaneous background ocular abnormalities (nuclear opacities & bleeding events) were noted in pups born and nursed from a small percentage of oteseconazole-treated dams during gestation and lactation. Assessing direct agent causality is challenging when the incidence of spontaneous background opacities in young rats can range up to 50% (Ban et al., 2008) and ophthalmic examinations are not conducted in rat PPND studies for currently marketed drugs. Since antioxidants are linked to cataract prevention, the mechanism of nuclear cataract formation and its dependence on rat chow dietary antioxidant status and various antioxidants were examined *in vivo* and *in vitro*, respect-

tively. **Methods:** For drug registration, pregnant Sprague-Dawley Crl:CD(SD), Hsd(SD), or Crl:WI(Han) dams in 4 PPND studies were dosed with oteseconazole (7.5 mg/kg/d) from gestation day 6 (GD6) through lactation day 20 (LD20), inclusively, with ophthalmic examinations by indirect ophthalmoscope and slit lamp biomicroscope and/or gross assessments along with clinical pathology sampling for aberrations in hematology, coagulation and serum chemistry parameters performed during study. Subsequent studies used cross-fostering designs at two contract research facilities to determine a susceptibility period during lens development. Recent PPND studies used diets of decreasing antioxidant content (PMI 5002>Teklad 2016C>custom) as determined by the Ferric Reducing Antioxidant Power (FRAP) assay. *In vitro* studies used both mouse lens explants and mouse and human lens epithelial cells. Oxidative stress was quantified by 4-hydroxynonenal (4-HNE) staining in lenses from treated rat pups and in mouse and human lens cells. **Results:** Rat pups from control and treated dams showed variable incidence of predominantly nuclear opacities across strains (range 0-15% for Sprague-Dawley Crl:CD(SD), 0-40% for Crl:WI(Han), and 13-48% for Hsd(SD)). Subsequent PPND and cross-fostering studies demonstrated variability in spontaneous background and treatment-associated ocular abnormalities between contract labs later suspected to be diet related (5002 and 2016C diet). Isolated serum γ -glutamyltranspeptidase (GGT) elevations across studies and diet type in treated rat pups and dams indicated liver oxidative stress. Two PPND studies showed no treatment nuclear opacities when dietary FRAP values were >3000 μM Fe^{3+} reduction potential (5002 and 2016C diets), but were observed with lower FRAP values (2016C, custom) with dietary FRAP variability based on lot surveys. 4-HNE staining was found in the anterior suture lines that touched the outside fetal nuclear area in lenses from treated pups that increased in intensity and severity with declining dietary FRAP values, suggesting opacity formation during lactation due to higher exposure. Mouse lens explants confirmed increased 4-HNE and disrupted glutathione homeostasis. Liproxstatin-1 and menaquinone-4 delayed opacification in whole lens culture, suggesting a small role for ferroptosis. Combinations of antioxidants (lutein/zeaxanthin, eicosapentanoic acid/docosahexanoic acid, β -carotene/ α -carotene/retinoic acid/ascorbic acid and N-acetylcysteine/ascorbic acid) were protective of mouse and human lens epithelial cell death, where the minimal toxic concentration of oteseconazole was 5 and 10 μM after 96 hr in mouse and humans lens cultures, respectively. **Conclusions:** While rat strains and contract research facilities influenced ophthalmic findings, nuclear cataract formation was linked to innate differences and intrinsic variability in dietary antioxidant capacity. Oxidative stress is a primary mechanism of nuclear cataract formation and inadequate dietary nutrition to maternal dams leads to nuclear cataract formation in rat pups. *In vitro* studies indicate that a wide variety of antioxidants commonly found in the human diet are protective. Given the broad nutritional status of human, it is inferred that these rat findings have limited relevance to humans.

PS 4332 Dietary Vitamin K-Dependent Coagulopathy and Ocular Bleeding Events in Rat Pups Treated with Oteseconazole During Peri-Postnatal Development (PPND) Studies

S. Brand¹, T. Degenhardt¹, M. Brooks², V. Lattard³, N. Chatron³, and M. D. Aleo⁴.
¹Mycovia Pharmaceuticals, Inc., Durham, NC; ²Cornell University College of Veterinary Medicine, Ithaca, NY; ³VetAgro Sup, Marcy l'Etoile, France; and ⁴TOXinsights360, LLC, Boiling Springs, PA.

Background and Purpose: Oteseconazole (VIVJOA®) is an antifungal agent approved for recurrent vulvovaginal candidiasis (RVVC) however its use is restricted to women not of child-bearing potential. This restriction is based on rat PPND studies describing a higher incidence rate of ocular opacities and bleeding events in treated pups compared to untreated controls. Ocular opacity incidence rates range from 0-50% in young rats (Ban *et al.*, 2008), but no comparable data exists for pups. Investigations were initiated to better define the translational relevance of PPND findings and gain mechanistic understanding of an apparent treatment-related coagulopathy. **Methods:** Initial PPND studies used pregnant Sprague-Dawley Crl:CD(SD), Hsd(SD), or Crl:WI(Han) dams dosed with oteseconazole (7.5 mg/kg/d) from gestation day 6 (GD6) through lactation day 20 (LD20) that included full ophthalmic and gross necropsy examinations performed on PND21/35. Clinical pathologic testing included blood cell counts, coagulation screening tests (aPTT/PT), and serum chemistry panels. Because subsequent PPND and cross-fostering studies demonstrated variability in spontaneous background and treatment-associated ocular abnormalities between contract research sites, potentially related to feed composition (PMI 5002 vs Teklad 2016C), assays to detect vitamin K deficiency were performed. These assays included measurement of plasma vitamin K and procoagulant activities of vitamin K-dependent factors (II, VII, IX, X). In addition, a subset of rats was administered intramuscular vitamin K daily (10 mg/kg phyloquinone). Subsequent PPND studies evaluated diets with varying vitamin K content (2016C>5002>custom). Analytical sensitivity issues precluded determination of vitamin K-epoxide formation, therefore the inhibitory potential of oteseconazole was measured in rat and human microsomal vitamin K-epoxide reductase (VKORC1) prepared from transfected yeast cells, using warfarin as a known inhibitor. Banked human plasma samples from previous clinical trials were obtained with IRB approvals. **Results:** PPND clinicopathologic findings in pups included subcutaneous and ocular hemorrhage, red cell mortality, pronounced prolongation of aPTT/PT, and decreased fibrinogen and red cell counts (C_{max} >40 μM). The presence and severity of signs appeared variable between sites that fed either 5002 or 2016C diets as their standard rodent chow. Studies revealed reductions in maternal/pup plasma and liver vitamin K and low activities of factors

II, VII, IX, X. Marked prolongation of aPTT/PT after 28 days of oteseconazole dosing (15 mg/kg/d) in young adult rats fed 5002 diet were reversed by daily phyloquinone administration through day 35. Coagulopathy with ocular bleeding were attenuated/absent in pups from maternal rats fed the 2016C diet but present for diets with lower vitamin K (5002 and custom). Oteseconazole inhibition of rVKORC1 and hVKORC1 showed IC_{50} values of 74 and 53 μM compared to 0.14 and 0.56 μM for warfarin, respectively. Systemic exposure margins of 0.8x the IC_{50} for rVKORC1 on PND10 lead to coagulopathy and ocular bleeding in rat pups on the 5002 and custom diet while systemic/liver exposure margins of 0.42/9.8x the IC_{50} for rVKORC1 inhibition on GD18 led to aPTT increases in pregnant rat dams on the custom diet. In humans, aPTT/PT were unchanged in Phase 1 single and multiple ascending dose trials, plasma vitamin K was not altered and protein induced by vitamin K absence or antagonist-II (PIVKA-II) was unchanged in clinical trial subjects after 12-week of treatment in Phase 3, randomized, double-blind, placebo-controlled studies where C_{max} =5.3 μM . **Conclusions:** While rat strain and husbandry differed across sites, wide variability in vitamin K content across diet selection (natural phyloquinone or added menaquinone) had direct effects on coagulopathy and exposure differences could account for variable incidence of ocular bleeding events in PPND studies. Oteseconazole was determined to be a weak rVKORC1 and weaker hVKORC1 inhibitor, at least 100x less potent than warfarin. Weak hVKORC1 enzyme inhibition results in a therapeutic exposure margin of at least 10x, suggesting limited relevance to humans.

PS 4333 Multifocal ERG and VEP-Based Evaluation of Retinal and Cortical Function in Cynomolgus Monkeys with Simulated Deficits and Ocular Hypertension

A. Masuda, T. Araki, and K. Hayashida. Shin Nippon Biomedical Laboratories Ltd., Kagoshima-city, Japan. Sponsor: T. Araki, Japanese Society of Toxicology

Background and Purpose: Glaucoma, typically associated with elevated intraocular pressure, is a neurodegenerative disease characterized by the irreversible loss of retinal ganglion cell axons within the optic nerve, ultimately resulting in localized visual field defects. Even in toxicological studies, early identification of these localized functional impairments including visual field defects is essential for safety assessment and translational research. Multifocal electroretinography (mfERG) and multifocal visual evoked potentials (mfVEP) enable sector-wise mapping of retinal and cortical responses, respectively. Stimulus design (On-Off white/black alternation for mfERG; pattern reversal for mfVEP) plays a pivotal role for reliable recordings. This study aimed to establish and validate mfERG/mfVEP protocols in cynomolgus monkeys following a sequence: first, evaluate reproducibility under intact (normal) conditions; second, introduce localized masking to simulate sector-specific deficits and validate abnormality detection; finally, apply the protocols to laser-induced ocular hypertension to assess sensitivity to pathological change. **Methods:** Purpose-bred cynomolgus monkeys (three males, 2-8 years, 2.0-8.0 kg, B virus antibody-negative) were studied: two with laser-induced unilateral ocular hypertension (≥ 30 mmHg) and one normotensive bilaterally. Recordings were acquired under ketamine (i.m.) followed by propofol (i.v.) anesthesia. Retinal signals were measured using contact lens electrodes; cortical signals were recorded with transcutaneous cup electrodes at Fz and Oz. Visual stimuli were presented on a 23.8-inch monitor at 35 cm ($\approx 34^\circ \times 34^\circ$ visual angle). Using a 511-frame m-sequence, three paradigms were tested: (1) On-Off white/black alternation across 61 hexagonal sectors; (2) whole-field pattern reversal across 48 sectors; and (3) quadrant-based pattern reversal across 48 sectors. Each paradigm was recorded twice: intact, then with two localized black circular masks to simulate sector-specific impairment. The evoked signal was quantified as signal-to-noise ratio (SNR, dB) from peak-to-peak amplitudes relative to baseline noise. Reproducibility was assessed by intraclass correlation coefficients (ICC) for P1 or N1 amplitudes between the first and second recordings. Group comparisons used two-sample t-tests. **Results:** Under intact conditions, mfERG reproducibility varied by paradigm: On-Off alternation showed moderate stability for P1 (ICC = 0.589), whereas quadrant-based reversal yielded the highest reproducibility (ICC = 0.943). Reproducibility in mfVEP was consistently high across paradigms (P1 ICC = 0.792-0.927; N1 ICC = 0.731-1.000). Localized masking significantly reduced SNR in targeted sectors for both modalities, confirming sensitivity to simulated deficits: mfERG showed reductions under On-Off alternation (-4.65 dB, $p < 0.001$) and quadrant-based reversal (-1.69 dB, $p = 0.0351$), while mfVEP exhibited the largest drop under quadrant-based reversal (-3.70 dB, $p = 0.0002$). In the ocular hypertension model, mfERG under pattern reversal showed higher SNR compared to normotensive eyes (whole-field: +3.13 dB; quadrant-based: +4.29 dB; both $p < 0.001$), likely reflecting reduced baseline noise rather than improved retinal function. In contrast, mfVEP demonstrated consistent SNR decreases in hypertensive eyes (whole-field: -2.67 dB; quadrant-based: -1.80 dB), supporting reduced cortical responses resulting from visual pathway disturbance. Quadrant-based pattern reversal provided the most stable and sensitive detection of simulated deficits and cortical changes. **Conclusions:** We demonstrated that mfERG and mfVEP provide complementary and reproducible assessments of retinal and cortical visual function in non-human primates. Quadrant-based pattern reversal showed higher stability and sensitivity, making it a preferred paradigm for detecting localized and disease-related functional changes. Responses of mfERG under pattern reversal, on the other hand, exhibited variable SNR changes in hypertensive eyes, suggesting that its role in disease detection requires further investigation. The present analysis was performed using sector-level averages; future studies should incorporate higher-resolution spatial mapping to clarify the extent of localized functional impairment.

L. Zhang¹, C. Madden¹, J. Ma², H. Zhu¹, K. Swindle-Reilly¹, and H. Chandler¹. ¹The Ohio State University, Columbus, OH; and ²University of Virginia, Charlottesville, VA.

Background and Purpose: Chemical injuries, including nitrogen mustard (NM), cause acute and prolonged corneal damage, emphasizing the need for therapeutics to enhance healing. MG53 is a membrane repair protein with known cytoprotective effects in multiple tissues, while its ocular function remains largely unexplored. This study investigates the therapeutic potential of recombinant human (rh)MG53 in mitigating NM-induced corneal injury. **Methods:** Human corneal epithelial cells (hCEC) were treated $\pm$ NM (100 μ M, 2h) $\pm$ rhMG53 (50 μ g/mL, 12h) (n=4); ELISAs were used to evaluate expression of γ H2AX, 4HNE, and VEGF. Dissected and isolated rabbit corneas were stabilized on agar and randomly assigned to treatment groups. NM (100 μ M, 2h) was applied to the central cornea using filter paper discs; uninjured corneas were used as controls. After rinsing, corneas received 50 μ L of topical thermosensitive hydrogel (thermogel) $\pm$ rhMG53 (0.8mg/mL, 24 h) (n=5). Corneas were collected and processed for real-time PCR to evaluate expression of Cox2 and MMP9. To evaluate the effects of rhMG53 *in vivo*, the right eye of wildtype (WT) mice received a 2% NM injury and was randomly assigned to a treatment group. rhMG53 treated mice received 5 μ L of thermogel loaded with 0.8mg/mL rhMG53 (n=11), while control mice received thermogel alone (n=10). Treatment was applied once a day for 14 days. Fluorescein staining and photographs were taken on days 0, 1, 3, 5, 7, 10, and 14 post-NM injury. Corneal opacity and fluorescein staining were quantified using a published scoring system. At study termination, corneal flat mount staining was performed for the nerve marker β -III tubulin. To evaluate how MG53 influences baseline corneal nerve density, uninjured corneas from WT, MG53 knockout (KO), and MG53 overexpressing (OE) transgenic mice were stained for β -III tubulin (n=3). Expression of β -III tubulin was measured and quantified using confocal microscopy and ImageJ. ANOVA and Mann-Whitney U tests were performed to determine statistical significance. **Results:** hCEC exposed to NM had increased expression of γ -H2AX (p<0.001), 4HNE (p<0.05), and VEGF (p<0.05), compared to NM-injured cells treated with rhMG53. NM-injured corneas treated with thermogel alone had significantly higher Cox2 (p<0.01) and MMP9 (p<0.05) expression compared to NM-injured corneas treated with rhMG53-loaded thermogel. NM-injured mice treated with rhMG53 showed significantly (p<0.05) reduced fluorescein staining, an indicator of re-epithelialization, and significantly (p<0.05) reduced corneal opacity, compared to controls. Injured corneas treated with rhMG53 had a corneal nerve density and branching pattern similar to uninjured corneas. Injured corneas treated with unloaded thermogel had a significant (p<0.05) reduction in nerve density and a disrupted nerve pattern, compared to uninjured eyes. Uninjured eyes from MG53 OE mice showed a significantly higher corneal nerve density than KO (p<0.01) and WT mice (p<0.05); KO mice showed significantly (p<0.01) lower corneal nerve density than WT mice. **Conclusions:** rhMG53 significantly reduces NM-induced acute DNA damage, oxidative stress, and pro-angiogenic signaling in hCEC. *Ex vivo*, rhMG53 significantly reduces NM-induced corneal inflammatory and protease signaling. *In vivo*, topical rhMG53 significantly accelerated re-epithelialization and reduced opacity, supporting its pro-regenerative effects. Notably, our findings identified a neuroregenerative function of MG53. The observed variation in baseline corneal nerve density in MG53 KO and OE mice highlights MG53's potential role in regulating corneal nerve homeostasis. These findings provide molecular insights into rhMG53's regenerative mechanisms, supporting its therapeutic potential for treating corneal injury.

PS 4335 Development of a Quantitative and Objective Scoring System for Drug-induced Ocular Toxicity

J. Choi, Y. Lee, Y. Ko, H. Chung, D. Go, J. Gwon, J. Kim, and S. Park. Biotextech Co., Ltd., Cheongju-si, Korea, Republic of.

Background and Purpose: Growing awareness of ocular diseases such as glaucoma, diabetic retinopathy and age-related macular degeneration (AMD) has prompted varied approaches to pharmaceutical development worldwide. Advances in drug administration techniques have enabled specialized delivery methods, including intravitreal (IVT), subretinal, and intracorneal injections. While the importance of evaluating ocular toxicity is widely recognized, challenges persist in achieving quantitative and objective assessments of ocular toxicity. The Draize test in particular, although commonly used for evaluating ocular toxicity, is limited to assessing the external structures of the eye. To overcome these limitations, we have developed a modified scoring system designed to enable quantitative and objective evaluation of overall ocular condition. **Methods:** The modified scoring system evaluates eight parameters: Conjunctival Hyperemia (CH), Keratic Precipitates (KP), Aqueous Cell (AC), Aqueous Flare (AF), Iris Involvement (II), Anterior Lens Capsule Deposits (AL), Posterior Lens Capsule Deposits (PL), and Vitreous Haze (VH). Each parameter is scored on a scale from 0 (normal) to 3 or 4 (severe). The criteria for scoring the severity of each finding were established based on substantial references. The evaluation was performed using slit-lamp biomicroscopy and ophthalmoscopy. **Results:** This scoring system was applied to evaluate ocular toxicity in a single IVT injection nonclinical toxicity study. There were no significant changes in parameters, other than KP and AC, in either the control or low-dose groups. These findings suggest that KP and AC were likely induced by the injection procedure, rather than the test article. Other findings-particularly those related to the posterior segment of the eye (PL,

VH)-showed dose-dependent increases in severity, indicating a likely correlation with the test article. **Conclusions:** Using the newly developed scoring system, ocular toxicity was evaluated quantitatively and objectively, allowing a more detailed assessment of both the anterior and posterior ocular structures. This system builds upon the Draize test in providing quantitative and objective evaluations, but overcomes its limitations by enabling comprehensive assessments of the posterior segment of the eye. As specialized ocular administration methods continue to evolve, and as ocular toxicity evaluations can be anticipated to grow in importance, this scoring system has the potential to become an essential tool in ocular toxicity assessment. Although this scoring system was applied to New Zealand White rabbits, it is planned to expand its use in future studies to evaluate ocular toxicity in rodents, dogs and monkeys.

PS 4336 Reproductive Risk Assessment of Intravitreal Biopharmaceuticals in the Last 20 Years: A Comparative Evaluation of Marketed IVT Biologics

G. Campoy¹, and J. A. Lansita². ¹ToxAlliance, Seattle, WA; and ²ToxAlliance, Kennett Square, PA. Sponsor: G. Campoy, American College of Toxicology

Background and Purpose: Intravitreal (IVT) biologics targeting VEGF and Ang-2 pathways have transformed the management of retinal diseases. However, despite the availability of these approved therapeutics, fewer than half of treated patients experience meaningful visual improvement. This highlights the need for novel drugs that address both endothelial dysfunction and structural vascular changes. At the same time, concerns about the reproductive safety of these agents remain. **Methods:** This review compares nonclinical reproductive toxicity data for four biologic agents approved in the last 20 years, faricimab (Vabysmo®), brolucizumab (Beuvo®), aflibercept (Eylea®), and ranibizumab (Lucentis®), using publicly available regulatory documents and literature across species and study designs. **Results:** Species selection and study design varied significantly across reproductive studies presented in regulatory documents and US package inserts. Nonhuman primates (NHPs) were the pharmacologically relevant species selected for faricimab and brolucizumab dosed IVT, while rabbits were dosed intravenously for aflibercept and ranibizumab, achieving systemic exposures far exceeding clinical intravitreal (IVT) levels. In an NHP embryofetal development study, faricimab induced a non-dose-dependent increase in pregnancy loss in NHPs at IV doses 158 $\times$ human peak concentration (Cmax), with no NOAEL identified. Aflibercept caused fetal malformations and maternal toxicity in rabbits at all tested doses, with no developmental NOAEL identified. In an NHP fertility study, aflibercept disrupted menstrual cycles and sperm morphology at systemic exposures up to 1500 $\times$ human levels. Ranibizumab showed minimal skeletal abnormalities in NHPs at high IVT doses (~13 $\times$ human exposure), with no placental or maternal toxicity. Brolucizumab demonstrated no reproductive toxicity in NHPs at 10 $\times$ human IVT exposure. Anti-VEGF mechanisms are associated with impaired placental angiogenesis, fetal resorption, and fertility disruption. Molecular design influences placental transfer and systemic exposure; agents lacking intact Fc regions (e.g., ranibizumab, faricimab) may offer reduced fetal risk. While anti-drug antibody (ADA) formation was observed across products, its impact on toxicokinetics and reproductive outcomes was generally limited. However, ocular inflammation following intravitreal administration of recombinant biologics is a well-documented phenomenon across preclinical species and is often linked to both local and systemic ADA responses. These immune reactions can compromise animal health and confound study interpretation, particularly in species like rabbits that can exhibit heightened immunogenicity. Systemic ADA formation has been shown to precede ocular ADA detection, suggesting a systemic origin that may contribute to broader physiological changes such as inflammation, weight loss, and organ toxicity. These systemic effects can exacerbate pregnancy loss and developmental abnormalities, complicating the interpretation of DART findings. Regulatory guidance and peer-reviewed literature emphasize that ADA-related effects in animals may not reliably predict human immunogenicity or clinical risk, underscoring the importance of integrating mechanistic understanding, improved bioanalytical tools, and thoughtful species selection into nonclinical study design. **Conclusions:** In conclusion, these findings underscore the importance of species selection, dosing route, and molecular format in evaluating reproductive risks per ICH S5 (R3) and S6 (R1) guidance. While systemic exposure is limited with IVT administration, the shared antiangiogenic mechanism warrants caution, particularly in women of childbearing potential. Interpretation of animal data should consider species-specific sensitivity, ADA-related inflammation, and pharmacokinetic profiles to inform clinical decision-making and labeling.

PS 4337 Comparison of Ocular Features in Bama and Göttingen Minipigs

X. Jing, C. Guo, Y. Zhang, and Y. Zhou. WuXi AppTec (Suzhou) Co., Ltd., Suzhou, China.

Background and Purpose: Minipigs have become increasingly popular in ocular research due to their anatomical similarities to human eyes. In the USA and Europe, the Göttingen minipig is commonly used for ocular research, while the Bama minipig is typically the strain of choice in China. This study aims to provide comparative data on the ocular features between the two strains. **Methods:** Bama mini-

pigs aged 4-9 months (females: n=14 eyes; males: n=12 eyes) were used for ocular parameters collection. The anatomical parameters—axial length, anterior chamber depth, lens thickness, and vitreous chamber depth—were measured with an ultrasound scanner; central corneal thickness was measured with a corneal pachymeter; retinal thickness was measured by Optical Coherence Tomography (OCT); vitreous volume was measured using *ex vivo* eyeballs. The physiological parameter, intraocular pressure (IOP), was measured with a tonometer. Fundus photographs (FP) were also collected. The data obtained from Bama minipigs was analyzed across three age groups (4-5, 6-7, and 8-9 months) and compared with the published data on Göttingen minipigs of comparable ages. Toxicity bridging studies were also conducted to compare the test-article-related responses between the two strains. **Results:** With increasing age, the measured anatomical parameters were as below: axial length was 16.39±0.44, 17.89±0.60, and 19.72±0.04 mm; anterior chamber depth was 1.55±0.23, 2.82±0.29, and 3.27±0.19 mm; lens thickness was 5.79±0.24, 6.40±0.22, and 7.20±0.10 mm; vitreous chamber depth was 8.02±0.32, 8.59±0.38, and 9.25±0.05 mm; central corneal thickness was 632±42, 674±58, and 776±13 µm; retinal thickness ranged from 264±21 to 273±12 µm; intraocular pressure ranged from 15±1 mmHg to 17±3 mmHg. The measured vitreous volume was 2.1±0.2 mL. Compared with the published data, the ocular anatomical parameters, IOP, and FP in Bama minipigs were comparable to those in Göttingen minipigs. In toxicity bridging studies, the endpoints, including ophthalmologic examination, IOP, electroretinography (ERG), OCT, and histopathology examinations, were consistent in both strains. **Conclusions:** Based on the comparable ocular anatomical parameters, IOP, and FP results, and consistent test article-related responses observed between age-matched Bama and Göttingen minipigs, Bama minipigs could also serve as an appropriate species selection for ocular pharmacokinetics, pharmacodynamics, and toxicology research.

PS 4338 Safety Profiling of Ocular Buffers in the Context of Posterior Segment Gene and Cell Therapeutics

X. Zhang, S. Puri, G. Gum, and S. Kumar. Pharmaron San Diego Lab Services, Carlsbad, CA. Sponsor: M. Lyulkin

Background and Purpose: Ocular gene and cell therapies have shown transformative potential in treating inherited and acquired retinal disorders, including retinitis pigmentosa, age-related macular degeneration (AMD), and diabetic retinopathy. The success of these therapeutic modalities depends not only on vector or cell design but also on the physicochemical properties and tolerability of the formulation excipients used for intravitreal (IVT) and subretinal (SR) administration. Ocular formulations are often supplemented with stabilizers, salts, and surfactants such as albumin, hyaluronate, and Pluronic to enhance vector or cell viability; however, their intraocular safety has not been comprehensively profiled. The objective of this study was to evaluate the ocular tolerability of commonly used buffer formulations following IVT or SR delivery in preclinical rodent models. **Methods:** A total of 60 Rowett Nude (RNU) rats (N=10/group) received either IVT or SR injections with one of the following formulations: balanced salt solution (BSS), BSS Plus, 0.2% sodium hyaluronate in BSS, 0.1% human serum albumin (HSA) in BSS, and 1% or 5% dimethyl sulfoxide (DMSO) in phosphate-buffered saline (PBS). Additionally, 20 C57BL/6 mice (N=10/group) were injected IVT with high-salt PBS with or without 0.001% Pluronic F68. Retinal structure and injection quality were assessed immediately post-dose (Day 1) using optical coherence tomography (OCT) and fundus imaging, and again at Day 30 to assess recovery and tolerability. Retinal function was evaluated using full-field or pattern electroretinography (ERG) on Day 30. **Results:** Successful delivery into vitreous and subretinal compartments was confirmed by Day 1 imaging. Animals with lens damage or vascular injury were excluded. By Day 30, all groups exhibited normal retinal architecture, except for mild to moderate vitreous inflammation observed in both IVT and SR groups administered 0.1% HSA in BSS. ERG analysis revealed preserved a- and b-wave amplitudes in all buffer groups except DMSO formulations. A dose-dependent SR toxicity was evident with 1% and 5% DMSO, characterized by reduced ERG amplitudes and outer retinal disruption, whereas IVT delivery of DMSO at comparable concentrations was well tolerated. **Conclusions:** These findings demonstrate that ocular buffers such as BSS, BSS Plus, and sodium hyaluronate are well tolerated following IVT and SR injection, whereas formulations containing albumin or DMSO can induce route-dependent retinal stress or inflammation. The results underscore the importance of excipient selection and imaging confirmation for safety evaluation in the development of posterior segment gene and cell therapeutics.

PS 4339 Ocular Topical RTA 408-Mediated NRF2 Activation Mitigates Chloropicrin-Induced Corneal Injury

O. E. Okoyeocha, P. Chu, C. McGreer, K. Zach, S. Lundback, A. Roney, A. Stambersky, and N. Tewari-Singh. Michigan State University, East Lansing, MI.

Background and Purpose: Chloropicrin (CP; CCl₃NO₂, trichloronitromethane) is a volatile chemical that causes immediate ocular irritation, intense pain, excessive tearing, and temporary blindness. Currently, there are no approved treatments for CP-induced ocular toxicity. Beyond its historical use in warfare and terrorism, CP-related occupational and accidental exposures have risen in the United States

due to its increasing use as a fumigant and pesticide. The nuclear factor erythroid 2-related factor 2 (NRF2) signaling pathway regulates cellular defense against oxidative stress and inflammation through the induction of antioxidant genes and detoxifying enzymes. Previous studies using NRF2 knockout (KO) mice have shown that loss of NRF2 exacerbates CP-induced oxidative stress and inflammation in the cornea. Based on this, we evaluated the efficacy of RTA 408 (omevaloxone), a synthetic triterpenoid and an FDA-approved NRF2 activator, in mitigating CP-induced corneal injury. **Methods:** Male Balb/C mice (8-10 weeks old; 4-5 mice per group) were exposed to 2.5% CP vapor for 1 minute using a vapor cap. Control mice were exposed to the vehicle only. Mice in treatment groups received either a 30-minute pre- or post-exposure application of topical RTA 408 (0.1 and 1%), while control groups received corn oil. Clinical examinations were performed using slit-lamp microscopy from 3 hours up to 7 days post-exposure. Mice were euthanized at 1- and 7-days post-exposure, and corneal tissues were collected for cDNA preparation. Gene expression analyses were conducted using qPCR for oxidative stress marker [NAD(P)H: quinone oxidoreductase 1 (*Nqo1*)] and proinflammatory cytokines [Interleukin-1 beta (*Il-1β*), C-C motif chemokine ligand 2 (*Ccl2*), C-C motif chemokine receptor 2 (*Ccr2*), Interleukin-6 (*Il-6*)]. Statistical analyses were performed using one-way ANOVA with multiple comparisons, and significance was set at *p* < 0.05. **Results:** Topical RTA 408 treatment increased *Nqo1* expression in the cornea, confirming NRF2 pathway activation. In contrast, CP exposure suppressed *Nqo1* expression at both day 1 and day 7 while significantly upregulating *Ccl2*, *Il-1β*, *Ccr2*, and *Il-6* at day 1 post-exposure. By day 7, mice treated with RTA 408 exhibited a 16-99% reduction in proinflammatory cytokine expression compared to untreated CP-exposed mice (*p* < 0.05). These molecular findings correlated with clinical observations: untreated mice developed severe corneal ulceration, whereas RTA 408-treated mice showed markedly reduced ulceration at 1-day post-exposure. **Conclusions:** Our findings demonstrate that topical RTA 408 effectively activates the NRF2 signaling pathway in the cornea, thereby reducing inflammation and tissue injury following CP exposure. These results identify NRF2 activation as a promising therapeutic strategy for CP-induced ocular injuries. Ongoing studies are exploring the combined efficacy of NRF2 activators and super-saturated oxygen emulsion therapy in further mitigating CP-induced corneal damage.

PS 4340 Generation of a Novel Immortalized Human Corneal Epithelial Cell Line for Reliable In Vitro Ocular Toxicity Studies

O. Beebe, N. Lee, F. Tian, and X. Zhao. ATCC, Gaithersburg, MD. Sponsor: F. Tian, American Association for Cancer Research

Background and Purpose: The corneal epithelium is a transparent cell layer that covers the cornea and allows light to enter the eye. It serves as a critical barrier against pathogens and environmental insults, protecting deeper ocular tissues. Due to its protective and regenerative functions, the corneal epithelium is widely used in studies of wound healing, drug development, permeation, and toxicity. While animal models are commonly employed in ocular toxicity testing, they often fail to accurately reflect human responses. Human primary corneal epithelial cells offer a more relevant alternative, but their short lifespan and donor-dependent variability limit their suitability in long-term, reproducible studies. To address these limitations, we developed an immortalized human corneal epithelial cell line that retains key functional characteristics of primary cells while enabling extended culture and consistent performance in ocular toxicity assays. **Methods:** We established a clonal immortalized human corneal epithelial cell line by stably expressing human telomerase reverse transcriptase (hTERT) and a mutant cyclin-dependent kinase 4 (CDK4^{R24C}) in normal primary human corneal epithelial cells. We assessed cell morphology, proliferation rate, expression of epithelial markers, migratory capacity, and performance in *in vitro* eye irritation assays. **Results:** The resulting cell line, hTERT HCEC (ATCC® CRL-4067™), was cultured for over 125 population doublings without signs of replicative senescence. It exhibited an abnormal female human karyotype and maintained epithelial-like morphology. Both primary cells and hTERT HCEC expressed cytokeratin 14 (KRT14) and demonstrated migratory ability. In irritation assays, treatment with glycolic acid or benzalkonium chloride led to a dose-dependent reduction in cell viability, confirming the cell line's responsiveness to toxic agents. **Conclusions:** The hTERT HCEC cell line successfully overcomes the limitations of primary human corneal epithelial cells while preserving essential functional attributes. This model provides a robust and reproducible platform for *in vitro* eye irritation testing and broader ocular toxicology applications.

PS 4341 Novel putative mechanism of corneal toxicity associated with netarsudil

S. Kaja, B. Hussein, E. G. Krupa, D. Simoens, and L. D. Troughton. Loyola University Chicago, Maywood, IL.

Background and Purpose: Ocular irritation manifesting as instillation pain, hyperemia, and erythema are common adverse events associated with topical administration of the Rho-associated protein kinase (ROCK) inhibitor, netarsudil, and occur in >50% patients. Generally attributed to the vasodilative effects of ROCK inhibitors, the purpose of this study was to evaluate whether netarsudil elicits changes in corneal permeability that may contribute to ocular irritation. **Methods:** Human corneal epithelial cells (HCE-T) were seeded in 12 mm transwell inserts with 0.4 µm pore polycar-

bonate membranes (cellQART®) and cultured in Dulbecco's modified Eagle's medium (supplemented with 5% fetal bovine serum, 0.5% dimethyl sulfoxide, 5 mg/mL insulin, 10 ng/mL human recombinant epidermal growth factor and 100 U/mL penicillin-100 µg/mL streptomycin; 0.3 mL donor, 1 mL receiver chambers) until confluent (1 wk). In a separate set of experiments, HCE-T cells were stratified in an air-liquid interface in transwells (4 wk). Cells in the donor chamber were exposed to 0.02% netarsudil or vehicle (DMSO) for up to 1 h. Permeability of 6-carboxyfluorescein (6-CF; 376 Da, paracellular), Dextran-Texas Red (DTR; 10 kDa, paracellular), Rhodamine B (479 Da, transcellular) and AlexaFluor™488-conjugated immunoglobulin G (IgG; 150 kDa, low permeability) were calculated from fluorescence values measured with Cytation5 plate reader (Agilent) and the apparent permeability coefficient was calculated. **Results:** In monolayer corneal epithelial cells, netarsudil elicited a time-dependent decrease in transcellular transport (RhoB, $n=7$, $p<0.01$) and a concomitant increase in paracellular transport for 6-CF ($n=11$, $p<0.01$) and DTR ($n=6$, $p<0.05$). Permeability of AlexaFluor™488-conjugated IgG was similar between vehicle and netarsudil treated cells ($n=6$, $p=0.31$). In stratified corneal epithelial cells, netarsudil resulted in a decrease in the P_{app} ($n=6$, $p<0.01$). **Conclusions:** Our findings suggest that netarsudil perturbs epithelial barrier function via disruption of tight junctions. Diverging effects observed in monolayer vs. stratified corneal epithelial cells likely result from differences in actin cytoskeletal tension and mechanics, and diffusion kinetics across a multilayered corneal epithelium. Our findings are consistent with the reported adverse events associated with netarsudil and may offer an additional mechanism contributing to corneal toxicity associated with ROCK inhibitors.

PS 4342 Particulate matter PM₄ and PM₁₀ elicit neutrophil pathology *in vitro*

E. G. Krupa¹, S. Iqbal¹, S. Jain², and S. Kaja¹. ¹Loyola University Chicago, Maywood, IL; and ²University of Illinois Chicago, Chicago, IL.

Background and Purpose: Particulate matter (PM) poses a significant toxicologic concern to the ocular surface, causing acute ocular toxicity and increasing the risk for developing long term sequelae including chronic dry eye disease. Formation of neutrophil extracellular traps is a contributor to ocular surface pathophysiology in >50% of patients with different subtypes of dry eye. The purpose of this study was to investigate effects of small and large fine atmospheric particulate matter on human neutrophils *in vitro*. **Methods:** Standard Reference Material PM₄ (SRM® 2786) and PM₁₀ (SRM® 2787) were obtained from the National Institute of Standards and Technology. Primary human neutrophils were isolated from human whole blood using bead-based immunopurification (Miltenyi). Extracellular DNA was quantified by Sytox™ Green labeling and quantification of neutrophil markers by flow cytometry. Effects of PM on neutrophil adhesion to corneal epithelial cells (HCE-T) was determined using plate-reader based quantification of calcein-labeled neutrophils. Data were analyzed by One-Way or Two-Way ANOVA with Holm-Sidak's multiple comparisons test, as appropriate, and graphed in Prism software. **Results:** Freshly-isolated primary human neutrophils were exposed to PM₄ or PM₁₀ for 2 h, or the positive control, PMA (20 nM), for 20 min. Exposure resulted in increased expression of CD11b and CD16. Furthermore, exposure to PM₄ (75 and 150 µg/mL) and PM₁₀ (150 µg/mL) significantly increased the percentage neutrophils undergoing NETosis as measured by Sytox™ Green fluorescence ($n=5$, $P < 0.01$). PM₄ (10-300 µg/mL) dose-dependently increased neutrophil adhesion to corneal epithelial cells ($n = 3$). The level of adhesion was similar to that elicited by pathophysiologically relevant anti-citrullinated autoantibodies (ACPA, 100 ng/mL). Pooled human immune globulins (ocular surface immune globulins, OSIG) are currently developed for the treatment of dry eye disease and prevented PM-induced adhesion to corneal epithelial cells ($n=3$, $P<0.01$). **Conclusions:** These findings extend prior evidence that PM exacerbates neutrophilic inflammation and provide mechanistic insight into the association between PM exposure and both acute ocular toxicity and chronic ocular surface disease. The ability of OSIG to block PM-induced neutrophil adhesion highlights a potential therapeutic strategy for mitigating pollutant-driven ocular surface inflammation.

PS 4343 Distinct retinal epithelial responses to carbon black nanoparticles versus PM2.5: oxidative stress-driven EMT and barrier disruption

A. Jiménez-Chávez, K. Castillo, D. A. Herman, M. T. Kleinman, and A. De Vizcaya-Ruiz. University of California, Irvine, Irvine, CA.

Background and Purpose: Retinal fibrotic diseases affect more than 11 million people in the United States, leading to irreversible vision loss in these patients. Emerging evidence links particulate matter to fibrotic processes in ocular tissues. Our previous studies in C57BL/6 mice demonstrated that chronic exposure to ultrafine particulate matter alters retinal and corneal thickness and induces TGF- β -mediated α -SMA-expression consistent with fibrotic remodeling. Activation of the TGF- β /SMAD axis and α -SMA overexpression are known to initiate epithelial-mesenchymal transition (EMT) in epithelial cells, a pivotal event in ocular fibrosis. Particulate matter of less than 2.5 microns (PM2.5) generally exhibits an elemental carbon core coated with diverse organic compounds, which together influence their reactivity and biological effects. Currently, there is limited understanding of how the carbon core from PM2.5 interacts with and affects the retinal layer. The present study investigates how expo-

sure of human retinal pigmented epithelial (ARPE-19) cells to PM2.5 or carbon black nanoparticles (CBNPs) activates the TGF- β /SMAD/ α -SMA pathway, leading to EMT and barrier disruption. **Methods:** To demonstrate the differential effect between the carbon core and the complete PM2.5, CBNPs were employed as a simile of the carbon core in this study. PM2.5 was collected during the Summer 2025 in Irvine, California, using a PM2.5 High Volume Air Sampler with a HiVol cascade impactor (Tisch, USA). Monarch 120 CBNPs were purchased from Cabot Corporation (USA) (particle size range 10 - 300 nm). ARPE-19 cells were exposed to increasing concentrations (0 - 10 µg/cm²) of PM2.5 or CBNPs for 24, 48, and 72 hours. After exposure, cell viability was assessed using MTS and LDH assays. Additionally, cells were fixed and stained with an α -SMA antibody (to evaluate protein expression) or a BODIPY antibody (to assess lipidic oxidative damage) at 72 hours. Images of the fixed cells were collected in a High-Resolution Fluorescence Microscope Keyence KV-8000. Lastly, trans-epithelial electrical resistance (TEER) was measured after 24, 48, and 72 hours. **Results:** Cell viability assays showed no cytotoxicity at any concentration or time point tested for either particle. After 72 hours, CNBP exposure produced a concentration-dependent increase in lipid oxidation and α -SMA protein expression, accompanied by an increased TEER at 1.0 µg/cm² but a decrease at 5.0 µg/cm², indicating loss of epithelial integrity at higher doses. In contrast, exposure to PM2.5 exhibited elevated lipid oxidation, and increased TEER values at 1.0 and 5.0 µg/cm², suggesting an adaptive or barrier-strengthening response. These findings indicate that CBNPs, but not PM2.5, induce dose-dependent oxidative stress and α -SMA upregulation consistent with the initiation of epithelial-mesenchymal transition (EMT). The contrasting TEER responses highlight particle-specific effects on retinal epithelial barrier function, likely driven by differences in particle size and chemical composition. **Conclusions:** Together, these findings demonstrate particle-specific molecular responses in retinal pigmented epithelial cells. CBNPs induced oxidative stress, α -SMA overexpression, and loss of barrier integrity, consistent with the initiation of epithelial-mesenchymal transition (EMT) and early fibrotic remodeling. In contrast, PM2.5 exposure caused lipid oxidation but preserved or enhanced barrier function, suggesting a transient or adaptive response. Overall, the results indicate that retina epithelial is more prone to interact with smaller particles, underscoring the potential role of ultrafine particles in promoting ocular fibrosis and vision impairment.

PS 4344 Topical dexamethasone intervention reduces acute and delayed ocular damage in sulfur mustard vapor-exposed rabbit eyes

R. Tripathi, S. Ahmad, A. T. Doney, A. B. Stone, C. A. Sousa, S. Cayea, V. H. Vuong, S. P. Shenoy, K. A. Brigham, and P. M. McNutt. Wake Forest Institute for Regenerative Medicine, Wake Forest University School of Medicine, Winston-Salem, NC.

Background and Purpose: Sulfur mustard (SM) is a potent alkylating agent, causes acute corneal injury and progressive, irreversible damage termed mustard gas keratopathy (MGK). MGK is characterized by chronic discomfort, corneal degeneration, vision loss, and dose-dependent recurrent lesions (RELs). No therapy currently halts MGK progression. This study investigates early dexamethasone (Dex) treatment to suppress inflammation, limit initial injury, and reduce delayed lesion incidence and chronic corneal degeneration following SM exposure. **Methods:** New Zealand White rabbits ($n = 32$) were SM exposed for 60 s using a novel vapor cap model, inducing recurrent lesions in 50% of eyes within 8 weeks. Post-exposure, 0.1% dexamethasone was administered topically three times daily for 5 days. Weekly assessments via slit-lamp and optical coherence tomography (OCT) monitored disease progression. At study termination, corneal tissues were harvested for histopathological and molecular analyses. **Results:** Slit-lamp and OCT images reveal progressive corneal opacity and edema post-SM exposure, with fluorescein uptake indicate epithelial disruption at day 3 and recovery by day 5. -Dex eyes show sustained thickening, hypercellularity, and stromal edema, while +Dex mitigates these changes ($p = 0.0135$). At day 56, -Dex exhibits bullous keratopathy as recurrent lesions, +Dex suppresses recurrence and preserves corneal integrity. The Kaplan-Meier analysis for corneal thickness confirms delayed lesion onset and significantly ($p = 0.0300$) reduced recurrence with Dex treatment through day 56. **Conclusions:** Dexamethasone reduces acute corneal edema following sulfur mustard (SM) vapor exposure and suggests its potential to attenuate acute ocular inflammatory responses. It also mitigates recurrent lesion emergence and chronic pathologies. Early intervention with dexamethasone reduces both acute and later long-term SM-induced ocular injury, potentially by suppressing inflammatory cascades that drive progressive corneal degeneration. These findings advance ocular toxicology by establishing a pharmacological framework for counter-acting vesicant-induced tissue damage and guiding therapeutic strategies in chemical injury models.

PS 4345 The Effect of Glucagon-like Peptide 1 (GLP-1) Receptor Agonists and Estradiol Treatment on the Diabetic Inner Retinal Blood Barrier

M. Soe, K. Zhang, and M. Vazquez. Rutgers University, Piscataway, NJ.

Background and Purpose: Diabetic Retinopathy (DR) is a major cause of vision loss in millions of U.S. adults. Here, toxins and other harmful compounds enter the retina via lowered integrity of the inner blood-retinal barrier (iBRB), a multi-partite cellular tissue that regulates molecular transport between the bloodstream and neuroretina.

A rapidly increasing number of American adults are prescribed Glucagon-like Peptide 1 Receptor Agonist (GLP-1RA), such as Semaglutide, as treatment for diabetes and/or obesity. However, rapid weight loss and significant improvements in blood glucose caused by Semaglutide have been linked to a higher risk of DR exacerbation in some overweight or obese patients. Our research focuses on estradiol (E2), a known regulator of glycemic control and retinal health. Studies show that E2 helps preserve retinal ganglion cells and maintain iBRB integrity. Previous studies from our lab have also shown that moderate E2 levels are critical for maintaining iBRB integrity and lowering harmful reactive oxygen species production in iBRB cells. It is our hypothesis that estrogen can be used as a co-treatment to improve Semaglutide actions that impact vision. **Methods:** Rat progenitor retinal cells (R28) were used to model Muller glia, which are regulators of iBRB integrity. Cells were conditioned in media containing 1 µg/mL of advanced glycation end products (AGEs) for at least 7 days to create diet-induced hyperglycemic condition. The AGE treated cells were treated with Semaglutide (100 nM), E2 (10 pM), or a combination of Semaglutide and E2 treatments for 7 days. AGE treated and non-AGE treated cells serve as controls in the following readouts. Cells were seeded to collagen and fibronectin coated transwell inserts on day 3. Permeability assay was performed on day 7 by adding Rhodamine B (1 mg/mL) and 4kDa fluorescein isothiocyanate dextran molecules (1 mg/mL) to the apical side of the transwell inserts containing the cells. Media from the basolateral side were collected at 1, 3, 5 and 12 hr time points for fluorescent plate reading. Immunocytochemistry was done for AGE receptor, AGER and the mean fluorescent intensity was quantified to determine the effect of Semaglutide and E2 treatments. **Results:** Rhodamine B diffused easily across cells, irrespective of treatment, likely facilitated by paracellular transport. On the other hand, AGE conditioning caused a statistically significant increase in the passage of 4 kDa Dextran. Semaglutide and E2 treatments did not improve the permeability of the 4 kDa Dextran. AGER expression in AGE conditioned cells which received both Semaglutide and E2 treatments were statistically lower than cells that received only the AGE conditioning without treatment. Additionally, combined treatment of Semaglutide and E2 treatments were significantly lower than either treatment alone. In non-AGE treated cells, AGER expression was higher in the nucleus as per the nucleus to cell mean intensity ratio. AGE treatment statistically reduced AGER expression in the nucleus. Only the combined treatment of Semaglutide and E2 to the AGE treatment restored the increased nuclear localization. Our current studies examine the expression of GLP-1R and GPER30 through immunocytochemistry and perform permeability assay of 70 kDa Dextran molecules to increase our mechanistic understanding of the effect on iBRB cells. **Conclusions:** Our current results show that combined treatment of Semaglutide and E2 may restore the AGE receptor expression that is associated with cell permeability and barrier function. To increase our understanding of the permeability function, we aim to perform Transepithelial Electrical Resistance (TEER) across the cells in the future. This current investigation behind iBRB disruption could lead to improved understanding on adverse effects from GLP-1RA treatment to the retina as well as offer improved treatment plan to mitigate those effects.

PS 4346 Development of an *in chemico* test battery to assess eye irritation of surfactants and surfactant-dominant consumer products

A. Stacy, S. Engled, D. Alers, and J. Rose. Procter and Gamble, Mason, OH.

Background and Purpose: Assessment of eye irritation following accidental exposure is critical to the holistic quantitative risk assessment of surfactant-dominant consumer products. Historically, albino rabbits were used to classify materials based on their extent of ocular damage in the Draize test. However, the use of the Draize method is restricted by major regulatory authorities because of ethical concerns, the subjective nature of the methods data interpretation, and human relevancy due to species differences. Given that new chemistries with no eye irritation data are continually innovated, alternative methods that allow for the efficient assessment of eye irritation must be innovated. Protein denaturation and lipid disruption are key molecular initiating events in the eye irritation adverse outcome pathway. Multiple *in chemico* assays measuring protein denaturation and lipid disruption have been proposed as methods to assess eye irritation. Still, to date no single test has been demonstrated to sufficiently predict the eye irritation potential of surfactant-dominant mixtures. Therefore, our objective is to develop an *in chemico* test battery to determine relative eye irritation potencies based on a test materials ability to disrupt cellular proteins and lipids. Therefore, we are 1) investigating the physical chemical properties of surfactants which drive these effects to understand assay applicability; and 2) building a mechanistic understanding of the molecular changes which promote eye irritation **Methods:** **Hemoglobin Denaturation Assay (%HDR):** %HDR is utilized to determine the ability of a test item to denature hemoglobin as a representative protein hemoglobin. A dilution series of the test material is prepared in water and added to a 96-well plate. An Hb/phosphate buffer solution is then added to the samples. This mixture is incubated for 5 minutes before its optical absorbance is measured by a spectrophotometer. The %HDR is then calculated $(100 - (100 \times (\text{Hb} + \text{test item}/\text{Hb} + \text{H}_2\text{O})))$ using values blanked to H₂O. **Ca²⁺ Sequestration Assay:** Intracellular Ca²⁺ maintains the structural integrity of tight junction proteins that preserves corneal epithelium connections. A dilution series of the test material is prepared in HEPES buffer solution containing CaCl₂ and added to a 96-well plate. A calcium detecting dye is added to the samples, which are then incubated for 5 minutes before the optical absorbance is recorded. The % sequestered calcium is then calculated $(\% \text{ sequestered calcium} = 100 - (100 \times (\text{test item}/\text{H}_2\text{O})))$ using values blanked to the buffer without CaCl₂. **Liposomal Disruption Assay:** A commercially

available liposome permeability fluorescence assay (ProFoldin, Hudson, MA) is used as a surrogate to understand the potential of a test material to disrupt a lipid bilayer. The assay is performed according to manufacturers instructions. **OptiSafe:** OptiSafe is a commercially available *in chemico* test method which measures changes in macromolecules to assess eye irritation potential (Lebrun Labs, Anaheim, CA). It is validated to classify chemicals that are non-classified (OECD TG 496), but has not been validated for mixtures. To investigate mixture potency, surfactants and formulas with well characterized eye irritation potencies were diluted and prepared according to manufacturer's directions. **Results:** The tested surfactants exhibited reliable inter and intra-experimental reproducibility. Moreover, more potent eye irritants as determined by historical methods (e.g., isolated chicken eye (ICE) test) were demonstrated to induce elevated responses across the *in chemico* test battery. Finally, surfactant-dominant formulations were observed to induce scores in each assay that correlated with their established eye irritation potential. **Conclusions:** Development and optimization of eye irritation assays that are reproducible and relevant for surfactant-dominant cosmetic formulations is critical for assessing the human safety of finished products. This work demonstrates that an *in chemico* test battery, which measures protein and lipid macromolecular disruptions central to the development of eye irritation, has promise to be used in a weight of evidence assessment of surfactants and surfactant-dominant consumer product formulations.

PS 4347 NWD-19: A First-in-Class Mitochondrial Therapeutic Demonstrating Safety and Efficacy in Chemical-Induced Ocular Surface Injury

A. Banerjee¹, S. Kaja², T. Czepiel¹, T. Nguyen¹, M. Lindeblad¹, and R. Giri³. ¹University of Illinois at Chicago, Chicago, IL; ²Loyola University Chicago, Maywood, IL; and ³N'wari Inc., Chicago, IL.

Background and Purpose: This study was performed to evaluate the cytotoxicity of NWD-19 in human corneal epithelial cells *in vitro*. Additionally, *in vivo* therapeutic efficacy of NWD-19 was determined when administered by topical ophthalmic instillation in mice following benzalkonium chloride (BAK) induced chemical toxicity. **Methods:** For *in vitro* assessment, cells were seeded (10⁵ cells/well) on 96-well plates and grown for 2 days. Cells were then exposed overnight to a dose-range of NWD-19 (0.005-10 µM) in complete culture medium, DMSO vehicle (0.1%), or media only for 16 h. Toxicity was assessed using 3-(4,5-dimethylthiazol-2-yl)-2,5-diphenyltetrazolium bromide (MTT) uptake and lactate dehydrogenase (LDH) release assays. For *in vivo* effect, BAK toxicity was induced by instilling 10 µL of 0.2% BAK once daily to both eyes in C57BL/6J mice (n=10/group) from Day 0 to Day 21. Mice received either vehicle (1% carboxymethylcellulose) or 0.003% NWD-19 (5 µL/eye) by three times daily (TID) bilateral topical ophthalmic instillation from Day 8 to Day 21. Mitochondrial selectivity and kinetics were studied for dosing regimen determination. **Results:** *In vitro* concentrations up to 5 µM had no biologically or toxicologically relevant effect on LDH release as a surrogate marker of cytotoxicity or MTT absorbance as a surrogate marker for proliferation. In mice eyes, BAK caused severe dryness and corneal lesions. NWD-19 resulted in a significant reduction in fluorescein scoring at Day 14 and Day 21 compared to the vehicle (p<0.05). Corneal fibrosis predominantly noted by Day 7 was significantly cleared following 7 days of NWD-19 administration. Corneal neovascularization was noted in both vehicle and NWD-19 treated eyes at Day 14 and Day 21 but was lower in the NWD-19 treated group at both timepoints. **Conclusions:** In extended time exposure experiments, NWD-19 was well-tolerated by human corneal epithelial cells at concentrations up to 5 µM. C57BL/6J mice, topical instillation of 0.003% NWD-19, equivalent to a dose of 0.45 µg/eye/day was well tolerated and resulted in a significant attenuation of BAK-induced ocular surface and internal tissue pathology. NWD-19 is being developed as a novel first-in-class mitochondrial therapy for the treatment of dry eye disease.

PS 4349 Modeling Exposure to Polycyclic Aromatic Hydrocarbons (PAHs) in Placentae using Antibody-based Array Proteomics and Machine Learning

C. Coarfa, S. L. Grimm, A. Koirala, V. Putluri, A. H. Kamal, N. Putluri, S. Huang, B. Moorthy, and M. Suter. Baylor College of Medicine, Houston, TX.

Background and Purpose: The placenta plays a critical role in fetal development and is sensitive to both clinical and environmental influences. In this study, we employed high-throughput proteomic and epigenomic profiling to explore how placental molecular features relate to clinical outcomes and environmental exposures. **Methods:** Using reverse phase protein arrays (RPPA) and gas chromatography-mass spectrometry (GC-MS), we analyzed protein expression, histone post-translational modifications, and levels of three polycyclic aromatic hydrocarbons (PAHs) in placental samples from 41 term and 36 preterm deliveries. Analysis approaches included Weighted Gene Correlation Network Analysis (WGCNA) and machine learning (ML). **Results:** Unbiased analytical approaches, including WGCNA and machine learning ML, revealed distinct protein modules associated with gestational age, birthweight, and maternal BMI. Notably, expression of lactate dehydrogenase A (LDHA) emerged as a top predictor of gestational age and birthweight. PAH levels, particularly benzo(a)pyrene (BaP), were significantly correlated with specific protein expression patterns and maternal BMI. WGCNA revealed a blue module correlated with BaP

at $r=0.328$, enriching for apoptosis, PI3K/AKT/MTOR, and p53 signaling. Machine learning regression enabled modeling of BaP with a goodness-of-fit $R^2=0.47$ using the k-Nearest Neighbor method; top informative proteins with negative association with BaP were pAkt, pAMPKb1, Vimentin, and pBCL2; as little as 5 proteins were sufficient for effective machine learning regression of BaP. **Conclusions:** These findings highlight the utility of integrative molecular profiling in identifying biomarkers of placental function and environmental exposures, enabling the study of their interaction on pregnancy outcomes.

PS 4350 ToxIndex: An agentic AI orchestrator for toxicology expert tools

K. Han, M. Nagyal, J. Mikhail, S. Mitra, I. Ballone, T. Bozada, Z. Mughal, and T. Luechtefeld. Insilica, Rockville, MD.

Background and Purpose: Toxicologists face expanding heterogeneous data sources (regulatory dossiers, mechanistic literature, and cheminformatic repositories) that are difficult to synthesize within time-sensitive decision windows. ToxIndex is a web-based, agentic AI orchestration platform coordinating analytical workflows, enabling scientists to employ automated processes that interrogate public data, and execute analytical pipelines. The platform integrates cheminformatic engines for metabolite prediction, adverse outcome pathway (AOP) extracting agents, probabilistic toxicology modules, and report-generation utilities. We describe the architecture and application for endocrine and general toxicity assessment. **Methods:** ToxIndex employs a scalable graph-directed workflow engine built with Kubernetes, Redis, and CloudSQL that manages multi-step agent and tool invocations. Users initiate analyses through the web application, where large language model (LLM) powered agents sequence tasks such as (1) invoking the SyGMA metabolite predictor and structure normalization pipelines (RDKit, PubChem); (2) querying curated, ontology mapped, property databases, and literature search APIs; (3) parsing PDFs or regulatory studies to extract AOP evidence; and (4) synthesizing probabilistic risk summaries by fitting beta distributions to observed toxicity rates and calculating posterior probabilities of adversity. Intermediate data products are cached in Google Cloud Storage and surfaced through interactive dashboards for iterative review. **Results:** ToxIndex demonstrates the impact of agentic workflows that determines the potential of developmental neurotoxicity of chemicals through a case-study on acetaminophen. SyGMA metabolite enumeration generated 31 candidate products, which mapped to downstream hazard indices through integrated knowledge bases. The automated system retrieved 2766 publications from PubMed, CTD, and PubTator3 databases. This corpus was reduced to a subset of candidate papers after screening for relevance and reliability checks as defined by the Toxicological data Reliability Tool (ToxRTTool) criteria and classified via an LLM-based approach using Gemini-2.5-Pro. For systematic evaluation of mechanistic plausibility, a weight-of-evidence framework was employed on the selected papers to extract 8394 key events related to developmental neurotoxicity, which were then clustered into 2774 key event clusters based on their causal relationships. Across broader workflow validation, ToxIndex reduced expert review cycle time by an order of magnitude compared to human-based manual document review. The evidence-supported key events converged on ten core mechanistic pathways underlying toxicity in the evaluated chemicals, including disruptions such as redox imbalance with associated antioxidant depletion, as well as Ca^{2+} signaling defects in developing neurons. Probabilistic toxicity modules, integrating clinical cohorts and *in vivo* data, produced posterior risk distributions consistent with historical assessments in validation cases. Stakeholders reported substantial gains in transparency through the system's audit trail, including step-level logs, evidence citations, and reproducible Python artifacts. **Conclusions:** ToxIndex demonstrates how orchestrated LLM agents, cheminformatics, and probabilistic modeling converge in a regulatory-compliant web application to accelerate toxicological evaluations. By unifying document ingestion, pathway mapping, metabolite prediction, and evidence synthesis, ToxIndex enables reproducible, explainable decision support for endocrine disruption and broader toxicity domains. Ongoing development expands the tool catalog and refines active learning loops. This approach provides a blueprint for deploying agentic AI systems that augment expert judgment without sacrificing scientific rigor.

PS 4351 ToxInsightor: Exploring Alternatives to Animal Use for Safety Assessment - a Case Study of Antibody-Drug Conjugates (ADCs)

L. Millin, and Z. Liu. Boehringer Ingelheim, Ridgefield, CT.

Background and Purpose: New Approach Methods (NAMs) are increasingly adopted in risk assessment as regulatory agencies prioritize predictive, human-relevant, and ethical strategies. Selecting a "fit-for-purpose" derisking and mitigation approach requires a robust understanding of current practices for marketed drugs and clinical candidates. Manual collection of this information is time-consuming, labor-intensive, and often incomplete. **Methods:** To address this gap, we developed ToxInsightor, an agentic AI-based platform leveraging a deep tox-specific research framework built on LangChain architecture, Model Context Protocol (MCP), and GPT-4o with tailored toxicology prompt engineering. ToxInsightor provides an integrated solution to curate relevant data, perform automated analysis, and generate evidence-based recommendations for nonclinical risk strategies. **Results:** To validate ToxInsightor, we applied it to antibody-drug conjugates (ADCs) focusing on nonclinical risk strategies. The platform autonomously aggregated and analyzed animal models

and NAMs for ADCs, extrapolating findings to human toxicities and recommending "fit-for-purpose" strategies. For example, extrapolation rates for bone marrow toxicity were 0.82, 0.54, and 0.48 for cynomolgus monkeys, rats, and dogs, respectively; hepatotoxicity rates were 0.43, 0.28, and 0.22 for the same species. Recommended NAMs for hepatotoxicity included cell-based *in vitro* assays and *in-silico* models, with detailed context of use. Toxicologists reviewed these outputs and provided positive feedback on their potential utility for facilitating decision-making. **Conclusions:** ToxInsightor demonstrates strong potential as a tox-specific, multi-agent AI assistant to streamline data curation, enhance risk assessment, and support strategic decision-making in nonclinical safety evaluation.

PS 4352 A Comparative Assessment of Large Language Model (LLM) Performance in Answering Target Safety Assessment Questions

V. B. Siramshetty¹, Y. Chang², S. Mielke¹, L. T. Anger¹, E. Mutter-Rottmayer¹, S. Laing¹, R. Sullivan¹, S. Ra¹, and C. Hasselgren¹. ¹Genentech, Inc., South San Francisco, CA; and ²Rancho Biosciences, San Diego, CA.

Background and Purpose: Target safety assessment (TSA) is a critical first step in assessing the potential hazards associated with modulating a biological target in an organism. This requires synthesizing information on phenotypes of genetically engineered organisms and human mutations, expression profiles, and known risks. This process traditionally requires extensive manual evaluation of disparate data from public databases and a vast body of scientific literature. This manual process is time-consuming, resource-intensive, and faces limitations in scalability and speed. Large Language Models (LLMs) present a significant opportunity to accelerate evidence synthesis and analysis in toxicology. However, their reliability and accuracy in addressing specialized, high-stakes domains like TSA require rigorous validation before they can be integrated into toxicology workflows. This study evaluates the performance of several internal and external LLMs in answering complex, expert-generated toxicology questions. **Methods:** A dataset of 120 TSA-related questions was crowd-sourced from practicing toxicologists, covering over 20 drug targets. Target safety themes were categorized by their primary focus i.e., on-target toxicities/risks. Phenotypic outcomes were the most common (40%), followed by established toxicities/risks (20%), tissue expression (15%), and biological function (15%). Target structure and specific molecules in development were less frequent (5% each). Four LLMs were evaluated that included two internally developed LLMs and two external LLMs (Gemini 2.5 Flash Preview 05-20 and Gemini 2.5 Pro Preview 06-05) from Google. The models were tested in two settings: (1) with retrieval-augmented generation (RAG), where models were provided automatically-retrieved scientific literature snippets and asked to synthesize an answer, and (2) without RAG, generating free-form answers without retrieval of external knowledge. A comprehensive scoring rubric was developed to evaluate response quality based on length appropriateness, well-formedness/coherence, relevance, completeness, accuracy, overconfidence, underconfidence, and use of citations (when applicable). All responses were scored by both expert human evaluators and the GPT-4.1 model from OpenAI. **Results:** A comparison of model performance revealed that the internal models (both with RAG and without RAG) and Gemini 2.5 Pro provided the highest-quality responses, scoring particularly well in terms of length appropriateness (80-95%) and well-formedness (60-90%) while Gemini 2.5 Flash provided suboptimal responses particularly with RAG for both length appropriateness (45%) and well-formedness (35%). For all models, the accuracy of the responses improved with RAG, whereas the overconfidence was more pronounced without RAG. Across the evaluation, a good agreement was observed between the scores from the human annotators and the GPT-4.1 evaluator, further indicating the potential for using LLMs in scalable evaluation frameworks. **Conclusions:** These results are encouraging and demonstrate the capability of state-of-the-art LLMs to generate relevant and coherent answers to key TSA related questions. The strong performance, particularly with RAG, supports the continued development and integration of LLMs into internal pipelines to assist in evaluating target safety.

PS 4353 Predicting Multi-Protein Corona Adsorption Patterns Using a Deep Conditional VAE-GAN Model

A. Canchola, H. Le, K. Li, and W. Chou. University of California, Riverside, Riverside, CA.

Background and Purpose: The protein corona (PC) has widely been demonstrated to impact the pharmacokinetics, safety, and efficiency of nanoparticle (NP) systems for clinical applications such as drug or vaccine delivery. Recently, machine learning (ML) algorithms have increasingly been used to analyze PC formation datasets to predict PC formation and identify complex patterns in NP-PC interactions to improve NP design optimization and pharmacological outcomes. While current models have proven to be robust, they largely focus on single-task objectives, such as predicting individual protein adsorption, which limits their ability to capture complex and dynamic NP-PC interactions like protein co-adsorption that occur *in vivo*. To address this gap, this study aimed to develop a variational autoencoder-generative adversarial model (VAE-GAN) to predict multi-protein adsorption profiles from NP and experimental parameters. **Methods:** NP design and experimental parameters alongside corresponding quantitative PC profiles were obtained from the Protein

Corona Database (PC-DB), a publicly accessible repository. A conditional VAE-GAN model was implemented in PyTorch. Abundance data from 100 frequently adsorbed proteins were min-max scaled, and NP condition features were one-hot encoded. The model comprised an encoder-decoder pair with LayerNorm, LeakyReLU activations, and dropout for latent representation learning, and a batch-normalized discriminator to distinguish real from synthetic profiles. Training minimized composite loss integrating weighted reconstruction, Kullback-Leibler divergence, and adversarial terms, optimized with KL-annealing and a one-cycle learning rate schedule. Model performance was evaluated using RMSE and R^2 metrics, while latent space structure and generated protein corona profiles were analyzed through PCA, t-SNE, and histogram visualizations. **Results:** The optimized VAE-GAN model demonstrated high predictive performance, achieving an average test set R^2 of 0.780 and RMSE of 0.767 across the 100 selected proteins. Latent space visualizations revealed distinct clustering patterns within the generated PC profiles that closely match real experimental data, indicating effective encoding of underlying NP-PC interaction features. These findings demonstrate that the conditional VAE-GAN framework effectively captures multivariate dependencies in NP-PC interactions and can generate realistic, high-fidelity PC compositions *in silico*. **Conclusions:** This study demonstrates that a VAE-GAN framework can effectively generate realistic PC composition predictions that reflect the variability and complexity of experimental datasets. Future work will focus on expanding the dataset with experimental NP-PC data, particularly for understudied *in vivo* exposure and organic NP (e.g., lipid) formulations. In addition, further incorporation of explainable artificial intelligence (XAI) techniques will enhance model interpretability and accessibility for NP-PC researchers.

PS 4354 Dual Readout: Predicting Affinity and Actionable Holo-Complex Structures with *In Silico* Safety Screening

E. B. Miller¹, D. Coskun¹, M. Lihan¹, H. Hwang¹, L. Denluck², C. Andersen¹, M. Liu¹, K. Lewis¹, R. A. Friesner³, and R. Abel¹. ¹Schrodinger, New York, NY; ²Schrodinger, Portland, OR; and ³Columbia University, New York, NY.

Background and Purpose: The increasing use of secondary pharmacology screening early in drug discovery programs has led to superior drugs with fewer patient adverse events. However, discovering one or more off-target hits in a secondary pharmacology screening panel does not immediately provide guidance on how to derisk such potential liabilities. **Methods:** Using a physics-based computational platform consisting of induced fit molecular docking and free energy perturbation we created an *in silico* safety panel of kinases, GPCRs and hormone receptors. We found that the approximate assignment of protein re-organization free energy was the missing component needed to successfully employ existing computational tools. Furthermore, using the results of the physics-based calculations we can generate sufficient training data to develop ML models particular to individual anti-targets to rapidly predict binding affinity as a function of the predicted protein-ligand complex. **Results:** We quantify the accuracy of the panel by predicting selectivity of selected compounds against a range of off-targets. Specifically, correlating predicted to experimental affinity, we observe R^2 values of 0.53, 0.69, and 0.60 for sets of unrelated small molecules bound to Estrogen Receptor Alpha, SSTR2, and ACM1, respectively. In the task of predicting kinase selectivity for a set of 19 inhibitors, we observe an R^2 of 0.85 correlating predicted versus the experimental number of hits for each inhibitor against a panel of 55 kinases. A hit is defined as a K_D of 10 μ M or stronger. **Conclusions:** The computational screening panel provides a highly valuable dual readout: (1) a predicted binding affinity (K_D) and (2) an atomistic structural model (holo-complex structure) of the ligand binding to the off-target. This structural model is a superior readout to affinity alone, as it offers mechanistic insight into the binding interaction that is often unavailable from a standard experimental assay. This combined information allows drug discovery teams to efficiently iterate safer molecular designs by using the structural models to rationalize chemical modifications that disrupt the off-target interaction without affecting the primary target.

PS 4355 Evaluation of Single and Multitask Methods for Secondary Pharmacology Prediction with Cross-Panel Validation

X. Niu, V. B. Siramshetty, L. Anger, S. Kakiuchi-Kiyota, C. Hasselgren, and F. Melnikov. Genentech, South San Francisco, CA.

Background and Purpose: The prediction of secondary pharmacological effects of small molecules is a critical aspect of drug discovery, aiding in the identification of potential off-target effects. In this study, we systematically evaluated the performance of both single and multitask methods using diverse machine learning algorithms. Single-task methods, including k-Nearest Neighbors, Random Forest, Gradient Boosting, and Support Vector Machines, were compared against multitask methods such as Bayesian matrix factorization (Macau) and a Graph-Convolutional Neural Network (GCNN). **Methods:** The dataset comprises over 3,000 proprietary small molecules screened at Genentech in a standard secondary pharmacology assay panel that covers a wide range of off-targets (>40 targets/assays considered in this study) with variable hit rates. To evaluate the influence of public domain data, bioactivity data was pooled from ChEMBL target records. In addition, we performed cross-panel comparisons using Novartis's published Secondary Pharmacology Database (SPD) and Eurofins's SafetyScreen Panel, alongside Genentech internal

data, to assess concordance and model portability across public and private sectors. Single- and multitask regression models were trained and validated on both proprietary and combined proprietary and public datasets using standard cross-validation and time-split validation methods, and were benchmarked against historical internal controls and reference compounds. **Results:** Our findings reveal that the performance of these methods depends on the nature of the task (i.e., assay) and data distributions, such as the fraction of active ($pIC50 \geq 5$) compounds. Overall, multitask methods demonstrated superior performance, especially in data-rich tasks. Even more notably, multitask learners improved recall for tasks with fewer active compounds. On the other hand, as expected, single-task methods exhibited higher precision due to the skewness of the $pIC50$ distribution toward inactive compounds. The addition of public domain data improved model performance overall and increased cross-source portability. **Conclusions:** Together, these findings suggest that multitask learning may help alleviate class-imbalance problems and improve rare event detection. Furthermore, public-private data integration can help make better predictions especially in data-poor or data-imbalanced tasks. In most cases, multitask methods were best suited to take advantage of data-rich tasks and transfer information to more data-poor ones. However, single-task methods remain generally competitive. In safety assessment, these insights are used to refine predictive modeling strategies and ultimately facilitate more informed decision-making in early drug development.

PS 4356 Investigating the mechanisms of emerging and legacy contaminants bioconcentration in fish tissues using machine learning models

S. Dhayade¹, D. Chodvadiya¹, Y. Fan², F. Gao², and Y. Shen¹. ¹University of Texas at Arlington, Arlington, TX; and ²University of California Los Angeles, Los Angeles, CA.

Background and Purpose: The rapid increase in the production and usage of anthropogenic organic chemicals inevitably results in their release into the environment. These contaminants can bioaccumulate in aquatic animals and pose potential threats to human health. Surface water is a major reservoir for the release of anthropogenic chemicals. These contaminants could be absorbed, distributed, metabolized, or excreted across different tissues in aquatic animals and pose harm or even death to the aquatic animals. Although existing models such as QSAR (Quantitative Structure-Activity Relationship) and CART (Classification and Regression Trees) have been used to predict key mechanisms, they either focused on a set of pre-selected physicochemical descriptors or had low prediction accuracy. This study aimed to leverage multiple feature representations and advanced machine learning models to improve the prediction of bioconcentration mechanisms. **Methods:** We used a published Bioconcentration factor (BCF) dataset with 763 chemicals categorized into three classes of fish bioconcentration mechanisms: (1) inert chemicals that accumulate in lipids, (2) chemicals interacting with tissues, and (3) chemicals undergoing metabolism or elimination. We tested four types of input features: (1) physicochemical descriptors; (2) RDKit-generated molecular features from chemical SMILES; (3) molecular fingerprints; and (4) a combination of molecular features and physicochemical descriptors. We trained and fine-tuned multiple machine learning models, including Gradient Boosting Decision Trees (GBDT), Support Vector Classifier (SVC), Logistic Regression (LR), and Random Forest (RF), and compared their predictive model performance. We further developed a webtool based on model performance and user convenience. **Results:** GBDT model achieved the best predictive performance among all tested models, with an accuracy of 0.899 ± 0.024 and a recall of 0.811 ± 0.064 using physicochemical features. RDKit-derived descriptors with the addition of logKow and logBCF had competitive performance with 0.859 ± 0.026 accuracy and 0.756 ± 0.037 recall. LogBCF and logKOW were the most influential physicochemical features in classifying the chemicals' bioconcentration mechanism, followed by RDKit descriptors such as Chi1n and VSA_Estate1. Molecular fingerprints had poor prediction performance in this dataset. Recall was prioritized to minimize misclassification of highly bioaccumulative chemicals. We successfully built a webtool where users only need to input a chemical's CAS number and logKOW value to obtain a predicted bioconcentration mechanism class from our combined feature set of molecular features and physicochemical descriptors. **Conclusions:** This study demonstrates that machine learning models, particularly GBDT, can accurately classify fish bioconcentration mechanisms. Physicochemical descriptors offered the highest predictive value, while RDKit-derived features provided complementary performance advantages and ease of automated feature retrieval. Our web-based prediction tool facilitates rapid, accessible prediction of chemical bioconcentration mechanisms, supporting chemical risk assessment and regulatory decision-making in ecotoxicology.

PS 4357 Examining Lead Emissions in the Computers/Electronics Industry and Their Relationship with Socioeconomic and Health Outcomes

S. Dhayade¹, N. Ho², F. Gao², and Y. Shen¹. ¹University of Texas at Arlington, Arlington, TX; and ²University of California Los Angeles, Los Angeles, CA.

Background and Purpose: With the rapid advancement of artificial intelligence (AI) and the growing global demand for electronic products, the computers and electronics industry has expanded substantially in recent years. Lead emissions from this sector may exacerbate existing socioeconomic and health disparities, particularly

in industrialized and urbanized regions. This study aimed to examine temporal and spatial trends in lead emissions from the computers and electronics industry across the United States between 2010 and 2024 and to investigate their relationship with socioeconomic and health indicators. **Methods:** Lead emission data from the U.S. Environmental Protection Agency's Toxics Release Inventory (TRI) were extracted and analyzed for the years 2010-2024 for computer and electronics manufacturing facilities. Spatial maps were generated annually to identify spatial and temporal patterns. Socioeconomic variables such as household income, age, education, race, population size, and insurance coverage were extracted using U.S. Census data at the county level for matched years. We used unsupervised t-SNE and UMAP visualization to explore patterns in socioeconomic outcomes within high and low emission county groups. **Results:** Lead emissions showed substantial temporal and spatial heterogeneity, peaking in 2012 at 9272 pounds, compared with a mean of 4,646 pounds across the remaining years. Emissions were concentrated in urban and suburban regions, with notable hotspots in Allen County (IN), Oakland County (MI), and Madison County (AL). Disproportionately high emissions were observed in Middlesex (MA), Alameda (CA), and Hillsborough (FL). High-emission counties such as Jackson, MO, and Madison, AL had a median age of 37.7 years, a median household income of \$58,654, and a bachelor's degree attainment rate of 15.8%. In contrast, low-emission counties, including Anderson, TN, and El Paso, CO, had a higher median age of 43.4 years, a median household income of \$54,290, and a lower bachelor's degree completion rate of 11.1%. **Conclusions:** This study highlights lead emissions from the electronics manufacturing sector and their uneven distribution across U.S. regions, with notable concentrations in specific urban and industrial regions. Further work will be done using mortality data from CDC WONDER to quantify the spatiotemporal influence of lead emissions on disease-specific death rates. Our findings underscore the need for continued monitoring and regulation of heavy metal emissions to mitigate environmental and health inequities associated with industrial growth.

PS 4358 Leveraging Targeted Gene Sets and Neural Networks for Zebrafish Transcriptome Extrapolation in High-Throughput Toxicogenomics

B. E. Howard¹, D. Mav¹, M. Balik-Meisner¹, D. Phadke¹, E. H. Scholl¹, A. J. Green¹, R. R. Shah¹, L. Truong², L. Lin², and R. L. Tanguay². ¹Sciome LLC, Research Triangle Park, NC; and ²Oregon State University, Corvallis, OR.

Background and Purpose: Zebrafish (*Danio rerio*) are a powerful vertebrate model for developmental toxicology and chemical safety assessment, yet large-scale transcriptomics in zebrafish remains limited by cost and data heterogeneity. Targeted transcriptomics offers a cost-effective alternative, but extrapolation methods tailored to zebrafish have not been systematically developed or evaluated. While the S1500+ platform is widely used for toxicogenomics research with rat, mouse, and human cell lines as model systems, its use in zebrafish has been limited due to lack of bioinformatics approaches for analysis of such data. To that end, we sought to (i) curate a large zebrafish transcriptomic training data resource, and (ii) evaluate multiple extrapolation strategies to reconstruct unmeasured transcriptome-wide expression profiles for data originating from the zebrafish-specific reduced representation gene set ("S1500+"). **Methods:** We assembled 14,924 zebrafish RNA-Seq samples covering 21,930 genes across 1,246 studies. Using the S1500+ gene subset (3,062 genes), we trained and tested three extrapolation approaches: principal components regression (PCR), a locally weighted extension (PCR+), and a neural network mixture-of-experts model (NN-MoE). Model performance was assessed by mean absolute error (MAE), mean squared regression error (MSRE), and weighted variants of these metrics. **Results:** Extrapolation performance using the baseline approach was strongly influenced by tissue and developmental context, with within-tissue models outperforming cross-tissue models. Errors were lowest when training and testing were conducted within the same tissue or between developmentally related tissues. Both PCR+ and NN-MoE improved upon the baseline PCR approach, with NN-MoE reducing average MAE by ~20% and MSRE by ~17%. Importantly, extrapolation remained reliable for the majority of genes, even when restricting predictions to those below a practical MAE threshold. **Conclusions:** We demonstrate that targeted transcriptomics can be effectively extended to zebrafish, enabling robust transcriptome-wide extrapolation at reduced cost. The NN-MoE method provided the most substantial gains, highlighting the value of non-linear and ensemble modeling in heterogeneous datasets. These results establish a scalable framework for zebrafish toxicogenomics and suggest that accuracy will continue to improve with larger, better-annotated datasets, paving the way for broader application in chemical safety assessment.

PS 4359 Learning Aging and Disease related Epigenetic Trajectory for Type 1 Diabetes

F. Gao. UCLA, Los Angeles, CA.

Background and Purpose: Type 1 diabetes (T1D) is a chronic autoimmune disease that leads to insulin deficiency due to the destruction of β cells in the pancreas, and patients often exhibit signs of accelerated aging. Emerging evidence suggests that epigenetic modifications play a critical role in T1D; however, the continuous trajectory of epigenetic changes related to T1D remains largely undiscovered. To

address this, we developed a novel mixed-effects neural ODE model that learns aging and disease related epigenetic trajectory for T1D from longitudinal DNA methylation data. **Methods:** The proposed model incorporates a population level age-modulated fixed effect, a disease group effect, and an individual level random effect to separate universal aging patterns from disease-specific methylation trajectories. The study uses a peripheral whole blood DNA methylation dataset consisting of 87 healthy control and 87 T1D cases with up to five visits each. To reduce dimensionality, we identified 200 age related CpGs, 285 T1D related CpGs, and 250 individual features using random forest models. Model performance was evaluated through 5-fold cross validation and compared to an RNN baseline. **Results:** The mixed-effects neural ODE achieved better performance compared to the baseline models with RMSE = 0.24 and R^2 = 0.97, demonstrating its ability to efficiently learn population dynamics while incorporating group and individual differences. Predicted trajectories for a T1D-associated CpG showed distinct patterns between T1D and control cases. **Conclusions:** The study proposed a novel mixed-effects neural ODE model that learns continuous epigenetic trajectories for longitudinal DNA methylation data while distinguishing disease specific patterns from universal aging related trajectories. While effective, the approach may be limited by the use of a targeted CpG panel and simplified dynamic assumptions. Future work includes comparison with other sequence models and biological interpretation of selected CpG sites.

PS 4360 Advancing Molecular Design: Leveraging Language Models for Modular De Novo Compound Generation via LlamaSMILES

C. Norman, B. E. Howard, A. J. Green, A. Y. Sedykh, A. Borrel, V. K. Gombar, D. Svoboda, and R. R. Shah. Sciome LLC, Research Triangle Park, NC.

Background and Purpose: Molecular design traditionally involves several cycles of generation, evaluation, and optimization. This trial-and-error approach is time-consuming and costly. *De novo* design of chemicals based on *in silico* methods and machine learning faces challenges in flexibility, efficiency, and synthetic feasibility. Here, we present LlamaSMILES, an innovative approach for training large language models (LLMs) to generate Simplified Molecular Input Line Entry System (SMILES) strings fine-tuned to facilitate multi-parameter optimization. **Methods:** The model was pretrained on large public chemical databases, including PubChem, ZINC, and DSSTox, to learn general molecular representations. After pretraining, the base model was fine-tuned on specific tasks or properties of interest, such as non-toxicity, non-carcinogenicity, and other desirable molecular characteristics. The fine-tuned model was then used to generate novel molecules that met predefined criteria. Additionally, user-supplied or proprietary data were incorporated for further fine-tuning to optimize the model for specific applications or domains. This iterative pretraining and fine-tuning process enabled efficient generation of customized molecules with targeted chemical and biological properties. As a proof of concept, we employed our novel approach to design safer and more effective flame retardants (FRs). FRs are high-volume chemicals widely used in industrial and consumer products, but many existing compounds exhibit high toxicity and bioaccumulation, resulting in widespread regulatory bans. To efficiently evaluate LLM model performance, we developed a custom Quantitative Structure-Activity Relationship (QSAR) model trained on 315 publicly available FRs with a range of limiting oxygen indexes (LOI) to predict FR efficacy and retrosynthesis feasibility using ASKCOS. **Results:** The LOI QSAR model achieved an R^2 of 0.618 in a 3x5-fold cross-validation, indicating good predictive performance for limiting oxygen index. We then applied this model to a library of 2,369 newly generated, novel flame-retardant (FR) candidate molecules to predict their flame-retardant properties. The QSAR predictions indicated that over 67% of the generated molecules are likely to be FRs with LOI values > 26, with an additional ~10% predicted to be flame resistant (LOI > 25), confirming a high LOI for the majority of the novel FR molecules. Among these, 176 of the 2,369 novel FRs simultaneously met our high-efficacy criterion (LOI > 27), low-toxicity criteria (non-mutagenic and non-carcinogenic), and exhibited high retrosynthetic accessibility, as assessed by ASKCOS. **Conclusions:** Our *in silico* results show robust model performance, and we are currently evaluating the novel FRs using combustion tests. Our novel LLM-based molecular design approach is easily customizable to work on a desired set of chemical properties, lending itself to a broad range of molecular design tasks.

PS 4362 AI-Assisted Physiologically Based Pharmacokinetic (PBPK) Modeling with Transfer Learning to Predict Biodistribution of Diverse Microplastics

A. Ukbamichael, A. Canchola, H. Nandula, and W. Chou. University of California Riverside, Riverside, CA.

Background and Purpose: Microplastics (MPs) are emerging contaminants of growing concern in environmental and human health, yet their toxicokinetic behavior remains poorly characterized due to limited experimental *in vivo* data. Physiologically based pharmacokinetic (PBPK) models can mechanistically predict tissue distribution and internal exposure; however, existing PBPK models are typically developed for specific MP types and cannot be readily extrapolated to diverse MPs due to their physicochemical heterogeneity. To address this challenge, we developed an integrated computational framework that leverages nanoparticle (NP) pharmacoki-

netic knowledge to predict MPs biodistribution using transfer learning. The goal is to establish a data-driven, AI-assisted PBPK modeling approach capable of inferring critical kinetic parameters for MPs from their physicochemical properties. **Methods:** A comprehensive NP database was established by curating biodistribution data from previous peer-reviewed studies, covering physicochemical properties including particle size, surface charge, surface coating, and core material. A multi-compartment, membrane-limited PBPK model was constructed by incorporating mechanistic features including organ-specific partition coefficients, permeability-surface area products, saturable mononuclear phagocyte system uptake with Hill kinetics, first-order release rates, and biliary and renal elimination pathways. Each NP formulation's time-concentration profile in blood, liver, spleen, kidney, lung, and tumor was fitted to optimize critical NP-specific parameters. Local sensitivity analysis identified the top 10 influential parameters governing biodistribution. Optimized parameter sets, paired with physicochemical descriptors, were used to train a deep neural network (DNN) for predicting PBPK parameters from material properties. The trained NP DNN will then serve as the source model for transfer learning, enabling fine-tuning of the network with limited MP data to predict MP-specific PBPK parameters and simulate biodistribution profiles. **Results:** The calibrated NP PBPK model accurately predicted time-concentration profiles across six organs and multiple formulations, achieving an average $R^2 = 0.65$, representing substantial improvement over common parameter approaches. Organ-specific accuracy was highest in lung ($R^2 = 0.76$, $RMSE = 4.6\%ID/g$) and tumor ($R^2 = 0.61$, $RMSE = 2.13\%ID/g$). Sensitivity analysis revealed that partition coefficients (lung, kidney), permeability-surface area products (spleen, lung, kidney), biliary and urinary elimination constants, and half-saturation constants (liver, kidney, spleen) were consistently among the top-ranked parameters. Parameter variability spanned 0.01-100 $\times$ relative to initial estimates, reflecting formulation-dependent kinetic diversity. The resulting parameter-descriptor matrix forms the foundation for machine learning-based inference of PBPK parameters for new nanomaterials and, through transfer learning, for MPs with sparse experimental data. **Conclusions:** This study establishes a mechanistic-AI hybrid framework that integrates PBPK modeling, machine learning, and transfer learning to bridge the data gap in MPs toxicokinetic. By learning transferable pharmacokinetic representations from NP, the model can infer MP-specific parameters and predict biodistribution even in the absence of *in vivo* calibration. This AI-assisted PBPK approach supports quantitative risk assessment of emerging contaminants, aligns with the 3Rs principles, and represents a scalable paradigm for predicting internal dosimetry across data-poor materials. Once verified, this framework can be extrapolated to model the biodistribution of diverse MPs with varying physicochemical properties.

PS 4363 CONNECT Knowledgebase: Cohort-Oriented Network kKnowledgebase for Enhanced Collaboration

Y. Shen¹, L. T. Mwibashiye¹, D. A. Chodvadiya¹, X. Wang¹, J. A. Stingone², and F. Gao³. ¹University of Texas at Arlington, Arlington, TX; ²Columbia University, New York, NY; and ³University of California, Los Angeles, Los Angeles, CA.

Background and Purpose: Environmental health cohorts have expanded substantially through recent efforts to pool diverse study populations, increasing the need for efficient summarization and integration of findings across studies. Children are uniquely vulnerable to environmental exposures, yet knowledge from existing cohort publications remains difficult to synthesize because investigators must manually review hundreds of papers and environmental-health terminology lacks harmonization. These challenges limit scalable knowledge extraction and slow evidence dissemination for early-life environmental risks. To address this gap, we are developing CONNECT Knowledgebase, a Cohort-Oriented Network kKnowledgebase for Enhanced Collaboration. CONNECT aims to streamline knowledge curation through web scraping and large language model, unify environmental-health language, and provide an interactive platform for summarizing, visualizing, and advancing discovery across population-based cohort studies. **Methods:** We developed a multi-stage AI-assisted knowledge-extraction pipeline using our previous Normative Aging Study Cohort Network (121 publications). First, we implemented automated literature extraction through Selenium-based web scraping of DOI links, applying a $\geq 3,000$ -word threshold to identify full-text articles suitable for analysis. Second, we used the GPT-3.5-turbo API with prompt-engineering strategies to extract exposures and outcomes. Extracted terms were mapped to a three-layer hierarchical taxonomy: Layer 1: broad exposure or outcome class; Layer 2: specific exposure or outcome category; Layer 3: measurement-level detail. Fuzzy string matching ($\geq 80\%$ similarity) was applied to capture formatting variants and validate semantic consistency. Third, we tested prompting approaches (e.g., zero-shot/few-shots prompting, role prompting, chain of thoughts prompting, self-consistency prompting) and tuned ChatGPT hyperparameters to improve extraction accuracy. We are currently manually curating a children's environmental health cohort knowledgebase, and our next step is to validate this AI-assisted pipeline using the newly curated dataset. This pipeline represents the foundational step for scalable development of the CONNECT Knowledgebase. **Results:** Our evaluation across 121 publications showed strong performance of the AI-assisted extraction pipeline for both exposures and outcomes. At the terms level, exposure extraction achieved 98.2% accuracy at Layer 1, 86.6% at Layer 2, and 92.8% at Layer 3. Outcome extraction showed a similar pattern, with 97.4% accuracy at Layer 1, 86.5% at Layer 2, and 80.6% at Layer 3. Paper-level evaluation, which assesses whether the model correctly identified at least one accurate term in each publication, demonstrated consistently high coverage across taxonomy layers. Exposure extraction reached 100% at Layer 1, 99.2% at Layer 2, and 98.3%

at Layer 3. Outcome extraction reached 99.2% at Layer 1, 95.8% at Layer 2, and 87.6% at Layer 3. Overall, the pipeline reliably captured high-level concepts and maintained strong performance at more granular measurement layers, supporting its use for scalable knowledge curation in environmental health cohorts. Additionally, we built an interactive website (cohortnetwork.org) to enable more convenient access to the knowledge graph and to facilitate exploration of cohort-related publications. **Conclusions:** We successfully developed an AI-assisted pipeline as the foundational first step of CONNECT, enabling systematic and scalable extraction of environmental health information from cohort publications. The pipeline demonstrated strong performance across hierarchical taxonomy layers and supports efficient knowledge graph construction. As we continue building our children's environmental health knowledgebase, future work will validate this approach in the newly curated cohort dataset and expand extraction to include additional entities such as study population and statistical link.

PS 4364 Predictive Modeling for Toxicovigilance in HIV Therapy: Leveraging Machine Learning and National Surveillance Data in Resource-Limited Settings

V. Thurairasu. Department of Public Health, Ministry of Health, Malaysia.

Background and Purpose: In resource-limited settings, pharmacovigilance systems often lack the capacity for real-time detection of antiretroviral therapy (ART)-related toxicities such as hepatotoxicity, nephrotoxicity, and treatment-limiting adverse drug reactions. This study developed and validated a machine learning-based predictive model to identify risk patterns for ART-related complications using Malaysia's national HIV surveillance data. **Methods:** Key programmatic indicators were extracted from Malaysia's Global AIDS Monitoring (GAM) reports (2023-2024), including ART coverage, viral suppression rates, CD4 counts at diagnosis, and regional disparities in service delivery. A gradient boosting classifier was trained on demographic and clinical variables—emphasizing late ART initiation ($CD4 < 350$ cells/mm³), treatment continuity, and viral suppression status—to stratify patients into risk categories for long-term ART toxicity. Model performance was evaluated using stratified 10-fold cross-validation and independent test data. Feature importance analysis identified the strongest predictors. **Results:** Late ART initiation, suboptimal viral suppression, and regional health service gaps emerged as key predictors of ART-related toxicities. The model achieved an overall accuracy of 85% and an AUROC of 0.89, indicating excellent discriminatory ability in differentiating high- from low-risk patients. High-risk profiles clustered in Sabah, Kelantan, and underserved urban districts. The top predictors were CD4 count at entry, viral suppression at 12 months, and treatment continuity. These findings demonstrate the potential of real-world HIV surveillance data to inform predictive toxicovigilance and guide targeted follow-up strategies, particularly in resource-constrained settings. **Conclusions:** Integrating machine learning with national HIV surveillance data enables predictive toxicovigilance tools that can proactively identify patients at risk for ART-related toxicities. Such approaches are scalable, data-driven, and well-suited for resource-limited health systems, supporting early intervention, safer ART delivery, and more efficient allocation of clinical follow-up resources.

PS 4366 Safety-ome and Panels for Over 3,000 Phenotypes: a Systematic and Translational Approach Using Human Genetics and Pharmacology

Y. Chen, X. Liu, X. Xu, D. Smith, and F. Fan. Johnson and Johnson, San Diego, CA.

Background and Purpose: Drug candidates are often evaluated for their activities against unexpected targets (off-targets), to either prospectively flag potential hazards or to provide mechanistic insights for a given phenotype. The *in vitro* to *in vivo* translatability is critical when selecting "phenotypically consequential" off-targets. **Methods:** Human genetics and indication-based pharmacology offered unraveled insights. Enhanced natural language processing tools were applied to harness the power of large data obtained from 7 genetics and 2 pharmacology databases. **Results:** Mapping biological roles to organ systems, we curated targets implicated in 22 organ systems of safety concerns, resulting in a Safety-ome composed of over ~11,000 proteins. This is a significant expansion from the previously selected off-target proteome, whose scope include 5 organ systems. Prioritization of the large panel using expression pattern and gene conservation across species resulted in a core panel of 500 targets. Mapping biological roles obtained from the databases to more specific terms than organ systems allowed us to systematically generate over 3,000 phenotype-based panels, which can be used as gene or protein sets for issue resolution. All curated components were systematically and successfully validated using independent data source, i.e., gene expression data from the Comparative Toxicogenomics Database. All panels, together with a user-friendly App, are published to aid effective safety assessment and issue resolution with strong "translational" focus. **Conclusions:** This study integrated evidence from human genetics and pharmacology to identify crucial safety-related proteins (termed Safety-ome), as well as a small-footprint gene panel to support screening and user-friendly app. Utilizing standardized vocabulary for mapping phenotypes enables the systematic collection of gene or protein sets. These phenotype-centric panels can be used to guide safety issue resolution and provide mechanistic insights.

T. Wang^{1,2}, C. Potts³, X. Jia^{1,2}, B. Ji^{1,2}, G. R. Warner³, and H. Zhu^{1,2}. ¹Center for Biomedical Informatics and Genomics, School of Medicine, Tulane University, New Orleans, LA; ²Department of Chemistry and Biochemistry, Rowan University, Glassboro, NJ; and ³Department of Chemistry and Environmental Science, New Jersey Institute of Technology, Newark, NJ.

Background and Purpose: Phthalates are high-production-volume chemicals widely used as plasticizers in consumer products. Phthalate exposure can disrupt ovarian function and lead to reproductive toxicity. There is an urgent need to develop new approach methodologies (NAMs) to evaluate phthalate toxicity and elucidate associated underlying toxicity mechanisms. Here, we integrated machine learning (ML) with *in vitro* screening assays to evaluate phthalate-induced reproductive toxicity by identifying associated molecular targets and pathways. **Methods:** We retrieved all available bioassay data from PubChem for a curated phthalate dataset comprising phthalates (ortho-phthalates) and their analogs (isophthalates and terephthalates), and prioritized assays suitable for toxicity evaluations and computational modeling. Quantitative structure-activity relationship (QSAR) models were developed using five ML algorithms and four types of chemical descriptors for these assays. The resulting models were applied to impute activities within the target compounds without experimental data for the selected assays, thereby constructing a bioprofile that enabled the construction of pathway models for evaluating reproductive toxicities. To ensure reliability, an in-house quantitative PCR (qPCR) assay was used to assess the phthalate-induced molecular initiating events (MIEs) and key events (KEs) by measuring expression changes in candidate genes in mouse ovarian follicles exposed to phthalates or their analogs. **Results:** QSAR models across all 56 selected assays showed good predictive performance, with an average correct classification rate (CCR) of 0.74. Fourteen top-hit assays for phthalates and analogs were prioritized, encompassing nuclear receptors, metabolic enzymes, and cellular toxicity markers, which are potential targets involved in regulating steroidogenesis, cell cycle progression, and apoptosis in ovarian follicles. Phthalates and analogs exhibited similar bioprofiles across these top-hit assays, indicating shared modes of action of reproductive toxicity. qPCR assays validated target gene expression changes consistent with predictions, enabling construction of an adverse outcome pathway (AOP) network. In this network, phthalates and analogs activate nuclear receptors such as PPAR γ (MIEs), which alters downstream gene expression (KE1), disrupts steroidogenesis and promotes granulosa cell apoptosis (KE2), and leads to estradiol reduction and hormone imbalance (KE3). These perturbations ultimately result in ovarian dysfunction and impaired fertility as adverse outcomes (AOs). The AOP network provides a mechanistic framework for evaluating reproductive toxicity of phthalate-related chemicals and other toxicants acting through the same MIEs. **Conclusions:** This study establishes a hybrid NAM that integrates ML modeling with *in vitro* assays to evaluate phthalate-induced reproductive toxicity. We identified critical molecular targets and developed an AOP network that captures the cascade from MIEs to AOs. This novel framework can be broadly applied for chemical prioritization and regulatory decision-making, ultimately protecting female reproductive health.

PS 4368 *In silico* modeling of on-target and off-target safety pharmacology of oligonucleotides

K. Hu, J. Zhang, X. Du, and F. He. Pharmaron Beijing Co., Ltd., Beijing, China. Sponsor: S. Luo

Background and Purpose: Therapeutic oligonucleotides are rapidly expanding modalities for metabolic, cardiovascular and rare diseases, yet their clinical success is often limited by hybridization-dependent and hybridization-independent off-target effects, immune-stimulation, and on-target overdose in tissues with high exposure. Early de-risking therefore demands a mechanism-based safety assessment integrated into lead optimization. We constructed a comprehensive *in-silico* toxicology platform that combines sequence bioinformatics, machine-learning models and targeted wet-lab assays to predict and rank safety liabilities of double-stranded oligos. The workflow supports rational sequence selection, reduces animal usage and aligns with the FDA predictive toxicology roadmap. **Methods:** Four sequential modules were developed. (1) Lead sequence design: A base-walk algorithm sliding 1 nt across the start region of the gene of interest was used to generate all possible 19-23-mer siRNA duplexes; empirical rules of guide strand selection and thermodynamic asymmetry were applied for candidate filtering, and sequences containing TLR-agonist motifs were removed to avoid immune response. (2) Off-target prediction: The full sequence of the guide strand was aligned on full transcriptome using BLAST, and the seed region (positions 2-8) was specifically searched against human 3' UTRs; predicted off-target hits were filtered by degree of sequence complementarity and weighted by tissue-specific expression levels. (3) Secondary structure prediction: RNAfold-derived free energy for candidate siRNAs, siRNA-mRNA duplex, and the local secondary structure of the target mRNA at each potential binding site were compared and integrated into a machine learning model to rank candidates. (4) Experimental validation: On-target silencing efficiency was evaluated by qPCR, and transcriptome-wide off-target effects were assessed using RNA-seq. **Results:** The platform was applied to an INHBE-targeting, GalNAc-conjugated siRNA program for metabolic disease. Starting from 23 possible 19-mer duplexes, we shortlisted five leads with predicted Abs. IC50 < 0.1 nM. Genome-wide mapping identified X high-

risk off-target transcripts in liver; RNA-seq confirmed no significant suppression of these genes in hepatocytes. One sequence containing a TLR-stimulating motif was removed. **Conclusions:** Integrating sequence-based bioinformatics and ML-driven activity ranking provides a transferable safety assessment for GalNAc-siRNA therapeutics. The case study delivered a development candidate with robust hepatic potency and minimal immunostimulatory potential.

PS 4369 Predicting Target Tissues of Chemical Exposure Using Coupled Tensor-Matrix Completion

K. Wang. Indiana University, Bloomington, IN.

Background and Purpose: Accurately predicting which tissues are affected by environmental chemical exposures remains challenging due to complex exposure patterns and limited toxicity data. Traditional *in vitro* and *in vivo* approaches are still essential for testing chemical toxicity. However, these methods require substantial time and resources. The existing toxicology-related biological data now make it feasible to build computational approaches that can help prioritize toxicity testing. Given the high sparsity of toxicology data, matrix completion offers a promising approach for uncovering meaningful patterns of chemical toxicity. The purpose of this study is to apply a novel algorithm, Coupled Tensor-Matrix Completion (CTMC), to predict tissue-specific toxicity by integrating tissue-specific gene expression profiles. **Methods:** Human-related chemical-gene interaction data were extracted from the Comparative Toxicogenomics Database (CTD). Chemicals annotated as "approved" drugs in DrugBank were removed. Chemical-gene pair counts were normalized and rescaled to reduce the influence of extreme values while preserving variation among low-abundance signals. The gene-gene similarity tensor included three gene similarity matrices, and one tissue-specific gene expression correlation matrix. The three gene similarity matrices were calculated with R package GOSemSim based on Gene Ontology (GO) annotations. Tissue-specific genes were identified from GTEx transcriptomic profiles, with highly expressed genes selected using an automated elbow-point detection algorithm that determines the inflection point in ranked expression values. The chemical similarity tensor incorporated two types of chemical similarities with Morgan and topological torsion fingerprints using the RDKit package. Three tissue-specific benchmark chemical gene interaction datasets were constructed for the kidney, liver, and lung, each containing the highly expressed genes of the corresponding tissue along with randomly selected genes. To evaluate algorithm performance, overall interaction values for two randomly selected chemicals, one well-studied and one less characterized in the CTD, were removed from the matrix and subsequently predicted. For each tissue, the above procedure was repeated ten times, each time with a different pair of randomly selected chemicals, to generate ten distinct datasets. Thus, each tissue was tested with 10 well-studied and 10 less characterized chemicals. The CTMC algorithm was implemented in C++ with Armadillo and OpenBLAS, enabling efficient processing of matrices containing 1,000 chemicals and 1,000 genes. **Results:** To evaluate model performance, the number of original interactions that could be recovered was first assessed. In the kidney dataset, the model recovered 97% (66/68) of tissue-specific and 96% (43/45) of non-tissue-specific interactions for 10 well-studied chemicals, and 94% (17/18) and 98% (42/43), respectively, for 10 less-characterized chemicals. In the liver dataset, recovery rates were 86% (304/354) and 80% (119/149) for well-studied chemicals, and 76% (34/45) and 100% (13/13) for less-characterized chemicals. In the lung dataset, all interactions for less-characterized chemicals were correctly predicted, while 88% (71/81) of tissue-specific and 73% (16/22) of non-tissue-specific interactions were recovered for well-studied chemicals. To characterize tissue-specific toxicity, overall chemical-gene interaction profiles were evaluated for each chemical by comparing interaction values between tissue-specific and non-tissue-specific genes. A Wilcoxon rank-sum test was conducted to compare predicted interaction scores between tissue-specific and non-tissue-specific targets. Significant differences (FDR < 0.05) in interactions with tissue-specific genes were observed for 17 of 20 chemicals in kidney and lung, and for 14 chemicals in liver, with chemicals showing higher interaction values demonstrating stronger tissue-specific effects. **Conclusions:** The results from the tissue-specific analysis not only demonstrate the CTMC method's ability to predict single chemical-gene interactions but also its strong potential for predicting tissue-specific toxicity. Benchmark analyses indicate that CTMC effectively captures chemical-gene interaction patterns across different tissues, suggesting its capability to identify tissue-specific toxic effects.

PS 4370 Mechanistic insights in toxicological risk assessment: integration of transcriptomics into the Adverse Outcome Pathways liver network

M. van Schaick¹, M. Martens², S. Adil², E. Willighagen², B. van de Water¹, and G. Callegaro¹. ¹Division of Cell Systems and Drug Safety, Leiden Academic Centre for Drug Research, Leiden University, Leiden, Netherlands; and ²Department of Translational Genomics Maastricht University, Maastricht, Netherlands.

Background and Purpose: Risk assessment of pharmaceuticals, additives and other chemicals are crucial in protecting the public from potentially hazardous substances. Though advancements have been made to elucidate toxicity of compounds in animal models and *in vitro* assays, these models often lack insights into the mechanism

that leads to toxicity and lack high-throughput capabilities, which is critical given the magnitude of compounds to be assessed. The Adverse Outcome Pathway (AOP) frames biological processes from Molecular Initiating Events through Key Events (KE) to the Adverse Outcome (AO), describing how a molecular event can lead to an Adverse Outcome at the Organ, Organism or Population level. To quantify AOPs for risk assessment, integration of omics data, in particular co-expression gene sets, would enable high-throughput quantification of KEs and reduce the need for traditional, animal-based testing of untested compounds. The aim of this research is to integrate gene co-expression network modules (WGCNA) from toxicogenomics (TXG) data in the AOP framework for liver adverse events, to quantify the potential of compounds exposure to perturb KEs. Biological relevance of the integrated modules in the context of the KEs will also be assessed to determine the performance of the integration methods. **Methods:** We analyzed TXG data from large perturbational studies of primary human hepatocytes (PHH) and rat *in vivo* liver data (both from the TG-GATES datasets), and HepG2 (Wijaya et al., 2023) and constructed specific WGCNA networks for each dataset (Callegaro et al., 2019; Callegaro et al., 2023). Then, we constructed a liver AOP network by collecting AOP data from the AOP-Wiki RDF (Martens et al., 2023) and integrated co-expression modules based on gene content of both sources as well as contextual matching of the biology by performing NLP. Finally, a case study assessed the performance and applicability of the matching within the context of liver steatosis (LS). **Results:** Transcriptomic modules into key events (KEs) are matched thanks to the combination of the several methods implied, highlighting that transcriptomic integration is achievable only by looking at gene, ontology and description content. Around 1/3 of all KEs are assigned to one or more modules, while nearly all modules from the three test systems were integrated in the AOP data, highlighting the need for better curation of several KEs. Several KEs of the liver steatosis networks are matched to multiple modules in more than one liver test system, being PHH and rat *in vivo* modules more represented than HepG2 modules. Interestingly, modules from different test systems matched to the same KE shows a large portion of non-overlapping genes, indicating that omics integration should take into account test systems specifications. **Conclusions:** By applying several orthogonal methods of integration we have delivered transcriptomic integration in the liver AOP network employing gene co-expression network analysis, gene content, ontology content and NLP-based matching. Importantly, we highlight how each species and cell type (and condition of cell growth) influences the integration, delivering different genes sets associated to KE depending on the test system. This is of crucial importance when considering the application of omics integration to AOP for quantification of KE for, for example, read-across and transcriptomic Point of Departure determination. This work is currently supported by the EFSA funded project TXG-MAP and has received funding from Partnership for the Assessment of Risks from Chemicals (PARC) (grant agreement No 101057014).

PS 4371 Tricyclic pyrone CP2 restores lipid and energy dyshomeostasis in the APP/PS1 mouse model of Alzheimer's disease

E. Gabal^{1,2}, T. Nguyen³, C. Funk⁴, P. Balon^{1,2}, and E. Trushina^{3,5}. ¹School of Health Sciences, Purdue University, West Lafayette, IN; ²Purdue Institute for Integrative Neuroscience, Purdue University, West Lafayette, IN; ³Department of Neurology, Mayo Clinic, Rochester, MN; ⁴Institute for Systems Biology, Seattle, WA; and ⁵Department of Molecular Pharmacology and Experimental Therapeutics, Mayo Clinic, Rochester, MN.

Background and Purpose: Alzheimer's disease (AD) is a progressive neurodegenerative disorder and the leading cause of dementia worldwide. Increasing evidence supports that AD is also a metabolic disorder, where mitochondrial dysfunction is associated with cognitive decline and disease progression. Mitochondria, therefore, represent both a source and a target of neurotoxic stress in AD pathogenesis. Recent findings demonstrated that mild inhibition of mitochondrial complex I with tricyclic pyrone compound CP2 elicits a broad neuroprotective response in early-onset AD models. The present study investigated the potential effects of CP2 to reverse metabolic dysregulation associated with late-onset AD using the APP/PS1 mouse model. **Methods:** 19-month-old female APP/PS1 transgenic mice and non-transgenic littermates were treated with CP2 or vehicle for six weeks. Brain tissues from the cortico-hippocampal region were analyzed using bulk RNA sequencing and targeted metabolomics. Transcriptomic profiling, along with systems biology approaches, was used for assessing molecular and metabolic alterations associated with CP2 treatment. We generated the first manually curated genome-scale metabolic model of the mouse brain, namely iMiceBrain, for simulating metabolic flux changes to predict metabolic shifts in control and CP2-treated conditions. This systems toxicology approach enabled assessment of CP2's effect on pathways related to energy production, lipid metabolism and redox balance. **Results:** Transcriptomic analysis of APP/PS1 mouse brains showed altered expression of *Cdkn1*, *Foxm1*, *Pik1*, and *Akt2*, indicating disrupted cellular senescence, FOXO signaling, and mitotic control, characteristic of late-onset AD. Differential expression of *Hmgcs1*, *Acaca*, *Lss*, *Sqle*, and *Slc27a1* was suggestive of alterations in cholesterol and lipid metabolism, as well as PPAR signaling. *Ldlr*, *Trem2*, and *Gfap* upregulation indicated the activation of glial cells and a link to neuroinflammation. CP2 treatment in APP/PS1 mice restored the expression levels of *Neurog1* and *Nfe2l*, suggestive of neurogenesis. Downregulation of *Lss*, *Apoa1*, and *Lcat* genes in CP2-treated APP/PS1 mice suggests a role in cholesterol homeostasis and clearance. Integrating transcriptomic data with the iMiceBrain model identified lipid and energy metabolism-related pathways, including cholesterol, bile acid, glycerophospholipids, the pentose phosphate pathway (PPP),

and β -oxidation, associated with CP2 treatment in APP/PS1 mice. **Conclusions:** Our systematic transcriptomic profiling and integrated metabolic modeling provides mechanisms of how CP2 restores mitochondrial functions and metabolic shifts in late-onset AD mouse model.

PS 4372 Performance of Different Virtual Control Group Generation Approaches

N. Becker¹, M. Dammann¹, K. Becker¹, F. M. Kluxen², J. Cairns¹, D. Funk-Weyer¹, C. Gomes¹, R. Buesen¹, and M. Dilger¹. ¹BASF SE, Ludwigshafen, Germany; and ²BASF SE, Limburgerhof, Germany. Sponsor: R. Landsiedel

Background and Purpose: Virtual Control Groups (VCGs) could be a potential 3R approach in toxicological study design as an ethically favorable alternative to traditional Concurrent Control Groups (CCGs). By stringent filtering of control animal data from previously conducted studies (Historical Control Data, HCD), VCGs can be generated and used instead of CCGs to determine treatment relation, if statistical integrity or biological relevance assessments are not compromised. This study investigates the development, validation, and application of VCGs in 28-day oral toxicity studies in rats. **Methods:** Using a HCD database of 185 studies performed at BASF between 2009 and 2023, four distinct approaches for generating VCGs were explored: sampling individual animals, sampling entire control groups from complete studies, domain-wise sampling based on filtered subsets of the HCD, and simulation-based modeling. The simulation approach probabilistically generates virtual control animals by leveraging endpoint-specific distribution patterns, offering a data-driven alternative to traditional control group design. Each method was applied to twelve 28-day legacy studies, and the resulting statistical results for the various endpoints in each study were compared to those derived from conventional CCGs. VCGs were generated using a multi-iteration approach to enhance statistical robustness. **Results:** Among the evaluated methods, simulation-based VCGs demonstrated superior performance in terms of flexibility, predictive accuracy, and reproducibility. However, the analysis also highlighted challenges in modeling endpoints with high intrinsic intra- and interstudy variability, like elements of the Functional Observational Battery (FOB). A reanalysis of three studies, each involving blinded analysis by subject matter experts for the investigated endpoints, found that multi-iteration VCGs generally accurately captured population characteristics. The VCG generation procedure provided a stable baseline across most endpoints, potentially making the VCGs more robust than traditional CCGs. **Conclusions:** In conclusion, the results support further investigation of the VCG concept, identification of mitigation strategies for endpoints where modeling is still challenging, and exploration of the path toward regulatory acceptance.

PS 4373 Machine Learning-Enabled Extraction and Analysis of Thyroid Endpoints from Regulatory Documents

M. Nagyal¹, T. Luechtefeld¹, F. Bailey², C. Koenig³, B. Riffle⁴, E. Freeman⁵, and A. Karmaus⁶. ¹Insilica LLC, Rockville, MD; ²NuFarm, Toronto, ON, Canada; ³Corteva, Indianapolis, IN; ⁴BASF Agricultural Solutions US LLC, RTP, NC; ⁵Exponent, Washington DC, DC; and ⁶Syngenta Crop Protection LLC, Greensboro, NC.

Background and Purpose: Thyroid disruption testing presents interpretive challenges due to the hormone's broad physiological influence on multiple organ systems. Regulatory studies are often complicated in identifying and contextualizing thyroid-related findings due to heterogeneous structure and various reporting formats of these documents. To systematically evaluate how thyroid endpoints inform regulatory decision-making, publicly available regulatory studies from the U.S. Environmental Protection Agency (EPA) and other agencies were retrospectively analyzed using a document-level machine learning pipeline. By replacing extensive manual review with reproducible automation, this approach enhances efficiency in evidence synthesis. Thyroid-relevant endpoints (e.g., T3, T4, TSH levels) were extracted and standardized into a tabularized dataset suitable for cross-study comparison. This enabled quantitative assessment of which endpoints are most frequently measured, most often statistically significant, and most influential in determining adversity and risk conclusions. **Methods:** We employed an automated pipeline that integrates document retrieval, relevance screening, structured extraction, and post-processing to build a thyroid-focused dataset from regulatory documents. Initial retrieval drew on the Google Search API alongside the EPA ChemView database, constrained by curated queries for thyroid-related language (e.g., "thyroid", "TSH", etc.). Retrieved documents were evaluated and screened for relevance programmatically. The large language model (LLM) driven extraction workflow mapped documents to structured outputs covering study metadata, chemical identifiers, and thyroid endpoints (e.g., serum hormone measures). The consolidated results were harmonized and quality-checked, producing the final searchable compendium of thyroid biomarkers for cross-study quantitative comparison. **Results:** The automated retrieval pipeline identified 6,214 unique regulatory studies of which 1,851 documents were down-selected after relevance filtering. The LLM-powered structured data extraction parsed thyroid-specific quantitative endpoints and compiled alongside study level metadata and statistical outcomes. The resulting dataset enabled cross-study comparison of thyroid endpoint frequency, directionality, and regulatory interpretation. Preliminary analyses reveal variation in endpoint frequency and interpretation across

study designs, underscoring the value of harmonized data structures for cross-study comparison. Integrating regulatory context directly within the dataset provides a unique opportunity to evaluate how thyroid data contributes to risk assessment decisions. Ongoing efforts aim to quantify endpoint-specific variability and its impact on adversity determinations. **Conclusions:** This work demonstrates the feasibility and value of using machine learning based extraction to systematically compile and analyze thyroid-related endpoints from regulatory documents. The resulting work not only streamlines evidence synthesis but also enables quantitative evaluation of endpoint variability and regulatory interpretation. By integrating structured *in vivo* toxicological data with risk assessment context, this machine learning approach establishes a framework for retrospective analyses that enhances efficiency of endocrine-related risk assessments, while aligning traditional toxicology with next-generation approaches.

PS 4374 Understanding the mechanisms behind liver vs. kidney susceptibility to fenofibrate overdose

V. R. Pannala^{1,2}, M. R. Balik-Meisner³, D. Mav³, D. P. Phadke³, E. H. Scholl³, R. R. Shah³, W. Casey⁴, S. S. Auerbach⁴, and A. Wallqvist². ¹The Henry M. Jackson Foundation for the Advancement of Military Medicine, Inc., Bethesda, MD; ²Department of Defense Biotechnology High Performance Computing Software Applications Institute, Defense Health Agency Research & Development, Medical Research and Development Command, Fort Detrick, MD; ³Sciome LLC, Research Triangle Park, NC; and ⁴Division of Translational Toxicology, National Institute of Environmental Health Sciences, Research Triangle Park, NC.

Background and Purpose: Fenofibrate, a peroxisome proliferator-activated receptor α (PPAR α) agonist, is widely prescribed to treat hyperlipidemia and has therapeutic potential in liver and kidney diseases. However, fenofibrate is also associated with adverse effects, including elevated creatinine and liver and kidney toxicity, although the underlying mechanisms remain unclear. In addition, how fenofibrate regulates lipid metabolism differently in the liver and kidney is not well understood. Therefore, in this study, we investigated the dose-dependent effects of fenofibrate on liver and kidney metabolism in rats, with a focus on PPAR α activation and potential mechanisms contributing to organ-specific toxicity. **Methods:** We used high-throughput transcriptomic data from 5-day rat *in vivo* studies, where rats received either vehicle control or fenofibrate at eight different concentration levels ($n = 4$ per group) daily for five consecutive days, after which liver and kidney tissue samples were collected on the sixth day for a targeted RNA sequencing analysis. We then performed differential gene expression, injury signature, pathway enrichment, and detailed individual gene comparison analyses to investigate how liver and kidney metabolism were differentially altered between the two organs. **Results:** Our results show that fenofibrate exposure significantly increased liver but not kidney weights and caused larger perturbations in the liver compared to the kidney transcriptome, with many of the changes related to PPAR α regulation. Interestingly, our study revealed that the PPAR α and RXR α genes are differentially regulated between the liver and kidney. In addition, we identified several differences between the liver and kidney in cellular and mitochondrial fatty acid transport, lipoprotein metabolism, fatty acid oxidation, branched-chain amino acid degradation, and glucose metabolism pathways. Furthermore, using our individual gene level comparison and universal toxicity gene signatures, we identified transcriptomic inflection points at which the changes in the PPAR α -mediated regulation of lipid metabolism switched from beneficial to deleterious as the fenofibrate concentration increased leading to liver injury. Our analysis revealed that fenofibrate overdose overwhelmed several mitochondrial-driven processes related to lipid metabolism in the liver, leading to redox imbalance and oxidative stress, which ultimately resulted in the development of liver injury. **Conclusions:** Using fenofibrate dose-response studies, our study identified potential differences in the PPAR α -mediated activation of lipid metabolism between the liver and kidney and elucidated potential mechanisms through which fenofibrate overdose may cause liver injury. Therefore, our study provides an improved understanding of PPAR α activation by its agonists and may guide the development of future therapeutics targeting the modulation of lipid metabolism in the liver and kidney.

PS 4375 Identifying mitochondrial bioenergetic changes and NAD⁺ modulation associated with cognitive resilience in Alzheimer's Disease

P. Baloni¹, P. Mandal¹, E. Trushina², M. Arnold³, and R. Kaddurah-Daouk⁴. ¹Purdue University, West Lafayette, IN; ²Mayo Clinic, Rochester, MN; ³Institute of Computational Biology, Neuherberg, Germany; and ⁴Duke University, Durham, NC.

Background and Purpose: Alzheimer's disease (AD) is marked by progressive cognitive decline and mitochondrial dysfunction. Asymptomatic Alzheimer's disease (AsymAD) individuals retain normal cognitive functions despite comparable amyloid and tau pathology. Comparison of bioenergetic changes associated with mitochondrial dysfunction has not been performed for AD and AsymAD. Molecular mechanisms underlying mitochondrial dysfunction in AD and AsymAD are important for identifying therapeutic strategies that can restore the bioenergetics in disease state. **Methods:** We performed an integrated multiomics analysis of postmortem brain tissue from ROSMAP, Mayo Clinic and Mount Sinai Brain Bank cohorts to investi-

gate mitochondrial dysfunction in AD and AsymAD. We classified the samples into three groups: AD ($n = 182$), Asymptomatic-AD ($n = 200$), and controls ($n=106$), based on Braak stage, CERAD score and Mini-mental state examination (MMSE) scores. Proteomics and single nucleus RNA sequencing data from different brain regions such as prefrontal, temporal, and hippocampus were analyzed across neuronal and glial subtypes to assess mitochondrial pathways in the study groups. We developed a machine learning model to identify important bioenergetic features that distinguish AsymAD from AD. Differentially expressed proteins were queried against DrugBank database to identify candidate small molecules that could potentially restore mitochondrial bioenergetics. **Results:** We used an integrated approach combining proteomics, machine learning, and single-nucleus RNA sequencing to identify mitochondrial genes/proteins that were differentially expressed between AD and AsymAD across cell types, brain regions, and cohorts (ROSMAP, Banner, and Mount Sinai). Proteomic analysis showed AsymAD exhibited enhanced mitochondrial metabolism including branched chain amino acid catabolism (ECHS1, BCKDHB), TCA cycle (IDH2, SUCLA2), fatty acid oxidation (CPT2, ACADSB). Upregulation of mitochondrial translation (MRPL37, TOMM40), structural proteins formation (PDHB, FIS1), and calcium ion transport (MCU, VDAC2) supporting improved energy regulation in AsymAD. DrugBank analysis identified 16 candidate drugs or small molecules, including NADH, Carvedilol, Radicolol, and L-glutamic acid, interacting with resilience-associated proteins. Most druggable proteins from our analysis showed interactions with NADH, and although NADH does not cross the blood brain barrier, our findings suggest that enhancing NAD⁺ metabolism in brain could restore redox balance and preserve mitochondrial function in AD. **Conclusions:** This systems toxicology analysis shows that cognitive resilience in AsymAD is associated with maintenance of mitochondrial bioenergetics and antioxidant defenses that prevents neurotoxic stress. The identification of proteins and NAD⁺-linked metabolic regulators provides the mechanistic basis for developing interventions focused on preventing or reversing energy failures in AD. These findings highlight the power of multiomics and machine learning approaches in identify molecular signatures of neuroprotection relevant to both chemical- and disease-induced mitochondrial toxicity.

PS 4376 Development of an Interpretable Structure-Activity Relationship Model for Predicting Hepatotoxicity in Repeated-Dose Toxicity Studies

K. Jojima^{1,2}, T. Yamada¹, S. Matsumura¹, M. Fujii¹, and K. Masumura¹. ¹National Institute of Health Sciences, Kawasaki, Kanagawa, Japan; and ²Graduate School of Pharmaceutical Sciences, Osaka University, Suita, Osaka, Japan.

Background and Purpose: *In silico* toxicity prediction based on Structure-Activity Relationship (SAR) is one of the promising approaches for efficient chemical safety assessment. However, utilization of SAR models for complex toxicity endpoints such as organ and systemic toxicity observed in repeated exposure to chemicals is limited. For regulatory acceptance and use of SAR models and their predictions, interpretability as well as predictive performance is important. In this study, we developed machine learning-based SAR models for hepatotoxicity observed in repeated dose toxicity (RDT) studies in rats and selected the best model through performance evaluation. Subsequently, the atom-level visualization method based on molecular fingerprints was applied to the best model to enhance prediction interpretability. **Methods:** Data for oral RDT studies with administration periods of 28-100 days were collected from databases. Chemicals showing histopathological changes in the liver at doses $\leq 1,000$ mg/kg bw/day were classified as positive for hepatotoxicity, while chemicals showing no changes at doses $\leq 1,000$ mg/kg bw/day were classified as negative. A total of 1,269 chemicals (631 positives and 638 negatives) were collected. Then, 100 positive and 100 negative chemicals were randomly selected to form the test dataset, and the remaining 1,069 chemicals were used for model training. Four machine learning algorithms, Stochastic Gradient Descent (SGD), Random Forest (RF), Support Vector Machine (SVM), and Light Gradient Boosting Machine (LGBM) were employed to develop each predictive model. Morgan fingerprints were used as explanatory variables. Structural and physicochemical descriptors were used to define the applicability domain. For performance evaluation, leave-one-out cross-validation (LOOCV) on the training dataset and external validation (EV) on the test dataset were performed. The atom-level visualization method based on molecular fingerprints was applied to the constructed model. Analysis of contributing substructure for each prediction was conducted to confirm the enhancement of interpretability by applying the method to the developed model. **Results:** All models achieved an area under the receiver operating characteristic curve (AUROC) greater than 0.75 in both LOOCV and EV. Among them, the RF model exhibited the highest AUROC score of 0.800 in LOOCV and 0.829 in EV. Regarding other metrics, the highest sensitivity of 0.750 was exhibited by the RF model in LOOCV and 0.725 by the SGD model in EV. On the other hand, the highest specificity of 0.727 in LOOCV and 0.795 in EV was obtained by the LGBM model. Based on its balanced performance, the RF model was selected as the best model. Functional group-based analysis of the RF model revealed that the functional groups which contributed most to positive predictions were halogens, followed by nitro groups, nitriles, and azole groups. Except for nitriles, these functional groups were known as structural alerts associated with hepatotoxicity. In contrast, hydrophilic moieties such as sulfo groups, carboxylic groups, and serine side chains contributed to negative predictions. These hydrophilic groups are considered to attenuate chemical toxicity by decreasing membrane permeability and increasing excretion from the body. **Conclusions:** Predictive models for hepatotoxicity observed in rat RDT studies were developed. The best model achieved

AUROC values above 0.8 in both LOOCV and EV. The application of the atom-level visualization method enhanced model interpretability by clarifying the rationale for positive and negative predictions. This study contributes to regulatory acceptance and use of machine learning-based toxicity predictive models for complex toxicological endpoints.

PS 4377 Bridging *In Vitro* Bioactivity to Clinical Adverse Drug Events Through a Multimodal Knowledge Graph Modeling Framework

N. J. Daoud^{1,2}, J. Ouyang³, L. Li³, and H. Zhu^{1,2}. ¹Tulane University School of Medicine, New Orleans, LA; ²Rowan University, Glassboro, NJ; and ³The Ohio State University, Columbus, OH.

Background and Purpose: The use of *in vitro* assay outcomes to predict clinically relevant adverse drug events (ADEs) continues to be a critical challenge in predictive toxicology. Many ADEs result from off-target binding that may not be adequately captured in experimental toxicity testing. To answer this challenge, we developed a data-driven modeling framework that correlates *in vitro* bioprofiles to clinical outcomes from the FDA Adverse Effect Reporting System (FAERS), using a multimodal knowledge graph and deep learning approach. **Methods:** Publicly available databases were integrated to construct a knowledge graph that links drugs to targets to ADEs/diseases. Beginning with over 2,000 drugs with clinical ADEs reported by FAERS, *in vitro* target activity for these drugs was retrieved from PubChem. The resulting 10,000+ drug-target activities were searched in the Comparative Toxicogenomics Database (CTD), where curated drug-disease and target-disease links from the scientific literature were retrieved. ADEs/diseases were then hierarchically mapped to the Medical Dictionary for Regulatory Activities (MedDRA). A multimodal neural network was then trained based on this integrated dataset, combining chemical structure, *in vitro* bioassay activities, and clinical outcomes to identify potential relationships between drug-target activity and observed ADEs. **Results:** The knowledge graph revealed significant target-disease correlations, including several off-target associations that aligned with known cardiac, metabolic, and hepatobiliary ADEs. The integrative multimodal models demonstrated good predictive performance, achieving AUROC scores above 0.7 across multiple ADEs. Network-based phenotypes obtained from CTD and Human Phenotype Ontology highlighted mechanistic connections linking drug-target activity to clinical endpoints, illustrating potential adverse outcome pathways. **Conclusions:** This study presents an interpretable mechanistic approach linking multimodal *in vitro* assay data to adverse clinical outcomes. By leveraging multimodal integration and knowledge graph representations, our framework enables the prediction of specific ADEs by shared target biology and chemical structures, offering a new framework to mechanistically grounded *in silico* toxicity assessments that can aid in early identification of off-target outcomes in drug discovery.

PS 4378 Integrating Chemical Perturbation Signatures for *In Silico* Toxicity Prediction

S. Mikami^{1,2}, J. Takeshita², A. Ohoka³, K. Ambe⁴, K. Yoshinari³, and M. Iida¹. ¹Kyushu Institute of Technology, Iizuka, Japan; ²National Institute of Advanced Industrial Science and Technology (AIST), Tsukuba, Japan; ³University of Shizuoka, Shizuoka, Japan; and ⁴Nagoya City University, Nagoya, Japan.

Background and Purpose: The gene expression profiles observed when biological organisms or cells are exposed to chemical substances—known as chemical perturbation signatures—provide crucial information for predicting pharmacological effects and toxicities. However, unlike drugs, for which large-scale chemical perturbation signature datasets have been established, such datasets for pesticides and general industrial chemicals remain largely undeveloped. As a result, the development of *in silico* prediction models for these chemicals has been significantly delayed due to the lack of appropriate training data. To address this issue, we aim to establish a comprehensive information platform and develop prediction models to understand the relationships between chemical substances and biological responses by collecting gene expression data related to chemical exposure from the Gene Expression Omnibus (GEO) and constructing a chemical perturbation signature database. **Methods:** Gene expression data were collected for three species—rat, mouse, and human—targeting 2,040 general industrial chemicals whose toxicity data are registered in the AI-SHIPS Chemical Toxicity Database (AI-SHIPS ToxDB) and 380 pesticides registered in our in-house pesticide database. An automated search program extracted relevant datasets (GSEs) from GEO by identifying experimental metadata (e.g., titles and abstracts) that included the target chemicals. For the same chemical, data obtained under different conditions were treated as separate samples to comprehensively capture gene expression alterations across diverse exposure scenarios. **Results:** In the automated search phase, datasets were obtained for 11 general industrial chemicals and 15 pesticides in male rats, 164 and 152 in mice, and 37 and 162 in humans, respectively. After curation, the coverage of gene expression data relative to the AI-SHIPS toxicity dataset and in our pesticide database was approximately 3% for general industrial chemicals and 2% for pesticides in rats and mice. The collected gene expression data were statistically analyzed to identify sets of genes that exhibited expression changes in response to chemical exposure. Through this analysis, key gene sets involved in the mechanisms of chemical toxicity (chemical-associated genes) were identified. For these chemical-associated genes,

proximity evaluations were conducted with outcome-related genes on a protein-protein interaction (PPI) network. **Conclusions:** These signatures will be utilized as training data for inferring the mechanisms of action of chemical substances, grouping chemicals with similar toxicity profiles, and reconstructing exposure-related gene expression patterns. This work provides a foundation for an *in silico* evaluation system capable of predicting the toxicity of novel chemical substances based on gene expression data.

PS 4379 An AI-powered method for evaluating *in vivo* level toxicity from genomic dose-response data

A. Weissmann¹, and K. Shao². ¹DREAM Tech, LLC, Bloomington, IN; and ²Indiana University, Bloomington, IN.

Background and Purpose: For more than a century, animal studies have been used to identify the potential adverse consequences induced by exposure to chemicals and to facilitate human health risk assessment. Recently, there has been a significant push to move from animal testing to new approach methodologies (NAMs) including transcriptomics and *in silico* methods such as AI. Genomic data based risk assessments being developed focus on establishing a transcriptomic point of departure (tPOD) for genomic level changes, however, the tPODs do not cleanly map to organ level effects and are thus more difficult to use for hazard characterization and decision making. Here we propose a different approach in which data at the genomic level is first converted to an organ level response via an AI model, then the model's predictions are used to derive a POD at the *in vivo* level. This approach allows risk assessors to continue using well-established approaches to evaluate toxicity while still taking advantage of, in terms of efficiency, performing transcriptomic studies. The objective of this project was to develop an AI-driven methodological framework that enables *in vivo* toxicity evaluation at the organ level from transcriptomic dose-response data. It is hypothesized that genomic dose-response profiles, together with key experimental context [e.g., exposure durations, species, strains, etc.] from either *in vitro* or *in vivo* studies contain sufficient information to infer *in vivo* organ-level toxicity [e.g., endpoints and response levels]. **Methods:** We trained an AI model to predict *in vivo* response levels given a chemical structure, *in vivo* exposure information, and the result of a genomic measurement. We also developed an approach to calculate a benchmark dose (BMD) from AI model predictions at specified dose levels. Since chemicals in the Open TG-GATES database have both *in vivo* data and genomic dose-response data, the database provides an excellent testing point for our methodology. This gave us a total of 150 chemicals and 120 of which were used for training and 30 of which were used for validation. The model was trained by randomly selecting a genomic measurement from the set of genomic measurements for that chemical. Model training was performed using an 80-20 train validation split and took about a day on an RTX-5090. From the model predictions, we were able to calculate BMDs for 3,880 of 3,884 datasets with a significant dose response trend. **Results:** Our preliminary results show that the AI model had a relative dose-level prediction error of 10.13%, indicating reasonable accuracy for predictions from the AI model. The calculated BMDs were also well correlated with the BMDs calculated from the *in vivo* data with an R value of 0.7294. This is similar to the correlation between tPODs and their *in vivo* counterparts, indicating our method is comparable to current genomic data based risk assessment methods regarding POD derivation. Uncertainty calibration was also strong as the 90% CI showed a coverage of 94.05% indicating only modest over-coverage. Additionally, our methodology is naturally conservative with 80.9% of predicted BMDs being lower than their observed counterpart. **Conclusions:** Our AI-powered method for using genomic data for *in vivo* level risk assessment showed strong results on Open TG-GATES data, demonstrating reasonable levels of accuracy with some other nice properties including strong uncertainty calibration and natural conservatism. This validates our hypothesis that an AI-powered approach is capable of bridging the gap between transcriptomic results and *in vivo* level outcomes. In the future, we will train more advanced models with more data likely yielding further improvements in the accuracy of the model which will lead to downstream improvements in the derived PODs.

PS 4381 Mitigating features in quinoline derivatives: an expert-review SAR analysis of indeterminate QSAR predictions

M. Lettieri, M. Rodda, G. De Angelis, G. Baldone, L. Brunasso, E. Gillio Tos, V. Carlucci, and A. Conto. Chemsafe, Coleretto Giacosa, Italy.

Background and Purpose: Indeterminate QSAR predictions might hinder regulatory toxicology by leading to inconclusive conclusions. Expert review can augment *in silico* assessments and help interpret ambiguous outcomes. While QSAR models emphasize positive features and structural alerts, countervailing or deactivating features can substantially weight the overall prediction and reduce false positives. This work aims to investigate whether specific mitigating features within quinoline-containing structures hamper Michael addition and ultimately diminish mutagenic potential. **Methods:** An expert-review approach is applied to indeterminate QSAR results. An SAR-based analysis of the quinoline chemical environment is conducted, emphasizing deactivating features that may hinder activation of the quinoline moiety and prevent Michael addition. Data and (Q)SAR predictions for quinoline derivatives have been considered. Putative mitigating features have been

identified and characterised. **Results:** The SAR assessment highlighted consistent patterns where certain substituents or electronic/steric hindrance reduced likelihood of Michael-type nucleophilic attack, correlating with decreased mutagenic signal in subsets of compounds. Experimental data supported the notion that deactivating features can mitigate predicted reactivity, thereby clarifying ambiguous QSAR outcomes when integrated with expert review. **Conclusions:** Expert review remains essential when leveraging *in silico* tools for toxicology, particularly for regulatory purposes. To reduce inconclusive outcomes, the expert review with an SAR-focused evaluation of the chemical environment can provide a more nuanced, mechanism-informed conclusion. These integrated approaches help manage indeterminate QSAR predictions and support more robust decision-making in safety assessments.

PS 4382 QSAR Models to Anticipate the Degradation of Common Chemical Functional Groups

K. Reiss, and S. Chakravarti. MultiCASE Inc., Mayfield Heights, OH.

Background and Purpose: When determining the toxicity of pharmaceuticals and other chemical products, significant consideration must go towards the presence of impurities, many of which can be formed as byproducts during synthesis. However, additional impurities can form spontaneously over time as chemicals sit in storage, even under ideal conditions. Degradation includes numerous mechanisms and can be catalyzed by several factors, such as heat, pH, oxidative species (including air), and light. The exact degradation pathway a compound will follow depends entirely on which functional groups are present and what conditions the compound is exposed to. Many common functional groups are susceptible to hydrolysis, including esters, amides, thioesters, halides, and more. Hydrolysis generally occurs by one of two mechanisms: base-catalyzed and acid-catalyzed. In a basic environment, an electropositive atom, such as the carbon attached to a halogen, is attacked by a nucleophilic hydroxide ion. In an acidic environment, free H^+ ions protonate an electronegative atom, such as the oxygen in an ether. Both mechanisms generally result in the molecule being split into an alcohol and a second group that varies based on the parent functional group. Some groups are equally susceptible to both acid- and base-catalyzed hydrolysis while others are only susceptible to one. **Methods:** Hundreds of hydrolysis rate constants for various species have been collected over the past century, which can be used to construct a robust Quantitative Structure Activity Relationship (QSAR) model to predict the hydrolysis rates of new compounds. If there is enough data for a particular functional group, a statistical model can be built. Statistical models are created using an in-house code that extracts structural fragments from each molecule and then looks for any correlation between these fragments and the rate of hydrolysis, expressed as $\log(k)$. If data is more limited but still sufficiently varied and systematic, an expert rule-based model can be built. The rules focus on the environment on either side of the hydrolyzed bond, checking for substructures that can either alter the charge or are bulky enough to block an ion from bonding. Determining the magnitude of the effects of these fragments requires data collected under similar experimental conditions, particularly solvent and temperature. **Results:** Both methods are powerful for predicting the rate of hydrolysis, provided that sufficient data is available. For groups, such as esters, where hundreds of molecules have published data, the statistical models were very reliable for predicting the rate, with the ester model having a RMSE of 0.77 and R^2 of 0.91. Expert rule-based systems could be built for most functional groups but were particularly useful for those with datasets too small to build a statistical model. For esters and amides, the RMSE was 0.63 and 0.41, respectively, with an R^2 of 0.86 and 0.92, respectively, showing a modest improvement over the statistical ester model. A benefit of the rule-based models is that the rules could be reused between select similar functional groups, such as esters and amides or thiols and hydroxyls, with minimal adjustments. For example, while oxygen will generally only form two bonds, nitrogen will make at least three, meaning that an amide can have either a hydrogen or an additional third branch to consider. The broad applicability of the rules simplified the creation of expert rule-based models and also helped to confirm the rules' robustness. **Conclusions:** The similarity across most hydrolysis mechanisms made building accurate QSAR models relatively straightforward, despite the wide range of functional groups to be covered. Where enough data was available, a robust statistical model was built that could reliably predict the rate of hydrolysis. For functional groups that had not been studied as thoroughly, expert rule-based systems were derived from the data that was available, leveraging the similarity between certain functional groups to expand the rule set when possible. Using these models, both the structure and prevalence of hydrolyzed impurities can be anticipated so that they can be included in a chemical's risk assessment and mitigated, if necessary.

PS 4383 ToxMet: a web-tool for the analysis of toxicogenomic data using genome-scale metabolic modeling

A. Hari^{1,2}, Z. Xu^{1,2}, Z. Smith^{1,2}, V. Desai^{1,2}, W. Casey³, S. S. Auerbach³, A. Wallqvist¹, and V. R. Pannala^{1,2}. ¹Department of Defense Biotechnology High Performance Computing Software Applications Institute, Frederick, MD; ²The Henry M. Jackson Foundation for the Advancement of Military Medicine Inc., Bethesda, MD; and ³Division of Translational Toxicology, National Institute of Environmental Health Sciences, Research Triangle Park, NC.

Background and Purpose: Chemical-induced organ toxicity is routinely assessed using rat transcriptomic data collected at various timepoints and dose conditions, and understanding its underlying mechanisms relies on analyzing changes in gene expression using various statistical methods, such as gene set enrichment analysis, dose-response modeling, or identification of genes whose expression correlates with injury phenotypes. Recently, genome-scale metabolic models (GSMs) have been used to provide a systems-level understanding of gene expression changes by correlating them with organ metabolism and injury phenotypes. However, most of the algorithms that integrate gene expression with GSMs require familiarity with MATLAB or Python programming, making them less accessible for users without computational experience. Furthermore, these algorithms' results cannot be readily visualized in the context of metabolic networks. Therefore, we developed a user-friendly web-application that integrates transcriptomic data with a rat GSM to understand changes in organ metabolism and predict potential metabolites for targeted biomarker discovery. **Methods:** GSMs represent the entire metabolic network of a cell or organism, including all the metabolic reactions, the genes catalyzing the reactions, and the relationship between the genes and reactions in a computational framework. In our web-application, we implemented the rat GSM contents as explorable tables for the users, with additional information related to genes, reactions, and metabolites provided via external links. For transcriptomic data integration, we implemented two well-validated computational algorithms related to flux balance analysis, i.e., Pheflux and TIMBR, which predict alterations in organ metabolism at the metabolic reaction level and plasma metabolite alterations, respectively. **Results:** Here, we introduce ToxMet, a user-friendly web-application that integrates transcriptomics to predict and visualize chemical-induced metabolic perturbations in rat tissues using toxicogenomic measurements and GSMs. ToxMet takes rat transcriptomic data as input and predicts chemical-induced changes in metabolite secretions and metabolic pathway activity, providing prediction results as interactive and downloadable tables, scatter plots, and network visualizations. The scatter plots provide a summary of changes across the subsystems and major pathways, which helps identify the most altered pathways and their direction of alteration (increase or decrease in activity) with respect to controls. The network visualizations provide details of reactions and metabolites contained within the subsystems, which can help trace changes across reactions when analyzed in conjunction with the algorithms' predictions. Users can download the raw results for other downstream analyses or to generate plots in other formats and can search and visualize the rat GSM network for the presence of metabolites, reactions, genes, and subsystems of interest. Finally, we demonstrate ToxMet's applicability by predicting known toxicity mechanisms using publicly available toxicogenomic data. **Conclusions:** ToxMet is a free and easy-to-use web-based software that can predict metabolic alterations from gene expression data. ToxMet's predictions provide novel insights into the metabolic mechanisms of chemical-induced toxicity and can aid in the discovery of biomarkers and therapeutics.

PS 4384 Supporting source-to-outcome assessment in toxicology through data interoperability

D. Hines¹, S. Bell¹, C. M. Hamilton¹, N. Harris², S. Moxon², C. Mungall², M. Nelms¹, J. Rineer¹, and D. Williams¹. ¹RTI International, Research Triangle Park, NC; and ²Lawrence Berkeley National Laboratory, Berkeley, CA.

Background and Purpose: Environmental Health Science (EHS) is an inherently interdisciplinary field that studies how environmental factors, both natural and human-made, affect human health. This field integrates concepts from biology, chemistry, toxicology, epidemiology, and public health to understand environmental risks that can lead to disease or adverse health outcomes. Source-to-outcome (S2O) analyses can provide insight into risks and mitigation strategies associated with environmental exposures but require integration of multiple EHS data streams. Data integration can provide evidence-based support to inform risk assessment and decision making, but the practicality of data integration across EHS fields can be challenging because the current landscape is largely fragmented. Domains such as toxicology and exposure science have heterogeneous and inconsistent data formats, nuanced methodologies, and varied reporting practices. Integrating mechanistic data from across these domains is challenging because datasets end up siloed, and the metadata that can be critical for understanding how to appropriately understand and use measurements may not be available. This work aims to advance infrastructure for integrated analyses across EHS domains by leveraging standards and terminologies to promote data interoperability, findability, and reusability. We highlight a use case that develops a source-to-outcome computational model to support standards development across EHS domains. We emphasize model construction, preliminary results, and application to advance integrated analyses. **Methods:** We present a pilot use case that spans the S2O continuum and focuses on $PM_{2.5}$ exposure and decreased lung function to exemplify the complexity of linking real-world environmental exposure

data to health impacts. We used the Aggregate Exposure Pathway (AEP), and Adverse Outcome Pathway (AOP) frameworks as a scaffold to describe the S2O continuum and guide our work, linking them together to form the continuum. The exposure component of the use case employs a synthetic population, air quality data, and variation in demographic factors to simulate the AEP influencing PM_{2.5} intake during wildfire events. The biological component leverages AOP networks to represent mechanistic relationships through AOP Bayesian Network (AOPBN) modeling. This methodology provides a probabilistic structure for integrating evidence streams and evaluating the impacts of data integration on predictive confidence. We used the multiple-path particle dosimetry model (MPPD) to simulate lung deposition resulting from exposures, linking the exposure and outcome components through dosimetry. **Results:** We present preliminary results of exposure, dosimetry, and outcome modeling. Exposure modeling results include predicted daily PM_{2.5} exposure from forest fires in synthetic individuals, simulated through RTI's Synthetic Population Modeling system. We demonstrate variability across time and across individuals in the population, and highlight differences in exposure among census demographic groups. Particle dosimetry modeling results from MPPD are provided, accounting for physiological factors such as age and sex. We present network construction and preliminary results from AOPBN analyses, including probabilistic predictions of decreased lung function given input dosing conditions. **Conclusions:** Our use case demonstrates how standardized, interoperable data ecosystems that span the S2O continuum can support comprehensive risk assessments and inform on human health outcomes. We show that data interoperability is key to the future of mechanistic analyses in EHS, including S2O analyses, for helping to assemble information into meaningful knowledge. We emphasize that interoperability goes beyond compatibility of units and extends to making data searchable and easily processed by computational tools, as well as ensuring that contextualizing information that informs on the appropriate interpretation of data is available. We emphasize that building tools that anticipate data reuse and standardize the capture of this information is essential, and highlight opportunities for improved interoperability. This work is funded by the National Institute of Environmental Health Sciences under award number 1R24ES036127.

PS 4385 Statistical Evaluation of DrugMatrix and Open TG-GATEs for Construction of an Integrated Toxicogenomics Resource

Y. Chen¹, G. Cong², S. Lim², F. Chao³, and S. S. Auerbach³. ¹University of Minnesota Twin Cities, Minneapolis, MN; ²Oak Ridge National Laboratory, Oak Ridge, TN; and ³National Institute of Environmental Health Sciences, Durham, NC.

Background and Purpose: DrugMatrix (US) and Open TG-GATEs (Japan) are two of the largest publicly available toxicogenomics datasets, each containing thousands of microarray profiles across multiple tissues, dose levels, and chemical exposures. Because animal studies are costly, and constrained by ethical and scalability limitations, maximizing the utility of existing datasets is essential for developing predictive models that can support future toxicological risk assessment. The objective of this study is to determine whether DrugMatrix and Open TG-GATEs possess compatible gene-expression characteristics after being processed under a unified normalization pipeline, thereby evaluating the feasibility of integrating the two datasets into a single training resource. **Methods:** Raw Affymetrix CEL files containing probe-level intensity measurements were processed using the Robust Multi-Array Average (RMA) algorithm, including convolution background correction, quantile normalization, and median-polish summarization, to reduce technical noise and platform-specific variability. Biological replicates were averaged to generate one expression profile per treatment condition. Cross-dataset compatibility was evaluated by comparing descriptive statistics, global expression distributions under the matched tissues and experimental modes. Kernel density estimation (KDE) was applied to obtain smoothed probability density curves for gene-expression values. Graphical diagnostics were used to assess distributional concordance: Probability-Probability (P-P) plots were used to compare the cumulative distribution functions of the two datasets, assessing whether they assign similar proportions of genes to each expression range. Quantile-Quantile (Q-Q) plots evaluated agreement of expression intensities at matched quantile levels, assessing whether the datasets share comparable dynamic ranges after normalization. These distributional diagnostics quantify whether the two datasets share comparable expression scales, tail behavior, and overall shaping after unified normalization. **Results:** RMA normalization produced highly comparable global expression patterns across the two datasets. DrugMatrix and TG-GATEs exhibited similar expression ranges (min $\approx$ 2.4-3.1; max $\approx$ 14.5-15.2), interquartile ranges ($\approx$ 3.1-3.5), median values ($\approx$ 5.4-6.7), and standard deviations ($\approx$ 2.1-2.3). These matched comparisons demonstrate that gene-expression measurements across the two platforms operate on the same numerical scale. Density curves from both sources displayed the characteristic bimodal distribution common in toxicogenomics microarray datasets, and the relative ordering of tissues by median expression was consistent across platforms. Probability-Probability and Quantile-Quantile comparisons further confirmed distributional agreement: both plots showed near-linear alignment across the central distribution, with mild tail deviations. These findings show that platform-specific variation is effectively reduced under the unified preprocessing pipeline. **Conclusions:** The consistency of the distributional properties observed between DrugMatrix and Open TG-GATEs after uniform preprocessing provide evidence that large-scale integration of the two datasets is feasible from a statistical standpoint. A merged dataset would expand chemicals, dose, and temporal coverage, which could serve as a more informative training foundation for toxicogenomics prediction models.

The integration supports ongoing efforts to reduce reliance on animal studies by enabling more accurate, data-driven inference of transcriptional responses to chemical exposures.

PS 4386 BioBricks-OKG: An Open Knowledge Graph Infrastructure for Integrating Chemical Safety and Toxicology Data

Z. Mughal, A. Nagyal, J. Mikhail, K. Han, M. Nagyal, S. Mitra, and T. Luechtefeld. Insilica, Rockville, MD.

Background and Purpose: Regulatory agencies face mounting pressure to evaluate chemical safety using alternative methods while maintaining rigorous scientific standards. Critical barriers include inconsistent chemical nomenclature across databases, ambiguous test method descriptions, and fragmented toxicity endpoint definitions that complicate systematic evidence evaluation. These data quality and interoperability issues are essential challenges in computational approaches and read-across methodologies for regulatory submissions. BioBricks-OKG was developed in partnership with NICEATM to address these fundamental data infrastructure challenges by creating a harmonized knowledge graph that standardizes chemical identifiers, test methods, and endpoint definitions across major toxicology databases, thereby supporting evidence-based regulatory decision-making and facilitating transparent, reproducible chemical risk assessments. **Methods:** BioBricks-OKG implements ontology-driven harmonization of chemical safety data from authoritative toxicology sources, including EPA CompTox, ToxCast, Tox21, ICE (Integrated Chemical Environment), CTD, and AOP-Wiki, as well as more general biological and chemical databases such as PubChem and ChEBI. Many of these datasets are extracted as tabular data that are versioned using the BioBricks system, which are then transformed and mapped to entities that integrate multiple datasets. Chemical substances are harmonized using PubChem CIDs as common identifiers to link chemical entities across databases. The ontology approach utilizes existing standard ontologies from the OBO Foundry and controlled vocabularies employed by biological databases. In combination, this allows for creating a workflow where the source data for data integration are reproducible and there is provenance tracking for knowledge graph assertions. **Results:** BioBricks-OKG successfully harmonized chemical identifiers across major toxicology databases by mapping diverse nomenclature systems to PubChem CIDs, resolving inconsistencies that previously prevented cross-database queries. The knowledge graph enables complex regulatory queries that were previously impractical due to variations in database schemas and inconsistent identifier use. Specific examples include: identifying all substances classified as GHS Category 1 carcinogens with available ToxCast high-throughput screening data and linking chemicals to relevant adverse outcome pathways based on mechanistic assay results. Each part of the overall knowledge graph is available as KG bricks modeled in RDF with serialization in standard formats, as well as in pre-indexed HDT format for immediate local queries after downloading. In addition, KG bricks can be loaded into any number of triple-store servers to support efficient cross-graph querying over the network using SPARQL. By combining all these data sources into a shared schema, the data source can also be queried via an LLM front-end, allowing for various applications, such as natural language querying or as a source for retrieval-augmented generation of toxicology reports. **Conclusions:** BioBricks-OKG directly impacts toxicology practice by providing infrastructure that enables regulatory agencies to systematically evaluate chemical safety using integrated evidence from multiple sources. This addresses a documented need identified by NICEATM and regulatory stakeholders for improved data interoperability in alternative method evaluations. The harmonized knowledge graph reduces technical barriers to implementing read-across approaches and weight-of-evidence assessments required for regulatory submissions. This infrastructure supports ICCVAM's mission to promote scientifically valid alternative methods, accelerating the transition away from animal testing while maintaining rigorous standards for human health protection. The open-source, version-controlled design provides sustainable infrastructure adaptable to future NAM data types and evolving regulatory needs.

PS 4387 Human liver microtissue gene networks enable mechanisms-based chemical safety assessment

S. J. Kunnen¹, A. Borgström², L. Fäs², A. Pawlowska², T. M. Hagens¹, L. J. Sinke¹, S. Bahtiri¹, L. S. Wijaya¹, G. Callegaro¹, W. Moritz², and B. van de Water¹. ¹Leiden University, Leiden, Netherlands; and ²InSphero, Schlieren, Switzerland.

Background and Purpose: Next generation risk assessment (NGRA) is crucial for understanding the potential risks posed to human health by chemical or drug exposures. Within the NGRA framework, various new approach methods (NAMs) have been developed as alternative of animal studies. Human liver microtissues (hLiMT) are a physiologically relevant liver model, cultured in 3D spheroids and are composed of human primary hepatocytes and non-parenchymal cells, including Kupffer and endothelial cells. High-throughput transcriptomics of these spheroids after chemical exposures have the potential to derive mechanism-based transcriptional points of departure for chemical safety assessment. **Methods:** Human liver microtissues were cultured in a high-throughput 384-wells format and exposed to 56 chemicals, cytokines or growth factors at three concentrations (five-fold dilutions), not exceeding 15% cytotoxicity. Samples were collected at 8, 24 and 168 hours after exposure and

analyzed using targeted whole transcriptome sequencing (TempO-Seq), followed by weighted gene co-expression network analysis (WGCNA) to identify modules of co-regulated genes. **Results:** Transcriptome analysis of 500 unique treatments in hLiMT yielded over 250 liver spheroid specific gene co-expression networks, which are visualized in the interactive R-shiny based TXG-MAPr platform. These modules cover genes involved in various key biological processes, including cellular stress responses, inflammation, metabolism, cell cycle regulation and translation. Most of these modules were preserved in other liver cultures, like primary human hepatocytes. Known reference compounds, like tunicamycin, diethyl maleate and cytokines, activate expected stress response modules for unfolded protein response, oxidative stress and inflammation, respectively, confirming the mechanistic relevance of the gene networks in liver spheroids. Uploading and integration of external data from liver toxicant exposure further demonstrated the potential to link module activity with liver adverse outcome pathways (AOPs). **Conclusions:** The hLiMT TXG-MAPr tool provides a comprehensive, mechanism-based framework for chemical hazard identification and characterization. It enables comparative interpretation of transcriptomic responses, supporting industry and regulatory stakeholders in applying NAMs for next-generation chemical safety assessments.

PS 4388 Integrated Multiomic analysis of arsenic-induced perturbations to the pluripotency network of mouse embryonic and epiblast-like stem cells

S. Deme, Y. Kang, S. Armstrong Suthahar, and P. Allard. UCLA, Los Angeles, CA.

Background and Purpose: Arsenic contamination in water impacts the health of up to 220 million individuals worldwide. Despite arsenic's status as one of the most well-studied toxicants, the mechanisms underlying arsenic's carcinogenicity following *in utero* exposure remain poorly understood. The current, most prevalent theory for arsenic's carcinogenicity centers on S-adenosyl methionine (SAM), a key metabolite that serves as the cell's primary methyl donor. Following exposure, cells methylate arsenic to facilitate its excretion from the body, leading to a depletion of SAM that is thought to lead to global hypomethylation and, eventually, cancer. However, our preliminary evidence in murine embryonic stem cells (ESCs) and epiblast-like stem cells (EpiLCs) shows that the SAM hypothesis fails to explain arsenic's etiology in germ cells. The ESC and EpiLC models are especially informative to understanding the impacts of arsenic *in utero* as they represent two key, differentially methylated stages of embryonic development. Furthermore, studies have shown that arsenic impacts the ability of stem cells to maintain pluripotency, suggesting a potential avenue for long-term impacts following short-term *in-utero* exposure. **Methods:** Our study leverages multi-omics data (bulk RNA-seq, RRBS, metabolomics, and Chip-Seq) to better understand the multiple mechanisms through which arsenic impacts the pluripotency network of mouse ESCs and EpiLCs. Cells were exposed to arsenic for 48 hours before analysis. The datasets were analyzed separately using k-means clustering and ontological analyses of differential features to identify key components impacted by arsenic exposure. These datasets were then integrated using MOFA (multi-omics factor analysis) and regulatory network construction to investigate pluripotency network-specific impacts. **Results:** Integrated analysis reveals clusters that showcase cell type differences between ESCs and EpiLCs, and both cell-type specific and general perturbations caused by arsenic on multiple cellular levels. CpGs in ESCs became hypermethylated on average while EpiLCs become hypomethylated, contrary to the general trend of arsenic inducing global hypomethylation in most cell types. Bulk RNA-seq data showed clusters of genes similarly dysregulated in both cell types related to mitochondrial function and cell cycle regulation. ESC-specific perturbations show that arsenic pushes ESCs towards a partial loss of naïve pluripotency. Cluster dynamics and results of rescue experiments indicate that the dysregulation of histone post-translational modifications triggers cascading effects on DNA methylation and gene expression, leading to aberrant differentiation control. **Conclusions:** This study underscores the relationship between epigenetics and genetics in regulating the pluripotency network. Our analysis reveals that arsenic partially disrupts the pluripotency network while preserving key features of cell identity. These early embryonic disruptions can inform lifetime disease risk assessment. The multi-omic approach employed in this study provides several critical advantages over single-platform analyses. The integrated analysis identifies shared and cell-type-specific variance across molecular layers, allowing us to distinguish primary arsenic targets from secondary downstream effects. This comprehensive molecular profiling strategy establishes a framework for understanding how environmental toxicants disrupt complex biological networks during critical developmental windows.

PS 4389 Metabolism of Selected N-Nitrosamine Drug Substance-Related Impurities: Insights from the MUTAMIND Project

K. P. Cross¹, S. Greco², A. Bassan², J. Irwan³, A. Londenberg³, D. Palazzotti², and S. E. Escher³. ¹Instem, Conshohocken, PA; ²Innovatune, Padova, Italy; and ³Fraunhofer Institute for Toxicology and Experimental Medicine, Hannover, Germany.

Background and Purpose: N-Nitrosamines are mutagenic compounds and often potent carcinogens. When they occur as residual impurities related to active pharmaceutical ingredients, known as N-nitrosamine drug substance related impurities (NDSRIs), their hazard depends on chemical context, in particular the envi-

ronment around the N-NO moiety. Understanding the mechanisms underlying their metabolism is crucial, as it is closely linked to the carcinogenic potential of these compounds. The MUTAMIND SC05 project aims to experimentally elucidate the major metabolic sites of NDSRIs that govern their activation and deactivation pathways. Within this project, *in silico* methods are initially being used to explore these pathways and guide subsequent *in vitro* metabolism experiments in the project. **Methods:** Computational tools for metabolism prediction (Metasite from Molecular Discovery) were applied to seven representative NDSRIs (N-nitroso-bethahistine, N-nitroso-duloxetine, N-nitroso-ketamine, N-nitroso-propranolol, N-nitroso-sertraline, N-nitroso-trimetazidine, and N-nitroso-varenicline) to identify probable sites of metabolism, predict reactive metabolite formation, and evaluate competing activation and detoxification pathways. These compounds were selected to represent diverse structural classes and metabolic scenarios. **Results:** *In silico* metabolism predictions identified the cytochrome P450 (CYP) isoforms most likely involved in NDSRI metabolism. Some isoforms (e.g., CYP1A2, CYP2C19) were highlighted as key contributors to α -hydroxylation of the nitrosamine moiety, a critical step in metabolic activation. N-nitroso-trimetazidine showed high selectivity toward a single isoform, while N-nitroso-varenicline was predicted to be a poor CYP substrate, consistent with experimental data. For most NDSRIs, the less substituted α -carbon was the preferred site of metabolism; however, in N-nitroso-propranolol, the more substituted α -carbon was favored, likely due to electronic effects from the adjacent hydroxyl group, consistent with the CPCA classification of the β -hydroxyl group as deactivating. The analysis distinguished activation driven by chemical reactivity from interactions within the CYP active site. For example, the three methoxy substituents of N-nitroso-trimetazidine appear to act as deactivating features, steering CYP-mediated oxidation toward these groups rather than the α -carbons, likely due to both their favorable electronic properties and spatial orientation in the active site. A similar trend is observed for N-nitroso-varenicline, where the α -positions are less favorable sites for CYP-mediated oxidation compared to other more distant parts of the structure. The detoxification pathways were also analyzed to assess potential competing Phase II detoxification mechanisms (e.g., those mediated by glutathione S-transferases or sulfotransferases). Most NDSRIs were predicted to undergo detoxification reactions, particularly glutathione conjugation with a high probability and similar to that of at least one CYP isoform. However, N-nitroso-ketamine, detoxification pathways were predicted as less probable than CYP-mediated α -hydroxylation. **Conclusions:** The analysis indicates a complex interplay between electronic and steric factors at the α -carbons and other sites of metabolism of the molecule, influencing chemical reactivity, CYP-mediated activation and competing enzymatic detoxification pathways. The computational results identified key CYP isoforms and metabolism routes likely involved in the activation and detoxification of NDSRIs, offering valuable insights to guide experimental *in vitro* metabolism investigations of the compounds in this project.

PS 4390 Unified Transcriptomic Cell Atlas of Human Neural *In Vitro* Systems

D. S. Umbaugh, J. G. Roth, S. Niu, A. Lopez Tobon, S. Kang, and F. Melnikov. Genentech, South San Francisco, CA.

Background and Purpose: Human stem cell-derived neural organoids, spheroids, and 2D co-culture systems are foundational new approach methodologies (NAMs) for studying brain development and disease, yet an integrated, high-resolution transcriptomic characterization of these distinct platforms is lacking. Such an atlas is critical for benchmarking model fidelity and standardizing their use throughout drug discovery and development pipelines. As such, we sought to use single-cell RNA sequencing (scRNAseq) to extensively profile the transcriptome of an array of *in vitro* models. Our goal is to build a unified transcriptomic cell atlas of different *in vitro* neural systems and to leverage this atlas to expand the utilization of NAMs within pharmaceutical research and development. **Methods:** We performed scRNAseq on *in vitro* models derived from human induced pluripotent stem cells. This profiling spanned multiple culture dimensions, differentiation protocols, cell donors, and time to yield a comprehensive database. **Results:** Our analysis resolved hundreds of thousands of cells, including multiple neuronal subtypes across brain regions, neural progenitor cells at various stages of differentiation, and major glial and non-neuronal lineages. A direct transcriptomic comparison revealed a general induction of stress and hypoxia-related genes in 2D co-culture systems compared to 3D models. **Conclusions:** We provide the first and largest unified single-cell atlas of diverse neural *in vitro* models. This resource provides a foundational resource to evaluate the physiological limitations of different NAMs, directly informing the selection of appropriate models for pharmacological studies.

PS 4391 **Bayesian Evaluation of a Physiologically Based Pharmacokinetic (PBPK) Model to Characterize Size-Dependent Biodistribution of Microplastics in Mice**

A. Ukbamichael, H. Nandula, A. Canchola, and W. Chou. University of California, Riverside, Riverside, CA.

Background and Purpose: Microplastics (MPs) are emerging environmental contaminants that can cross biological barriers and accumulate in multiple tissues. Due to their diverse physicochemical characteristics, including particle size, surface charge, and surface modification, the mechanisms governing their *in vivo* behavior are complex and difficult to predict. Conventional modeling approaches are often insufficient to capture these variations. This study applied a Bayesian evaluation of a physiologically based pharmacokinetic (PBPK) model to quantify the size-dependent biodistribution of MPs in mice and to characterize uncertainty across different datasets and particle sizes. **Methods:** Experimental biodistribution data (% injected dose, %ID) for MPs ranging from 20 nm to 5 μ m were compiled from multiple published *in vivo* studies covering major organs (liver, kidney, spleen, lungs, gastrointestinal tract, and urine). A multi-compartment PBPK model implemented in *mrgsolve* was designed to simulate the processes of absorption, systemic distribution, and elimination. The model explicitly included kinetic processes for gastrointestinal transport, tissue uptake, reticuloendothelial system (RES) sequestration, and excretory clearance. These kinetic rates were first fitted deterministically and then refined through Bayesian Markov Chain Monte Carlo (MCMC) calibration using the Differential Evolution Adaptive Metropolis (DRAM) algorithm to generate posterior parameter distributions. A Bayesian meta-analysis was subsequently applied to quantify size-dependent variability in these kinetic processes, enabling the model to extrapolate across a continuum of MP sizes. **Results:** The Bayesian PBPK model accurately captured the biodistribution of MPs across all size groups and studies, achieving $R^2 > 0.93$ with 85 % of observed data within a two-fold error range. Model evaluation indicated that the majority of data points in the independent evaluation dataset fell within the 95 % credible intervals (CIs) of model simulations. Posterior predictive checks and forest plots confirmed the model's ability to reproduce observed tissue concentrations with reliable uncertainty bounds. Sensitivity analysis identified gastrointestinal absorption, RES sequestration, and systemic clearance as dominant factors controlling size-dependent behavior. **Conclusions:** This Bayesian evaluation of a PBPK model provides a robust and quantitative framework for assessing microplastic biodistribution and propagating uncertainty across particle sizes. Incorporating meta-analytic estimates of size variability allows the model to predict tissue distribution for a broad range of microplastic sizes, supporting mechanistic interpretation, cross-study comparison, and health risk assessment of micro- and nanoplastics in biological systems

PS 4392 **Integrating Artificial Intelligence to Advance Chemical and Carcinogenic Risk Assessment in Medico-Legal QME Practice**

A. Radfar, I. Filip, and A. Derekhshani. Avicenna Clinical and Medical Research Institute, Mission Viejo, CA.

Background and Purpose: Evaluating carcinogenic potential for structurally diverse chemicals remains challenging using traditional toxicologic approaches, particularly when exposures involve mixtures, aromatic hydrocarbons, or low-dose chronic profiles frequently encountered in medico-legal QME assessments. Advances in artificial intelligence (AI) and machine learning provide opportunities to integrate mechanistic toxicology with chemical structure features and public hazard classifications. Published tools such as the RASAR read-across system and machine-learning models applied to genomic instability signatures demonstrate how open toxicology resources can support evidence-based carcinogenicity evaluation. This project examined whether AI-driven modeling, using *only* publicly available chemical datasets, could generate mechanistically interpretable predictions relevant to carcinogenic hazard assessment within QME practice. **Methods:** A dataset of chemicals was compiled entirely from public toxicology resources, including PubChem structural data, RDKit-derived physicochemical descriptors, structural alerts from the OECD QSAR Toolbox, and carcinogenicity classifications from IARC and the NTP Report on Carcinogens. Three descriptor classes were extracted: (1) molecular features such as molecular weight, hydrogen-bond donor count, and aromaticity; (2) structural alerts associated with genotoxic or DNA-reactive mechanisms; and (3) hazard groupings derived from established carcinogenicity lists. Gradient boosting, random forest, and a simple neural network were evaluated as modeling approaches to predict carcinogenicity-relevant signatures. Interpretability was assessed using feature-importance methods, and representative chemicals were examined to evaluate biological plausibility and alignment with known mechanistic pathways. **Results:** Across modeling approaches, chemically and biologically meaningful predictors consistently emerged. Aromatic ring count, hydrogen-bond donor number, and DNA-reactivity alerts contributed most strongly to separating known carcinogens from low-toxicity comparator chemicals. For example, benzene contains one aromatic ring, whereas higher-potency polycyclic aromatic hydrocarbons possess three or more, a pattern reflected in the importance of aromaticity-related descriptors. Model interpretability analyses highlighted mechanistic drivers corresponding to recognized carcinogenicity pathways, including aromaticity-linked genotoxicity, electrophilic reactivity, and other structural alerts commonly used in regulatory toxicology. In representative examples, the models consistently assigned higher carcinogenicity-related scores

to compounds historically classified as carcinogenic, demonstrating alignment between computational outputs, chemical structure, and established hazard classifications. **Conclusions:** AI-based toxicologic modeling using publicly available chemical datasets can provide mechanistically transparent insights that complement traditional carcinogenic hazard evaluation. Integrating structural alerts, physicochemical features, and established classifications supports evidence-based toxicology and enhances interpretability in medico-legal and occupational settings. These findings illustrate the feasibility of using open data and accessible machine-learning methods to support carcinogenicity assessment within QME practice. Future work will incorporate larger public datasets (e.g., ToxCast and Tox21) and expand mechanistic coverage to strengthen alignment with regulatory read-across frameworks used in contemporary toxicology.

PS 4393 **SMILES to brain: predicting blood-brain barrier permeability of environmental chemicals.**

N. Pelayo¹, D. Li², and F. Gao¹. ¹University of California Los Angeles, Los Angeles, CA; and ²University of Nevada Reno, Reno, NV.

Background and Purpose: The blood-brain barrier (BBB) plays a critical role in protecting the central nervous system by tightly regulating the passage of circulating molecules into the brain. While the BBB is highly selective, multiple environmental toxicants, such as commercial and industrial chemicals, pesticides, microplastic associated additives and emerging pollutants, have been shown to penetrate the BBB and accumulate in neural tissue. Such contaminants may contribute to neurotoxicity and disease risks. Yet, current knowledge of the BBB permeability for environmental chemicals remains limited. Most existing datasets and predicting models are developed primarily for pharmaceuticals and do not adequately represent the structural diversity or physicochemical properties of environmental toxicants. In addition, testing chemical BBB permeability is labor intensive, time consuming and highly costly, requiring specialized *in vitro* models or animal studies that are impractical to scale across thousands of untested chemicals. Therefore, the critical data and methodologies gaps of BBB permeability studies of environmental neurotoxins persist. For instance, machine learning models to accurately assess the BBB permeability of chemicals of environmental concern are still lacking. To address these gaps, in this study, we developed a machine-learning framework to predict chemical BBB permeability and strengthen mechanistic interpretation of neurotoxicity screening. **Methods:** We leveraged a parallel artificial membrane permeability assay for brain membranes (PAMPA-BBB) dataset of 106 compounds of environmental concerns to develop machine learning models to predict their permeability. Multiple models including random forest, gradient boosting machine, and neural networks using various molecular fingerprints and molecular descriptors were developed. A nested 5-fold cross-validation was used for model evaluation and hyperparameter tuning. Various model evaluation metrics such as accuracy, AUROC, specificity, and sensitivity were used. Feature-importance and cumulative-importance analyses were applied to identify important molecular sub-structures and properties. **Results:** Our preliminary results showed that random forest achieved the highest accuracy (0.793 +/- 0.064) and AUROC (0.69 +/- 0.081) with high specificity (0.939 +/- 0.061) but low sensitivity (0.286 +/- 0.181), indicating strong identification of low permeability compounds while underpredicting high permeability ones. Gradient boosting showed slightly lower accuracy (0.783 +/- 0.077) and AUROC (0.679 +/- 0.098) with improved sensitivity (0.419 +/- 0.075). The MLP classifier had the highest sensitivity (0.514 +/- 0.029) but lower accuracy (0.727 +/- 0.138) and specificity (0.782 +/- 0.155) reflecting a tradeoff between detecting high permeability compound and overall predictive performance. Feature importance analysis revealed that features associated with lipophilicity, polar surface area, and hydrogen-bonds donors were among the strongest predictors of BBB penetration, in line with mechanistic expectations. **Conclusions:** Our preliminary results demonstrated that machine learning models can effectively predict the BBB permeability of environmental chemicals, addressing a critical gap in neurotoxicity risk assessment. Using a PAMP-BBB dataset of 106 environmental relevant compounds, random forest, gradient boosting, and MLP classifiers were developed leveraging molecular fingerprints and descriptors. The MLP classifier achieves best overall performance. Future work will focus on improving model sensitivity and performance with imbalanced dataset. Collectively, these results underscore the value of integrating machine learning approaches into BBB permeability studies, providing a scalable, cost effective and informative strategy to prioritize environmental chemicals for neurotoxicity evaluation and support public health decision making.

PS 4394 **Filling Gaps in Toxicity Data of Pesticides with OrbTox - a repository of multidomain experimental data and predictive models**

V. K. Gombar, T. Petty, A. Y. Sedykh, A. Borrel, A. J. Green, A. P. Ross, and R. R. Shah. Sciome LLC, Research Triangle Park, NC.

Background and Purpose: The new approach methodologies including *in silico* methods (read across and QSAR models) are gaining importance for hazard and risk assessments, especially as the regulatory and economic emphasis is on reducing reliance on traditional animal testing. The genotoxicity assessment of pesticides and

their metabolites is important to assess their harmful effects on the environment and human health. However, for a large number of pesticides/biocides limited or no data exists from six commonly employed regulatory genotoxicity assays. We have recently developed and validated predictors of Ames test outcome in OECD-recommended strains with and without metabolic activation. Herein we describe using these QSAR models for filling gaps in the bacterial mutagenicity assessments for pesticides and identifying structural features responsible for mutagenicity. **Methods:** Publicly available CCRIS database which contains over 80K Ames test records was harmonized to compile a cleaned data set of over 6K unique compounds with experimental details compliant with the OECD Test Guidelines # 471. QSAR model to predict Ames test results in each of the ten Strain-S9 combinations was developed using Saagar descriptors to fill gaps in the compounds not tested in all ten Strain-S9 combinations to create a unified modeling data set that guarantees a compound labeled Neg in Ames test is Neg by all ten Strain-S9 models. The final QSAR model, Unf(All), was used (via OrbiTox) for predictions of bacterial mutagenicity of new chemicals. 4826 unique pesticide substances collated from 18 public pesticide/biocide databases by Foil *et al.* were used to find gaps in genotoxicity evaluation by overlapping substances with data from six commonly used six genotoxicity assays. Substances missing Ames test evaluations were processed through OrbiTox. Among the 4826 pesticides, 1592 were found to be Ames Neg, 382 Ames Pos, and 2852 without Ames test evaluation. **Results:** In 3x5-fold cross validation, the final Unf(All) model returned AUROC, Kappa, PPV, NPV, Sensitivity, and Specificity, respectively, 0.951, 0.769, 93.7%, 82.1%, 89.3%, and 89.1%. Structures of these 2852 compounds with missing Ames test evaluation were processed through the Unf(All) Ames model installed in OrbiTox². Due to structural reasons, e.g., inorganics, organometallics, etc., 172 compounds could not be processed. Additional 156 isomeric structures with InChI key identical to the corresponding 2D SMILES were excluded. Model's applicability domain (AD) check rendered 156 predictions unreliable. The acceptable predictions were labeled Neg (1655), Ind (418, Indeterminate), and Pos (336), respectively, based on predicted probability of being an Ames Pos <0.4, 0.4 to 0.6, >0.6. Analyses of the structures of compounds predicted Pos or Neg revealed several substructures predominantly present in Ames Pos and Neg compounds. For example, meta-dinitrobenzene substructure had Pos:Neg distribution of 44:0 and aliphatic or nitro group had Pos:Neg distribution of 97:6. Similarly, substructures with predominant Neg:Pos distribution include delta lactones and cyclohexane ketones with 56:0 distribution and tetra alkyl methane with 130:3 distribution. Additional substructures with differing distributions in Ames Pos and Neg compounds will be presented in the poster. **Conclusions:** The robust QSAR Ames mutagenicity predictor derived from harmonized experimental data compliant with OECD Test Guideline 471, given its accuracy in cross-validation and test sets, is an excellent resource for filling gaps in data for untested compounds. The Saagar descriptors used for building QSAR models allow visualization of structural features likely to render a compound Ames Pos or Neg. The Ames mutagenicity predictor described here and over hundred other QSAR models of various toxicity endpoints are available in OrbiTox, which is free for non-commercial use.

PS 4395 ChemHydra: A Novel AI-Driven Pipeline for ADME, Physicochemical, and Toxicity Endpoint Prediction Integrating Advanced Chemical Characterization

A. Borrel, A. J. Green, A. Y. Sedykh, T. Petty, A. P. Ross, V. K. Gombur, and R. R. Shah. Sciome LLC, Research Triangle Park, NC.

Background and Purpose: As data from New Approach Methodologies (NAMs) rapidly expand alongside modern artificial intelligence (AI), there is a clear need for an updated QSAR pipeline that integrates cutting-edge AI approaches to model and benchmark complex toxicity, physicochemical, and ADME endpoints. To meet this need, our team has developed a comprehensive, Python-based cheminformatics pipeline, ChemHydra, engineered to generate robust, predictive, and interpretable QSAR models that comply with all OECD principles. Our methodology advances the traditional workflow by focusing on rigorous chemical preprocessing, comprehensive descriptor generation, flexible modeling with robust benchmarking, and detailed model interpretation. **Methods:** ChemHydra is built on three advanced steps. The first is rigorous chemical standardization, which is optimized by processing large-scale databases (e.g., PubChem, DSSTox, ChEMBL); we use an in-house salt list to remove counter-ions, SMARTS-based reactions to standardize complex chemical states, and a proprietary method to assign correct protonation states. This is followed by comprehensive descriptor generation, where we integrate a diverse set of molecular descriptors, including 1D/2D/3D properties, custom substructure descriptors, Saagar, and vector-based embeddings from pre-trained SMILES-based language models. Finally, ChemHydra features flexible modeling and benchmarking, integrating over 40 machine learning (e.g., XGBoost, Random Forest) and deep learning (e.g., MLP, Transformers, Multitask Learning) algorithms. This suite allows us to benchmark a full range of models, selecting the optimal architecture for any given dataset. All models are paired with local interpretation methods to fulfill OECD Principle 5 as well as standard QMRF report. **Results:** We benchmarked our pipeline on large, publicly available datasets for physicochemical, ADME, and toxicity endpoints, with performance compared to established models like ChemProp, OPERA, and Vega. Our generated models consistently performed comparably to or outperformed these benchmarks. For physicochemical properties, we are able to predict logP and the Henry's Law constant using a Saagar descriptor and an XGBoost approach with high performance ($R^2 = 0.92$ and $R^2 = 0.93$, respectively, in 5-fold

cross-validation). For ADME property modeling of plasma protein binding, our deep learning model (utilizing Saagar descriptors and LLM embeddings) achieved an R^2 of 0.76. We also predict the biotransformation rate constant with an R^2 above 0.9 using a deep learning approach. Finally, for toxicity endpoints such as carcinogenicity, a consensus model using Saagar descriptors predicted mammalian carcinogenicity with an AUROC of 0.971. Furthermore, for mutagenicity, a multitask deep learning model applied to Ames data achieved a mean balanced accuracy (B-Acc) of 0.85 across all strains. **Conclusions:** We present an integrated, modern QSAR pipeline that builds more accurate and interpretable models by leveraging advanced AI and novel descriptors. This pipeline has led to the development of over 100 models for ADME/Toxicity endpoints that are also accessible on our OrbiTox web platform (<https://orbitox.org/>).

PS 4396 Systematic Evidence Mapping of Per- and Polyfluoroalkyl Substances (PFAS): A Large Language Model-Based Toxicokinetic Database

Q. Chen^{1,2}, P. Wu^{1,2}, V. N. Kamineni^{1,2}, Z. Zhang^{1,2}, and Z. Lin^{1,2}. ¹Department of Environmental and Global Health, College of Public Health and Health Professions, University of Florida, Gainesville, FL; and ²Center for Environmental and Human Toxicology, University of Florida, Gainesville, FL.

Background and Purpose: Per- and Polyfluoroalkyl Substances (PFAS) are synthetic compounds ubiquitously present in the environment and living organisms, including humans. Understanding their toxicokinetic (TK) profiles is critical for exposure and human health risk assessment. The objective of this study was to develop a comprehensive PFAS TK database by leveraging large language models (LLMs) to systematically identify, extract, and compile concentration-time and tissue distribution data from published scientific literature. **Methods:** A systematic PubMed search (1980-August 2025) identified TK studies using terms related to pharmacokinetics, absorption, distribution, metabolism, excretion, toxicokinetics, and biodistribution, combined with species identifiers and 578 PFAS compounds curated by the U.S. EPA's Center for Computational Toxicology and Exposure. Full texts of eligible studies were processed with the GPT-oss-120b large language model to extract structured data on compounds, species, organs, exposure routes, and biological matrices. Extracted data were consolidated, deduplicated, manually validated, and integrated into a relational database supporting query and visualization by chemical, species, tissue, and TK parameter. **Results:** A total of 888 articles were screened, and 874 records covering 578 PFAS compounds were included. After manual verification for relevance to PFAS TK, 639 records were retained. Among these, perfluorooctanoic acid (PFOA) (n = 458), perfluorooctane sulfonic acid (PFOS) (n = 427), and perfluorononanoic acid (PFNA) (n = 222) were the most frequently reported compounds. Studies primarily involved humans (n = 280), rats (n = 199), fish (n = 138), and mice (n = 129). The most represented biological matrices were liver (n = 378), kidney (n = 238), and serum (n = 189). The resulting database enables systematic comparison of PFAS TK profiles across species and tissues to support data-driven modeling and risk assessment. **Conclusions:** This study demonstrates the feasibility of applying LLMs to systematically extract and organize PFAS TK data from scientific literature. The curated database integrates 639 curated records covering 578 PFAS compounds, species, and organs, providing the most comprehensive PFAS TK evidence resource to date. This LLM-assisted framework enhances data accessibility and supports evidence-based exposure and human health risk assessment for PFAS.

PS 4397 Leveraging continuous, real-time air quality monitoring in agricultural settings to improve health and economic outcomes

D. L. Palliyaguru^{1,2,3}, V. Kulasena Fernando², and M. R. Wijesinghe². ¹HealthSurveil LC, San Antonio, TX; ²University of Colombo, Colombo, Sri Lanka; and ³Fulbright US Scholar Program and the United States Fulbright Commission, Colombo, Sri Lanka.

Background and Purpose: Agriculture contributes to a high percentage of air pollutants globally. Air pollution in agricultural settings arise from pesticide and fertilizer usage, burning practices, as well as livestock and manure management. Aerosolized pollutants from these sources pose significant challenges to farmers, consumers, and ecosystems — not only through their direct effects but also by persisting in the environment for extended periods. A major challenge in measuring agricultural air pollution is capturing its highly variable, short-lived emissions from diffuse sources like fields. Pollutant levels shift rapidly with weather, soil, and farming practices — making reliable measurement difficult. **Methods:** We developed a high-resolution solar-powered internet of things (IoT) device integrated with remote sensing and real-time data aggregation capabilities. Through a U.S. Fulbright Scholar Award, we are currently collecting continuous, longitudinal data on parameters such as particulate matter (PM_{2.5}, PM₅ and PM₁₀), volatile organic compounds (VOC), temperature, humidity and NO_x in rice fields in Sri Lanka through the entire cultivation cycle from land preparation to post-harvest. **Results:** Our proof-of-concept testing studies indicate technical feasibility for long-term (>90 days) uninterrupted air quality monitoring and remote sensing. Preliminary data on pollutant levels during the first cultivation cycle will be presented. Machine learning and advanced data analytical models will be applied to make predictions on air quality events. These data will also be aligned with crop yield data as well as human, occupational and ecological health

outcomes data. **Conclusions:** Using these technologies for continuous, real-time air quality monitoring can help improve multiple health and economic outcomes in agricultural settings.

PS 4398 Chemical Effects in Biological Systems (CEBS): A Curated Toxicology Database with Extensive Data, Integrated Datasets, and User-friendly Interface.

C. Baril¹, Y. Liu², H. Cunney², G. Roberts², M. Stout², and C. Schmitt². ¹ASRC Federal Data Solutions, Beltsville, MD; and ²NIEHS, Research Triangle Park, NC.

Background and Purpose: The Chemical Effects in Biological Systems database (CEBS) contains extensive data from toxicology studies in support of the Division of Translational Toxicology (DTT) at the National Institute of Environmental Health Sciences (NIEHS), along with data from other studies of environmental health relevance. It encompasses a wide range of *in vivo* and *in vitro* data types at the individual animal/subject level, summary level, and conclusion level. CEBS incorporates active internal databases into a central data repository and provides high quality curated datasets with rich standardized metadata to better serve the scientific community. This effort includes harmonizing legacy terms and metadata with current standards and aligning terms to OBO (Open Biological and Biomedical Ontology). These curated datasets are updated with modern data from new research efforts, while novel datasets, like individual animal data for genetic toxicology studies, are also being made available through CEBS. **Methods:** Not applicable. Abstract is for non-laboratory or non-field Studies. **Results:** CEBS grants public access to data from over 10,000 studies for 12,750 test articles (chemicals, environmental agents). The CEBS user interface features a single search bar to query test articles, study identifiers, and other keywords related to study metadata and publications. Search results are consolidated onto dedicated pages for each test article, including study data, protocol, conclusions, publications, datasets, and links to related articles and projects. Data are also organized by endpoint into data collections and are accessible through a filterable and downloadable application at <https://cebs-ext.niehs.nih.gov/datasets/>, as well as in flat file format for computational analysis and AI applications at <https://doi.org/10.22427/NTF-DATA-110-021-001-000-6>. CEBS also offers guided applications for exploring and analyzing specific data types, such as gene expression, pathology (<https://cebs.niehs.nih.gov/organsites/>), etc. High-interest datasets, including TOX21 data, studies containing both genomic and apical endpoints with benchmark dose (BMD) analysis, and expression data, are readily accessible. **Conclusions:** Not applicable. Abstract is for non-laboratory or non-field Studies.

PS 4399 Exploring ToxCast: Enhancing Public Access to Targeted Bioactivity Screening Data

M. Feshuk¹, J. Abedini¹, K. Carstens¹, P. Kruse², and K. Paul Friedman³. ¹US EPA/OCSPP, Research Triangle Park, NC; ²NIEHS/DTT, Research Triangle Park, NC; and ³former US EPA/ORD, Research Triangle Park, NC.

Background and Purpose: Building confidence in new approach methods (NAMs) for prioritization and hazard characterization requires bioactivity data to be accessible and easily interpretable. The US Environmental Protection Agency Toxicity Forecaster (ToxCast) program makes *in vitro* medium- and high-throughput screening assay data publicly available for thousands of chemicals. The ToxCast pipeline (tcpl) is an open-source R package that stores, manages, curve-fits, and visualizes data while populating the linked MySQL database, invitrodb. Tcpl is released in versions at the Comprehensive R Archive Network (CRAN), available here: <https://CRAN.R-project.org/package=tcpl>. Vignettes describing an introduction to tcpl, database structure, assay annotation, processing, and data retrieval are available for users seeking additional details on the functionality of tcpl. The latest invitrodb release (v4.3, August 2025) includes data from 29 different assay sources, including the Toxicology in the 21st Century (Tox21) federal consortium, 717 assay platforms with 1,647 normalized assay readouts across a diverse biological space with over 500 mapped gene targets for 10,487 unique chemicals. Ongoing work is focused on augmenting and enhancing how ToxCast data can be accessed to address toxicology research questions for a diverse user group. **Methods:** The agile nature of the ToxCast project allows for integration and interoperability with other software applications. To accommodate recent software and database releases while supporting a growing ToxCast userbase, accessibility has been expanded within existing tools via updates to the CompTox Chemicals Dashboard (CCD, <https://comptox.epa.gov/dashboard/>), Computational Toxicology and Exposure Application Programming Interfaces (CTX APIs), and database downloads. **Results:** For a new user, the CCD presents a view of potency and relative efficacy metrics across ToxCast endpoints within the bioactivity module for chemicals of interest. Herein, users can sort, filter, and export results. In CCD v2.6, feature updates associated with invitrodb v4.2 include new visualizations, export options, and integration of analytical data to inform chemical applicability domain for *in vitro* screening. Users with more customized ToxCast data needs, or with a need to use tcpl for their own data processing, may wish to set up a personal instance of invitrodb and interact with the data via tcpl. The CTX Bioactivity API is the default connection for tcpl, allowing users to avoid large data downloads by accessing invitrodb programmatically via an API. APIs provide a read-only solution for users who require more flexibility than the CCD can provide. Additionally, comprehensive

assay documentation aligned with the OECD Guidance Document 211 has been released for all 1647 ToxCast endpoints, which improve ToxCast targeted bioactivity data interpretability. Visit the Exploring ToxCast Data webpage for more information. **Conclusions:** ToxCast provides a standard for consistent and reproducible data delivery for diverse, targeted bioactivity assay data with readily available documentation and a unified open-source software approach. Recent software and database updates expand the data delivery options. These updates enable use of ToxCast data within an integrated data landscape by a diverse group of users for a myriad of toxicology applications. *This abstract does not necessarily reflect U.S. EPA policy.*

PS 4400 Leveraging Machine Learning for Efficient Prediction of Acute Inhalation Toxicity of Environmental Chemicals

Y. Chen¹, K. Salazar¹, K. Mansour², and N. Kleinstreuer³. ¹U.S. EPA, Washington DC, DC; ²NTP Interagency Center for the Evaluation of Alternative Toxicological Methods, National Institute of Environmental Health Sciences, Durham, NC; and ³Division of Program Coordination, Planning, and Strategic Initiatives, National Institutes of Health, Durham, NC.

Background and Purpose: Assessing the acute inhalation toxicity of chemicals, indicated by median lethal concentration (LC50) values, is key for evaluating human health risks from exposure to environmental chemicals. Traditional *in vivo* testing methods are often lengthy and require significant resources, highlighting the need for developing computational models that can predict toxicity for a wide array of chemicals efficiently. **Methods:** In this research, we introduce a regression model based on machine learning to predict acute inhalation LC50 values in units of ppm and mg/L. We utilized a dataset consisting of 612 chemicals with experimentally determined 4-hour LC50 values as the training set. The Python RDKit library was employed to compute 210 molecular descriptors for each chemical, covering various physico-chemical properties. Initially, 15 machine learning algorithms were assessed for their predictive capabilities. The Extra Trees algorithm showed the most promising results, and further enhancements were made through recursive feature elimination (RFE), optimization of data transformation, and hyperparameter tuning to refine the model's accuracy. Furthermore, we evaluated the model's applicability domain using a chemical library of 47,768 environmental chemicals and the K-Nearest Neighbor method to assess its practical utility. **Results:** Two separate models were developed to predict LC50 values in ppm and mg/L. The final model for ppm achieved an R² of 0.619 and a root-mean-square error (RMSE) of 0.873, while the mg/L model achieved an R² of 0.538 with an RMSE of 0.904. Both models demonstrated reasonable applicability domains based on the selected threshold. **Conclusions:** The regression model based on machine learning presented in this study demonstrates significant accuracy and efficiency in predicting LC50 values. It provides a scalable and effective approach suitable for high-throughput toxicity screening. By incorporating machine learning, this model can streamline toxicological evaluations and lessen reliance on experimental testing, thereby aiding regulatory and safety efforts.

PS 4401 ChatAOP: AI-Driven Multi-omics Framework for Revealing New Modality Tox Mechanisms in Adverse Outcome Pathways

D. Hahm, and Z. Liu. Boehringer Ingelheim, Ridgefield, CT.

Background and Purpose: The Adverse Outcome Pathway (AOP) framework plays an important role in organizing toxicological information and enabling early risk mitigation during drug development. Increased integration of multi-omics datasets with advanced AI methodologies will enhance AOP generation and derisking of new molecular entities in nonclinical contexts. **Methods:** Herein, we developed ChatAOP, an AI-driven framework designed to predict and prioritize mechanisms underlying new molecular entities through the integration of diverse data sources. The platform combines multi-omics datasets; curated relationships among proteins, diseases, and adverse effects, existing information from the AOP-Wiki, and human protein-protein interactions from the STRING v11 database. This integration enables localization of molecular initiating events, key events, and corresponding outcomes to specific tissues and cell types. Additionally, ChatAOP incorporates a prompt-based interface to provide an intuitive, user-friendly experience for users. **Results:** To validate the performance of the proposed ChatAOP framework, we utilized in-house multi-omics data from patient populations to uncover specific toxicological mechanisms across different stages of chronic disease progression. This analysis identified more than 300 differentially expressed genes DEGs associated with distinct disease states and generated a list of potential Adverse Outcome Pathways AOPs linked to toxicological liabilities. Specifically, the analysis uncovered AOPs linking key mechanistic pathways to distant organ toxicities: 1) ROR2 to Diabetic Nephropathy via podocyte effacement and glomerular basement membrane degradation, 2) IL6 to Aortic Dissection via the inflammatory/remodeling cascade and loss of structural integrity, and 3) THRB to Neurodevelopmental Disorders via impaired neural circuit formation. **Conclusions:** The proposed ChatAOP framework represents a promising tool for safety target identification, hypothesis generation for potential safety mechanisms, and the discovery of novel biomarkers and alternative therapeutic indications for disease states.

A. Schaffert, A. Serra, M. Torres Maia, and D. Greco. Tampere University, Tampere, Finland. Sponsor: B. Meek

Background and Purpose: The Safe and Sustainable by Design (SSbD) framework aims to assess the holistic impact of a chemical throughout their life cycle. However, current impact assessment methodologies mostly operate in isolation, lacking integration of human and ecotoxicity mechanistic insights with environmental, social, and economic factors. To address this gap, this study developed a unified, mechanistically grounded framework that strengthens holistic understanding of chemical impacts within SSbD by expanding the Adverse Outcome Pathway (AOP) framework with environmental and socioeconomic pathway structures. The work specifically assessed how these novel Impact Outcome Pathways (IOPs) could enable more coherent cause-effect reasoning across different types of impacts relevant to chemical design. **Methods:** Established cause-effect connections from life cycle assessment and socioeconomic literature were extracted to develop pathway structures analogous to AOPs. These connections, formalised as Key Events (KEs), were used to build an interconnected network consisting of mechanistic pathways for environmental, health, social, and economic outcomes, termed Impact Outcome Pathways (IOPs). A natural language processing (NLP) approach was applied to link mechanistic events from AOP-Wiki entries with the established IOP KEs, thereby identifying cross-dimensional Key Event Relationships (KERs) in which safety-related KEs connect to environmental or socioeconomic KEs. In addition, a proof-of-concept case study is planned to evaluate whether integration of NAM-derived mechanistic data into the IOP network provides more holistic, decision-relevant information than conventional SSbD assessment. **Results:** The resulting network contains over 450 nodes (KEs) and 650 KERs. Shared KEs connect both within individual environmental, health, social, and economic domains and across domains, highlighting cross-dimensional influences for integrated assessment. NLP-based mapping captured connections between AOP KEs and IOPs that can be represented either as direct KERs or as modulating factors. Cross-dimensional KERs were observed between all domains, illustrating how highly interconnected chemical impacts become when described through detailed mechanistic pathways. **Conclusions:** The IOP framework provides a coherent basis for enhancing SSbD by embedding mechanistic toxicology into broader sustainability assessment. This approach supports more integrated and holistic evaluation of chemical impacts by linking AOP-structured, NAM-derived evidence directly to environmental, health, social, and economic outcomes.

PS 4403 Evaluation of a comprehensive and flexible behavior analysis tool for neurotoxicity testing in larval zebrafish (NeuroBEAT)

J. Raab, S. Gutsfeld, and T. Tal. Helmholtz Centre for Environmental Research - UFZ, Leipzig, Germany.

Background and Purpose: There are hundreds of thousands of chemicals in commerce, yet less than 150 chemicals have been tested for their potential to harm the developing nervous system using OECD-approved test guidelines. This data gap largely reflects the absence of OECD-approved alternative methods for developmental neurotoxicity (DNT) testing. Zebrafish larvae have emerged as a promising alternative model for DNT testing. Zebrafish behavior in response to various light or acoustic stimuli can be used as a functional readout for neurodevelopment. However, progress in this field is hindered by the lack of standardized, user-friendly analysis pipelines capable of visualizing automated behavioral data, statistically comparing treatment groups, and deriving toxicologically relevant metrics such as AC₅₀ values. Here, we introduce a novel and adaptable analysis pipeline which can cover a wide range of commonly used light-dark transition assay designs, as well as new human-relevant endpoints, including non-associative habituation which is a conserved form of learning and memory retention. **Methods:** Zebrafish motor activity was quantified using a video-based tracking system (Δpixels/second). Timeseries data comprised of distance moved over time (phase data, habituation data) and immediate startle responses to light or acoustic stimuli (1 sec post-stimulus) were analyzed. Timeseries data involved repeated measures of the same larva and were analyzed using generalized additive mixed effects models (GAMMs). Startle responses consisted of single measurements per larva and were modeled using linear mixed effects models (LMMs). For GAMM-modeled endpoints, the Fréchet distance between fitted splines was used to capture differences between treatment groups and controls regardless of effect direction. Concentration-response data for all endpoints were competitively fitted using 10 different curve-fitting models included in the US EPA tcpl v3.0 pipeline. Toxicologically relevant metrics were extracted from the winning model, some of which, including AC₅₀ and scaled top values, were used for comparison with *in vitro* ToxCast assays. **Results:** Both GAMMs and LMMs delivered accurate results and captured diverse behavioral responses in zebrafish behavior including altered locomotion, altered startle responses and habituation learning. R²-values ranging from 0.6-0.85. AC₅₀ values derived from concentration-response models aligned well with *in vitro* ToxCast assays data and in some cases suggest enhanced sensitivity. **Conclusions:** We developed a novel, adaptable pipeline to analyze automated zebrafish behavior data. We used a range of example chemicals causing different behavior effects to demonstrate the robustness and flexibility of our mixed effects modeling strategies. For all endpoints tested, concentration-response analyses produced toxicologically meaningful metrics independent

of effect direction. Overall, implementation of a flexible and standardized analysis pipeline could enhance confidence in using zebrafish behavioral data to predict the neurotoxic potential of environmental chemicals and pharmaceutical compounds.

PS 4404 Multi omics integration of transcriptional and metabolic responses to DILI compounds across human liver models

T. Danilyuk¹, E. J. Burgers¹, F. M. Zickgraf², P. Ternes³, N. Rocker³, P. J. Bouwman¹, J. B. Beltman¹, G. Callegaro¹, and B. van de Water¹. ¹Leiden University, Leiden, Netherlands; ²BASF SE, Ludwigshafen, Germany; and ³BASF Metabolome Solutions GmbH, Berlin, Germany.

Background and Purpose: Cellular stress responses rely on coordinated transcriptional programs where co-expressed genes support specific functions. Yet, transcriptomics captures only one regulatory layer. Post-transcriptional mechanisms—including mRNA stability, translational control, and protein modifications—further shape outcomes, meaning gene expression changes do not always predict metabolic consequences. Integrating transcriptomics with metabolomics provides a more complete mechanistic view by linking regulatory networks to biochemical effects. Drug-induced liver injury (DILI) remains a major cause of drug failure and withdrawal. Mechanistic understanding in human-relevant systems requires quantitative frameworks connecting molecular initiating events (MIEs) to adverse outcomes. This study integrates targeted transcriptomics and metabolomics across three human liver models to characterize DILI mechanisms and evaluate the sensitivity and reproducibility of omics-based points of departure (PODs) for risk assessment. **Methods:** Three Class A DILI compounds—nitrofurantoin, diclofenac, and ketoconazole—were profiled in primary human hepatocytes (PHHs), HepG2 cells, and hiPSC-derived hepatocyte-like cells (HLCs). Targeted transcriptomics used the TempO-Seq platform, and broad targeted metabolomics applied a high-throughput LC-MS/MS panel covering ~250 metabolites across 13 classes. HepG2 cells were analyzed in time-course (3-48 h, two doses) and dose-response (five to six concentrations, 24 h) formats, while HLCs and PHHs were assessed in 24 h dose-response series. Differentially expressed genes showed clear time- and dose-dependent patterns and were projected onto the PHH Toxicogenomics Mapper (TXG-MAPr) framework containing 398 functionally annotated gene modules. This module-based approach reduced data complexity and improved biological interpretability, enabling cross-system comparison. Spearman correlations between metabolites and module eigen-gene scores identified strongly associated metabolite-gene network pairs. For example, oxidative stress activation corresponded to negative correlations between glutathione (GSH) depletion and modules enriched for NRF2-driven (modules 144, 337) and ATF4-regulated (module 295) genes. Benchmark dose (BMD) modeling of 24 h dose-response data yielded transcriptomic (tPOD) and metabolomic (mPOD) points of departure. Module-level tPODs were the median BMD of genes within enriched modules (≥3 genes covering ≥5% of membership). Individual metabolite BMDs were defined as mPODs. For correlated metabolite-gene pairs, tPODs and mPODs were compared to determine which omics layer responded at lower concentrations and assess POD reproducibility across systems. **Results:** Correlation-based integration successfully linked metabolic shifts with transcriptional network activation across all liver models, demonstrating the broad metabolomics panel's utility in different contexts. Time- and dose-dependent responses confirmed conserved activation of oxidative stress, ER stress, and mitochondrial dysfunction modules across systems, though magnitudes varied. Omics-based POD modeling showed that comparing mPODs and tPODs for correlated metabolite-gene networks identified the more sensitive regulatory layer, providing insight into cross-system consistency and endpoint uncertainty. **Conclusions:** This integrative multi-omics framework aligns metabolic and transcriptional changes across human liver systems, linking metabolite alterations to activation or repression of defined gene networks. It enhances interpretability of high-throughput NAM data and supports quantitative evaluation of sensitivity and reproducibility across PHH, HepG2, and HLCs. By comparing tPODs and mPODs, this study establishes a foundation for selecting the most sensitive omics layer for protective POD derivation, advancing mechanism-based safety assessment in next-generation chemical testing strategies.

PS 4405 Genome-scale CRISPR Screening Identifies C18orf32 as a Novel Regulator of Lipid Metabolism Mediating PFOA-induced Liver Toxicity

C. Kim, M. Tagmount, W. Barbazuk, R. Bacher, Z. Zhu, and C. D. Vulpe. University of Florida, Gainesville, FL.

Background and Purpose: Perfluorooctanoic acid (PFOA) remains a public health concern due to its persistence in the environment, despite global production bans. Epidemiological, animal, and *in vitro* studies have consistently linked PFOA exposure to liver toxicity characterized by lipid dysregulation; however, the molecular mechanisms underlying these adverse effects in humans remain poorly understood. Conventional correlative approaches cannot establish causal gene-phenotype relationships, highlighting the need to identify functional genetic determinants of PFOA-induced lipid perturbations. **Methods:** To address this gap, we employed an integrated functional toxicogenomics framework combining CRISPR screening (target gene identification), target validation, and assessment of target-derived cellular and

molecular phenotypes. **Results:** From a genome-wide CRISPR screen in HepG2/C3A human liver cells, we identified 319 candidate genes (140 sensitive and 179 resistant) that modulate PFOA toxicity. Among these, *C18orf32*—a lipid droplet (LD)-associated protein and the top resistant candidate—was selected for further mechanistic investigation. Targeted knockout (KO) of *C18orf32* conferred marked resistance to PFOA, accompanied by reduced LD accumulation under exposure conditions, suggesting a functional role of *C18orf32* in lipid dysregulation. To elucidate molecular mechanisms underlying the resistance, we conducted systematic transcriptomic profiling of WT, *C18orf32* KO, WT+PFOA, and *C18orf32* KO+PFOA cells. *C18orf32* KO caused extensive gene expression reprogramming, with over one-third of coding genes differentially expressed. Notably, lipid metabolic pathways including cholesterol metabolism, PPAR signaling, fatty acid metabolism, and peroxisomal functions—known mediators of PFOA-induced hepatotoxicity—were significantly downregulated in *C18orf32* KO cells. **Conclusions:** Collectively, our results identify *C18orf32* as a previously unrecognized regulator of hepatic lipid homeostasis and a key molecular determinant of PFOA-induced lipid dysregulation and liver toxicity in humans.

PS 4406 Tire antiozonants 6PPD and its quinone derivative effects on *Saccharomyces cerevisiae*

E. Braun, M. Metcalf, and K. Kim. Missouri State University, Springfield, MO.

Background and Purpose: N-(1,3-dimethylbutyl)-N'-phenyl-p-phenylenediamine or 6PPD is a tire coating that prevents the degradation of rubber bonds. When introduced to atmospheric ozone, 6PPD oxidizes to 6PPD-Quinone (6PPD-Q). Both 6PPD and 6PPD-Q have been found in road water runoff, dust particles, and various rubber products. The introduction of 6PPD into the environment has also led to a deadly impact on the coho salmon population among other aquatic species. The discovery of the toxicological effects of 6PPD and its quinone derivative is new and not thoroughly understood. Understanding the underlying mechanism in various model organisms is essential to further our knowledge base and help establish regulations on the use of these chemicals. **Methods:** 6PPD and 6PPD-Q were tested for toxicity in *Saccharomyces cerevisiae* yeast. The yeast proliferation was determined after 6 hours using spectrophotometry. Mitochondrial staining was also employed to visualize 6PPD and 6PPD-Q's effect on the mitochondrial structure and function. Furthermore, RNA sequencing was completed for both 6PPD and 6PPD-Q to analyze the genes, pathways and proteins effected by each chemical. **Results:** The yeast cell viability showed a stepwise decrease when exposed to 6PPD. When completing the same experiment for 6PPD-Q the optical density for the yeast increased in a step wise manner when exposed to 100, 50, and 25 μ M of 6PPD-Q. Mitochondrial staining was completed for 6PPD to validate the decrease in cellular growth. The fluorescence intensity of treated cells compared to the non-treated control showed a significant decrease indicating a reduction in mitochondrial activity. RNA sequencing was completed for both 6PPD and 6PPD-Q. For both treatments oxidative phosphorylation KEGG pathway genes were downregulated. 6PPD caused an upregulation in pyruvate metabolism while 6PPD-Q caused an increase in starch and sucrose metabolism. **Conclusions:** 6PPD and 6PPD-Q differentially effect *Saccharomyces cerevisiae* through various pathways. Future studies will focus on mitochondrial staining for 6PPD-Q and rtPCR to validate the RNA sequencing data.

PS 4407 The cytotoxic effect of Trichloroethylene (TCE) involves both the extrinsic and intrinsic apoptosis pathways via potential binding of TCE to Calmodulin and Fas receptor in human neuronal cells

J. Li¹, W. Zhu², and B. Li³. ¹Dept. of Chemistry, University of Rochester, Rochester, NY; ²Neuroscience Research Institute, SUNY College at Old Westbury, Old Westbury, NY; and ³Dept. of Oncology, Weill Cornell Medical College, New York, NY. Sponsor: B. Li, American Association for Cancer Research

Background and Purpose: Trichloroethylene (TCE) is a common environmental pollutant. Environmental exposure to TCE is associated with a variety of neurological effects which was supported by findings that TCE affected the mitochondria in human nerve cells, causing degeneration. There is a relatively small body of evidence supporting the connection between TCE and apoptosis. This study is to determine the role of TCE in apoptosis in neuron cells/tissues and the potential target(s) of TCE. **Methods:** TCE was obtained from Sigma-Aldrich, pre-dissolved in 50 μ L of DMSO and added to 10 mL of culture medium. Human neuronal cells (HTB-11) were cultured per ATCC guideline and treated with TCE of different concentrations (0.5 μ M, 5 μ M and 50 μ M) for 24 hours. To assess environmental effects, ganglia were isolated from blue mussels (*Mytilus edulis*) and exposed to the same concentrations of TCE. According to the manufacture's instructions (Sigma-Aldrich), cell viability was tested in MTT assays and cell membrane permeability was tested in LDH assay for cytotoxicity levels. Caspase 3, caspase 8 and caspase 9 activity were measured using the ApoAlert caspase fluorescent assay kit (Clontech). All experiments were repeated 3 times. P-values, calculated from two-tailed student t-tests and one-way ANOVA. Molecular docking was performed to identify potential binding target molecules and intermolecular interaction. Chemical structure of TCE was obtained from PubChem compound database. A total of 23 distinct PDB coordinates of 9 different protein compounds from the apoptosis pathway were downloaded from Protein Data Bank. Software PyRx was used for virtual screening of ligand-receptor interactions.

AutoDock Vina and AutoDock 4.2 were used as docking software. For visualization and analysis of the docked results, Discovery Studio Visualizer software was used. **Results:** In HTB-11 cell line, there was a dose-response relationship between TCE and cell viability, with survival rate of 89% ($p < 0.05$), 82% ($p < 0.05$) and 70% ($p < 0.01$) at 0.5 μ M, 5 μ M and 50 μ M of TCE respectively. In *M. edulis*, ganglia tissues exhibited $59\% \pm 3.7$ dead cells at 50 μ M compared with $14\% \pm 2.1$ in controls ($p < 0.001$). LDH assay showed that TCE caused a small and negligible damage to cell membrane ranging from 0.7% to 1.9% ($p > 0.05$). To investigate the possible role of TCE in apoptosis pathway, caspase assays were performed. At 0.5 μ M, 5 μ M, and 50 μ M of TCE, caspase 3 activity in HTB-11 cells increased by 15% ($p < 0.05$), 28% ($p < 0.01$), and 4% ($p < 0.05$), respectively. To determine the involved pathway, caspase 8 and caspase 9 activities were performed as caspase 8 mostly works in the extrinsic pathway and caspase 9 in the intrinsic pathway. In HTB-11 cells, there was a dose-dependent induction of both caspase 8 and caspase 9 activities by TCE. At the highest level of 50 μ M of TCE, caspase 8 and caspase 9 activities increased by 443% ($p < 0.01$) and 164% ($p < 0.01$) respectively. Molecular docking experiments that the two most stable ligand-receptor complex were calmodulin (PDB ID 3ewt) with binding energy of -4.2 kcal/mol and Fas receptor (PDB ID 3ezq), with binding energy of -3.9 kcal/mol, both of which have been shown to be critically involved the extrinsic apoptosis pathway (Fas receptor) and the cytochrome c/mitochondria-mediated intrinsic pathway (Calmodulin) although the Calmodulin is less established than Fas receptor. **Conclusions:** The results demonstrated that the cytotoxic effect of TCE involves both intrinsic and extrinsic apoptosis pathways in human neuronal cell line and marine invertebrate ganglia. The apoptotic effect is likely mediated through a novel mechanism in which TCE directly binds to calmodulin molecule and Fas receptor. As TCE is found to be associated with diseases of nerve system, the present study could potentially lead to development of targeted therapeutic strategies.

PS 4408 Concentration-dependent induction of proliferation and oxidative stress by phthalates (DEHP and MEHP) in RWPE-1 prostate epithelial cells

Z. A. Kasuske, J. E. Cañas-Carrell, and K. P. Singh. Texas Tech University, Department of Environmental Toxicology, Lubbock, TX.

Background and Purpose: Epidemiological studies suggest a strong association between phthalates exposure and proliferative diseases in the prostate including prostate cancer. Previous studies have also shown increased proliferation of prostate cancer cells via phthalate exposure. Increased cell proliferation is a hallmark of carcinogenesis. However, whether phthalates can cause increased proliferation in normal prostate epithelial cells is not known. Therefore, the objective of this study was to evaluate the effects of both parent compound (DEHP) and its primary metabolite (MEHP) on the proliferation of normal prostate epithelial cells. The role of oxidative stress and the molecular mechanism through which these phthalates exert their effects on these cells was further investigated. **Methods:** RWPE-1 cells, an immortalized prostate epithelial cell line derived from normal prostate epithelium, were exposed to the phthalate di-2-ethylhexyl phthalate (DEHP), and its active metabolite mono(2-ethylhexyl) (MEHP) separately at various concentrations (0.1, 1, 10, and 100 μ M) for 24 and 72 h. Cell viability was assessed using MTT assay and oxidative stress was assessed using DCFH assay. Cell cycle via flow cytometry was used to further confirm the effects of these phthalates on cell proliferation. **Results:** RWPE-1 cell exposure to DEHP and MEHP at concentrations of 0.1, 1, 10, and 100 μ M, resulted in a dose-dependent decrease in cell viability. There was also a significant increase in ROS production across all respective treatments for both DEHP and MEHP. Using flow cytometry there was an observed agonist and antagonist dose-dependent relationship between cell cycle arrest and cellular proliferation for the respective treatments. **Conclusions:** This study, for the first time, revealed that phthalates can induce proliferation at lower concentrations whereas growth inhibition/cytotoxicity occurred at higher concentrations in normal prostate epithelial cells. Cell cycle analysis further confirmed the increased proliferation observed by MTT assay. A concentration-dependent increase in ROS production as well as an increase in population of S phase cells due to phthalate exposure, and attenuation of these effects by antioxidant NAC, further suggests the role of oxidative stress on proliferation and cytotoxicity in RWPE-1 cells. To further analyze the effects of these phthalates at the molecular level, RNA and proteins have already been collected and are currently being analyzed to determine effects on gene expression, inflammatory cytokines, and growth signaling pathways including estrogen/androgen receptor-dependent signaling.

PS 4409 The Effects of Diisononyl Phthalate and its Primary Metabolite on Non-malignant Colonocytes

S. V. Dolphin, Z. S. Bomstein, K. F. Allred, and C. D. Allred. University of North Carolina Greensboro, Greensboro, NC.

Background and Purpose: Diisononyl phthalate (DiNP) is a commonly used plasticizer in a variety of PVC based products, including food packaging. Estimates of average human exposure to DiNP fall between 1-2 μ g/kg/bw/day, with the 95th percentile of exposure estimated between 5-10 μ g/kg/bw/day. DiNP is readily hydrolyzed in the gastrointestinal tract to its primary metabolite mono-isononyl phthalate

(MiNP), however, MiNP is not further metabolized until it reaches the liver. Because the gastrointestinal tract is the primary route of exposure to these phthalates and previous research has primarily focused only on DiNP, it is important to understand the effects of both DiNP and MiNP on colonic epithelia. **Methods:** Young adult mouse colonocyte (YAMC) cells were exposed to varying concentrations of DiNP or MiNP between 0.01 μ M and 100 μ M in multiple assays to assess cell growth, proliferation measured via 5-bromo-2-deoxyuridine (BrdU) incorporation, apoptosis measured via caspase 3/7 release, and gene expression measured via RTqPCR. **Results:** Reductions in cell number were observed after 72 hours at DiNP concentrations of 10 μ M and 100 μ M, and MiNP concentration of 100 μ M. A reduction in cell proliferation was also seen at 100 μ M of each phthalate. Interestingly, a reduction in apoptosis was seen at the 100 μ M concentration of each phthalate. There were also significant changes in mRNA expression in genes related to cell cycle regulation and apoptosis. **Conclusions:** Both DiNP and MiNP decrease cell number, proliferation, and apoptosis in nonmalignant mouse colonocytes. There were also significant changes in gene expression at an environmentally relevant dose (0.01 μ M). Our results suggest that these phthalates can alter colonic cell physiology in an *in vitro* model that we have shown to closely mimic colonocyte response to toxicants *in vivo*. Ongoing analyses to better understand these changes include assessing the potential cytotoxicity of DiNP and MiNP, their potential effect on cell senescence, and their effect on cell cycle progression.

PS 4410 Deconjugation of Polychlorinated Biphenyl Sulfates to Hydroxylated PCBs by Anaerobically Cultured Mouse and Human Gut Microbiota

C. Rong¹, J. Lim², X. Li³, H. Lehmler³, A. J. Annalora¹, and J. Y. Cui¹. ¹Oregon State University, Corvallis, OR; ²Institute for Systems Biology, Seattle, WA; and ³University of Iowa, Iowa City, IA.

Background and Purpose: Polychlorinated biphenyls (PCBs) are persistent environmental contaminants linked to neurotoxicity, hepatotoxicity, endocrine disruption, and cancer in humans. The gut microbiome is increasingly recognized as a critical player in xenobiotic metabolism, and it displays wide variations across individuals due to differences in human genetics, diet, lifestyle, and exposures. We hypothesize that variations in individual susceptibility to PCB toxicity may be partly due to differences in gut microbiome composition and function, which can influence the metabolism of PCBs. To test this hypothesis, the present study cultured fecal microbiomes in anaerobic conditions that mimic the gut environment. The aim was to investigate the metabolism of PCB sulfates, which are major metabolites produced during the hepatic phase II conjugation and detoxification processes, into hydroxylated PCBs (OH-PCBs), which are typically more toxic. The liver metabolizes PCBs through Phase I oxidation to hydroxylated metabolites, followed by Phase II conjugates the metabolites with sulfate to form water-soluble conjugates that are excreted. **Methods:** Anaerobic incubations were performed in a 48-well plate using a Whitley DG250 Anaerobic Workstation at 37 °C. Two groups of human fecal microbiome communities were diluted in phosphate buffered saline containing L-cysteine as a reducing agent and resazurin as an oxygen indicator (50 mg fecal content/mL anoxic PBS). To determine the necessity of microbiome in PCB metabolism, large intestinal content from germ-free or conventional C57BL/6 wild-type mice (n=3 per group) were used. The human and mouse fecal microbiomes (1 mg/mL) were incubated with either dimethyl sulfoxide (DMSO; control), or a mixture of PCB3, 11, 25, and 52 sulfates (0.71 mM each, totaling 2.83 mM) in DPBS buffer for 6 hours. The reactions were then collected and quenched with formic acid to stop enzymatic activity. Analysis of PCB metabolites was performed using an Agilent 1290 Infinity II UPLC system coupled to a SCIEX Triple Quad 7500 mass spectrometer. **Results:** Both human and conventional mice microbiomes enzymatically hydrolyzed PCB sulfates. Higher chlorinated PCB sulfates were metabolized more readily. Gut microbiota from male conventional mice showed greater conversion of PCB sulfates to OH-PCBs than those from females, and human microbiomes metabolized PCB sulfates more extensively than mouse microbiomes, with clear interindividual variability linked to microbial community composition. To identify tractable microbial targets to interrupt this reactivation, we performed a bioinformatics survey of gut sulfatases and their anaerobic sulfatase-maturing enzymes (anSMEs). We compiled 2,161 nonredundant sulfatases, which were highly sequence-diverse, and 245 anSMEs with conserved radical-SAM/SPASM motifs that mapped to the Unified Human Gastrointestinal Protein catalog with >99% representation. Alignment of translation-initiation regions (~30 to +18 nt) revealed a tight 9-nt start-site consensus for anSMEs but substantial divergence across sulfatases, indicating that anSMEs are more amenable to pan-antisense targeting, whereas discrete sulfatases in dominant taxa will require strain-specific designs. Guided by these patterns, antisense PNA-CPP candidates are now being designed and prioritized for anaerobic *ex vivo* testing, with the goal of transiently suppressing desulfation and limiting the conversion of PCB sulfates to OH-PCBs while preserving community structure. **Conclusions:** Our study demonstrates that the gut microbiome is a critical driver of PCB sulfate metabolism, with clear interspecies, interindividual, and sex-dependent differences in the conversion of PCB sulfates to more toxic OH-PCBs. By coupling anaerobic *ex vivo* incubations with a targeted bioinformatics survey of sulfatases and anSMEs, we identify microbial sulfatase pathways as actionable nodes for intervention and establish anSMEs as particularly attractive candidates for pan-antisense inhibition. These findings lay the groundwork for non-antibiotic, precision strategies to dampen xenobiotic reactivation in the gut and ultimately mitigate PCB-associated toxicity.

PS 4411 Spatial Transcriptomic Mapping of Toxicity Differences Between Benzo[a]pyrene and an Alkylated Derivative

S. Stinson, M. L. Morshead, L. Truong, and R. L. Tanguay. Oregon State University, Corvallis, OR.

Background and Purpose: Polycyclic aromatic hydrocarbons (PAHs) are a ubiquitous class of petro- and pyrogenic-derived contaminants characterized by at least two fused aromatic rings. Many PAHs are known to act through the Aryl Hydrocarbon Receptor (AHR), which acts as a transcription factor responsible for activating downstream genes primarily responsible for metabolizing xenobiotics. Current regulatory practices often group PAHs by their parent compound, though functional group additions to the parent can result in differential toxicity. Of these derivatives, alkylated forms are among the most environmentally abundant. A developmental screen of Benzo[a]pyrene (BaP), one of the most studied PAHs to date, and 6 alkylated derivatives revealed differential toxicity. Of these, only 8-methylbenzo[a]pyrene (8MBaP) produced significant adverse morphological outcomes. These endpoints emerge at 72 hours post fertilization (hpf) at low nominal concentrations of 0.133 μ M. At similar concentrations and developmental timepoints, BaP produced no morphological abnormalities, yet both BaP and 8MBaP have previously been shown to act through AHR2 in zebrafish. This shows that the addition of a single methyl group to BaP significantly impacts *in vivo* toxicity while activating the same receptor. To begin to understand what might be driving these differential responses to BaP and 8MBaP exposures, we combined previously collected, phenotypically anchored bulk RNA sequencing with spatial transcriptomics. **Methods:** Specific pathogen-free wild-type 5D strain zebrafish from the Sinnhuber Aquatic Research Laboratory were used for all studies following IACUC-approved guidelines. At 8 hours post fertilization (hpf), embryos were plated in 96-well plates and exposed to 1% DMSO, 13.3 μ M Benzo[a]pyrene, or 13.3 μ M 8MBaP via an HP D3000e digital dispenser and kept in the dark. At 72 hpf, larvae were euthanized on ice, arranged in 10x10 mm cubes of Optimal Cutting Temperature compound, flash-frozen, and sectioned using a cryotome. Two sagittal sections of tissue were placed on Curio-Seeker™ spatial transcriptomic slides with two adjacent H&E. cDNA was generated, followed by library preparation, bead purification, and QC. Samples were sequenced using a NovaSeq 6000 with a read depth of 2 billion reads per tile. The Latchbio bioinformatic pipeline was used to align and match associated bead barcodes, with Seurat being used to identify unique clusters of cells. Spatial visualization was performed using the Excelxgene application, comparing larvae that had similar spatial orientation and representation of cell and tissue types. **Results:** AHR2 related gene transcripts, such as *cyp1a*, *cyp1b1*, *cyp1c1*, *sult6b1*, and *slnr* were all overexpressed in both exposed groups. In all cases, the 8MBaP exposed larvae had higher fold change induction compared to that of BaP. Spatial analysis revealed that these transcripts had increased expression in the liver, whereas 8MBaP had increased expression in the liver and cartilage-containing cells lining the trunk. Transcripts such as *foxq1a* and *pigm* were highly expressed in 8MBaP exposed larvae, especially in craniofacial cartilage. Other genes uniquely overexpressed in the 8MBaP-exposed larvae were isolated to liver cells such as *arg2*, *pck1*, and *agxtb*. Shared under-expressed genes between BaP and 8MBaP were *Krt4* and *Krt15* in the cartilage and skeletal muscle spanning the trunk, with *ctyl1* being uniquely under-expressed in 8MBaP. **Conclusions:** The spatial transcriptomics showed that AHR2 activation was present in both BaP and 8MBaP, but the magnitude and spatial distribution differed, in congruence with previous bulk RNA sequencing data. Cartilage cells appear to be highly responsive to 8MBaP than to BaP especially with respect to canonical AHR2 genes and genes associated with cellular development, cell migration, and membrane stability. Liver transcripts from 8MBaP-exposed larvae showed an increase in inflammatory stress response and metabolic dysfunction. Transcripts involved in cytoskeletal and epithelial structure were all under-expressed throughout muscle and cartilage cells, suggesting dysregulated tissue development. This data suggests 8MBaP causes increased dysregulation of various genes associated with drug metabolism, cell migration, cellular structure, and stress, with a particular susceptibility in cartilage-containing cells throughout the entirety of the larvae.

PS 4412 Toxicity Profiling of Polycyclic Aromatic Hydrocarbon Mixtures in Primary Human Bronchial Epithelial Cells

R. Juarez Murguía, M. Allison, A. Biggerstaff, R. Valdez, J. M. Pennington, and S. C. Tilton. Oregon State University, Corvallis, OR.

Background and Purpose: Individuals are commonly exposed to polycyclic aromatic hydrocarbons (PAHs); a class of environmental contaminants composed of benzene rings derived from incomplete combustion of natural and manufactured organic material. There is strong evidence supporting that PAHs are known to cause detrimental effects such as lung cancer, irritation, and difficulty breathing. Individuals are predominantly exposed to PAHs in complex mixtures in the environment; however, limited toxicity data exists for PAH mixtures, as well as many of the less commonly studied PAHs in environmental samples. This study examines and compares cytotoxicity, oxidative stress, and mitochondrial membrane potential among four PAH mixtures and their 25 derived chemical components originating from air and water samples obtained near sources of PAH exposure at wildfires and contaminated creosote sites. We hypothesize that toxicity of the environmentally relevant PAH mixtures is reflective of toxicity of the individual components due to chemical interactions and the potential for additive response. **Methods:** Primary human bronchial epithe-

lial cells (HBEC) were treated with mixtures and their individual components in a dose-response (0-600 μ M) for 24 hours and then assessed for cytotoxicity by release of lactate dehydrogenase (LDH), oxidative stress by formation of reactive oxygen species (ROS) with 2',7'-dichlorofluorescein diacetate (DCFDA), and mitochondrial membrane potential. **Results:** Overall, toxicity was observed in a chemical-specific manner across dose and endpoint contributing to the response of PAHs mixtures. **Conclusions:** These studies are the first to assess toxicity of these environmentally-relevant PAH mixtures in HBEC and contribute to our understanding of how PAHs contribute to toxicity in environmental mixtures.

PS 4413 Sex-Specific Regulation of Hepatic Cytochrome P450 Enzymes by Arsenic Trioxide in Mice: Insights into Drug Metabolism and Hepatotoxicity

S. Elmahrouk, and A. El-Kadi. University of Alberta, Edmonton, AB, Canada.

Background and Purpose: Arsenic trioxide (ATO) is a chemotherapeutic agent used in acute promyelocytic leukemia, but its clinical application is limited by dose-dependent hepatotoxicity primarily driven by oxidative damage and changes in hepatic gene expression. CYP enzymes play a key role in the metabolism of many therapeutic agents, and alterations in their activity can impact drug efficacy and safety. Moreover, sex-based differences in CYP expression influence hepatic drug metabolism, susceptibility to tissue injury, and cancer progression. To elucidate sex-specific hepatic responses to ATO, we investigated the expression patterns of key CYP in male and female C57BL/6 mice following ATO treatment. **Methods:** Male and female C57BL/6 mice received a single intraperitoneal dose of ATO (8 mg/kg). Hepatic CYP mRNA levels were quantified at 6- and 24-hours post-treatment, and protein expression was assessed at 24 hours. **Results:** After ATO exposure, both sexes showed significant upregulation of CYP1A1 mRNA expression. Female mice exhibited pronounced suppression of CYP2C, CYP3A, CYP4A, and CYP4F isoforms; notably, CYP4A10 and CYP4A14 decreased in females while increasing in males. Several CYP2J isoforms demonstrated sex-specific regulation, with CYP2J5 and CYP2J6 suppressed in females, whereas CYP2J9, CYP2J11, and CYP2J13 showed induction. These findings highlight strong sexual dimorphism in hepatic CYP regulation following ATO treatment. **Conclusions:** ATO induces marked, sex-specific modulation of hepatic CYP enzymes, impacting pathways critical for drug metabolism and hepatotoxic risk. The data highlight the importance of considering sex-based biological differences in optimizing ATO dosing regimens and reducing adverse effects in cancer patients. Future studies should further explore mechanistic pathways underlying these differences to enhance personalized therapy.

PS 4414 Single-Cell Multiomic Insights into Zinc Modulation of Cadmium and Arsenic Effects During Lung Alveolarization

A. R. Bly, B. Minasenko, D. Wang, F. Hassounah, C. Su, and X. Hu. Emory University, Atlanta, GA.

Background and Purpose: Prenatal exposure to environmental heavy metal contaminants, including cadmium (Cd) and arsenic (As), has been shown to disrupt fetal lung development, a critical period characterized by extensive cellular diversification. Zinc (Zn) supplementation is an increasingly explored mechanism for reducing mortality and supporting development in premature infants given its essential role in diverse cellular activities, including oxidative stress response and interaction with other metals. Our previous work identified Zn-dependent proteins as molecular targets for Cd and As, implicating Zn-related pathways in heavy metal-induced developmental lung defects. In this study, we investigated the mechanistic interplay between Zn, Cd, and As in developing mouse lungs to elucidate how Zn modulates single-cell epigenomic and transcriptomic responses to heavy metals during alveolarization, thereby revealing cell type-specific molecular mechanisms underlying its potential protective effects. **Methods:** We collected single-cell multiome (scATAC-seq + scRNA-seq) data on three post-natal day P9 lungs from mice prenatally exposed to drinking water dosed with 250 ppb each of CdCl₂ and NaAsO₂ (CdAs), 250 ppb each of CdCl₂, NaAsO₂, and ZnC₄H₆O₄ (CdAsZn), or control. We analyzed 18,178 nuclei across conditions. Pre-processed data were integrated via weighted-nearest neighbor analysis, visualized using uniform manifold approximation and projection (UMAP), and clustered using the Leiden algorithm. Cell clusters were manually annotated using established marker genes. Differentially expressed genes (DEGs) were identified for each cell type using the Wilcoxon rank sum test in Seurat. **Results:** We identified 18 cell clusters through integrated scRNA- and scATAC-seq analysis which were broadly categorized as epithelial, mesenchymal, immune, and endothelial cells. Epithelial cell sub-types included alveolar type 1 (AT1), alveolar type 2 (AT2), airway secretory (Club) cells, and ciliated airway cells. CdAs and CdAsZn treatments induced largely overlapping transcriptomic alterations in epithelial cells when compared to control, indicating that Zn supplementation only partially mitigates the effects of heavy metal exposure. Genes upregulated by both treatment conditions were related to actin cytoskeleton reorganization (*Sema3e*), the integrin superfamily (*Itgb6*), and cell adhesion (*Ctnnd2*) (*BH-adjusted p-value* < 0.05). Despite overlapping transcriptional changes, distinct Zn-dependent effects were found in specific epithelial cell types. In AT1 cells, CdAsZn treatment downregulated several cytoskeleton and migration related genes that were upregulated by CdAs, including

genes linked to cell adhesion (*Cadm1*, *Magi3*), cellular reshaping (*Shroom3*), actin filament network formation (*Ctnna1*), and migration (*Pde1c*, *Nisch*). In AT2 cells, Zn mitigated CdAs-induced downregulation of structural scaffold genes (*Camk1d*, *Flna*, *Ahna*) and upregulation of others (*Nckap5*, *Pde4d*). Zn also attenuated CdAs effects on genes involved in vascular growth (*Vegfa*), RNA processing, and translation (*Sf1*, *Eef2*, *Nxf1*). With respect to cell-type markers, Zn reversed the CdAs-induced upregulation of *Scgb1a1* (Club cell marker) and reduced *Sftpc* expression (AT2 marker). Compared to CdAs, Zn also downregulated *Malat1* in both AT2 and immune cells, a long non-coding RNA controlling cellular proliferation and angiogenesis in lung cancer. Ongoing analyses based on chromatin accessibility and transcriptional kinetics reconstruct and compare single-cell differentiation trajectories across exposures. **Conclusions:** In this exploratory analysis, CdAs treatment altered expression of genes involved in cellular morphology, differentiation, and adhesion in lungs undergoing alveolarization, a developmental stage characterized by extensive tissue remodeling, cell migration, and vascular expansion. While Zn supplementation did not fully prevent these cellular responses, it modulated and attenuated CdAs effects on structural and motility-associated genes in epithelial cells. As this developmental stage corresponds to a critical window of lung maturation in preterm human infants—often associated with bronchopulmonary dysplasia and impaired alveolar growth—these findings highlight Zn as a partial modulator of heavy metal-induced risks for preterm infant lung disease.

PS 4415 Investigating mechanisms of chlorpromazine protection against cadmium-induced toxicity in cardiomyocytes

C. J. Kline¹, D. Brambila², H. Hammerlindl², L. Rao², J. S. Kim¹, S. Altschuler², L. Wu², and S. Q. Shen¹. ¹University of Iowa, Iowa City, IA; and ²University of California, San Francisco, San Francisco, CA.

Background and Purpose: Cadmium (Cd) is a heavy metal that induces oxidative stress and causes a variety of adverse health outcomes, including damage to the cardiovascular system. Cigarette smoking is a common source of chronic low-dose Cd exposure, and individuals diagnosed with schizophrenia have a high incidence of cigarette smoking (75-90%). This population also experiences markedly elevated cardiovascular mortality, dying 10-20 years earlier than the general population. Antipsychotics are the cornerstone of pharmacologic treatment for schizophrenia, yet little is known about interactions between antipsychotics and heavy metals. While antipsychotics are often assumed to exacerbate oxidative stress, emerging evidence including our preliminary studies suggests that chlorpromazine (CPZ), a first-generation antipsychotic, has antioxidant effects. Since oxidative stress is thought to be a major mechanism of Cd toxicity, we hypothesized that CPZ would protect against Cd-induced cellular toxicity by mitigating oxidative stress in cardiomyocytes. **Methods:** Immortalized human cardiomyocytes (AC16 cell line) cultured in 96-well plates were exposed to cadmium chloride (CdCl₂, 10 μ M - 30 μ M) with or without CPZ (4 μ M). Two experimental designs were used: (1) co-treatment, where cells were exposed to CdCl₂ and CPZ simultaneously, and (2) pre-treatment, where cells were treated with CPZ for 24 hours before exposure to CdCl₂ alone. Cells were tracked with live microscopy imaging and analyzed for growth and cell death. To explore potential mechanisms for this protection, we conducted RNA-sequencing on AC16 cells treated with CdCl₂, CPZ, or vehicle control for 48 hours. **Results:** In both approaches, CPZ protected cells from Cd-induced cytotoxicity, as shown by improved cell growth and decreased cell death. In contrast, haloperidol (another first-generation antipsychotic) did not confer protection, suggesting specific protective properties of CPZ. Transcriptomic profiling showed that Cd strongly induced metallothioneins, while CPZ altered the expression of genes implicated in key pathways related to cell survival and oxidative stress. Ongoing studies are quantifying biomarkers of oxidative stress and assessing the activity of candidate pathways and perturbation of candidate genes. **Conclusions:** These findings provide initial evidence that CPZ can protect against Cd-induced cardiomyocyte toxicity and highlight the importance of studying co-exposures in toxicology, not only to better model the complex interactions between environmental and pharmacological agents, but also as a step towards informing clinical decision-making based on individual risk factors.

PS 4416 Novel Insights into Antimicrobial's Cetylpyridinium Chloride Mechanism of Mitochondrial Toxicity

N. E. Adelman, E. L. Ledue, S. K. Trafton, E. Biro, and J. A. Gosse. University of Maine, Orono, ME.

Background and Purpose: Cetylpyridinium chloride (CPC) is a widely used antimicrobial implicated in mitochondrial toxicity comparable to canonical mitochondrial toxicants such as carbonyl cyanide m-chlorophenyl hydrazone. A quaternary ammonium compound (QAC), CPC possesses a permanently charged nitrogen head and a hydrophobic hydrocarbon tail. Estimates suggest CPC levels in human blood are ~0.6 μ M from personal care product and food exposures. Low-concentration CPC crosses the blood-brain barrier, suppresses immune cell signaling, and is toxic to eukaryotes. CPC induces mitochondrial deformation, a phenomenon linked to debilitating human diseases such as Parkinson's and Alzheimer's. This correlation indicates the importance in understanding the mechanisms behind CPC-induced mitotoxic-

ity. Our lab published CPC interference with two vital endpoints of cellular respiration: acute (1.5 hours) exposure severely diminishes both ATP production (IC_{50} 1.7 μ M RBL mast cells; 1.2 μ M primary human keratinocytes) and oxygen consumption rate (1.75 μ M IC_{50} in RBLs). Recent work demonstrates CPC (0.5 μ M) suppresses electron flow (in permeabilized RBLs) from several TCA cycle intermediates including malate and succinate, suggesting inhibition of Complexes I, II, or downstream components directly, though data has thus far indicated malate dehydrogenase is unaffected. Additional inquiry therefore led us to investigate the direct effects of CPC on Complexes I, II, III, and IV in isolated bovine mitochondria. Additionally, our lab previously discovered CPC inhibition of specific phosphorylation events, leading us to the hypothesis that CPC may also alter signaling involving adenosine-monophosphate activated protein kinase (AMPK). AMPK is a central protein of the AMPK/mTOR (mechanistic target of rapamycin) signaling pathway that, through downstream members, such as 4E-BP1 (eukaryotic translation initiation factor 4E-binding protein 1), regulates mitochondrial dynamics. Since CPC deforms the mitochondria, CPC effects on the phosphorylation status of members of the AMPK/mTOR pathway were therefore investigated. Work is underway to elucidate the precise biochemical mechanism(s) by which CPC inhibits these critical cellular processes. **Methods:** The activity of the mitochondrial complexes were probed via colorimetric plate reader assays in the presence of varying concentrations of CPC using endogenous and exogenous terminal electron acceptors. Western blotting was used to quantify CPC's impacts on the phosphorylation of key members of the AMPK/mTOR pathway and compared to controls. **Results:** The data show that CPC significantly disrupts mitochondrial Complexes I (at 5 μ M) and IV (at 10 μ M; more potent than cyanide) during a 60-minute exposure, but doesn't directly affect Complexes II or III, revealing novel mechanisms of toxicity for QACs. Additionally, the findings provide evidence that CPC (5 μ M) induces alteration of the phosphorylation of key members, including 4E-BP1 of the AMPK/mTOR pathway involved in mitochondrial dynamics. **Conclusions:** CPC is an antimicrobial that people are widely exposed to, yet our research has revealed that consumer relevant doses of CPC target specific components of the ETC and critical proteins in the AMPK/mTOR signaling pathway, revealing novel biochemical mechanisms underlying CPC mitochondrial toxicity.

PS 4417 The Pesticide Propargite Induces and Exacerbates Ferroptotic Toxicity: Implications for the Pathogenesis of Parkinson's Disease

M. Jakaria¹, S. R. Sammi², and J. Cannon¹. ¹School of Health Sciences & Purdue Institute for Integrative Neuroscience, Purdue University, West Lafayette, IN; and ²Department of Translational Neuroscience, Michigan State University, Grand Rapids, MI.

Background and Purpose: Pesticides such as acaricides can negatively impact human health through various cellular mechanisms. Propargite, an organosulfur acaricide used worldwide on crops, has been linked to toxicity in dopaminergic neurons and an increased risk of developing Parkinson's disease (PD). While existing research has preliminarily identified dopaminergic neurotoxicity relevant to PD, the mechanisms underlying this neurotoxicity remain unclear, highlighting a significant gap in the literature. Ferroptosis—a specific type of cell death caused by dysregulated phospholipid peroxidation—has been recognized as a mechanism involved in neurotoxicity and neurodegenerative diseases such as PD. This study tested the hypothesis that propargite induces and sensitizes cells to ferroptosis. **Methods:** Complementary cell-based and free assays were utilized to evaluate the potential effects of propargite on cellular toxicity and ferroptosis. Classical inducers, such as erastin and RSL3, were used to activate ferroptosis, while liproxstatin-1 was utilized as a standard ferroptosis inhibitor. Additionally, Z-VAD-FMK was used to inhibit apoptosis. Cytotoxicity was assessed by measuring cell viability with a calcein-AM assay, and cell death was evaluated using a lactate dehydrogenase (LDH) release assay. The impact of the compounds on lipid peroxidation was investigated using a C11-BODIPY 581/591 assay. The RhoNox-1 assay was used to measure intracellular labile iron levels, and the monochlorobimane assay was utilized to assess intracellular glutathione levels. Furthermore, a cell-free ABTS assay and a newly established combined iron- and arachidonic acid-induced C11-BODIPY oxidation assay were used to evaluate the potential radical-trapping antioxidant (RTA) activity of anti-ferroptotic compounds. **Results:** We found that propargite, tested at concentrations ranging from 0.625 to 20 μ M, is highly toxic to immortalized HT-22 mouse hippocampal neurons and N27 rat dopaminergic neurons, with IC_{50} values of 0.76 μ M and 0.64 μ M, respectively. Our research demonstrated that propargite specifically induces ferroptosis in both HT-22 and N27 neurons. This was evidenced by the significant protective effect of the ferroptosis inhibitor liproxstatin-1 against propargite toxicity, while the apoptosis inhibitor Z-VAD-FMK did not provide any detectable protection. Lipid peroxidation assays showed that propargite increased the C11-BODIPY signal in a dose-dependent manner, and this heightened lipid peroxidation was significantly ameliorated by liproxstatin-1. Using both cell-based and cell-free assays, we identified 4-hydroxyindole as a new ferroptosis inhibitor, and this inhibitor also rescued cells from propargite-induced toxicity, further supporting the notion that propargite specifically induces ferroptosis. Additionally, we found that a non-toxic dose (500 nM) of propargite sensitizes HT-22 neurons to ferroptosis. By elucidating the underlying mechanism, we determined that propargite significantly decreases glutathione levels, which explains how it induces and sensitizes cells to ferroptosis. **Conclusions:** This study is the first to identify ferroptosis as a neurotoxic mechanism associated with the pesticide propargite. Propargite not only induces ferroptosis but

also makes neurons more susceptible to it, likely due to decreased glutathione levels. This research advances our understanding of how pesticides cause neurotoxicity. Additionally, the study shows that ferroptosis inhibitors can effectively counteract propargite-induced neuronal toxicity. Targeting ferroptosis represents a promising approach for neuroprotective therapies that could mitigate neurodegeneration associated with pesticide exposure in incurable PD.

PS 4418 Role of Advanced glycation end products and their receptors on myoblast senescence *in vitro* and regeneration retardation of aging muscles *in vivo*

S. Liu¹, D. Chan¹, J. Zhuang¹, F. Chang¹, M. Sheu², and K. Lan³. ¹National Taiwan University, Taipei, Taiwan; ²National Chung Hsing University, Taichung, Taiwan; and ³National Defense Medical University, Taipei, Taiwan.

Background and Purpose: The global population is rapidly aging, leading to a significant increase in age-related diseases in the coming decades. Muscle dysfunction is a prevalent chronic condition among older adults, posing significant public health challenges. One of the key age-related changes in muscle tissue is the accumulation of advanced glycation end products (AGEs). Previous studies have reported that AGEs are highly associated with muscle dysfunction, particularly in diabetes. However, the relationship between AGEs and muscle aging remains unclear. This study aimed to investigate the effects of AGEs on muscle repair function through both cellular and aging/senescence animal models. **Methods:** Mouse C2C12 myoblasts were cultured and used as an *in vitro* model. A D-galactose-accelerated senescence/aging mouse model (male C57BL/6J mice) was induced and used as an *in vivo* model with or without AGEs inhibitor aminoguanidine treatment (oral for 0.1 g/kg/day). Mice received subcutaneous injections of D-galactose at a daily dose of 1 g/kg for 4 consecutive weeks. Analyses included immunoblotting, senescence-associated β -galactosidase staining, hematoxylin and eosin (H&E) staining, immunohistochemistry (IHC), a glycerol injection-induced muscle regeneration experiment, and rota-rod muscular endurance trials. **Results:** In the cell model, non-cytotoxic concentrations of AGEs (25 and 50 μ g/mL) induced cell senescence and inhibited myogenic differentiation in C2C12 myoblasts, as evidenced by senescence-associated β -galactosidase staining and H&E staining ($p < 0.05$, $n \geq 3$). These effects of AGEs could be reversed by treatment with a neutralizing antibody against the receptor for AGEs (RAGE; 5 and 10 μ g/mL; $p < 0.05$, $n \geq 3$). In the D-galactose-accelerated senescence/aging mouse model, IHC staining showed substantial AGEs accumulation and RAGE expression in the muscles, which were reduced by treatment with the AGEs inhibitor aminoguanidine (0.1 g/kg, orally for 4 weeks; $p < 0.05$, $n = 3-6$). Muscle regeneration was assessed via glycerol injection into the tibialis anterior muscle. Early regenerating myofibers, characterized by central nuclei, were observed 5 days post-injury. At this time point, muscular endurance (as measured by rotarod latency) in the D-galactose-accelerated aging group was significantly shorter than in the control group, and was significantly improved by aminoguanidine treatment ($p < 0.05$, $n = 6$). The muscle regeneration/repair capacity was significantly impaired and the myogenesis markers Pax7 and MyoD expression were reduced in senescence/aging mice, both of which were restored by aminoguanidine treatment ($p < 0.05$, $n = 6$). **Conclusions:** These findings suggest that the AGEs/RAGE axis promotes myoblast senescence, inhibits their differentiation, and may impair muscle repair capacity in aging animals. AGEs may act as a risk factor for impaired myogenesis/muscle regeneration due to the promotion of premature cellular senescence. However, further studies are required to elucidate the detailed underlying mechanisms.

PS 4419 Employing a High-Throughput Screen to Identify Human Pregnane X Receptor Antagonists

C. Lynch, S. Sakamuru, J. Travers, T. Zhao, R. Huang, and M. Xia. NIH/NCATS, Rockville, MD.

Background and Purpose: The xenobiotic-sensing nuclear receptor, pregnane X receptor (PXR), regulates drug metabolism and clearance. Recently, PXR has been associated with modulating cell proliferation, apoptosis, immune response, and energy homeostasis. Pinpointing compounds that can change PXR activity is necessary to prevent drug-drug interactions, determine compounds which generate toxicity, and locate compounds for further development towards therapeutic usage. **Methods:** Here, we have screened the National Center for Advancing Translational Sciences Pharmacologically Active Chemical Toolbox library, which consists of 5,099 unique pharmacologically active synthetic and naturally derived small molecules using a HepG2-CYP3A4-hPXR cell line to identify PXR antagonists. Based on efficacy, potency, and novelty, a group of potential PXR antagonists were selected for further studies including pharmacological shift assays, mRNA gene expression experiments, and molecular docking analysis. **Results:** From the primary screening, 94 compounds were identified as potential PXR antagonists and 66 were confirmed in the second run of confirmation experiments. From these, twenty potential PXR antagonists were selected to a more in-depth analysis to confirm their PXR antagonism. GSM2, JNJ-31020028, fusidic acid, and PU-H71 inhibited CYP3A4 mRNA expression in HepaRG cells, a physiologically competent cell line. Also, GSM2 and fusidic acid acquired the pharmacological shift results necessary to affirm PXR antagonism. These two compounds were also able to be docked into the PXR ligand

binding domain suggesting their ability to bind. **Conclusions:** GSM2 and fusidic acid have been identified as novel PXR antagonists. These two compounds should be further investigated to identify useful information regarding possible drug-drug interactions or other toxic consequences. Potential therapeutic effects may also be a target of interest for these newly classified PXR antagonists.

PS 4420 Development of Spatial Transcriptomics Methods for Integrating Molecular Changes with Pathologic Findings: Proof of Concept Studies with Kidney Toxicants in Rat and NHP

E. Hornung, D. Petraitis Quay, O. Mendes, T. Forest, K. Tanis, and R. Gonzalez. Merck, West Point, PA.

Background and Purpose: Transcriptomic assays are being leveraged to evaluate the potential safety liabilities of preclinical drug candidates, and to understand the molecular mechanisms of toxicities observed during drug development. However, it can be difficult to deconvolute and associate gene expression changes in highly heterogeneous bulk tissue samples with spatially resolved histopathological findings. Single cell resolution spatial transcriptomics can bridge this gap by assessing genome-wide RNA expression changes within the anatomical context of histopathology slides, providing deeper insights into the molecular mechanisms of observed pathology for the derisking of preclinical drug candidates. **Methods:** As a proof of concept for the utility of spatial transcriptomics for mechanistic toxicology, we generated single cell spatial RNA-seq (Visium HD) data on kidney samples from NHPs and rats treated with the tubular toxicants Tobramycin and Cisplatin, respectively, as well as from rats treated with the glomerular toxicants Doxorubicin and Puromycin. **Results:** We first assessed the performance of the human and mouse probe sets on NHP and rat samples, respectively. We next used unsupervised clustering and well-established transcriptomic markers to identify major cell types in the kidney. H&E images were used to identify necrotic proximal tubules and glomeruli. Differential gene expression analysis was conducted between treated and vehicle control cells of the same type, and between normal and necrotic cells, to characterize treatment effects and transcriptional changes linked to pathological lesions. Cell type-specific molecular changes revealed pathways modulated with drug-induced kidney toxicity, distinguishing glomerular from tubular toxicants. **Conclusions:** These proof-of-concept studies are being used to demonstrate the utility of transcriptomics for illuminating spatially-resolved molecular mechanisms associated with histopathology findings. The onset and progression of glomerular and tubular toxicity is known to involve the activation of a number of different pathways across multiple cell types in the kidney, not only those specific to the glomeruli and tubules, respectively. Assaying cell-specific transcriptional profiles and their associations with anatomical manifestations of drug-induced pathophysiology in the kidney or other tissues, greatly advances mechanistic understanding of toxicity to support drug development as well as the potential development of novel biomarkers for risk assessment and monitoring.

PS 4422 Transcriptomic Characterization of Birth Defects-Associated Genes During Early Organogenesis

J. Gomes, L. Li, A. M. Gutierrez, T. Sengupta, V. Chauhan, and J. F. Robinson. UCSF, San Francisco, CA.

Background and Purpose: Early organogenesis is a critical developmental window susceptible to environmental and genetic disruptions. Disruption of this process can give rise to functional and structural birth defects (BDs). Although most causes of BD remain unknown, genetic factors alone or in combination with environmental exposures are estimated to account for ~50% of cases. An informative strategy for investigating teratogenesis is the analysis of human genetic disorders that phenocopy teratogen-induced embryopathies. In this context, although pathogenic variants in specific genes have been associated with BD in humans and rodents, the temporal and cell-type-specific expression patterns of these genes within developmental networks remain poorly understood. To address this gap, we applied a multi-scale approach, integrating a systematic literature review with single cell transcriptomic and systems biology analysis to map the embryonic expression of genes previously linked to birth defects and to identify novel correlates potentially associated with teratogenicity. **Methods:** The literature review was conducted on PubMed using Medical Subject Headings terms related to BD and genetic predisposition to diseases. Only systematic reviews and meta-analyses conducted in humans and rodents were included. Single cell RNA sequencing (scRNA-seq) datasets were obtained from human (GSE157329, 7 embryos, Carnegie Stages 12-16) and rat (Li et al. in preparation, 32 embryos, Gestational Days 10-12), representing comparable developmental stages of early organogenesis. Data processing and analyses were performed in R, with systems biology analyses conducted using STRING v.12.0 and Cytoscape v.3.10.0. **Results:** From the literature review, 510 studies were retrieved, and following screening, 147 were included in the present study. Through these studies, we identified 426 candidate genes across human and rodent models that are associated with some of the most prevalent structural birth defects: 36 linked to cortical defects, 14 to neural tube defects, 129 to musculoskeletal defects (e.g. limbs, cranium, others), 93 to heart defects, 89 to oral clefts, 27 to genitourinary defects, 12 to gastrointestinal defects, and 23 to multiple of these BD. Functional

enrichment of these genes highlighted their key role on embryonic developmental and morphogenesis, as well as in WNT, Hippo, mTOR signaling pathways. mRNA profiles of human and rodent embryos revealed that ~90% (n=397 in human, and 374 in rats) of our candidate genes exhibited differential expression across the developmental stages. More than 85% of these candidate genes (n=368) exhibited conserved expression. scRNA-seq data from human embryos were partitioned into 19 clusters and annotated as specific cell types, whereas rat embryonic samples were classified into 35 clusters. Overall, genes associated with specific types of BD were expressed in cell types related to the development of the corresponding organs or systems. Primordial germ cells exhibited high expression levels of the candidate genes. Some genes exhibited broader, more ubiquitous expression across multiple cell populations (e.g. associated with cytoskeleton organization, such as *ACTG1*, *CALD1*, *TUBA1A*; or with transcriptional regulation, *CITED2*, *NONO*, *SON*, *SMARCA4*, or multiple BD, *FGFR1*, *RFC1*). Interaction networks were independently created and analyzed for each type of BD, identifying highly correlated genes (FDR < 0.01). Furthermore, key genes integrated into candidate genes networks emerged as potentially involved in the etiology of birth defects. **Conclusions:** Our findings demonstrate the conserved regulation of genes associated with BD across species in a temporal and cell-type-specific manner, and highlight novel network-based correlates, providing a framework to study genes and pathways that, when disrupted by environmental factors, can potentially lead to BD. Ongoing work aims to explore in depth the cell-type-specific expression patterns of these genes across species, as well as their co-expression relationships with other potentially important genes involved in the embryo development, whose disruption may lead to birth defects.

PS 4423 Placental Nrf2-regulated gene expression in a rat model of pre- and gestational fluoride exposure

A. Dominguez Reyes^{1,2}, J. Guerrero Arroyo¹, A. Larrañaga Parrado¹, Á. Barrera Hernández¹, L. M. Del Razo¹, E. J. Córdova Alarcón³, and M. I. Jiménez Córdova^{1,4}. ¹Invivestav, Mexico, Mexico; ²Instituto Politécnico Nacional, Mexico, Mexico; ³Instituto Nacional de Medicina Genómica, Mexico, Mexico; and ⁴Programa de Investigadores e Investigadores por México, Secretaría de Ciencia, humanidades, Tecnología e Innovación (Secihti), Mexico, Mexico.

Background and Purpose: Fluoride (F⁻), a naturally occurring element in earth's crust, can be found in groundwater and reach concentrations that pose health risks in several regions worldwide. It has been documented that F⁻ can induce oxidative stress through the production of reactive oxygen species. During gestation, this imbalance may compromise placental function, a critical organ for fetal growth and maturation, leading to embryonic or fetal toxicity. The nuclear factor erythroid 2-related factor 2 (Nrf2) pathway regulates essential antioxidant genes involved in placental redox homeostasis. However, it remains unclear if F⁻ exposure at environmentally relevant concentrations alters the expression of these genes in the placenta. Therefore, the aim of this study was to evaluate the effect of pre- and gestational F⁻ exposure on the expression of Nrf2-regulated genes in rat placentas. **Methods:** Female Wistar rats (n= 5 per group) were assigned into three experimental groups: a control group and two F⁻ treated groups receiving 2.5 and 5.0 mg F⁻/kg/day by oral gavage from 14 days prior to mating until gestational day 19. Total RNA was extracted from placental samples and subsequently reverse-transcribed into cDNA. The expression levels of *NQO1*, *HMOX1*, *GCLC*, *GST*, *GCLM*, *TXN* and *GPX2* were quantified by real-time PCR (qPCR) and normalized to *GAPDH* expression to evaluate the activation of the Nrf2 pathway. **Results:** A significant increase in *TXN* gene expression were observed between the control group and the group exposed to 2.5 mg F⁻/kg/day (p= 0.0195). Additionally, *GPX2* expression was increased in the 5.0 mg F⁻/kg/day group compared to 2.5 mg F⁻/kg/day group (p= 0.0053). No significant changes were detected in the expression of *NQO1*, *HMOX1*, *GCLC*, *GST* and *GCLM*. **Conclusions:** These results suggest that pre- and gestational F⁻ exposure modulates placental redox systems in a dose-dependent manner. The selective activation of *TXN* and *GPX2* suggests distinct adaptive responses of the thioredoxin and glutathione pathways, without global activation of Nrf2-mediated antioxidant response.

PS 4424 Impact of RNA Binding Proteins on Nrf2 De Novo Synthesis During Oxidative Stress

D. Wurm, H. Qu, Y. Lu, L. An, L. An, and Q. M. Chen. University of Arizona, Tucson, AZ.

Background and Purpose: Oxidative stress plays an important role in a variety of diseases. Environmental exposure to excessive sun, cigarette smoke, air pollution, or several different types of toxins can cause an increase in oxidative stress. Oxidative stress has been shown to inhibit global protein translation. Increasing evidence supports the fact that selective protein translation occurs under oxidative stress. Among the selectively translated proteins are Nrf2, a transcription factor involved in the antioxidant response, and other components essential for cell survival or damage repair. **Methods:** To better understand the protein translation machinery under oxidative stress, tandem mass tag isobaric labeling quantitative proteomics was performed on ribosomes isolated by ultracentrifugation from either control cells or cells briefly exposed to oxidative stress in culture. Results from the proteomic analysis were confirmed via western blot. **Results:** The analysis identified 1871 proteins with 115 showing a significant 1.2-fold or more increase. The increased proteins

include RNA binding proteins such as DHX9, ILF3, FUBP1, YTHDF2, PABPC4, PAIRB, SMU1, and STAU2. Using western blot, these increased proteins were confirmed to have a higher association with ribosomes in HeLa cells treated with 100 μ M H₂O₂ for 1 hour. Using a biotinylated 5'-UTR of Nrf2 mRNA, DHX9, FUBP1, and YTHDF2 showed an increased binding affinity to Nrf2 mRNA during oxidative stress, while PAIRB and ILF3 did not bind to Nrf2 mRNA. Blocking DHX9, ILF3, FUBP1, YTHDF2, or PABPC4 with siRNA was able to prevent H₂O₂ from inducing Nrf2 protein synthesis. PAIRB, SMU1, or STAU2 siRNA had no effect on Nrf2 translation. DHX9 and PABPC4 were shown to have increased association with the complete 80S ribosome after treatment, while YTHDF2 was shown to have increased association with the 40S ribosome. **Conclusions:** The data supports that ribosomes undergo remodeling through changes in RNA binding protein association due to oxidative stress. While some of these changes mediate selective protein translation to relieve oxidative stress, the functional significance for others remains to be known.

PS 4425 CYP2E1 Influences GLO1 Abundance and Methylglyoxal Detoxification Across Multiple Organs

R. M. Roberts, A. Tomasevich, K. Stayer, H. Gonzalez, and J. Hartman. Medical University of South Carolina, Charleston, SC.

Background and Purpose: Cytochrome P450 isoform 2E1 (CYP2E1) is a highly conserved monooxygenase enzyme involved in xenobiotic and endogenous metabolism and implicated in multiple liver pathologies, including alcoholic and non-alcoholic liver disease. CYP2E1 is known to produce toxic metabolites from ethanol, acetaminophen, and several pollutants. In addition to these established roles in xenobiotic transformation, CYP2E1 also contributes to formation of the toxic metabolite methylglyoxal (MGO) from the ketone body acetone. MGO is a precursor to advanced glycation end products (AGEs), which promote oxidative stress and inflammation. Detoxification of MGO occurs primarily through the glyoxalase pathway, with glyoxalase-1 (GLO1) functioning as the rate-limiting enzyme under transcriptional control of NRF2. Incidental observations in CYP2E1-knockout (KO) mice suggested altered GLO1 expression, prompting investigation into the relationship between CYP2E1, GLO1, and MGO. **Methods:** Male and female CYP2E1-KO mice and strain matched wild-type (WT) controls were evaluated for GLO1 expression across liver, kidney, heart, and small intestine. GLO1 protein levels were quantified using automated western blotting, and transcriptional changes were evaluated by RNA sequencing. Tissue MGO concentrations were measured by LC/MS, and untargeted liver metabolomics was used to assess downstream metabolites, including S-D-lactoylglutathione, the enzymatic product of GLO1 activity. **Results:** CYP2E1 deletion caused a consistent and significant ($p < 0.05$) reduction in GLO1 protein expression across all tissue types tested, including liver, kidney, heart, and small intestine, indicating a systemic regulatory impact. In all tissues, GLO1 levels were reduced to around half or less of the levels in WT animals. Liver metabolomic data from CYP2E1-KO mice showed decreased S-lactoylglutathione that is consistent with the decrease in GLO1 expression (about 50% of wild-type levels, $p < 0.05$). Lastly, preliminary LC/MS data has shown a 2.5-fold increase in MGO within CYP2E1-KO livers ($p < 0.01$). **Conclusions:** These findings reveal a previously unrecognized role for CYP2E1 in supporting glyoxalase pathway function and regulating GLO1 expression across multiple organs. Loss of CYP2E1 reduces GLO1 abundance and disrupts MGO metabolism, indicating that CYP2E1 may influence cellular redox balance through NRF2-dependent signaling. Overall, this work identifies CYP2E1 as a potential modulator of MGO-driven stress, with implications for metabolic dysfunction, diabetic complications, alcoholic and non-alcoholic liver disease, and other pathologies linked to MGO accumulation.

PS 4426 Sulfenyl Aziridines as Stereoselective Covalent Destabilizing Degradors of the Oncogenic Transcription Factor MYC

H. T. Rosen, K. Li, T. J. Maimone, and D. K. Nomura. University of California, Berkeley, Berkeley, CA.

Background and Purpose: Although MYC is a significant oncogenic transcription factor driver of cancer, directly targeting MYC has remained challenging due to its intrinsic disorder and poorly defined structure, deeming it "undruggable." Whether transient pockets formed within unstructured regions of proteins can be selectively targeted with small molecules remains an outstanding challenge. We discovered that spirocyclic oxindole-based sulfenyl aziridines can stereoselectively modulate MYC levels and thus inhibit MYC transcriptional activity in cells. **Methods:** We developed a stereochemically paired spirocyclic oxindole aziridine covalent library and screened this library for degradation of MYC. We used molecular biology and chemoproteomic approaches to study our molecule and also optimized our hit compound to generate a more potent, selective, and durable MYC degrader. **Results:** We identified a hit covalent ligand, KL2-236, bearing a unique sulfenyl aziridine warhead, that engaged MYC as a pure MYC/MAX protein complex, and in cancer cells to destabilize MYC, inhibit MYC transcriptional activity and degrade MYC in a proteasome-dependent manner through targeting intrinsically disordered C203 and D205 residues. Notably, this reactivity was most pronounced for specific stereoisomers of KL2-236 with a diastereomer, KL4-019, that was largely inactive. Mutagenesis of both C203 and D205 completely attenuated KL2-236-mediated MYC degradation. **Conclusions:** Our results reveal a novel ligandable site within MYC and indicate that certain intrinsically

disordered regions within transcription factors, such as MYC, can be interrogated by isomerically unique chiral small molecules, leading to destabilization and degradation.

PS 4427 From Start to Finish: Casein Kinase 2 Negatively Regulates G_{αs}-GPCR Signaling in Multiple Ways

J. Lee, M. Khurram, R. Sherpa, and S. S. An. Rutgers University, New Brunswick, NJ.

Background and Purpose: Casein Kinase 2 (CK2) is a constitutively active serine/threonine protein kinase composed of 2 catalytic subunits (α or α') and 2 regulatory subunits (β). The catalytic and regulatory subunits have unique functions and targets, including pertinent regulators of G_{αs}-GPCR signaling. Namely, CK2 α directly phosphorylates ABCC1 and PKA (leading to activation and inhibition, respectively), whereas CK2 β represses G_{αs} signaling. Herein, we explored the contribution of CK2 to G_{αs} signaling in human airway smooth muscle (HASM) cells, which are the primary cause of airway narrowing in asthma. **Methods:** For these studies, we used a model of cultured primary HASM cells isolated from adult tissue. We measured transcript expression of CK2 (CSNK2A1, CSNK2A2, CSNK2B) and the β 2-adrenergic receptor (ADRB2) using a previously publicly available RNA-Seq dataset or RT-qPCR. Protein expression of CK2, P-T²⁴⁹ ABCC1, P-VASP, and P-HSP20 were determined by immunoblot. Protein-protein interactions were assessed by co-immunoprecipitation and activation of G_{αs} by Bioluminescence Resonance Energy Transfer (BRET) biosensor. To measure cellular stiffness of living cells on a single-cell level, we used optical magnetic twisting cytometry (MTC). **Results:** We first established the presence of CK2 transcript and protein in HASM derived from 8 donors. Co-immunoprecipitation confirmed that CK2 α physically associates with ABCC1 and PKA-Ril under homeostatic conditions. The phosphorylated form of T²⁴⁹ (the reported CK2 phospho-site) of ABCC1 is present under basal conditions. However, inhibiting CK2 α using siRNA did not decrease phosphorylation of T²⁴⁹, suggesting a different residue is involved in the constitutive regulation of ABCC1. We then tested the effect of 4,5,6,7-tetrabromobenzotriazole (TBB), a pharmacological CK2 inhibitor, on G_{αs} mobilization. TBB increased G_{αs} mobilization, supporting that CK2 reduces available G_{αs}. To test the functional impacts of CK2, we measured phosphorylation of VASP and HSP20 (markers of PKA activation) and cellular stiffness. TBB increased P-VASP and P-HSP20 in a time- and dose-dependent manner and evoked cell relaxation in a dose-dependent manner. CK2 α -targeting siRNA similarly decreased cell stiffness, indicating CK2 α increases HASM basal tone. Inhibiting PKA using H89 did not affect TBB-evoked cell relaxation; this implicates a PKA-independent mechanism. Of note, we also found that prolonged (24 h) TBB treatment upregulated transcript expression of ADRB2 by >5 fold. **Conclusions:** These data support that CK2 α functions as a constitutive multi-nodal inhibitor of G_{αs}-GPCR signaling; CK2 acts on G_{αs}, PKA, ABCC1, and receptor transcription. Therefore, CK2 may be involved in the pathological mechanical properties of airway smooth muscle of asthma patients and is an exciting potential druggable target.

PS 4428 Mechanistic Insights into Species-Specific ABC Transporter Regulation by Acetaminophen in the Intestinal Epithelium

C. I. Ghanem^{1,2}, A. P. Laddha³, J. B. Allegro¹, Z. Bazzi¹, M. De Sousa¹, and J. E. Manautou³. ¹Instituto de Investigaciones Farmacológicas (ININFA-UBA-CONICET), Buenos Aires, Argentina; ²and Cátedra de Fisiopatología, Facultad de Farmacia y Bioquímica (FFYB). Universidad de Buenos Aires (UBA), Buenos Aires, Argentina; and ³Department of Pharmaceutical Sciences, University of Connecticut, Storrs, CT.

Background and Purpose: Preliminary findings from our laboratory indicate that apical ABC transporters (P-gp, Mrp2, and Bcrp) in the small intestine may be modulated post-transcriptionally following acetaminophen (APAP) administration in mice. Given that several studies have reported regulation of these transporters by specific microRNAs (miRNAs) under various physiological and pathological conditions, we conducted a miRNA microarray analysis to identify potential miRNAs involved. This study aims to explore the underlying regulatory mechanisms governing intestinal transporter expression after APAP exposure and to compare these findings with a human intestinal cell line model. **Methods:** Male C57BL/6 mice were administered APAP (400 mg/kg, i.p.). Distal section of the small intestine was collected 6 hours after treatment, and miRNA expression profiles were analyzed using Illumina microarrays. An *in silico* analysis was then performed by integrating data from DIANA microT-CDS, miRDB, TargetScan, and TarBase to predict miRNA-mRNA interactions. Differentially expressed miRNAs were further evaluated for their potential mRNA binding using MIENTURNET with miRTarBase-supported interactions. mRNA expression of miRNA-targeted genes involved in the post-transcriptional regulation was measured by RT-qPCR. To compare these *in vivo* findings with human intestinal cells, Caco-2 cells were exposed to 10 mM APAP for 24 h to assess mRNA and protein expression of ABC transporters and identified miRNA targets were assessed. **Results:** miRNA sequencing cluster analysis revealed that 12 miRNAs were differentially expressed in the APAP-treated group out of a total of 709 detected miRNA species ($P < 0.01$). However, *in silico* target prediction analysis did not identify any of these miRNAs as potential regulators of apical ABC transporters at the post-transcriptional level. Following the analysis performed in MIENTURNET, we identified an increase of Igf2bp2, Hpk3, and circHpk3 in APAP-intoxicated mice. In contrast, when

the effects of APAP were examined in a human intestinal cell line, post-transcriptional regulation was observed for MRP2 and BCRP, but not for P-gp. Additionally, no changes in the expression of Igf2bp2 or circHIPK3 were observed in the human cells. Comparative analysis between mouse and human miRNAs revealed that two of the differentially expressed mouse miRNAs, mmu-miR-6240 and mmu-miR-106a-5p, lack human homologs. These miRNAs were predicted to target the 3'UTR region of Igf2bp2. Two predicted binding sites for mmu-miR-6240 were identified in the 3'UTR region of Igf2bp2 at positions 2559-2565 and 3584-3590, along with three predicted sites for mmu-miR-106a-5p at positions 2884-2890, 3669-3675, and 3830-3836. These sites may contribute to species-specific post-transcriptional regulation observed in mice. **Conclusions:** Post-transcriptional regulation of MRP2 and BCRP was observed in both mouse and human intestinal cell lines; however, species-specific regulation of P-gp was noted. Although miRNA sequencing and *in silico* analyses indicated that none of the dysregulated miRNAs were predicted to modulate ABC transporters directly, we observed an increase in the expression of circHIPK3 and the RNA-binding protein Igf2bp2. These molecules are known to interact and may form a complex capable of binding to the 3'UTR regions of target genes, thereby influencing their post-transcriptional regulation in mice. This effect was not observed in human, as the expression levels of these complex components did not significantly change following APAP exposure in human cells. Notably, two mouse-specific miRNAs, mmu-miR-6240 and mmu-miR-106a-5p, were identified as potential candidates contributing to the species-specific post-transcriptional regulation of P-gp through the circHIPK3-Igf2bp2 complex, because several predicted binding sites for these miRNAs are present in the 3'UTR region of Igf2bp2. These sites may underline the species-specific post-transcriptional regulation observed in mice, although further studies are warranted to confirm this regulatory mechanism.

PS 4429 Role of GDF15 in asparaginase-induced food aversion and liver steatosis.

D. Bermeo Grajales, E. M. Lopez, M. Gomez Jenkins, M. Ibrahim, C. T. Bhavsar, B. A. Zalma, E. White, and T. G. Anthony. Rutgers University, New Brunswick, NJ.

Background and Purpose: Asparaginase is a chemotherapeutic enzyme used to treat pediatric and adult forms of acute lymphoblastic leukemia (ALL). Its enzymatic activity depletes circulating asparagine and glutamine, triggering the Integrated Stress Response (ISR) an adaptive signaling pathway, which induces the transcription of many genes, including *Gdf15*. GDF15 contributes to anorexia and weight loss by suppressing appetite. Weight loss during asparaginase exposure is linked to hepatic steatosis and toxicity in mice, especially in obesity. Previously, we reported that asparaginase elevates circulating GDF15 in mice and this correlated with reduced body weight. A secondary analysis of an unpublished dataset from lean and obese mice fed either low-fat (10% fat by kcal) or high fat (60% fat by kcal) diets during asparaginase exposure also showed an inverse relationship between hepatic *Gdf15* mRNA with body weight change ($p < 0.001$) and food intake ($p = 0.0036$). Based on these findings, we hypothesized that genetic deletion of *Gdf15* would rescue asparaginase-associated food aversion and body weight loss. **Methods:** To test this hypothesis, global *Gdf15* knockout (*Gdf15*KO) mice and their wild type controls (WT) were intraperitoneally injected with pegylated asparaginase (1.5 international units per gram body weight) or equivalent saline vehicle ($n = 24$ mice; 6 males and 6 females per group). Daily body weight and food intake were recorded for four consecutive days after injection, and biospecimens (serum, liver) were collected on the last day. **Results:** Asparaginase exposure in WT mice significantly reduced food intake ($p = 0.0363$), and body weight $\sim 8\%$ ($p = 0.0021$) and increased hepatic *Gdf15* mRNA levels, as expected. In contrast, *Gdf15*KO mice maintained normal food intake ($p = 0.6465$) and were resistant to asparaginase-induced weight loss (body weight change $\leq 4\%$). We noted that asparaginase-induced activation of the hepatic ISR and liver ISR target genes in *Gdf15*KO mice were similar to WT mice, indicating that systemic loss of GDF15 did not alter other aspects of the hepatic ISR to asparaginase. Importantly, liver triglyceride accumulation was rescued in asparaginase-exposed *Gdf15*KO mice. **Conclusions:** Overall, these data suggest GDF15 is a crucial mediator of asparaginase-associated food aversion and protects against body weight loss and associated liver steatosis by rescuing normal intake.

PS 4430 Apoptotic Bodies Derived from HIV- and Alcohol-Exposed Hepatocytes Amplify Inflammation and Programmed Cell Death Pathways in Liver Parenchymal Cells.

L. A. Adepoju, A. Pathania, G. Bybee, and N. Osna. University of Nebraska Medical Center, Omaha, NE.

Background and Purpose: Liver disease remains a leading cause of morbidity in people living with HIV (PLWH), particularly among those who consume alcohol. While HIV and ethanol independently promote hepatocyte injury, their combined mechanisms of toxicity especially regarding apoptotic body (AB) formation and intercellular propagation of cell death remain poorly defined. This study aimed to determine how HIV and alcohol synergistically activate multiple programmed cell death pathways in hepatocytes and to assess whether ABs mediate secondary inflammation and hepatocyte injury. Understanding these pathways may reveal novel therapeutic targets to prevent alcohol-accelerated liver disease in PLWH. **Methods:**

Huh7.5-CYP2E1 hepatocytes were treated with HIV-1 ADA and an acetaldehyde-generating system (AGS) containing yeast alcohol dehydrogenase, 50 mM ethanol, and NAD to mimic chronic alcohol metabolism. Apoptotic bodies (ABs) generated from co-exposed cells were isolated and introduced (1:3 ratio) into naïve and AGS-pretreated hepatocytes at defined kinetic time points. Apoptosis was evaluated by cleaved caspase-3 and PARP cleavage; necroptosis by RIPK3 and phosphorylated MLKL; pyroptosis and inflammasome activation by cleaved gasdermin D, cleaved caspase-1, NLRP3, IL-1 β , and IL-18. Reactive oxygen species (ROS) and lactate dehydrogenase (LDH) release were measured to assess oxidative stress and necrosis. Pathway specificity was validated using inhibitors: Z-VAD-FMK (apoptosis/AB release), Necrostatin-1 (necroptosis), and VX-765 (pyroptosis). **Results:** Dual exposure to HIV and AGS significantly increased apoptotic markers (cleaved caspase-3 and PARP cleavage). Engulfment of these ABs by naïve AGS pretreated hepatocytes induced secondary apoptosis (caspase-3 and cleaved PARP activities) and upregulated pro-inflammatory cytokines IL-1 β and IL-18 ($p < 0.01$). Elevated p-MLKL and cleaved gasdermin D levels confirmed activation of necroptotic and pyroptotic pathways. Both ROS generation and LDH release increase in the pretreated treatment group compared to naïve treatments. Application of Z-VAD-FMK, Necrostatin-1, and VX-765 each reduced corresponding pathway markers by 50-70%, validating specificity of the observed responses. **Conclusions:** This study demonstrates that HIV and alcohol synergistically induce hepatotoxicity through the simultaneous activation of apoptotic, necroptotic, and pyroptotic cell death pathways. Importantly, apoptotic bodies act as vectors of injury propagation, transferring death signals to neighboring hepatocytes and amplifying inflammation. These findings highlight AB-mediated intercellular signaling as a critical toxicological mechanism underlying alcohol-exacerbated liver injury in HIV infection. Targeting AB formation or uptake may therefore represent a novel therapeutic strategy to mitigate viral-alcohol co-toxicity and prevent progression to end-stage liver disease in vulnerable populations.

PS 4431 Quantum Dots Interaction with Cytoskeletal Proteins via Experimental Observations and Computational Predictions.

E. Billue¹, A. Chand¹, N. Le², T. Astuhuaman Davila¹, R. Sakdja¹, and K. Kim¹. ¹Missouri State University, Springfield, MO; and ²Johns Hopkins University, Large City, MD.

Background and Purpose: Quantum dots (QDs) are biocompatible nanoparticles with a unique range of optical and fluorescent properties, making them a promising medical diagnostic tool for applications in cell labeling, bioimaging, and drug administration. However, their biological integration has been hindered by QDs' ability to non-specifically interact with the cells and intracellular proteins. As such, this study investigates QDs' interaction with cytoskeletal proteins such as actin and α -actinin, through biochemical and computational approaches to unravel the consequences on cytoskeletal dynamics. **Methods:** We conducted spin-down assays to examine the effects of QDs on actin polymerization and depolymerization as well as the interaction between QDs and actin in the presence of α -actinin. Next, we performed fluorometric assays to monitor pyrene-labeled actin polymerization and depolymerization over time in the presence of varying concentrations of QD, followed by quenching between QDs and α -actinin. We are currently working on performing comparative molecular docking studies using AutoDock Vina and Boltz-2 to model QD binding with proteins. Furthermore, a custom generative AI model is being developed to predict novel ligands capable of interacting with cytoskeletal proteins to compare their binding profile with those of surface-functionalized QDs. **Results:** Our spin-down experiment showed that high concentrations of QD hinder actin polymerization and promote depolymerization. Furthermore, our spin-down assay also demonstrated the ability of QD to cause bundling of actin filaments. However, in the presence of both α -actinin and high QD concentration, actin bundling does not occur. This indicates an interaction between QD and α -actinin, which was confirmed by the quenching assay. In addition, our fluorometer assay revealed that high concentrations of QD inhibit actin polymerization while lower concentrations stimulate polymerization. Preliminary docking studies revealed potential binding sites for QDs on actin and α -actinin. **Conclusions:** Our study provided novel insights on how QDs disrupt cytoskeletal integrity and cause toxicity. The integration of molecular docking and AI-driven ligand prediction provides a framework to identify binding surfaces and potential drug discovery and nanoparticle design. Understanding these molecular interactions between QDs and proteins is essential to maximize their potential in biomedical applications while mitigating any side effects.

PS 4432 SERPINA3 Upregulation Marks Fine Particulate Matter-Induced Impairment of Osteogenic Differentiation

M. Vera-Colón, and N. Sparks. University of California, Irvine, Irvine, CA.

Background and Purpose: Air pollution, particularly particulate matter (PM), poses a significant public health risk, with established links to respiratory disease, cancers, and cardiovascular diseases. Emerging evidence suggests that PM exposure is a risk factor for poor adult bone health, such as osteoporosis. Additionally, prenatal PM exposure has been associated with adverse birth outcomes, including increased risk for skeletal defects, though the underlying mechanisms remain unclear. Osteogenesis, the formation of bone, is governed by a complex network of epigenetic

mechanisms, microRNAs, and transcription factors that are susceptible to environmental perturbations and can manifest embryonic skeletal defects. **Methods:** We sought to investigate how PM exposure alters embryonic molecular signatures and identify potential biomarkers in human embryonic stem cells (hESCs) before cell fate commitment, potentially predisposing to skeletal birth defects. Using the H9 hESC line, we differentiated cells into osteoblasts and exposed to fine PM (PM_{2.5}) or urban dust at concentrations inhibiting differentiation by 25% (ID₂₅) or 50% (ID₅₀). **Results:** Fine PM exposure inhibited osteogenesis in a dose-dependent manner, as evidenced by reduced protein expression, alkaline phosphatase activity, matrix mineralization, and cell viability. A human molecular toxicology profiler microarray identified a distinct pattern of increased expression in the inflammation marker, *SERPINA3* in differentiating cells exposed to PM_{2.5}. Validation experiments confirmed this effect at both the transcript and protein levels. RT-qPCR analysis demonstrated a robust and reproducible upregulation of *SERPINA3* mRNA in osteoblasts exposed to FPM compared with untreated controls. Additionally, transcriptomic analysis revealed *SERPINA3* targets were differentially expressed from PM_{2.5} exposure. **Conclusions:** This increase was consistent across exposure replicates and concentrations, underscoring the reproducibility and sensitivity of the response. Given the limited understanding of *SERPINA3*'s function in bone, these results highlight the need for further molecular characterization to determine whether *SERPINA3* directly mediates or reflects PM_{2.5}-induced inhibition of osteogenesis.

PS 4433 Tracing the Evolutionary Origins of the Aryl Hydrocarbon Receptor Ligand Specificity

T. Steiniche¹, S. I. Karchner¹, J. V. Goldstone¹, C. Mandl¹, J. W. Thornton², and M. E. Hahn¹. ¹Woods Hole Oceanographic Institution, Woods Hole, MA; and ²University of Chicago, Chicago, IL.

Background and Purpose: The aryl hydrocarbon receptor (AHR) is an evolutionarily conserved transcription factor best known in vertebrates for mediating responses to dioxins and other environmental contaminants. While vertebrate AHRs exhibit binding to a diverse array of endo- and xenobiotic compounds, the functions of invertebrate AHR homologs remain poorly understood. To better understand the physiological roles and evolutionary trajectory of the AHR in early metazoan evolution, we investigated the ligand specificity of AHRs from invertebrate taxa representing key phylogenetic lineages. **Methods:** Chimeric fusion constructs with species-specific ligand binding domains were expressed in a one-hybrid reporter system to evaluate ligand-dependent transcriptional activity. The species analyzed represented major invertebrate lineages, including pre-bilaterians (Cnidaria-*N. vectensis*), protostomes (Nematoda-*C. elegans*; Arthropoda-*D. melanogaster*; Mollusca-*M. arenaria*), deuterostomes (Echinoderm-*S. purpuratus*), and invertebrate chordates (Urochordata-*C. intestinalis*; Cephalochordata-*B. floridae*). We screened a panel of more than fifteen compounds, including endogenous, dietary, and microbial metabolites, as well as natural and anthropogenic xenobiotics. **Results:** Multiple protostome AHRs (i.e., *C. elegans*, *D. melanogaster*, *M. arenaria*) exhibited robust, ligand-independent transcriptional activity. Several control experiments were performed to rule out experimental artifacts. Our comparative framework indicates that constitutive activation may be an ancestral or derived feature among protostome AHRs. **Conclusions:** Ongoing functional analyses and reconstructions of the ancestral protostome and pre-bilaterian AHRs are underway. By tracing the emergence and diversification of AHR ligand-binding properties across invertebrate taxa, this work provides new insights into the early evolutionary history of the AHR signaling pathway and a basis for understanding the molecular mechanisms underlying disruption by anthropogenic pollutants. [Research is supported by the National Institute of Environmental Health Sciences: R01ES035261.]

PS 4434 Early Life Microbiota Shape Metabolic Programming and Mitochondrial Resilience to Toxicants

E. Green, and N. Jayasundara. Duke University, Durham, NC.

Background and Purpose: Exposure to environmental toxicants during critical developmental windows can alter growth and metabolic programming. While the microbiome regulates xenobiotic metabolism and host energy balance, most studies focus on post-embryonic stages, leaving microbial regulation during embryogenesis, when energetic demands and toxicant sensitivity are highest, poorly understood. Traditionally, the embryo was considered insulated from microbial influence by the chorion, but our previous work challenges this view. We show embryos raised in the absence of a microbiome during the first half of embryonic development exhibit reduced mitochondrial respiration, effects further exacerbated by xenobiotic exposure, while germ-free embryos maintain respiration. In the absence of a microbiome, lipid metabolism genes were universally upregulated alongside shifts in lipid metabolites, contrasting post-embryonic studies that report reduced lipid synthesis. These findings suggest microbial regulation of lipid metabolism is developmentally dynamic and embryonic metabolic reprogramming occurs in the absence of microbial cues. However, the mechanisms underlying these temporal effects and their consequence for toxicant sensitivity remain unresolved. Therefore, here, we mechanistically expand upon our previous findings to test the hypothesis that microbial cues are critical for mitochondrial efficiency, lipid substrate utilization, redox homeo-

stasis, and ATP production during embryonic development. **Methods:** Zebrafish (*Danio rerio*) embryos were reared under germ-free (GF) conditions or conventionalized with microbes (CV) at 6 hours post-fertilization (hpf). Embryos were exposed to either 10 μ M of benzo(a)pyrene, a potent aryl hydrocarbon receptor agonist, or a DMSO vehicle control. Endpoints were collected at 32 hpf to evaluate effects of microbial cues and BaP exposure on embryonic metabolic reprogramming and mitochondrial resilience. Molecular impacts were assessed through analysis of gene expression and metabolite abundance using our previously published transcriptomic and metabolomic datasets. Physiological consequences were determined by quantifying total ATP and ADP, while mitochondrial efficiency, glycolytic activity, β -oxidation, and redox homeostasis were measured to identify mechanisms by which microbial cues and BaP exposure alter embryonic energy production. **Results:** Although GF embryos sustained mitochondrial respiration, this occurred at reduced efficiency, indicated by increased proton leak and lower ATP production. GF embryos also exhibited decreased glycolytic activity, likely driven by triacylglycerol accumulation, which may further exacerbate ATP depletion. Consistent with this, lipid accumulation in GF embryos was accompanied by upregulation of β -oxidation. However, inhibition of β -oxidation significantly reduced respiration in CV embryos, but not GF embryos, suggesting that efficiency of utilizing lipid substrates was reduced in the absence of microbial cues. This reduced reliance on β -oxidation likely contributes to temporal accumulation of lipid stores observed under GF conditions. While BaP exposure did not alter the relationship between the microbial community and embryonic energy production, it induced a significant increase in ROS in GF compared to CV embryos and further impaired antioxidant defenses, marked by decreased catalase activity. Together, these findings indicate microbial colonization affects both metabolic efficiency and redox balance, influencing embryonic responses to environmental stressors such as BaP. **Conclusions:** We expand upon our previous findings that the surrounding microbiome plays a fundamental role in shaping energy metabolism during the earliest stages of development. Results illustrate that microbial cues are essential for maintaining energetic efficiency during embryogenesis and disruption of these cues induces metabolic reprogramming. We demonstrate the microbiome supports both aerobic and anaerobic energy production, preserves redox homeostasis, and enhances mitochondrial resilience to environmental stressors. These findings emphasize the importance of incorporating the microbiome in toxicological assessments and informs mechanistic insight to how the maternal microbiome shapes embryonic and fetal metabolic development, with implications for understanding metabolic disorders and risks of *in utero* chemical exposures.

PS 4435 Aip Mutation Reduces Sensitivity to Ahr Ligands in a Context-Dependent Manner

D. M. Perone¹, J. K. La Du¹, S. I. Karchner², N. Aluru², S. Stinson¹, L. Truong¹, M. E. Hahn², and R. L. Tanguay¹. ¹Oregon State University, Corvallis, OR; and ²Woods Hole Oceanographic Institution, Woods Hole, MA.

Background and Purpose: Chemical contaminants, including polycyclic aromatic hydrocarbons (PAHs) and polychlorinated biphenyls (PCBs), are known to elicit their effects through activation of the aryl hydrocarbon receptor (AHR). Some populations of Atlantic Killifish rapidly developed resistance to high levels of these contaminants. Genome-wide association studies using these populations demonstrated that variation in the AHR interacting protein (AIP) is associated with resistance to AHR ligands such as 3,3',4,4',5-pentachlorobiphenyl (PCB 126). AIP associates with the AHR in the cytosol where it's thought to play a role in stability, ligand binding, and nuclear localization. However, AIP's exact role in AHR signaling and chemical sensitivity is poorly understood. To investigate this, two *aip* mutant zebrafish lines were utilized. Zebrafish homozygous for these mutations die at 8-10 days post-fertilization (dpf) while *ahr* knockout zebrafish exhibit no such phenotype. In addition to investigating AIP-AHR-mediated signaling and chemical sensitivity, these mutants were used to explore AIP's role beyond the AHR. **Methods:** CRISPR-Cas9 technology was used to induce a deletion in exon 2 (*aip*^{wh86} line) or exon 5 (*aip*^{wh239} line) of *aip*. Both result in an early stop codon and protein truncation. The *aip*^{wh86} line is missing 4/4 protein-interacting domains, while the *aip*^{wh239} line is missing 3/4 domains. Due to early mortality, heterozygous (+/-) adults are increased to generate offspring for experimentation. To investigate susceptibility to chemical exposure, 6-hour post-fertilization offspring of *aip*^{wh239} +/- zebrafish were exposed to a diverse set of AHR ligands. These included PCB 126, a strong Ahr2 ligand; 5-nitroacenaphthene (5-NAN), an Ahr1a ligand; and benzo(k)fluoranthene (BkF), which induces a unique caudal fin malformation called x-fin in an Ahr2-dependent manner. Embryos were exposed to a DMSO control or an Ahr ligand near the EC₅₀ concentration. At 5 dpf, the larvae were evaluated for defects by screening for 9 morphological endpoints. The number of larvae exhibiting malformations was evaluated between condition and genotype using multiple comparisons. To investigate early mortality, mRNA sequencing was performed on pooled whole larvae from both lines, and differentially expressed gene (DEG) analysis was performed. To investigate cell-type-specific changes in expression, the R package MuSiC was used to deconvolute the bulk sequencing data using a single-cell RNA-seq reference. **Results:** *aip*^{wh239} -/- zebrafish exposed to PCB 126 and BkF had fewer morphological defects overall compared to +/- and +/- animals. When considering specific morphological endpoints -/- zebrafish demonstrated some resistance to each chemical tested. Notably, 5-NAN-exposed -/- zebrafish had a lower incidence of the brain endpoint. In BkF-exposed zebrafish, there was no difference in the incidence of cranial and edema endpoints between genotypes, while -/- animals had reduced incidence of the x-fin endpoint. Unexposed

aip^{wh86} and *aip*^{wh239} larvae had 1,231 and 972 DEGs (p-value ≤ 0.05 , Log₂(FC) $\geq |1|$) in a -/- vs +/- comparison, respectively. Only 47% of the DEGs were shared between the lines. Using gene ontology analysis, biological processes involving metabolism, homeostasis, the extracellular matrix, chromosomal segregation, immune response, and bacterial defense were enriched in one line or the other, but processes shared between lines primarily involved extracellular matrix and immune response-related terms. Using MuSiC bulk RNA-seq deconvolution, changes in cell-type-specific transcript abundance were observed. **Conclusions:** We demonstrate that disruption of the *aip* gene partially protects against exposure to several Ahr ligands in a context and tissue-specific manner. Disruption also leads to large changes in gene expression and early mortality. Many of the severe phenotypes observed in *Aip* mutants are likely the result of changes in non-Ahr pathways, as Ahr null zebrafish survive into adulthood. mRNA sequencing and bulk sequencing deconvolution were used to investigate the biological processes and organ systems that are most affected by disruption of *aip* and highlight important areas for future study and validation. Supported by R01 ES033888, P30 ES030287, P42ES016465, & T32 ES007060.

PS 4436 Role of aryl hydrocarbon receptor (AhR) ligands in the regulation of microRNAs in the mouse thymus

N. P. Singh, T. Jannusch, M. Nagarkatti, and P. Nagarkatti. University of South Carolina School of Medicine, Columbia, SC.

Background and Purpose: Aryl hydrocarbon receptor (AhR) is a ligand-activated transcription factor involved in immune regulation in response to environmental toxins such as Dioxin (TCDD). Recent research highlights the role of AhR in biological processes such as immune function, inflammation, cancer development, and cell differentiation through miRNA-related epigenetic mechanisms. In this study, we investigated the effect of four AhR ligands (TCDD, resveratrol (RES), indole-3-carbinol (I3C), and 6-formylindolo[3,2-b] carbazole (FICZ) on miRNA expression in the thymus of C57BL/6 mice. **Methods:** Female mice were treated either with vehicle (VEH), TCDD (10 μ g/kg), RES (100 mg/kg), I3C (50 mg/kg), or FICZ (50 μ g/kg). On day 3, the mice were sacrificed, and thymic cells were harvested for RNA extraction and miRNA arrays. **Results:** Of 1117 miRNAs analyzed, 135 miRNAs were downregulated, and 147 miRNAs were upregulated when compared to VEH. Differential expression analysis revealed 16 upregulated microRNAs, including mmu-let-7f, miR-127, miR-142a, miR-144, miR-15b, miR-26a, miR-297a, miR-29b-1, miR-374b, miR-449a, miR-465a, miR-465b-1, miR-466a, miR-467b, miR-470, and miR-7077, and 3 downregulated miRNAs, including miR-365-1, miR-202, and miR-6970, common to all AhR ligand-treated groups. Notably, miR-let-7f and miR-142a were among the miRNAs identified, both of which have conserved sequences in humans. Predicted targets of miR-let-7f include IL33, IL7, and possibly aryl hydrocarbon receptor nuclear translocator-like 2, though further validation is needed to confirm specificity. Additionally, miR-142a may regulate the aryl hydrocarbon receptor nuclear translocator-like protein. **Conclusions:** These findings suggest a potential role for AhR signaling in miRNA-mediated immune regulation, which provides insight into molecular mechanisms underlying AhR's immunomodulatory effects. This work was supported in part by NIH grants: P30GM154631, P20GM103641, R01ES030144 and R01AI160896.

PS 4437 Role of AHR-interacting protein (AIP) variants in controlling sensitivity and resistance to dioxin-like compounds

S. I. Karchner¹, J. V. Goldstone¹, B. W. Clark², D. Nacci³, N. M. Reid⁴, A. Whitehead⁵, and M. E. Hahn¹. ¹Woods Hole Oceanographic Institution, Woods Hole, MA; ²United States Environmental Protection Agency, Narragansett, RI; ³United States Environmental Protection Agency (retired), Narragansett, RI; ⁴University of Connecticut, Storrs, CT; and ⁵University of California, Davis, CA.

Background and Purpose: Humans are exposed to chemicals such as 2,3,7,8-tetrachlorodibenzo-p-dioxin (TCDD), polychlorinated biphenyls (PCBs), and polycyclic aromatic hydrocarbons (PAHs) that cause toxicity through activation of the aryl hydrocarbon receptor (AHR). Inter-individual variation in sensitivity to effects of AHR agonists is not fully explained by variation in the AHR. A clue to other mechanisms underlying differential sensitivity to dioxin-like compounds (DLCs) has emerged from studies of fish populations with multi-generational exposure to PCBs, TCDD, and PAHs. Four populations of the Atlantic killifish (*Fundulus heteroclitus*) have independently evolved resistance to these toxicants, resulting in a >100-fold reduction in sensitivity. Genomic studies identified the AHR chaperone AHR-interacting protein (AIP/Ara9/XAP2) as the strongest candidate resistance gene, but the role of AIP in the mechanism of resistance is unknown. In addition to its role in the AHR complex, AIP is a susceptibility gene for human Familial Isolated Pituitary Adenoma (FIPA); dozens of single-nucleotide variants (SNVs) in AIP predispose to this disease. To understand the role of AIP in the toxicity of DLCs and how variation in AIP may affect sensitivity to DLCs, we are investigating AIP function in fish and mammalian cell models. **Methods:** We used RNA-seq and qRT-PCR to measure AIP expression in killifish that were sensitive or resistant to PCB126 (3,3',4,4',5-pentachlorobiphenyl). We characterized SNVs in killifish AIP sequences using genome re-sequencing data, data from RNA-seq reads from adults and embryos, and targeted sequencing of AIP in field-caught fish. To study the function of AIP variants, we transiently transfected COS-7 cells with expression constructs for AIP variants, AHR, and a luciferase reporter gene and then measured TCDD-inducible luciferase activity and nuclear localization of YFP-tagged AHR. To understand the structural implications of AIP variation, we performed homology modeling of killifish and human AIP variants, using the crystal structure of human AIP as a template. **Results:** *AIP expression:* There was no difference in AIP mRNA levels between sensitive and tolerant killifish, suggesting that altered AIP mRNA expression was not a cause of the resistance. *AIP variation:* We identified several non-synonymous SNVs in killifish AIP, including potential candidates that exhibit different allele frequencies in NBH vs. SC. Two of the variants (P219T and W224L) occur at residues conserved among humans, zebrafish, and PCB-sensitive killifish. Most killifish from the PCB-resistant NBH population have at least one of the variant residues. *AIP structure:* Homology modeling of AIP variants suggested that some of the polymorphisms could be functionally significant. Pro219 is important for the tight kink between two helices and mutation to Thr in this position can affect folding, while Trp224 seems to stabilize the loop position through hydrophobic interactions. *AIP function:* In transient transfection experiments, wild-type killifish or human AIP retained AHR in the cytoplasm and reduced both basal and TCDD-inducible luciferase activity as compared to cells without transfected AIP. Human AIP variants identified in FIPA patients or shown previously to exhibit reduced binding to AHR did not affect transactivation. In contrast, killifish AIP W224L and its human counterpart AIP W223L displayed enhanced function, retaining AHR in the cytoplasm and strongly reducing both basal and TCDD-inducible luciferase expression. **Conclusions:** The results suggest that variation in AIP protein structure can affect the sensitivity of the AHR signaling pathway. Understanding the role of AIP in controlling sensitivity to AHR agonists may shed light on the factors that determine differential susceptibility of humans to DLCs and on the role of AIP in human disease. [Supported by P42ES007381, R01ES032323, and R01ES033888.]

Background and Purpose: Mercury (Hg) is a naturally occurring element that can enter the environment through both natural and anthropogenic sources. After Hg enters the environment, it can transform into more toxic, especially neurotoxic forms, which readily bioaccumulate in the food web, raising health and environmental concerns. To study this transformation process at the basic level, specifically the reduction of mercuric mercury (HgII) to elemental mercury (Hg⁰), we examined the green algal species *Chlamydomonas reinhardtii*, which is key in Hg uptake and known to play a role in Hg cycling through its production of thiols. **Methods:** We prepared gas-tight vial cultures to observe the kinetics of gaseous Hg concentrations measured over 18 days in comparison to the controls under light and dark conditions. To compare conditions, a Lumex analyzer device measured the time to reach the maximal Hg⁰ concentration and the area under the curve. An ANOVA test has been performed to statistically test the significant differences (p-value < 0.05). **Results:** Our results showed that algae inoculated with Hg can effectively reduce Hg through volatilization. In all cultures inoculated with algae (50 μ L), peak gaseous Hg⁰ emissions were observed at a faster rate under light conditions in comparison to our controls. However, peak Hg⁰ concentrations in dark conditions were not as quick, which may point to other reduction processes performed. **Conclusions:** For future studies, we will measure the HgII concentrations in the liquid to quantify the remaining Hg in our samples. This will tell us how much Hg is transformed by the algae and how much Hg remains inside the algae, which will assist in potential mercury bioremediation efforts.

PS 4438 Investigating Mercury Transformation Potential by *Chlamydomonas reinhardtii* Algae

W. R. Davis¹, L. Stevenson², A. Minet², P. Ku², and T. Mathews². ¹North Carolina Agricultural and Technical State University, Greensboro, NC; and ²Oak Ridge National Laboratory, Oak Ridge, TN.

Background and Purpose: Mercury (Hg) is a naturally occurring element that can enter the environment through both natural and anthropogenic sources. After Hg enters the environment, it can transform into more toxic, especially neurotoxic forms, which readily bioaccumulate in the food web, raising health and environmental concerns. To study this transformation process at the basic level, specifically the reduction of mercuric mercury (HgII) to elemental mercury (Hg⁰), we examined the green algal species *Chlamydomonas reinhardtii*, which is key in Hg uptake and known to play a role in Hg cycling through its production of thiols. **Methods:** We prepared gas-tight vial cultures to observe the kinetics of gaseous Hg concentrations measured over 18 days in comparison to the controls under light and dark conditions. This will tell us how much Hg is transformed by the algae and how much Hg remains inside the algae, which will assist in potential mercury bioremediation efforts.

PS 4439 Ozone-Mediated Oxidation of 4-Alkoxy-2(3)-nitroacetanilides: Rapid Mineralization and Implications for Wastewater Treatment

J. E. Hines III, O. A. Agu, C. J. Deere, S. V. Bai, and R. M. Uppu. Southern University and A&M College, Baton Rouge, LA.

Background and Purpose: 4-Alkoxyacetanilides (4-AAs), such as phenacetin, were widely used analgesics from their introduction before World War I until concerns over kidney toxicity led to their withdrawal in the 1980s. Despite discontinued medical use, they have occasionally appeared as adulterants in illicit drugs and been linked to toxicity. Our laboratory has shown that nitroderivatives of 4-AAs can form through reactions with cellular oxidants such as peroxynitrite-CO₂. These nitrated analogs, particularly N-(4-alkoxy-3-nitrophenyl)acetamides, are environmentally concerning due to their persistence and potential toxicity. In contrast to halogenation by hypochlorite/hypochlorous acid, which produces chlorinated intermediates [e.g., N-(4-alkoxy-3-chlorophenyl)acetamides], ozonation may offer a rapid and cleaner pathway for degradation. This study examined the efficacy of ozone (O₃) in oxidizing nitroacetanilides under aqueous conditions relevant to water treatment. **Methods:** Ozone was generated from O₂ by corona discharge, and the O₃ in O₂ mixtures (~1% O₃) were bubbled through 100 mL of 0.1 M phosphate buffer (pH 7.0) containing 0.4 mM N-(4-methoxy-2-nitrophenyl)acetamide, N-(4-methoxy-3-nitrophenyl)acetamide, N-(4-ethoxy-3-nitrophenyl)acetamide, or N-(4-methoxy-2-methyl-5-nitrophenyl)acetamide at 25 $\pm$ 1 °C. Reaction progress was monitored by UV-Vis (220-540 nm) and

RP-HPLC with UV detection at 254 nm at intervals 0.5-2.0 min for a total of 10 min. RP-HPLC analysis was carried out using an Agilent ODS column (4.6x250 mm; particle size: 5 μ) and a mobile phase consisting of 50% acetonitrile in water at a flow of 1.2 mL.min⁻¹ (injection volume: 20 μ L). **Results:** Ozone treatment caused rapid loss of UV-Vis absorbance and RP-HPLC peaks of the parent *N*-(4-alkoxy-2[3 or 5]-nitrophenyl)acetamides, with complete disappearance in 4-8 min. Transient, uncharacterized intermediates appeared briefly but were fully degraded by the end of ozonation. HPLC-UV showed >99% reduction within 8 min, consistent with near-complete mineralization. Compared with hypochlorite-hypochlorous acid and peroxydinitrite-CO₂ oxidations, O₃-mediated oxidations were more efficient and produced no persistent byproducts with significant absorption at 254 nm (indicative of aromatic rings). The UV-Vis results were fully corroborated and confirmed by RP-HPLC analysis. **Conclusions:** This study demonstrates that O₃ is a highly effective oxidant for rapid degradation and mineralization of nitroacetanilides under aqueous conditions. The findings highlight the potential of ozonation as a viable advanced oxidation process for removing pharmaceutical residues and their nitro-derivatives from wastewater sources. These results also underscore the mechanistic differences between O₃ and other oxidants, supporting its role as a clean, sustainable technology in environmental toxicology and water treatment.

PS 4440 Overlooked role of sulfur in the production of microcystin.

A. Biswas, M. Minghetti, J. Belden, and P. Jeyasingh. Oklahoma State University, Stillwater, OK.

Background and Purpose: Cyanobacterial harmful algal blooms (HABs) represent a growing global toxicological concern because of their ability to produce microcystin (MC), a family of cyclic heptapeptide hepatotoxins that inhibit protein phosphatases PP1 and PP2A, disrupt phosphorylation-dependent signaling, and contribute to liver injury, including non-alcoholic liver disease. Forecasting MC occurrence and potency remains a major challenge in environmental toxicology. Despite decades of research, sulfur availability has never been systematically evaluated as a determinant of MC biosynthesis, largely because sulfur is absent from the final MC structure. However, sulfur metabolism is deeply embedded in the enzymology of MC biosynthesis: sulfur atoms at catalytic centers of NRPS/PKS enzymes support chain elongation and cyclization, while cysteine-derived metabolites such as S-adenosylmethionine (SAM) and malonyl-CoA facilitate biosynthesis. Beyond biosynthesis, sulfur also underpins thiol metabolism and detoxification pathways, including glutathione conjugation, highlighting its relevance to both toxin production and organismal susceptibility. We hypothesized that environmental sulfur availability regulates growth and MC quotas in *Microcystis aeruginosa*. **Methods:** To test this hypothesis, *M. aeruginosa* was cultured in batch systems across a sulfate gradient (0-300 μ M) under identical light and nutrient conditions aside from sulfur. Biomass, cell counts, and MC quotas were measured using ADDA-ELISA at defined intervals, with three independent replicates per treatment. The experimental design simulated environmentally relevant sulfate concentrations to assess how sulfur availability influences cyanobacterial growth and toxin biosynthesis. **Results:** Sulfur availability and MC production were positively related. Biomass and cell density increased with sulfur concentration, and MC quotas expressed on a per-cell and per-biomass basis rose strongly with sulfur supply, culminating in an eight-fold increase across the sulfur gradient. These results provide one of the first empirical demonstrations that sulfur is a critical driver of MC production in cyanobacteria. **Conclusions:** This study reveals that an element historically overlooked in bloom toxicology, because it is absent from the final toxin structure, is nonetheless indispensable to the biochemical machinery of toxin synthesis. In natural ecosystems, sulfur availability varies over 100-fold due to watershed geology, redox cycling, and anthropogenic inputs, suggesting a potential mechanistic link between sulfur dynamics and spatial or temporal heterogeneity in MC concentrations. By identifying sulfur as a key environmental regulator in cyanotoxin biosynthesis, this work introduces a new dimension in environmental toxicology, ecological monitoring, and the management of eutrophication and its toxic symptoms in Oklahoma and globally.

PS 4442 Germination to Pollination: Effects of Heavy Metals on *Phacelia parryi*

C. Baker, and W. Recart González. University of San Diego, San Diego, CA.

Background and Purpose: Pollination is a vital ecological process that sustains biodiversity and food production, yet it is increasingly threatened by environmental pollution. Heavy metal contamination, particularly copper (Cu) and zinc (Zn) pollution in cities, originates from automotive wear and runoff, accumulating in roadside soils during rainfall. Areas with increased traffic and urbanization have elevated concentrations of Cu and Zn pollution in roadside soil. This study examines how Cu and Zn pollution affect the germination rate and reproductive traits of *Phacelia parryi*, a native southern California wildflower. We hypothesized that elevated Cu and Zn exposure would cause higher levels of metal sequestration, negatively affecting germination rate, floral development, and decreasing pollinator visitation rate. **Methods:** Four soil treatments were applied to *P. parryi* seeds and plants: 60 parts per million (ppm) Cu, 85 ppm Zn, and 60 ppm Cu + 85 ppm Zn in addition to a control group. All of the seedlings were grown in an incubator at 28° C with 12 hours of light, then 24° C with no light. Germination was tracked during the first two weeks,

then 35 seedlings were transplanted into their corresponding soil treatments. For example, seedlings grown in 60 ppm Cu were transplanted to 60 ppm Cu soil. The control group was split into an additional delayed 60 ppm Cu group, representing post-germination pollution. This provides insight into how the timing of contamination influences plant development and reproductive success. All plants were grown in pollinator exclusion cages outside during the summer of 2025. Morphological traits such as flower petal length, flower petal width, anther length, and leaf size were measured in mm using a caliper. Additional phenological markers, such as first bud, first bloom, and total flower count, were collected, and pollinator visitation data were collected once flowering began. **Results:** Preliminary analyses revealed no significant differences in germination rate among treatments ($\chi^2 = 3.50$, $df = 4$, $p > 0.05$) and no significant effect of heavy metal exposure on petal length (ANOVA: $F = 1.30$, $df = 4$, 153 , $p > 0.05$). These results suggest that moderate levels of Cu and Zn may not impair early developmental or petal length in *P. parryi*. Additional traits such as petal width, anther length, leaf morphology, and pollinator visitation are being analyzed to determine whether there are any differences in reproductive or ecological responses. X-ray fluorescence (XRF) analysis verified that soil Cu and Zn concentrations matched intended treatment levels, confirming that non-significant results were not caused by inaccurate metal applications. Future data analysis will look at metal sequestration. **Conclusions:** These findings suggest that *P. parryi* shows early-stage tolerance to Cu and Zn exposure, as neither germination nor petal length was significantly affected. Future analyses will clarify whether other morphological or time-dependent effects occur. Understanding how heavy metal contamination influences native wildflowers is key to predicting ecological responses to urban pollution. This research contributes to the field of toxicology by demonstrating how soil contaminants can alter biological systems, linking environmental toxicology to plant reproduction and pollination ecology.

PS 4443 Unique Toxic Mechanism of *Chlamydomonas reinhardtii* Exposed to Gold Nanoparticles with Different Shapes

C. Wang, and K. Du. University of California, Riverside, Riverside, CA. Sponsor: Y. Wei

Background and Purpose: Nanoparticles (NPs) are widely utilized in a variety of commercial and research applications. In the process of NPs production, usage, transportation, and disposal, they inevitably enter the environments through migration and transformation. The aquatic environment is the primary medium through which NPs enter and diffuse into other environmental resources. Microalgae play a crucial role in mitigating eco-environmental changes. The ecotoxicological impact of nanoparticles with different shapes on aquatic systems, particularly their cellular and molecular interactions with algae, remain insufficiently characterized. **Methods:** In this study, 100 nm star (AuNS) and spherical (AuNP) silica-coated gold nanospheres were used as the representative shapes of NPs, and exposed *C. reinhardtii* to varying concentrations (1-50 mg/L) NPs with different shapes to investigate their differential effects on algal growth and primary photosynthetic processes. Confocal and transmission electron microscope were employed to detect the interaction and accumulation of different shapes of AuNPs and *C. reinhardtii*. RNA-seq was employed to elucidate the unique toxicity mechanisms of these differently shaped AuNPs in microalgae. **Results:** The results demonstrate that exposure to 10 mg/L AuNS for 72 hr results in more pronounced inhibition of cell growth and photosynthesis compared to the same concentration of AuNP. Morphometric profiling reveals that AuNS induce greater cellular damage in *C. reinhardtii* than AuNP at equivalent exposure concentrations, including cell enlargement, debris production, and subcellular structure disruption. Confocal imaging suggests this heightened toxicity may stem from distinct internalization patterns: AuNP primarily adhere to chloroplast surfaces, while AuNS penetrate more deeply into intracellular compartments. RNA sequencing identifies 9 upregulated and 38 downregulated differentially expressed genes (DEGs) in the 10 mg/L AuNP group, impairing photosynthesis and energy storage via the photosystem II subunit S1 (PSBS1)/ early light-inducible protein (ELI3) pathway. In contrast, the AuNS group exhibits 246 upregulated and 145 downregulated DEGs, affecting membrane integrity and nitrogen metabolism through the nitrate reductase (NIT1)/ aminomethyl transferase (AMT1)/ protein kinase domain-containing protein (AOA2K3CRU5) pathway. **Conclusions:** This study elucidates the unique toxic mechanisms by which different nanoparticle shapes interact with microalgae, underscoring the importance of nanoparticle shape in assessing ecotoxicity. Our findings suggest that in the development and production of nanoparticles, consideration should extend beyond application performance stability and functional enhancements to include potential ecological and human health impacts. Emphasizing nanoparticle shape optimization to maintain safety and stability while preserving functionality is essential for minimizing adverse environmental effects.

PS 4444 Embryonic exposure to Bisphenol F disrupts early neurodevelopment and induces anxiety-like behaviour in zebrafish (*Danio rerio*)

A. Hasan, A. York, S. Niyogi, and D. P. Chivers. University of Saskatchewan, Saskatoon, SK, Canada.

Background and Purpose: Bisphenol F (BPF), a structural analogue of bisphenol A, is increasingly used in industrial and consumer applications and has been detected in aquatic systems worldwide. Although promoted as a safer alternative, limited information exists regarding its developmental neurotoxicity. This study aimed to evaluate whether embryonic exposure to environmentally relevant concentrations of BPF disrupts early neurodevelopment and behaviour in zebrafish (*Danio rerio*) and to identify potential molecular mechanisms underlying these effects. **Methods:** Zebrafish embryos were exposed to 0, 5, 20, and 50 µg/L BPF from 4-120 hours post-fertilization (hpf). Spontaneous tail-coiling was assessed at 20 and 30 hpf to detect early neuro-excitation. At 120 hpf, larvae were tested for thigmotaxis, dark/light preference, and locomotor activity using automated video tracking system. Whole larvae were analyzed for BDNF protein and the relative expression of neuroplasticity- and stress-related genes. **Results:** Larval zebrafish exposed to BPF at 5, 20, and 50 µg/L from 4 to 120 hpf exhibited distinct behavioural and molecular alterations, despite showing no significant change in spontaneous tail-coiling activity at 20 or 30 hpf. In the thigmotaxis assay, BPF-exposed larvae demonstrated heightened anxiety-like behaviour, as reflected by a significant reduction in total distance traveled within the outer (peripheral) zone at 5 and 50 µg/L. Moreover, the proportion of time spent in the outer zone was consistently reduced across all treatment groups (5-50 µg/L), further indicating increased thigmotactic preference for the inner zone and a greater tendency toward anxiety. The reflexive movement test showed a significant increase in activity per minute at 5, 20 and 50 µg/L, with the most pronounced response at 20 µg/L, indicating transient hyper-reactivity or heightened neural excitability. In the dark/light preference assay, locomotor activity during the dark phase was markedly suppressed in all BPF-exposed groups, suggesting hypoactive or anxiogenic behaviour under reduced illumination, whereas total locomotor distance increased at 20 and 50 µg/L, indicative of mild hyperactivity and altered exploratory behaviour. At the molecular level, significant upregulation of *bdnf* mRNA and BDNF protein was observed at 50 µg/L, implying activation of neurotrophic signaling. Similarly, *grin2a* expression increased at 50 µg/L, suggesting enhanced N-methyl-D-aspartate receptor (NMDAR) activity and excitatory neurotransmission. Conversely, *ntrk2a* was downregulated across all concentrations, indicating suppression of TrkB-mediated feedback regulation. Elevated *akt1* expression at 50 µg/L supported activation of the PI3K-Akt survival pathway, whereas increased *inhibab* transcripts at the same concentration pointed to activin/inhibin A-mediated stress modulation. In contrast, *sypa* expression was significantly reduced at 50 µg/L, suggesting potential impairment of synaptic vesicle cycling and neurotransmission. **Conclusions:** Embryonic exposure to BPF at concentrations between 5 and 50 µg/L perturbs neurotrophic and excitatory-inhibitory signaling in developing zebrafish, resulting in anxiety-like and hyperactive behavioural phenotypes. These findings identify BPF as a potential developmental neurotoxicant, demonstrating that even short-term exposure during embryogenesis can disrupt early neuronal excitability and behaviour. The results contribute to understanding bisphenol analog-induced neurotoxicity and emphasize the need for mechanistic and generational studies to evaluate long-term risks of BPF contamination in aquatic environments.

PS 4445 Mixture Interactions of Haloacetonitriles Disinfection By-Products in Zebrafish

Y. Chien, J. Hsu, and C. Wu. National Yang Ming Chiao Tung University, Hsinchu City, Taiwan.

Background and Purpose: Haloacetonitriles (HANs) are nitrogenous disinfection by-products (DBPs) commonly formed during chlorination or bromination processes. Previous studies have shown that HANs exhibit higher cytotoxicity than regulated DBPs such as trihalomethanes, haloacetic acids, and bromate. However, the interactions and mechanisms among different HAN species during combined exposure remain unclear. In this study, we used the zebrafish model to investigate the effects of three common HANs (BCAN, DBAN, and DCAN) under single and combined exposures on embryonic development, locomotor behavior, and oxidative stress responses. **Methods:** Four hours post-fertilization zebrafish embryos were exposed to various concentrations of BCAN, DBAN, and DCAN for five days, with exposure levels ranging from 0 to 200 ppb. At 120 hpf, mortality, unhatched rate, morphological abnormalities, and locomotor activity were assessed to characterize dose response relationships. Interactive effects were evaluated by three binary combinations (BCAN+DBAN, BCAN+DCAN, and DBAN+DCAN) following the same exposure scheme, with DBAN fixed at its teratogenic EC₂₀ (70 ppb). Transcriptomic and differential gene expression analyses will be conducted to identify oxidative stress responses and associated functional and disease pathways. **Results:** Following single-HAN exposures, DBAN caused a significant increase in mortality and unhatched embryos at concentrations above 150 ppb, whereas BCAN and DCAN induced only minimal lethality at the same concentrations. DBAN exposure also showed a marked increase in morphological abnormalities beginning at 80 ppb, while BCAN and DCAN did not elicit noticeable malformations. Locomotor behavior test showed that DBAN exposure induced hyperactivity at 60-80 ppb but

reduced movement at 100-120 ppb, whereas BCAN and DCAN did not cause significant effects on locomotor activity. These results indicate that DBAN exhibited the highest toxicity among the three HANs. In mixture exposure experiments, no significant differences in mortality or unhatched rate were observed compared with the control group. However, when DBAN was fixed at 70 ppb, co-exposure with 10 ppb of either BCAN or DCAN induced significant developmental abnormalities, whereas co-exposure with 50 ppb reduced these developmental effects. Behavioral patterns in the mixture groups were consistent with those observed under DBAN single exposure. Notably, these behavioral effects occurred at concentrations lower than the teratogenic (80 ppb) and lethal (180 ppb) thresholds, suggesting that the nervous system may be affected at relatively low exposure levels. **Conclusions:** Our preliminary findings indicate DBAN induces both lethal and teratogenic effects at 80 ppb and causes biphasic neurobehavioral disturbances, potentially relevant with oxidative stress responses. Mixture interactions between DBAN and other HANs suggest a possible antagonistic effect. Future work will identify the molecular mechanisms underlying these responses through transcriptomic analysis and differential gene expression profiling.

PS 4446 A Proteomic Study Assessing the Impact of Brevetoxin on Zebrafish (*Danio rerio*) Embryo Development

J. M. Williams¹, K. Rein¹, T. A. Cabrera², and J. Berry². ¹Florida Gulf Coast University, Fort Myers, FL; and ²Florida International University, Miami, FL. Sponsor: J. Luyendyk

Background and Purpose: Brevetoxin (PbTx) is a neurotoxin produced by the marine dinoflagellate, *Karenia brevis* which causes harmful algal blooms (HABs) known as the Florida red tide. Brevetoxins pose risks to both human and animal health. Red-tide blooms are known to cause massive fish kills linked to the brevetoxins which activate the voltage-gated sodium channels present in neuronal and skeletal muscle cells. Ingestion of filter-feeding shellfish that are contaminated with brevetoxins can also cause neurotoxic shellfish poisoning (NSP). Inhalation of aerosolized toxins can lead to respiratory problems. Given these health and ecological risks, understanding how brevetoxins impact aquatic organisms at the molecular level are crucial. While previous studies have shown the developmental impacts of environmental toxins in zebrafish and other fish species, such as medaka or mahi-mahi, the molecular mechanisms involved in brevetoxins' effects on early-stage zebrafish remain poorly understood. We aim to understand how marine biotoxins can impact early vertebrate development by comparing protein profiles. Red tide is an ongoing issue in Southwest Florida; the findings from this study will help contribute to our understanding of red-tide effects on ecosystem health by way of understanding its impacts on early fish development. **Methods:** To investigate these effects, zebrafish will be exposed to three concentrations of PbTx-2 (0.5, 1 and 5 ppm) and liquid-chromatography tandem mass spectrometry (LC-MS/MS) based proteomic methods will be applied to identify and quantify proteins across treatment groups. In this study, we sought to determine the effect of PbTx-2 on zebrafish embryos during early development. For this purpose, zebrafish were exposed to PbTx-2 at 72 hours post-fertilization with concentrations of 0.5, 1, and 5 ppb for 24 hours. **Results:** Distinct pathway alterations were observed across treatment comparisons. In the 1 ppb vs. 5 ppb group, *synaptic vesicle trafficking* was uniquely enriched. The 0.5 ppb vs. 5 ppb comparison revealed exclusive enrichment of *axon guidance*, *mannose metabolism*, and *acetate utilization* pathways. In the 5 ppb vs. 0 ppb group, *thiamine metabolism* and *adenine/hypoxanthine salvage* pathways were identified. In comparison, the 1 ppb vs. 0.5 ppb group showed exclusive enrichment of *asparagine and aspartate biosynthesis*, *JAK/STAT signaling*, *heterotrimeric G-protein signaling*, *plasminogen activation cascade*, *glutamine-glutamate conversion*, and *aminobutyrate degradation* pathways. **Conclusions:** Brevetoxin exposure disrupts key proteostasis mechanisms—including protein folding, degradation, and antioxidant defense—leading to protein accumulation, oxidative stress, and heightened vulnerability of embryos to cellular toxicity and apoptosis.

PS 4447 Drivers of Contaminant Load in Elasmobranchs: Coastal Development and Feeding Ecology

M. A. Walker¹, P. C. Powell¹, G. D. Aniolek¹, Z. J. Padgett¹, K. Artosky¹, E. J. Zheltov¹, E. Wittman¹, J. M. Schulte², E. Personius², J. Donaldson³, D. Feinstein⁴, S. L. Kim⁴, J. H. Bisesi³, J. A. Bowden³, M. M. Holst⁵, T. K. Chapple⁶, B. S. Frazier⁷, and K. D. Rock¹. ¹Clemson University, Clemson, SC; ²Coastal Oregon Marine Science Experiment Station, Oregon State University, Newport, OR; ³Center for Environmental and Human Toxicology, University of Florida, Gainesville, FL; ⁴Dept. of Life and Environmental Sciences, University of California - Merced, Merced, CA; ⁵Dept. of Anatomy, Physiology, and Cell Biology, University of California - Davis, Davis, CA; ⁶Fisheries, Wildlife, and Conservation Sciences, Oregon State University, Corvallis, OR; and ⁷South Carolina Dept. of Natural Resources, Marine Resources Research Institute, Charleston, SC.

Background and Purpose: Pollution is a major driver of biodiversity loss in marine ecosystems and poses risks to sharks, a subgroup of elasmobranchs that serve as apex/meso- predators and keystone species vulnerable to the bioaccumulation of persistent contaminants. Coastal estuaries function as critical feeding and nursery habitats for many shark species but often overlap with urban development and

pollutant inputs. While contaminant bioaccumulation varies by species, age class, and trophic position, few studies have examined how coastal urbanization and feeding ecology interact to influence contaminant burdens, and even fewer have addressed the co-occurrence and potential interactive effects of multiple contaminant classes. This research aims to (1) evaluate how residence in urbanized versus non-urbanized estuaries influences contaminant concentrations in broadnose sevengill sharks (*Notorynchus cepedianus*), and (2) assess how specialist versus generalist feeding strategies affect contaminant levels in finetooth (*Carcharhinus isodon*) and sandbar (*Carcharhinus plumbeus*) sharks. By integrating measurements of mercury (Hg) and per- and polyfluoroalkyl substances (PFAS), this study investigates mixture exposure dynamics in estuarine predators. I hypothesize that sharks from urbanized estuaries will have higher Hg and PFAS concentrations than those from less-impacted areas, and that generalist feeders will accumulate more of these contaminants through consumption of higher-trophic-level prey. **Methods:** Environmental samples of water and sediment were collected along with shark muscle and blood samples using catch-and-release methods. Project 1 focused on sevengill sharks from San Francisco Bay (SFB), CA, and Willapa Bay (WB), WA, urbanized versus non-urbanized estuaries. Project 2 targeted finetooth and sandbar sharks from Bulls Bay (BB) and St. Helena Sound (SHS), SC, with prey muscle samples for comparative analysis. Mercury was quantified via thermal decomposition, amalgamation, and atomic absorption spectrophotometry, and 21 PFAS were analyzed using LC-MS. Stable isotope ($\delta^{13}\text{C}$ and $\delta^{15}\text{N}$) and prey Hg data support trophic positioning and contaminant transfer assessment. **Results:** Preliminary Project 1 results show significant differences in muscle total mercury (tHg) levels by age class in SFB broadnose sevengill sharks, with subadults having the highest concentrations versus juveniles and neonates/YOY (Young of the Year). Blood tHg from WB broadnose sevengill sharks show significant differences in tHg between adults and subadults. Across sites, subadult broadnose sevengill shark blood show significantly higher tHg levels in SFB samples versus WB. In Project 2, blood tHg levels in sandbar sharks are significantly higher than in finetooth sharks by age class, and both finetooth and sandbar tHg concentrations trend upward with size/age class. Parallel analysis of PFAS profiles will help determine whether co-exposure trends mirror or diverge from mercury accumulation patterns, revealing whether these contaminants share exposure pathways or partition differently across tissues. PFAS were detected in water and sediment samples across all sample collection locations. Prey, blood, tissue, water and sediment tHg, PFAS and Stable Isotope analyses are ongoing. **Conclusions:** These studies provide new insight into how habitat use and ecological traits shape multi-contaminant exposure in elasmobranchs. Results may inform conservation strategies, improve understanding of combined contaminant effects and trophic transfer, and support more integrative Hg and PFAS risk assessments for vulnerable marine predators.

PS 4448 Multiorgan integrative toxicity of emerging contaminants thallium and gallium in zebrafish

Y. Chang¹, Y. Chang¹, J. Chen¹, T. Jao², S. Liu¹, and C. Chiang^{1,3}. ¹Graduate Institute of Toxicology, College of Medicine, National Taiwan University, Taipei, Taiwan; ²Global Innovation Joint-Degree Program International Joint Degree Master's Program in Agro-Biomedical Science in Food and Health, National Taiwan University, Taipei, Taiwan; and ³Department of Integrated Diagnostics & Therapeutics, National Taiwan University Hospital, Taipei, Taiwan.

Background and Purpose: Thallium (Tl) and gallium (Ga) are emerging metal contaminants that have recently attracted increasing attention. Both are widely used in the semiconductor and optoelectronic industries, such as in optical fibers, high-performance chips, light-emitting devices, and thin-film solar cells (CIGS). Although they possess significant economic value, their emissions have led to environmental accumulation risks. Tl concentrations in surface waters can reach up to 1520 µg/L, while Ga has been detected at 40 ppb in water and 40 ppm in sediments. Tl is highly stable and bioaccumulative, readily enriched in vegetables and fruits, whereas Ga can accumulate in the roots of crops such as wheat and rice and be translocated to grains, becoming a potential dietary exposure source. Both metals pose threats to food safety and ecological health. Therefore, it is essential to conduct a systematic toxicological evaluation of Tl and Ga, elucidate their molecular mechanisms involving apoptosis, cellular stress, and endoplasmic reticulum stress, and further explore potential protective strategies. **Methods:** At 6 hours post-fertilization (hpf), healthy zebrafish embryos were selected and placed in 24-well plates for exposure to different concentrations of thallium (Tl) and gallium (Ga) solutions, with embryo medium as the control. Some groups were co-treated with IXA4 or TUDCA from 6 to 48, 72, or 144 hpf. Evaluations included embryo survival, hatching rate, morphological assessment, target gene expression (qPCR), RNA sequencing (RNA-seq), and bioinformatic analysis. **Results:** This study employed zebrafish embryos to investigate the developmental toxicity induced by Tl and Ga, as well as the protective effects mediated by endoplasmic reticulum (ER) stress modulation. Exposure to Tl and Ga significantly increased embryo mortality and malformation rates. In particular, Ga exposure not only caused swim bladder shrinkage and cardiac abnormalities but also induced systemic iron metabolism imbalance and neurotoxicity, indicating strong interference with energy homeostasis and neural development. Tl exposure markedly upregulated multiple genes associated with the unfolded protein response (UPR). Treatment with the selective XBP1 activator IXA4 or the chemical chaperone TUDCA significantly improved embryo survival, hatching rates, and organ morphology. Transcriptomic analysis revealed that IXA4 reversed Tl-suppressed pathways

related to neurocardiac development and enhanced DNA repair mechanisms, particularly nucleotide excision repair (NER). Collectively, IXA4 mitigates Tl-induced multi-organ toxicity by reinforcing UPR adaptation and DNA repair, providing new insights into the toxicological mechanisms and potential protective strategies against emerging metal contaminants. **Conclusions:** Both Tl and Ga induce systemic developmental toxicity in zebrafish, while UPR modulation by IXA4 or TUDCA effectively alleviates Tl-induced toxicity and provides cellular protection.

PS 4449 Skin irritation caused by drilling fluid

U. A. Satybaldiyeva, A. A. Zhurgenova, and A. A. Mamyrbayev. West Kazakhstan Medical University named after Marat Ospanov, Aqtobe, Kazakhstan.

Background and Purpose: The process of extracting hydrocarbon raw materials involves the widespread application of a wide variety of drilling fluids. Drilling fluids are multicomponent mixtures containing a wide variety of organic and inorganic substances. The toxicological properties of drilling fluids have been basically studied in species of fish fauna and protozoa. At the same time the impact of the toxicological properties of drilling fluid on mammals have hardly been studied. Our previous studies have shown that drilling fluid, under acute experimental conditions, when administered directly into the stomach of adult male rats, leads to changes in behavioral responses and feeding behavior. The median lethal doses of drilling fluid were determined using the probit analysis method. The aim of the study was to investigate the skin irritant effect of drilling fluid in acute and subacute experiments on sexually mature male rats. **Methods:** The experiment was conducted on sexually mature male rats under conditions of skin irritation and skin resorption. All procedures involving animals were performed in accordance with ARRIVE guidelines and in compliance with the 3Rs ethical standards. In the course of the acute experiment the local irritant effect of drilling fluid on the skin was studied by applying epy drilling fluid at a rate of 20 ml/cm². The skin resorptive effect of drilling fluid was evaluated in the course of the subacute experiment lasting 30 days. The general state of the animals was assessed, signs of toxicity were identified, the number and time of death of animals, feed and water intake were recorded. The general condition of the animals, the condition of their coat and skin, the intensity and nature of spontaneous motor activity were assessed. A biochemical blood count was performed. Dermis samples were taken for histological examination. The research materials were prepared as part of IRN AP19676915 scientific project funded by the Science Committee of the Ministry of Science and Higher Education of the Republic of Kazakhstan. **Results:** Under the conditions of acute single exposure of drilling fluid to the skin of rats, moderately pronounced (pink-red tone) erythema was observed, which corresponded to 2 points. When assessing the intensity of skin edema some weak intensity of skin edema was identified, which corresponded to 1 point. The skin fold thickness gain was 0.3 mm. The assessment of the degree of erythema and edema was summarized and the average total score was calculated, which equaled 3 points. The effects of the skin-resorptive effect of the drilling fluid in the subacute experiment were assessed based on a number of indicators: feed and water intake, changes in body weight dynamics, behavioral reactions as well as external signs of intoxication. It is noteworthy that by the end of the experiment the test group of animals showed stiffness and impaired coordination of movement. Feed intake declined, which led to a change in the body weight of the test animals. It should be noted that the duration of posture in the experimental animals showed a pronounced tendency to decrease on day 15, with a gradual increase towards the end of the experiment (by day 30). A similar tendency was observed in the number of postures, which decreased by the middle of the experiment with a gradual recovery of behavioral responses. One of the important indicators characterizing the functional features of the animals' condition is grooming. It was found that in the experimental animals this type of behavior also tended to deteriorate compared to that in the reference animals. It should be noted that there were pronounced changes in the leukocyte formula and the activity of detoxification enzymes in the experimental groups compared to those in the reference group. Moderately pronounced focal inflammatory infiltrates were observed in the papillary layer of the dermis, and varying degrees of edema of fibrous structures and intercellular substance, swelling of collagen fibers and an increase in their thickness were noted in the reticular layer. **Conclusions:** Under conditions of skin irritation and skin resorption the drilling fluid leads to adverse changes in behavioral responses, clinical and biochemical blood parameters, and histomorphological alterations in the dermis.

PS 4450 Metabolic activities in Rainbow trout (*Oncorhynchus mykiss*) S9 fractions from liver and extrahepatic organs as an alternative *in vitro* ecotoxicity assessment approach

A. Ullrich, M. Reu, M. Thiede, A. Alkufairi, A. Sattler, J. Schuldt, and D. Runge. PRIMACYT GmbH, Schwerin, Germany.

Background and Purpose: Whole body biotransformation rate constants can be calculated by using *in vitro* to *in vivo* extrapolation (IVIVE) models. These models use *in vitro* intrinsic clearance $CL_{in\ vitro, int}$ rates derived with OECD Test Guidelines (TG) 319A and/or 319B to estimate liver clearance rates in Rainbow trout, which are then extrapolated to a whole-body (*in vivo*) biotransformation rate constant. Primacyt supports this approach and therefore contributes to alternative methods to animal

experiments. **Methods:** Rainbow trout were kept under environmental controlled housing conditions according to OECD TG 319A/B. Organs were obtained from sexually immature non-infectious, non-contagious and healthy animals. After removal, the organs were cut, immediately flash frozen in liquid nitrogen and stored at -80 °C. The tissues from 8 individual animals (per lot) were homogenized for preparation of S9 fractions in phosphate buffer, in total 2 lots. S9 fractions of liver, intestine, gill, brain, heart and spleen were produced and stored at -150 °C. S9 fractions were prepared to determine the Phase I and Phase II Cytochrome P450 enzyme activities by using liquid chromatography-mass spectrometry analysis. Phase I enzymatic activities of Cytochrome P450 in Rainbow trout organs were determined by using 1 mg protein extract incubated with 7 reference compounds, including Bupropion, Chlorzoxazone, Coumarin, Diclofenac, Midazolam, Phenacetin and S-Mephenytoin at 14 °C in 0.1 M phosphate buffer. Time dependence of enzyme activity were determined in intestine S9 fractions for 10 to 60 min and in liver for 5 to 120 min. The distribution of Phase I/II enzyme activities in Rainbow trout organs were determined by using 1 mg protein extract incubated with reference compounds at 14 °C for 60 min (Phase I) and 30 min (Phase II) in 0.1 M phosphate buffer. Glucuronidation and sulfation of 7-OH Coumarin were determined for Cytochrome P450 Phase II enzyme activities in all prepared organs. **Results:** The Phase I formation of Acetaminophen, OH-Bupropion, 4-OH-Diclofenac and 6-OH-Chlorzoxazone was linear up to 60 min in intestine and up to 120 min in liver. In both intestine and liver, a linear increase of protein concentration from 1 to 2 mg/ml led to a linear increase of enzyme activities in Phenacetin O-Deethylase, Diclofenac 4'-Hydroxylase and a minor increase of Chlorzoxazone 6'-Hydroxylase. Additionally, in liver Midazolam 1'-Hydroxylase activities led also to a linear increase. Bupropion-Hydroxylase and Coumarin 7'-Hydroxylase enzyme activities indicated no effect by doubling the protein concentration in both organs. Phase I Cytochrome P450 activities were found in all organs after 60 min of incubation. Liver accounted for the highest enzyme activities of all organs tested. Intestine accounted for the highest extrahepatic enzyme activities of Phenacetin O-Deethylase (57 % of total activity (OTA), Midazolam 1'-Hydroxylase (27 % OTA), Chlorzoxazone 6'-Hydroxylase (24 % OTA), Diclofenac 4'-Hydroxylase (22 % OTA). Bupropion-Hydroxylase activities were almost equally distributed (15-21 %) among all organs. Minor enzyme activities were also found in gill, heart, brain and spleen. Phase II activities were detected in liver, intestine, gill and heart. Liver accounted the highest activities of 7-OH-Coumarin glucuronidation (59 % OTA) and its sulfation (83 % OTA). 34 % of total 7-OH-Coumarin glucuronidation activity was detected in intestine and less in gill (4 % OTA) and heart (2 % OTA). Besides liver, 7-OH-Coumarin sulfation activity was only detectable in gill (17 % OTA). **Conclusions:** In summary, the liver is the major organ for detoxification of compounds in Rainbow trout. Liver and intestine have shown a linear increase of enzyme activity for at least 60 min of incubation time. However, extrahepatic organs, mainly intestine, but also brain, gill, heart and spleen exhibit certain Phase I Cytochrome P450 activities with different specification to the reference compounds. Phase II enzyme activities were besides liver also detectable in intestine and gill. Our results suggest that extrahepatic organs, mainly intestine, should also be taken into account when bioaccumulation and *in vitro* clearance rates are determined for IVIVE modeling in Rainbow trout.

PS 4451 Effect of tire wear particle 6PPD and 6PPDQ on HepG2 liver cancer cell metabolism

M. Singleton, E. Braun, and K. Kim. Missouri State University, Springfield, MO.

Background and Purpose: In the United States alone, it is estimated that 1.12 million tons/year of tire wear particles are produced when automobile tires come in contact with the road. Tire wear particles, 6PPD and its quinine version, 6PPDQ, have been tested in many *in vivo* studies, revealing impaired swimming capabilities in zebrafish, and were found to be accumulated in animal livers. Nevertheless, little is known how 6PPD and 6PPDQ are impacting organisms on a cellular level, specifically how mitochondrial processes are interrupted in mammalian cells by 6PPD and 6PPDQ. **Methods:** In this study, we sought to understand if 6PPD and 6PPDQ cause changes in mammalian mitochondrial morphology and function. We incubated five different concentrations of 6PPD and 6PPDQ (200uM, 100uM, 50uM, 25uM, and 12.5uM) with a HepG2 liver cell line for 24 hours. XTT cell viability was performed following 24 hour treatment of 6PPD and 6PPDQ. Furthermore, mitochondrial staining, and ATP quantification experiments were performed following 24 hour treatment of 6PPD. **Results:** Dose dependent reduction in cell viability, mitochondrial mean branch length, and ATP levels were observed after 6PPD treatment. 6PPDQ showed an increase in cell viability across all concentrations, and was further studied morphologically. Qualitative results suggest linear polymerization of 6PPDQ and therefore reduced capacity to enter the cell. **Conclusions:** Ongoing studies, such as RNA sequencing, are being conducted to explore the specific genes 6PPD acts on to impact a cell's mitochondrial metabolism to better understand the specific pathways leading to mitochondrial dysfunction after 6PPD treatment.

PS 4452 Assessing PFAS Contamination and PFOS Biodegradation Potential in South Carolina Estuarine Sediments

Z. J. Padgett¹, P. C. Powell¹, A. C. Elkins¹, M. C. Boland¹, M. Walker¹, M. Afghah¹, R. Dotson¹, M. Heselton¹, D. Patabandige¹, B. C. Campbell¹, E. Friend², N. Shea², A. Tweel², S. D. Hamilton-Brehm³, and K. Rock¹. ¹Clemson University, Clemson, SC; ²South Carolina Department of Natural Resources, Charleston, SC; and ³Southern Illinois University, Carbondale, IL.

Background and Purpose: Per- and polyfluoroalkyl substances (PFAS) are synthetic chemicals widely used in industrial and consumer applications, including firefighting foams, non-stick cookware, and food packaging. Their exceptionally strong carbon-fluorine bonds contribute to their environmental persistence and tendency to bioaccumulate. Among them, perfluorooctanesulfonic acid (PFOS) remains a pervasive contaminant in marine ecosystems despite its phaseout from U.S. production, largely because it is readily transported to and retained in estuarine sediments, where it can persist for decades. Estuaries, which provide critical habitat and essential ecosystem services, are increasingly threatened by coastal urbanization and associated contaminant inputs. Charleston Harbor (CH), a highly urbanized estuary in South Carolina, is known to contain elevated PFAS levels, whereas nearby St. Helena Sound (SHS), a comparatively undeveloped system, has not yet been analyzed for PFAS contamination. Because microbial communities in estuarine sediments regulate organic matter cycling and pollutant transformation under both aerobic and anaerobic conditions, they may also initiate PFOS degradation and therefore serve as potential bioindicators of PFAS exposure and ecosystem health. In this study, we quantify PFAS concentrations and characterize sediment microbial community composition in CH and SHS. We test three hypotheses: (1) PFAS concentrations will be higher in CH than in SHS; (2) sites with elevated PFAS will harbor microbial communities enriched in taxa resistant to or capable of degrading these compounds; and (3) microbial inoculum from those sediments, when exposed to elevated PFOS, will transform it into less bioaccumulative metabolites. **Methods:** Sediment was collected with a Van Veen grab and split for PFAS and microbial analyses, and surface water for PFAS was collected in 1-L HDPE bottles. PFAS concentrations in sediment water were quantified by HPLC-MS/MS. Microbial community composition in sediment was characterized by NextGen Illumina 16S rRNA gene sequencing and processed in QIIME 2. Alpha diversity (Shannon index, Pielou's evenness) and beta diversity (Bray-Curtis dissimilarity, unweighted UniFrac) were used to compare microbial communities in sites and estuaries. To evaluate PFOS biodegradation potential, sediment inocula from selected sites were incubated at elevated PFOS concentrations under aerobic and anaerobic conditions. PFOS loss and metabolite formation were measured by IM-MS and fluoride ion release was monitored using a fluoride ion selective electrode, and TOPO cloning was used to identify candidate taxa potentially responsible for PFOS degradation. **Results:** Preliminary results show some differences in PFAS between estuaries, with PFOS emerging as the dominant PFAS in both sediment and surface water and generally higher in CH than in SHS. Shannon diversity decreased from Fall to Spring with October sediments showing higher diversity than March. Unweighted UniFrac indicated that microbial communities were more similar within the same site and season, while Bray-Curtis shows distinct, site-specific clustering across months. These patterns, together with the persistence and dominance of PFOS, motivated the targeted culture experiments to test PFOS degradation and link it to specific microbial taxa. **Conclusions:** Overall, we find PFAS contamination in both estuaries, with PFOS consistently the dominant compound across each site. Additionally, there are clear differences in sediment microbial diversity and community composition between the more urbanized and less urbanized sites. Because these field patterns are correlative and multiple stressors can influence sediment microbiomes, they highlight the need for controlled culturing studies. Ongoing incubations with sediment inocula and elevated PFOS exposure will directly test whether estuarine microbes can transform PFOS and help identify the taxa that may contribute to the natural attenuation of PFAS in these systems.

PS 4453 Mechanism of Liver Injury Induced by Cr⁶⁺ in Zebrafish and Protective Effect of Organic Selenium

Y. Xu¹, X. Bo¹, Y. Zhang¹, X. Li¹, H. Chen², L. Xie², Y. Yang¹, J. Yu¹, and W. Dong¹. ¹Inner Mongolia Minzu University, Tongliao City, China; and ²SCNU Environmental Research Institute, Guangdong Provincial Key Laboratory of Chemical Pollution and Environmental Safety & MOE Key Laboratory of Theoretical Chemistry of Environment, South China Normal University, Guangzhou City, China.

Background and Purpose: Hexavalent chromium (Cr⁶⁺) is a form of chromium with extremely strong oxidizability, high mobility, and the highest toxicity, and it is classified as a Group A human carcinogen. It is mainly released into the environment through leather and textile production processes and metallurgical applications, leading to widespread contamination of soil and groundwater. After transmission through the food chain, Cr⁶⁺ accumulates in target organs (such as the liver) in humans and animals, posing a potential threat to human health. In addition to promoting hepatocyte death and secondary liver fibrosis, Cr⁶⁺ can also induce hepatic steatosis. However, the mechanism underlying the association between Cr⁶⁺ and these liver pathological changes has not been fully elucidated. **Methods:** In this study, liver transgenic zebrafish were used as an experimental model to explore the mechanism of liver steatosis and hepatocyte death induced by Cr⁶⁺. Meanwhile, we evaluated the protective effect of low-dose selenomethionine (Se-Met) on Cr⁶⁺.

mediated hepatotoxicity. **Results:** Exposure to Cr⁶⁺ caused hepatic steatosis and hepatocyte mitochondrial damage in zebrafish. At the biochemical and molecular levels, Cr⁶⁺ exposure upregulated the expression of genes related to lipid metabolism and ferroptosis, while reducing the protein expression level of glutathione peroxidase 4 (GPX4) and the content of glutathione (GSH). Notably, both ferroptosis inhibitor Fer-1 and low-dose Se-Met could alleviate Cr⁶⁺-induced hepatic steatosis, mitochondrial dysfunction, and GPX4/GSH regulatory imbalance. Cr⁶⁺ significantly affected fatty acid metabolism, fatty acid biosynthesis, linoleic acid metabolism, and oxidoreductase activity. **Conclusions:** The results of this study indicate that the mechanism of liver injury induced by Cr⁶⁺ is related to the ferroptosis pathway, and the ferroptosis inhibitor Fer-1 and low-dose Se-Met can prevent this injury. The results also suggest that low-dose Se-Met can be used as a feed additive to prevent the harm caused by chromium.

PS 4454 Ecotoxicological Assessment of Effluents from a Combined Anaerobic-Anoxic-Aerobic Wastewater Treatment System Reveals Unexpected Oxidative Stress in *Chironomus sancticarioli*

M. N. Araujo^{1,2}, D. F. Gomes², T. V. Soeira², H. P. Brito³, J. N. Swihart¹, W. A. Tamagno¹, M. Zaiat², and J. H. Shannahan¹. ¹Purdue University, Lafayette, IN; ²University of São Paulo, São Carlos, Brazil; and ³Federal University of São Carlos, São Carlos, Brazil.

Background and Purpose: Traditional wastewater treatment plants are usually based on anaerobic or aerobic processes and often fail to efficiently remove organic micropollutants, posing risks to both environmental and human health. Besides low removal efficiencies, biotransformation products are usually derived from biological processes, which may have potentially higher toxicity. To overcome these drawbacks, combined biological processes have been proposed as a hidden solution. Notwithstanding research examining the ecotoxicity of effluents from treatment units, investigation into the ecotoxicological effects of effluents from combined alternative systems, such as anaerobic-anoxic-aerobic systems, remains lacking, especially involving biomarkers assessments. It was hypothesized that effluents from the aerobic stage would exhibit lower toxic potential than those from preceding units, as enhanced oxidation could favor micropollutant degradation and reduce the formation of reactive intermediates. **Methods:** This study assessed the ecotoxicological effects of an innovative treatment system integrating anaerobic, anoxic, and aerobic fixed-film reactors, producing effluents with low organic matter and nitrogen. The system comprised an anaerobic reactor fed with raw domestic wastewater (RDW), whose effluent supplied an anoxic-aerobic stage. The anoxic reactor received the anaerobic effluent with sodium bicarbonate addition and a recirculated stream from the aerobic reactor, which finalized treatment. Four samples were tested at 25%, 50%, and 100% dilutions: RDW, anaerobically treated wastewater (ATDW), ATDW with sodium bicarbonate (ATDW+NaHCO₃), and anoxic-aerobically treated wastewater (AATDW). *Chironomus sancticarioli* was used in chronic exposures (7 days) assessing survival, dry weight, and biomarkers as catalase (CAT), glutathione (GSH), glutathione S-transferase (GST), and lipid peroxidation (LPO). **Results:** No significant changes occurred in survival or dry weight. However, distinct oxidative stress patterns emerged. RDW and ATDW showed no significant CAT variation, but GSH was significantly upregulated at 50% and 100% RDW and all ATDW dilutions, especially at 100% ATDW. This increase coincided with a remarkable GST downregulation in 100% RDW and all ATDW dilutions. LPO decreased in 100% RDW and 50-100% ATDW, suggesting effective antioxidant compensation. The stable CAT levels may reflect compensation via GSH-Px activity or oxidative imbalance driven by organic micropollutants rather than H₂O₂. The rise in GSH indicates adaptive redox regulation against stress, while reduced GST suggests enzyme inhibition or structural damage. Despite redox disturbance, oxidative damage (LPO) remained controlled in anaerobic treatments. Conversely, the anoxic-aerobic effluent (AATDW) produced unexpected effects. CAT was consistently downregulated across all dilutions, while ATDW+NaHCO₃ showed no changes. GSH was upregulated in both ATDW+NaHCO₃ and AATDW, whereas GST was reduced. Notably, LPO levels doubled in 50% and 100% AATDW, indicating enhanced lipid damage despite higher organic matter and nitrogen removal. It is worth noting that all the exposures were carried out under aeration, which rules out the hypothesis of oxygen levels present in the AATDW samples. Thus, the anoxic-aerobic stage induced greater oxidative stress than the anaerobic stage, challenging the notion that higher oxidative levels from aerobic systems necessarily produce effluents with less alteration. **Conclusions:** The combined anaerobic-anoxic-aerobic system effectively reduced conventional pollutants but induced distinct oxidative stress responses at the cellular level. Anaerobic treatment maintained redox balance without oxidative damage but affected the antioxidant defense system. On the other hand, the anoxic-aerobic effluent triggered lipid peroxidation and enzyme inhibition in *C. sancticarioli*. These findings highlight that improved conventional removal does not necessarily correlate with reduced ecotoxicity, reinforcing the importance of biomarker-based assessments in evaluating advanced treatment systems.

PS 4455 Hair analysis as a non-invasive method for assessing the exposure of mammals with different dietary habits to poly- and perfluoroalkyl substances

C. Merola¹, A. Menozzi¹, S. Gonkowski², A. Petrini³, S. V. Defourny³, S. Mikolajczyk⁴, and K. Makowska². ¹University of Teramo, Teramo, Italy; ²University of Warmia and Mazury in Olsztyn, Olsztyn, Poland; ³Istituto Zooprofilattico Sperimentale dell'Abruzzo e Molise "G. Caporale", Teramo, Italy; and ⁴National Veterinary Research Institute, Pulawy, Poland.

Background and Purpose: Poly- and perfluoroalkyl substances (PFASs) are persistent environmental pollutants found across various ecosystems. While human and domestic animal exposure to PFASs is well documented, data on wild terrestrial mammals remain scarce, particularly when using hair as a biomonitoring matrix. Hair appears particularly valuable for PFAS biomonitoring in wildlife, as it accumulates chemicals over time and reflects long-term exposure remaining intact after death. Despite this potential, very few studies have investigated PFAS accumulation in the hair of wild terrestrial mammals. This study aimed to assess the levels of selected PFASs in the hair of different wild mammal species with varying diets, using liquid chromatography-tandem mass spectrometry (LC-MS/MS). **Methods:** Samples were collected between January and June 2023 in the Abruzzo region, located in central Italy. The study encompassed 58 adult individuals, belonging to three groups in term of feeding behaviour: 1) herbivores (n=23) including roe deer and red deer; 2) predators (n=25) including red fox, European badger and wolf; 3) omnivores (n=10) including wild boar. The PFASs analysed included perfluorobutanesulfonic acid (PFBS), perfluorohexanoic acid (PFHxA), perfluoroheptanoic acid (PFHpA), perfluorohexanesulfonic acid (PFHxS), perfluorooctanoic acid (PFOA), perfluorononanoic acid (PFNA), linear and branched perfluorooctane sulfonic acid (L-PFOS and B-PFOS), perfluoropentanesulfonic acid (PFPeS), perfluorheptanesulfonic acid (PFHpS), perfluoroundecanoic acid (PFUnDA) and perfluorododecanoic acid (PFDoDA). Quantification of analytes was conducted using LC-MS/MS, employing a Sciex Triple Quad™ 7500 system (Sciex, Framingham, MA, USA) operated in negative electrospray ionization (ESI-) mode. Descriptive statistics were applied to summarize the data. To compare PFAS concentrations among animals with different feeding behaviours, the non-parametric Kruskal-Wallis test was employed. **Results:** The levels of PFASs detected in this study varied significantly depending on both the specific compound and the mammalian species analysed. When considering all 58 hair samples collectively, the highest mean concentrations were observed for PFNA and PFOA. PFNA exhibited a mean ± SD of 0.309 ± 0.33 ng/g (median: 0.37 ng/g) and was detected above LOQ in 93.1% of samples. PFOA was present in 96.6% of samples (mean ± SD: 0.272 ± 146.051 ng/g; median: 0.15 ng/g). Significant inter-group differences were also observed for individual compounds. The clearest differences between predators and herbivores were noted in the case of L-PFOS and PFDoDA. Mean level of L-PFOS in predators was 0.291±0.046 ng/g (median 0.143 ng/g) and was statistically significantly higher (p<0.0001) than value noted in herbivores (mean 0.033±0.09 ng/g, median<LOQ). Mean level of L-PFOS in generalist omnivores was 0.093±0.08 ng/g (median 0.068 ng/g) and was also statistically significantly higher (p=0.0269) than that noticed in herbivores. Similar situation was found in the case of PFDoDA. Moreover, mean level of PFUnDA in predators amounted to 0.091±0.11 ng/g (median 0.054 ng/g) and was statistically significantly higher (p=0.031) than the level in herbivores (mean 0.038±0.03ng/g and median 0.033 ng/g). **Conclusions:** This study contributes valuable insights into the environmental exposure of wild terrestrial mammals to PFASs, reinforcing the utility of hair as a biomonitoring matrix. Trophic position appears to play a central role in PFAS bioaccumulation, with higher concentrations observed in carnivores. Species-specific behaviours (such as opportunistic feeding near human settlements) may also influence exposure levels. The differences in PFAS compound profiles across studies underscore the complex environmental dynamics and highlight the need to monitor both legacy and emerging PFAS. Despite generally low concentrations, the toxic potential of PFASs at environmentally relevant levels, combined with possible mixture effects, raises concerns for wildlife health and conservation.

PS 4456 Developing a Protocol for Measuring Environmentally Sourced Microplastics through Flow Cytometry

H. Brown, A. Holian, and R. L. Kendall. University of Montana, Missoula, MT.

Background and Purpose: Microplastics are ubiquitous in our environment, being found in every medium. A microplastic, as defined by the EPA, is derived from any different form of plastic in the size range of 5 millimeters to as small as 1 nanometer or referred to as nanoplastic. Evidence suggests that microplastics are present in nearly every environment, regardless of location. However, existing methods for measuring and identifying these microplastics have typically relied on lab-milled plastics and microplastics under ideal conditions, with minimal consideration of natural variability. The goal of this project was to develop a protocol to not only detect the presence of microplastics, but also efficiently quantitate environmentally sourced microplastics. **Methods:** For this study, water samples were taken from two sources around Missoula, MT, Frenchtown Pond State Park and the Clark Fork River through Missoula. Both being highly recreated bodies of water with lots of anthropogenic activity in their vicinities. The samples were treated with hydrogen peroxide and left to sit for 24 hours before each measurement was taken. Milli-Q water was used as a control to establish a baseline for microplastics. Fluorescent Nile

Red Dye was used to stain for microplastics in the samples, as it has a high affinity towards plastic particles, allowing quantitation of microplastic particles based on fluorescence intensity. Each sample was stained with Nile Red for 30 minutes before measuring, to give it ample time to adhere to the plastic within the water samples. Flow Cytometry was used as the main method for identifying microplastic presence using excitation at 488 nm and emission at 530 nm to separate microplastics from the background signal of the sample. As Flow Cytometry proved to be more efficient than other methods established, another method tried was measuring the fluorescent intensity, with a plate reader, as an indicator for microplastic concentration. **Results:** Flow Cytometry allowed us to separate the microplastic content from fluorescent intensity to get an accurate concentration. By developing a detailed and reproducible protocol we were able to quantify different microplastic concentrations from multiple environmental samples from Frenchtown Pond and the Clark Fork. For each, Frenchtown Pond had concentrations of microplastics ranging from 87-222 𝜇g per 100 𝜇l and the Clark Fork had concentrations ranging from 126-254 𝜇g per 100 𝜇l. **Conclusions:** Flow Cytometry proved to be an effective and efficient quantitation of microplastics in environmental sampling.

PS 4457 Crested porcupines (*Hystrix cristata*) as sentinels of environmental metal contamination in Central Italy

A. Menozzi^{1,2}, S. V. Defourny², C. Merola¹, M. Bellocchi², V. Melai², G. Scortichini², R. Salini², S. Tora², S. Salucci², and A. Petri². ¹University of Teramo, Teramo, Italy; and ²Istituto Zooprofilattico Sperimentale dell'Abruzzo e Molise "G. Caporale", Teramo, Italy.

Background and Purpose: Contamination by potentially toxic metals represents one of the main environmental issues threatening biodiversity and the proper functioning of ecosystems, with direct repercussions on human health. In this context, toxicological biomonitoring plays a fundamental role in assessing the presence and spread of such substances. The selection of representative "sentinel" species is crucial to ensure effective monitoring. In Italy, one such species is the crested porcupine (*Hystrix cristata*), a large semi-fossorial rodent of African origin. Its broad ecological tolerance, generalist diet, sedentary and territorial habits, and close contact with soil and vegetation make *H. cristata* an excellent indicator of local contamination. Furthermore, its long lifespan allows for the progressive accumulation of contaminants over time, making it a suitable species for evaluating chronic exposure to pollutants in mixed agricultural and forested environments. This study aimed, for the first time on a global scale, to assess the concentrations of barium (Ba), cadmium (Cd) and lead (Pb) in liver and kidney of crested porcupine. The investigation sought to determine the presence and quantitative levels of these elements within a selected area, the Abruzzo region, to evaluate potential differences in concentrations between the two tissues, sex and age and to explore possible correlations between contamination levels and land use. **Methods:** Between 2022 and 2025, liver and kidney were collected from 30 carcasses of *Hystrix cristata*. Local authorities granted permission for the necropsy of the carcasses. Anamnestic information including age and sex were desumed from the necropsy and sampled animals were categorized based on the latitude and longitude coordinates in the WGS84 (EPSG: 4326) reference system of their deaths for inclusion in the CORINE Land Cover (CLC) classes. The instrumental analysis of Ba, Cd, and Pb was performed using an inductively coupled plasma mass spectrometer (Q-ICP-MS iCAP RQ) in standard mode using matrix-matching calibration to minimize the effect of the matrix. Shapiro-Wilk normality tests showed that the distribution of elements' concentrations was not normal. Non-parametric Mann-Whitney and Kruskal-Wallis tests were applied to compare concentrations of inorganic elements among matrixes, animal sex, age and CLC distribution. Data were shown as median with 1st (Q1) and 3rd (Q3) quartiles and as mean and standard deviation (SD). **Results:** In liver and kidney metal concentrations were distributed as follows: Cd>Ba>Pb. The mean and median value of metals in liver were: Ba (138.7±118.7 µg/kg; 112 µg/kg Q1=46.8, Q3=171.8); Cd (140.3±199.6 µg/kg; 40 µg/kg Q1 22, Q3 220); Pb (61.5±87.4; 33 µg/kg Q1=24.5, Q3=54.5). In kidney mean and median concentrations were as follows: Ba (140.2±302; 60.5 Q1=42.3, Q3=114.5); Cd (950.4±1453.3, 326.5 Q1 121, Q3 1191.8); Pb (75.8±71.7, 53.5 Q1=35.5, Q3=88). The differences between matrixes showed as Cd were statistically significant higher in kidney compared to liver (p<0.05). Differences in concentrations of metals were not significant according to sex, age and CLC distribution. However, according to CLC dated animals were distributed as follows: 17% urban fabric, 27% arable land, 13% permanent crops, 27% heterogeneous agricultural areas, and 17% forests. **Conclusions:** The ecological traits of *Hystrix cristata* support its use as an effective sentinel species for terrestrial ecosystem monitoring. The results presented in this study provide the first global baseline values for potentially toxic metal concentrations in this species, contributing to a better understanding of contaminant bioaccumulation processes in Mediterranean terrestrial mammals. Cadmium concentrations in the kidney matrix were found to be significantly higher than those of other metals. According to the CLC dataset, the species' distribution is consistent with its ecological characteristics. Considering its ongoing northward expansion and increasing interaction with anthropogenic environments, *H. cristata* may represent a highly valuable biological model for integrated studies on wildlife toxicology, environmental change, conservation management, and human health protection.

PS 4458 Ecological Risk Assessment and CLP Classification of Beryllium and Beryllium Compounds in Aquatic Environments

A. Massarsky¹, E. de Gandia², J. Jackson³, M. L. Kreider⁴, and G. H. Heldt⁵. ¹Stantec, Irvine, CA; ²SciTox, Huntington Beach, CA; ³Stantec, Burnaby, BC, Canada; ⁴Stantec, Pittsburgh, PA; and ⁵Materion Corporation, Elmore, OH.

Background and Purpose: Beryllium (Be) and its compounds are used in various industries and may be released into aquatic environments. Despite their widespread use, ecological risks to aquatic species are not well characterized, and regulatory classifications under the Globally Harmonized System (GHS) and European Union (EU) Classification, Labeling, and Packaging (CLP) regulations are inconsistent and lack a clear scientific basis. **Methods:** Aquatic toxicity thresholds for Be and Be compounds were compiled from peer-reviewed literature and regulatory databases. Environmental Be concentrations in surface waters were obtained from the National Water Quality Monitoring Council (NWQMC) Water Quality Portal (WQP). Acute and chronic risk quotients (RQs) were calculated by comparing environmental concentrations to toxicity thresholds. CLP hazard classifications were assigned according to EU guidance. **Results:** Aquatic toxicity thresholds for Be compounds ranged from 'practically nontoxic' to 'moderately toxic,' with most values orders of magnitude higher than measured environmental Be concentrations. Acute and chronic RQs were generally below 1.0, indicating low risk to aquatic species. CLP classification varied by compound: insoluble Be metal and Be(OH)₂ were assigned to Chronic 2 and 4, respectively, while soluble compounds such as BeCl₂, BeNO₃, and BeSO₄·4H₂O were classified as Chronic 1-3 and Acute 1. Only one chronic RQ exceedance was observed for BeSO₄·4H₂O in crustaceans at the 95th percentile Be water concentration. **Conclusions:** Be and its compounds are not anticipated to pose significant acute or chronic risks to aquatic life under current environmental conditions, but compound-specific hazard classification is warranted. Data gaps remain for chronic toxicity and the influence of water chemistry, highlighting the need for further research.

PS 4459 Microplastics in Motion: Comparative Uptake and Immune Responses in Coastal Shark Species

G. D. Aniolek, and K. Rock. Clemson University, Clemson, SC.

Background and Purpose: Microplastics (MPs) are an emerging class of environmental pollutants that are now considered a global ecotoxicological concern due to their persistence, ubiquity, and potential for biological interaction. MPs are introduced into marine systems through urban runoff, wastewater effluent, and degradation of larger plastic debris, where they absorb hydrophobic contaminants and concentrate in sediments and biota. Mounting evidence from laboratory models, including zebrafish, bivalves, and marine worms, demonstrate that MPs can induce oxidative stress, inflammation, reproductive impairment, as well as altered behavior through physical obstruction and endocrine disruption. However, data on the biological effects of MPs in large marine vertebrates remain sparse, particularly in long-lived predators such as sharks. Coastal South Carolina estuaries, including Charleston Harbor and Winyah Bay represent MP hotspots, receiving high inputs from urban, industrial, and riverine sources. MPs have been documented in local sediments, plankton, fishes, and even dolphins, but shark exposure remains uncharacterized. Because sharks occupy high trophic positions, exhibit species-specific feeding strategies (pelagic, demersal, omnivorous), and possess a conserved vertebrate immune system, they represent ideal sentinels for evaluating MP bioaccumulation and associated physiological effects. **We hypothesize that demersal feeders will exhibit higher MP burdens than pelagic species due to greater benthic contact and ingestion of sediment-associated prey, and that increasing MP load will correspond with elevated oxidative stress and innate immune activation in liver and blood tissues.** **Methods:** Sharks are collected exclusively from incidental bycatch mortalities during ongoing South Carolina Department of Natural Resources (SCDNR) longline, drumline, and gillnet surveys to ensure ethical sample acquisition. Three ecologically distinct species are targeted: finetooth (*C. isodon*; pelagic mesopredator), blacktip (*C. limbatus*; generalist carnivore), and bonnethead (*S. tiburo*; demersal omnivore) for cross trophic comparisons of MP uptake. Dissected tissues (gut, liver, brain, gonad, kidney, intestine) are digested in 10% potassium hydroxide (KOH) at 40°C, sieved through a graded cascade, and filtered on 10 µm membranes. Retained particles are stained with Nile Red and visualized under 254 nm UV light for fluorescent quantification, while polymer identity is confirmed using Fourier Transform Infrared Spectroscopy (FT-IR). To evaluate physiological responses, liver homogenates are analyzed for key antioxidant and oxidative stress biomarkers, including catalase (CAT), superoxide dismutase (SOD), glutathione peroxidase (GPx), total glutathione (GSH), and lipid peroxidation (MDA). Blood samples are assessed for leukocyte differentials, plasma lysozyme activity, and total protein as indicators of immune activation. **Results:** Pilot analyses demonstrate efficient tissue digestion and recovery of synthetic polymers. MPs were visualized in liver, gastrointestinal, and muscle tissues, confirming bioavailability and retention in higher-trophic vertebrates. Quantitative assessments show tissue-specific variation, with the highest MP concentrations in intestine, followed by liver, muscle, and gonads. Particle morphologies, fragments, fibers, and films, suggest multiple exposure routes through both waterborne and dietary pathways. Ongoing analyses will use FTIR to confirm polymer composition and integrate MP load with oxidative stress and immune biomarkers to assess potential dose-dependent physiological responses. Continued sampling through 2025-2026 will expand

species coverage and enable modeling of exposure, accumulation, and biological impact. **Conclusions:** This work represents one of the first integrative studies to quantify MP exposure risk factors and associated biological effects in estuarine sharks. By linking trophic ecology, contaminant characterization, and biomarkers of oxidative and immune function, the project will establish a mechanistic foundation for understanding plastic-associated toxicity in marine predators. These findings will inform ecotoxicological risk assessment frameworks, contribute to the development of biomonitoring indicators for apex species, and support conservation strategies that address plastic pollution impacts in South Carolina's coastal ecosystems.

PS 4460 Neurotoxicity of β -N-methylamino-L-alanine (BMAA) in larval zebrafish: behavioural and transcriptomic insights

J. Ritu, M. Uddin, M. C. Ferrari, and D. P. Chivers. University of Saskatchewan, Saskatoon, SK, Canada. Sponsor: J. Luyendyk

Background and Purpose: β -N-Methylamino-L-alanine (BMAA), a neurotoxic non-protein amino acid produced by cyanobacteria, diatoms and dinoflagellates, has become a global concern due to its potent neurotoxicity and its possible link to neurodegenerative diseases. BMAA bioaccumulates and biomagnifies through aquatic food webs, posing ecological risks to aquatic organisms and raising concerns for human exposure. Despite this, investigation of BMAA neurotoxicity to aquatic species is still in its early stages. **Methods:** To address this gap, zebrafish (*Danio rerio*) embryos were exposed to three environmentally relevant concentrations of BMAA (10, 20, and 40 μ g/L) and a control for 28 days. Behavioural assay was performed to evaluate social interactions, and transcriptomic profiling was conducted to identify dose-dependent alterations in molecular, cellular, and biological pathways. **Results:** Exposure to higher concentrations of BMAA (20 and 40 μ g/L) significantly reduced the time larvae spent with conspecifics, indicating altered social behaviour. Transcriptomic analysis revealed that BMAA disrupts multiple molecular pathways in a dose-dependent manner, including excitatory signalling, mitochondrial function, oxidative stress regulation, lipid, protein, and energy metabolism, proteostasis, and neuroinflammatory responses. These disruptions resulted in apoptosis, neuronal dysfunction, and developmental impairments. **Conclusions:** This study provides important insights into the neurotoxic effects of BMAA on zebrafish, establishing a clear link between exposure to environmentally relevant concentrations of BMAA and adverse behavioural and molecular outcomes. Advancing mechanistic insights into BMAA effects in aquatic organisms is essential for effective ecological risk assessments and the development of regulatory standards to safeguard aquatic ecosystems and public health.

PS 4461 Parent vs. Metabolite: Transcriptional Responses to the Phthalate DEHP and its Alternative Plasticizers in *Danio rerio* embryo-larvae

B. M. Smith, and J. Crago. Texas Tech University, Lubbock, TX.

Background and Purpose: Non-phthalate plasticizers (NPPs) are increasingly being used as replacements for traditional phthalates such as di(2-ethylhexyl) phthalate (DEHP), due to growing evidence of adverse human health effects associated with phthalate exposure. Among these alternatives, di(2-ethylhexyl) adipate (DEHA) and tris(2-ethylhexyl) trimellitate (TOTM) have been introduced as potential substitutes for DEHP. However, these NPPs share key structural similarities with DEHP, including the primary ester-linked 2-ethylhexyl side chains (TOTM and DEHA) and the phthalic acid head (TOTM). Emerging evidence indicates that these compounds can produce metabolites identical to those of their DEHP counterparts. This raises important questions about whether such replacements represent a meaningful improvement in safety. The objective of this study was to compare the induction of Phase I-III biotransformation transcripts in zebrafish (*Danio rerio*) larvae following exposure to DEHP, DEHA, TOTM, and their shared metabolite, 2-ethylhexanol (2EH), to determine whether DEHP-induced effects are mediated by 2EH. **Methods:** Zebrafish embryos were exposed under matched dose conditions equimolar concentrations of DEHP, 2EH, DEHA, and TOTM. Following five-day exposures, gene expression of Phase I-III transcripts were measured, followed by measurement of endocrine-associated transcripts that have been identified to be altered during DEHP exposure. Fold changes relative to controls were calculated, and treatment effects were assessed. **Results:** Principle component analysis revealed that TOTM, DEHA, DEHP, and 2EH were associated with the same Phase II-III transcripts, PXR, UGTb5, SULT1st3, SULT2st3, and Steroid sulfatase. Analysis of endocrine-associated transcripts revealed no difference among treatments. **Conclusions:** These results suggest that TOTM and DEHA may differentially modulate genes associated with Phase II-III metabolism in a similar manner to DEHP.

PS 4462 Estrogenic activity of PFAS with variable length and structure using human cell bioassays and rainbow trout (*Oncorhynchus mykiss*) liver slice assays

C. G. Baettig¹, M. Nash¹, D. Lew¹, P. J. Ankley¹, D. L. Villeneuve², and M. Tapper². ¹ORISE at US EPA, Duluth, MN; and ²US EPA, Duluth, MN.

Background and Purpose: Per- and polyfluoroalkyl substances (PFAS) are a diverse class of synthetic fluorinated chemicals that are ubiquitous in the environment due to their diverse usage in both consumer and industrial products. The majority of PFAS have little or no toxicity information. Previous high throughput screening identified three PFAS - 1H,1H,8H,8H-perfluorooctane-1,8-diol (FC8-diol), 1H,1H,10H,10H-perfluoro-decane-1,10-diol (FC10-diol), and 1H,1H,8H,8H-perfluoro-3,6-dioxaoctane-1,8-diol (FC8-DOD) as the most estrogenic PFAS among 140 structures tested. *In vivo*, these three PFAS caused concentration-dependent increases in the expression of estrogenic genes with their rank order of potency *in vivo* matching the *in vitro* results. The aim of this study was to further evaluate the potential of PFAS with structural similarity to FC8-DOD, FC8-diol, or FC10-diol, to cause estrogenic effects. **Methods:** Five PFAS, four diols with chain lengths varying from five to 12 carbons, and PFAS with different structure but a high similarity score, were selected using tools in the U.S. EPA's CompTox Chemicals Dashboard v2.5.3. The five selected PFAS were tested using Indigo Bioscience human estrogen receptor bioassay kits. To further test potential estrogenic effects and verify the activity previously seen in FC10-diol and FC8-DOD, liver slices derived from immature male rainbow trout were exposed to selected PFAS. Slices were incubated with six doses of each PFAS for 48 h, then RNA extracted, and expression of estrogen receptor regulated genes was investigated by RT-qPCR. **Results:** Among the five tested PFAS, FC9-diol and FC12-diol elicited significant estrogenic activity in the human-based system. Exposures to FC9-diol, FC10-diol, FC12-diol and FC8-DOD induced vitellogenin mRNA expression in exposed liver slices, but exposure to diols of other chain lengths did not. Hepatic transcription of insulin-like growth factor 1 and apolipoprotein b mRNA was significantly upregulated in FC9-diol and FC8-DOD at their highest concentrations, but significant modulation was not observed in FC10-diol. **Conclusions:** The present study demonstrates that some PFAS exhibited strong estrogenic potential in both a human estrogen receptor (ER) reporter assay and *ex vivo* rainbow trout liver slices. Active PFAS were found to be those with 10.3 to 13.39 angstroms distance between hydroxyl groups suggesting diol chain lengths confer estrogenic activity which relates to their affinity for the ligand binding domain. These data provide insights into the narrow range of PFAS structures capable of eliciting estrogenic activity in humans and fish. The contents of this abstract neither constitute nor necessarily reflect US EPA policy.

PS 4463 Xenometabolome Profiling of Structurally Diverse PFAS in Rainbow Trout (*Oncorhynchus mykiss*) Liver Slices

P. Ankley¹, C. Baettig¹, D. Lew¹, M. Tapper², and D. Villeneuve². ¹ORISE U.S. EPA, Duluth, MN; and ²U.S. EPA, Duluth, MN.

Background and Purpose: Per- and polyfluoroalkyl substances, or PFAS, are manmade chemicals that are now widely distributed throughout the environment from human usage. Many PFAS are resistant to biodegradation leading to concerns over sublethal toxicity. Fish are known to bioaccumulate PFAS and the ability of the fish to detoxify potential reactive species via Phase I and II metabolism is an ongoing research area. **Methods:** This study investigated the xenometabolome of liver slice media exposed to three PFAS chemicals differing in chain length and structure including FC8-DOD (1H,1H,8H,8H-Perfluoro-3,6-dioxaoctane-1,8-diol), FC9-Diol (1H,1H,9H,9H-perfluorodecane-1,9-diol), and FC10-Diol (1H,1H,10H,10H-perfluorodecane-1,10-diol), with the study PFAS compounds shown to have estrogenic effects. Liver slices derived from immature male rainbow trout were incubated with six doses of PFAS treated exposure media for 48 h before the liver slice media was collected and non-targeted mass spectrometry analysis was performed to profile the biological transformation products (bioTPs) from PFAS metabolism (xenometabolome). **Results:** The main enzymatic pathways detected to be involved in biotransformation of the three PFAS were alcohol oxidation and glucuronidation. At comparable nominal concentrations, FC9-Diol and FC10-Diol had greater summed peak area of bioTPs compared to the precursor analyte reflecting a potential greater capability to detoxify and differences in estrogenicity relative to FC8-DOD. **Conclusions:** Differences in chain length and structure could have implications regarding the ability to detoxify PFAS chemicals and the respective toxicological response. Future research efforts will use molecular docking of the PFAS diols and their bioTPs to understand binding affinity to estrogen receptors.

PS 4464 Evaluation of Aquatic Toxicity of Phototransformed Hexanitrohexaazaisowurtzitane

N. Hall, J. Morrill, J. Irwin, A. East, and L. Schneider. Defense Centers for Public Health, Gunpowder, MD.

Background and Purpose: Energetics and munitions are used in nearly every aspect of military operations and have potential to be released both directly and indirectly into the environment through production, training, use, and disposal; poten-

tially affecting warfighters and civilians by drinking water, and crop contamination. Hexanitrohexaazaisowurtzitane commonly known as CL-20, is known as one of the most powerful non-nuclear compounds created. However, assessing the toxicity risk to the warfighter and the environment prior to fielding is imperative prior to its adoption as a commonly used energetic material at home and abroad. While degradation of CL-20 with environmental exposure was confirmed in a previous study using *Ceriodaphnia dubia* exposed to CL-20, using aged and weathered Sassafras Sandy Loam soil; it resulted in limited data and variable findings. Therefore, we investigated the hypothesis that CL-20 toxicity to *D. magna* increased after radiant sunlight exposure. **Methods:** Daphnia neonates <24 hours old, were obtained by EA Engineering in Hunt Valley, MD. The experimental design was validated by using potassium chloride (KCl) according to OECD TG202. The published KCl EC₅₀ is 340.0 mg/L and our observed KCl EC₅₀ = 324.0 mg/L. Using a stock concentration of 1mg/L, CL-20 was irradiated using the Atlas Suntest CPS+ photoreactor to simulate the natural UV/VIS irradiation at 16.203 MJ/m² representing sun exposure during an average 24H period in Bagdad, Iraq. Eight nominal concentrations were made following the exposure ranging from 1.0mg/L to 0.001mg/L. Daphnia were exposed, kept in the dark at room temperature, and immobilized daphnia were recorded at 24 and 48 hours. **Results:** 24H EC₅₀ of UV(-) CL-20 was determined to be 0.001 mg/L and UV(+) is 0.12 mg/L, 48H exposure data demonstrated increased variability in mortality rates. Water quality before and after UV exposure was also monitored; however, little change was observed in salinity, pH, and total nitrates, nitrites, ammonia, and formic acid; though, we noted some control death in a previous round with irradiated water. **Conclusions:** A decrease in toxicity of CL-20 after UV radiation was observed, demonstrating that CL-20 does breakdown in the presence of UV exposure. A repeated study should be conducted on daphnia cultures cultured in house, instead of obtaining them from external sources. This will allow us to troubleshoot the control mortality we observed in previous exposures, and allow us to increase our sample size and modify our concentration range. This study was run in conjunction with other *in vivo* tests consisting of acute (one dose), 14-day repeated dose, and 90-day repeated dose exposure studies to assess toxicity.

PS 4465 The drivers of chemosensitization: naturally-occurring marine microbial organohalogenes are substrates of the drug transporter ABCB1

E. R. Tjeerdema, R. Metry, S. Adak, M. Schorn, B. Moore, and A. Hamdoun. Scripps Institution of Oceanography, La Jolla, CA. Sponsor: E. Tjeerdema, Society of Environmental Toxicology and Chemistry

Background and Purpose: The drug transporter ABCB1, highly expressed at barrier tissues and conserved across species, is well studied for its role in limiting the accumulation and toxicity of xenobiotics. Although ABCB1 effluxes many toxic compounds, it is ineffective against certain persistent organic pollutants (POPs) such as PBDE-100 and DDT, which instead bind to and inhibit the transporter. These are termed Transporter Interfering Compounds (TICs), and the inhibition the cause results in chemosensitization: the heightened toxicity of additional compounds that are normally effluxed. Importantly, inhibition alone is not toxic; toxicity emerges only when ABCB1 substrates are present concurrently with TICs. However, the natural substrates of ABCB1 in marine environments—the compounds that may drive toxicity during chemosensitization—remain unknown. We propose that naturally occurring marine microbial organohalogenes (MOHs) are substrates of ABCB1, based on: (1) high drug transporter expression in marine invertebrates inhabiting microbially rich sediments; (2) heightened immune response in ABCB1-knockout (KO) sea urchin larvae challenged with bacteria; and (3) structural similarity between microbial MOHs and synthetic organohalogenes known to bind ABCB1. Using the sea urchin as a model organism, we sought to determine if ABCB1 protects marine embryos from MOH toxicity by limiting their intracellular accumulation. **Methods:** We developed a high-content imaging pipeline using sea urchin embryos, enabling large-scale dosing, imaging, and phenotyping of thousands of individuals. Using a recently established ABCB1-KO line, which exhibits reduced efflux and heightened sensitivity to transporter substrates, we screened 68 purified MOHs produced by Pacific marine bacteria (*Streptomyces*, *Pseudoalteromonas*, *Hormosilla*, and others). A point screen at 2 μ M identified compounds causing developmental toxicity; hits showing >45% abnormal development were subjected to full dose-response assays in both wildtype (WT) and KO backgrounds. EC₅₀ values were compared to determine ABCB1-dependent protection. Embryos were also harvested for LC-MS analysis of intracellular compound accumulation. **Results:** Sixteen of the 68 compounds tested induced >45% abnormal development. These included three pyrroles, one bipyrrrole, nine phenyl pyrroles, one indole, and two hydroxylated PBDEs. Five have known bioactivities (cytotoxicity, antimicrobial activity, thyroid disruption, and mutagenesis). All 16 hits were more potent to ABCB1-KO embryos than WTs. WT EC₅₀ values ranged from 0.08-6.4 μ M, whereas KO EC₅₀ values ranged from 0.02-4.1 μ M. On average, KO embryos were 3.3X more sensitive, with maximum potency increase of 5.3X. Compounds showing the greatest potency increase had log Kow values of 3-4, consistent with other strong ABCB1 binders. Preliminary LC-MS data indicate KO embryos accumulate roughly twice as much of certain compounds as WT embryos. **Conclusions:** We identified 16 naturally occurring MOHs as toxic substrates of ABCB1 in a marine organism, the sea urchin. This fills a long-standing knowledge gap in chemosensitization: as TICs and their binding interactions with ABCB1 are increasingly characterized, the environmental substrates whose toxicity is amplified by transporter inhibition have remained unclear. For instance, both synthetic

and naturally-occurring organohalogenes bioaccumulate in marine organisms and are transferred to humans via consumption of contaminated seafood. While drug transporters may be effective at limiting accumulation of microbial MOHs in low-pollutant conditions, co-exposure with TICs could increase their tissue burden by reducing efflux activity. The consequences of such mixture interactions on human health and development are unknown. Identifying which compounds may be of concern, as we have done here, is a crucial step forward for predicting, understanding, and mitigating the toxic effects of chemosensitization.

PS 4466 Integrated Spatial Transcriptomic, Behavioral, and Immunophenotypic Analyses Reveal Heat Wave-Driven Neurocognitive and Neuroinflammatory Vulnerabilities in Aging

S. Roy¹, A. Trivedi¹, S. Sarkar¹, M. More¹, R. Kumar¹, and S. Chatterjee^{1,2}. ¹University of California, Irvine, Irvine, CA; and ²Department of Veterans Affairs Long Beach (VA Medical Center), Long Beach, CA.

Background and Purpose: Climate change-associated heat waves are an escalating environmental stressor and represent an under-recognized form of environmental neurotoxicity with disproportionate impact on the elderly. While both aging and acute heat stress impair brain function, their combined effects on cognition and neuroimmune processes remain poorly understood. Young brains may mount adaptive stress programs, whereas aged brains are hypothesized to exhibit maladaptive inflammatory cascades and accelerated decline. We applied spatial transcriptomics, behavioral profiling, and immunophenotyping to map how heat waves differentially affect young and aged brains. **Methods:** Young (3 mo) and aged (18 mo) C57BL/6J mice (2x2 design) were exposed to periodic heat stress (40 °C, 3 h) for 14 consecutive days or maintained at thermoneutrality. Spatial transcriptomics (10x Xenium) was performed on prefrontal cortex, hippocampus, hypothalamus, and brainstem to resolve cell-type-specific transcriptional programs within intact tissue architecture. Cognitive and motor performance were assessed using Morris Water Maze (MWM; spatial memory), Novel Object Recognition (NOR; recognition memory), Rotarod (motor coordination), and Open Field (locomotion/anxiety). Multi-parameter flow cytometry quantified resident microglia (CD11b⁺CD45^{low}) and infiltrating myeloid cells (CD11b⁺CD45^{high}) to validate transcriptomic findings at the cellular level. **Results:** Spatial transcriptomics uniquely revealed hippocampal and hypothalamic microdomains in aged heat-stressed mice where proinflammatory transcripts co-localized with downregulation of synaptic plasticity markers (Bdnf, Camk2a), forming maladaptive inflammatory “hotspots.” These signatures were not that elevated in young cohorts, which instead showed transient upregulation of heat-shock genes without sustained inflammatory activation. Behaviorally, aged heat-stressed mice exhibited impaired spatial learning (MWM escape latency $\approx$ 52 $\pm$ 3 s vs. 38 $\pm$ 2 s in aged controls, p < 0.05), $\sim$ 20% lower NOR discrimination index (p < 0.05), and reduced center time in the Open Field ($\sim$ 15%, p < 0.05), whereas young mice demonstrated resilience across tasks but MWM. Flow cytometry confirmed $\sim$ 2-fold expansion of activated microglia and CD45^{high} infiltrating myeloid cells in aged heat-stressed brains (p < 0.05), with only modest activation in young mice. **Conclusions:** Preliminary findings indicate that acute heat stress elicits fundamentally different responses across the aging spectrum. Spatial transcriptomics provided exclusive resolution of region- and cell-type-specific vulnerabilities linking synaptic dysfunction with localized inflammatory hotspots that corresponded with behavioral decline in aged mice. Young brains mounted adaptive, reversible stress programs, while aged brains exhibited maladaptive immune activation and measurable cognitive impairments. By integrating spatial transcriptomics, behavioral outcomes, and immunophenotyping, this study establishes a mechanistic brain-behavior-immunity framework for environmental neurotoxicity. These results highlight aging as a critical modifier of climate-linked neurotoxicity and demonstrate the value of advanced multimodal approaches for predicting population vulnerability to heat waves. This study was supported by NIH/NIEHS Grant 1P01ES028942-01#Project 4 Toxicology awarded to Dr. Saurabh Chatterjee.

PS 4467 Air pollution and heat co-exposure induced cardiac dysfunction: Role of Nod-like Receptor X-1

C. Monge¹, Y. Li¹, A. Razazan¹, T. Goldsmith², T. Nurkiewicz², M. Velayutham³, J. Hollander¹, and S. Hussain¹. ¹Department of Physiology, Pharmacology and Toxicology, School of Medicine, West Virginia University, Morgantown, WV; ²Centre for Inhalation Toxicology (iTOX), School of Medicine, West Virginia University, Morgantown, WV; and ³Biochemistry and Molecular Medicine, School of Medicine, West Virginia University, Morgantown, WV.

Background and Purpose: Extreme heat events are increasing in frequency, duration and severity. These increases are associated with raised air pollutant levels. Epidemiological data associate cardiovascular events as major drivers of increased mortality due to air pollution. While individually air pollution and heat stress are extensively studied, the mechanism behind the cardiac impact of their combined exposure are still largely unknown. NLRX1 is a mitochondrial protein involved in the cellular stress pathway. However, its involvement in air pollution and heat exposure co-exposure-induced pulmonary and cardiac dysfunction is still unknown. **Methods:** *Nlr1^{+/-}* and *Nlr1^{-/-}* mice were exposed to either Air (CTR), 2.5 mg/m³ ultrafine carbon

black (CB) with 1 ppm ozone (O₃), at room temperature or 102°F high temperature (HT). Exposure was performed by whole body inhalation for 3 hours and animals were euthanized 24 hours after exposure and lung inflammation was assessed by bronchoalveolar lavage cytology and inflammation-related gene and protein expression. Cardiac function was assessed immediately after exposure using ultrasound Doppler Echocardiography (Vevo F2 High Frequency Ultrasound Echocardiography). LV M-mode images were used to assess conventional echocardiographic assessment of short and long axis, while strain analysis was applied to B-mode videos captured in the parasternal short and long axes. Heart tissue mitochondrial function was assessed by mitochondrial complex activity assays and isolated mitochondria coupling assay. **Results:** Aerosol characterization by scanning and transmission electron microscopy demonstrated ultrafine size agglomerates. Stable aerosol concentration, temperature, and humidity were achieved and monitored by real-time software-assisted feedback loops. Combined heat and air pollution exposure induced greater lung inflammation in *Nlr1^{-/-}* mice compared to *Nlr1^{+/+}* mice. In contrast to *Nlr1^{+/+}* mice, no significant changes in stroke volume and cardiac output were observed in *Nlr1^{-/-}* mice after air pollution exposure and heat stress. In addition, *Nlr1^{-/-}* mice demonstrated a significant decrease in longitudinal time to the peak (TTP% %) strain which indicates a potential cardiac contractile issue after co-exposure to heat and air pollution. Moreover, *Nlr1^{-/-}* mice demonstrated a significant decrease in activity of mitochondrial complexes (III, IV, V) after HT+CB+O₃ co-exposure. The coupling assay further demonstrated a significantly impaired state 3 respiration in *Nlr1^{-/-}* mice. **Conclusions:** In conclusion, we demonstrate that air pollution exposure induces impaired cardiac functional physiological adaptation to heat in an NLRX1-dependent manner. **Funding:** Supported by NIH grants R01ES031253 (SH), R01ES03125304S1 (SH).

PS 4468 Effect of Heat Stress on Vascular Functions

H. Husain, S. McFall, A. Hussain, M. V. Malovichko, I. Zelko, J. Hellmann, D. J. Conklin, and S. Srivastava. University of Louisville, Louisville, KY.

Background and Purpose: Thermal stress is an important environmental stressor which affects cardiovascular disease. Both hypothermia and hyperthermia have been suggested to increase the risk of atherosclerosis, the underlying cause of most cardiovascular disease. While the effect of hypothermia has been examined in experimental animals, no animal models have been established to rigorously test the plausibility that hyperthermia is sufficient to exacerbate cardiovascular disease and delineate the underlying cellular and molecular mechanisms. In this study, we established murine model of thermal stress-induced vascular function - the primary drivers of vascular inflammation and atherosclerosis. **Methods:** Young adult (12-20-week-old) male C57BL/6J mice were exposed to heat stress (37 °C, 3h/day, 4 days/week) for up to 4 weeks in temperature and humidity (40%) controlled Sable Systems cabinets. Mice maintained at 22 °C (room temperature) and 30 °C (thermoneutral conditions) in identical cabinets served as controls. Core body temperature was measured using SoHo implants and the data were analyzed by Ponemah-DSI software. For metabolic profiling, the mice were housed singly for 4days/week, 3h/day and the data were analyzed by microinterpreter & calR software. To examine the effect of heat stress on vascular functions we measured vascular permeability (Evans blue dye) (n=10/group), measured arterial stiffness (by ECHO cardiography) (n=10/group) and leukocyte trafficking (by multi-photon intravital microscopy) (n=10/group). **Results:** Core body temperature of mice maintained at thermoneutral conditions was comparable with the core body temperature of mice maintained at 22 °C (36 °C-37 °C). However, exposure to heat stress (37 °C) increased the core body temperature to 40 °C. The core body temperature in heat stress-exposed mice returned to normal within an hour of withdrawal of heat stress. Metabolic profiling showed significant increase in total food (32.24 kcal) & total water (6.8 mL) intake of heat stressed mice than the control group (18.95 kcal & 4.8 mL) (P < 0.01). But no significant change in body weight was observed. The heat-stressed mice also showed decrease in oxygen consumption (78.96 mL/h) and carbon dioxide expulsion (70.92 mL/h) than the control group (P < 0.01). Mice subjected to 37 °C also showed significant decrease in locomotor activity (beam breaks/h) and pedestrian locomotion (m). Vascular permeability was also compromised with heat stress, and we observed a decrease in permeability by 42% (P < 0.01). Heat stress also increased leukocyte adhesion. We observed a significant increase in adhering cells (3.07 cells/2 min) and rolling cells (2.5 cells/2 min) (P < 0.0001) than the mice subjected to 22 °C (room temperature) (0.27 cells/2 min) & (0.5 cells/2 min) respectively. There was no significant change in arterial stiffness. **Conclusions:** These studies established a well characterized murine model of heat stress-induced vascular dysfunctions.

PS 4469 Heat Stress and Perfluorooctanoic Acid impacts Endometrial Function in post-pubertal gilts: Implications for Reproductive Toxicology

O. Z. Adeyanju, C. Antwi-Boasiako, E. M. González-Alvarez, B. M. Buol, L. H. Baumgard, and A. F. Keating. Iowa State University, Ames, IA.

Background and Purpose: Heat stress (HS) and chemical exposure alter physiological homeostasis and can negatively impact reproductive performance, impair chemical biotransformation, and increase health risks. Heat stress occurs when

the environmental temperature surpasses the core body temperature of the organism, resulting in physiological and metabolic disturbances. Perfluorooctanoic acid (PFOA) impairs fertility and induces endocrine disruption. This study aimed to understand the individual and combined effects of PFOA exposure and HS on endometrial health and functioning in post-pubertal gilts. **Methods:** Pigs (n = 48) were housed in thermal neutral (TN; 20 °C) or heat stress (HS; 26.6 to 32.2 °C) conditions, synchronized in estrus with MATRIX® and fed either unadulterated cookie dough or cookie dough containing 70 mg/Kg of PFOA. Thus, there were four treatment groups: TN control (TC); TN PFOA (TP); HS control (HC), and HS PFOA (HP), with treatments lasting for 19 d. The uterus was weighed at euthanasia and endometrial samples collected. Isolated protein was analyzed by LC-MS/MS coupled with bioinformatic analysis. Fold-changes were identified between pre-planned contrasts with significance considered at P < 0.05. **Results:** Neither PFOA nor HS altered uterine weight. Compared to TC, PFOA exposure altered 69 proteins, with 36 proteins increased and 33 decreased. HS alone increased 59 proteins and decreased 90 compared to TC gilts, resulting in a total of 149 proteins altered. In the HS group, PFOA exposure increased the abundance of 78 proteins and decreased 33 proteins, resulting in a total of 111 proteins altered. In the groups exposed to PFOA, HS impacted 114 proteins, with 54 increased and 60 decreased. Exposure to PFOA during HS decreased the expression of 37 proteins and increased the expression of 40 proteins, compared to TC. PFOA altered six identical proteins in varying directions and extent between TC vs TP and HC vs HP gilts. Similarly, HS altered fourteen identical proteins between TC vs HC and TP vs HP. Metascape analysis identified biological pathways affected, which included reproduction and homeostatic processes. **Conclusions:** This study reveals that the endometrial proteome of post-pubertal gilts is altered by PFOA exposure, both basally state and in combination with HS, potentially contributing to endometrial dysfunction.

PS 4470 Perfluorooctanoic acid exposure differentially affects the follicular fluid proteome in post-pubertal gilts during thermal neutral and heat stress conditions

C. Antwi-Boasiako, E. Gonzalez Alvarez, B. M. Buol, L. H. Baumgard, and A. F. Keating. Iowa State University, Ames, IA.

Background and Purpose: Environmental stressors, such as heat and chemical exposures, can adversely affect female reproduction. Perfluorooctanoic acid (PFOA), a long-lasting pollutant, is linked to reproductive toxicity, including reduced fertility and endocrine disruption. Heat stress (HS), which occurs when environmental temperature exceeds core body temperature, impairs reproductive function in mammals by disrupting gamete development, oocyte maturation, and early embryonic survival. To explore the individual and combined effects of HS and PFOA exposure, this study investigated the hypothesis that PFOA would alter the follicular fluid proteome of post-pubertal gilts, with differential impacts observed under thermal neutral (TN) and HS conditions. **Methods:** Pigs (n = 48) were estrus synchronized and experienced TN (20 °C) or HS (26.6 to 32.2 °C) conditions during which they were exposed to cookie dough ± 70 ng/kg PFOA daily for 19 d. Thus, there were four treatment groups: TN control (TC); TN PFOA (TP); HS control (HC), and HS PFOA (HP). Follicular fluid was collected on d 20 post-euthanasia and analyzed by LC-MS/MS with bioinformatic analysis. **Results:** In the follicular fluid, 221 proteins were identified. When compared to TC pigs, PFOA exposure altered the abundance of one protein (P < 0.1). In HC gilts, 22 proteins differed in abundance (P < 0.1) when compared to TC gilts. Of these, two were increased and 11 were decreased at P < 0.05, and three were increased and six were decreased at P < 0.1. The follicular fluid of HP gilts had two proteins increased and six proteins decreased at P < 0.05, while an additional two proteins were increased and six proteins were decreased at P < 0.1. String gene ontology analysis of TC vs HC identified 17 biological pathways associated with immune and inflammatory response, stress response, and metabolic processes, with a protein-protein interaction network comprising 15 nodes and 17 edges. In the TC vs HP gilt follicular fluid proteome, 16 biological pathways associated with translation and gene expression were identified, comprising 15 nodes and 18 edges. **Conclusions:** This study identified the follicular fluid proteome of post-pubertal gilts and examined how PFOA affects protein levels, both with and without HS. The results indicated that PFOA exposure could lead to or contribute to metabolic disorders and disrupt the ovarian steroidogenic pathway. HS may impair immune and inflammatory responses, alter structural and cellular components, and contribute to metabolic disorders. Additionally, the data suggest that PFOA exposure in combination with HS might compromise the immune and inflammatory response, alter cellular and structural components, and interfere with the coagulation and transport systems.

PS 4471 Fresh water salinization exposure heightens risk of poor Vibriosis outcomes and systemic inflammation

S. Sarkar¹, S. Chatterjee², S. Roy¹, A. Trivedi¹, M. P. More¹, R. K. Varma¹, and S. C. Bondy¹. ¹University of California Irvine, Irvine, CA; and ²University High School, Irvine, CA.

Background and Purpose: Freshwater salinization and subsequent human exposure via drinking water is a global health concern, yet its role in modulating susceptibility to bacterial infections is unknown. *Vibrio vulnificus* is a halophilic pathogen that

causes severe septicemia, especially in individuals with underlying hepatic dysfunction. This study investigated whether chronic saltwater exposure alters gut microbiota composition, systemic inflammation, and liver injury in mice challenged with *V. vulnificus*. **Methods:** Male C57BL/6 mice were divided into four groups: control (regular water), salt-water treated (1.2 g NaCl/L), *V. vulnificus* infection (10^8 CFU, oral gavage), and combined salt-water plus *V. vulnificus* exposure. Salt-water treatment continued for 4 weeks prior to bacterial challenge. Mice were euthanized 24 hours post-infection. Serum samples were analyzed for endotoxin, proinflammatory cytokines (IL-1 β , IL-6, TNF- α), C-reactive protein (CRP), and hepatic enzymes (ALT, AST). Metagenomic sequencing of fecal DNA was performed to evaluate microbial diversity, taxa abundance, and antimicrobial resistance gene profiles. **Results:** Chronic salt-water exposure alone did not elevate serum endotoxin or cytokine levels compared to controls. In contrast, *V. vulnificus* infection markedly increased serum endotoxin ($p < 0.001$), IL-1 β , IL-6, and TNF- α (all $p < 0.001$), and CRP ($p < 0.001$), confirming systemic inflammation. The combination of salt-water and *V. vulnificus* induced synergistic cytokine elevation (IL-1 β and TNF- α , $p < 0.001$) and a modest but reproducible increase in CRP ($p = 0.041$), suggesting a heightened inflammatory response. Liver enzyme analysis revealed significant AST elevation in infected and salt-water + infection groups ($p < 0.001$), whereas ALT remained unchanged, indicating hepatic stress without overt necrosis. Metagenomic profiling showed reduced α -diversity in salt-water + infection mice, with notable enrichment of *Clostridioides difficile* and *Staphylococcus xylosus*, taxa associated with dysbiosis and intestinal inflammation. Antimicrobial resistance gene abundance did not differ significantly among groups. **Conclusions:** Prolonged salt-water exposure sensitizes the host to enhanced inflammatory and microbial responses following *V. vulnificus* infection, accompanied by altered gut microbiome composition. These findings highlight a potential mechanistic link between high-salt consumption, gut-liver axis perturbation, and increased susceptibility to enteric pathogens. Understanding how environmental and dietary salt interact with pathogenic bacteria could inform risk mitigation strategies for coastal populations and individuals with compromised hepatic or gut barrier function.

PS 4472 Metabolic Stress Potentiates Renal Maladaptive Repair Following *Vibrio vulnificus* Sepsis: Implications for a Warming Climate

M. P. More, S. Roy, A. Trivedi, S. Sarkar, R. Kumar, and S. Chatterjee. Joe C. Wen School of Population and Public Health, University of California - Irvine, Irvine, CA.

Background and Purpose: In the United States, cases of non-cholera *Vibrio* infections are projected to increase by 50 % by 2090 relative to 1995 due to rising sea surface temperatures—underscoring how climate change is intensifying exposure to pathogens such as *Vibrio vulnificus* (VV). Sepsis caused by VV is a growing public health concern, particularly for individuals with underlying metabolic disease. Acute kidney injury (AKI) caused by sepsis is a major driver of chronic kidney disease (CKD) when maladaptive repair leads to persistent inflammation and fibrosis. High-fat diet (HFD) consumption induces metabolic dysfunction, mitochondrial stress, and inflammation, all of which heighten renal vulnerability. This study investigated how HFD-driven metabolic stress influences tubular epithelial maladaptive repair and fibrotic progression following sepsis-induced AKI using a clinically relevant VV infection model. **Methods:** Male C57BL/6J mice ($n=60$) were assigned to chow or HFD (60% kcal fat). At 18 weeks, mice received either VV intragastric infection or vehicle, generating four groups: CHOW, HFD, VV, and HFD+VV. Mice were sacrificed at 24 hours, 30 days, and 90 days post-infection. Serum creatinine was measured, and renal structural injury, tubular degeneration, inflammation, and fibrosis were quantified using Masson's Trichrome staining. **Results:** At 24 hours, serum creatinine was significantly elevated in HFD+VV versus HFD and VV, demonstrating parallel metabolic and infectious stress. Tubular injury increased across groups, with HFD+VV showing extensive tubular dilation, epithelial vacuolization, dense inflammatory infiltrates, and early peritubular fibrosis. Glomerular injury peaked in HFD+VV. At 30 days, HFD+VV mice retained the highest structural injury and fibrosis, without differences in serum creatinine values. By 90 days, creatinine levels again differed significantly between VV and HFD+VV, indicating recurrent or persistent injury. Cortical fibrosis remained highest in HFD+VV, with sustained glomerular damage in VV and HFD+VV groups. **Conclusions:** HFD-induced metabolic dysfunction markedly exacerbates renal injury, prolongs maladaptive tubular repair, and accelerates fibrotic progression following VV sepsis. These findings highlight a critical interaction between metabolic stress and a climate change-driven emerging infectious threat. Understanding these mechanisms provides crucial insight for identifying vulnerable populations and designing interventions to mitigate long-term renal consequences in a changing climate.

PS 4473 Enhancing Disaster Preparedness Through Inclusive Science Communication and Early Warning Systems

O. Dada, and A. Ogunyiola. Murray State University, Murray, KY.

Background and Purpose: Effective science communication is crucial for bridging the gap between research and its societal impact, particularly in disaster preparedness and risk management. This study explores risk perception, protective actions, and the role of early warning systems during the July 18-19, 2023, flash floods in Mayfield, Kentucky. **Methods:** Using a mixed-methods approach, which included

interviews and surveys, we analyzed how residents responded to warnings and the factors that influenced their actions. **Results:** We found that traditional media sources, such as local television and the Weather Channel, were the most relied upon for information during the event. However, many residents received warnings only shortly before the flood, limiting their preparedness. Risk perception and access to diverse information channels significantly influenced protective actions. At the same time, demographic factors, such as ethnicity, revealed disparities in response behaviors, with Hispanic or Latino residents less likely to take protective measures. **Conclusions:** These findings underscore the urgent need for inclusive, timely, and targeted communication strategies to enhance disaster preparedness across diverse communities. We propose integrating localized social media alerts and culturally tailored messaging into existing frameworks to improve communication effectiveness. This research informs disaster preparedness strategies and provides a scalable framework for science communication across various fields, including public health and environmental risk management. By engaging diverse stakeholders and leveraging modern digital tools, this study highlights the critical role of tailored communication in fostering societal resilience and driving equitable policy change.

PS 4474 ECHA Writes Back: The Reasons for Rejection of Read-Across in Compliance Check Decisions by the European Chemicals Agency

H. M. Roe¹, N. Ball², W. A. Chiu¹, and I. Rusyn¹. ¹Texas A&M University Interdisciplinary Faculty of Toxicology, College Station, TX; and ²The Dow Chemical Company, Horgen, Switzerland.

Background and Purpose: As part of the European Union's REACH (Registration, Evaluation, Authorisation and Restriction of Chemicals) regulation, the European Chemicals Agency (ECHA) is required to assess the completeness of data submitted by registrants to demonstrate the safety of their substances. By law, ECHA must examine at least 20% of registration dossiers through a process known as compliance checks (CCHs). If a dossier is found to be non-compliant with REACH requirements, a formal decision is published. Common reasons for non-compliance include missing required information or insufficient justification for adaptations to standard information requirements (e.g., read-across, weight-of-evidence approaches). **Methods:** Our prior review of CCH decisions published between 2010 and 2023 identified 2,313 issued decisions. Of these, 48% ($n = 1,111$) included read-across hypotheses for at least one endpoint, and among those, 93% contained read-across adaptations deemed inadequate. In this study, we systematically evaluated and extracted information on all read-across hypotheses that ECHA found unacceptable for fulfilling standard information requirements, including extension of the dataset to the decisions published in 2024 and 2025. For each case, we recorded the adapted endpoint, source substance(s), read-across type, and the scientific rationale supporting the proposed adaptation. Information related to the proposed read-across rationales was categorized using 17 assessment elements that represent key components of read-across hypotheses, including structural, toxicokinetic, and toxicodynamic similarities. **Results:** These 17 elements were used to identify the reasons for ECHA's rejection of the proposed read-across and to analyze associations between hypothesis characteristics and CCH outcomes. Our analysis revealed that inadequate read-across adaptations often lacked supporting data demonstrating toxicokinetic and toxicodynamic similarity. Furthermore, we identified specific elements within the read-across hypotheses that could be strengthened by incorporating data from New Approach Methods (NAMs) to reduce uncertainty. **Conclusions:** Overall, this systematic evaluation provides critical insights into the reasons why ECHA deems certain read-across adaptations inadequate. The findings highlight opportunities to enhance confidence in read-across approaches and to design scientifically robust adaptations that can better withstand regulatory scrutiny.

PS 4475 New EU Endocrine Disruptor Hazard Classes: Classification Criteria, Testing Requirements, and Industry Implications

W. Mune¹, and R. Gioia². ¹Yordas Group, Forcheim, Germany; and ²Yordas Group, Lancaster, United Kingdom. Sponsor: W. MUNE, EUROTOX

Background and Purpose: The European Union has introduced new hazard classes for endocrine disruptors in the Classification, Labelling and Packaging (CLP) Regulation, establishing the first dedicated classification system for these substances. The European Commission's Delegated Regulation (EU) 2023/707 mandates compliance from May 1, 2025, for substances and May 1, 2026, for mixtures. This framework introduces two distinct hazard classes: endocrine disruption for human health (ED HH) and endocrine disruption for the environment (ED ENV), each subdivided into Category 1 (known or presumed endocrine disruptors) and Category 2 (suspected endocrine disruptors). Previously, endocrine disruptors were regulated indirectly through other hazard categories, such as reproductive toxicity or aquatic toxicity, creating regulatory gaps. This presentation describes the classification system, assessment criteria, critical testing endpoints, and implications for industry and regulators. **Methods:** This presentation analyses the new ED classification framework based on EU guidance, CLP amendments, and ECHA criteria guidance published in late 2024. The classification system operates on a weight-of-evidence approach requiring demonstration of three key criteria: an adverse effect in an intact organism or its progeny, an endocrine mode of action, and

a biologically plausible link between the two. The presentation outlines Category 1 versus Category 2 decision logic and testing strategies for estrogenic, androgenic, thyroid, and steroidogenic (EAST) modalities, including *in vitro* screening assays and *in vivo* confirmatory studies. The integration of New Approach Methodologies, including high-throughput screening, adverse outcome pathways, and computational predictions alongside traditional studies, is examined. Case studies demonstrate how data packages are evaluated and classification decisions evolve based on evidence quality and completeness. **Results:** ED classification requires specific criteria based on evidence strength, mechanistic understanding, and EAST modality. Category 1 demands convincing evidence from human or robust animal data demonstrating adverse effects linked to endocrine mechanisms; Category 2 applies when evidence suggests but doesn't confirm endocrine disruption. Classification under the new CLP ED hazard classes triggers regulatory consequences under REACH, including potential inclusion in the Candidate List of Substances of Very High Concern (SVHC), inclusion on the Candidate List for authorisation, Annex XIV (requiring authorisation for use), or Annex XVII restrictions (imposing use bans or limitations), and enhanced risk management requirements in chemical safety assessments and Safety Data Sheets. Critical endpoints include reproductive organ weights and histopathology, hormone measurements, developmental effects, thyroid parameters, sexual maturation effects, and transgenerational effects. Data gap analysis reveals that many REACH registrations lack endocrine-specific endpoints, requiring additional information to conclude the ED classification. Industry implications include mandatory portfolio screening, potential triggering of REACH authorisation or restriction procedures, reformulation requirements for classified substances in consumer products, and supply chain communication obligations through updated Safety Data Sheets. **Conclusions:** The new ED hazard classes establish a science-based framework for identifying endocrine-disrupting substances, closing critical regulatory gaps. Implementation requires industry engagement through systematic evaluation, high-quality data generation, transparent reporting, and participation in harmonised classification proposals. These classifications drive prioritisation across EU regulations, including REACH, cosmetic and food contact materials regulations to enhance chemical safety protection.

PS 4476 Enhancing Chemical Hazard Assessment in California's Safer Consumer Products Program: Translating Toxicological Data into Hazard Scores and Addressing Challenges with Alternatives Analysis

A. Lim, J. Jackson, N. Pham, and X. Zhou. California Environmental Protection Agency, Sacramento, CA.

Background and Purpose: California's Safer Consumer Products (SCP) Program uses a hazard-based approach to evaluate chemicals, rather than traditional risk assessment. Our science-driven process identifies specific consumer products that contain potentially harmful chemicals. Manufacturers who produce these specific product-chemical combinations, or Priority Products, perform a comprehensive Alternatives Analysis (AA) to evaluate potential alternatives to avoid regrettable substitutions. An integral part of the AA process is the chemical hazard assessment (CHA), which involves evaluating chemicals to determine their potential to cause harm to human health and the environment. However, challenges have emerged in these manufacturer-led CHAs, prompting the exploration of new approaches to improve the quality and consistency of CHAs for the benefit of product manufacturers, regulators, and consumers. **Methods:** We reviewed AAs submitted by manufacturers and evaluated their comparison of alternatives, with particular focus on: (1) CHA methodologies and scoring systems, (2) approaches to translate diverse toxicological data into hazard benchmarks, and (3) strategies for addressing incomplete data. **Results:** While manufacturers may employ a range of different CHA methods and criteria for benchmarking, many fail to address all the hazard endpoints required by SCP regulations. Manufacturers use the results of their CHA to weigh trade-offs and identify an alternative to replace the harmful chemical in their product. However, we have encountered several challenges, including variability in the quality of submitted CHAs, limited industry expertise in alternatives assessment and hazard evaluation, inconsistent translation of toxicological data into comparable hazard scores, lack of tools to consider transformation products, different approaches to handling data gaps, and limited methodologies to assess the hazards of mixtures and formulations. Collectively, these challenges can increase the potential for regrettable substitutions, because the quality of the CHA may not sufficiently support a manufacturer in weighing trade-offs. **Conclusions:** SCP is exploring several initiatives designed to strengthen CHA quality, reduce resource disparities across manufacturers, and facilitate informed substitution. These include updating our AA guide to provide clearer guidance to manufacturers performing CHAs, increasing earlier engagement with manufacturers to better understand performance needs and increase awareness of SCP's AA process and requirements, and the creation of an AA database that publicly lists potential alternatives with hazard assessments completed by product manufacturers. SCP is also exploring a collaborative AA approach, in which the program would lead elements such as the CHA, but meaningfully engage with and receive targeted information from industry for a given Priority Product. These steps could help reduce disparities between manufacturers while improving consistency and scientific rigor. We welcome input to continue to refine these concepts and ensure they are scientifically sound and implementable.

PS 4477 California Cannabis Consumption Survey - a Foundation for Health-Based Pesticide Limits for Edible Cannabis

A. A. Kalashnikova¹, S. Koshlukova¹, Q. Dong¹, B. Darsie¹, J. C. Tomassilli², S. DuTeaux¹, and J. Teerlink¹. ¹Department of Pesticide Regulation, Sacramento, CA; and ²California State University, Sacramento, CA.

Background and Purpose: Cannabis remains a federally illegal crop in the United States, and pesticide use on cannabis and pesticide residue on cannabis products cannot be regulated in the same way as other agricultural crops. This has left US states that have legalized cannabis to develop their own regulatory frameworks. In California, the Department of Pesticide Regulation (DPR) advises the Department of Cannabis Control on health-protective pesticide residue limits known as "action levels" for cannabis products, including edibles, beverages, and tinctures. A major challenge in establishing health-based action levels from pesticide residues in cannabis is the lack of both cannabis pesticide concentration data and cannabis product use and consumption data, both of which are essential for estimating pesticide exposure from cannabis use. When DPR initially developed its pesticide action level methodology, the department selected watermelon as a surrogate agricultural commodity because of its high consumption rates. This was the most health-protective strategy to account for the wide variety and consumption range of cannabis-infused edibles. However, this model lacked real-world relevance. To refine its methodology, DPR partnered with California State University, Sacramento (CSUS) to conduct the California Cannabis Consumption (C3) Survey in 2020 and 2023. The C3 Survey provides the first comprehensive dataset on cannabis consumption patterns in the California marketplace and supports the development of more accurate, health-based exposure scenarios. **Methods:** DPR and CSUS's Public Health Survey Research Program jointly developed the C3 Survey with the main objective of determining the quantity of commercial and legal cannabis products consumers use in the California marketplace for each type of manufactured cannabis product. The 31-page survey was administered in both pilot and full cohort phases via in-person interviews. The survey was conducted in 2020 and 2023 throughout California, including in the Los Angeles/San Diego area, Central Valley, greater Sacramento area, and the North Coast. The survey tool was designed to ensure representative sampling of California legal cannabis consumers over 18 years old. **Results:** The C3 survey included 381 participants who averaged 38.8 years old (range 18-95 years old), with 54% male and 45% female respondents. Most participants self-identified as White, non-Hispanic (46%) or Hispanic/Latino (32%) and they reported using an average of 2.7 cannabis product types in the past 28 days. Flower was the most commonly used product (324 respondents), followed by vapes (220), edibles (148), and resin (121). Fewer participants reported using topicals, beverages, or liquid concentrates. Among non-inhalable products, significant differences in consumption rates were observed. Notably, cannabis-infused beverages (e.g., teas, sodas) were consumed at rates approximately 14 times higher than other edible products (e.g., gummies, cookies, chocolates, mints, and liquid concentrates). This consumption rate reflects total product volume or mass, not delta-9-tetrahydrocannabinol (THC) content. **Conclusions:** California is the first state to develop a comprehensive methodology for the health-based evaluation of pesticide residues in cannabis products. DPR's methodology initially used an agricultural surrogate for cannabis consumption data. However, with the completion of the C3 Survey, DPR has now refined its methodology for deriving health-based action levels of pesticides in cannabis based on upper-bound (95-99th percentile) consumption data for various cannabis products. This framework is grounded in toxicology, real-world consumption data, and the best regulatory practices, and could be applied by regulatory agencies seeking to assess the health impact of pesticide residues on hemp products.

PS 4478 Developing Human Health Reference Levels for Pesticide Residues in Groundwater

C. Zhang, D. Bonnar, B. Brown, Q. Dong, M. Geier, A. Kalashnikova, S. Tiscione, P. Lohstroh, S. Koshlukova, and S. DuTeaux. CalEPA, DPR, HHA, Sacramento, CA.

Background and Purpose: In accordance with California's Pesticide Contamination Prevention Act (PCPA), the Department of Pesticide Regulation (DPR) established pesticide detection and response processes to prevent potential contamination of groundwater from legal agricultural use of pesticides. Detection of pesticides in groundwater following routine monitoring may trigger a request to DPR's Human Health Assessment (HHA) Branch for a human health risk evaluation. These evaluations are fit-for-purpose formal reviews that determine if the pesticide was detected after legal agricultural use and, if so, whether uses can continue with or without added restrictions. HHA evaluations establish one or more Groundwater Human Health Reference Levels (HHRLs) for screening pesticides and any relevant pesticide degradates in groundwater. **Methods:** An HHRL is the threshold pesticide and/or pesticide degrade concentration for a maximum water intake that results in the maximum safe oral exposure. A pesticide and its degradate(s) may be covered by the same HHRL when they are considered to be toxicologically equivalent and their residue concentrations summed for evaluation. DPR uses established regulatory reference doses (RfDs) and high-end drinking water intakes (DWIs) to calculate HHRLs. Pesticide concentrations in groundwater at or below the HHRL are considered to have no significant health concern. Detections above the HHRL may indicate potential pollution of groundwater as defined by PCPA. **Results:** Unique HHRLs have been used to screen residues of the parent pesticide as well as chemically

related pesticides and degradates with equivalent toxicity. As of November 2025, 19 Groundwater HHRLs have been established for pesticides and related degrade species. **Conclusions:** DPR HHRLs are based on health-protective and scientifically supportable assumptions and are specific for evaluations of pesticides in groundwater. They provide context for interpreting the potential human health impact of groundwater pesticide monitoring data.

PS 4479 Setting Maximum Levels for PFAS in Farm Products

A. P. Bline, A. E. Smith, and T. L. Simones. Maine Center for Disease Control and Prevention, Augusta, ME.

Background and Purpose: The State of Maine has been testing soil, water, and farm products for per- and polyfluoroalkyl substances (PFAS) at properties with records of past sewage sludge spreading. This testing has identified PFAS contamination of a number of products, including milk, beef, eggs, and certain vegetables. The Maine Center for Disease Control and Prevention (Maine CDC) developed perfluorooctane sulfonic acid (PFOS) action levels for milk in 2017, beef in 2020, and eggs in 2025 for the state's Department of Agriculture, Conservation and Forestry (DACF) to identify when a product would be considered adulterated and no longer fit to be sold by a producer. In 2025, the state legislature formally established the DACF PFAS Response Program and authorized the state to set maximum levels for PFAS in farm products. As part of expected DACF rulemaking, Maine CDC is updating existing maximum levels for PFOS in milk, beef, and eggs, and developing additional maximum levels for PFOS in other farm products produced in Maine. **Methods:** We calculated product consumption rates in g/kg-day using 2015-2023 National Health and Nutrition Examination Survey (NHANES) dietary intake data. Survey foods were mapped to individual farm products using the Food and Drug Administration's (FDA) Food Disaggregation Database. Consumption rates were calculated as two-day means for individuals who completed dietary surveys on two non-consecutive days and reported product consumption on at least one day. As-consumed product quantities were converted to raw, edible forms using adjustment factors calculated from composition data reported on the United States Department of Agriculture's Food Data Central website. We estimated mean and 90th percentile consumption rates for child subpopulations recommended by the FDA using the "survey" package in R to account for the complex NHANES survey design. We calculated maximum levels for PFOS as the toxicity value divided by the consumption rates for 14 farm products. We used PFOS toxicity values published by the Agency for Toxic Substances and Disease Registry (ATSDR) and the United States Environmental Protection Agency (USEPA) and compared the results to maximum limits set by the European Commission in 2023 and to current laboratory reporting limits. **Results:** Of the 14 farm products, 90th percentile consumption rates calculated from NHANES for children aged 0 to 6 years were highest for fluid milk (42.52g/kg-day) and lowest for lettuce (0.99g/kg-day). Using ATSDR's 2021 minimum risk level (MRL) of 2ng/kg-day for PFOS, the maximum level for fluid milk would be 0.05ng/g (48ng/L) and for other products would range from 0.2ng/g to 2.0ng/g. The maximum levels for PFOS in beef and eggs (both 0.5ng/g) would be similar to the maximum levels set by the European Commission for combined beef, pork, and poultry meats (0.3ng/g) and for eggs (1.0ng/g). Maximum levels calculated using USEPA's 2024 PFOS reference dose (RfD) of 0.1ng/kg-day would be 20-fold lower and well below current commercial lab reporting limits for PFOS. **Conclusions:** Maximum levels for PFAS in farm products have not been established at the federal level in the US. Maximum levels for PFOS in beef and eggs calculated using ATSDR's MRL and consumption rates from NHANES would be similar to levels set for these products by the European Commission. Using either ATSDR's MRL or USEPA's RfD as the toxicity value would result in PFOS maximum levels near or below current laboratory detection limits for many products.

PS 4480 Tracking the Persistence of Replaceable Animal Tests: The Replace Animal Tests (RAT) List as a Tool for Advancing Non-Animal Toxicology

L. Alvarez. Cruelty Free International, London, United Kingdom.

Background and Purpose: It is often assumed that animal tests for which non-animal replacements exist are no longer conducted, or at least rarely used. However, evidence shows that these tests continue—and in some cases even increase—long after scientifically valid alternatives have been established. The *Replace Animal Tests (RAT) List*, developed by Cruelty Free International, is a data-driven tool designed to systematically track regulatory animal tests that remain in use despite the availability of scientifically validated non-animal approaches. The tool currently monitors ten key tests across regions including Europe, North America, South America, and Asia. **Methods:** For each test, the list includes the estimated number of animals used annually, based on EU data, to show the scale of impact. It also tracks trends over time to see whether animal use is going up, down, or staying the same. A detailed description of the animal tests and the available non-animal methods is included. It sets out which sectors are driving the use of these tests, what guidelines or legislation require them, and in which regions. It tracks the acceptance status of the non-animal replacements across different regions. And finally, it highlights the key barriers to replacement — and some possible solutions. **Results:** The RAT list tests include rabbit pyrogen, skin and eye irritation, skin sensitisation, antibody production, and

batch potency and safety tests. Collectively, these ten tests result in an estimated 1.2 million animals being used annually in Europe, according to publicly available data from 2022. This persists even though the EU has legal requirements for the adoption of non-animal methods where feasible. In regions without such legal mandates, the extent of animal use is likely even higher. While most other regions do not yet have equivalent legal obligations, global momentum is building. Governments, regulators, and international harmonization bodies are developing strategies and roadmaps to reduce animal testing. The U.S. Food and Drug Administration's roadmap, for example, identifies several RAT List tests—such as shellfish toxin, leptospirosis potency, pyrogen, and skin irritation tests—as priority areas for reduction. **Conclusions:** By integrating regulatory data and expert input, the RAT List quantifies the persistence of outdated tests and identifies scientific, regulatory, and operational barriers impeding adoption of modern toxicological methods. The RAT List provides an evidence-based framework to help scientists, regulators, and policymakers prioritize areas for transition and advance global efforts toward predictive, human-relevant toxicology.

PS 4481 An Evaluation of the Science and Recent Regulatory Initiatives Regarding Formaldehyde

J. Siracusa¹, Q. Perry¹, M. Stevens², P. Underwood³, and D. Paustenbach¹. ¹TRC Companies, Jackson, WY; ²TRC Companies, Denver, CO; and ³TRC Companies, Manassas, VA.

Background and Purpose: For more than five decades, formaldehyde has been exhaustively studied and been the focus of numerous recent regulatory initiatives. Few chemicals have been examined with greater experimental rigor or generated more policy disagreement. The extensive toxicological and mechanistic data present a remarkably consistent picture, e.g., a concentration-dependent continuum of portal-of-entry effects with clear biological thresholds. Nonetheless, regulatory agencies have recently reached markedly different conclusions about acceptable exposure limits. This divergence reflects not a deficiency of data, but rather fundamental differences in the interpretation of evidence and the application of the precautionary principle. **Methods:** Relevant literature was identified through systematic searches of PubMed, Scopus, and Google Scholar (1960-2025) and supplemented by key technical assessments (CIIT, 1999; WHO, 2010; ECHA, 2012). Only peer-reviewed studies or authoritative reports with quantitative exposure-response, histopathologic, or mechanistic data were considered. Human, animal, and computational findings were integrated to characterize the relationships among concentration, exposure duration, and tissue response. The weight of evidence was used to describe the biological processes linking irritation, cytotoxicity, and tumorigenesis. **Results:** Controlled human chamber studies, chronic rodent bioassays, and computational dosimetry collectively demonstrate that formaldehyde's toxicity is confined to tissues of initial contact. Mild sensory irritation occurs at 0.3-0.5 ppm, reversible epithelial adaptation near 1 ppm, and cytotoxic injury with regenerative proliferation occurring above 6 ppm. Chronic inhalation studies in rats and mice confirmed that nasal tumors developed only under conditions of sustained epithelial injury and compensatory hyperplasia, findings consistent with a threshold-driven, local mode-of-action. Biologically based dose-response (BBDR) modeling utilizes the experimental DPX kinetics which continues to support that formaldehyde's effects arise from the local saturation of metabolic and binding capacities in the nasal epithelium, resulting in prolonged cytotoxicity and regenerative proliferation: a mechanism not influenced by cumulative systemic dose. Despite this mechanistic clarity, regulatory decisions have often emphasized epidemiologic correlations and default linear low-dose extrapolations. Today, occupational and environmental limits among different countries vary by more than an order of magnitude. The EPA's reliance on linearized cancer models for carcinogenesis contrasts sharply with threshold-based approaches adopted by ACGIH, ECHA, and several international agencies. **Conclusions:** The history of formaldehyde regulation highlights the persistent gap between the science of dose-response and the policy frameworks that govern its interpretation. Integrating mechanistic toxicology into risk assessments allows for an approach that 1) links inhaled concentration to local tissue dose, 2) differentiates adaptive from adverse responses, 3) appropriately weights controlled human and animal data, and 4) promotes regulatory consistency grounded in empirical evidence. Formaldehyde, therefore, stands as both a case study in inhalation toxicology and a lens through which to examine how abundant, well-characterized science can yield divergent regulatory outcomes when viewed through differing philosophical and statutory frameworks.

PS 4482 Impact of single-use plastics at intensive care units: Costs, toxicity, and environmental sustainability

J. Franco-Mesa, B. J. Arroyo-Salgado, and M. Godin-Cuadrado. Biomedical, Toxicological and Environmental Research Group BIOTOXAM – SEMILLERO SEMIDET, School of Medicine, Universidad de Cartagena, Cartagena, Colombia.

Background and Purpose: The extensive use of single-use plastics in Intensive Care Units (ICUs) presents a growing challenge in environmental, health, and economic terms. Although their use ensures asepsis and clinical efficiency, it generates large volumes of waste and high disposal costs, which can be up to ten times higher than those of household waste. In hospitals, plastic waste represents between 20% and 30% of total waste generated, with averages of up to 2 kg per bed per day. In 2023,

healthcare systems in Europe and North America faced costs exceeding 56 billion USD, and by 2040 these figures could surpass 76 billion if no mitigation strategies are implemented. In ICUs, the most commonly used plastic devices include catheters, IV bags, ventilator components, endotracheal tubes, dialysis systems, cannulas, connectors, and sterile packaging. Most are made of polyvinyl chloride (PVC), polyethylene (PE), polypropylene (PP), polycarbonate (PC), and polyurethane (PU). Among these, PVC and PC remain critical materials due to the potential presence of plasticizers such as di(2-ethylhexyl) phthalate (DEHP) and Bisphenol A (BPA), compounds with recognized endocrine-disrupting effects that may pose health risks to critically ill patients. In Colombia, ICU waste generation has been documented at up to 3.87 kg/bed/day, and circular-economy models have been proposed for the recovery of these materials; however, research on BPA or DEHP exposure in clinical settings remains limited. **Methods:** This review was conducted following the Preferred Reporting Items for Systematic Reviews and Meta-Analyses (PRISMA) guidelines. Based on the PICO method (Population, Intervention, Comparison, Outcome), the following scientific question was formulated: Can circular-economy strategies generate successful models for the recovery and reuse of materials derived from single-use plastics in ICUs, in order to reduce environmental impact, decrease the consumption of high-value raw materials, improve energy recovery, and enhance sustainability? Databases such as Medline, Latin America & Iberia, and platforms including PubMed, ScienceDirect, Scopus, and Scielo were used, applying inclusion and exclusion criteria to publications from 2020 to 2024, reviewing hospitals worldwide. Critical appraisal and quality assessment of the included studies were performed using the Cochrane risk-of-bias tool. **Results:** This review will provide information to support circular-economy models that reintegrate single-use ICU plastics into the value chain. **Conclusions:** The information generated will allow the development of alternative strategies for circular-economy models.

PS 4483 EPA's Implementation of the Endocrine Disruptor Screening Program (EDSP) Near-Term Strategies

R. Loudon, G. Akerman, M. Perron, C. Aubee, and S. Lynn. United States Environmental Protection Agency, Office of Pesticide Programs, Washington, DC. Sponsor: C. Tan

Background and Purpose: The Federal Food, Drug, and Cosmetic Act (FFDCA) 408(p) required EPA to develop a screening program to determine whether certain substances (including pesticides) may have an effect in humans similar to an effect produced by "naturally occurring estrogen, or other such endocrine effects". As a result, the Agency established the EDSP in 1998, which includes human and wildlife testing for estrogen, androgen, and thyroid pathways using a two-tiered testing approach. Since then, EPA has faced several challenges with program implementation. In order to begin addressing these challenges and rebuilding the EDSP over the next several years, EPA is prioritizing screening of conventional pesticides in order to fulfill the Agency's obligations and commitments under FFDCA, which requires the EPA to screen for and protect against endocrine disrupting effects in humans. **Methods:** In 2023, EPA issued a Federal Register Notice describing the development of initial near-term strategies, which includes how existing data submitted to EPA can be used to evaluate endocrine systems. Under the EDSP near-term strategies, EPA is evaluating existing data obtained through Federal Insecticide, Fungicide, and Rodenticide Act (FIFRA) registration and registration review and other scientifically relevant information (OSRI) to determine if additional human health data are needed to inform FFDCA section 408(p) decisions. For example, endocrine-related data for numerous conventional pesticides are available through either two-generation reproduction toxicity or extended one-generation reproductive toxicity (EOGRT) studies that would eliminate the need for any further estrogen or androgen data. Additionally, EPA developed a framework to organize and prioritize the large number of conventional pesticides in registration review. "Group 1" cases demonstrated potential activity in ToxCast Pathway Models and were identified as highest priority for needing additional data. EPA committed to issuing data call-ins (DCIs) to obtain additional data for "Group 1" cases. For the remaining pesticides in "Group 2" or "Group 3", EPA committed to reevaluating the available data to determine what additional studies, if any, might be needed to confirm EPA's assessment of the potential for impacts to endocrine pathways in humans. Since the release of the EDSP near-term strategies, EPA has updated these groups for conventional pesticides based on public comments and additional information. **Results:** EPA has made progress in EDSP implementation since the release of the near-term strategies. Over 100 conventional pesticide cases were identified with existing reproductive toxicity studies performed under current guidelines that provide adequate estrogen and androgen data for humans. Additionally, EPA has completed FFDCA 408(p)(6)-related commitments and obligations for several new active ingredients and chemicals undergoing registration review. EPA has created a website to track the status of EDSP DCI Notices for "Group 1" chemicals. To date, out of the DCIs issued for approximately 30 "Group 1" chemicals, EPA has received responses for at least 21. EPA has begun evaluating these responses, which include waiver requests and/or data submissions, with a small number planning to generate new data. For "Group 2" and "Group 3" chemicals, EPA's Hazard and Science Policy Council (HASPOC) continues to consider the need for additional thyroid data when there is evidence of thyroid toxicity. Additionally, the Endocrine Disruptor Screening Policy Council (EDSPOC) was formed in 2022 to review hazard and exposure data and recommend whether additional endocrine-related data are needed. In fiscal year 2025, EDSPOC considered endocrine-related data needs or exemptions for over 10 chemicals and recommendations will be

incorporated into public documents to inform 408(p) EDSP decisions in the future. **Conclusions:** The near-term strategies that have been implemented thus far are the initial steps EPA is taking to generate momentum toward the longer-term goal of addressing its FFDCA 408(p) obligations and commitments. Use of the EDSP near-term strategies thus far has highlighted the utility and sufficiency of existing data to address data needs and decisions under FFDCA 408(p). EPA will continue to provide status updates through its tracking website and consider further improvements for implementation.

PS 4484 Network toxicology applied to titanium dioxide nanoparticles: implications for human health

D. Gomez-Caballero, and J. Olivero-Verbel. University of Cartagena, Cartagena, Bolivar, Colombia.

Background and Purpose: Titanium dioxide nanoparticles (TiO₂-NPs), widely used in consumer products, are emerging environmental contaminants. Although their ability to induce oxidative stress is known, the molecular mechanisms underlying their toxicity remain unclear. This study explored the immunotoxic mechanisms of TiO₂-NPs by analyzing transcriptomic changes in human macrophages. **Methods:** The study was based on a network toxicology approach that integrated a dual strategy for gene identification, construction of molecular interaction networks, functional characterization, and projection to pathological contexts. The analysis included transcriptomic data from human CD14⁺ macrophages exposed to TiO₂-NPs (GSE179543), processed using the limma package ($|\log_2FC| > 0.58$, FDR < 0.05), complemented by exhaustive mining of toxicogenomic databases (CTD, GeneCards, DisGeNET) using "titanium dioxide nanoparticles" as the search term. This integration enabled the selection of 200 genes with altered expression for subsequent analysis. Protein-protein interaction networks were constructed in STRING (confidence > 0.900), and hub genes were identified through topological analysis with CytoHubba in Cytoscape. Functional characterization was performed through enrichment analysis in Reactome (FDR < 0.05), with validation via multi-platform triangulation (Metascape, g:Profiler, DAVID), exclusively retaining significant functional terms consistently reproduced in at least two analytical tools. **Results:** Network topology analysis identified four central hub genes: CCL2, CXCL10, CXCL9, and CD4, functioning as key regulators of the TiO₂-NP response. These demonstrated significant enrichment in critical biological pathways including Interleukin-10 signaling (FDR = 6.24×10^{-7}), interleukin signaling cascades (FDR = 1.51×10^{-5}), chemokine receptor binding (FDR = 1.51×10^{-5}), and the NFE2L2 oxidative stress pathway (FDR = 3.42×10^{-5}). Functional analysis confirmed sustained activation of both inflammatory responses and oxidative stress mechanisms. Disease ontology assessment revealed that titanium dioxide nanoparticles exhibit significant associations (FDR < 0.05) with systemic lupus erythematosus, atherosclerosis, rheumatoid arthritis, neurodegenerative disorders, and neoplastic processes, highlighting their broad pathogenic potential. **Conclusions:** Titanium dioxide nanoparticles possess the potential to induce transcriptional reprogramming in CD14⁺ human macrophages through coordinated activation of immunoinflammatory and oxidative stress pathways governed by key molecular hubs. The widespread presence of these nanoparticles in consumer products positions them as significant components of the global human exposome, calling for greater attention regarding their toxicological implications. The identified molecular and pathological outcomes support the critical need to prioritize safety assessments and implement specific protective measures against this emerging public health concern worldwide. [UniCartagena. Support to Research Groups and Doctoral Programs. 2024-2025].

PS 4485 Cross-Platform Translation of Toxicogenomic Profiles Using a Transformer Model to Enable Data Harmonization

G. Cong¹, S. Auerbach², J. Erickson², and P. Combs². ¹Oak Ridge National Laboratory, Oak Ridge, TN; and ²NIEHS, RTP, NC.

Background and Purpose: Toxicogenomic studies rely on transcriptomic profiling platforms that vary in dynamic range, probe chemistry, and transcript coverage. These differences introduce systematic technical variation that limits cross-study analysis and re-use of historical data. There are at least three generations of profiling platforms with many legacy data samples. For example, two main toxicogenomics databases, open-TGGATs and DrugMatrix, contain measurement data from older platforms including CodeLink and Affymetrix. There remains a gap for toxicologists to utilize the broadest possible range of existing data. We developed a transformer-based model to translate treatment-derived gene expression profiles across platforms, enabling harmonization and integrated interpretation of toxicology datasets. **Methods:** Paired gene expression datasets were curated from the DrugMatrix and used to train a customized profile-to-profile attention model that learns a shared latent representation of treatment-induced transcriptomic responses and reconstructs them in a target platform space. Different from Seq2Seq transformers, our model does not enforce artificial ordering on the gene profiles, and is able to concurrently decode for multiple regions in the target profiles. In our evaluation we focused on translating CodeLink and Affymetrix microarray profiles to BioSpyder Whole Transcriptome (BioSpyderWT) TempO-Seq profiles. Model performance was evaluated by gene-wise correlation, concordance of differential expression analyses,

and pathway enrichment similarity. We also compare prediction accuracy against two baselines, a multi-layer perception (MLP) and a seq2seq transformer. **Results:** Dependent on the amount of available data samples per tissue in the database, we explore three training modes (mixed-tissue, single-tissue, and cross-tissue). In all three modes, our model beats the two baselines in prediction performance. In mixed-tissue mode, our model reduces mean absolute error by more than 50%, that is, 0.043 vs. 0.09, and doubles the Pearson correlation, ≈ 0.71 vs. 0.37, relative to baselines. Critically, it preserves rare but biologically important over- and under-expressed signals with MAE < 0.22 . Single-tissue models yield further gains for well-represented organs, for example, liver mean absolute error $> 10\%$, while highlighting the need for data-augmentation strategies in low-sample tissues. The model accurately reconstructed target platform expression signatures. Across chemicals and tissues, gene-level **Pearson Correlation Coefficients are up to 0.75**, with foldchange data for tissues with plenty of training samples. Differential expression analyses performed on translated profiles exhibited **$\sim 60\text{--}80\%$ overlap in top perturbed genes**, and downstream biological interpretation was preserved, with **pathway-level Jaccard similarity of up to 0.85**, particularly for pathways associated with xenobiotic metabolism, oxidative stress, immune activation, and mitochondrial function. These results indicate that the model captures conserved biological signal despite technical platform differences. To further demonstrate the utility of our model for modern AI applications, we harmonize liver data from two platforms in DrugMatrix, CodeLink and BioSynderWT, for bio-marker identification in liver necrosis analysis. Our experiment shows that harmonized data improves the predictive performance of a simple MLP model over data on the BioSynderWT platform alone. **The F1 score increases from 0.64 to 0.72. Conclusions:** By enabling reliable cross-platform harmonization, our model unlocks decades of legacy toxicogenomic data for contemporary analyses, bolsters biomarker discovery, and promises more reproducible predictive toxicology and regulatory assessments. This study demonstrates that transformer-based platform translation can harmonize toxicogenomic datasets across measurement technologies while preserving biologically meaningful response patterns. This approach supports greater reuse of existing *in vivo* transcriptomic data and aligns with New Approach Methodologies aimed at improving mechanistic inference and reducing reliance on new animal testing.

PS 4486 Mapping the landscape of pharmacological target interactions in RPTEC/TERT1 cells using transcriptomics and cell painting

H. W. van Kessel¹, M. Wedler², P. Helmke³, E. Liepinš⁴, G. F. Ecker³, S. Liu², M. J. Moné¹, G. Callegaro¹, and B. van de Water¹. ¹Leiden University, Leiden, Netherlands; ²German Federal Institute for Risk Assessment, Berlin, Germany; ³University of Vienna, Vienna, Austria; and ⁴Latvian Institute of Organic Synthesis, Riga, Latvia.

Background and Purpose: New approach methods (NAMs) could revolutionize current safety assessment through mechanistic understanding of chemical-biological interactions, but their regulatory uptake remains limited. A perceived limitation is reproducibility across methods and cell systems. Does pharmacological modulation of a target by different compounds always induce identical downstream effects? Do transcriptional or phenotypic signatures predict upstream target interactions? And what is the complementarity of transcriptional and phenotypic changes in describing downstream effects of target modulation? We evaluated transcriptional and morphological profiles upon exposure to a large pharmacologically active reference chemical set with overlapping target interactions. **Methods:** The reference chemical set was derived from RefChemDB, which compiles chemical-target-mode-activity relationships from multiple public sources. This set includes > 300 compounds that interact with some 150 distinct drug targets, with each target associated with 2-4 compounds designed to modulate a specific cellular function. First, we collected affinity measurements from ChEMBL of compound-target activity calls to evaluate the call-combination in RefChemDB and identify further possible targets and performed MS experiments to evaluate the stability of reference chemicals. To determine transcriptional and phenotypic profiles, we exposed RPTEC/TERT1 cells to 8 non-cytotoxic concentrations and conducted TempO-Seq high-throughput transcriptomic profiling and Cell Painting PLUS (CPP) after 24 h. We projected transcriptomic profiling to *in vitro* human RPTEC/TERT1 TXG-MAPr, a weighted gene co-expression network built on toxicogenomic responses upon exposure to nephrotoxics. Finally, BMD modeling of morphological features and TXG-MAPr module responses was performed to determine PODs and evaluate if both methods captured biological activity of reference chemicals. **Results:** Quantitative affinity data collected from ChEMBL confirmed compound-target activity calls defined in RefChemDB as most sensitive but further identified additional significant interactions. Transcriptomics identified 75 targets for which at least one associated compound gave transcriptional changes. When pairs were both able to trigger a transcriptomic response, differential gene expression correlation between pairs showed high similarity. When using the *in vitro* human RPTEC/TERT1 TXG-MAPr, clusters of co-expressed genes for pairs of reference compounds could be related to their target. CPP showed lysosome features to be often perturbed by the selected compound set. Compounds showing high transcriptomic correlation often had similar CPP profiles, e.g., EGFR antagonists Lapatinib and Canertinib had similar transcriptomic profiles marked by a downregulation in the activity of RPTEC/TERT1 TXG-MAPr modules 88 and 95, associated with MAPK signaling. CPP profiles for the ER, mitochondria, lysosome, and actin displayed similar activity, indicating that both platforms capture a shared mechanism. Many compounds that showed positive results in the transcriptome exhibited minimal activity in the CPP assay. Surprisingly, MAP2K1 inhibitors Selumetinib and

PD0325901 showed high correlation with EGFR antagonists at gene and module level, yet the CPP profile of the MAP2K1 inhibitors was not perturbed. Also, TOP1 antagonists Topotecan and Irinotecan exhibited transcriptomic activity but only Topotecan gave changes in CPP features related to ER and mitochondrial activity. This indicates that the different assays may offer different biological interpretations. **Conclusions:** We present a definition on the target space leading to transcriptomic and morphological responses in RPTEC/TERT1 and an interpretative framework based on co-expressed network analysis to obtain mechanistic information for safety assessment. Our work aims to define the chemical-target transcriptomic landscape to assess which biological events can be captured by which cell lines and tissues, thus contributing to define the relevance for chemical risk assessment.

PS 4487 Single cell RNA-sequencing reveals divergent genes in cynomolgus macaque versus human in CD3-CD28 mediated immune response

L. K. Mack, Z. Huang, K. Hoyt, L. Dzielak, B. Flynn, A. R. Masters, C. Wood, E. L. Raymond, and K. Neier. Boehringer Ingelheim Pharmaceuticals, Inc., Ridgefield, CT.

Background and Purpose: The binding specificity achieved by many new immunomodulating therapeutics necessitates the use of non-human primates to achieve thorough safety assessment. Cynomolgus macaques (cyno) are the most widely used non-human primate for drug safety assessment due to their small size, non-seasonal reproductive cycle, and high homology with humans. However, differences in the adaptive immune response between species is not fully characterized, slowing development of immunomodulating therapeutics. **Methods:** To elucidate differences in this response between species, we utilized single cell RNA-sequencing (scRNA-seq) to perform a cross-species integrative analysis of gene expression in immune cells across a 3-day time course after *in vitro* anti-CD3/anti-CD28 stimulation. **Results:** We observed that T cell activation markers upregulated at different time points after stimulation: human CD8+ T cells reaching max CD25 expression 48 hours after stimulation ($\sim 80\%$ of cells expressing) and cyno 72 hours after stimulation ($\sim 85\%$ of cells expressing). However, there were limited statistically significant differences in the expression of T cell signaling related genes between species. To more thoroughly assess temporal differences in gene expression between species, we assessed the variance explained by the interaction of time and species. We identified 270 genes with over 55% of the variation observed in gene expression explained by the interaction between time and species. **Conclusions:** An in-depth understanding of this response between species will accelerate decision-making in the safety assessment of immunomodulating therapeutics.

PS 4488 Evaluation of Anti-Arthritic Effects of Acupen a Polyherbal Formulation Using Adjuvant-Induced Arthritis Model in Wistar Rats

S. L. Jadhav, G. V. Mahajan, K. N. Shah, and M. V. Patel. Jai Research Foundation, Vapi, India.

Background and Purpose: Arthritis is a chronic inflammatory disorder of the joints characterised by pain, swelling, stiffness, and progressive structural damage, ultimately impairing musculoskeletal function. Despite available treatments, long-term management remains challenging due to the adverse effects of conventional drugs. Acupen (300 mg tablet) is a polyherbal formulation containing extracts of *Apium*, *Leptophyllum*, *Aloe vera*, *Commiphora mukul*, *Ricinus communis*, *Myristica fragrans*, *Boerhavia diffusa*, and *Triphala*. The diverse bioactive compounds in these herbs are reported to possess anti-inflammatory and antioxidant properties, offering a potential synergistic effect against arthritis. The objective of this research is to evaluate the potential antiarthritic properties of the Acupen using adjuvant-induced arthritis model in Wistar rats. **Methods:** Arthritis was induced by Subplantar injection of 0.1 mL complete Freund's adjuvant (CFA) in the left hind limb in all rats except the negative control group. Negative control (G1) received vehicle only (0.5% CMC), Disease Control (G2) was kept untreated, Positive Control (G3) received methotrexate (1 mg/kg b. wt./day), and the Acupen-treated groups were treated at 60 (G4) and 120 (G5) mg/kg b. wt./day. Vehicle, methotrexate, and acupen treatment were given orally for 28 consecutive days. Endpoints evaluated included clinical signs, mortality, arthritis scoring, paw volume measurement, cytokine estimation, and histopathology. **Results:** The disease control group showed progressive inflammation and increased paw volume throughout the study period. Methotrexate treatment significantly reduced arthritis scores and paw edema compared with the disease control. Acupen treatment reduced arthritis severity, with a higher dose, which was marginal compared to the positive control. **Conclusions:** Based on the results obtained in the current study, it is concluded that Acupen polyherbal formulation exhibits promising anti-inflammatory and anti-arthritic activity in the CFA-induced arthritis model in Wistar rats, supporting its potential as a complementary therapeutic approach for arthritis management.

PS 4489 Differential Gene Expression in 3D-printer exposed BEAS-2B Human Bronchial Cells Varies with Filament Material and Exposure Time

D. T. Pruss, M. Shojiv, T. Jefferis, J. Beard, C. Worth, J. H. Taube, M. Benton, and C. M. Sayes. Baylor University, Waco, TX.

Background and Purpose: The use of 3D printers, particularly fused filament fabrication (FFF) printers, has increased in residential, educational, and occupational spaces. These printers emit aerosols, including particulate matter and volatile organic compounds, which may cause toxic effects in humans when inhaled. The health effects after exposure have not been adequately characterized. **Methods:** This study analyzes RNA-sequenced data from an FFF printer exposed to a BEAS-2B lung cell model for five different filament types: black-colored acrylonitrile butadiene styrene (ABS), transparent ABS, blue-colored polylactic acid (PLA), transparent PLA, and a mixed steel-and-polymer. Differential gene expression (DEGs) and protein-protein interactions (PPIs) were compared at 1 and 4 hours of exposure. **Results:** There was significant variability in the numbers and identities of DEGs and PPIs among the different exposure groups. The highest number of DEGs and PPIs was observed in the 4-hour exposure to the transparent PLA (401 DEGs and 474 PPIs), and the smallest number of DEGs was observed in the 1-hour exposure to the steel filament (12 DEGs and 0 PPIs). Only a few perturbed genes were common across exposure groups, possibly indicating distinct mechanisms of action induced by each aerosol exposure. **Conclusions:** This research emphasizes the need for further investigation into the underlying mechanisms of 3D-printer emission-induced toxicity.

PS 4490 A similarity-based transcriptomics analysis workflow enables rapid investigation of potential mechanisms of compound toxicity during nonclinical development

J. D. Rogers¹, A. Hu², M. Kesapragada², S. Seal¹, R. Wang¹, S. Denecke¹, K. Q. Tanis¹, R. J. Gonzalez¹, and F. Shah¹. ¹Merck & Co. Inc., West Point, PA; and ²Merck & Co. Inc., South San Francisco, CA.

Background and Purpose: Investigating the mechanisms causing adverse effects during nonclinical toxicity testing directly impacts drug development by derisking potential human health liabilities. While inferences of a compound's safety profile can be made using toxicity data from structurally similar compounds, shared structural features alone may not always be indicative of adverse or undesirable effects. Toxicogenomics provides an additional means of assessing compound safety prior to initiating further testing, as historical compounds with similar profiles of differentially expressed genes could be examined for mechanisms of toxicity. Here, we developed a computational workflow to (1) identify compounds from historical nonclinical studies with similar gene expression to compounds of interest, and (2) compile and contextualize multimodal safety data for rapid interpretation and use in mechanistic investigation. **Methods:** Bulk RNA-seq and mid-density array data from internal *in vivo* and *in vitro* studies comprising over 11000 gene expression profiles were harmonized into a reference database. Cosine similarities (a measure of similarity between two vectors) were then computed from log-transformed fold-change values for all pairs of profiles. A downstream workflow and web application was developed to assemble internal safety data for profiles exceeding a user-defined threshold of cosine similarity versus a user-supplied compound or list of gene fold change values. Data collected for each query included chemical structures, ancillary pharmacology, clinical chemistry, pathway enrichment via overrepresentation analysis and transcriptomic signature scores, and histopathology phenotypes. The application was developed to enable flexible querying starting with any data modality (e.g. any phenotype, biomarker, etc.) to support a variety of mechanistic investigations. **Results:** To evaluate whether cosine similarity accurately prioritizes compounds with similar transcriptional effects, cosine similarity values were compared across 560 compounds that were profiled in multiple mid-density array studies. Cosine similarity values for matching treatment groups (i.e. same compound and dose) and matching compounds only (i.e. same compound at different doses) were both significantly higher than values for mismatching compounds ($p=1.4E-79$ and $p=4.7E-44$ via Mann-Whitney U tests). Cosine similarity values between 1673 compounds profiled via mid-density array were also compared to Tanimoto similarity values (a measure of 2D chemical similarity) computed from Morgan fingerprints to evaluate whether chemical structure-based similarity was associated with cosine similarity values. Tanimoto similarity values were not predictive of cosine similarity values via ordinary least squares regression ($R^2=0.015$), indicating that compounds eliciting similar gene expression may not necessarily be structurally similar. A case study querying compounds known to modulate xenobiotic nuclear receptor CAR yielded analogous compounds with enriched activity towards CAR via transcriptional biomarker scores. Compounds with high incidences of liver hypertrophy in rats were also queried for differentially expressed genes in rat liver samples, where hits were defined as an absolute $\log_{10}$ (fold-change) ≥ 0.5 . These compounds were found to have high hit rates of CAR-regulated genes CYP1B1, CYP1B2 and CYP2C6 (48%, 65% and 49% respectively) whereas compounds that did not cause hypertrophy had lower hit rates (29%, 40% and 18% respectively), in agreement with the known association of CAR activation with liver hypertrophy. **Conclusions:** This workflow underscores the value of large-scale multimodal datasets for providing rapid support during nonclinical toxicology investigations. These data can also support new initiatives to predict safety liabilities earlier in drug development by serving as a basis for machine learn-

ing models and AI-enabled hypothesis generation. Integration of external data could augment predictive capabilities by expanding the diversity of compounds and model systems tested. Altogether, this workflow accelerates current safety investigations and supports future drug development by providing real-time mechanistic insights into potential safety liabilities.

PS 4491 Visualizing Structural Relationships with Clustering in Mass Spectrometry Datasets

A. N. Dickey¹, F. A. Wright¹, and E. S. Baker². ¹North Carolina State University, Raleigh, NC; and ²University of North Carolina at Chapel Hill, Chapel Hill, NC.

Background and Purpose: We have developed an R Shiny application to visualize molecule clustering using dendrograms based on mass spectrometry features. Feature-based clustering can identify structural relationships between molecules without requiring prior knowledge of molecular formulas. This work expands upon the SCOPE (Structural-based Connectivity and Omic Phenotype Evaluations) cheminformatics toolbox, which generates dendrograms and heatmaps to help assess links between lipid class and changes in lipid abundance. SCOPE uses SMILES (Simplified Molecular Input Line Entry System) to represent molecular structure and it can effectively cluster lipids in a dataset that belong to the same class. The use of SMILES limits the clustering to molecules that have known annotations. The feature-based clustering used in the Shiny app may be applied to datasets that contain unknown compounds. **Methods:** Features that can be included in the clustering are the LC retention times (RT), IMS collision cross sections (CCS), and mass-to-charge ratio (m/z) values. The features are detected in a platform that contains coupled liquid chromatography, ion mobility spectrometry and mass spectrometry separations (LC-IMS-MS). The Kendrick mass defect (KMD) may optionally be included in the clustering, where different homologous series in a dataset can have distinct values. The app displays interactive scatter plots for the individual features to help identify potential dataset outliers. The dendrograms show how molecules cluster based on structural similarities for the user-selected features. As with SCOPE, for datasets that have abundance data, the fold change values are displayed on a heatmap adjacent to the dendrogram. This combined visualization can be used to ascertain whether clustered molecules show similar changes in abundance for sample comparisons. **Results:** The functionality of the app is not restricted to a specific molecule type and we highlight two use cases from published studies for lipid and per- and polyfluoroalkyl substances (PFAS). In the first study, mice were exposed to PFAS compounds and the resulting changes to the hepatic lipid abundance were evaluated. The characterization of lipid samples is often challenging due to the variety of molecules and physicochemical properties of the lipidome. In the second study, PFAS with previously unknown structures were elucidated through nontargeted analyses. Like lipids, there are thousands of different PFAS, and having a visualization tool that provides insights into the structural properties of unknown compounds can be useful for these types of datasets. **Conclusions:** The resulting dendrograms show molecule clustering by both structural complexity and group classifications, where the contribution of each is dependent upon the composition of the dataset.

PS 4492 Using methylation profiling to improve bioinformatics pipelines for the identification of dioxin response elements

J. J. Park¹, L. B. Wilson², P. Thunga¹, L. Truong², A. Dickey¹, D. M. Reif¹, R. L. Tanguay², and F. Wright¹. ¹North Carolina State University, Raleigh, NC; and ²Oregon State University, Corvallis, OR.

Background and Purpose: The aryl hydrocarbon receptor (AHR) is a cytosolic ligand-activated transcription factor that binds a wide range of ligands, including families of dioxin-like substances such as polychlorobiphenyls, polychlorinated dibenzo-para-dioxins, and polycyclic aromatic hydrocarbons. AHR forms a nuclear-localized complex that recognizes and binds dioxin response elements (DREs) in gene promoters. The resulting target gene regulation causes various transcriptional, epigenetic, and metabolic responses leading to physiological and developmental effects on immune response, cell cycle control, cellular differentiation, and organ development, and reproductive outcomes. Although the canonical DRE is well-defined by a 5-bp core motif (5-GCGTG-3), studies have shown that extended flanking sequences influence AHR binding and tissue specificity. This raises an unresolved computational challenge of distinguishing functional DREs from the many instances of the core motif across the genome. **Methods:** While considerable attention has been given to the effects of AHR on gene transcription, DNA methylation has also been shown to be intertwined with the AHR gene regulation process, through direct inhibition, or indirectly through effects on chromatin accessibility. The standard approach to the identification of AHR targets has included a combination of motif searching for a DRE consensus genomic sequence, with additional refinement based on transcriptomics and ChIP-seq or other protein-DNA binding assays to better distinguish among putative DREs. We propose to further extend our understanding of active DREs by including results from methylation profiling in response to chemical exposure and activation of AHR, which can be used in combined analyses to produce refined computational models to identify DREs. **Results:** As proof of principle in an important model organism, we analyzed whole-genome bisulfite sequencing (WGBS) data from the sperm of F2-generation zebrafish for which progenitors

had been subjected to a factorial treatment design consisting of the presence or absence of an *ahr2* morpholino knockdown and exposure to benzo[a]pyrene (BaP, known to activate AHR). We quantified differential methylation and examined how these changes correspond to the DRE motifs of varying lengths (5-bp, 8-bp, and 12-bp) to investigate the relationship between AHR binding potential and epigenetic modification. We applied machine learning models to evaluate which variants best predict AHR-associated methylation responses. **Conclusions:** To identify additional AHR targets in zebrafish, we generated a position specific scoring matrix (PSSM) based on the DRE motifs identified for CYP1A to construct a genome-wide library of DRE motifs, expanding beyond the core 5-base-pair consensus motif. Generating PSSMs using these longer motifs reduces the number of genome hits and may lead to discovery of relevant DREs. Results from the machine learning models revealed a subset of longer motifs with improved predictive scores for methylation response. In addition, we describe an approach for gene-level analysis that effectively considers DRE consensus sequences as “soft” pathways suitable for gene set enrichment analyses in the analysis of differential methylation responses.

PS 4493 Comparative Toxicogenomics Database: A data integration and visualization resource to inform the exposome and disease etiologies

C. Mattingly, A. P. Davis, T. C. Wiegiers, J. A. Wiegiers, D. Sciaky, F. Barkalow, B. H. Wyatt, R. McMorran, and S. Abrar. North Carolina State University, Raleigh, NC.

Background and Purpose: Environmental exposures are critical contributors to most chronic diseases. Exposure sources include, but are not limited to, industrial contamination, dietary factors, commercial products, lifestyle choices, and psychosocial stressors. The Comparative Toxicogenomics Database (CTD; <https://ctdbase.org>) was established and publicly launched in 2004 to facilitate data integration and discovery about how environmental factors affect human disease. CTD is a highly cited, globally-used resource that continues to evolve and inform emerging environmental health frameworks such as Adverse Outcome Pathways (AOPs) and the Exposome, which aims to describe the totality of exposures across an individual's lifetime. Here, we present updates on CTD's data and functionality and demonstrate how this resource can be used to survey the environmental health landscape - from model-based mechanisms to exposed populations - to generate testable hypotheses that advance environmental health research. **Methods:** CTD biocurators read the peer-reviewed literature and use community-based data standards to manually curate relationships between chemicals, genes/proteins, phenotypes, anatomical terms, diseases, taxa, and exposure measurements. These data are integrated with select external data sets and analytical and visualization tools designed to discover novel, mechanistic connections between exposures and adverse health outcomes. CTD is accessible via its public website and provides user-friendly query pages, analytical and visualization tools, and downloadable data files. **Results:** CTD currently contains manually curated information for over 19,000 chemicals; 56,000 cross-species genes; 6,800 phenotypes; 7,200 diseases; 630 organisms; and 1,000 anatomical terms. Integrating these curated data-sets further generates more than 100 million toxicogenomic relationships. Importantly, CTD continues to expand, with ~17,000 interactions from over 300 newly curated scientific articles added every month. There are a variety of methods by which users access CTD data, including browser-based keyword searches, advanced query options, analytical tools, and embedded functionality that enables refinement of queries and analyses on demand. Here, we demonstrate CTD's breadth and utility with examples that explore connections between specific chemicals and disease outcomes; however, the same methodologies can be applied to any chemical or disease of interest in CTD. **Conclusions:** Over the last two decades, CTD has evolved into a unique, analytical tool to explore cross-species information about the biological repercussions of chemical exposures. CTD's data and functionality are positioned to inform testable hypotheses that advance understanding about the etiologies and underlying mechanisms of chronic diseases, and as such, environmental health frameworks such as AOPs and the Exposome.

PS 4494 NeTan: A Network-based Tool for Multi-Omics Integration across Cohort and Molecular levels

B. Minasenko, and X. Hu. Emory University, Atlanta, GA.

Background and Purpose: Large multi-omics datasets exhibit complex structures at both cohort and molecular levels. Relationships among data points, whether representing individuals within a cohort or molecules within a biological system, provide key insights into system behavior and individual responses to environmental challenges. While several computational tools have been developed to construct cross-omics molecular networks, few account for cohort-level relationships. We developed NeTan, a user-friendly, graph-based tool that connects the exposome, molecular responses, clinical parameters, and phenotypes across both cohort and molecular level. This unified framework provides a mechanistic basis for hypothesis generation and individualized risk-relevant interpretation. **Methods:** NeTan constructs networks in two modes: (1) cohort-level, where nodes represent participants, and (2) molecular-level, where nodes represent omics features. At the cohort level, NeTan can generate either a single “stacked” consensus network graph or

a multi-layer graph preserving participant relationships within each omics layer. Edges inference is supported by multiple algorithms, including Spearman correlation, Context Likelihood of Relatedness for mutual information, Random Forest similarity for nonlinear associations, and Graphical Lasso for partial correlations. Adjacency matrices are thresholded but retain continuous edge weights, enabling users to tune edge strength and facilitate interpretation. The resulting graphs include network statistics, node attributes, and community detection for identifying hubs and sub-network modules. **Results:** NeTan builds single-layer or multi-layer networks at the cohort level and the molecular level. It is implemented as a user-friendly web application, available at <https://netan.io>, and as a Python package at <https://github.com/bm-boris/netan-lib>. The platform ensures data security by not retaining uploaded data and supports interactive network visualization, standard export formats (e.g., Cytoscape) for downstream visualization and analysis. Users can save and share their analysis configurations to reproduce results. A unique advantage of NeTan is the population network, where edges between individuals reveal similarities in molecular profiles. Using this mode, we identified network communities in a cohort of young healthy adults, showing that occupational exposures have a dominant effect on metabolomics profile in that cohort. This exemplifies the power of NeTan in prioritizing factors that drive biological responses. **Conclusions:** NeTan provides a unified, scalable framework for multi-omics integration that simultaneously captures inter-sample (cohort) structures and molecular co-variations. By combining multiple edge inference algorithms, NeTan enhances robustness and confidence in detected associations. This platform facilitates mechanistic interpretation of complex biological responses and supports risk assessment through transparent, reproducible network-based analysis. Research reported in this publication was supported by the Advanced Research Projects Agency for Health (ARPA-H) under award number D24AC00345-00.

PS 4495 In Vitro Profiling of Cosmetic Ingredients within the Tox21 10K Compound Library for Bioactivity and Potential Toxicity

L. Kruger¹, D. K. Ngan¹, T. Xu¹, M. Xia¹, S. S. Ferguson², D. M. Reif², and R. Huang¹. ¹Division of Preclinical Innovation (DPI), National Center for Advancing Translational Sciences (NCATS), National Institutes of Health (NIH), Rockville, MD; and ²Division of Translational Toxicology, National Institute of Environmental Health Sciences (NIEHS), National Institutes of Health (NIH), Research Triangle Park, NC.

Background and Purpose: The United States Food and Drug Administration (FDA) defines cosmetics as “articles intended to be rubbed, poured, sprinkled, or sprayed on, introduced into, or otherwise applied to the human body...for cleansing, beautifying, promoting attractiveness, or altering the appearance” in the Federal Food, Drug & Cosmetic Act (FD&C Act) Section 201(i). However, the ingredients within these cosmetics are not currently monitored by the FDA. Thus, some states such as California are banning specific chemicals at the state level in bills such as AB-496 Cosmetic safety. This bill bans 26 chemicals (and their salts totaling 70 compounds) from being used in cosmetics which includes known endocrine disruptors such as dibutyl phthalate, diethylhexyl phthalate, and per- and polyfluoroalkyl substances (PFAS). **Methods:** The Tox21 10K compound library was previously screened against a panel of ~80 cell- and biochemical-based assays. The Tox21 10K compound library included 34 compounds (and their variations) that were within the California ban. In this study, banned cosmetic ingredients and non-cosmetic compounds were compared across the Tox21 assays. **Results:** We found that the banned cosmetic compounds were significantly more active in 10 antagonist assays and 7 agonist assays compared to the non-cosmetic compounds. The antagonist assays included enzymes such as CYP2C19 and aromatase (CYP19A1), and the agonist assays included the Keap1/Nrf2 antioxidant response element pathway (KS-ARE). **Conclusions:** The results of this analysis will help identify specific pathways affected by the cosmetic compounds and create a further understanding of the compounds mechanisms of action.

PS 4496 Evaluating Potential Hepatotoxic and Metabolic Disruption by Emerging HFPO Homologues in Adult Female Mice

D. S. Guzman, M. L. Goodson, A. K. Ehrlich, and M. A. La Merrill. University of California, Davis, Davis, CA.

Background and Purpose: The phase-out of legacy per- and polyfluoroalkyl substances (PFAS) such as perfluorooctanoic acid (PFOA) and perfluorooctane sulfonic acid (PFOS) has led to the introduction of replacement compounds based on hexafluoropropylene oxide (HFPO) chemistry. Among these, HFPO dimer acid (HFPO-DA), trimer acid (HFPO-TA), and tetramer acid (HFPO-TeA) are increasingly detected in the environment, yet their toxicological profiles remain poorly characterized. Given their structural similarity to legacy PFAS, this study aimed to evaluate the immunotoxic, hepatotoxic, and metabolic effects of HFPO homologues in adult female mice to assess potential health risks associated with PFAS substitution. **Methods:** Adult female C57BL/6J mice were exposed via drinking water to HFPO-DA, HFPO-TA, or HFPO-TeA at concentrations that were similar to human exposure levels over 3 orders of magnitude for 28 days, followed by immunization with sheep red blood cells to assess a T-cell-dependent antibody response (n = 8/group). To evaluate hepatic and metabolic outcomes, a 14-day study exposed mice

to equal concentrations of HFPO-DA, HFPO-TA, HFPO-TeA, or vehicle control without immunization ($n = 8/\text{group}$). A 7-day comparative study included PFOS at the EFSA tolerable daily intake (TDI) level or at a much lower sub-TDI concentration. Liver and serum samples were analyzed for histopathology, metabolic biomarkers, and transcriptional changes in lipid metabolism and inflammatory pathways. **Results:** Across all exposure durations, HFPO-TA consistently induced dose-dependent increases in liver-to-body weight ratios and significantly decreased circulating triglyceride concentrations, indicative of hepatic and metabolic disruption. HFPO-DA and HFPO-TeA elicited no significant hepatic or metabolic effects. Histopathology confirmed mild hepatocellular hypertrophy in HFPO-TA exposed mice. No overt immunotoxicity was detected in antibody response assays. **Conclusions:** HFPO-TA was identified as the most hepatotoxic and metabolically-disrupting of the HFPO homologues tested, producing consistent hepatic enlargement and altered lipid metabolism. HFPO-DA and HFPO-TeA showed limited biological activity at comparable concentrations. These findings suggest that not all HFPO-based PFAS are toxicologically equivalent, and that HFPO-TA may pose hepatometabolic risks similar to or exceeding those of legacy PFAS. This work underscores the need for mechanistic and dose-response studies to evaluate the safety and regulatory implications of PFAS alternatives currently detected in the environment. Ongoing analyses aim to elucidate the molecular mechanisms underlying HFPO-TA induced hepatotoxicity to inform risk assessment of emerging PFAS alternatives.

PS 4497 Innovative Co-Culture Approach to Investigate Cellular Responses to Fluorotelomer Alcohol Exposure

L. Rios-Colon¹, M. Bailey¹, S. Khan¹, J. Shipman², V. Sivaraman², and E. Sozzi¹. ¹RTI International, Durham, NC; and ²North Carolina Central University, Durham, NC.

Background and Purpose: Fluorotelomer alcohols (FTOHs) are neutral, volatile compounds widely used for their water-, grease-, and stain-repellent properties in consumer products such as textiles, carpets, outdoor gear, and food packaging. These compounds are primarily released from treated materials under ambient conditions and represent the most abundant polyfluorinated substances detected in indoor air. Human exposure occurs mainly through inhalation and ingestion of contaminated house dust, posing particular concern for children due to behavioral and developmental factors. In this study, we aimed to characterize the effects of exposure and identify potential protein targets of four FTOHs in relevant airway cell models. **Methods:** We first employed live-cell monitoring technology to evaluate the biological effects of varying concentrations of the selected PTOHs compounds on airway cellular models using two human airway epithelial cell lines: A549 (lung adenocarcinoma) and BBM (bronchial epithelial cell line derived from BEAS-2B cells). These two models represent distinct areas of the human airway. We exposed these cells to increasing concentrations of 4 compounds: perfluorooctylethyl acrylate, 2-Perfluoro-Octyl ethanol, 2-Perfluoro-Hexyl ethanol, and 2-Perfluoro-Decyl ethanol for up to 120 hours. Real-time assessments of cell proliferation, growth rates, and morphology were used to establish baseline toxicity profiles and characterize alterations in cellular health and function. We also performed an MTT (3-(4,5-Dimethylthiazol-2-yl)-2,5-Diphenyltetrazolium Bromide) assay to assess cell metabolism/viability. Additionally, we employed a co-culture model of primary human bronchial epithelial cells differentiated at the air-liquid interface (ALI) over THP-1-derived macrophages, representing a physiologically relevant human lung airway model. We assessed macrophage activation (CD86) expression utilizing a flow cytometry assay. Finally, we utilized bottom-up quantitative proteomics to measure differential protein expression of human ALI cells upon exposure to 2-Perfluoro-Octyl ethanol. **Results:** Our preliminary experiments showed that perfluorooctylethyl acrylate showed increased toxicity as demonstrated by significant decreased growth and cell viability in both cell lines tested in a concentration-dependent manner. We also observed increased toxicity with the other three compounds, but only at higher concentrations in both A549 and BBM cells. Preliminary experiments involving exposure to FTOH compounds in the ALI-macrophage co-culture model demonstrated macrophage activation, particularly following exposure to perfluorooctylethyl acrylate and 2-perfluorooctyl ethanol. Additionally, we identified 176 unique proteins with significantly altered expression levels in response to FTOH exposure in this model. **Conclusions:** Our findings demonstrate that FTOHs can elicit concentration-dependent cytotoxic effects and alter cellular function in human airway models. Collectively, these results highlight the potential impact of FTOHs on human respiratory health through both cytotoxic and immunomodulatory mechanisms, warranting further investigation into their molecular targets and long-term effects on human airway physiology.

PS 4498 Cell type-specific transcriptomic effects of PFAS in human cortical organoids

G. Gomez¹, T. Khaled¹, J. Lam¹, H. Hipps¹, Z. Liew², A. Muotri¹, and L. Lakoucheva¹. ¹University of California San Diego, San Diego, CA; and ²Yale School of Public Health, New Haven, CT. Sponsor: A. Bowman

Background and Purpose: Per- and polyfluoroalkyl substances (PFAS) are a large class of synthetic chemicals widely used in industrial and consumer products. Due to their chemical stability, PFAS persist in the environment, accumulate in biological systems, and have been linked to cancer, immune dysfunction, endo-

crine disruption, and developmental toxicity. Although PFAS can cross both the blood-brain barrier and the placenta, their effects on human neurodevelopment remain poorly understood. **Methods:** We investigated the cell type-specific transcriptomic effects of six PFAS included in the U.S. EPA National Primary Drinking Water Regulation (Perfluorobutanesulfonic Acid, PFBS; Perfluorohexanesulfonic Acid, PFHxS; Perfluorooctanoic Acid, PFOA; Perfluorononanoic Acid, PFNA; Perfluorooctanesulfonic Acid, PFOS; and GenX) on early neurodevelopment. We generated human cortical organoids (COs) from six iPSC lines derived from healthy female and male donors, and chronically exposed them to each PFAS for up to 50 days, followed by single-cell RNA sequencing. **Results:** Single-cell clustering identified neurons, progenitors, and intermediate progenitor cells as major cell type populations. PFAS exposure did not significantly alter overall cell type proportions, although subtle non-significant reductions in radial glia-like progenitors were observed following PFOS, PFOA, and PFHxS exposure. Pseudo-bulk differential gene expression analyses revealed that PFOS induced the greatest number of differentially expressed genes, followed by PFOA and PFHxS, with progenitors exhibiting greater transcriptional vulnerability compared to neurons. Across compounds, gene expression changes were positively correlated, reflecting shared molecular responses. Most PFAS broadly perturbed non-neuronal processes (RNA metabolism, translation, cell cycle), while neuronal processes (axonogenesis, synaptogenesis) were mainly impacted by PFOS, PFOA, and GenX. Weighted gene co-expression network analysis revealed modules preserved across PFAS and cell types, suggesting disruption of convergent pathways. Notably, PFOS-affected modules were enriched for high-risk neurodevelopmental disorder genes. Preliminary multielectrode array recordings indicated that PFOA and PFHxS may reduce neuronal network activity, although effects were variable and not statistically significant. **Conclusions:** These findings provide mechanistic insight into how PFAS exposure may impact human brain development. Our findings indicate that PFAS exert both cell type-specific and convergent transcriptional effects in cortical organoids, with progenitors showing particular vulnerability, and highlighting shared molecular pathways.

PS 4499 Mechanistic Toxicity Profiling of Legacy and Emerging PFAS Using New Approach Methodologies Integrating Target-Based and Translational Models

J. Hsu¹, L. Fan¹, S. Lin¹, C. Teng¹, B. Huang¹, L. Galdieri², A. J. King², and C. Lee¹. ¹Eurofins Discovery, Taipei, Taiwan; and ²Eurofins Discovery, St. Charles, MO. Sponsor: Y. Zhao

Background and Purpose: Per- and polyfluoroalkyl substances (PFAS) are persistent environmental contaminants posing significant health risks, including endocrine disruption, hepatotoxicity, immunotoxicity, and developmental effects. Following recent FDA actions—including the 2024 withdrawal of PFAS-containing grease-proofing agents and information requests on PFAS in seafood—comprehensive toxicological assessment has become essential. Current assessments predominantly focus on legacy PFAS such as PFOA, PFOS, and PFHxS, leaving critical data gaps for emerging compounds. EPA Method 1633 enables detection of 40 PFAS across multiple matrices at low detection limits. However, mechanisms of action remain poorly characterized for many compounds, including nuclear receptor modulation, metabolic enzyme interference, oxidative stress, and inflammatory pathway activation. This study systematically screened EPA 1633 PFAS using target-based toxicology panels and translational assays to inform safety assessment and regulatory decision-making. **Methods:** I Compound selection: Selected PFAS from the EPA Method 1633 list, including perfluoroalkyl carboxylic acids (PFCAs), perfluoroalkyl sulfonic acids (PFSAAs), precursors, and replacement compounds. I Primary screening: Conducted target-based assays including (1) nuclear receptor panel to assess related cellular functional activation/inhibition, and (2) cytochrome P450 panel to evaluate enzyme inhibition through fluorescence changes in specific substrates. I Testing conditions: Compounds tested at 10 μM ; hits defined as >50% inhibition or activation. I Follow-up assessment: PFAS showing significant activity are being evaluated in the BioMAP® translational platform to assess human-relevant responses across vascular, immune, and fibroblast tissue systems. **Results:** CYP inhibition was the most common PFAS activity, with 63% of compounds inhibiting at least one isoform (>50%). CYP2C9 was the most frequently affected (58%), followed by CYP2C19 (32%) and CYP2C8 (21%), while CYP1A2 and CYP2B6 showed minimal susceptibility (5%). Structure-activity patterns emerged: perfluoroalkyl sulfonates showed the strongest CYP2C9 inhibition (e.g., PFHpS 97%), sulfonamide precursors exhibited broad multi-CYP activity (e.g., PFOSA 91%, NMeFOSA 88%, NeTFOSA 78% CYP2C9 / 74% CYP2C19), and short-chain perfluorocarboxylic acids (C7-C9) displayed selective CYP2C9 inhibition (PFHpA 76%, PFNA 92%). Nuclear receptor modulation was less frequent (16% of compounds). PFDA inhibited ER β (55%) and PR (87%), NeTFOSAA showed dual inhibition (ER β 73%, PR 100%), and 9Cl-PF3ONS had the broadest profile (5 α -reductase 77%, PR 100%, TR α 70%), indicating highly selective receptor targeting. These results highlight that sulfonate head groups with longer chains preferentially inhibit CYP2C9, sulfonamide modifications broaden CYP selectivity, and structural complexity (ether linkages, halogen substitutions) may drive multi-target nuclear receptor activity. BioMAP® studies are being used to validate these mechanistic trends in human-relevant cellular phenotypic systems. **Conclusions:** This integrated approach mechanistically characterizes PFAS toxicity, identifying CYP inhibition as the predominant activity and nuclear receptor modulation as structure-selective. Structure-activity relationships, influenced by head group chemistry, chain length, and substituents, enable mechanism-informed risk assess-

ment. Target-based assays combined with BioMAP® translational systems generate human-relevant data linking molecular targets to tissue-level responses. This framework supports comprehensive toxicity profiling without animal testing, addressing data gaps for legacy and emerging PFAS, and informing regulatory decision-making aligned with FDA/EPA priorities.

PS 4500 Role of the gut microbiota in PFAS-induced changes to hepatic toxicity and cholesterol metabolism

K. Roth¹, A. Burrows², X. Ye², J. M. Brown², and M. Petriello¹. ¹Wayne State University, Detroit, MI; and ²Cleveland Clinic, Cleveland, OH.

Background and Purpose: Per- and polyfluoroalkyl substances (PFAS) are a large family of man-made chemicals used in many consumer and industrial products. Due to their high stability and resistance to degradation, PFAS persist and accumulate as environmental contaminants around the world. PFAS have been measured in human blood and found associated with numerous adverse health effects, including liver disease and elevated circulating cholesterol. In previous studies, we have observed that exposing mice to a PFAS mixture led to increased hepatic toxicity, especially in female mice, as well as elevated plasma cholesterol and bile acid levels, which may be due to PFAS-induced modulation of intestinal bile acid reuptake. Additionally, it was also observed that the form and function of the gut microbiota was changed due to PFAS exposure. PFAS exposure led to alterations of gut microbiota diversity measures and female PFAS-exposed mice also had increased abundance of the genera *Clostridium* and *Bifidobacterium*, which have important roles in the production of secondary bile acids. Therefore, we wanted to test the hypothesis that PFAS exposure modulates hepatic toxicity as well as cholesterol and bile acid metabolism through its effects on the gut microbiota. **Methods:** To do this, female C57BL/6 murine pathogen-free (MPF) mice or germ-free (GF) mice were fed an atherogenic diet and exposed to a mixture of PFAS representing legacy, replacement, and emerging subtypes (i.e., PFOA, PFOS, PFHxS, GenX, and 2-(Perfluoroalkyl)ethanol). Mice were exposed to the PFAS mixture through their drinking water for 7 weeks, with each PFAS at a concentration of 2mg/L. **Results:** After the 7 weeks exposure, circulating total cholesterol was significantly lower in the GF PFAS-exposed mice vs MPF PFAS-exposed mice ($p=0.02$). In addition, total hepatic cholesterol levels were also significantly lower in the GF PFAS-exposed mice vs MPF PFAS-exposed mice ($p=0.002$). As a measure of liver injury, plasma alanine aminotransferase (ALT) levels were significantly lower in the GF PFAS-exposed mice vs MPF PFAS-exposed mice ($p=0.01$). RNA sequencing was performed for liver tissue. Hepatic expression of the inflammatory C-C motif chemokine ligand 6 (*Ccl6*) was also significantly lower in the GF PFAS-exposed mice vs MPF PFAS-exposed mice ($p<0.001$). Hepatic gene ontology (GO) enrichment analysis identified 66 pathways that had a significant interaction between PFAS exposure and mouse line (Benjamini Hochberg-adjusted p -value <0.05), with the cholesterol and sterol biosynthetic processes as the most highly significant GO terms. Individual differentially expressed genes belonging to the cholesterol biosynthetic process were further examined. Expression of *Hmgcs1* was significantly upregulated in the GF PFAS-exposed mice ($p<0.001$), while there was no significant effect in the MPF mice (interaction FDR <0.001). Expression of bile acid synthesis enzymes *Cyp7a1* and *Cyp27a1* also were significantly lower in the GF PFAS-exposed mice compared to the MPF PFAS-exposed mice. The secondary bile acid deoxycholic acid was also found to be significantly increased in the MPF PFAS-exposed mice (FDR <0.05), but not in the GF mice. Finally, PFAS levels were measured in the plasma, urine, and liver tissues collected from the mice after 7 weeks of PFAS exposure. Hepatic levels of PFOS and GenX were both significantly decreased in the GF PFAS-exposed mice compared to MPF PFAS-exposed mice with no differences observed for urine or plasma. **Conclusions:** Overall, our results suggest that GF mice are at least partially protected from PFAS-induced hepatic toxicity and hypercholesterolemia, which may in part be due to changes in the distribution of specific PFAS. Future clinical interventions that target the gut microbiome may be beneficial for individuals exposed to PFAS.

PS 4501 PPAR α -Mediated Species-Specific Hepatic Responses to PFOS Exposure in Humanized and Knockout Mouse Models of Alcohol-Associated Liver Disease

F. A. Ekuban¹, P. M. Ames¹, A. Ekuban¹, O. E. Bolatimi¹, A. Centers¹, Y. Hua¹, J. Luo¹, J. H. Hardesty¹, T. C. Gripshover¹, W. H. Watson¹, B. Wahlang¹, D. Bello², J. J. Schlezinger³, C. J. McClain¹, and M. C. Cave¹. ¹University of Louisville, Louisville, KY; ²University of Massachusetts Lowell, Lowell, MA; and ³Boston University, Boston, MA.

Background and Purpose: Perfluorooctane sulfonate (PFOS) exposure is increasingly linked to metabolic dysfunction-associated steatotic liver disease (MASLD; PMID: 35475652), yet its role in alcohol-associated liver disease (ALD) remains understudied. Our previous wild-type studies demonstrated that PFOS exacerbates ALD severity via peroxisome proliferator-activated receptor α (PPAR α ; PMID: 40347464), but the mechanistic role of PPAR α and its species specificity remain elusive. Given that PFOS is a strong mouse but weak human PPAR α agonist, the relevance of murine models to human health risk is uncertain. Here, we investigated species-specific hepatic responses using humanized PPAR α (hPPAR α) and PPAR α -knockout (KO)

mice. **Methods:** Male hPPAR α and PPAR α -KO mice (C57BL/6J background) received Lieber-DeCarli liquid diet containing 5% ethanol (EtOH) or isocaloric control and were concurrently gavaged with 1 mg/kg PFOS, or Tween-80 vehicle for 10 days, followed by a 5 g/kg EtOH binge dose and euthanasia 5-6h later. Assessments included body composition, biochemistry, liver histology (H&E), gene expression analysis, and high-content imaging of isolated primary hepatocytes. **Results:** EtOH decreased body weight across genotypes, with divergent liver-to-body weight ratios (decrease in hPPAR α , increase in PPAR α -KO). Both genotypes showed ethanol-induced triglyceride and VLDL elevations, with PFOS augmenting VLDL levels. Notably, PFOS attenuated EtOH-induced ALT/AST increases in both genotypes, contrasting with wild-type studies where PFOS exacerbated hepatotoxicity (PMID:40347464). Blood alcohol concentrations decreased significantly in PPAR α -KO mice and trended lower in hPPAR α mice with PFOS co-exposure. Histological examination revealed marked genotype-dependent differences: hPPAR α mice maintained normal liver morphology in controls and developed progressive steatosis from mild (PFOS alone) to moderate (ethanol alone) to severe (PFOS+ethanol), whereas PPAR α -KO mice demonstrated significant baseline steatosis even in vehicle controls, with persistent severe steatosis across all treatments. Gene expression analyses showed that PFOS-ethanol significantly upregulated PXR and Cyp3a11 in both genotypes, with PPAR α -KO maintaining stable CAR/Cyp2b10 expression while hPPAR α exhibited decreasing trends. In pair-fed controls, PFOS alone significantly induced Cyp3a11 across all genotypes. Lipogenic genes (PPAR γ , Cd36, Fasn) showed distinct genotype-specific patterns, with PPAR α -KO displaying significant upregulation versus hPPAR α 's downregulation trend in PFOS-ethanol groups. High-content imaging confirmed cellular differences: hPPAR α hepatocytes showed 4-fold increased mitochondrial function with PFOS-ethanol, while PPAR α -KO hepatocytes exhibited 5-fold increased lipid peroxidation. **Conclusions:** These findings reveal species-specific, PPAR α -mediated responses and underscore its central role in modulating hepatic outcomes during PFOS-ethanol co-exposure. Mechanistically, PPAR α exhibits dual and context-dependent functions: it preserves lipid homeostasis yet exacerbates hepatocellular injury under combined PFOS and ethanol exposure. Humanized PPAR α mice display intermediate phenotypes, highlighting species-specific receptor activation and signaling. Notably, the alteration of PXR and CAR pathways in the absence of PPAR α suggests compensatory cross-regulatory crosstalk beyond PPAR α signaling. Collectively, this work provides mechanistic and translational insights into how environmental pollutants modulate alcohol-associated liver injury and emphasizes the need for human-relevant models in toxicological risk assessment.

PS 4502 Photodynamic Priming (PDP) Mitigates Chemoresistance and Mitochondrial Enhancements in Ovarian Cancer Cells with a History of Chronic PFAS Exposure

B. P. Rickard¹, L. A. Sapienza-Lundie², M. M. Dillon¹, I. Rizvi², and S. E. Fenton¹. ¹North Carolina State University, Raleigh, NC; and ²University of North Carolina at Chapel Hill, Chapel Hill, NC.

Background and Purpose: Photodynamic priming (PDP), which generates reactive molecular species following light-based activation of an intracellular photosensitizer, can synergize with traditional chemotherapies to overcome chemoresistance. Such contemporary treatment combinations are needed in ovarian cancer, where ~80% of patients develop platinum-resistant disease characterized by functional mitochondrial enhancements. Importantly, several photosensitizers localize to mitochondria and enable preferential photodamage to this organelle. As a result, PDP may also be valuable for targeting mitochondrial effects known to be induced by environmental toxicants, such as perfluoroalkyl substances (PFAS). PFAS are drinking water contaminants present in the blood of nearly all Americans that have been shown to induce chemoresistance in a duration-dependent manner in ovarian cancer cells, potentially via inciting mitochondrial biogenesis. Here, we hypothesized that mitochondria-localized PDP in combination with chemotherapy would overcome PFAS-induced chemoresistance in ovarian cancer cells. **Methods:** The present study evaluated the ability of PDP $\pm$ chemotherapy to overcome chemoresistance in two OVCAR-3 cell cohorts: PFAS chronically-exposed (~35 days of 0.5 μ M perfluoroheptanoic acid exposure) and outgrown (allowed to "recover" for ~35 days following chronic PFAS exposure). Two mitochondria-localized photosensitizers, benzoporphyrin derivative (BPD) and aminolevulinic acid-induced protoporphyrin IX (ALA-PpIX), were employed for PDP. Efficacy of PDP + carboplatin (1st line) or doxorubicin (2nd line) and impacts on mitochondrial membrane potential (MMP) and content were compared. Survival post-combination therapy was measured via relative ATP content and mitochondrial parameters via high-content imaging, PCR, and/or fluorescence-based assays. All studies had at least 3 biological replicates with 2 technical replicates each. **Results:** In PFAS chronically-exposed cells, which displayed significant resistance to carboplatin and doxorubicin, heightened sensitivity to BPD-PDP + carboplatin and BPD-PDP + doxorubicin was observed compared to outgrown cells, which had renewed sensitivity to most chemotherapy only treatments. Conversely, while ALA-PpIX-PDP + carboplatin displayed similar efficacies in both cell cohorts, ALA-PpIX-PDP + doxorubicin was much more potent in PFAS chronically-exposed cells. In both cell cohorts, regardless of photosensitizer used, PDP + doxorubicin was not as effective at reducing cell survival as PDP + carboplatin. When evaluating mitochondrial parameters, significant decreases in MMP, which are suggestive of apoptosis, occurred in both cell cohorts treated with ALA-PpIX-PDP + carboplatin and ALA-PpIX-PDP + doxorubicin, but not following combination therapy using BPD-PDP. Mitochondrial content, however, decreased across all combination

therapy groups, indicative of mitochondrial photodamage. **Conclusions:** These findings demonstrate the efficacy of PDP-based combinations for overcoming chronic PFAS-induced chemoresistance and associated mitochondrial enhancements. Future studies will expand to pre-clinical models of ovarian cancer (i.e. spheroids, *in vivo*) and patient samples with the goals of 1) identifying biomarkers of PFAS exposure and/or platinum resistance, and 2) informing mechanism-targeted, PDP-based treatment regimens for patient populations at risk for chemoresistance to improve survivorship.

PS 4503 CYP2E1 Dependent Effects of PFOS in Mouse Liver and HepaRG Models

K. R. Driggers¹, B. R. Deaton¹, F. Ekuban², M. Cave², and J. H. Hartman¹. ¹Medical University of South Carolina College of Medicine, Charleston, SC; and ²University of Louisville, Louisville, KY.

Background and Purpose: Perfluorooctane sulfonic acid (PFOS) is a member of the perfluoroalkyl substances (PFAS), a class of environmentally persistent and bioaccumulative chemicals widely used in manufacturing. PFAS exposure has been linked to increased incidence of alcohol related liver disease, yet the mechanisms underlying PFAS interactions with ethanol remain poorly understood. CYP2E1 is a monooxygenase that metabolizes numerous xenobiotics as well as endogenous fatty acids and ketones. Although CYP2E1 is most highly expressed in the liver, it is present in multiple tissues. The interaction between PFOS and CYP2E1 and the consequences for liver function remain understudied. This study aims to define the effects of PFOS in a CYP2E1 dependent context using complementary *in vivo* and *in vitro* approaches. **Methods:** We first examined livers from wild-type (C57BL/6J), PPAR α -KO, and humanized PPAR α transgenic mice exposed to PFOS, ethanol, or both and quantified CYP2E1 expression area and intensity by immunofluorescence. We then used differentiated HepaRG hepatic cell co-culture to investigate the effects of PFOS on cellular respiration and to determine how these responses depend on CYP2E1 activity. Respiration, quantified as oxygen flux, was monitored continuously overnight before addition of PFOS, clomethiazole (a suicide inhibitor of CYP2E1), or both. Oxygen flux was measured for either 24 hours or 7 days during exposure using a Resipher continuous oxygen consumption monitoring system (Lucid Scientific). Mitochondrial membrane potential and ATP content was assessed in differentiated HepaRG cells after 7 days of exposure to PFOS, clomethiazole, or both. All experiments tested increasing doses of PFOS with and without ethanol and clomethiazole. **Results:** PFOS exposure did not alter CYP2E1 expression intensity overall, but it significantly increased the area of CYP2E1 expression surrounding the central vein, indicating a loss of normal zonation ($p < 0.05$). Ethanol increased overall CYP2E1 levels and similarly expanded the expression area ($p < 0.05$ for both effects). In HepaRG cells, PFOS alone or PFOS with ethanol had minimal effects on respiration over 24 hours at doses up to 100 micromolar. Inhibition of CYP2E1 with clomethiazole significantly exacerbated the effect of PFOS on respiration ($p < 0.001$), causing an 18 percent reduction in oxygen consumption at 50 μ M PFOS and a 29 percent reduction at 100 μ M PFOS. Over 7 days, PFOS with and without clomethiazole decreased respiration across all groups. Mitochondrial membrane potential with PFOS alone resulted in no significant change across all doses, but PFOS with CMZ resulted in a decrease of 50 percent with a dose of 0.05 μ M of PFOS ($p < 0.05$). ATP assays indicate PFOS-induced increase in total ATP content without the presence of CMZ at higher doses of PFOS (1, 5, and 10 μ M doses), but in the presence of CMZ, ATP levels are increased at lower PFOS doses (0.1 μ M to 10 μ M). Increased ATP may reflect inhibition of ATP-dependent processes, or a compensatory increase in ATP synthesis. Ongoing experiments are aimed at defining the mechanism underlying this mixture effect. **Conclusions:** These findings provide new insight into PFOS toxicity and highlight a relationship between PFOS and CYP2E1 activity that may have relevance for human exposures.

PS 4504 Impact of Albuminuria on PFAS Kinetics using Physiologically Based Toxicokinetic (PBTK) Modeling

J. Bunis¹, H. Sharkey², A. Slitt¹, J. A. Goodrich², J. W. Nelson², and F. C. Fischer¹. ¹University of Rhode Island, Kingston, RI; and ²University of Southern California, Los Angeles, CA.

Background and Purpose: Per- and polyfluoroalkyl substances (PFAS) are persistent environmental contaminants that bioaccumulate and have been linked to diverse adverse health effects. Previous studies demonstrate that serum albumin binding governs the accumulation of PFAS with six or more perfluorinated carbons by retaining them in circulation. In advanced kidney disease such as Diabetic Kidney Disease (DKD), and Chronic Kidney Disease (CKD), glomerular damage and impaired proximal tubular reabsorption contribute to progressive albuminuria, or elevated excretion of albumin through the urine. These conditions are extremely common, especially in those with diabetes. We hypothesized that albumin-bound PFAS would be co-excreted during albuminuria, accelerating their elimination. Using a mechanistic physiologically based toxicokinetic (PBTK) model, we investigated how albuminuria influences PFAS toxicokinetics in mice, testing whether kidney disease fundamentally alters PFAS clearance pathways while accounting for parallel competing distribution and elimination processes. **Methods:** We extended an established PBTK framework

to simulate perfluorohexanoic acid (PFHxA), Perfluoroheptanoic acid (PFHpA), perfluorooctanoic acid (PFOA), perfluorononanoic acid (PFNA), perfluorodecanoic acid (PFDA), perfluoroundecanoic acid (PFUdA), perfluorobutanesulfonic acid (PFBS), perfluorohexanesulfonic acid (PFHxS), perfluorooctanesulfonic acid (PFOS) (npfc= 4-10). The novel model incorporates tissue blood flows, membrane permeability, albumin and phospholipid binding, and renal/hepatic transport processes. Wild-type parameters were derived from *in vitro* transporter/binding data and *in vivo* mouse studies. We modeled albuminuria by reducing serum albumin concentrations by 40% and increasing urinary albumin excretion from under 0.02 mg/day to 3 mg/day, to reflect impaired proximal tubular reabsorption. Model performance was evaluated by comparing half-lives, areas under the plasma concentration-time profile (AUC), and urine concentrations between wild-type and DKD phenotypes following single oral doses of 5mg/kg. **Results:** Simulations support the hypothesis that albuminuria accelerates PFAS elimination in a manner proportional to albumin-binding affinity. Following oral administration, the $t_{1/2}$ of PFOA decreased by 25% and AUC by 61%. PFOS showed a 20% reduction in $t_{1/2}$ and 39% decrease in AUC. The strongest effects were observed for PFUdA, with a 31% reduction in $t_{1/2}$. PFBS, which exhibits weak binding to albumin, showed only a 6.6% reduction in $t_{1/2}$ but a 52% decrease in AUC, consistent with primary renal handling of this PFAS species. Additional results to be presented at a later stage. **Conclusions:** These findings suggest albumin-mediated renal elimination as a newly appreciated and key mechanism contributing to PFAS clearance under albuminuric conditions, underscoring the need to incorporate disease-related changes in protein binding and renal function into PBTK models. Future directions include the integration of clinical data from individuals with albuminuria to evaluate model performance and quantify the impact of progressive albuminuria on PFAS exposure in clinical cohorts of patients with DKD.

PS 4505 Presence of Legacy and Emerging PFAS in Human Livers Specimens in the United States from 2000-2024

J. Agudelo Areiza¹, J. Becanova², S. Vojta², J. Ganglbauer², U. Apte³, L. Brunetti⁴, S. Kumer³, F. Haque⁵, E. Kim⁵, E. M. Sunderland⁵, R. Lohmann², F. C. Fischer¹, and A. L. Slitt¹. ¹University of Rhode Island, Kingston, RI; ²University of Rhode Island, Narragansett, RI; ³University of Kansas Medical Center, Kansas City, KS; ⁴Rutgers University, Piscataway, NJ; and ⁵Harvard University, Boston, MA.

Background and Purpose: Per- and polyfluoroalkyl substances (PFAS) are persistent bioaccumulative chemicals linked to liver toxicity, such as hepatocellular injury, steatosis, dysregulated lipid metabolism, and metabolic disease. The widespread use of PFAS has led to near-universal human exposure, with detectable serum levels in 98-99% of U.S. individuals. The National Academies of Sciences, Engineering, and Medicine recommends clinical monitoring for a set of 9 PFAS. However, little is known regarding tissue bioaccumulation in humans despite clear evidence that some PFAS accumulate in protein-rich organs. The liver is a target organ for PFAS-associated toxicity. Therefore, it was hypothesized that measurements of PFAS in serum may underestimate accumulation risks because legacy and some replacement PFAS concentrate in the liver. The goal of this study was to quantify PFAS concentrations in livers from individuals in the U.S. and assess whether hepatic PFAS profiles have shifted over the past 24 years due to legacy phaseouts and the emergence of replacement compounds. **Methods:** A highly sensitive solid-phase extraction liquid chromatography high-resolution mass spectrometry method using ENVI-Carb[™] sorbent was developed to measure a total of 54 PFAS - including legacy compounds, emerging alternatives, and precursors in 211 adult human livers collected between 2000 and 2024 to quantify liver PFAS profiles. Regression analyses were used to assess temporal trends in hepatic PFAS and evaluate the influence of sampling year, age, sex, and liver health status on individual PFAS and the sum of total PFAS concentrations per individual (Total PFAS). Extractable Organofluorine (EOF) was quantified in a subset of liver samples to determine the fraction of organofluorine not explained by targeted PFAS measurements. **Results:** PFAS were detected in 210 individuals, with 25 compounds, including linear and branched isomers, found in ≥ 3 livers and 15 compounds found in ≥ 30 livers. Total PFAS decreased 94% over the 24-year period, corresponding to 68% after adjusting for covariates. Since 2019, a ~950-fold variability in concentration was observed, and the PFAS profile in liver shifted from sulfonates and carboxylates to proportionally more sulfonamides and fluorotelomers. Multivariate linear regression analyses for PFAS detected in ≥ 30 ($n=15$) of the 211 human livers sampled resulted in sampling year being the strongest predictor of hepatic PFAS concentrations - associated with 13/15 compounds and total PFAS. The largest decade-scale declines were observed for 8:2 fluorotelomer sulfonic acid (8:2 FTS, -44%) and linear-perfluorooctanesulfonic acid (L-PFOS, -39%), while a 7% decade-scale increase was observed for 9-Chlorohexadecafluoro-3-oxanonane-1-sulfonic acid (9ClPF3ONS) ($p < 0.01$). Age was positively associated with several long-chain PFAS, which is consistent with years-long elimination half-lives. Males had higher PFUdA, PFDoA, and 9ClPF3ONS concentrations than females, whereas females had higher 8:2 fluorotelomer sulfonic acid concentrations than males. Metabolic dysfunction-associated steatotic liver disease (MASLD) was associated with lower concentrations of perfluorononanoic acid (PFNA, -12%), PFUdA (-18%), PFDoA (-24%), L-PFOS (-22%), branched (Br)-PFOS (-26%), 8:2 FTS (-27%), 9ClPF3ONS (-8%), and total PFAS (-23%) ($p < 0.05$). MASLD was also associated with lower concentrations of PFAS with a molecular weight range of 500-600 and/or > 600 g/mol, and an npfc of 8, 10, and 11. EOF was detected in all measured specimens, with a mean concentration of 184 ± 151 ng F/g liver (range: 50-304 ng F/g). The data illustrate that targeted PFAS comprised $< 10\%$ of

EOF, revealing that a substance-by-substance regulatory approach likely underestimates exposure. **Conclusions:** Despite two decades of regulatory action, these results highlight the human liver as a critical tissue-accumulation reservoir for both legacy and emerging PFAS and demonstrate the pressing need to expand regulatory oversight beyond currently controlled substances.

PS 4506 Oxidative Stress as a Mediator of Long-Chain PFAS-Induced Mitochondrial Impairment

M. Khatun, U. Sathisaran, and J. L. Freeman. Purdue University, West Lafayette, IN.

Background and Purpose: Per- and polyfluoroalkyl substances (PFAS) are a large group of man-made chemicals that are made of a chain of carbon (C) atoms with multiple fluorine (F) atoms. Among all the PFAS, long-chain PFAS (C>6) are more bioaccumulative, persistent, and toxic. Although some long chain PFAS production has phased out, long-chain PFAS such as perfluorooctane sulfonate (PFOS, C-8), perfluorodecanoic acid (PFDA, C-10), and perfluoroundecanoic acid (PFUnA, C-11) are of concern because they persist in the environment and bioaccumulate in fish tissues, which are consumed by humans and pose a serious threat to public health. PFAS exposure is associated with developmental toxicity, developmental neurotoxicity, carcinogenicity, endocrine disruption, and immunotoxicity. Growing evidence suggest that PFAS can disrupt oxidative balance, impair mitochondrial function and alter neurotransmitter systems. However, the molecular mechanism of long chain PFAS on mitochondrial impairment via oxidative stress such as generating reactive oxygen species (ROS) is not well documented. The hypothesis of this study is long-chain PFAS may increase production of reactive oxygen species (ROS) and oxidative stress that can cause mitochondrial impairment. Therefore, this study has been designed to evaluate the effects of long-chain PFAS induced mitochondrial impairment through oxidative stress in developmental neurotoxicity. **Methods:** This study utilized zebrafish (*Danio rerio*) embryos to investigate the developmental neurotoxicity of these compounds, with a focus on oxidative stress markers and mitochondrial distributions. Zebrafish embryos were exposed to PFOS, PFDA, or PFUnA at concentrations of 0, 0.004, 0.04, 0.4, 4, or 40 ppb (µg/L) from 1 to 72 hours post fertilization (hpf). Oxidative stress markers such as reactive oxygen species (ROS) were measured using H2DCFDA (2',7'-dichlorodihydrofluorescein diacetate), thiobarbituric acid reactive substances (TBARS) as an indicator of lipid peroxidation, antioxidant activity such as catalase were measured using colorimetric assay at 120 hpf. Additionally, the relative mitochondrial content was assessed using MitoTracker™ Red CMXRos at 120 hpf. Larval head region was considered for measuring ROS and mitochondrial distribution. **Results:** All the three PFAS showed increased levels of ROS in all concentrations, with the exception of 0.004 ppb, where PFDA and PFUnA did not show significant changes. For all the PFAS compounds, TBARS levels also increased in almost all the concentrations compared to 0 ppb group. The results revealed a general decline in antioxidant enzyme activity across PFAS treatments compared to the 0 ppb group. The activities following PFDA exposure caused reductions at all tested concentrations, whereas the other PFAS showed a different response. Finally, relative mitochondrial content showed changes when compared to the 0 ppb group in PFOS and PFDA. **Conclusions:** These findings suggest that PFAS exposure increases oxidative stress through the induction of ROS generation resulting in lipid peroxidation and disruption of the oxidative balance, leading to mitochondrial impairment. These mitochondrial impairments can cause bioenergetics failure. However, future studies are needed to further investigate the molecular mechanisms underlying long-chain PFAS-induced oxidative stress and their role in mitochondrial impairment during developmental period.

PS 4507 Early-Life PFAS Exposure Impairs Mitochondrial Bioenergetics and Dopaminergic Development in Zebrafish

U. Sathisaran, and J. L. Freeman. Purdue University, West Lafayette, IN.

Background and Purpose: Per- and polyfluoroalkyl substances (PFAS) are synthetic chemicals known for their persistence, bioaccumulation, and resistance to degradation. Long-chain PFAS such as perfluorooctanoic acid (PFOA; C8) are recognized neurotoxicants, but the safety of newer short-chain replacements, including hexafluoropropylene oxide dimer acid (GenX; C6) and perfluorobutanoic acid (PFBA; C4), remains uncertain. These compounds can cross the blood-brain barrier and may interfere with energy metabolism during development. Because mitochondria are critical for neuronal differentiation and redox balance, their disruption could impair dopamine signalling and increase susceptibility to neurodegenerative outcomes. This study examined whether exposure to PFAS of varying chain lengths during early development alters mitochondrial function and dopaminergic integrity in zebrafish (*Danio rerio*), a model organism widely used to study developmental neurotoxicity. **Methods:** Embryos were exposed to 0, 0.04, 0.4, 4, or 40 ppb of PFOA, GenX, or PFBA from 1 to 72 hours post-fertilization. Mitochondrial content and distribution were visualized with MitoTracker CMXRos fluorescence imaging, and adenosine triphosphate (ATP) levels were measured to assess mitochondrial bioenergetics. Monoamine oxidase (MAO) activity, dopamine (DA), and its metabolite 3,4-dihydroxyphenylacetic acid (DOPAC) were quantified using ELISA. Tyrosine hydroxylase (TH)-positive dopaminergic neurons in forebrain and midbrain regions were counted from confocal images, and cell death was evaluated using Sytox Blue staining. Data

were analyzed using one-way ANOVA with Least Significant Difference (LSD) post hoc tests ($p < 0.05$). **Results:** PFAS exposure produced chain-length-independent mitochondrial and dopaminergic impairments. Mitochondrial content and ATP levels were significantly reduced in PFOA- and GenX-treated larvae (0.4-40 ppb) and even at 0.04 ppb PFBA, indicating high sensitivity to short-chain PFAS. Elevated monoamine oxidase activity and increased DOPAC levels at higher concentrations suggested enhanced oxidative dopamine turnover, while dopamine levels declined in PFOA- and PFBA-treated larvae (0.4-40 ppb) and at 4 ppb GenX. Confocal imaging revealed fewer TH-positive neurons and smaller forebrain and midbrain regions in high-dose PFOA and GenX groups, reflecting dopaminergic developmental deficits. Increased Sytox Blue fluorescence confirmed higher neuronal death in corresponding exposure groups. **Conclusions:** These findings demonstrate that early-life exposure to both long- and short-chain PFAS disrupts mitochondrial bioenergetics and impairs dopaminergic development. Mitochondrial dysfunction appears to be a key mechanism linking PFAS exposure to developmental neurotoxicity. Notably, short-chain PFAS elicited effects at low concentrations, challenging the assumption that they are safer alternatives. This work provides mechanistic evidence relevant to developmental, neurotoxic, and regulatory toxicology, emphasizing mitochondrial disruption as a sensitive biomarker for PFAS-induced neurotoxicity. Ongoing confocal analyses of larval brain mitochondria aim to further define these mechanisms.

PS 4508 Perfluorooctanoic Acid (PFOA) exposure accelerates *Drosophila melanogaster* growth and development.

E. A. Kilbourn¹, M. R. Lowe¹, K. Panda², A. Bhaskaran², A. R. Aalati¹, A. Malave¹, A. Graber¹, S. White¹, N. Zulkowski¹, P. Reddy², E. Meyhofer², and J. M. Tennessen¹. ¹Indiana University Bloomington, Bloomington, IN; and ²University of Michigan, Ann Arbor, MI. Sponsor: M. Bondesson

Background and Purpose: Per- and polyfluoroalkyl substances (PFAS) are persistent environmental pollutants that pose a serious threat to global public health. Perfluorooctanoic acid (PFOA), the most prevalent PFAS, contaminates ecosystems across all seven continents and affects the water supplies of over 100 million U.S. residents. With PFOA exposure linked to numerous human diseases, there is an urgent need to understand the molecular mechanisms by which this molecule affects human and environmental health. **Methods:** In this study, we used the reproducible and highly predictable developmental events that occur during *Drosophila melanogaster* juvenile development to investigate how PFOA influence animal growth, development and sexual maturation. Using a combination of genetics, RNA-seq, and semi-targeted metabolomics, we examined PFOA treated animals for defects in developmentally-regulated changes in gene expression programs and metabolite abundance. In addition, we supplemented this multiomic approach with examination of mitochondrial metabolism and real-time monitoring of juvenile metabolism using high-resolution biocalorimetry. **Results:** Our phenotypic analysis revealed that PFOA exposure significantly accelerated larval development, with concentrations as low as 36 nM inducing precocious activation of the metamorphic gene expression program. Moreover, we found that these changes in gene expression were dose responsive, with the highest PFOA concentrations inducing sexual maturation nearly a day earlier than controls. Intriguingly, this accelerated growth rate had no negative effect on final body mass, with the highest PFOA concentrations inducing a significant increase in female body mass - a result that hints at an increase in the overall biosynthetic rate of PFOA exposed animals. Consistent with this finding, high-resolution biocalorimetry revealed a nearly 40% increase in heat production from PFOA exposed larvae. **Conclusions:** Together, our findings demonstrate that PFOA profoundly affects *Drosophila* development and establish the fruit fly as a powerful New Approach Methodology (NAM) for studying PFAS toxicity. Our results also suggest that PFOA contamination may have far-reaching ecological consequences, as induction of premature sexual maturation in insects would inevitably lead to altered fitness and survival in the wild.

PS 4509 Persistent Effects of PFAS on Marine Medaka (*Oryzias latipes*) Immune Competence

A. Rizzo¹, E. R. DiBona², and F. Seemann¹. ¹Texas A&M University-Corpus Christi, Corpus Christi, TX; and ²University of Texas, Austin, TX.

Background and Purpose: Per- and polyfluoroalkyl substances (PFAS) are persistent environmental pollutants used in many industrial applications, including the production of non-stick cookware, water-repellent fabrics, and firefighting foams. Their carbon-fluorine bonds make them extremely resistant to degradation, making them known as "forever chemicals". The toxicity of PFAS has been extensively studied over the last years, particularly for legacy compounds such as perfluorooctanoic acid (PFOA), which have been linked to immunotoxicity, endocrine disruption, hepatotoxicity, metabolic dysfunction, and carcinogenesis. Although PFOA has been phased out in many countries due to environmental and health concerns, industry replacements like 2,3,3,3-tetrafluoro-2-(heptafluoropropoxy)propanoic acid (GenX), a short-chain alternative to PFOA have emerged in production and use. While these replacements were originally considered less hazardous, growing evidence suggests they pose significant risks, particularly concerning developmental toxicity and immune function. A major gap in PFAS research is understanding the long-

term effects of early-life exposure on immune competence. The marine medaka (*Oryzias melastigma*) is a well-established model for addressing this gap due to its rapid development, well-characterized immune and endocrine systems, and relevance to aquatic toxicology. **Methods:** Marine medaka larvae were sourced from the TAMU-CC husbandry colony and subjected to PFAS exposure from 12 days post-hatch (dph) until 19 dph. Treatment groups included control, PFOA, and GenX at 0.5 ng/mL. These concentrations were selected for their relevance to human prenatal and postnatal exposure levels via maternal cord blood, breast milk, and other early-life sources. After exposure, larvae were raised until 4 months post-hatching and monitored for long-term outcomes, including immune competence through host resistance assays with *Edwardsiella piscicida* (n=15) and leukocyte profiles via flow cytometry (n=5). For transcriptomic analyses, RNA was extracted from female *O. melastigma* livers (n = 3-5). RNA-seq reads were aligned to the *O. melastigma* reference genome using HISAT2, and gene-level counts were obtained with featureCounts. Differential expression analysis and variance-stabilized visualization were performed in R using DESeq2. Pathway enrichment analysis was done using gProfiler. **Results:** Developmental exposure to PFOA and GenX resulted in reduced long-term survival and significant decreases in lymphocyte and granulocyte counts in adult females, but not in males. Preliminary RNA-seq results revealed clear, treatment-specific transcriptional responses in medaka liver following PFOA and GenX exposure. Variance-stabilized counts of the top 50 most carryable genes showed strong clustering by treatment group. Most PFOA exposed samples displayed a consistent pattern of downregulation. In contrast, GenX exposed fish showed a different pattern characterized by more frequent upregulation. These early patterns suggest exposure-dependent changes in liver gene expression and point towards potentially different effects between PFOA and GenX that may involve immune- and stress-related pathways. **Conclusions:** Collectively, these results demonstrate that short-chain replacement PFAS do not represent a biologically benign alternative; indeed, GenX evoked immunotoxic outcomes equal to or stronger than those elicited by PFOA. These findings align with the developmental origins of health and disease framework and highlight the importance of early-life exposure assessments in PFAS risk characterization. The integrated organismal, cellular, and transcriptomic evidence presented here supports the urgent need to re-evaluate regulatory assumptions regarding the safety of replacement PFAS and underscores the value of medaka as a sensitive model system for uncovering long-term immune disruption that may otherwise remain undetected. In a broader context, these data reinforce that PFAS-induced immune toxicity is not limited to legacy compounds and that continued use of structurally similar alternatives may perpetuate public health and environmental risks persistently across the life-span.

PS 4510 PFAS-mediated eicosanoid changes in a mouse model of pancreatic cancer

L. M. Kamendulis, and B. A. Hocevar. Indiana University, Bloomington, IN.

Background and Purpose: Pancreatic cancer is predicted to become the second leading cause of cancer deaths in the US by 2030. Obesity, diabetes and chronic pancreatitis have been identified as potential risk factors in pancreatic cancer development. In rodents, PFOA is associated with diabetic outcomes and pancreatic cancer, while in humans, studies have linked PFOA exposure to diabetes, obesity, and pancreatic cancer. Previously, using the LSL-KRas^{G12D}; Pdx-1-Cre (KC) mouse model of pancreatic cancer, we have shown that PFOA accelerated pancreatic lesion development and altered several lipid classes in the pancreas, with thromboxane B2 (TXB2), a proinflammatory eicosanoid, being the most upregulated lipid. In humans as well as animal models, dysregulation of eicosanoid species have been associated with pancreatic cancer. However, to date, few studies have examined the link between PFAS exposure and changes in eicosanoid levels. As our previous lipidomic analysis profiled only a limited number of eicosanoids, in the present study, we evaluated additional COX and LOX-derived eicosanoids to determine if PFOA and its replacement chemical, GenX, alters their production in the pancreas of KC mice. **Methods:** Male and female KC mice were exposed to tap water (control), or water containing 1ppm PFOA or GenX beginning at 8 weeks of age through 6 months of age when tissues were collected. Approximately 10 mg of each pancreatic sample was processed for determination of eicosanoids using Ultra Performance Liquid Chromatography (UPLC) and tandem mass spectrometry (MS/MS; Agilent), using a dynamic MRM method. The COX/LOX MassSpec LCMS standard panel (Cayman Chemical) containing 9 primary eicosanoids [6-keto Prostaglandin F1α (6-keto PGF1α), TXB2, Prostaglandin F2α (PGF2α), Prostaglandin E2 (PGE2), Prostaglandin D2 (PGD2); 12(S)-HHTRE, 15(S)-HETE, 12(S)-HETE, and 5(S)-HETE] was used to quantify pancreatic eicosanoid levels. Expression of enzymes involved in eicosanoid synthesis were evaluated by qPCR, Western and IHC analyses. **Results:** All 9 eicosanoids profiled were detected in the pancreas of all experimental groups. Following exposure to 1 ppm PFOA, levels of 6-keto PGF1α, TXB2, PGE2 and PGE2 were found to be significantly elevated relative to control KC mouse pancreas. Conversely, exposure to 1 ppm GenX resulted in elevated levels of PGF2α, 12(S)-HHTRE, and 15(S)-HETE in the pancreas relative to control KC mice. Supporting an elevation in eicosanoid species by PFAS, Cox-1 levels were found to be increased in the pancreas. Further, in addition to endothelial cells, IHC analysis identified Cox-1 expression in PanIN lesions, infiltrating immune cells, and the stroma in the pancreas of KC mice. **Conclusions:** Environmental factors are postulated to play a major contributing role in pancreatic cancer development and progression as inherited genetic factors are associated with only a small percentage of pancreatic cancer cases. Functioning

as lipid signaling molecules, several eicosanoids have been implicated as drivers of pancreatic cancer by influencing cell proliferation, inflammation and immunosuppression. While GenX was introduced as a replacement chemical for PFOA, similar to PFOA, GenX also increased the incidence of pancreatic acinar adenomas and carcinomas in a 2-year rodent bioassay. Our results demonstrate that both PFOA and GenX increase levels of eicosanoids that are proinflammatory and protumorigenic. Our results suggest that further research directed at understanding the mechanistic link between PFAS-mediated changes in eicosanoids and pancreatic cancer progression is necessary.

PS 4511 Cluster of differentiation 36 (CD36) has a modest effect on perfluorooctanesulfonic acid (PFOS)-induced liver alterations and deposition

J. Zeng¹, J. Agudelo Areiza¹, S. Vojta², J. Becanova², O. Skende¹, F. C. Fischer¹, C. Liu¹, and A. L. Slitt¹. ¹University of Rhode Island, Kingston, RI; and ²Graduate School of Oceanography, University of Rhode Island, Narragansett, RI.

Background and Purpose: Perfluorooctanesulfonic acid (PFOS) is a synthetic perfluoroalkyl substance widely present in the environment that is persistent and associated with adverse human health effects. PFOS exposure in humans is associated with elevation of serum liver injury markers and liver disease. In preclinical rodents, such as mice, PFOS administration markedly increases liver weight. Cluster of differentiation 36 (CD36) is a membrane glycoprotein that facilitates the import of long-chain fatty acids into cells and contributes to lipid accumulation within the liver. Because the chemical structure of PFOS closely resembles a long-chain fatty acid, it has been hypothesized that CD36 may facilitate PFOS uptake into the liver, and that CD36 is a critical mechanism for PFOS uptake and adverse liver effects. *In vitro* and modeling studies point to possible PFOS binding interactions with CD36, and CD36 has been strongly suggested in the literature as a relevant mechanism for PFOS uptake into the liver. **Methods:** To investigate *in vivo* CD36 relevance, wild-type (WT, C57BL6/J) or CD36 mice with a global deletion (CD36^{-/-}, B6.129S1-Cd36tm1Mfe/J) between the ages of 7-9 weeks were administered vehicle (0.5% Tween20 in PBS) or PFOS (10 mg/kg in 0.5% Tween20 in PBS) by oral gavage for seven days. **Results:** PFOS administration increased liver-to-body weight ratio by 66% in WT mice and 72% in CD36^{-/-} mice. It also increased total liver lipids concentration similarly in WT and CD36^{-/-} mice by ~97%. PFOS administration elevated liver triglyceride concentration by 62.3% in WT mice and by 19% in CD36^{-/-} mice. PFOS concentrations in the liver were similar between WT and CD36^{-/-} mice, suggesting that deletion of CD36 does not significantly affect PFOS uptake into the liver. Preliminary proteomic analysis identified overlapping PFOS-induced upregulation of proteins involved in lipid metabolism and oxidative processes in both genotypes within the liver. **Conclusions:** Ongoing proteomics analyses will help further clarify the extent and specificity of CD36's involvement in PFOS-associated liver responses. Overall, these preliminary findings suggest that CD36 has a modest effect on PFOS-induced liver alterations and deposition.

PS 4512 Examining sex-specific relationships between PFOS & reward responsivity

A. K. Moline, K. M. Witkowski, L. Q. Larson, Y. Choi, L. S. Lee, and D. Foti. Purdue University, West Lafayette, IN.

Background and Purpose: Per- and polyfluoroalkyl substances (PFAS) are toxic chemicals detectable in most human blood, but its impacts on human health are unknown. Preclinical models suggest that PFAS exposure downregulates dopaminergic functioning in core reward-related brain regions, which is consistent with an anhedonic phenotype. Further evidence suggests that these effects may be sex-specific, particularly for perfluorooctanesulfonic acid (PFOS). A next step is to begin to test (a) the candidate association between PFOS exposure and reward-related brain activity in humans, and (b) the potential moderation of this association by sex. **Methods:** Forty-three young adults (28 female) had 5mL of blood extracted as part of a larger ongoing study, and blood samples were tested for a variety of PFAS compounds, including PFOS. Given prior literature suggesting sex differences in PFOS in preclinical models, only this compound was analyzed. Participants also completed an EEG recording with a battery of behavioral experiments. Of interest here was one task designed to elicit reward-related brain activity. The task is a simple guessing task where participants win or lose a nominal amount of money on each trial. The primary outcome measure is an event-related potential called the reward positivity (RewP), which is conceptualized as a neurophysiological indicator of the initial evaluation of outcomes as better or worse than expected. Larger RewP amplitude indicates greater neural sensitivity to reward outcomes. Analyses focused on characterizing relationships between sex, PFOS concentration, and RewP amplitude. **Results:** Detectable PFOS levels were available for all 43 participants included in the present analysis. Exposure levels were comparable between female (M=1.47, SD=1.26) and male participants (M=1.84, SD=2.12, t(41)= -0.24, p=0.48, d=-0.23). RewP amplitude was numerically smaller among female participants (M=3.62, SD=2.78) versus male participants (M=5.03, SD=2.80), with a medium effect size, although the group difference was not statistically significant (t(41)=1.58, p=0.12, d=0.51). Next, we calculated the correlation between PFOS level and RewP amplitude separately for female

and male participants. Although not statistically significant, opposing effects were observed, such that there was a numerically negative association among female participants ($r=-0.21$, $p=0.29$) and a numerically positive association among male participants ($r=0.43$, $p=0.11$). Fisher's r -to- z was used to compare the strength of association between male and female participants. A trend-level effect was observed ($z=1.93$, $p=.054$), offering preliminary support for a role of sex-specific processes. **Conclusions:** These preliminary findings offer initial support for clinical translation, such that higher PFOS exposure may be differentially associated with reward-related brain activity among female versus male adults. Ongoing work is being done to better understand links between PFAS compounds and reward processing in humans, with particular interest in the potential implications for anhedonic phenotype and risk for major depressive disorder. It will be of interest to revisit the present analysis within the full cohort for the parent project, which will total 300 young adults.

PS 4513 Perfluorooctane sulfonate exacerbates AHR-mediated toxicity by inhibiting CYP1A and altering its gene expression

D. H. Miller, A. Lachapelle, K. Satbhai, and A. R. Timme-Laragy. University of Massachusetts Amherst, Amherst, MA.

Background and Purpose: Per- and poly- fluoroalkyl substances (PFAS) are persistent environmental pollutants and developmental toxicants used in nonstick coatings, as surfactants, and in firefighting foams. Some PFAS (e.g. perfluorooctane sulfonate, perfluorohexane sulfonate; PFOS, PFHxS) have been shown to inhibit cytochrome p450 (CYP) proteins and (e.g. perfluorodecane sulfonate; PFDS) activate the aryl hydrocarbon receptor (AHR) which regulates many genes responsible for xenobiotic metabolism. Cytochrome p450 1A1 (*cyp1a1*, zebrafish ortholog *cyp1a*) is the most inducible AHR battery gene. Inhibition of CYP proteins can lead to reaction uncoupling and production of reactive oxygen species. Dysregulation of the AHR pathway during embryonic development can lead to "blue sac" disease characterized by pericardial edema and craniofacial malformations. **Methods:** Here we investigated how developmental exposure to PFAS interferes with CYP1A-like activity as induced by a model AHR agonist, Beta naphthoflavone (BNF) *in vivo* using a zebrafish model. We also investigated the enzyme kinetics of isolated human CYP1A1 exposed to PFAS *in vitro*. We used *in silico* molecular docking (AutoDock Vina 1.1.2, AlphaFold 3) to predict affinities of a more extensive selection of PFAS for AHR-relevant proteins as well as possible molecular interactions. **Results:** Co-exposure of 16 μ M PFOS, but not PFHxS, reduced EROD activity as induced by BNF by as much as 56%. This reduction was concomitant with increases in pericardial area and decreases in *cyp1a* gene expression. Human CYP1A1 was inhibited at tested concentrations by PFOS and to a lesser degree 6:2 fluorotelomer sulfonate (6:2 FTS). *In silico* predicted PFAS-CYP1A1 affinities aligned closely with percent inhibition *in vitro*. This suggests PFAS interferes with canonical *cyp1a* expression, CYP1A activity, or both, thus exacerbating toxicity of AHR agonists. **Conclusions:** This has important implications for environmental risk assessments that may underestimate exposure hazards of PFAS and PAH mixtures. Furthermore, this supports that *in vitro* and *in silico* experimentation can make accurate predictions about PFAS-CYP interactions.

PS 4514 PFOS and Mitochondrial Function: Unveiling an Inert Molecule's Metabolic Disruption

D. Greig¹, M. Erol¹, M. Jang¹, M. Grimes¹, S. Y. Park^{1,2}, and G. Layec¹. ¹University of Nebraska at Omaha, Omaha, NE; and ²University of Nebraska Medical Center, Omaha, NE. Sponsor: G. Layec, American Physiological Society

Background and Purpose: Perfluorooctane sulfonate (PFOS) is a manufactured compound that has been accumulating in the soil and water sources around the globe. Despite being initially considered metabolically inert, PFOS has recently been linked to metabolic dysregulation and obesity in humans. However, the cellular mechanisms underlying potential PFOS-associated metabolic disruption are unknown. Given the central role of mitochondria in metabolic control and fuel oxidation, mitochondrial oxidative phosphorylation may represent a potential target of PFOS. Therefore, the purpose of this study is to determine whether mitochondrial respiratory function is affected by PFOS by establishing the dose-response curve across metabolically active tissues (white adipose, liver, skeletal muscle, and cardiac tissues). **Methods:** Maximal mitochondrial respiration was measured by high-resolution respirometry in permeabilized tissue samples from C57/Bl6J mice using glycolytic substrates specific to complex I (CI) or complex II (CII). Dose-response curves were analyzed to estimate 50% inhibition concentration (IC_{50}), Hill coefficient (nH), and maximum inhibition (I_{max}) of maximal CI- or CII- driven respiration by PFOS. **Results:** At physiological PFOS concentrations for humans (0.01 and 2 μ M), CI and CII specific respiration were significantly inhibited in white adipose ($p<0.01$) and cardiac ($p<0.001$) tissues. The liver tissue was significantly inhibited at physiological concentrations for CII-driven respiration only ($p<0.01$). For CI-driven respiration, I_{max} in cardiac (93 $\pm$ 4%) and skeletal muscle (91 $\pm$ 9%) tissues were significantly greater than liver (61 $\pm$ 5%, $p<0.001$) and white adipose tissues (69 $\pm$ 8%, $p<0.001$). The IC_{50} of cardiac (1461 $\pm$ 402 μ M) and skeletal muscle (1433 $\pm$ 689 μ M) tissues with CI specific substrates were lower than those of liver (2426 $\pm$ 492 μ M, $p<0.05$) and white adipose tissues (2593 $\pm$ 736 μ M, $p<0.05$). The cardiac muscle IC_{50} (1217 $\pm$ 220 μ M) was significantly lower than the skeletal muscle (1991 $\pm$ 436 μ M, $p<0.05$) with CII

specific substrates. **Conclusions:** Although IC_{50} values of PFOS on mitochondrial respiration were elevated, this study revealed that PFOS can impair mitochondrial respiratory function, with cardiac and skeletal muscle tissues demonstrating the greatest susceptibility to PFOS toxicity. In addition, physiological levels of PFOS were sufficient to substantially inhibit mitochondrial respiration in cardiac, liver, and white adipose tissues, thus providing a potential underlying mechanism for PFOS induced metabolic disruptions.

PS 4515 Evaluation of Occupational Exposure and Bioavailability of Micropowders of Polytetrafluoroethylene (PTFE): Integrated *In Vivo* and *In Silico* Approaches

J. Anderson¹, J. Vargas², D. Singh³, and M. Schlipf⁴. ¹Exponent Inc., Austin, TX; ²Exponent Inc., Phoenix, AZ; ³Exponent Inc., Oakland, CA; and ⁴Fluorocarbon Polymer Solutions GmbH, Burgkirchen, Germany.

Background and Purpose: Polytetrafluoroethylene (PTFE), a high molecular weight fluoropolymer, is widely used in high performance industrial applications, yet its exposure and toxicological profile remains poorly characterized. Unlike smaller non-polymeric per- and polyfluoroalkyl substances (PFAS), fluoropolymers like PTFE are generally considered inert and non-bioavailable due to the large molecular weight. However, occupational exposure to aerosols of PTFE micropowders (ranging from tens of μ m to hundreds of μ m in size) that may be generated during manufacturing, handling and processing steps—particularly via inhalation and incidental ingestion—raises questions about potential health risks. This study was initiated to address critical data gaps related to PTFE uptake in the gut and resulting bioavailability for the ingestion exposure pathway and PTFE deposition in the lung for the inhalation pathway, with the goal of informing regulatory frameworks that currently lack substance-specific guidance for evaluating risks of potential occupational exposures to fluoropolymers. **Methods:** Two complementary approaches are employed. First, an acute *in vivo* absorption, distribution, metabolism, and excretion (ADME) study was conducted in rodents (following the OECD 417 method principles) using a composite blended PTFE sample representative of four commercially relevant forms (i.e., Suspension Fine Cut, Suspension Free Flow, Emulsion Coagulated, and Emulsion Micropowder). PTFE was administered via oral gavage, and tissue histology and serum filtration were used to assess particle absorption and distribution. Second, *in silico* inhalation dosimetry modeling of the PTFE aerosols of the four representative PTFE samples was performed using the widely used and validated Multiple-Path Particle Dosimetry (MPPD) model to simulate deposition patterns and deposited doses of PTFE aerosols in the head, tracheobronchial and alveolar regions of the human respiratory tract under relevant occupational exposure scenarios. Retained particle doses following pulmonary clearance of particles were also modeled for the tracheobronchial and pulmonary regions. Key input parameters to the MPPD model included PTFE aerosol characteristics (i.e., aerodynamic size distribution, particle density, aspect ratio) that were derived from empirical testing and published literature, as well as exposure characteristics (i.e., average airborne concentrations, exposure duration, exposure frequency) that were assessed from representative worker handling procedures, shift schedules and room conditions. **Results:** Existing literature indicates low oral toxicity and negligible systemic uptake of PTFE in rodents, with no genotoxic or carcinogenic classification. Available literature predicts that PTFE particles $\geq 10 \mu$ m are unlikely to translocate across biological barriers, providing a preliminary indication that micropowders of PTFE used in our study that range between 10 - 600 μ m in particle size are likely to show limited uptake and bioavailability. The *in vivo* study is designed to confirm presence/absence of PTFE uptake in selected tissues, while the *in silico* model provides quantitative estimates of retained PTFE dose and deposition location in the human lung. Preliminary size analysis of the four PTFE samples also indicates that there is expected to be a significant fractional deposition of these aerosolized powders in the upper human respiratory tract (i.e., the head region from nose/mouth through the larynx). These findings will help clarify whether PTFE micropowders pose a realistic risk of bioavailability or inhalation burden and toxicity in occupational settings. **Conclusions:** This integrated study provides foundational data to support differentiation of human health risks of fluoropolymers from those of other non-polymeric PFAS. The results will inform occupational safety standards and contribute to science-based risk assessments for PTFE exposures in occupational scenarios across the PTFE value chain. Given the widespread industrial use of PTFE and the evolving regulatory landscape for PFAS, these findings are critical for establishing appropriate worker health protection measures and guiding future regulatory and policy decisions.

PS 4516 Region- and sex-dependent accumulation of perfluorooctanesulfonic acid (PFOS) in the rat brain revealed by Desorption Electrospray Ionization Mass Spectrometry Imaging (DESI-MSI)

H. Pol, J. M. Brown-Leung, F. Currin, C. Ferreira, and J. R. Cannon. Purdue University, West Lafayette, IN.

Background and Purpose: Per- and polyfluoroalkyl substances (PFAS) are a group of persistent organic pollutants known to accumulate in the human body including the brain. Perfluorooctanesulfonic acid (PFOS), the most prevalent PFAS pollutant,

is estimated to have a systemic blood half-life of about 3-6 years in humans and 30 days in rodents. Although PFOS levels in the blood have decreased over time in the United States, the half-life of PFOS and other PFAS in the brain is unknown. Furthermore, how PFOS is distributed throughout the brain is also poorly understood. Because PFOS and other PFAS have potential links to various neurodegenerative and neuropsychiatric disorders such as Alzheimer's disease, attention deficit hyperactivity disorder, and major depressive disorder, it is important to understand if PFOS accumulation corresponds with brain regions associated with these conditions. Previous research has demonstrated that PFOS alters neurotransmitter levels in brain regions including the prefrontal cortex, dorsal striatum, ventral striatum, ventral midbrain, and hippocampus. We tested the hypothesis that PFOS accumulation in the brain leads to altered neurotransmitter levels, resulting in neurotoxicity. Here, we aimed to characterize the region- and sex-specific accumulation of PFOS to better understand its potential for neurofunctional disruption. We utilized Desorption Electrospray Ionizing-Mass Spectroscopy Imaging (DESI-MSI) to visualize PFOS accumulation in various regions of the brain. **Methods:** Three-month-old male and female Sprague-Dawley rats were dosed with a single bolus of 10 mg/kg PFOS or 10% DMSO vehicle via oral gavage. Brain, liver, blood, and cerebrospinal fluid (CSF) were collected 1, 3, 7, 28, and 112 days post-treatment. One hemisphere of the brain was flash-frozen in a 2-methylbutane bath surrounded by dry ice and stored at -80°C until cut. The remaining tissue was analyzed with high-performance liquid chromatography coupled with mass spectrometry (HPLC-MS) for PFOS quantification. The other hemisphere was sectioned coronally at 50 µm on a cryostat for DESI-MSI imaging conducted on a SYNAPT XS mass spectrometer (Waters Instruments) paired with a DESI XS Ion Source. Data were analyzed qualitatively using MassLynx Waters software v.4.2 to determine relative PFOS intensity across brain regions. **Results:** PFOS accumulated in multiple brain regions of male and female rats with distinct region- and sex-dependent patterns. The dorsal striatum exhibited the highest overall PFOS accumulation in both sexes, corresponding to its role in movement control and habit learning. Males displayed higher PFOS concentrations in the ventral striatum, a region associated with reward and motivation via the mesolimbic pathway, while females exhibited greater accumulation in the hippocampus, amygdala, thalamus, and hypothalamus; regions involved in memory encoding, emotional regulation, sensory relay, and hormone control. Females also exhibited reduced PFOS elimination over time, indicating greater retention relative to males. Notably, PFOS preferentially accumulated in gray matter rather than white matter, suggesting region-specific vulnerability of neuronal tissue. These results collectively demonstrate that PFOS distribution in the brain is both region- and sex-dependent, with implications for distinct neurofunctional outcomes. **Conclusions:** This study expands the characterization of PFOS distribution in the brain, confirming region-specific and sex-dependent accumulation patterns. The dorsal striatum, hippocampus, and hypothalamus exhibited particularly high PFOS retention, with marked differences between males and females. The preferential accumulation in gray matter suggests vulnerability of neuronal regions involved in motor, emotional, and cognitive regulation. Future studies will analyze additional brain regions of interest (prefrontal cortex, ventral tegmental area, substantia nigra), increase sample size, perform quantitative PFOS analysis in micro-dissected brain tissue (UHPLC), determine PFOS half-life, and compare findings to chronic PFOS exposure models. These data provide a foundation for understanding how persistent PFOS exposure may contribute to sex-specific neurotoxic mechanisms and neurodegenerative risk.

PS 4517 Perfluoroalkyl Substances (PFAS) Exposure Exacerbates Metabolic Dysfunction in Alcohol-Associated Liver Disease

K. Nguyen, and H. Ni. University of Kansas Medical Center, Kansas City, KS.

Background and Purpose: Polyfluoroalkyl substances (PFAS) are persistent environmental pollutants that are widely found in industrial applications and consumer products. Due to their strong perfluoroalkyl bonds, these substances bioaccumulate in humans and have been shown to disrupt hormone production, impair reproduction and development, and promote tumorigenesis. In the liver, studies showed that PFAS disrupt hepatic metabolism, increase oxidative stress, inflammation, and lipid accumulation. Similarly, alcohol consumption leads to alcohol-associated liver disease (ALD), by impairing mitochondrial fatty acid oxidation, VLDL secretion, and elevating lipid deposition. Nevertheless, approximately 35% of alcohol drinkers develop to advanced stages of liver disease, suggesting additional factors- including environmental exposures- further contribute to its progression. Emerging evidence suggests that environmental toxicants, including PFAS, further exacerbate alcohol-induced hepatotoxicity and ALD. However, the distinct and similar impacts of PFAS exposure and alcohol alone, or their combination, in inducing liver disease remains under characterized. **Methods:** Wild-type C57BL/6J mice are pre-exposed to a mixture of PFAS compounds containing PFOA (1mg/L), PFOS (1mg/L), and GENX (2mg/L) at the concentration of occupational doses in drinking water for 28 days. They are then subjected to a chronic plus binge alcohol model with concurrent PFAS mixture maintained throughout. Serum and liver tissues are collected for histological analysis, evaluation of liver injury markers, assessment of lipid metabolism, and fibrosis. **Results:** PFOA and PFOS accumulate in both serum and liver, whereas GENX is detected only in serum at minimal levels. PFAS exposure does not affect food intake and body weight during pre-exposure and alcohol feeding. Both alcohol consumption and PFAS exposure induces liver injury. PFAS-exposed mice exhibit enlarged livers and exacerbate alcohol-induced steatosis by further elevating hepatic triglyceride and cholesterol, while significantly reducing serum cholesterol. Sirius

Red staining reveals increased portal myofibroblast in both alcohol- and PFAS-fed groups. **Conclusions:** Occupational-level PFAS exposure accumulates in the liver and exacerbates ALD by increasing hepatic lipids and fibrosis.

PS 4518 Effects of PFOA on Physiology and Locomotor Behavior on *Drosophila melanogaster*

E. Rodriguez Borrero¹, A. Garced Diaz¹, A. Rivera Alsina¹, Z. Blasini Picart¹, A. Rodríguez González¹, N. Rosario Ramos¹, K. Castrodad Rolón¹, and L. B. Mendez². ¹University of Puerto Rico at Cayey, Cayey, PR; and ²Ana G. Mendez University, Carolina, PR.

Background and Purpose: Per- and polyfluoroalkyl substances (PFAS) are characterized by a hydrophobic perfluorinated alkyl chain—typically 2 to 16 carbon atoms in length—attached to various functional groups. These compounds are highly persistent in the environment and have been shown to bioaccumulate in brain regions such as the hippocampus, hypothalamus, and pons/medulla, where they are associated with disruptions in neural and hormonal homeostasis across multiple species. However, the long-term behavioral and physiological consequences of PFAS accumulation remain poorly understood. *Drosophila melanogaster* serves as an ideal model organism for addressing these knowledge gaps due to its genetic tractability, conserved neurobiological pathways, and the availability of well-characterized and reproducible behavioral assays. We hypothesized that PFAS accumulation in the brain induces neurotoxic effects by impairing neurotransmitter signaling, thereby disrupting overall fly physiology. To test this hypothesis, the present study investigates the effects of a long-chain PFAS, perfluorooctanoic acid (PFOA), on survival, reproductive capacity, and locomotor activity in *Drosophila melanogaster*. **Methods:** For the survival assay, male and female *Drosophila melanogaster* (Canton S strain), 2-5 days old, were exposed for 28 days to PFOA concentrations ranging from 1 µM to 1 mM in their culture media. Flies were transferred to fresh food vials every 7 days, and the number of surviving flies per vial was recorded. Reproductive capacity was assessed by placing 10 mating pairs in vials containing food supplemented with 100 µM, 300 µM, 700 µM, or 1 mM PFOA for 3 days. The number of offspring was counted over 7 days following the first egg hatching. Locomotor performance was evaluated using the Rapid Iterative Negative Geotaxis (RING) assay after 14 days of exposure to PFOA concentrations ranging from 1 µM to 1 mM. The number of flies reaching the 4 cm mark within 3 seconds was recorded as a measure of climbing ability. **Results:** Our findings indicate that PFAS exposure affects survival in a concentration- and sex-dependent manner. Reproductive output decreased significantly with increasing PFAS concentrations. No egg hatching was observed at 700 µM. Interestingly, at 1 mM, egg hatching was delayed rather than completely inhibited. Locomotor ability declined in a dose-dependent fashion, with the most pronounced reduction observed at 300 µM; however, no significant sex differences were detected. **Conclusions:** These results suggest that PFOA may impair survival, reproductive capacity, and negative geotaxis behavior in *Drosophila melanogaster* in a concentration- and exposure time-dependent manner. Further research is warranted to validate these preliminary findings and to elucidate the molecular and physiological mechanisms underlying PFOA-induced neurotoxicity.

PS 4519 Exploring the Role of SIRT1 in PFAS Mediated Steatosis

J. M. Woodward, E. Mitchem, P. Harris, K. Fritz, J. N. Lampe, and R. L. McCullough. University of Colorado Anschutz Medical Campus, Aurora, CO.

Background and Purpose: Per- and polyfluoroalkyl substances (PFAS) are widespread environmental contaminants found in contaminated groundwaters that are often located near industrial manufacturing and military airfield sites. Commercial and industrial use of next-generation (next-gen) PFAS, such as perfluoroalkyl sulfonamides (FASAs) and fluorotelomer sulfonic acids (FTSAs), has replaced legacy PFAS (e.g., perfluoroalkyl sulfonic acid [PFSA], perfluorooctane sulfonic acid [PFOS]). Despite this replacement approach, there remain gaps in our knowledge related to the adverse effects of next-gen PFAS on the liver. Further, Sirtuin 1 (SIRT 1), a protein deacetylase that regulates a wide variety of biological processes, including lipid metabolism, has been noted as a target of PFOS. Thus, it is our working hypothesis that next-gen PFAS (FASAs, FTSAs, and additional PFASs) can inhibit SIRT 1 prompting alterations in the post-translational acetylation landscape, leading to increased lipid burden in hepatocytes. **Methods:** To test this hypothesis, differentiated hepatocyte-like cells (HepaRG) were exposed to an occupational exposure concentration of 25 µM PFAS for 72 hours, and neutral lipids were quantified using Nile Red. Total protein acetylation and SIRT 1 were measured by Western Blot. SIRT1 activity was determined using modified methods from Mitchem et al. *Redox Biochemistry and Chemistry* 2025. *In silico* modelling was utilized to model sites of PFAS-SIRT 1 interaction; screening was performed using FASA (perfluorobutane sulfonamide [FBSA], perfluorohexane sulfonamide [FHxSA]), perfluorooctane sulfonamide [PFOSA]), FTSAs (perfluorobutane sulfonic acid [PFBS], perfluorohexane sulfonic acid [PFHxS], PFOS) and FTSA (1,1,2,2 perfluorohexane sulfonic acid [4:2 FTS], 1,1,2,2 perfluorooctane sulfonic acid [6:2 FTS], 1,1,2,2 perfluorodecane sulfonic acid [8:2 FTS]) PFAS (Autodock vina v1.2, UCSF Chimera X). The SIRT 1 inhibitor EX-527 (10 µM) was utilized as a positive control in all experiments. **Results:** Neutral lipids increased 2-fold following PFSA, FASA, FTSA, and EX-527 exposure in HepaRG cells. Total protein acetylation increased between 13-25% following PFSA exposures while next-

gen FASA and FTSA increased acetylation between 27.5-34%. EX-527 increased acetylation by 50%. Making use of Autodock vina molecular docking software, we find that FASA, FTSA, and PFSA interact within the NAD⁺ cofactor binding pocket of SIRT 1, suggesting PFAS competitively inhibit SIRT 1. Further, we demonstrate that the predicted binding affinities of PFSA, FTSA, and FASA to the cofactor binding pocket positively correlate with PFAS carbon backbone length. These observations were noted independent of functional group. All PFAS docked in the NAD⁺ binding pocket of SIRT 1 with similar orientations, whereby the sulfonic acid and sulfonamide functional groups localized near the conserved adenine ribose binding moiety of NAD⁺ (1-6 Å). Hydrogen bonds and Van der Waal (VDW) interactions were characterized for each PFAS to SIRT 1 pairing and prevailed throughout the NAD⁺ binding pocket. **Conclusions:** Overall, these data suggest that FASA, FTSA, and PFSA negatively impact SIRT 1 at occupationally relevant exposure levels. Our data describe, for the first time, that next-gen PFAS may have greater lipogenic potential compared to legacy PFAS, warranting further research in this area. *In silico* modelling of PFAS with SIRT 1 suggests PFAS may competitively inhibit NAD⁺ cofactor binding, preventing the deacetylation process. The impact of next-gen PFAS on SIRT 1 and additional sites of SIRT 1-regulated protein acetylation remains uncharacterized *in vitro*, making it important for future studies to profile functional outcomes of PFAS exposure and acetylation on metabolic processes that are monitored by SIRT 1, such as *de novo* lipogenesis and fatty acid oxidation. Additionally, other studies should explore the contribution of PFAS exposure on other SIRT1s to better define the PTM landscape associated with steatotic phenotypes in the liver. Overall, our data elucidates a novel mechanism in which emerging and legacy PFAS classes may act to cause metabolic stress in human hepatocytes. This work is supported, in part, by NIH/NIEHS grant R21ES032529 to JL/RM and a T32 ES029074 awarded to JW.

PS 4520 Drosophila melanogaster as a Research Model to Study the Impact of PFAS on Neuroplasticity of Complex Motor Behaviors

E. Rodriguez Borrero¹, A. Y. Diaz Flores¹, A. Garced Diaz¹, A. Gonzalez Fuentes¹, M. V. Candelario Gonzalez¹, and L. B. Mendez². ¹University of Puerto Rico at Cayey, Cayey, PR; and ²Ana G. Mendez University, Carolina, PR.

Background and Purpose: Per- and polyfluoroalkyl substances (PFAS) are persistent environmental pollutants known for their stability and bioaccumulative properties, raising concerns about their potential to disrupt biological systems. They tend to notably accumulate in brain regions such as the hippocampus, hypothalamus, and pons/medulla. Despite increasing evidence that PFAS disrupts homeostasis of the nervous system, the long-term behavioral consequences of their accumulation remain poorly understood. This study utilized *Drosophila melanogaster*—an ideal model organism due to its genetic tractability, conserved neurobiological pathways, and well-established behavioral assays. We hypothesized that PFOA accumulation within the brain induces changes in complex motoric behavior. To test our hypothesis, this study investigates to evaluate the effects of exposure to a long-chain PFAS, perfluorooctanoic acid (PFOA), on grooming behavior and acute ethanol tolerance development, two traits associated with neuroplasticity. **Methods:** To assess acute alcohol tolerance development, 2 to 5 days old *Drosophila melanogaster* (Canton S) males and females flies were exposed to 300 µM, 700 µM, and 1 mM PFAS for 14 days. On day 1 of the ethanol tolerance assay the flies were separated on control and experimental group. Control flies were exposed to water vapor while experimental group was exposed to 50% ethanol vapor. On day 2 all flies were exposed to 50 % ethanol vapor. The difference in time to reach 50% of sedated flies was scored. To assess the effect of PFOA on grooming behavior females' flies were exposed for 14 days to 10 nM, 100 nM, 1 µM, and 10 µM concentrations. After exposure, a dusting assay was performed in which flies were coated with Reactive Yellow 86 to induce self-grooming behavior. The amount of dust remaining on each fly after cleaning was measured to assess potential induced neurotoxicity that disrupts circuits responsible for grooming. **Results:** Ethanol tolerance development was significantly affected by PFOA exposure, as indicated by the increase in time to reach 50% sedation in both sexes. Preliminary data also suggest that PFOA exposure impairs normal grooming behavior in a dose-dependent manner, with the most pronounced reduction observed at higher concentrations, particularly at 10 µM. **Conclusions:** These results suggest that PFOA disrupts complex motor behaviors in *Drosophila melanogaster* in a concentration-dependent manner, with no significant differences observed between sexes. Further research is warranted to confirm these preliminary findings and to elucidate the molecular and cellular mechanisms underlying PFOA-induced neurotoxicity.

PS 4521 High-Throughput Prediction of PFAS Binding Affinities with Human Liver-Fatty Acid Binding Protein Using Machine Learning and QSAR Model

Y. Jia^{1,2}, and L. Zhu¹. ¹College of Environmental Science and Engineering, Nankai University, Tianjin, China; and ²Brigham and Women's Hospital, Harvard Medical School, Boston, MA.

Background and Purpose: Per- and polyfluoroalkyl substances (PFAS) are ubiquitous environmental contaminants known for their capacity to bioaccumulate in humans. Exposure to legacy PFAS, such as PFOS and PFOA have been associated with adverse health effects. However, a far larger number of structurally diverse

novel PFAS are currently in use, yet their bioaccumulation potential remains largely unknown. Experimental evidence shows strong correlations between PFAS binding affinity to liver fatty acid-binding protein (L-FABP) and hepatic PFAS concentrations across species, and pharmacokinetic modeling has further identified this binding affinity as a key parameter governing liver burden. Nevertheless, the vast number of PFAS (>12,000 registered in the U.S. EPA Master List), coupled with the limited availability of commercial analytical standards, presents a major challenge for experimentally determining their binding. Machine-learning-based quantitative structure-activity relationship (QSAR) models provide a promising pathway to bridge this data gap by predicting binding affinities ($K_{d, FABP}$) directly from molecular descriptors. **Methods:** An integrated experimental-computational framework was developed to quantify and predict the K_d FABP. Using an ultrafiltration-based assay, we first conducted a high-throughput experimental evaluation of $K_{d, FABP}$ for both PFAS analytical standards and PFAS extracted and semi-quantified from environmental samples through suspect-screening analysis. These experimentally derived K_d FABP values were then used to construct QSAR models through model comparison, feature selection, and hyperparameter optimization. Key physicochemical properties and structural descriptors were identified. Finally, the optimized model was applied to predict $K_{d, FABP}$ for PFAS listed in the U.S. EPA Master List as well as PFAS generated by artificial intelligence generated PFAS (PFAS-AI). **Results:** The ultrafiltration assay successfully enabled high-throughput measurement of $K_{d, FABP}$ values for a wide range of PFAS, including many compounds lacking commercial analytical standards. Among the machine-learning algorithms evaluated, extreme gradient boosting regression demonstrated the best predictive performance, achieving an R^2 of 0.77 on the test set. Feature importance analysis revealed that descriptors about atomic electronegativity, van der Waals volume, and ionization potential, were key determinants of binding affinity. Applying the optimized model to 9,117 PFAS from the U.S. EPA Master List within the model's applicability domain showed that 14% of these PFAS exhibit binding comparable to or stronger than PFOS and PFOA. Notably, DTXSID40896722, a compound containing three perfluorinated branches, was predicted to have the strongest binding. Evaluation of 76,216 PFAS-AI structures further identified more than 3,500 AI-generated PFAS with exceptionally strong predicted binding, signaling potential concern for future environmental or commercial use. Conversely, 7,567 PFAS-AI demonstrated extremely weak binding affinities, and 94% of these compounds were predicted to be synthetically less complex than current PFOA alternative, following additional evaluation, may serve as promising environmentally benign PFAS replacements. **Conclusions:** This study establishes a high-throughput experimental-computational framework for evaluating PFAS-L-FABP binding affinity. By integrating ultrafiltration measurements with machine learning models and expanding coverage across broad chemical space, including EPA-listed PFAS and AI-generated structures, we identified key molecular descriptors and structural motifs that govern PFAS-L-FABP interactions. The resulting QSAR models offer a powerful tool for PFAS prioritization and for accelerating the screening of emerging and novel PFAS. Moreover, the mechanistic insights gained from this work can inform the rational, *de novo* design of PFAS with reduced bioaccumulation potential, supporting the development of safer and more sustainable fluorinated chemistries.

PS 4522 Toxicological Perspectives on PFAS Exposure Shift: Hepatotoxicity and Gut-Liver Axis Disruption in Adult Zebrafish

S. Park, and K. Kim. Seoul National University of Science Technology, Seoul, Korea, Republic of.

Background and Purpose: When unexpected toxicity is discovered in existing compounds, they are replaced with less toxic alternatives. This substitution strategy creates a unique exposure scenario: rather than isolated exposure to individual compounds, organisms in real-world environments experience continuous transitions from existing chemicals to substitute chemicals. A prominent example of this phenomenon is the replacement of perfluorooctane sulfonate (PFOS), a legacy per- and polyfluoroalkyl substance (PFAS), with shorter-chain alternatives such as perfluorobutanesulfonate (PFBS) and perfluorobutanesulfonamide (FBSA) following global regulatory restrictions. However, studies on existing substitute substances have focused on the single toxicity of the substitute or the combined toxicity with the original substance. Research elucidating the biological effects caused by exposure transition has yet to be established. **Methods:** Using the adult zebrafish model, we evaluated how exposure shift from perfluorooctane sulfonate (PFOS) to its alternatives governs the biological responses in overall hepatotoxicity and gut-liver axis. Four exposure groups were used: a solvent control, PFOS-only, PFOS to perfluorobutanesulfonate (PFBS) transition, and PFOS to perfluorobutanesulfonamide (FBSA) transition. The overall exposure lasted 21 days, and the exposure transition was designed as 1 week of exposure to the PFOS followed by 2 weeks of exposure to the alternatives (i.e., PFBS or FBSA). Dissected liver samples were analyzed for hepatosomatic index (HSI), liver-specific enzyme activities, and histopathology. Individual changes in liver gene expression and intestinal microbiota community profiling were characterized using RNA-seq and 16S rRNA-seq. To elucidate the correlation between changes in gut microbiota composition and liver gene expression, a multi-omics integrated analysis was performed. **Results:** In all exposure groups, a decrease in ALT and AST activity was observed alongside increased HSI, and histopathological analysis confirmed hepatocyte necrosis and lipid accumulation. The PFOS-only group exhibited the most severe liver damage, while the FBSA conversion group showed similar damage; in contrast, the PFBS conversion group demonstrated relatively mild damage. The decrease in ALT/AST suggests reduced the

enzyme production capacity due to extensive hepatocyte damage. Transcriptomic analysis revealed downregulation of genes related to lipid metabolism and the PPAR signaling pathway in both transition groups, indicating that the observed effects in PFOS-only and exposure transition groups are associated with metabolic disruption. Intestinal microbiota dysbiosis occurred in all exposed groups. A multi-omics integrated analysis showed that the PFOS-only group and the FBSA transition group primarily exhibited microbial-gene networks associated with metabolic dysfunction, whereas the PFBS conversion group displayed an integrated profile related to barrier function recovery. These multi-layered changes at the gut-liver level suggest that PFAS toxicity may cause not only direct liver damage but also disruption of the gut-liver axis. **Conclusions:** This study is the first to elucidate the biological effects of PFAS exposure conversion from various perspectives, and show that the gut-liver effects of PFAS exposure switching using multi-omics. Notably, despite switching to PFBS, a relatively less toxic substance, the reduction in toxicity was limited. PFBS exhibited similar levels of gut-liver axis disruption and liver damage as PFOS. This raises the possibility that switching to less toxic alternatives alone may not fully guarantee toxicity reduction. As the results of this study may vary depending on the exposure period and substance, further research is needed.

PS 4523 Chronic apple juice administration enhances per- and polyfluoroalkyl substances (PFAS) elimination and lowers systemic and hepatic burden

O. Skende¹, S. Ryu¹, S. Vojta², J. Becanova², J. Zeng¹, J. Agudelo Areiza¹, Y. Zhang³, C. Messerlain⁴, F. C. Fischer¹, and A. L. Slitt¹. ¹Department of Biomedical and Pharmaceutical Sciences, University of Rhode Island, Kingston, RI; ²Graduate School of Oceanography, University of Rhode Island, Kingston, RI; ³Peking University, Beijing, China; and ⁴McGill University, Department of Epidemiology and Biostatistics, Montreal, QC, Canada.

Background and Purpose: Apple juice (AJ) administration can cause a clinically significant reduction in drug bioavailability. This is attributed to inhibition of Organic anion transporting polypeptide (Oatp)-facilitated uptake in the gastrointestinal tract GIT by polyphenols present in AJ (i.e. naringin and hesperidin). Per- and polyfluoroalkyl substances (PFAS) are a class of persistent amphiphilic pollutants that pose serious human exposure concerns, due to impacted drinking water, and have oral bioavailability. Mechanisms by which the GIT absorbs PFAS are unclear, but Oatp-related transport is likely. Previous studies indicate that PFAS are rat Oatp substrates. Our preliminary data indicate that human OAT2B1 transports PFBS and 6:2FTS in HEK293 transfected cells, and uptake is inhibited by rifamycin sv, naringin, and hesperidin. Thus, we hypothesized that administration of a 4X AJ concentrate (AJC) can decrease PFAS absorption in mice, presumably through Oatp inhibition. **Methods:** C57Bl/6J male mice (n=5-6/ treatment group) were administered a single oral dose of a PFAS cocktail (0.1mg/kg of PFOS, PFOA, PFHxS, PFBS and 6:2FTS at equal ratios) followed by 2 daily doses of either AJC or buffer for 7 days. Blood was collected via the submandibular vein 2hrs, 5hrs, 24hrs, 48hrs, and 72hrs post PFAS dosing. Blood and tissues were collected 7 days post PFAS administration. Additional C57Bl/6J male mice (n=6/treatment group) were administered a morning dose of PFAS cocktail prepared in either AJC/0.5%Tween20 or buffer/0.5%Tween20, followed by an evening dose of the same vehicle every day, for 7 days. Blood and tissues were collected after 7 days of PFAS dosing. All samples were processed utilizing QuEChERS extraction method for LC/MS analysis. **Results:** Following the administration of a single PFAS cocktail dose, AJC administration decreased PFOS and PFOA area under the curve (AUC), over 7 days, to 73% and 62% of the controls, respectively. AJC administration did not reduce PFHxS, 6:2FTS, or PFBS AUC, rather delayed absorption. PFBS concentrations decreased 2 hours after PFAS administration to 48% of the controls. PFHxS concentrations decreased 2 and 5 hours after PFAS administration to 30% and 61% of the controls, respectively. 6:2FTS concentrations decreased 2 and 5 hours after PFAS administration to 36% and 59% of the controls respectively. Following the administration of a PFAS cocktail dose, daily for 7 days, AJC administration decreased PFOS and PFOA plasma concentrations to 89% and 67% of PBS controls, respectively. PFBS, PFHxS, and 6:2FTS plasma concentrations were not impacted by AJC administration. In mice that received a single PFAS dose, AJC reduced liver PFOS and PFOA concentrations to 80% and 58% of PBS control, respectively, while in mice that received multiple PFAS doses, liver PFOS and PFOA concentrations were decreased to 75% and 59%, respectively. **Conclusions:** These findings suggest AJC likely impairs transporter mediated absorption and tissue distribution of PFAS, lowering the systemic exposure of PFOS and PFOA in mice. Overall, this study demonstrates the potential of AJC to decrease or delay PFAS absorption, suggesting that Oatp inhibition may be a critical mechanism to interfere with absorption in the GIT, decreasing PFAS bioavailability.

PS 4524 Half-life determination for oral perfluorooctanesulfonic acid (PFOS) in rat brain, cerebrospinal fluid, liver, and serum

J. M. Brown-Leung^{1,2}, F. Currim^{1,2,3}, H. Pol^{1,2}, Y. Choi³, M. S. Sepúlveda⁴, L. S. Lee³, and J. R. Cannon^{1,2}. ¹School of Health Sciences, Purdue University, West Lafayette, IN; ²Purdue Institute for Integrative Neuroscience, Purdue University, West Lafayette, IN; ³Department of Agronomy, Purdue University, West Lafayette, IN; and ⁴Department of Forestry and Natural Resources, Purdue University, West Lafayette, West Lafayette, IN.

Background and Purpose: Per- and polyfluoroalkyl substances (PFAS) are a group of persistent organic pollutants, termed "forever chemicals" that are ubiquitously found in the environment and virtually in all living organisms, including humans. Exposure to PFAS has been correlated with sex-specific effects including endocrine disruption and motor behavior deficits. Perfluorooctanesulfonic acid (PFOS), the most prevalent PFAS pollutant, is estimated to have a systemic blood half-life of about 3-6 years in humans and 30-60 days in rodents. Although PFOS levels in the blood have been decreasing over time in the USA, the half-life of PFOS and other PFAS in the brain is unknown. Because PFOS and other PFAS have potential links to Alzheimer's disease, attention deficit hyperactivity disorder, and major depressive disorder; it is important to understand if PFOS accumulation corresponds with brain regions associated with these neurological diseases and disorders. Our previous research demonstrated that PFOS changes neurotransmitter levels in a brain region-specific manner in mice. We hypothesized that PFOS accumulation in the brain leads to altered neurotransmitter levels, which result in neurotoxicity. Here, we aim to characterize how PFOS is retained in the brain and cerebrospinal fluid (CSF), which is excreted from the brain, and compare them to each other and to that of the liver and serum. This will determine if CSF and serum PFOS levels are viable biomarkers for PFOS levels in the brain. **Methods:** Three-month-old male (M) and female (F) Sprague-Dawley rats were given a single bolus dose of 10 mg/kg PFOS or 10% DMSO vehicle via oral gavage (n=4 per sex-treatment-timepoint). Brain, liver, blood, and CSF were collected 1, 3, 7, 28, and 112-d post-treatment. Only CSF that had no visible blood contamination was used for analysis. One hemisphere of the brain and one lobe of liver were frozen on dry ice for PFOS quantification. The other hemisphere of the brain was flash-frozen to be used for analyzing the distribution of PFOS in the brain via DESI-MSI. All tissues were stored at -80°C until analysis. Preliminary half-life analysis was conducted using non-linear regression modeling and was used to estimate half-life for each tissue and sex. Data were analyzed using 2-way ANOVA with a Holm-Sidak post-hoc analysis. **Results:** Preliminary analysis of PFOS content (n=3) demonstrated sex-dependent and tissue-dependent deposition and retention of PFOS. Vmax was detected at the d 1 timepoint for serum and was at d 3 for brain, CSF, and liver. At Cmax, the liver had the highest concentration of PFOS and was higher in males compared to females (p-value=0.0234). Serum had the second highest levels of PFOS at Cmax was higher in females compared to males (p-value=0.0096). The brain and CSF did not have sex effects. There were only sex effects in the liver for the 112-d timepoint with males having higher PFOS levels compared to females (p-value=0.0299). The preliminary half-life was highest in the liver for males (42d M, 32d F) and highest in the serum for females (35d M, 41d F). The half-life of the brain (20d M, 26d F) and CSF (21d M, 28d F) were similar and was longer for females compared to males. **Conclusions:** These results demonstrate that PFOS has sex-specific distribution and retention in different organs in the body. The liver has been previously determined to have the highest accumulation of PFOS and our results show that in male rats PFOS levels in the male liver may remain elevated, even after systemic PFOS levels decrease over-time. Interestingly, the half-life of PFOS in the CSF is slightly longer compared to the brain, suggesting the secretion of CSF from the brain may be a mechanism of PFOS removal from the brain and may indicate CSF could be a viable biomarker of PFOS levels in the brain. Future analysis will determine correlations between brain and CSF, liver, and serum levels. Importantly, these findings will allow for better characterize the accumulation of PFOS in the human brain and aid epidemiological studies in assessing how PFOS exposure correlates with different neurological diseases and disorders.

PS 4525 Effects of Early-Life Exposure to PFAS on Adolescent Neuroimmune Activity

G. Valdez¹, J. Ross¹, L. Zhao², R. M. Sargis², and M. R. Bell¹. ¹DePaul University, Chicago, IL; and ²University of Illinois Chicago, Chicago, IL.

Background and Purpose: Per-/polyfluoroalkyl substances (PFAS) are persistent organic pollutants commonly used in non-stick, oil-resistant, and water-proof food packaging as well as textiles; they are detected in more than 99% of human serum. Perfluorooctane sulfonic acid (PFOS), one of the most ubiquitous PFAS, is associated with altered lipid metabolism, immunotoxicity, and neurodevelopmental disorders. These outcomes all implicate microglia, resident macrophages in the brain critical for development and sensitive to lipid signaling, as key mediators of toxicity. However, developmental effects of PFOS on microglia are not well-characterized, nor is it clear how PFOS alters microglial inflammatory responses. We hypothesized that early-life PFOS exposure alters microglial responses to secondary inflammatory challenges later in life. **Methods:** To test this, pregnant Sprague Dawley dams were exposed to PFOS (0.5 ug/kg BW/day) or vehicle daily via Nilla wafers from gestation (22 days) until offspring weaning (postnatal day, P21). Offspring were weighed daily and development was monitored until euthanasia in adolescence (P42-47). Two

hours before euthanasia, adolescent offspring were given an inflammatory challenge (lipopolysaccharide, LPS, 0.5 mg/kg BW i.p.); sickness behaviors were monitored for two hours until euthanasia. Brains were collected and microglia were isolated from one cerebral hemisphere using CD11b+ magnetic beads. RNA was isolated from both the microglial and non-microglial pools. Five control and six PFOS litters were born over two cohorts, each contributing 2-4 animals per sex that were then distributed across the two inflammatory challenge groups. Final sample sizes ranged from 5-9 animals per sex, PFOS exposure, and LPS challenge. **Results:** Animals exposed to PFOS exhibited reduced weight gain from P7 to P21 relative to their P1 weight. Conversely, PFOS-exposed animals had greater weight gain after weaning, from P28 to P42 relative to P21. Because 'catch-up' weight gain in early development is linked to metabolic dysfunction in humans, lipid and thyroid hormone analyses are planned. Targeted gene expression analysis of non-microglial cells did not detect PFOS effects on expression of genes related to thyroid (Dio2), dopamine (Drd1a), and calcium (Camk1a) signaling or on synaptic regulation (Syt). While previously shown to be altered by PFOS exposure, the lack of PFOS-mediated alterations in expression of these genes in the current study may reflect region-specific responses undetectable in our whole brain samples. Unbiased analyses of the CD11b+ microglial transcriptome is currently underway, with preliminary results indicating widespread gene upregulation in response to LPS that is blunted with PFOS exposure among male rats. **Conclusions:** Our results indicate that perinatal PFOS exposure alters early-life body weight trajectories as well as inflammatory responses during adolescence. Ongoing work explores changes in brain and systemic lipid metabolism. Knowledge generated in these studies may inform regulatory approaches, risk reduction strategies, and/or treatments to address PFAS's significant threat to public health.

PS 4526 Assessment and Determination of Toxicological Endpoints of Sevoflurane Exposure in *C. elegans*

J. Tewksbury¹, C. Evans², and C. L. McGinnis². ¹Quinnipiac University, Frank H. Netter MD School of Medicine, North Haven, CT; and ²Quinnipiac University, Department of Biological Sciences, Hamden, CT.

Background and Purpose: Per- and polyfluoroalkyl substances (PFAS) are a group of nearly 15,000 synthetic chemicals that are often described as "forever chemicals" due to their persistent nature created by strong carbon fluorine bonds. PFASs are known to bioaccumulate in organisms and biomagnify in food webs. Sevoflurane is a volatile PFAS compound used for general anesthesia. Repeated exposure in childhood to sevoflurane has been associated with neurological complications. To investigate the molecular mechanism of action we assessed changes in gene expression in SOD3, a marker for oxidative stress, and several nuclear hormone receptors associated with lipid metabolism in *C. elegans*. **Methods:** Synchronized *C. elegans* were exposed to sevoflurane gas at clinically relevant concentrations (1.3% and 1.7% volume) for 3 hours within sealed glass containers. Worms were then collected at various timepoints (0, 1.5, and 3 hrs) post exposure and RNA was extracted, converted to cDNA, and analyzed via qPCR (Sybrgreen). Expression was normalized to the housekeeping gene, act-1. **Results:** Our data shows that immediately following sevoflurane exposure there was immediate decrease in relative expression of SOD3 gene (0.488±0.128) at the higher concentration of 1.7% and an immediate increase (1.91±0.856) at the 1.3% concentration. NHR-49 had a decreased expression immediately post exposure at both 1.3% (0.749±0.108) and 1.7% (0.614±0.176) sevoflurane concentrations. There was also an initial increase in NHR-80 (1.44±0.113) at the 1.3% concentration. Throughout the three-hour recovery period there was no statistically significant fluctuations in gene expression between time points. **Conclusions:** The data suggests that there is some disruption of lipid metabolism and oxidative stress genes during and hours after exposure to sevoflurane. The decrease in SOD3 and NHRs at higher concentrations suggests a suppressive effect of sevoflurane in lipid regulation and oxidative stress protection. At lower concentrations, increases in these genes suggest a threshold at which the suppressive effects take over from the body's physiologic response to the exposure.

PS 4527 Assessment of Aqueous Film-Forming Foam (AFFF)-Based Mixture of 27 PFAS Compared to the Mixture of Six Regulated PFAS on the Development and Toxicokinetics in Larval Zebrafish (*Danio rerio*)

K. M. Satbhaj, J. Lee, S. Emani, A. Lachapelle, H. Robertson, J. Doherty, J. Clark, and A. R. Timme-Laragy. University of Massachusetts, Amherst, MA.

Background and Purpose: Concerns regarding unintentional, although inevitable, exposures to chemical mixtures have been mounting. One of the widely known mixtures of per- and poly-fluorinated substances (PFAS)—known to exert adverse effects on environmental and human health—is aqueous film-forming foams (AFFF). Used extensively at airports and military bases, they are a primary source of drinking water contamination with PFAS. PFAS encompass approximately 15,000 chemicals, but only 0.001% of these have restrictions or maximum contaminant levels (MCLs) regulations. Although individual PFAS have been previously studied, less is understood about the effects of PFAS mixtures. The aim of this study is to assess the developmental toxicity and toxicokinetics of a mixture of environmentally-relevant PFAS in larval zebrafish, *Danio rerio*. As many PFAS have been shown to cause oxida-

tive stress, we also investigated the role of Nrf2, a transcription factor that controls the adaptive response to oxidative stress, in mediating these effects. **Methods:** A PFAS mixture was synthesized to mimic the composition and ratios of 27 PFAS previously identified in a legacy AFFF sample acquired through the Massachusetts Department of Environmental Protection, and another mixture with 6 PFAS commonly monitored (PFBS, PFHxS, PFOS, PFHxA, PFOA, PFNA). Homozygous Nrf2a wild-type and mutant (*nrf2a^{h318/-}*) with a mutation in the DNA binding domain crossed with *Tg(ptf1a:GFP)* and *Tg(iris:GFP)* fish were statically exposed to three different sub-lethal concentrations of the 27 PFAS and 6 PFAS mixture equivalent to 0.00005% of the 3% AFFF application concentration (197.52 ppb-low), 0.001% (4.11 ppm-medium), 0.0025% (10.07 ppm-high) and 0.1% methanol as a solvent control. At 4 days post-fertilization (4 dpf), larvae were assessed for fish length, spine shape, craniofacial malformations, pancreas length, islet area, yolk sac area, and pericardial area using brightfield and fluorescence microscopy. Blinded images were analyzed using Image J. PFAS concentrations in stock solutions, exposure media, and the 0- and 4-dpf larvae (normalized to wet weight) were measured by Sciex QTRAP 7500 with ¹³C₁₂ PFOS surrogate standard and respective corresponding internal standards. **Results:** Nrf2a wild-type and mutant zebrafish larvae showed dose-dependent decreases in fish length (*p* < 0.001) and endocrine islet area (*p* < 0.001). Nrf2a mutant fish had a greater decrease in the ratio of exocrine pancreas length to fish length with exposure to the 27 PFAS mixture, but not with 6 PFAS mixture. Internal larval tissue concentrations showed no significant difference between the wild-type and mutant fish, indicating that Nrf2a did not affect PFAS uptake. The PFAS body burdens were highest for sulfonated PFAS than carboxylated PFAS in both mixtures with PFOS, PFHxS, PFHpS, PFNS and PFOA, PFHxA, PFHpA, PFEA in the 27 PFAS mixture while in 6 PFAS mixture were PFOS, and PFHxA. Surprisingly, PFNA (in both mixtures) showed negligible internal concentration in zebrafish larvae. In the 27 PFAS mixture, the exposure media and internal concentrations were both negligible for PFNA, PFTA, and PFTDA—suggesting that carboxylic acids with higher molecular weight may potentially be less likely to cause PFAS-induced toxicity in a mixture context. **Conclusions:** Zebrafish, as a model organism, can shed light on the impacts of PFAS toxicity and toxicokinetics. PFAS mixtures affect pancreatic organogenesis in larval zebrafish, with Nrf2a playing a protective role in growth of the exocrine but not the endocrine compartment. The mixture of 27 environmentally-relevant PFAS was more toxic than the 6 PFAS mixture of those more commonly monitored for, despite the total sum of PFAS in each being comparable. This indicates that the composition of PFAS in an exposure may be more significant than the total concentration of PFAS, suggesting that the current assessments that measure only a few PFAS likely underestimate risk.

PS 4528 Methodological framework for enhancing the reliability of polymer plastic quantification in toxicological research

R. Herrera, M. E. Park, S. Patil, M. Garcia, R. Liu, E. Descher, J. Kingston, J. Kingston, L. Barela, M. MazloumiBakhshayesh, M. Campen, and E. El Hayek. University of New Mexico, Albuquerque, NM.

Background and Purpose: Micro(nano)plastics (MNP)s are ubiquitous in the environment and have recently been detected in human tissues, including the brain. Their ability to infiltrate biological systems raises concerns about toxicity and long-term health consequences. MNP exposure has been associated with organ dysfunction, reproductive and developmental toxicity, and neurotoxicity. Within the brain, lipids such as cholesterol, sphingomyelin, and docosahexaenoic acid (DHA) are critical for neuronal function. Alterations in lipid turnover or disruption of lipid balance are increasingly recognized as contributors to neurodegenerative disease. This study aims to simulate potential molecular mixtures between the major lipid classes in the brain and plastics by spiking cholesterol, sphingomyelin, and DHA with a mixed plastic polymer standard. We investigate how lipid-polymer mixtures influence molecular detections and how extraction techniques can be optimized to re-separate these components for accurate quantification by mass spectrometry. **Methods:** Our methodological approach employed sequential digestion using potassium hydroxide (KOH) followed by solvent washes (cyclohexane or nitric acid) to degrade lipids while preserving polymer integrity. Samples are then analyzed by pyrolysis gas chromatography-mass spectrometry (Py-GC/MS). **Results:** Our findings demonstrate that pure sphingomyelin generates up to 56% false-positive recovery of polyethylene (PE), which decreases to 7% following KOH digestion. Pure cholesterol produces up to 6% false-positive recovery, which decreases to 0.7% after KOH digestion. DHA increases from 1% false positive to up to 4% after digestion. **Conclusions:** Together, these results illustrate how endogenous brain lipids may interfere with MNP detection in biological matrices and provide a methodological framework for improving the reliability of polymer quantification in toxicological studies.

L. K. Heine¹, M. A. Esquibel¹, O. F. McDonald², A. M. Baca¹, G. A. Picha¹, B. B. Maes¹, M. A. Garcia¹, E. E. Hayek¹, J. J. Pestka^{2,3}, and S. Medina¹. ¹University of New Mexico College of Pharmacy, Albuquerque, NM; ²Department of Microbiology, Genetics, and Immunology, Michigan State University, East Lansing, MI; and ³Department of Food Science and Human Nutrition, Michigan State University, East Lansing, MI.

Background and Purpose: Microplastics (MPs) are persistent environmental pollutants that have emerged as a growing global health concern. Although MPs are widespread, the biological consequences of MP exposure remain poorly understood, particularly regarding their effects on the immune system. Macrophages play a central role in innate immunity; however, emerging evidence suggests they have limited capacity to phagocytose MPs, potentially leading to cellular dysfunction and dysregulated immune responses. The objective of this study was to evaluate the effects of polystyrene MPs on macrophage polarization and function using human and mouse macrophage cell models. **Methods:** THP-1 human monocytes were differentiated into macrophages with phorbol 12-myristate 13-acetate (PMA) and were polarized toward either M1 (via lipopolysaccharide, LPS) or M2 (via IL-4) phenotypes. Cells were then exposed to 1 µm or 5 µm polystyrene MPs at concentrations of 0, 10, or 100 µg/mL for up to six days. Various endpoints related to monocyte function and polarization were assessed such as cellular metabolic activity, phagocytic capacity, cytokine secretion, and pro-inflammatory gene expression. **Results:** We found that the highest concentration of MPs significantly suppressed THP-1 monocyte growth. Interestingly, exposure to MPs enhanced the metabolic and phagocytic activity of M1 macrophages, suggesting a heightened proinflammatory phenotype. Consistent with this, MP-treated M1 macrophages exhibited increased secretion of IL-1β and TNF-α following LPS stimulation. Conversely, MPs suppressed the secretion of the anti-inflammatory cytokine IL-10 in M2 macrophages, indicating impairment of a pro-resolving phenotype. **Conclusions:** Together, these findings suggest that MPs exacerbate inflammatory responses while suppressing anti-inflammatory pathways, thereby disrupting macrophage polarization dynamics. Complementary studies are currently underway to validate these findings using primary mouse alveolar macrophage-like models. Results from the present study provide important insight into the immunotoxicity of microplastics and will serve as a foundation for future mechanistic investigations.

PS 4530 Allergic Contact Dermatitis Model for Assessing Contaminated Microplastics Isolated by Nanomembrane Technology

A. Avila Oropeza, and L. DeLouise. University of Rochester School of Medicine and Dentistry, Rochester, NY.

Background and Purpose: Allergic Contact Dermatitis (ACD) is a prevalent inflammatory skin disease affecting approximately 15-20% of the U.S. population and is driven by allergen-specific T-cell activation. Although many allergens have been identified, the potential of microplastics (MPs) to influence allergic skin responses remains largely unexplored. MPs (1 µm-5 mm) are widespread environmental contaminants capable of adsorbing and transporting immune-activating agents such as persistent organic pollutants (POPs), heavy metals, and pathogens. While healthy skin serves as an effective barrier, MPs may penetrate through micro abrasions, follicles, or sweat glands, raising concerns about dermal exposure. Among these contaminants, 2,3,7,8-tetrachlorodibenzo-p-dioxin (TCDD) is a potent Aryl Hydrocarbon Receptor (AhR) agonist that regulates xenobiotic metabolism and skin homeostasis, whereas chronic activation by dioxins can cause pathologies such as sustained inflammation and chloracne. Nickel (Ni²⁺) is a common environmental pollutant and a leading cause of ACD. It is capable of penetrating the skin and eliciting proinflammatory cytokine release. Understanding how these contaminants interact on microplastic surfaces is key to evaluating their role in skin immunotoxicity. **Methods:** To examine how metal-POP co-contamination alters MP toxicity, 2-µm silicon nitride nanomembrane chips (SiMPore, Inc.) were used as a dual filtration and cell-culture platform. Negatively charged 5 µm polystyrene (PS) beads were soaked and aged in mixtures of nickel chloride (NiCl₂) and 1 nM TCDD to create contaminated microplastic (cMP) models. The mixtures were filtered through the nanomembrane chips to retain intact particles while maintaining their chemical and physical characteristics. HaCaT keratinocytes were then exposed directly to the filtered cMPs for 24 and 48 hours to assess cellular effects. Cytotoxicity was evaluated using the PrestoBlue cell viability assay, which quantifies metabolic activity via reduction of resazurin to the fluorescent compound resorufin, serving as an indicator of cell viability and mitochondrial function. Additionally, Inductively Coupled Plasma Mass Spectrometry (ICP-MS) was performed on filtered cMP samples to quantify the extent of Ni²⁺ adsorption (ng Ni²⁺/µg PS). **Results:** Preliminary data indicate that aged cMP containing PS + NiCl₂ + TCDD result in a significant decrease in cell viability, demonstrating enhanced cytotoxicity compared to PS + NiCl₂ alone or the negative control. This suggests that combined and aged pollutant exposure amplifies toxic effects on HaCaT cells. In parallel, preliminary ICP-MS analyses detected quantifiable levels of Ni²⁺ on the PS MPs which may contribute to the observed cellular responses. **Conclusions:** This work establishes a novel nanomembrane-based model for assessing how environmental contaminants interact on microplastic surfaces and influence skin cell responses. Ongoing analyses will clarify how Ni²⁺ and TCDD co-adsorption on MPs modulate AhR signaling, cellular viability, and potential pathways involved in allergic

contact dermatitis. Furthermore, these findings suggest that the surface chemistry of MP, combined with their ability to adsorb environmental pollutants like Ni²⁺ and TCDD, may alter their biological reactivity and potential to contribute to ACD pathogenesis. The nanomembrane filtration-cell culture system offers a powerful, loss-free platform to study microplastic-pollutant interactions under controlled conditions. Future studies will explore how these contaminated MP influence AhR activation, inflammatory cytokine release, and adaptive immune responses relevant to allergic skin disease in *in vivo* mouse models.

PS 4531 Microplastic exposure exacerbates atherosclerosis development in lean LDL receptor-deficient mice

T. Lin¹, J. Pan¹, N. Mya¹, Q. Ma², L. Sun², S. Tang¹, M. Campen³, H. Chen⁴, and C. Zhou¹. ¹UC Riverside, Riverside, CA; ²Boston Children's Hospital, Boston, MA; ³University of New Mexico Health Sciences, Albuquerque, NM; and ⁴Boston Children's Hospital and Harvard Medical School, Boston, MA.

Background and Purpose: Microplastics (MPs) emerge as ubiquitous environmental pollutants but the adverse effects of MPs on human health are still poorly understood. MPs can be detected in human atherosclerotic plaques and have been associated with a higher risk of cardiovascular disease (CVD) and stroke in humans. However, the impact of MP exposure on the cardiovascular system remains elusive. This study aimed to investigate the effects of MP exposure on atherosclerosis development in low-density lipoprotein receptor-deficient (LDLR^{-/-}) mice. **Methods:** Four-week-old male and female LDLR^{-/-} mice were fed a semisynthetic low-fat diet and exposed to 10 mg/kg body weight MPs via daily oral gavage for 9 weeks before euthanasia. Atherosclerotic lesions in the aortic root and brachiocephalic artery of these mice were analyzed. Single-cell RNA sequencing (scRNA-seq) of the whole aorta was performed to characterize MP-induced changes in cell populations and transcriptional programs. *In vitro* assays using murine and human endothelial cells (ECs) were conducted to investigate the effects of MP exposure on EC gene expression. **Results:** Male and female LDLR^{-/-} mice fed the low-fat diet did not develop obesity phenotype and exposure to MPs did not affect adiposity and circulating lipid profiles in those lean mice. Intriguingly, MP exposure led to significantly increased atherosclerosis in male but not female LDLR^{-/-} mice. scRNA-seq analysis revealed that exposure to MPs affected the proportions and cellular processes of key atherosclerosis-related cell types, especially ECs. Consistently, MP exposure elicited pro-atherogenic gene expression in murine and human ECs *in vitro*. **Conclusions:** Our results demonstrate sex-specific atherogenic effects of MPs in a suitable laboratory animal model and the impact of MP exposure on EC atherogenic gene expression *in vitro*. These findings contribute to our understanding of the association between MP exposure and increased CVD risk in humans.

PS 4532 Microplastics in Edible Tissues of Commercial Fisheries sampled from Major Marine Fish Landing Sites across Coastal States in Nigeria

T. O. Sogbanmu, D. G. Arokoyu, and O. O. Ogunfeiti. University of Lagos, Lagos, Nigeria.

Background and Purpose: There is a growing environmental and public health concern regarding plastic pollution, particularly the accumulation of microplastics (MPs) in marine ecosystems, which has significant implications for aquatic ecosystem and human health. In this study, MPs were examined in the muscle tissues of predominant commercial fish and benthic invertebrate species sampled from Nine (9) major marine fish landing sites across six (6) coastal states in Nigeria. **Methods:** Following ethics approval for the study, field expeditions were embarked upon in the wet season (May and June 2025) to identify and sample predominant commercial fish and benthic macroinvertebrate species landed from the ocean across major landing sites in Lagos (Epe, Apapa, Victoria Island and Badagry), Ogun (Iwopin), Ondo (Aiyetoro), Rivers (Oyokoroto), Akwa Ibom (Ibaka) and Cross River (Nsidung) states, Nigeria. The fisheries were transported to the laboratory on ice where taxonomic identification and morphometrics were done before extraction of the tissues. Thereafter, the tissues were digested, MPs therein were extracted, identified and counted with the aid of a stereomicroscope coupled with a digital camera following referenced protocols. The identified MPs were sorted by morphotypes, colour and quantified before spectroscopic identification of the polymers using ATR-FTIR. **Results:** The MPs count in the fish muscle tissues ranged from nd in the Blue Spot Mullet (*Mugil cephalus*) sampled from Aiyetoro, Ondo state to 96.6 particles/g muscle tissue in the Yellow Croacker (*Larimichthys polyactis*) sampled from Badagry in Lagos state. Fragments were the most preponderant MP morphotype followed by fibres and foam while the dominant colours were black, yellow, brown, white and blue. Sole fish (*Solea solea*) had the highest occurrence of fish species across four (4) (Epe, Apapa (Lagos), Nsidung (Cross River) and Ibaka (Akwa Ibom)) of the nine sites with corresponding highest MPs counts and colours (yellow, brown, white and black) in the tissues. MP counts in the macroinvertebrate muscle tissues ranged from 0.4 particles/g muscle tissues in the Guinean mantis shrimp (*Squilla aculeata*) - 43.9 particles/g muscle tissue in the Tiger prawn (*Penaeus monodon*). Fragments and fibres were the predominant MPs morphotypes while black, yellow and brown were the dominant colours in the macroinvertebrate species. Atlantic

Blue Crab (*Callinectes sapidus*) had the highest dominance of macroinvertebrates across seven of the nine sites while Tiger prawn (*P. monodon*) though less dominant, had the highest count of MPs observed across four sites. Polymer characterization of the MPs using ATR-FTIR are ongoing. **Conclusions:** Our results reveal for the first time, the occurrence of MPs in edible muscle tissues of commercial marine fisheries landed across coastal states in Nigeria. The high MPs counts, dominant colours observed (which points to single use plastic sources) poses a great concern to human and aquatic ecosystem health and calls for prompt action to curb plastic litter flows as well as curb dumping at sea.

PS 4533 Assessing the Influence of Nano-Plastic Particle Size on Developmental Toxicity, Bio-Distribution, and DNA Damage Using Chicken Embryos

F. Yasmin, and C. Wu. University of Delaware, Newark, DE.

Background and Purpose: The World Health Organization emphasizes the importance of quantifying human exposure to micro/nanoplastics (MNPs) <10 µm because the negative health impacts of MNPs increase with decreased particle sizes. Most of the existing studies only address MPs >10 µm, but these MPs are probably excreted directly. MNPs have been detected in the human body, including in human placentas and infant feces, raising particular concern over their effects in sensitive developmental periods. The purpose of this study is to evaluate the developmental toxicity, biodistribution, and DNA damage with three different sizes of commercial fluorescence labeled polystyrene nanoplastics (PS NPs at 50, 100, 500 nm) in early life stage using a chicken embryo model. **Methods:** The PS NPs were injected at day 6 of chicken embryos at concentrations of 1 or 10 µg/ml, and the liver samples were collected on day 18 for measurement of oxidative stress and developmental toxicity endpoints, including LSI (Liver somatic index) and relative REEW (ratio to egg weight to embryo weight). Additionally, mortality was recorded. The biodistribution of the NPs in three different tissues (chicken liver, heart, and brain) was determined by injecting the NPs on day 16, and the tissue samples were collected 24 hours after injection and, fluorescence intensity of the NPs was measured using a plate reader. DNA damage was assessed by comet assay for PS NPs 50 nm and 100 nm. **Results:** The highest mortality (64%) is detected in the chicken embryos injected with PS NPs 50 nm at the concentration of 10 µg/ml. The PS NPs at 50 nm at the concentration of 1 µg/ml induced the highest oxidative stress compared to the control group. The dose dependent mortality of PS 50 nm treatments revealed that the embryonic mortality increased from 28% at 1 µg/ml to 64% at 10 µg/ml. The LSI was lowest in the embryos exposed to PS 100 nm at the concentration of 1 µg/ml, although this difference is not statistically significant. The REEW index determined for the PS 50 nm treatment at the concentration of 1 µg/ml is lowest compared to the control group. These NPs (PS 50 nm, 100 nm, and 500 nm) are mostly deposited in the brain tissues, with the relative abundance when compared to findings in other tissues. The PS NPs 50 nm treatment has induced the highest DNA damage (25.60%, statistically significant), while the PS NPs 100 nm has induced the second highest DNA damage around 22.52%. **Conclusions:** The smallest MNPs, PS 50 nm, caused higher toxicity concern. The PS 50 nm induced greater developmental concern by lowering the REEW. The dose-dependent mortality in the PS 50 nm group demonstrated proportional mortality in response to the doses. The PS 50 nm at the lower dose caused the highest oxidative stress. Additionally, PS NPs 50 nm have shown greater biodistribution in the liver, heart, and brain compared to the PS 100 nm and PS 500 nm. The PS 50 nm caused the highest DNA damage compared to PS 100 nm. The smaller the size, the higher the toxicity concern.

PS 4534 Assessing the toxicity of fragmented virgin and UV-aged polyamide microplastics on human tissue-derived intestinal organoids

M. Kloukinit^{1,2}, M. G. Nooijens¹, F. J. van Schooten², I. Kooter¹, E. van de Steeg¹, L. Parker¹, and H. Braakhuis¹. ¹Netherlands Organization for Applied Scientific Research, TNO, Utrecht, Netherlands; and ²Department of Pharmacology and Toxicology, NUTRIM, Maastricht, Netherlands.

Background and Purpose: Ingestion is considered to be one of the main routes of human exposure to microplastics (MPs), and their potential impact on intestinal health has recently gained significant attention. While MPs have been detected in feces and shown to accumulate in the gut, their toxicity towards intestinal tissues remains poorly understood. Most of the studies often combine simplified models with pristine, uniformly spherical particles, limiting environmental and human relevance. In addition, toxicity testing usually focuses solely on the polymer itself, overlooking that these particles are complex mixtures containing multiple additives that may leach out and cause their own effects. **Methods:** In this study, the toxicity of fragmented polyamide (PA) MPs of two size classes (5 and 10 µm) and their leachates was investigated. Human tissue-derived intestinal organoids were exposed during their growth phase (6 days) to both virgin and UV-aged PA particles, in a dose-response setup (1-100 µg/mL). Copper (II) oxide (CuO) and titanium dioxide (TiO₂) particles served as reference particles. Changes in morphology were tracked through brightfield imaging, while their viability was assessed at the end of the exposure through a cell proliferation (MTS) assay. **Results:** Virgin particles exhibited a

greater overall toxicity compared to aged particles, significantly impairing organoid growth (in terms of size), morphology, and metabolic activity. A particle size effect was also observed. Notably, 5 µm virgin PA particles reduced metabolic activity by 25% even at the lowest concentration tested (1 µg/mL). No significant differences compared to the control group were observed at the same dose for the 10 µm PA. The highest potency of the smallest particles was evident for the aged particles as well, with the viability dropping to 65% at the highest dose (100 µg/mL), compared to 72% for the 10 µm particles. Since the aged particles appeared less potent, it was hypothesized that these effects were driven by chemical additives, which potentially are lost during the aging and milling process (wet milling in 1-propanol). To test this, both virgin and UV-aged PA particles were incubated in 1-propanol for 39 days at room temperature to create a worst-case leaching scenario. Preliminary data show that exposure to the leachate from the aged particles reduced metabolic activity without altering morphology, suggesting that particle-associated chemicals contribute to the observed toxicity. The observed toxicity of the leachate of the UV-aged MNPs suggests that the aging process increases the leaching of chemicals during milling, making the particles themselves less potent, as observed when testing the UV-aged MNPs. **Conclusions:** Our findings highlight the importance of approaching MPs as a mixture, giving emphasis on their physicochemical properties and aging state in order to assess their hazard potential and mode of action. Ongoing research is evaluating the leaching potency of the particles (virgin and aged) in cell culture medium, 1-propanol, and the role of genes associated with organoid development, such as the Hoxa family, on the effects observed.

PS 4535 Neurotoxic effects of pristine and aged micro- and nanoplastics in vitro

E. Kasteel, S. van Kaam, S. Dams, P. Wopken, and R. Westerink. Institute for Risk Assessment Sciences (IRAS), Faculty of Veterinary Medicine, Utrecht University, Utrecht, Netherlands.

Background and Purpose: Micro- and nanoplastics (MNPs) are increasingly recognized environmental contaminants to which humans are widely exposed through food, water, air, and consumer products. Their detection in human blood suggests systemic distribution and raises concerns about potential accumulation in sensitive organs, including the brain. Although emerging studies indicate that MNPs can reach the central nervous system, the extent, mechanisms, and consequences of brain exposure remain poorly understood. Environmental aging processes may further modify particle properties and toxicity, yet aged MNPs remain underexplored in a human-relevant context. This study therefore examines whether pristine and aged MNPs can interact with the blood-brain barrier (BBB) and affect neuronal function. **Methods:** A human *in vitro* BBB model using human induced pluripotent stem cell (iPSC)-derived brain microvascular endothelial cells (BMECs) cultured on transwell inserts was used to evaluate MNP interactions and barrier function following exposure to pristine and UV-aged PVC, PET, PA and PP particles of varying sizes (10 µg/mL). In parallel, fluorescent PS beads (200 nm and 1 µm) were included to visualize cellular uptake by confocal microscopy. BBB integrity and function were evaluated via transendothelial electrical resistance (TEER), sodium fluorescein permeability, and BMEC metabolic activity. Potential neurotoxic effects were assessed in primary rat cortical cultures exposed to the same MNPs (10 µg/mL), with neuronal activity monitored using multi-well microelectrode array (MEA) recordings after short-term (30 min) and prolonged (21 days) exposure. Neuroinflammatory responses were quantified in BV2 microglial cells by measuring tumor necrosis factor-alpha (TNFα) and interleukin 6 (IL-6) secretion using an enzyme-linked immunosorbent assay (ELISA). **Results:** PS beads (200 nm and 1 µm) were internalized by BMECs, indicating direct particle interaction with the BBB. Across four days of exposure, none of the tested pristine or aged MNPs altered barrier integrity, barrier permeability or metabolic activity. Acute MNP exposure produced no changes in neuronal activity for PVC, PET, PA or pristine PP. UV-aged PP (1-5 and 5-10 µm) reduced neuronal activity, however, responses remained within benchmark ranges. Following 21-day exposure, MNPs induced only minimal changes in network activity. Pristine and UV-aged PET (5-10 µm) and their leachates induced small increases in network bursting, yet all changes remained within expected biological variability. None of the tested MNPs induced TNFα or IL-6 secretion in BV2 microglia after 24-hour exposure. **Conclusions:** This work shows that selected pristine and aged MNPs interact with BBB and neuronal models, but do not cause significant disruption of barrier function, neuronal network activity, or microglial cytokine secretion at 10 µg/mL. Detected changes in neuronal activity were modest and not consistently indicative of toxicity. Collectively, these results provide early evidence that MNPs exert limited neurotoxic and neuroinflammatory effects under the conditions tested, while emphasizing the need for continued research into particle-specific responses and long-term exposure scenarios.

G. Kaur¹, M. Faizan¹, F. Effah¹, A. D. Decker², M. A. Garcia², M. J. Campen², and I. Rahman¹. ¹University of Rochester Medical Center, Rochester, NY; and ²University of New Mexico Health Sciences, Albuquerque, NM.

Background and Purpose: Airborne micro- and nano plastics (MNPs), generated from synthetic textiles, vehicle tires and plastic wastes, are omnipresent in the environment and known to deposit in human lungs. Bioaccumulation of MNPs in lung tissues has been studied, but effect of tobacco smoking on deposition is not well understood. Tobacco smoke is known to contain heavy metals which can get adsorbed to the MNP surface, leading to increased environmental bioavailability. We hypothesized that smoking leads to enhanced chelation of heavy metals with airborne MNPs leading to accentuated lung bioaccumulation, thereby leading to lung pathologies. **Methods:** Age (20-75 years) and sex-matched archival lung tissue samples from smokers (n = 9) and non-smokers (n = 10) were procured and quantified to assess: (a) the levels of MNPs by pyro-GC/MS and (b) heavy metals by ICP-MS. Furthermore, to establish if there exists a correlation between MNP deposition and disease occurrence in current smokers, tissue samples from age-matched patients with COPD (n = 4) and IPF (n = 4) underwent pyro-GC/MS analyses. **Results:** A relatively higher level of MNPs were found in the lungs of smokers (43.67 mcg/gm) as compared to non-smoker (34.53 mcg/gm) upon pyro-GC/MS analyses. We observed a marked increase in the levels of polyethylene (PE; p < 0.0076), polycarbonate (PC; p < 0.0947) and nylon6 (N6; p < 0.0653) polymers in the lungs of smokers as compared to non-smokers. Metal analyses showed a significant (p < 0.0001) increase in the levels of cadmium (Cd) in the lungs of smokers with the levels of deposited Cd being more pronounced for female smokers. Importantly, we observed a strong correlation (p < 0.05) between the amounts of accumulated PE and levels of Cd in the lungs. Pyro-GC/MS analyses did not reveal any relation between MNP deposition and disease occurrence in our study. Furthermore, little to no change in the level of deposited MNPs was observed in the lungs of current versus ex-smokers in disease cohorts. **Conclusions:** Overall, our results show that smoking promotes bioaccumulation of certain MNPs (PE) with heavy metals (Cd) which may lead to adverse lung effects in smokers.

PS 4537 Utilizing Single Particle ICP-MS (spICP-MS) to Measure Uptake, Depuration, and Transfer of Polydispersed Nano-Microplastics (NMPs) in *Daphnia magna*

C. Hietpas¹, J. Walker¹, E. Schneiderjan¹, E. Gray¹, J. Ravnille², H. Fairbrother³, and J. Crago¹. ¹Texas Tech University, Lubbock, TX; ²Colorado School of Mines, Golden, CO; and ³Johns Hopkins University, Baltimore, MD.

Background and Purpose: Current nano- and microplastic (NMP) research often lacks environmental relevance because they rely on spherical, monodispersions rather than the irregular, polydispersed fragments common in nature. As a result, most NMP uptake toxicity studies rely on nominal exposure concentrations calculated from single size particle mass rather than true particle quantification. This analytical gap constrains interpretation of dose-response relationships of NMP based on particle number and hinders assessment of how environmentally-relevant polydispersions of NMPs influence uptake, translocation, and clearance within an organism. To address this, we synthesized a metal-doped tantalum ethoxide poly(methyl methacrylate) (Ta-PMMA) polydispersion (~150-3350 nm) allowing for individual particle measurements in media and organisms using single-particle inductively coupled plasma mass spectrometry (spICP-MS). The goal of this study was to quantify particle uptake, depuration, and maternal transfer of a polydispersed solution of Ta-PMMA NMPs in the aquatic filter feeder *Daphnia magna* utilizing single particle spICP-MS. We hypothesized that (i) polydispersed NMPs exhibit distinct uptake and depuration kinetics compared to monodispersed nanoparticles, (ii) uptake and depuration rates differ among particle size fractions within a polydispersion, and (iii) chronic (21-day) exposures to Ta-PMMA exhibit a dose-dependent increase in particle number in neonates (offspring) and decrease in neonate number. **Methods:** We utilized the novel technique of synthesizing the metal doped Ta-PMMA polydispersion, in which individual particles could be distinguished using spICP-MS. This allowed for quantification of particle number uptake through time across size classes in *D. magna*. First, we exposed *D. magna* to 50 and 0.5 µg/L of Ta-PMMA particles for 24 hours to measure active uptake and determine sizes up took. Second, we exposed of *D. magna* to 50 µg/L of either Ta-PMMA polydispersion or 1.5 µg/L 200 nm silver NP monodispersion for 24 hours, followed by a 24 h depuration in clean media. For this, a subset of *Daphnia* were collected at 3, 6, 12, 18, and 24 h (particle exposure), followed by 30, 36 and 48 h (depuration). This was to compare monodispersion versus polydispersions and individual versus grouped polydispersion exposures. Next, we wanted to explore a chronic low dose exposure and look at potential maternal transfer of particles to neonates. Thus, adult *Daphnia* were exposed for 21 days to 0.1-1 µg /L of Ta-PMMA, where average clutch number, particle size, and number per neonate clutch was measured. **Results:** In the first experiment, *D. magna* exposed to 50 and 0.5 µg/L PMMA ingested an average of 66,420 and 850 particles per organism, respectively. Evaluation of NMP distributions in egg water relative to *D. magna* suggest these organisms may be able to size select NMP particles from a polydisperse exposure as there was a difference between media relative to *D. magna* slopes with NMPs >1 µm. This difference indicates that

D. magna do not take up the expected proportion of large particles from egg water. Surprisingly, the 24 h uptake-depuration study indicated that uptake of the polydispersed Ta-PMMA peaked at 6 hours, suggesting that *Daphnia* ingested particles and then stopped eating to allow for depuration before exposure was complete. There was minimal size-specific differences ($k_d < 1 \mu\text{m}$: 0.0744 h⁻¹; $> 1 \mu\text{m}$: 0.0711 h⁻¹) in depuration rates in *D. magna* exposed to the polydispersion. Finally, the 21-d chronic study of showed that particles were visually detected in spawned neonates as low as 100 ppt and that neonate clutch production decreased at concentrations as low as 250 ppt (p = 0.0303). **Conclusions:** These findings demonstrate the effectiveness of metal-tagged NMPs and spICP-MS in quantifying NMP uptake in aquatic organisms at environmentally relevant concentrations. This highlights the importance of polydispersions in uptake and depuration studies as it demonstrated the differences between polydispersed and monodispersed uptake and depuration patterns. This work also provides insight into how realistic NMP exposures affect aquatic invertebrates and their progeny.

PS 4538 Oral Exposure to Polyethylene microplastics aggravates steatosis and metabolic dysfunction

F. A. Ampadu¹, W. Jung², N. Y. Patil¹, I. Rus², T. Oh², and A. D. Joshi¹. ¹Texas A&M College of Veterinary Medicine & Biomedical Sciences, College Station, TX; and ²University of Oklahoma Health Sciences Center, Oklahoma City, OK.

Background and Purpose: Microplastics (MPs) are increasingly recognized as a global health concern with health-related annual economic losses of approximately \$1.5 trillion. MPs can enter the human body through ingestion, inhalation, and dermal contact accumulating in various organs and leading to multiple organ toxicities. Previous studies have shown critical exposure effects, including inflammation, oxidative stress, neurotoxicity, and metabolic dysfunction. Polyethylene (PE) is the most abundant polymer detected in humans. It is also present in raw and treated drinking water, bottled mineral water and in various forms, including buckets, crates, bags, films, sheets, bubble wraps, and toys. However, its effect on hepatotoxicity and metabolic dysfunction has not been comprehensively unraveled. Our present study investigates the toxicopathological effects and mechanism of PE induced hepatotoxicity. **Methods:** We assessed the effects of seven commonly used MPs - Polyethylene (PE), Polyvinylidene chloride (PVDC), Polyethylene terephthalate (PET), Polypropylene (PP), Polyamide-6 (PA-6), Polystyrene (PS), Polyvinyl chloride (PVC) on cell viability using MTT assay in isolated mouse primary hepatocytes. Furthermore, the role of oral exposure to polyethylene (PE) was investigated using *in vivo* models. Male C57BL6 (WT) mice were fed daily with 2 mg PE (10 - 150 µm diameter) per day using oral gavage for 8 weeks. Additionally, to determine the effects of PE microplastics on metabolic dysfunction-associated fatty liver disease (MASLD), male mice fed with a high-fat, high-fructose, high-cholesterol diet (HFHFC diet) were orally administered with PE for 8 weeks. Metabolic studies were performed. Moreover, combined bulk and spatial transcriptomic analyses evaluated gene expression patterns and cell type heterogeneity. **Results:** PE treatment showed significantly reduced cellular metabolic activity, resulting in only 78% viability of mouse primary hepatocytes, as measured using the MTT assay. *In vivo* oral administration of PE caused a significant increase in normalized body mass and liver-to-body weight ratio in HFHFC diet-fed groups compared to the HFHFC diet-only cohort. PE ingestion resulted in aggravated steatosis, inflammation, and liver injury. Bulk and spatial transcriptomic analyses revealed that PE resulted in hepatic dysfunction in mice fed on a control or HFHFC diet, driving both globally and spatially distinct transcriptional alterations. Spatial transcriptomics uncovered the cell-type heterogeneity and gene expression patterns masked in bulk analyses. Spatial clustering uncovered inflammatory hotspots characterized by reduced cellular diversity and distinct PE-responsive gene signatures. Among these, nuclear receptor signaling specifically Ppara emerged as a key regulator. **Conclusions:** The present study demonstrated that oral exposure to PE microplastics resulted in hepatic injury and inflammation. Moreover, in a diet-induced MASLD model, PE treatment aggravated steatosis, inflammation, and liver injury. Mechanistically, PE exposure modulated nuclear receptor signaling, with Ppara as a key regulator of hepatotoxicity. These findings offer new insights into how PE disrupts hepatic homeostasis and underscore the value of spatial transcriptomics in elucidating environmental impacts on tissue organization and gene expression regulation.

PS 4539 Bayesian Physiologically Based Pharmacokinetic (PBPK) Modeling Integrated with Particle Dosimetry to Predict Inhalation Exposure and Biodistribution of Airborne Microplastics in Humans

G. Li^{1,2}, A. Ukabamichael³, Y. Chen^{1,4}, and W. Chou^{4,3}. ¹National Institute of Environmental Health Sciences, National Health Research Institutes, Zhunan, Taiwan; ²Institute of Analytical and Environmental Sciences, National Tsing Hua University, Hsinchu, Taiwan; ³Environmental Toxicology Graduate Program, University of California, Riverside, Riverside, CA; and ⁴Department of Environmental Sciences, University of California, Riverside, Riverside, CA.

Background and Purpose: Airborne microplastics (MPs) have emerged as contaminants of increasing concern due to their widespread presence and potential human health impacts. While ingestion exposure has been relatively characterized, the internal distribution of inhaled MPs remains poorly understood. This study aims to develop a human inhalation PBPK model for MPs, extrapolated from the oral PBPK model previously developed in mice, to quantitatively predict absorption, distribution, and clearance following inhalation exposure. **Methods:** Atmospheric MP data were systematically compiled from peer-reviewed studies reporting particle number, size, shape, and polymer type characterized by μ FTIR, Raman spectroscopy, and pyrolysis-GC/MS. Particle number concentrations were converted to mass-based units using polymer densities and geometric assumptions. The MPPD model was applied to estimate size-dependent deposition efficiencies across the nasal, tracheobronchial, and alveolar regions, accounting for human breathing patterns and physiology. The resulting deposition fluxes were used as inputs to a Bayesian-calibrated PBPK model simulating absorption, systemic translocation, and clearance of MPs across major organs and tissues. Bayesian inference was employed for probabilistic parameter estimation, uncertainty quantification, and cross-route extrapolation from oral to inhalation exposure scenarios. **Results:** Integration of the MPPD and PBPK models enabled quantitative prediction of MP deposition and internal biodistribution across a wide range of particle sizes. The Bayesian calibration improved parameter convergence and uncertainty characterization under data-limited conditions. Model simulations produced physiologically consistent retention and systemic distribution patterns, with evaluation datasets showing observed data points largely within the 95% credible intervals of simulations. **Conclusions:** This integrative Bayesian PBPK modeling framework provides a mechanistic and quantitative approach for evaluating biodistribution and internal exposure of inhaled microplastics in humans. By combining particle dosimetry with Bayesian uncertainty analysis, the model enables extrapolation from oral to inhalation exposure and supports human health risk assessment for airborne microplastics.

PS 4540 The role of microplastic oxidation in promoting inflammation in lung cells

R. L. Kendall, J. M. Albright, M. G. Miller, R. F. Hamilton Jr., and A. Holian. University of Montana, Missoula, MT.

Background and Purpose: Micro- and nanoplastics (MNP) are ubiquitous environmental contaminants and their accumulation has been reported throughout the body. While their precise contributions to adverse health outcomes remains unclear, the growing evidence of respiratory exposures highlights the urgent need to define MNP's effects on lung macrophages and epithelial cells. MNP have previously been reported to initiate ROS and inflammation in lung cells; however, dosing, plastic type, and duration of exposure often result in contradictory reports. As such, the mechanisms of MNP-caused cell dysfunction remain poorly defined. Here, the effects of four MNP and their ultraviolet A (UVA) irradiated counterparts was evaluated in both macrophages and epithelial cells to define mechanisms and highlight the importance of environmental oxidation in the bioactivity of microplastics. **Methods:** Polyethylene terephthalate (PET), low density polyethylene (LDPE), high density polyethylene (HDPE), and polystyrene (PS) of a 1-5 μ m size range were purchased from Nanochemazone, washed with 70% EtOH, and allowed to dry overnight. PET, LDPE, HDPE, and PS were exposed to UVA (365nm) for 72 hours to mimic environmental exposure to sunlight (α_{ox}). MNP and MNP $_{ox}$ were characterized by SEM and Raman microscopy. Cell uptake of MNP/MNP $_{ox}$ was confirmed with flow cytometry and laser scanning confocal microscopy in murine *ex vivo* cultured macrophages and murine C-10 epithelial cells. Bioactivity of MNP/MNP $_{ox}$ was evaluated in macrophages and epithelial cells by quantifying ROS, cell death, lysosomal function, and cytokine release. Cells were exposed to MNP/MNP $_{ox}$ with and without LPS. 1 μ g/mL, 10 μ g/mL, 100 μ g/mL, and 1,000 μ g/mL doses of MNP/MNP $_{ox}$ were used for 24 or 48 hours. mRNA expression of NF κ B and NQO1 were evaluated in MNP/MNP $_{ox}$ exposed cells and optimized doses. MNP/MNP $_{ox}$ uptake by macrophages and epithelial cells was prevented with actin polymerization disrupter, Cytochalasin D, to confirm necessity of uptake to observed biological effects. Lysosomal function of MNP/MNP $_{ox}$ treated macrophages was evaluated with Lysotracker Red. **Results:** Raman microscopy of MNP $_{ox}$ demonstrated chemical changes as compared to pristine MNP, with PET $_{ox}$ showing broadening and dampening of peaks compared to PET at the corresponding wavenumber. PS $_{ox}$ showed the next greatest change by Raman spectra, while LDPE and HDPE showed subtle but notable changes to spectra with oxidation. In contrast, SEM showed no evident structural differences between pristine and oxidized MNP. PET and LDPE plastic fragments showed irregular shapes with more fragmented edges, while HDPE and PS demonstrated a more spherical

structure. Macrophages showed a slower uptake of MNP compared to crystalline silica (1.5 μ m) as indicated by change in median side scatter with flow cytometry. Oxidation enhanced the biological effects of the MNP on macrophage function with demonstrable increases in cell death observed with PET $_{ox}$ and LDPE $_{ox}$ compared to pristine PET or LDPE respectively. **Conclusions:** As MNP are so widely distributed this work helps further refine the toxicological parameters for relevant evaluations of MNP effects in biological systems. This study highlights the necessity of examining a variety of MNP polymer types in toxicological studies. Furthermore, it shows that oxidation of MNP enhances the biological effects of MNP, demonstrating the need for proper oxidative protocols in MNP research to more closely replicate true to life exposure scenarios. The research shown here builds upon the current knowledge of MNP toxicity and enhances our understanding of dosing and duration, and the contributions of chemical structure to bioactivity.

PS 4541 Chylomicron-Mediated Translocation of Oxidized Nano- and Microplastics into the Circulatory System and Human Heart Tissue

M. MazloumiBakshayesh¹, L. Lucchini¹, L. R. Barela¹, R. M. Clark¹, D. F. Gallego¹, G. Herbert¹, E. Risotto-Urbancowicz¹, J. G. Begay¹, S. Patil¹, P. Massie¹, B. E. Baird¹, E. Y. Suh¹, C. Cevering¹, E. Rowland¹, M. M. Vilay¹, R. M. Taylor¹, M. E. Park¹, R. M. Smith¹, E. El Hayek¹, R. R. Rama R. Gullapalli¹, B. E. Bleske¹, J. G. In¹, T. Hsiai², M. Garcia¹, and M. Campen¹. ¹The University of New Mexico, Albuquerque, NM; and ²University of California, Los Angeles, Los Angeles, CA.

Background and Purpose: Rising global concentrations of environmental microplastics and nanoplastics (MNPs) raise significant concerns regarding human exposure and long-term health outcomes. Previous studies from our group demonstrated widespread MNP deposition across multiple organs. In this study, we investigated the mechanisms underpinning intestinal absorption and systemic transport pathways that enable MNP entry into the circulatory system. **Methods:** MNPs primarily enter the human body through ingestion of contaminated food and water. We hypothesized that nanoplastics, which have comparable chemical structure to free fatty acids and bind to monoglycerides, will become packaged within the small intestine into chylomicron complexes by enterocytes. Using fluorescently labeled MNPs of varying sizes, we observed that gavaged 500 nm polystyrene particles could be found co-localized in the chylomicron fraction of serum but not in VLDL/IDL/LDL fractions 4h post exposure. Interestingly, 1 μ m particles were not detected in any fraction of the serum. These findings suggest a size-dependent mechanism of MNP trafficking within chylomicrons. **Results:** Further work in human cadaver samples has been initiated to confirm that MNPs enter lacteals, pass through mesenteric lymphatic vessels, and merging into the thoracic duct before finally draining into the left subclavian vein, the gateway to the circulatory system. We quantified the MNP burden and confirmed their presence within lipid-dependent cardiac tissue samples obtained from 24 different human hearts using pyrolysis gas chromatography-mass spectrometry (Py-GC/MS). MNPs were further confirmed by complementary analytical techniques including Fourier-transform infrared (FTIR) spectroscopy, Raman spectroscopy, and transmission electron microscopy (TEM). **Conclusions:** Collectively, our data supports a novel mechanistic model in which oxidized nanoplastics exploit lipid absorption pathways to reach systemic circulation and partially accumulate in cardiac tissue. These findings underscore the need for further investigation into MNP-lipid interactions and their implications for cardiovascular health.

PS 4542 Microplastics Exhibit Region Specific Retention in Kidney Tissue and Are Detected in Human Urine

R. M. Taylor¹, H. Steichen¹, S. Stoker¹, A. Arteaga Leon¹, H. H. Rahman², and M. J. Campen¹. ¹University of New Mexico Health Sciences Center, Albuquerque, NM; and ²New Mexico State University, Las Cruces, NM.

Background and Purpose: Micro- and nanoplastics (MNPs) have been recently detected in human biofluids and organs. However, it is unknown whether the kidney functions solely as a clearance organ or also as a site of MNP retention and injury. Here, we evaluated the occurrence, polymer composition, and spatial distribution of MNPs in human urine and mammalian kidney tissue to determine region-specific deposition patterns relevant to renal function. **Methods:** Fresh human urine samples were processed using four isolation workflows (centrifugal ultrafiltration, quartz filtration with and without basic digestion, and combined methods). Microplastics were quantified using Pyrolysis-GCMS targeting polymer-specific thermal fragments and TEM. Porcine kidneys were dissected into cortex and medulla regions and analyzed using identical methods following contamination-controlled digestion. **Results:** Five major polymers, polyethylene (PE), polypropylene (PP), polyethylene terephthalate (PET), acrylonitrile butadiene styrene (ABS), and styrene-butadiene rubber (SBR), were consistently detected in urine above the limit of quantification (LOQ). PE was dominant, exceeding 20 μ g/mL in some individuals; PET was also routinely measured across multiple human samples. Kidney mapping revealed non-uniform distribution: PE concentrations were ~1.3-fold higher in cortex (564 μ g/mg) than medulla (435 μ g/mg), with similar cortical enrichment observed for PP and ABS. PET was detectable in cortex (2.6 μ g/mg) but absent in medulla thus far, suggesting selective retention of environmentally relevant polymers with adsorbed

coronas. **Conclusions:** These findings provide evidence that renal handling of MNPs is polymer-dependent and region-specific, consistent with glomerular filtration threshold effects and potential proximal tubule uptake. Combined with urinary excretion levels, these patterns position the kidney as both a sentinel organ and an active site of MNP interception. Ongoing work will evaluate correlations between regional polymer burden, glomerular filtration rate, and molecular markers of renal injury to define mechanistic pathways of plastics-induced nephrotoxicity.

PS 4543 Prenatal Exposure to Polyethylene Nanoplastics: Preliminary Evidence of Accumulation and Potential Neurodevelopmental Effects in Human Brain Organoids

L. Trovò¹, A. Einhorn¹, S. Pati², E. El Hayek², and L. M. Iakoucheva¹. ¹University of California San Diego, San Diego, CA; and ²University of New Mexico, Albuquerque, NM.

Background and Purpose: Nanoplastics are emerging environmental contaminants that are increasingly detected in human tissues and biological fluids. Their nanoscale size raises the possibility of placental transfer and fetal exposure during critical windows of development. However, their potential impact on human brain development remains poorly understood. This study aims to investigate whether polyethylene (PE) nanoplastics accumulate in developing neural tissues and whether such accumulation could perturb early neurodevelopmental processes. Specifically, we examined the distribution of PE nanoparticles within human brain organoids as a model for fetal brain development. **Methods:** Human pluripotent stem cell-derived cortical organoids were exposed to fluorescently labeled PE nanoparticles (50-65 nm). Nanoparticle localization was assessed using confocal microscopy on both optically cleared whole organoids and cryosections. Accumulation was quantified within neural rosette regions, representing early neuroepithelial structures. Organoid diameter and growth dynamics will be monitored to detect morphological changes following exposure. To confirm nanoplastic identity and aggregation, transmission electron microscopy (TEM) and dynamic light scattering (DLS) analyses are being conducted. Cytotoxicity and apoptosis markers will be analyzed to evaluate potential neurotoxic effects of PE exposure. **Results:** Preliminary imaging data indicate that PE nanoplastics are internalized by brain organoids and appear to accumulate within neural rosette-like structures. These findings suggest that developing neural tissues can uptake and possibly retain nanoplastics during early differentiation. Ongoing analyses will determine nanoparticle aggregation state and the degree of cellular stress and apoptosis. **Conclusions:** These preliminary results support the notion that fetal-like neural tissues are capable of accumulating nanoplastics during early developmental stages. Future studies will include both fluorescently labeled and non-tagged environmentally relevant plastics—collected from ocean samples and subsequently prepared—to better mimic real-world exposure scenarios. Together, these efforts aim to clarify how prenatal exposure to environmental nanoplastics may pose risks to human neurodevelopment.

PS 4544 Physicochemical Influences on Metal Interactions and Toxicity in Exposure to Real-World Micro- and Nanoplastics

K. Robison, and J. Shannahan. Purdue University, West Lafayette, IN.

Background and Purpose: Micro- and nanoplastics (MNPs) are environmentally abundant as plastic production has increased. Degradation of plastic waste generates MNPs, which are commonly found in air, water, and soil, where interactions can occur with other environmental contaminants. Due to their environmental abundance and potential to interact with other contaminants, MNPs may pose a significant risk to human health. Epidemiology has reported the presence of MNPs in blood, feces, sputum, and placenta. Exposure to MNPs has been linked to respiratory diseases such as pulmonary fibrosis and intestinal diseases such as Crohn's Disease. Inhalation or ingestion of MNPs can initiate systemic inflammation, oxidative stress, and cytotoxicity, promoting cardiovascular diseases, reproductive disorders, and carcinogenesis. Traditionally, most studies use engineered polystyrene nanomaterials with uniform shape and size, however, environmental MNPs have a wide size distribution and irregular shapes. These physicochemical differences can impact interactions with environmental pollutants as well as toxicity. We hypothesize MNPs made from real-world plastic waste will differentially interact with environmental contaminants based on their physicochemical properties, resulting in altered toxicity compared to pristine MNPs and those without environmental contaminants. **Methods:** Mouse macrophages were exposed to 0, 0.01, 0.1, 1, 10, 25, 50, or 100 ug/ml of representative engineered polystyrene nanomaterials, MNPs generated from salt milling (PET, PS, PP), MNPs with adsorbed Pb, MNPs with an adsorbed metal mixture (Mn, Co, Zn, Cd, Pb), or to metal concentrations consistent with the amount adsorbed on MNP surfaces. Endpoints of toxicity, inflammation, and oxidative stress were evaluated 24- hours post-exposure. **Results:** Assessments of viability identified MNP-specific alterations where MNPs with adsorbed Pb or metal mixtures were more cytotoxic than Pb or metal mixtures alone, respectively. Gene expression analyses revealed significant upregulation of key inflammatory mediators following exposure. At 50 and 100 ug/ml all MNPs without metal induced expression of IL-6 and IL-1b without modifying CXCL2. Additionally, MNPs with heavy metal associated on their surface induced IL-6 and IL-1b expression that was less than MNP or metals

alone. Examination of HO-1 expression as a marker of oxidative stress demonstrated induction at 50 ug/ml in MNPs with metals adhered on their surface and at 100 ug/ml in MNPs with only Pb adhered on their surface. **Conclusions:** Overall, exposure to MNPs with or without surface adherence of heavy metals induce concentration-dependent cytotoxic responses and activate inflammatory pathways. This suggests investigating environmentally relevant MNPs with co-occurring exposures may enhance translatability of toxicity evaluations. Future assessments will aim to identify molecular signatures by assessing cellular uptake of MNPs after exposure via untargeted proteomics. Alterations in biological markers of ferroptosis and metal homeostasis will also be assessed. Together, these will be used to elucidate pathways of toxicity and disease.

PS 4545 Paternal exposure to microplastics alters sperm small non-coding RNA landscape and elicits offspring metabolic dysfunctions in mice

S. Park¹, J. Pan¹, X. Zhang², T. Lin¹, Q. Chen², T. Zhou³, and C. Zhou¹. ¹University of California, Riverside, Riverside, CA; ²University of Utah School of Medicine, Salt Lake City, UT; and ³University of Nevada, Reno, NV.

Background and Purpose: Microplastics (MPs) are small plastic particles emerging as significant environmental pollutants and humans are ubiquitously exposed to microplastics. Recent studies have associated MP exposure with the increased risk of chronic diseases in humans. MPs can also be detected in both male and female reproductive tissues in humans. However, the impact of parental MP exposure on offspring health is unknown. This study aimed to investigate the impact of paternal exposure to MPs on the metabolic health of F1 offspring in mice. **Methods:** In this study, eight-week-old male C57BL/6J wild-type (WT) mice were exposed with 10 mg/kg body weight of MPs or vehicle control by daily oral gavage for 4 weeks before mating with unexposed female mice to generate F1 offspring. Total RNAs were isolated from sperm of F0 sires and subjected to PANDORA-seq analysis. F1 offspring from MP- or control-exposed F0 sires were fed a high-fat diet before euthanasia at 12 weeks of age. **Results:** We found that paternal MPs exposure had sex-specific effects on diet-induced obesity in F1 offspring. Female F1 offspring from MP-exposed sires had decreased lean mass and exacerbated insulin resistance. PANDORA-seq revealed that MP exposure altered sperm tRNA-derived small RNA (tsRNA) and rRNA-derived small RNAs (rsRNA) profiles. Furthermore, microplastic-stimulated sperm tsRNAs/rsRNAs can induce early transcription changes in mouse embryonic stem cells, potentially contributing to paternal MP exposure-elicited metabolic disorders in offspring. **Conclusions:** Our results suggest that MPs exposure may have intergenerational adverse impact on offspring metabolic health, also underscore the urgency of better understanding the health consequences of plastic exposure in humans.

PS 4546 Development and characterization of reference environmentally relevant micro-nano-plastics for risk assessment studies

M. Das¹, L. Calderon¹, D. Singh², S. Majumder¹, L. Bazina¹, N. Vaze¹, U. Trivanovic³, G. M. Deloid¹, N. Zuverza-Mena⁴, M. Kaur⁴, J. Konkol¹, N. Tittikpina⁴, G. Tsilomelekis¹, O. Sadik⁵, J. C. White⁴, and P. Demokritou¹. ¹Rutgers University, New Brunswick, NJ; ²Exponent, Oakland, CA; ³Metas, Bern-Wabern, Switzerland; ⁴Connecticut Agricultural Experiment Station, New Haven, CT; and ⁵NJIT, Newark, NJ.

Background and Purpose: Most risk-assessment studies of micro-nanoplastics (MNPs) utilize commercial pristine, spherical, uniform primary MNPs. However, humans are primarily exposed to secondary MNPs produced by degradation of plastics in the environment, which have irregular shapes, varied sizes, and altered surface chemistries. The toxicological properties of these environmentally relevant MNPs may differ greatly from those of pristine spherical MNPs. **Methods:** We developed methods that replicate major degradation processes in the plastic life cycle, including mechanical fragmentation, photo-oxidation, and incineration. We employed cryomilling (mechanical fragmentation) and a UV-aging chamber (photo-oxidation) to generate secondary MNPs of polyvinyl chloride (PVC) and polyethylene terephthalate (PET). A dry and wet sieving protocol was used to collect the PM₁₀ size fraction. Multi-angle light diffraction (MALD) and scanning electron microscopy (SEM) were used to determine size distribution and morphology, and X-ray Photoelectron Spectroscopy (XPS) and Diffuse Reflectance Infrared Fourier Transform (DRIFT) were used to characterize surface chemistry. Incinerated MNPs of PVC, PET, high-density polyethylene (HDPE), acrylonitrile butadiene styrene (ABS), polycarbonate (PC), and polypropylene (PP) were created using our Integrated Exposure Generation System (INEXS). Emissions of CO and total volatile organic compounds (TVOCs) were monitored in real-time, and size analysis was conducted using a Scanning Mobility Particle Sizer (SMPS) and Aerodynamic Particle Sizer (APS). Emissions were size-fractionated using a Harvard Compact Cascade Impactor (CCI) to obtain PM_{0.1}, PM_{0.1-2.5}, PM_{2.5-10}, and PM_{>10} fractions for subsequent investigations. **Results:** The median sizes of the cryomilled and aged PVC and PET MNPs (by MALD) were ~10.7 and ~11.2 µm, respectively. The average sizes determined by SEM were 2.7 ± 1.4 µm and 4.8 ± 2.0 µm, respectively. SEM images showed that the particles maintained irregular morphology throughout the weathering process. The zeta potential for aged PVC and PET MNPs was -33.0 ± 0.8 mV and -36.3 ± 1.0 mV, respectively, indicating a stable

colloidal suspension. DRIFT analysis revealed the presence of oxygen-containing functional groups in UV-aged PVC MNPs, while XPS indicated a 5.5% increase in oxygen content compared to un-aged PVC. In contrast, no significant changes in surface oxygen content or functional groups were observed in 21-day UV-aged PET MNPs. During incineration, CO peaked for all plastics between 531°C and 715°C, with HDPE emitting the highest concentration (1240 ppm) and PVC the lowest (79.5 ppm). TVOC emissions reached ~26,400 ppb for most plastics, except for PC, which reached 1,440 ppb. SMPS measurements showed peak nanoscale particle concentrations ranging from 7.04×10^5 /cm³ (PVC) to 1.41×10^7 /cm³ (ABS). APS measurements showed peak micron-scale particle concentrations of 4.17×10^5 /cm³ (PVC) to 1.35×10^5 /cm³ (PP). Total aerosol concentrations ranged from 26.5 mg/m³ (PVC) to 60.6 mg/m³ (PET). EC/OC analysis revealed that PM_{0.1} MNPs were >99% organic carbon. PAH analysis identified multiple carcinogenic PAHs in all incinerated MNPs, with PC exhibiting the highest content (125.4 µg/kg). **Conclusions:** Using environmentally relevant secondary MNPs in toxicological studies will yield more accurate and applicable results compared to the pristine commercial MNPs commonly used. Thorough characterization of these reference materials will enable the identification of specific structure-activity relationships for environmentally relevant MNPs.

PS 4547 Assessing the Effects of UV Aging on Toxicity and Bioavailability of Inductively Coupled Plasma Mass Spectrometry (ICP-MS)-Traceable Core-Shell Polystyrene Nanoplastics in an *In Vitro* Triculture Model of Small Intestinal Epithelium

S. Majumder¹, L. Bazina¹, G. M. Deloid¹, A. G. Garcia², N. Zuverza-Mena², J. Konkol¹, G. Tsilomelekis¹, M. Verzi¹, H. Zhu³, J. C. White², and P. Demokritou¹. ¹Rutgers University, New Brunswick, NJ; ²Connecticut Agricultural Experiment Station, New Haven, CT; and ³Tulane University, New Orleans, LA.

Background and Purpose: Most studies of micro-nanoplastics (MNPs) toxicity have employed commercially available pristine MNPs, rather than environmentally relevant MNPs generated by fragmentation and photo-oxidation of plastics in the environment, or by incineration of plastic waste. An accurate assessment of the potential health impacts of MNPs requires understanding the complex physicochemical changes that occur during the aforementioned processes. Notably, photo-oxidation from UV exposure markedly alters the surface chemistry and morphology of MNPs, enhancing roughness and introducing reactive functional groups. Another challenge in assessing the risk of MNPs is the lack of robust analytical methods for precise and species-specific quantification, which is critical for evaluating their transport in biological systems. However, it is possible to engineer MNPs with a metallic (e.g., Au) core and a plastic shell, enabling highly accurate quantification in biological media and samples by inductively coupled plasma mass spectrometry (ICP-MS). **Methods:** In this study we investigated the impact of photo-aging on the physicochemical properties, toxicity, and bioavailability of ICP-MS traceable 25 nm gold-core shell polystyrene (AuPS25) in a triculture small intestinal epithelium (SIE) model. An aqueous suspension of AuPS25 was subjected to UV aging for 21 days in an accelerated UV-aging chamber (equivalent to 6 months of outdoor weathering). Dynamic light scattering (DLS), transmission electron microscopy (TEM), Fourier-transform infrared spectroscopy (FT-IR), and X-ray photoelectron spectroscopy (XPS) analysis were performed at days 0, 7, 14, and 21. The aged and un-aged AuPS25 was subjected to three-phase simulated digestion to replicate the physicochemical transformations during digestion, and the resulting digesta was applied to an *in vitro* transwell triculture SIE model. Toxicological assessments included oxidative stress, lactate dehydrogenase (LDH) release, trans-epithelial electrical resistance (TEER), and dextran permeability. AuPS25 uptake and translocation across the SIE were quantified via ICP-MS. **Results:** Physicochemical characterization revealed photo-oxidation of AuPS25 NPs at 14 days of UV-aging. TEM analysis revealed that the PS shell thickness remained unchanged after 7 and 14 days of UV aging; however, a significant reduction from ~4 nm to 0.80 nm occurred by day 21, indicating degradation. FT-IR analysis confirmed the formation of carboxyl groups after 7 and 14 days of UV exposure, signifying photo-oxidation. Similarly, XPS analysis revealed a 5.9% increase in oxygen content in 14-day UV-aged AuPS25 NPs, indicating the formation of oxygen-containing functional groups. Toxicological evaluations in the SIE model demonstrated that exposure to digestas of aged AuPS25 at oral concentrations of 4 and 40 µg/mL impaired barrier integrity by ~15% and ~18% and increased cytotoxicity by ~4.3% and ~5.4%, respectively, whereas exposure to digestas of un-aged AuPS25 had no significant effect. Although AuPS25 translocation rates were similar for aged and un-aged PS NPs, uptake of aged AuPS25 was significantly higher, reaching 72.2% at 4 µg/mL and 59.2% at 40 µg/mL. In contrast, less than 0.5% of the un-aged PS NPs were taken up at either concentration. **Conclusions:** UV aging significantly impacts the physicochemical properties of PS NPs, leading to photo-oxidation, increased cytotoxicity, disruption of the epithelial barrier, and enhanced SIE uptake. Using ICP-MS-traceable core-shell particles, we achieved NP detection at environmentally relevant concentrations and established a sensitive quantification framework. These results highlight the necessity of including aged and relevant MNPs in risk assessments to improve the accuracy of toxicological evaluations and inform public health decisions regarding this emerging contaminant.

PS 4548 Micro(nano)plastic (MNPs) in sinus tissue: A methodology comparison

M. E. Park, N. I. Leyva, S. S. Patil, R. M. Herrera, J. D. Kingston, M. A. Garcia, L. N. Shama, N. H. Reeve, M. X. Herzig, M. J. Campen, E. El Hayek, and D. A. Meiklejohn. University of New Mexico, Albuquerque, NM.

Background and Purpose: The human nasal cavity represents a potential deposition site for micro(nano)plastics (MNPs), including polymer fibers. The efficiency of MNPs deposition in the upper and lower respiratory tracts depends on their size, aspect ratios, and density, and the geometry of the nasal cavities. Synthetic and semi-synthetic fibers, widely generated from textiles, clothing, carpeting, and other sources, predominate the composition of indoor dust particles. Recent studies have raised concern about microplastic contamination in the nasal cavity, with alterations in microbial communities, and have associated the presence of microplastics with upper respiratory infections and the development of nasal polyps. **Methods:** For this study, 500mg of sinus tissue (4 samples) was tested for the efficacy of the MNPs isolation and quantification methodology using pyrolysis gas chromatography-mass spectrometry. Duplicates of two tissue samples were split into two treatments: The first group was digested with nitric acid and then 10% Potassium Hydroxide (KOH), and the second group was digested with 10% KOH only. Digestants from both groups were incubated for 24 hours in cyclohexane and then filtered through a quartz micro-fiber filter with a 50-nanometer pore size. **Results:** Preliminary results show that samples that didn't contain cartilage or bones didn't show significant concentrations of MNPs. In contrast, samples containing cartilage or bones contained polyethylene terephthalate (PET) (21.4-40.4 µg/g) and polyethylene (PE) (32.9-90.6 µg/g). **Conclusions:** More sample tissues will be analyzed to confirm how bone presence affects the bioaccumulation and quantifiability of MNPs in the sinus tissues.

PS 4549 Lifecycle implications of polyvinyl chloride (PVC) micronanoplastics (MNPs): Interactions with co-exposed environmental pollutants (EPs) and impact on their toxicity and bioavailability

S. Majumder¹, G. M. Deloid¹, M. Das¹, M. Kaur², E. Gaddi³, S. Alotaibi³, N. Zuverza-Mena², O. Sadiq³, J. C. White², and P. Demokritou¹. ¹Rutgers University, New Brunswick, NJ; ²Connecticut Agricultural Experiment Station, New Haven, CT; and ³NJIT, Newark, NJ.

Background and Purpose: Most risk-assessment studies on MNPs rely on commercially available, pristine, spherical MNPs, which differ substantially from environmentally relevant MNPs produced by mechanical fragmentation and photo-oxidation in the environment or incineration of plastic waste. Environmentally relevant MNPs have irregular morphologies, varied sizes, and distinct surface chemistries. This oversight has perpetuated significant knowledge gaps regarding the impacts of plastics life cycle and associated MNPs. MNPs have been found to sorb a range of environmental pollutants (EPs), including toxic metals and organic compounds. However, due to the lack of studies with environmentally relevant MNPs, critical questions remain unanswered, including the capacity of relevant aged and incinerated MNPs to sorb EPs, and the potential synergistic effects on gastrointestinal (GIT) toxicity and bioavailability of both MNPs and EPs. **Methods:** We investigated the biointeractions, toxicity, and bioavailability of PVC MNPs throughout the plastic waste lifecycle, alone and with EPs, in an *in vitro* transwell triculture small intestinal epithelium (SIE) model. Model MNPs included mechanical-fragmented/cryomilled and un-aged PM₁₀ (PVC-UA), cryomilled and UV-aged PM₁₀ (PVC-A), and incinerated PM_{0.1} (PVC-I) PVC MNPs. EPs tested included As(V), Cr(III), Pb(II), boscalid, and PFOS. We also assessed the sorption of each EP by different PVC MNP types in each phase of simulated digestion, the toxicity of PVC MNPs, alone and with EPs, and translocation of EPs and MNPs, alone or combined, in the SIE model. Toxicological assessments included oxidative stress, LDH release, trans-epithelial electrical resistance (TEER), and dextran permeability. Translocation of EPs through the SIE was quantified by inductively coupled plasma mass spectrometry (ICP-MS) and liquid chromatography-mass spectrometry (LC-MS), and bioavailability of PVC MNPs was assessed by pyrolysis-gas chromatography-mass spectrometry (Py-GCMS). Effects on gene expression were assessed by RNA-seq. **Results:** Sorption of most metals was MNP lifecycle-stage- and EP-specific, with aged-MNPs exhibiting a higher affinity for EP than unaged cryomilled and incinerated-MNPs. Whereas exposure to unaged MNPs and EPs alone or combined did not cause cytotoxicity in the SIE, aged-MNPs and incinerated-MNPs in the presence of EPs triggered significant oxidative stress. The presence of MNPs significantly increased the bioavailability of EPs and vice versa. The enhanced translocation influenced by PVC-A, PVC-I, and EPs correlated with the downregulation of tight junction, adherens junction, gap junction, intercellular adhesion, and focal adhesion genes. **Conclusions:** The lifecycle stage of PVC MNPs plays a significant role in the sorption of EPs, with aged MNPs exhibiting a higher affinity for EPs throughout the GIT. Additionally, exposure to UV-aged and incinerated PVC MNPs induces oxidative stress in the SIE and facilitates the enhanced translocation of EPs, and vice versa, by causing significant alterations in cell junction genes, which suggests leaky gut effects. Collectively, our findings offer significant toxicological insights into the lifecycle of ecologically relevant PVC MNPs, their interactions with EPs, and the consequent implications for the integrity of human intestinal epithelial structures.

PS 4550 Characterization of tire microplastic leachates and their impacts to human epithelial lung cells via *in vitro* studies and multi-omics analysis

I. Walker-Franklin¹, M. Bailey¹, Z. Eastman¹, S. Khan¹, K. Tober¹, S. Blake¹, J. Shipman², M. Hunter¹, V. Sivaraman², and L. Rios-Colon¹. ¹RTI International, Durham, NC; and ²North Carolina Central University, Durham, NC.

Background and Purpose: Microplastics (MPs) are small plastic particles of less than 5 millimeters in length that are generated from primary sources (manufactured at this size) or secondary sources (when large synthetic polymer products degrade into smaller pieces or are intentionally fragmented through mechanical or chemical recycling processes). These risks stem not only from their physical properties but also from the leaching of toxic chemical additives and their capacity to carry microbial contaminants. Tire wear particles represent one of the largest yet often overlooked sources of MPs, accounting for an estimated 26-74% of global MP pollution. Recycled tire materials used in recreational spaces further contribute to exposure, releasing complex mixtures of additives such as antioxidants, vulcanizers, and plasticizers with poorly characterized toxicities. In this study, we employed a multi-omic approach to investigate the biological effects of tire-derived MPs leachates on two human upper-respiratory cell models: lung carcinoma (A549) and bronchial epithelial transformed (BBM) cells. **Methods:** Tire MP particles (<45 µm) were leached in culture media shaken at 100 RPM for 24 hours at 37 °C and applied at concentrations of 0, 50, 100, and 150 µg/mL. These filtered (0.2 µm) and unfiltered MP leachate samples were dosed to both A549 and BBM cells. Over three days, we evaluated cell proliferation via Incucyte live-imager and viability using an MTT (3-(4,5-Dimethylthiazol-2-yl)-2,5-Diphenyltetrazolium Bromide) assay at 24 h, 48 h and 72 h. Media was collected at the end of the experiment to determine inflammatory cytokine release using a multiplex cytokine assay. In addition, control and 150 µg/mL treatment groups were analyzed for cellular uptake of tire-associated chemicals using inductively coupled plasma mass spectrometry (ICP-MS) for metals and liquid chromatography-high-resolution mass spectrometry (LC-HRMS) for organic tire additives and transformation products. LC-HRMS was also employed for both metabolomic and proteomic analyses. **Results:** Exposure to tire particle leachates induced concentration- and cell type-dependent increases in proliferation (*P≤0.05, **P≤0.01, ***P≤0.001), and cytokine release (*P≤0.05, **P≤0.01, ***P≤0.001). Metal analysis revealed in 150 µg/mL samples had significant cellular uptake of zinc, copper and lead. Non-targeted analysis revealed cellular uptake of diverse organic tire additives, including corrosion inhibitors, process regulators, antioxidants, adhesives, and transformation products. Notably, N-(1,3-dimethylbutyl)-N'-phenyl-p-phenylenediamine quinone (6PPD-quinone)—a toxic environmental transformation product of a common tire antioxidant—was detected in exposed cells. Reported hazards of the additional chemicals structurally annotated included potential toxicity to aquatic life, acute toxicity for human health, skin irritation, and reproductive harm. Additional structurally annotated chemicals were linked to hazards such as acute toxicity, skin irritation, and reproductive harm. In addition to upregulation of specific cellular metabolites with tire leachate dosing, bottom-up proteomic analysis identified a novel protein biomarker of airway exposure to quinone-derived tire-associated chemicals. In total, 2,332 unique proteins were identified across the BBM and A549 cells. Proteins hits with significant expression level changes were identified using a p-value cutoff of 0.01 and a Z-score of 1 resulting in the identification of 317 protein hits in the BBMs and 181 protein hits in the A549 with 46 hits overlapping in both. Many of the 46 protein hits are classified as heat shock and histone proteins that are important for gene expression and cell growth. **Conclusions:** We observed that Tire derived MP leachates can drive cellular responses to growth, metabolic activity, and inflammation in cell- and concentration-dependent ways. Several chemicals, including metals and transformation products of tire additives, were identified within exposed cells and may contribute to these observed effects. Collectively, these findings underscore the potential human health risks posed by tire-derived MPs as an emerging global and regional air pollutant.

PS 4551 Role of ApoEε3/4 variants in modifying endothelial uptake and toxicity of microplastics derived from the Pacific Gyre

P. Paramasivam, N. Leyva, M. Garcia, S. Patil, E. El Hayek, S. Phatak, J. Begay, G. W. Herbert, K. Bhaskar, K. Westlund, and M. J. Campen. University of New Mexico, Albuquerque, NM.

Background and Purpose: **Background:** Micro- and nanoplastics (MNPs) are emerging environmental pollutants with the potential to affect human health and contribute to diseases. Increasing evidence shows that MNPs accumulate in human organs, especially the brain, and their levels are rising over time. MNPs can cross the blood-brain barrier and stay as nanoscale fragments within brain tissue. Notably, concentrations of MNPs are higher in the brains of people with dementia, including Alzheimer's disease, compared to those without neurodegenerative conditions. This specific buildup may disrupt cerebrovascular walls and impair immune cell function, raising important questions about the role of environmental exposure in disease development. There is an urgent need to understand how MNPs enter brain cells, a process that is still being clarified. ApoEε4, the strongest genetic risk factor for Alzheimer's disease, not only disrupts lipid metabolism but also decreases the clearance of amyloid-beta and promotes neuroinflammation. Over recent decades, research has focused on how ApoEε4 interacts with lifestyle factors, but there is

a lack of studies on how MNPs interact with ApoEε4. **Aim of the Study:** The objective of the study is to investigate the effect of aged and unaged microplastics on primary human brain microvascular endothelial cells and how ApoEε3 or ApoEε4 proteins may modify these interactions. **Methods:** Environmental micro-nanoparticles (MNPs) derived from plastics obtained from the Pacific Gyre were labeled with Rhodamine B dye. Primary human brain microvascular endothelial cells were exposed to 10 µg/ml of either UV-aged and unaged MNPs, with or without dispersion media containing ApoEε3 or ApoEε4 lipoproteins. After 24h exposure, the integrity of the cell barrier and wound healing were monitored using the Electrical Cell Impedance System (ECIS). Localization of the MNPs was confirmed with confocal microscopy using Z-Stack analysis. The cellular uptake of Rhodamine B-dyed **Results:** MNPs was quantified using the AMNIS flow cytometry imaging system. **Results:** Confocal imaging showed that cells uptake Rhodamine B-dyed microplastics, and Z-stack analysis verified their presence inside the cells. The cell behavior analysis indicated that aged microplastics in the presence of ApoEε4 impaired cell migration in the wound healing assay than microplastics with ApoEε3 or microplastics alone. Additionally, the uptake of aged microplastics was higher in the presence of ApoEε4 compared to either ApoEε3 or microplastics alone in primary human brain microvascular endothelial cells. **Conclusions:** This study concludes that the ApoEε4 apolipoprotein, which likely carries microplastics in the circulation, may influence the biological effects of MNPs on neurovascular endothelial cells as well as the passage into the brain itself. This creates a novel GxE paradigm that could, in part, explain the dementia risk incurred by the ApoEε4 variant. **Funding:** National Institute of Aging 5U01AG088557-02.

PS 4552 Physicochemical Interaction Dependent Transportation of Pollutant Adsorbed Nanoplastics (PANs) in Lung Cells

E. J. Hale, E. F. Wooliever, S. C. Nicklisch, and R. P. Carney. University of California Davis, Davis, CA.

Background and Purpose: Microplastics are well established vectors for pollutants, absorbing harmful substances like pesticides and industrial chemicals, posing risks to human health and sparking regulatory initiatives against them. Compared to microplastics, smaller **nanoplastics (<1 µm)** can travel over long distances in the atmosphere and possess altered health risks via lung inhalation. Moreover, their increased surface area-to-volume ratio enhances their ability to adsorb pollutants, forming a complex material termed **pollutant-adsorbed nanoplastics, or PANs**. Nanoplastics have been linked to cancer progression by inducing pro-inflammatory responses, endocrine disruption, and oxidative stress, yet the alteration of these cellular functions because of nanoplastic interplay with small molecule pollutants found in complex atmospheric particulate matter (i.e., formation of PANs) is poorly understood. Current research on PAN toxicity provides limited characterization of their formation kinetics and affinity. The physicochemical interactions between pollutants and plastics drive PAN formation and their transportation and toxicity in the body. **Methods:** This research applies enhanced darkfield hyperspectral imaging (EDF-HSI) as a novel, label-free approach for single-particle chemical and spatial mapping of PANs, revealing how PANs exacerbate pollutant toxicity and carcinogenicity by resolving their composition and desorption in cells. **Results:** EDF-HSI was used to chemically detect and spatially map spectral shifts in 220 nm polystyrene diaziron (PSDZN) PANs compared to pristine PS controls, revealing significant adsorption heterogeneity (Fig. 1C). Principle component analysis (PCA) revealed clustering of PSDZN compared to pristine PS. Changes in cell uptake of PSDZN PANs compared to PS and PS incubated in methanol solvent (PSMeOH) were evaluated in human lung adenocarcinoma (A549) cells. Quantification of particle counts within cells showed trends of increased uptake for PSDZN compared to controls. Mean particle spectra were stratified by exposure condition and in/outside of cells for each exposure condition. PCA analysis revealed similar clustering of all groups, within and outside of cells except for PSDZN, which exhibited blue spectral shifts. **Conclusions:** This data established the feasibility of EDF-HSI for non-destructive, label-free, single-particle spatial and chemical characterization of PAN formation kinetics and interactions in cells and highlights the significance of pollutant adsorption on nanoplastic transportation in lung cells.

PS 4553 Real-World Micro/Nanoplastics and Pristine Nanoplastics Differentially Disrupt Microglial Mitochondrial and Redox Homeostasis

A. M. Nunes, S. Vogt, and P. Falagan Lutsch. Auburn University, Auburn, AL.

Background and Purpose: Global plastic production now exceeds 390 million tons per year, resulting in pervasive environmental contamination and increasing human exposure to micro- and nanoplastics (MNPs). These particles have recently been detected in multiple human tissues, including the brain, raising concerns about their potential impact on neurological health. Emerging evidence indicates that MNP accumulation in brain tissue may contribute to neuroinflammation and cognitive decline, with preferential accumulation in microglia. Despite these concerns, most toxicological studies rely on commercially available pristine nanobeads, which inadequately reflect the physicochemical diversity of real-world MNPs. To address this gap, the present study investigated the subcytotoxic effects of MNPs generated

from common consumer items —disposable cups and forks (Cup-MNPs and Fork-MNPs) —on oxidative stress pathways and mitochondrial parameters in immortalized human fetal microglia (HMC3). These responses were directly compared with those elicited by pristine 50 nm polystyrene nanoplastics (PS-50), as they are known to reach the brain and induce neurotoxic and neurodegenerative markers *in vivo*. **Methods:** Disposable plastic cups and forks were manually cut, ground, and sieved to generate MNPs. The resulting particles were characterized by FT-IR spectroscopy, zeta potential analysis, and SEM imaging. Both consumer-derived MNP preparations consisted mostly of polystyrene. SEM showed mean particle sizes of $35.7 \pm 20 \mu\text{m}$ (Cup-MNPs) and $47.5 \pm 22 \mu\text{m}$ (Fork-MNPs), while hydrodynamic analysis revealed a larger nanoscale fraction in Fork-MNPs. Pristine polystyrene nanoplastics (PS-50; ~64 nm) were sourced commercially. All particle types exhibited slightly negative zeta potentials in cell culture media. HMC3 human microglial cells were exposed to 0.1 or 1.0 $\mu\text{g/mL}$ of each MNP type for 72 h. Endpoints included cell viability (Trypan Blue exclusion), intracellular and mitochondrial ROS (DCFDA and MitoROS by flow cytometry), antioxidant enzyme activity and glutathione redox status (GSH/GSSG) (colorimetric assays), mitochondrial membrane potential (TMRE), mitochondrial respiration (Seahorse XF), and mitophagy (MtPhagy probe by flow cytometry). **Results:** Although none of the particles were cytotoxic, Fork-MNPs and PS-50 at 0.1 $\mu\text{g/mL}$ significantly increased total ROS. All materials, including Cup-MNPs, elevated SOD activity without affecting catalase levels. At this low concentration, Fork-MNPs also reduced the GSH/GSSG ratio, indicating redox imbalance. At 1 $\mu\text{g/mL}$, all materials increased intracellular ROS, particularly PS-50. Fork- and Cup-MNPs further decreased the GSH/GSSG ratio, whereas PS-50 continued to enhance SOD activity. None of the treatments altered MMP or mtROS. However, PS-50 exposure reduced all mitochondrial oxygen consumption rate (OCR) parameters and lowered ATP levels, consistent with impaired mitochondrial function. In contrast, Fork-MNP-exposed cells showed increased OCR across all parameters, suggesting a compensatory upregulation of oxidative phosphorylation to meet energy demands under stress. Both Fork-MNPs and PS-50 induced mitophagy, as demonstrated by flow cytometry using a fluorescent probe and by co-localization analysis showing increased mitochondria-lysosome interaction. **Conclusions:** Both “real-world” MNPs and pristine NPs induced cellular stress at low, subcytotoxic doses, but the magnitude and nature of the responses differed markedly. Particle size, particularly the nanoscale fraction, emerged as a major driver of these effects. Pristine nanoplastics produced pronounced suppression of mitochondrial respiration, whereas Fork-MNPs triggered adaptive, compensatory mitochondrial responses at the same doses. Given the central role of microglia in maintaining neuronal homeostasis, such mitochondrial and redox disruptions could compromise brain energy balance and potentially increase vulnerability to neurodegeneration. Importantly, the divergent biological responses observed between pristine nanobeads and “real-world” particles underscore that pristine models may not accurately represent environmentally relevant exposures and should be interpreted with caution. Overall, these findings highlight the critical need to incorporate “real-world” MNPs into nanosafety assessments to capture biologically meaningful effects.

PS 4554 Methodological Approaches for Food Digestion in Micro(nano) plastic (MNP) Analysis and Quantification to Assess Human Dietary Exposure

E. R. Descher¹, C. L. Bren¹, C. R. Rabino², M. E. Park¹, S. S. Patil¹, R. M. Hernandez¹, G. Sanchez¹, A. Moranan³, J. D. Kingston¹, M. A. Garcia¹, J. Gonzalez-Estrella⁴, M. J. Campen¹, and E. El Hayek¹. ¹University of New Mexico, Albuquerque, NM; ²Zuni High School, Zuni, NM; ³Alamo High School, Alamo, NM; and ⁴Oklahoma State University, Stillwater, OK.

Background and Purpose: Microplastics and nanoplastics (MNPs) are now recognized as widespread environmental contaminants, with increasing evidence pointing to their presence in agricultural soils and food chains. Despite their growing detection, little is known about the extent to which MNPs accumulate in plant-based food sources that are regularly consumed by people worldwide. Rice and beans—staple crops in many global diets—have shown potential for MNP uptake, but current studies fall short of quantifying the levels humans might be exposed to through consumption. One of the significant roadblocks to accurate analysis lies in sample preparation: plant cell walls are difficult to break down using traditional MNPs digestion protocols, which employ lightly destructive chemical methods to preserve the structural integrity of MNPs. **Methods:** This study investigates the use of enzymatic digestion and diluted nitric acid (HNO_3) as pre-digestion methods, aiming to enhance the breakdown of plant tissues while preserving MNP integrity. **Results:** We found that nitric acid was sufficient to break down rice, but beans required the introduction of enzymes (amylase, protease, cellulase, and pectinase). Initial data reveal the occurrence of polyethylene, polystyrene, polyvinyl chloride, and Styrene-Butadiene Rubber in estimated total mass concentrations above 100 mg/kg per dry weight. **Conclusions:** By developing a more effective pre-treatment approach and quantifying MNPs in rice, beans, fruits, and vegetables, this research aims to determine human exposure through diet.

PS 4555 Mechanism of Pulmonary Toxicity by Inhaled Polyester Microplastic Fibers in Mice

A. O'Connor¹, T. Jilling², Y. Goddard¹, A. Lewis³, P. L. Ferguson², B. Mehrad¹, and T. Sabo-Attwood². ¹University of Florida, Gainesville, FL; ²University of South Carolina, Columbia, SC; and ³Duke University, Durham, NC.

Background and Purpose: Human respiratory exposure to microplastic fibers (MPF) can occur in occupational settings and in everyday life through numerous sources, including textiles. While toxicity of sphere-shaped microplastics in the respiratory system are relatively well-studied, our mechanistic understanding of MPF toxicity in the lung is lacking. In this study, we aimed to identify symptoms and mechanisms of pulmonary injury caused by oropharyngeal aspiration of lab-generated, size-standardized polyester MPF, with and without azobenzene disperse dyes (ADD), in mice. **Methods:** Anesthetized, 12-week-old male mice were exposed by oropharyngeal aspiration to 5,000, 14 μm diameter, 45 μm length clear polyethylene terephthalate (PET) filament MPFs, which were either undyed (UMPF) or dyed (DMPF) with ADD violet 93 (DV93) daily for 5 days/week for 4 weeks. A separate group received DV93 only (no fibers), and controls received equal volume of vehicle. At the end of the exposure period, six mice per group were anesthetized, lung function was analyzed by FlexiVent at baseline and with methacholine challenge (MC; 0-50 mg/mL), bronchoalveolar lavage fluid (BALF) was collected and, after euthanasia, then lungs were excised and RNA was isolated from the tissue. BALF was analyzed for total and differential cell counts. Following quality control and quantification RNA sequencing (RNAseq) was performed and analyzed using CLC Genomic Workbench (Qiagen) and by using R. Differences between groups were tested by one way analysis of variance (ANOVA) followed by Dunnett's post-hoc test for normally distributed data, and by Kruskal-Wallis ANOVA followed by Dunn's test for non-normal data using Graphpad Prism (Version 9.5.1 (733)). Significance was accepted at $p < 0.05$. **Results:** Mice exposed to either UMPF or DMPF had significantly reduced inspiratory capacity at baseline and increased tissue dampening and elastance with 20 and 50 mg/mL MC challenge compared to the control group. Additionally, DMPF had significantly increased total tissue and Newtonian resistance after 50 mg/mL MC. Total cell count, neutrophils and eosinophils were significantly increased in both UMPF and DMPF, while monocytes were only significantly increased in DMPF and lymphocytes were unchanged. No significant changes were observed in respiratory function parameters or differential cell counts in mice exposed only to the dye DV93. RNAseq performed on total lung RNA revealed that there were 194 and 200 transcripts that were significantly modulated compared to control in UMPF and DMPF, respectively, with 135 transcripts being common and 59 vs 65 transcripts being unique for UMPF and DMPF, respectively. The top ten most upregulated genes were identical in both UMPF and DMPF and included CLCA1, a calcium sensitive Cl⁻ channel, GP2, a cell surface glycoprotein, CYP4A11 with CYP22 CYP4A11, two paralogs in the cytochrome P450 superfamily and REG3G, a C-type lectin. Gene enrichment and over representation analysis performed using the list of significantly regulated genes revealed that in gene ontology (GO), Kyoto encyclopedia of genes and genomes (KEGG), Reactome and Wiki pathway terms pertaining to smooth muscle growth and contraction dominated the top enrichment terms and also included cAMP signaling and IL-17 signaling (in KEGG), PPAR signaling (KEGG and Wiki) and various terms related to cytochrome P450 function (KEGG, Reactome and Wiki). **Conclusions:** Exposure of mice to MPFs results in moderate changes in respiratory function, mild pulmonary inflammation, and transcriptomic changes indicative of increased smooth muscle proliferation and reactivity, PPAR signaling and cytochrome P450 activity. The relatively minute differences between dyed and undyed MPFs, suggest a primary role for the fibers rather than DV93 leaching into surrounding tissues. Regardless, RNA sequencing analysis revealed molecular pathways and networks that have not been widely described responses to MPFs in the lung. This is one of the few studies to evaluate biological responses in a model of chronic low dose respiratory exposure to MPFs that may more closely mimic ‘real-world’ exposures. These first-time data will provide the basis for more specific and probing studies of defined mechanisms of action.

PS 4556 Chemical Additive Leaching and Human Exposure Potential from PVC and PE Microplastics in U.S. Drinking Water

A. C. Jachak, S. Patel, T. Shughart, and A. Youngberg. RHP Risk Management, Inc., Chicago, IL.

Background and Purpose: Microplastics are increasingly detected in surface water, groundwater, and municipal drinking-water supplies, raising concerns about their role as vectors for human chemical exposure. These particles (<5 mm), originating from degrading larger plastics or the direct release of primary microplastics, can leach additives such as plasticizers, stabilizers, and antioxidants. Many of these substances exhibit persistence, bioaccumulation potential, or toxicological activity, including potential endocrine or developmental effects. As a result, ingestion of microplastics through drinking water may represent a low-level but continuous source of chemical exposure. This study evaluated potential oral exposure and chemical risk from microplastics in drinking water by quantifying particle occurrence, size distribution, and the leaching potential of representative polymer additives. **Methods:** Microplastic particles present in drinking-water samples collected in five U.S. states on two different days at two different times were analyzed using Confocal Raman Microscopy (CRM) to characterize particle morphology and identify polymer

types. Mosaic optical images were first captured to locate particles, after which Raman spectra were acquired under confocal conditions to improve compositional accuracy. Polymer identification was performed by comparing sample spectra with a validated reference database, with an High Quality Index (HQI) score $\geq 60\%$ used as the acceptance threshold. The method reliably identified particles between $\sim 20\ \mu\text{m}$ and $500\ \mu\text{m}$. Ten common polymer categories (including PE, PP, PS, PVC, PET, PC, PMMA, PA, PU, and PTFE) were included in the verified spectral library. To evaluate potential chemical migration, a diffusion-based model was applied to estimate additive release into water over 24 hours, assuming Fickian transport through spherical particles. Polymer-specific diffusion coefficients were applied, and the fraction of additive released was calculated as a function of particle radius and diffusion rate. Predicted water concentrations were combined with the U.S. EPA's adult drinking-water ingestion rate to estimate daily oral intake for each additive. These exposure estimates were then compared with established health-based reference values to determine the relative contribution of microplastic-associated leaching to overall human oral exposure. **Results:** PVC and PE microplastics were detected in all drinking-water samples collected across five U.S. states. PVC additives such as DEHP (di-(2-ethylhexyl) phthalate), DINP (diisononyl phthalate; mixture), DIDP (diisodecyl phthalate; mixture), and TOTM (tri-(2-ethylhexyl) trimellitate) produced estimated exposures of $\sim 20\text{--}22\ \mu\text{g/day}$, while PE additives resulted in $\sim 1\ \mu\text{g/day}$, corresponding to doses in the 10^{-5} to 10^{-4} mg/kg-day range which are well below toxicological benchmarks. Risk Characterization Ratios for nearly all additives fell between 10^{-3} and 10^{-4} , indicating low concern under the modeled conditions. The only notable exception was the organotin stabilizer Dioctyltin bis(2-ethylhexyl thioglycolate) (DOTE), which produced a higher RCR (~ 0.15). Overall, despite the widespread presence of PVC and PE microplastics in drinking water, modeled additive exposures remain far below health-based limits, with organotin stabilizers representing the primary substances warranting closer scrutiny. **Conclusions:** PVC and PE microplastics were consistently detected across drinking-water systems in multiple U.S. states and can contribute small amounts of additive-related chemical exposure. Modeled 24-hour leaching indicated that resulting adult oral intakes for most additives were well below health-based reference values. Only DOTE approached a higher level of concern due to its low toxicological threshold rather than elevated migration. Overall, estimated microplastic-associated chemical exposure from drinking water appears low, though continued monitoring of polymer additives and toxicity data remains important. These findings quantify the contribution of microplastic-associated chemicals to overall oral exposure and support future risk assessment and mitigation strategies for drinking-water systems.

PS 4552 Microplastic And Nanoplastic Testing Framework: Shortfalls and Recommendations Based on A Structured Review of Recent Research

J. Cubello¹, B. Head¹, E. Freeman¹, and K. Morris-Schaffer². ¹Exponent, Inc., Washington, DC; and ²Exponent, Inc., New York, NY.

Background and Purpose: Microplastics and nanoplastics (MNPs), particularly polystyrene (PS) and polyethylene (PE), have emerged as a global concern due to their widespread presence in the environment. Because of this, MNPs are now widely studied for their influence on various health outcomes, including potential genotoxic and carcinogenic effects. Authoritative agencies such as the World Health Organization (WHO) have developed tiered approaches to score the extent by which existing MNP research complies with testing standards, with emphasis placed on relevance of the exposure, rigor in experimental design, and the applicability for the study and its observed effects to existing risk assessment frameworks. However, the extent to which existing published studies adhere to these standards and employ robust analytical techniques is unclear. This investigation systematically evaluates the current body of literature on MNP genotoxicity and carcinogenicity, highlighting the need for harmonized protocols to strengthen the reliability of MNP hazard characterization. **Methods:** First, structured literature reviews were done in PubMed. A *priori* search terms and screening criteria were defined per PRISMA guidelines. A multi-level screening approach was applied to titles and abstracts to identify potentially relevant publications evaluating (i) PS and PE administered as an isolated test material and (ii) endpoints aligned with current testing guidance from the OECD for genotoxicity (gene mutation, chromosomal effects, DNA damage) and carcinogenicity (neoplasms, tumors) in relevant test systems. A quality assessment was then conducted to determine whether the qualitative and quantitative analytical techniques used to assess the MNPs were appropriate and sufficient. Test material deemed suitable for further review included materials sourced as analytical reference material, or synthesized test materials compositionally characterized by several acceptable techniques (e.g., spectroscopy, mass spectrometry, etc.). All test material was considered adequate if assessed for concentration, size, and shape of the particles dosed in their respective test systems. **Results:** A total of 701 publications were found, 471 when using key search terms for genotoxicity and 231 for carcinogenicity. Post title/abstract screening, 51 and 7 publications were identified as potentially relevant by test material and endpoint for genotoxicity and carcinogenicity, respectively. The majority of excluded studies did not assess the key toxicological endpoints for genotoxicity and carcinogenicity or if measured, were investigated in models not recognized by existing testing guideline frameworks for human health risk assessment. Of those that were included, the majority were *in vitro* or *in vivo* investigations using a Comet assay, a genotoxicity indicator test, to evaluate oxidative stress-mediated DNA damage. Fifteen genotoxicity and three carcinogenicity

publications had sufficient test material analytical information. However, the remaining experimental designs still had limitations including non-validated endpoints to assess human health risks and were deemed insufficient to incorporate into a risk assessment framework. **Conclusions:** Despite recent enthusiasm to understand the toxicological potential of MNPs, many publications suffer from methodological limitations that limit their usefulness in current risk assessment frameworks. Such limitations include non-compliance with existing testing guidelines (i.e., OECD), inadequate characterization of test models, which compromises the reliability of the observed effects, as well as analytical inadequacies (e.g., failure to characterize test material pre- and post-administration). Overall, this work provides a tiered approach for the evaluation of existing MNP research in accordance with a standardized review framework. It also highlights critical shortcomings in the current research landscape that hinder integration of published data into existing risk assessment frameworks.

PS 4558 Mechanistic Insights into Nanoplastic Uptake and Barrier Dysfunction in Human Cell Lines

A. M. Janiga-MacNelly, and R. Lavado. Baylor University, Waco, TX.

Background and Purpose: Nanoplastics (NPs) are emerging contaminants of global concern due to their widespread distribution and potential to infiltrate biological systems. Unlike larger microplastics, NPs can cross cellular membranes, accumulate in tissues, and disrupt essential processes. However, the dynamics of NP, cell interactions remain poorly characterized, and most studies have focused on hepatic and intestinal models. Other critical cell types, including endothelial cells, microglia, and keratinocytes, are underexplored despite their central roles in barrier function and immune defense. This study exposed seven human cell lines to NPs to evaluate cytotoxicity, rates of interaction, accumulation patterns, and uptake mechanisms. Additionally, Caco-2 monolayers were used to assess whether NPs compromise epithelial barrier integrity. **Methods:** Seven cell lines, Caco-2, MRC-5, HEK001, HepaRG, HEK293-hTLR2, HMEC-1, and HMC3 were exposed to 0.01-100 $\mu\text{g/mL}$ of polystyrene NPs ranging from 0.07 to 1.35 μm , as well as a mixed-size suspension, for 24-48 hours. Cytotoxicity was measured with PrestoBlue™ assay. Dynamic imaging was conducted with the Lionheart Automatic Microscope at 30-minute intervals for 48 hours. Fluorescent Nile Red-labeled polystyrene NPs were used to quantify uptake, with cytochalasin D applied to evaluate actin-dependent endocytosis. Barrier integrity was assessed in Caco-2 cells using transepithelial electrical resistance (TEER). **Results:** Cytotoxicity was observed only in endothelial cells (HMEC-1), which showed decreased viability with 1.35 μm NPs and mixed suspensions. Other cell lines maintained viability across exposures. Live-cell imaging revealed minimal NP uptake in Caco-2 and HepaRG cells, though HepaRG showed delayed accumulation. HEK001, HEK293, HMC3, HMEC-1, and MRC-5 actively internalized NPs, with perinuclear accumulation evident after 48 hours. Fluorescence analysis confirmed significant uptake in HepaRG, HEK293, MRC-5, and size-selective accumulation in HMEC-1, HMC3, and HEK001. Cytochalasin D reduced uptake in several models, confirming actin-mediated pathways, but paradoxically increased NP association in Caco-2 and MRC-5. Barrier testing showed that 1.35 μm NPs disrupted Caco-2 integrity, reducing TEER values comparably to Triton X-100, while smaller particles had no measurable effect. **Conclusions:** This study demonstrates that NPs interact with human cells in complex, cell-specific ways. Endothelial cells are especially vulnerable, while many other cell types internalize NPs via actin-dependent mechanisms. Larger NPs disrupt epithelial barriers, while smaller particles accumulate intracellularly, raising concerns about long-term, sublethal impacts. Together, these findings highlight NPs as biologically active contaminants and emphasize the need for chronic exposure studies targeting barrier dysfunction, immune activation, and subtle toxicity mechanisms.

PS 4559 Proquinazid: In Vitro Metabolism of an Agrochemical Fungicide to support Mechanistic Toxicology Testing and PBK Model Development

M. W. Himmelstein¹, M. P. Mawn¹, and L. Kent². ¹Corteva Agriscience, Newark, DE; and ²Corteva Agriscience, Milton Park, United Kingdom.

Background and Purpose: The mammalian metabolism of a crop protection chemical is an essential component to understanding relevance to human health risk assessment. The comparative *in vitro* metabolism of proquinazid-¹⁴C was investigated in human, rat, mouse, dog and rabbit hepatocytes. This type of study is a regulatory requirement in Europe; however, it can also support the interpretation of NAM mechanistic studies, and aid building *in vitro* to *in vivo* concordance for application to human PBK modeling. Here, the main objective was to identify metabolites unique to the human species at 5% of dose or greater relative to the other test species. Metabolites observed *in vitro* can be compared with *in vivo* ¹⁴C plasma metabolites in rats that formed the bases for PBK modeling of liver metabolism. **Methods:** Pooled cryopreserved hepatocytes were from male human (n=10), male Sprague Dawley rats (n=18), male CD-1 mouse (n=36), male beagle dogs (n=3) and male New Zealand white rabbit (n=4). Experiments were performed using proquinazid-phenyl-UL-¹⁴C (proquinazid-¹⁴C) prepared in acetonitrile stock solution. The cell viability by Trypan blue exclusion prior to the start of incubations ranged from 76 to 93%. The hepatocytes were suspended in an incubation volume of 1 mL containing 2×10^6 cells/mL at 37°C. Reactions were started by addition of 5 μL of dose stock solution (organic

solvent 0.5% of the incubation volume) for a starting incubation concentration of 18 μ M. Incubations were terminated at 15, 60 and 120 min by the addition of 1 mL of ice-cold acetonitrile. Specific endpoints included percent ^{14} C-recovery, extraction efficiency, and identification and quantitation of metabolites as percent of applied radioactive dose. The profile of metabolites was characterized in the extracts by HPLC mass spectrometry in conjunction with in-line ^{14} C-radiochromatography and retention time match with available metabolite standards. **Results:** The metabolite profile of proquinazid- ^{14} C in the human was compared with profiles for the rat, mouse, dog and rabbit species. Proquinazid and 12 metabolites (13 components total) were identified in the human species across all time points. Only one metabolite radiochemical peak was quantified in the human species at a level of 5% or greater of the applied radioactive dose. This radiochemical peak consisted of two coeluted metabolites, X12649845 and X12649855-a, that could not be fully separated. For all other species (rat, mouse, dog, and rabbit), this same peak consisting of coeluted X12649845 and X12649855-a metabolites was detected and quantified at a higher percent of the applied dose in at least one of the three incubation time points. The *in vitro* metabolism of proquinazid was extensive. Overall, the metabolic reactions involved a series of mono- and di-hydroxylations, ether hydrolysis (O-dealkylation), and glucuronide conjugation. The hydroxylated metabolites were further oxidized to ketone and/or carboxylic acid moieties. Three metabolites (X12649845, X12649801, and X12649859) in the rat species were subsequently identified in plasma of a ^{14} C *in vivo* study, two (X12649845 and X12649801) of these three were also observed in the current *in vitro* study with human hepatocytes. **Conclusions:** The proquinazid metabolite profile provides weight-of-evidence that metabolite formation maintains parity across toxicology test species and the human and between *in vitro* and *in vivo* test systems. Concordance with an *in vivo* rat study was observed and supported selection of 4 metabolites for PBK modeling. The overall results provide improved confidence for application to human health risk assessment.

PS 4560 Neurotoxicity Risk Modeling of Oral-Mucosal BPA Exposure from Dental Resin Composites: Implications for Reassessing the U.S. EPA Standard

R. Y. Kim¹, S. C. Simona², and Y. L. Kapila¹. ¹University of California, Los Angeles, Los Angeles, CA; and ²University of California, Irvine, Irvine, CA. Sponsor: O. Hankinson

Background and Purpose: Bisphenol A (BPA) is a ubiquitous organic monomer with well-documented endocrine-disrupting and neurotoxic effects. Dental materials frequently contain BPA derivatives, such as bisphenol A-glycidyl methacrylate (bis-GMA) in resin-based composite fillings, which can release BPA into the oral cavity upon degradation. Although BPA exposure from dental resin composites (DRCs) has been considered safe based on regulatory thresholds, these existing ingestion-based safety levels do not account for oral-mucosal absorption, a critical exposure route for dental materials that remain in the oral cavity for extended periods. Furthermore, the recent substantial downward revision of the BPA safety guideline by the European Food Safety Authority (EFSA) suggests the need for reevaluation. Despite the widespread use of DRCs—utilized in 96.1% of caries restorations in the U.S.-insured population in 2023—the neurotoxicity risk associated with BPA absorption through the oral mucosa remains uncharacterized. **Methods:** To evaluate neurotoxicity risk from BPA oral-mucosal absorption, we derived a novel serum reference dose (SRfD) by integrating data from a murine BPA neurotoxicity study and cross-species BPA metabolic studies. A one-compartment risk assessment model was used to estimate serum BPA levels resulting from chronic BPA mucosal absorption (BMA) in modeled U.S. pediatric (ages 6-11) and adult (ages 20-64) populations undergoing simulated caries treatment with 5% or 30% bis-GMA composites. Model parameters were obtained from published sources, including dental material fact sheets, population statistics, and human serum BPA measurements. **Results:** All BMA exposure scenarios, including 1% absorption from DRCs containing 5% bis-GMA, exceeded the neurotoxicity SRfD of 0.000328 ng/ml in both populations, regardless of other BPA sources. Whereas only 0.1% of ingested BPA enters systemic circulation as bioactive BPA, BMA was estimated to result in 4-5% steady-state serum concentration of bioactive BPA, suggesting greater bioavailability and potential for toxicity. The neurotoxicity risk associated with the current U.S. Environmental Protection Agency (EPA) reference dose exceeded the SRfD by at least 2,250-fold, whereas the EFSA guideline remained more than 100-fold below the derived SRfD. **Conclusions:** The derived SRfD enables neurotoxicity risk assessment across exposure routes, particularly oral-mucosal absorption, which is highly relevant to dental materials. The elevated risk from BMA highlights the importance of careful safety evaluation of dental materials, as substances retained in the oral cavity may serve as chronic sources of exposure to neurotoxicants, such as BPA. Reassessment of the EPA safety threshold is urgently warranted, given that it has remained unchanged since 1988, exceeds the updated EFSA guideline by 250,000-fold, and far surpasses the derived neurotoxicity SRfD.

PS 4561 A Key Biodistribution Study, with Fluorescent Acquisitions in Mice, for the Development of a Therapeutic Candidate for ALS Patients

J. Medina¹, M. Pierrelvein², O. Petit², V. Pierre², C. Levasseur², E. Chereul², and H. Perron¹. ¹GeNeuro Innovation, Geneva, Switzerland; and ²ERBC, Dommartin, France. Sponsor: R. Fares

Background and Purpose: K-ENV is present in affected brain neurons and cerebrospinal fluid (CSF) of sporadic amyotrophic lateral sclerosis (ALS) patients. A study was performed at ERBC Dommartin to evaluate biodistribution of GNK301, an IgG4 humanized antibody neutralizing the HERV-K ENV (K-ENV) neurotoxic endogenous retroviral protein. **Methods:** A fluo-labelled version of GNK301 was injected IV to 2 groups of mice previously injected intracerebrally by stereotaxy with K-ENV protein or its solution buffer. A third group of 4 mice served as untreated sham control. Clinical follow-up and fluorescent imaging using an IVIS Spectrum were performed over 5 days post administration. **Results:** A specific accumulation of fluo-GNK301 was observed in the cerebral hemispheres of treated mice. A significantly elevated signal was present in the left hemisphere, at the site of K-ENV stereotaxic injection, in comparison to the signal obtained in mice not injected with K-ENV. Sham mouse brains displayed no signal. **Conclusions:** These results indicate the passage of fluo-GNK301 across the blood brain barrier and its accumulation at the site of K-ENV antigen injection in the left brain hemisphere. This work highlights the usefulness of fluorescence detection in preclinical animal studies, in particular when exploring biodistribution in the central nervous system.

PS 4562 Analytical method development and dermal absorption of Pyranine Conc(G204), a cosmetic ingredient

K. Kim, J. Kim, H. Kim, H. Chung, J. Lee, J. Kim, and H. Kim. Dankook University, Cheonan, Korea, Republic of.

Background and Purpose: Pyranine Conc (G204) is utilized as a coloring agent of cosmetics at a maximum concentration of 0.01% in Korea and it is not allowed to be used around the eyes or on the lips. As no reports exist regarding the dermal absorption of G204 in cosmetic products, an *in vitro* dermal absorption study was conducted in compliance with the guidelines according to the Ministry of Food and Drug Safety (MFDS) of Korea. **Methods:** Prior to conducting the dermal absorption study, analytical methods were established using high-performance liquid chromatography with ultraviolet detection (HPLC-UV) technique for the quantification of G204 in various matrices, including swabs, stratum corneum (SC), skin (dermis and epidermis), and receptor fluid (RF). The G204 analytical method used in this study demonstrated excellent linearity ($r^2 = 0.9911$ - 0.9998), accuracy (81.1-109.1%), and precision (0.5-7.2%) in compliance with the validation guidelines. Considering the LLOQ values for each matrix, dermal absorption studies were conducted using 0.3% and 0.5% G204 formulations, concentrations higher than the maximum permitted level, in order to ensure the analytical accuracy of the study. To evaluate the skin absorption of G204 in coloring agent, a Franz diffusion cell was utilized. Cream formulation of G204 (0.3 and 0.5%) was applied to mini-pig skin at a dose of 10 μ l/cm². After 24 hours of application, the skin was wiped with a swab, and the stratum corneum (SC) was collected using tape stripping. Subsequently, the mini-pig skin was sectioned into eight pieces, and receptor fluid (RF) samples were collected at 0, 1, 2, 4, 8, 12, and 24 hours. **Results:** As a result, the total dermal absorption rate of G204 was determined to be 0.60 ± 0.39 μ g/cm² ($10.11 \pm 6.49\%$) and 1.38 ± 1.00 μ g/cm² ($13.75 \pm 9.90\%$) for the cream formulations of 0.3 and 0.5%, respectively. **Conclusions:** These results can be utilized for the exposure assessment of G204 when used as a cosmetic ingredient.

PS 4563 Hepatotoxic Mechanisms by Drug-Induced Cholestasis and Reactive Metabolites in Human Hepatocyte Co-Culture System

C. H. Cho¹, T. Landry², and M. Klausner². ¹Visikol, Inc, Ashland, MA; and ²MatTek Corporation, Ashland, MA.

Background and Purpose: Hepatotoxicity is a critical concern in drug development because the liver is the primary organ responsible for drug metabolism and detoxification. Drug-induced cholestasis (DIC) represents a major subtype of drug-induced liver injury (DILI) that arises when compounds disrupt bile acid synthesis, uptake, or efflux in hepatocytes. This leads to bile acid accumulation and liver injury. Early detection of cholestatic potential is essential, as DIC is often species-specific and not reliably predicted by conventional animal models. Reactive drug metabolites are unstable intermediates formed during xenobiotic biotransformation, primarily mediated by hepatic cytochrome P450 (CYP) enzymes. These metabolites can covalently bind to cellular macromolecules such as proteins, lipids, and DNA, causing oxidative stress, mitochondrial dysfunction, and immune-mediated hepatocellular injury. Traditional liver toxicity assessments relying on animal models and isolated liver tissues have limitations including high cost, low throughput, interspecies variability, ethical concerns, and limited predictivity for human outcomes. We previously developed an advanced hepatocyte co-culture system that maintains long-term viability (>4 weeks) and stable metabolic function. These models (human, dog, and rat) were

validated with 29 reference compounds, demonstrating dose-dependent hepatotoxicity, species-specific responses, and improved sensitivity (83-92%) compared to hepatocyte monocultures (50%). In the present study, we utilized the human hepatocyte co-culture system to evaluate compounds associated with DIC and determine the effect of reactive metabolites on hepatotoxicity. **Methods:** The human hepatocyte system was generated by co-culturing cryopreserved primary human hepatocytes with stromal fibroblast cells in collagen-coated 96-well plates for one week prior to test compound exposure. For the DIC study, cholestatic compounds (cyclosporin A and bosentan) were tested at seven concentrations in the presence and absence of a bile acid (BA) mixture to mimic physiological cholestatic conditions. For the reactive metabolite study, compounds known to produce bioactivated intermediates (cyclophosphamide and aflatoxin B₁) were tested at seven concentrations with and without a broad pan-CYP inhibitor, aminobenzotriazole (1 mM). Hepatotoxicity was assessed using an ATP cell viability assay after 7-day exposure to the test compounds. TC₅₀ values were calculated from non-linear regression curves fitted with GraphPad software. **Results:** The results demonstrated dose-dependent hepatotoxic effects for the test compounds. In the DIC study, TC₅₀ values for both cyclosporin A and bosentan were significantly lower with BA supplementation, indicating bile acid associated hepatotoxicity. In the reactive metabolite study, co-treatment with the CYP inhibitor significantly reduced the cytotoxicity of both cyclophosphamide and aflatoxin B₁. TC₅₀ values for these compounds were significantly higher with the CYP inhibitor, confirming that their hepatotoxicity is mediated by reactive metabolite formation. **Conclusions:** The human hepatocyte co-culture model provides a robust and predictive *in vitro* platform for elucidating hepatotoxic mechanisms associated with cholestasis and reactive metabolites. These models enable identification of cholestatic risk, mechanistic evaluation of bioactivation and detoxification pathways, and detection of delayed or cumulative hepatotoxicity from repeated exposure. Overall, these models reduce reliance on animal testing and improve human-relevant risk assessment, supporting the design and development of safer drug candidates.

PS 4564 Multi-Method, Interpretable Prediction of Oral Bioavailability and Formulation Vehicle Effects

S. Chakravarti¹, M. Girireddy¹, S. Parker², K. Ehman³, and G. Cioffi¹. ¹MultiCASE Inc., Mayfield Heights, OH; ²SParker Toxicology Consulting LLC, Fort Lauderdale, FL; and ³Eurofins Medical Device Services, Lancaster, PA.

Background and Purpose: Both active pharmaceutical ingredients (APIs) and trace chemical impurities can vary widely in oral bioavailability (BA), driven by differences in physicochemical properties, metabolism, transport mechanisms, and formulation characteristics. Solvent or vehicle choice, such as aqueous suspensions, co-solvent systems, or lipid carriers, can influence systemic exposure; however, practical tools for assessing overall BA and its sensitivity to vehicles remain limited. In addition to APIs, predicting the bioavailability of leachable or extractable impurities is critical for assessing systemic exposure related toxicological risks arising from container closure systems and medical devices. This work presents a novel, transparent and multi-method prediction framework that integrates data-driven QSAR models, read-across, and expert rules to (i) estimate baseline oral BA and (ii) evaluate how formulation vehicles may shift that baseline. **Methods:** The framework integrates several complementary components: 1. **Curated database:** A dataset of 1,594 compounds with experimentally measured BA from peer-reviewed literature. 2. **Baseline BA Prediction System:** Three independent methods provide qualitative BA classifications (Very Low, Low, Medium, High) with associated uncertainty estimates: i. **Analog-based prediction:** Using top analogs, based on structural, physicochemical and BA specific feature similarity. ii. **QSAR model:** Built using physicochemical and fragment-based molecular descriptors. iii. **Expert rule-based prediction:** Applies interpretable thresholds for molecular weight and LogP. 3. **Supplementary ADME Modifiers and Vehicle Sensitivity Module:** i. **ADME Modifiers:** QSARs for metabolic stability, CYP substrate likelihood, and MDR1 (P-gp) substrate potential. ii. **Vehicle Sensitivity:** Expert rules that evaluate LogP, LogS, TPSA, and HBD to characterize solubility-permeability balance and Biopharmaceutics Classification System (BCS) class. Logical criteria for aqueous CMC (0.5%), aqueous co-solvent (≤5% DMSO), and lipid or surfactant systems predict qualitative BA changes (significant, modest, or minimal) with mechanistic rationale. **Results:** Across diverse chemotypes, the multi-method framework produced consistent and interpretable outcomes. Analog-based and QSAR predictions generally agreed within uncertainty margins, while the rule-based method provided a transparent baseline and mechanistic rationale. In cross-validation, the analog-based approach achieved 47% strict and 89% within-one-tier accuracy, the QSAR model 45% and 88%, and the expert rules 39% and 79%, respectively. Supplementary ADME screens identified cases where rapid metabolism or transporter interactions restricted achievable BA despite favorable solubility-permeability profiles. Predicted formulation-property relationships aligned with experimental behavior—for example, lipid-based vehicles produced the largest BA gains for highly lipophilic, poorly soluble molecules (LogP > 5; LogS < -2) with adequate permeability (TPSA < 120 Å²; HBD ≤ 5). **Conclusions:** This integrated framework provides a mechanistically interpretable and validated approach for predicting oral bioavailability and its modulation by formulation vehicles. By combining analog-based inference, probabilistic QSARs, and expert rules within an ADME-aware context, it delivers both predictive confidence and mechanistic insight. Beyond APIs, the approach extends to predicting the bioavailability and systemic exposure of extractable and leachable impurities, supporting evaluation of their potential human health impact. Overall,

the framework unites empirical formulation science and computational modeling to inform early-stage formulation design, impurity risk assessment, and regulatory decision-making.

PS 4565 Proquinazid: Quantitative Blood and Plasma Metabolite Identification in the Sprague-Dawley Rat to Support an Improved Evaluation of Internal Dosimetry

C. McAllister¹, M. W. Himmelstein¹, L. Cai¹, and L. Kent². ¹Corteva Agriscience, Newark, DE; and ²Corteva Agriscience, Milton Park, United Kingdom.

Background and Purpose: Proquinazid is a crop protection fungicide for which an improved understanding of metabolism in the rat is needed to support safety testing and regulatory assessment. Previous absorption, distribution, metabolism and excretion (ADME) studies in the rat investigated proquinazid-¹⁴C metabolites in excreta (urine and feces), plasma pharmacokinetics, tissue distribution, and biliary elimination following single oral dose administration. A follow-up study was conducted with repeated oral dose administration of proquinazid-¹⁴C; however, neither study investigated the metabolite profile of proquinazid in the systemic circulation, a key matrix for advanced kinetic modeling to facilitate interpretation of toxicological findings. The current study identified and quantified the profile of proquinazid metabolites in plasma and blood of female Sprague Dawley rats, the species used for the existing regulatory toxicology package. **Methods:** The profile of metabolites in the blood and plasma of female Sprague Dawley (CrI:CD(SD)) rats was investigated following single oral gavage administration of proquinazid-Ph-UL-¹⁴C (proquinazid-¹⁴C) at 20 mg/kg bw (body weight). Female rats were selected since the metabolism and pharmacokinetic parameters were similar between sexes in previous ADME studies. The dose level matched that previously used. The ¹⁴C dose of 500 µCi/kg bw was prepared in 0.1% Tween 80 in 0.5% aqueous methylcellulose at a dose volume of 10 mL/kg bw. Blood and plasma samples were collected in a staggered design distributed among 4 rats to provide a ¹⁴C concentration time course at 0.25, 1, 2, 4, 6, 8, 10, and 12 h after administration. After total ¹⁴C counting, the parent proquinazid-Ph-UL-¹⁴C radiolabeled test substance and metabolites were quantified in the rat plasma and blood samples using HPLC with in-line radioactivity detection and identification was performed using high resolution accurate mass (HRAM) spectrometry with confirmation using available reference standards. Kinetic analysis of the plasma and blood time-course results included determination of T_{max}, C_{max}, area-under-the-curve (AUC), and metabolites as a percentage of the total ¹⁴C AUC. **Results:** Undifferentiated proquinazid-¹⁴C equivalents were reliably quantified through 12 h post dose administration. Parent proquinazid was extensively metabolized and was not quantifiable in either plasma or blood. Eleven metabolites were observed in rat plasma and blood. The metabolic pathway involved: 1) mono- and di-hydroxylation, 2) O-dealkylation, 3) N-dealkylation, 4) oxidation of terminal N-propyl carbon to carboxylic acid, 5) glucuronidation, 6) sulfate conjugation, and 7) combinations thereof. Ranked in order of plasma C_{max} values, the most abundant metabolites were X12649845, X12649801, X12688723, and X12649859, with similar rankings in blood. The overall T_{max} for ¹⁴C equivalents was 2 h, while T_{max} values for metabolites ranged from 1 to 10 h. AUC values of the 11 measured metabolites, summarized as percent of the total ¹⁴C equivalents, accounted for 97.2% and 98.0% of the total ¹⁴C AUC in plasma and blood, respectively. The four most abundant metabolites accounted for 84.3% and 86.8% of the total radioactivity in plasma and blood, respectively. The remaining 7 metabolites in plasma and blood accounted for ≤12.9% of the total ¹⁴C AUC. None of these 7 metabolites individually accounted for greater than 2.7% except for X12649849 and a tentative hydroxylated metabolite of X12649801 (MW346) which co-eluted and could not be distinguished from each other. **Conclusions:** Overall, systemic exposure was well characterized by the percent AUC rank order of the four most abundant metabolites in plasma and blood as X12649845 > X12649801 > X12688723 > X12649859. This data provides internal dosimetry of metabolites for proquinazid-induced liver effects and serves a key role for PBK modeling development in the rat for subsequent extrapolation to the human liver dosimetry.

PS 4566 iPSC-derived Intestinal Epithelial Cells Form a Functional, Relevant Barrier Model of the Human Gut

K. Twaroski, Y. Imakura, S. Burton, C. Savic, M. Donegan, R. Lewis, J. Liu, R. Fiene, D. Majewski, and C. Carlson. FUJIFILM Cellular Dynamics, Madison, WI. Sponsor: R. Vaidyanathan

Background and Purpose: Intestinal epithelial cells (IEC) make up the single layer lining of the small intestine. These cells act as a barrier to prevent entry of harmful products and regulate uptake of nutrients and fluid. The intestinal epithelial layer is composed of numerous cell types with varied roles, including goblet cells for mucin secretion and M-cells for the uptake of antigens and intestinal bacteria. Human iPSC-derived IEC offer a renewable source of cellular material with consistent intestinal function and are available for use in FDA-recommended New Approach Methodologies (NAM). **Methods:** iCell Intestinal Epithelial Cells (FUJIFILM Cellular Dynamics) were differentiated from two different donors (01279 and 21527) and cryopreserved at a density of >3M cells per vial. Upon thaw, cells were characterized by flow cytometry, ICC, and RNA expression using IEC identity markers CDX2, EpCAM, VIL1, and KRT20. Cells were cultured on Transwell® Inserts in both 24- and

96-well format. Barrier function was assessed over time by TEER assay and under inflammatory conditions +/- TNF α (100 ng/mL) and IFN γ (50 ng/mL). CYP activity was measured by P450-Glo™ Assays (Promega) and LC-MS/MS and correlated to human *in vivo* Fg. iCell IEC were assessed for proliferation by Ki-67 flow cytometry. Intestinal subtypes were identified by ICC. **Results:** Human iPSC-derived IEC express CDX2, EpCAM, and VIL1 at >80% by flow cytometry and KRT20 around 70% for both donors. After a 5-day maturation period post-thaw, iCell Intestinal Epithelial Cells showed TEER values >600 ohms x cm² and stably maintained that level for at least another 5 days. During this time frame, P-gp activity was assessed and iCell IEC exhibited an efflux ratio >2, indicating functional transporter activity. CYP3A4 activity from iPSC-derived IEC was equivalent to primary intestinal cells. Moreover, the estimated *in vitro* Fg for Felodipine, Midazolam, Verapamil, and Sildenafil were highly correlated to Human *in vivo* Fg. All of these suggest iCell IEC is a reliable system for studying intestinal drug metabolism and absorption. iCell IEC were nearly 50% positive for the proliferation marker Ki-67 by flow cytometry at thaw but decreased to less than 20% after 7 days of culture. Intestinal cell subtypes were identified by ICC, with a majority of enterocytes (KRT20) and presence of Goblet (MUC2), Paneth (LYZ), Enterendocrine (CHGA), Tuft (AVIL), and Microfold (GP2) cells at physiologically relevant levels. **Conclusions:** Nutrient and drug absorption and metabolism of the small intestine is critical to understanding drug efficacy and toxicity. iPSC-derived IEC provide a biologically relevant alternative to immortalized cancer lines without the inherent variability of primary tissue. Implementation of iCell IEC into assays for drug metabolism, uptake, and inflammatory response provides a novel platform for interrogating intestinal function in toxicology workflows with more human relevance.

PS 4567 Analyses of delta9-tetrahydrocannabinol and the endocannabinoids in mouse plasma and brain

S. H. Lusk, E. G. Romero, T. S. Freeman, K. S. Caldwell, L. Sun, M. D. Smith, C. A. Reilly, C. D. Rice, and J. E. Rower. University of Utah, Salt Lake City, UT.

Background and Purpose: Adolescence represents a critical period of neuromaturation, particularly within realms governing cognitive and behavioral function. Importantly, the endocannabinoid system (ECS) achieves peak expression and activity during this period. Delta9-tetrahydrocannabinol (THC) binds with high affinity to cannabinoid receptor 1 (CB1R) within the ECS, disrupting EC signaling and dysregulating neurotransmitters. A mouse model was utilized to test the hypothesis that vaporized THC dominant cannabis use causes sex- and age-dependent effects on the ECS. **Methods:** A commercially available THC dominant cannabis vape cartridge (75% THC) or vehicle (50:50 propylene glycol:vegetable glycerin, PG/VG) were administered once-daily to mice over 20 minutes via a SCIREQ In-Exposure inhalation system as part of an IACUC approved study. 8-week-old mice (adolescent) received either 1 or 5 weeks of cannabis, while 12-week-old mice (adult) received one week. Mice were sacrificed by decapitation at specified time points to collect plasma and brain, which were analyzed by liquid chromatography-tandem mass spectrometry (LC-MS/MS) to determine concentrations of THC/metabolites and the endocannabinoids anandamide (AEA) and 2-arachidonylglycerol (2-AG). Data analysis utilized Phoenix WinNonLin v8.5.2.4 and GraphPad Prism v10.6.1. **Results:** First-dose mean (standard deviation, SD) peak plasma concentrations of THC were 27.5 (14.0) and 25.8 (7.95) ng/mL for 8- and 12-week-old mice, respectively, and did not differ by sex. However, 8-week-old mice treated for 5 weeks had significantly lower peak THC plasma concentrations (mean (SD): 11.3 (2.57) ng/mL) than first dose in either 8- (p=0.0034) or 12-week-old (p<0.0001) mice. THC plasma half-life was 2.1 hr. OH-THC mean peak plasma concentrations were higher in males than females in both 8-week (3.45 vs. 2.00 ng/mL) and 12-week-old mice (3.37 vs. 2.13 ng/mL), though these values did not reach significance. Frontal cortex AEA in animals treated for one week did not differ by age or sex, but was significantly lower than vehicle treated animals (48.1 vs. 68.8 ng/g; p<0.0001). Similarly, frontal cortex 2-AG was lower in mice treated for one week compared to vehicles (3283 vs. 5273 ng/g; p=0.0003), but did not differ by age or sex. After 5 weeks of treatment, AEA (55.1 ng/g; p=0.01) and 2-AG (4334 ng/g; p=0.0004) were increased relative to a single week of treatment and similar to values observed in mice administered PG/VG vehicle for 5 weeks (AEA: 61.0 ng/g; 2-AG: 4593 ng/g). **Conclusions:** In summary, plasma PK of THC and its metabolites did not differ by age or sex, nor did frontal cortex concentrations of either AEA or 2-AG. Continued THC use over five weeks resulted in significantly lower THC plasma concentrations, likely indicating induced metabolism following chronic use. One week of THC dosing significantly reduced both AEA and 2-AG in the frontal cortex relative to vehicle controls, regardless of age, though decreases were attenuated after 5 weeks. These data suggest that acute THC dominant cannabis use has the potential to dysregulate neural function regardless of initiation age, while chronic use results in adaptations in metabolism of both exogenous and endogenous cannabinoids. Further work is needed to determine if ECS changes following the use of vaporized THC dominant cannabis drives changes in cognitive and/or behavioral function.

PS 4568 MSQ-DTR: A targeted proteomics tool for transporter quantification and validation of blood-brain barrier *in vitro* model systems

D. Melville, B. Prasad, and C. J. Watson. Precision Quantomics Inc, Spokane, WA. Sponsor: B. Prasad, American Society for Pharmacology and Experimental Therapeutics

Background and Purpose: Efflux transporters at the blood-brain barrier (BBB) play a critical role in protecting the central nervous system by actively transporting compounds out of the brain and into the surrounding vasculature, thereby limiting exposure to potentially harmful substances. The main classes of BBB efflux transporters include ATP-binding cassette (ABC) transporters namely P-glycoprotein (P-gp) and breast cancer resistance protein (BCRP), multidrug resistance proteins (MRPs), and solute carrier transporters such as organic anion transporting polypeptides (OATPs) and organic anion transporters (OATs). Current efforts to quantitatively characterize efflux transporter function at the BBB are often constrained by *in vitro* models that inadequately replicate the complex physiology of the BBB. A key limitation is the lack of accurate data on the proteomic abundance of transporters in these models, which hinders the translation of findings to *in vivo* contexts. For drug developers and toxicologists utilizing physiologically based pharmacokinetic (PBPK) models, this gap presents a significant challenge. Without reliable and translatable transporter expression data, predictions of drug disposition and CNS exposure remain uncertain, limiting the utility of these models in guiding therapeutic development and safety assessments. The objective of this study was to develop and validate an LC-MS assay tool kit (MSQ-DTR) for quantifying the abundance of efflux transporter proteins at the BBB. **Methods:** The MSQ-DTR kit includes unique and sensitive stable isotope-labeled (SIL) surrogate peptides for P-gp, BCRP, MRPs, and MATE1, as well as solute carrier transporters such as OATPs, OCTs, and OATs. Surrogate peptides were chosen to be conserved across multiple species to enhance translational relevance. We performed a simultaneous quantification of the target protein levels in commercially available samples of tissue and brain microvascular endothelial cells (BMECs) in humans and key preclinical species. Raw data was acquired using nanoLC coupled with a Q-Exactive HF mass spectrometer in the parallel reaction monitoring (PRM) mode and analyzed using Skyline software. **Results:** Validation of the MSQ-DTR quantification kit. The panel of surrogate peptides was shown to be linear, accurate, and reproducible across a wide range of concentrations, with coefficient of variation (%CV) values less than 20%. Surrogate peptides are stable in the matrix of human liver microsome digest for up to 48 hours at 6 °C, showing an 85-115% response at both the upper and lower limit of quantification (ULOQ and LLOQ). **Quantification of efflux transporters in samples.** The MSQ-DTR kit was used to analyze commercially supplied BMEC lots from single donors. In these test samples the expression levels of P-gp and BCRP in human, mouse, and monkey BMECs were found to be less than 1 pmol/mg. This value is significantly lower than previously published values and underscores a key challenge - technical variability in commercially available *in vitro* models. These results show that future efforts to improve reliability and translatability should always include samples from multiple donors and include rigorous validation across platforms. **Conclusions:** While there are numerous ongoing efforts to develop *in vitro* models of the BBB, incorporating transporter proteomics should be an integral piece of the qualification of such models. Our future work includes utilizing the MSQ-DTR kit to characterize *in vitro* and experimental models such as microphysiological systems and additional preclinical animal models, as well as assessment of donor and lot-to-lot variability of cell lines and other *in vitro* reagents. We envision the MSQ-DTR kit will provide researchers with a tool to collect robust abundance data on efflux transporters, ensuring the translational relevance and reliability of the data. A better understanding of BBB models allow for improved *in vitro* to *in vivo* extrapolation predictions and ultimately improved accuracy of drug metabolism and toxicity predictions.

PS 4569 Development and Application of a Physiologically-Based Kinetic Model for Evaluation of Internal Dose in the Rat and Human

J. Fitzpatrick¹, M. W. Himmelstein², and L. Kent³. ¹Corteva Agriscience, Indianapolis, IN; ²Corteva Agriscience, Newark, DE; and ³Corteva Agriscience, Milton Park, United Kingdom.

Background and Purpose: Proquinazid is a fungicide used on food crops. The regulatory toxicological package identifies the liver and thyroid as target organs in rats following exposure to proquinazid. The pattern of effects suggest that effects on the thyroid are likely due to higher thyroid hormone turnover as a consequence of liver induction, in particular increased UGT clearance of T4. A conservative reference point of 5 µM was taken from a study comparing UGT-T4 activity in Sprague-Dawley (SD) rat and human hepatocytes *in vitro*. A PBK model was used to determine if the human liver concentration of proquinazid and the sum of its metabolites would reach a 5 µM liver concentration *in vivo*, from estimated dietary exposure. **Methods:** A fit for purpose PBK model was created in R, using assumptions derived from available proquinazid *in vivo* and *in vitro* ADME studies. The PBK model was used to make predictions assuming an estimated, worst-case chronic dietary exposure of 0.84 µg/kg bw/day in humans (predicted from the EFSA PRIMo v3.1 dietary exposure model). **Results:** The predicted sum of proquinazid and its major metabolites in liver was 0.00240 and 0.00266 µM for male and female subjects, respectively. These results suggested that the margin-of-safety approaches 2000-fold relative to the much lower

estimated dietary exposure in humans. **Conclusions:** The human liver internal dose would not be expected to approach a level that would be associated with biologically relevant liver mediated thyroid effects, following worst-case human exposure estimates.

PS 4570 A Physiologically Based Pharmacokinetic (PBPK) Model to Align Dosimetry of the Isobutyl Metabolic Series in Rats and Humans

J. N. Smith^{1,2}, K. J. Tyrrell¹, K. K. Weitz¹, and W. Faber³. ¹Pacific Northwest National Laboratory, Richland, WA; ²Oregon State University, Corvallis, OR; and ³Willem Faber Toxicology Consulting, LLC, Victor, NY.

Background and Purpose: Traditional chemical risk assessment often involves evaluating toxicity data for individual chemicals in laboratory animals. However, for metabolically related chemicals, the metabolic series approach offers an alternative method to assess toxicity of downstream metabolites after exposure to a parent compound, provided that the chemical dosimetry is well understood. In this study, we developed a physiologically based pharmacokinetic (PBPK) model in rats and humans for the isobutyl metabolic series, which includes isobutyl acetate, isobutanol, isobutyraldehyde, and isobutyric acid. **Methods:** To construct the isobutyl PBPK model, we leveraged a previously developed PBPK model for the propyl metabolic series as a framework. To support model development, we measured *in vitro* metabolism of isobutyl acetate in rat and human blood and liver S9 fractions. **Results:** Our findings indicated that humans exhibited faster isobutyl acetate hydrolysis in liver S9 fractions compared to rats, while hydrolysis rates in blood were similar between the two species. Experiments involving closed chamber exposures of rats to isobutyl acetate or isobutanol revealed higher isobutanol concentrations in blood compared to other isobutyl compounds. Using these data to parameterize the model, the PBPK model accurately simulated available time-course concentrations of isobutyl compounds in rats and humans. **Conclusions:** The isobutyl PBPK model enables comparisons of internal dose metrics across various isobutyl compound exposures and species and allows for calculation of equivalent external exposures that result in the same dose metric. Regulators can employ this PBPK model to predict and align internal dose metrics of isobutyl compounds for risk assessment purposes.

PS 4571 MASH Impairs Renal Anion Transporter Function and Alters Cefazolin Disposition

M. M. Maloney, D. O. Farrera, L. J. Martinez-Guerrero, S. Marie, M. M. Alaaldin, P. Lindberg, K. Frost, P. A. Sample, C. S. LaMadrid, P. Lenzen-Hammerl, L. R. Radtke, S. H. Wright, and N. J. Cherrington. University of Arizona, Tucson, AZ.

Background and Purpose: Metabolic dysfunction-associated steatohepatitis (MASH), a progressive form of liver disease, affects up to 7% of the global population. While hepatic transporter alterations in MASH have been well characterized, far less is known about the effect of MASH on renal transport processes. In particular, the renal handling of organic anions remains poorly understood. Herein, we used cefazolin (CEF), an anionic antibiotic primarily used to prevent surgical site infection, as a model compound to investigate MASH-induced alterations in renal transporter function and their role in pharmacokinetics. **Methods:** MASH was induced in mice using fast food-dieted/thioacetamide (FFDTH) which has been shown to accurately model the renal transporter changes seen in human MASH. Transporter expression was evaluated using LC-MS/MS proteomics and plasma, urine, and tissue concentrations of CEF were determined. **Results:** Expression of Oat3 and Oat5 were significantly reduced (50% and 80%, respectively) in MASH animals compared to controls. In response, plasma concentrations of CEF increased to 183% in MASH compared to controls, while hepatic accumulation increased to 180% of control. No differences in renal accumulation or excretion of CEF were observed between MASH and healthy mice. **Conclusions:** This data suggests that MASH-induced OAT transporter reduction increases both systematic CEF concentration along with accumulation in liver, without differences in renal or urinary excretion. Overall, these findings highlight the risk of increased systemic exposure in MASH patients, ultimately suggesting that it would be beneficial to explore dose adjustments in these patients.

PS 4572 PCB-11 Induces Brain CYP2B10 Expression and Activity in Mice: Implications for Neurotoxicity and Drug Interaction Potential

D. Manhas¹, W. Han¹, M. Hollon¹, X. Wu¹, W. Yang¹, X. Li², Q. Zhang¹, H. Lehmler², P. J. Lein³, and X. Ding¹. ¹University of Arizona, Tucson, AZ; ²University of Iowa, Iowa, IA; and ³University of California Davis, Davis, CA.

Background and Purpose: 3,3'-Dichlorobiphenyl (PCB-11) is a persistent environmental contaminant unintentionally produced during the synthesis of diarylide yellow and other organic pigments, which are used in printing inks and other applications. It enters the environment through air, water, and consumer products, and has been detected in human tissues, raising concerns about its potential health risks. Experimental evidence suggests that PCB-11 and its metabolites can disrupt neuronal connectivity, implicating possible neurodevelopmental and neurotoxic

outcomes. Cytochrome P450 (CYP) enzymes are key mediators of xenobiotic and endogenous compound metabolism. Among them, CYP2B6 (and its murine homolog CYP2B10) plays an important role in metabolizing neuroactive drugs, thereby influencing both therapeutic efficacy and the risk of adverse effects. CYP enzymes also metabolize PCBs into hydroxylated metabolites (OH-PCBs), which can be more toxic than the parent compound. The aim of this study is to understand how PCB-11 influences CYP2B10 expression in the brain, which is essential for evaluating the potential of PCB-11 to alter drug metabolism and neurotoxic outcomes. **Methods:** Wild-type C57BL/6 mice were exposed to PCB-11 (500 µmol/kg body weight) or vehicle (peanut oil) via oral gavage for three consecutive days. Brain membrane preparations and liver microsomes were prepared 24 hours after the final exposure. CYP2B10 protein levels were quantified using Western blotting, and CYP2B enzyme activity was assessed using bupropion as a substrate. **Results:** The PCB-11 oral exposure significantly increased CYP2B10 protein expression in mouse whole brain membrane preparations, compared with vehicle controls. Enzyme activity assays using bupropion as a substrate confirmed a substantial increase in brain CYP2B10 activity. Consistent with these findings, liver microsomes from the same animals also showed a robust increase in CYP2B10 activity following PCB-11 treatment. These findings indicate that PCB-11 exposure upregulates CYP2B10 protein levels and activity in the brain. **Conclusions:** PCB-11 exposure induces significant increases in CYP2B10 expression and activity in both brain and liver of mice. This induction suggests potential for auto-induction of its own metabolism and formation of hydroxylated PCB metabolites that may contribute to neurotoxicity. Moreover, upregulation of CYP2B10 in the brain highlights the possibility of altered metabolism of neuroactive drugs, raising concern for PCB-related drug-environment interactions. Together, these findings identify a novel mechanism by which PCB-11 exposure may modulate brain metabolism, offering new insight into its neurotoxic and pharmacological implications. (supported in part by NIH grant ES014901).

PS 4573 Translating Internal Dosimetry of an Environmental Mixture of Polycyclic Aromatic Hydrocarbons (PAHs) from Zebrafish to Humans

J. N. Smith^{1,2}, C. I. Rude², K. A. Gaither¹, and R. L. Tanguay². ¹Pacific Northwest National Laboratory, Richland, WA; and ²Oregon State University, Corvallis, OR.

Background and Purpose: New Approach Methodologies (NAMs), such as high-throughput screening with zebrafish models, enables rapid assessment of chemical hazards. However, translating toxicity data from zebrafish experiments to humans poses significant challenges due to complexities associated with correlating zebrafish nominal exposures to human internal dosimetry. This study aims to address these challenges by using pharmacokinetic modeling to translate zebrafish exposures to Supermix-10, the ten most abundant PAHs found at the Portland Harbor Superfund Site, into corresponding human exposures. **Methods:** To facilitate cross-species comparison, we developed a generalized human physiologically based pharmacokinetic model (PBPK) to simulate the disposition of PAHs in humans. This model builds on a previous PBPK model framework developed in our lab for high molecular weight PAHs. We parameterized the model with measured human metabolism rates of naphthalene, 2-methylnaphthalene, chrysene, benzo(a)anthracene, pyrene, fluorene, fluoranthene, phenanthrene, and retene in humans and estimated partition coefficients using algorithms. A published zebrafish PBPK model estimated key internal dose metrics (e.g. peak concentration in zebrafish embryos and area under the curve (AUC)) for Supermix-10 exposures. Subsequently, we applied reverse dosimetry techniques to translate zebrafish internal dose metrics into human external dose equivalents, linking zebrafish toxicity outcomes to human exposure scenarios. **Results:** All Supermix-10 PAHs demonstrated rapid parent compound disappearance in human hepatic microsomes. PAH metabolism rates grouped into three patterns: high metabolism activity and capacity, where rapid metabolism did not saturate under the tested conditions (2-methylnaphthalene, acenaphthylene, fluorene, naphthalene, and retene); high affinity metabolism that rapidly achieves low-level saturation (benzo[a]anthracene and chrysene); or moderate metabolic activity and capacity (fluoranthene, pyrene, and phenanthrene). The zebrafish PBPK model accurately predicted 83% of 48-hour post fertilization (hpf) body burdens within a factor of two. Zebrafish PBPK models simulations of AUC of concentrations in zebrafish resulted in altered hazard rankings from nominal exposure concentrations. Reverse dosimetry using the human PBPK model predicted human exposure levels that would lead to toxicity threshold observed in zebrafish. **Conclusions:** Here, we demonstrate the utility of dosimetry modeling to translate nominal exposure levels in a zebrafish NAM system to external exposures in humans. This suite of dosimetry models can assist risk assessment and cleanup efforts at contaminated sites. This study demonstrates the utility of dosimetry modeling approaches for translating zebrafish NAM exposure data into human-relevant external exposures. By bridging the gap between nominal zebrafish exposures and human dosimetry, this framework enhances the utility of zebrafish systems for risk assessment and informs remediation strategies for contaminated sites. Supported by NIH Grant P42 ES016465.

A. Hasegawa, M. Okumura, Y. Suzuki, C. Matsuura, K. Kondo, T. Takahashi, and T. Shoda. Toxicology Research Laboratories, Yokohama Research Center, Shionogi & Co., Ltd., Yokohama, Kanagawa, Japan. Sponsor: E. Spicer

Background and Purpose: Urinalysis is one of the non-invasive methods in the toxicity assessment of drug candidates and is required by the ICH safety guidelines. The amount of urinary electrolyte excretion is typically calculated by multiplying the concentration of the urinary electrolyte by the urine volume (volume-based calculation method). However, in cases where only a limited volume of urine can be collected, such as in toxicity studies using small mice, this method is not applicable because of drying of the samples during collection or retention of the urine in the cage, resulting in incomplete collection. In the clinical field, a method for evaluating electrolyte excretion using correction based on urinary creatinine (CRN) (CRN-corrected method) has been established. However, the validity of this method remains unclear in small mice including the BALB/c strain. In this study, empagliflozin was administered orally for 10 days to ICR and BALB/c mice to evaluate the validity of the CRN-corrected method for assessing urinary electrolyte excretion. Using ICR mice, the validity of CRN-corrected electrolyte excretion was evaluated by comparing it with the volume-based calculation method. Furthermore, in BALB/c mice, changes in electrolyte excretion were assessed using the CRN-corrected method. By comparing the CRN-corrected results obtained from both strains, the applicability of this method in mice was examined. **Methods:** Empagliflozin was administered orally, once daily, to CrI:CD1(ICR) (ICR) and BALB/cJ (JLJ) male mice (9 weeks of age, 6 animals per group of both strains) at the dose levels of 100 and 1000 mg/kg for 10 days. The animals in the matched control groups (6 animals of both strains) were administered only the vehicle (0.5% hydroxyethylcellulose aqueous solution). The animals were placed in metabolism cages after dosing on Day 10 and urine samples were collected for approximately 24 hours. The urine concentrations of the following parameters were measured using an automatic analyzer: glucose (GLU), calcium (Ca), inorganic phosphorus (IP), sodium (Na), potassium (K), chloride (Cl) and creatinine (CRN). In ICR mice the amounts excreted of the urinary electrolytes and glucose were calculated by the volume-based calculation method and the CRN-corrected method (amount excreted per gram of CRN). In BALB/c mice the amounts excreted of the urinary electrolytes and glucose were calculated using only the CRN-corrected method. The electrolyte and glucose excretion levels calculated by this method were compared between the BALB/c and ICR mice. **Results:** When comparing the electrolyte excretion calculated using the urine volume-based calculation method with that calculated using the CRN correction method in ICR mice, there was a positive correlation for all the parameters of Na, K, Cl, Ca, IP, and GLU. The degree of change in the electrolyte and glucose excretion calculated by the CRN-corrected method at 100 mg/kg and 1000 mg/kg was comparable between ICR and BALB/c mice when compared with each control group. In ICR mice a positive correlation was observed between the electrolyte and glucose excretion calculated by the volume-based method and the CRN-corrected method, indicating that the CRN-corrected approach is also applicable for evaluating urinary electrolyte and glucose excretion in mice. In addition, since the CRN-corrected results were comparable between the two mouse strains, CRN correction was considered to be applicable for excretion assessment even in small mice, where use of the urine volume-based calculation is problematic due to the limited amount of urine collected. **Conclusions:** Although this approach may show slight differences in the rate of change compared with urine volume-based calculation, this method provides a useful alternative when measurement of the urine volume is problematic.

PS 4575 Considerations for Appropriate Application of One-Compartment Toxicokinetic Models to Assess Per- and Polyfluoroalkyl Substances (PFAS) Exposures

J. Chien, R. D. Rogers, and B. D. Beck. Gradient, Boston, MA.

Background and Purpose: A one-compartment (OC) model is the simplest form of a toxicokinetic model where the entire body is considered a single, homogenous unit. This is unlike physiologically based (PB) models that characterize the movement of substances between different compartments within the body (e.g., blood, bone, organs). A key advantage of OC models is the reduced data needs compared to PB models, allowing for broader applications. A good example of this is with PFAS OC models, which have been developed to characterize PFAS exposures in impacted communities. These models have been useful for PFAS research and in public health contexts; however, their limitations can be overlooked, and such models can be used inappropriately. In this analysis, we review several OC models that have been used for risk assessment, compare the models' strengths and limitations, demonstrate how specific inputs can impact model results, and propose a list of considerations to inform whether use of the OC model is appropriate. **Methods:** We identified OC PFAS models for inclusion based on the following considerations: 1) the model was developed for human exposure characterization; 2) the model was developed/updated in the last 15 years; 3) data used in development and calibration were well described; 4) model validation had been performed; and 5) the model has been applied in risk assessment. We compared model features and evaluated how differences between them impact model outputs by running them with the same hypothetical exposure scenarios. **Results:** We reviewed publications that developed or applied OC

models, including models developed as part of the C8 Health Study, by the Minnesota Department of Health, and by the Agency for Toxic Substances and Disease Registry. All models include variables for intake dose, clearance rate (calculated based on half-life [$t_{1/2}$]), and volume of distribution (V_d). The simplest OC models reflect steady-state conditions, while dynamic models include changes in parameters over time. Some models incorporate additional variables (e.g., placental transfer, lactation, menstruation) while maintaining an OC structure. A few models incorporate background PFAS exposures in their calculations. The choice of values for input variables such as V_d and $t_{1/2}$ can have significant impacts on model outputs. For individuals, behavioral (e.g., use of PFAS-containing consumer products) and physiological (e.g., kidney function, lactation) factors can impact PFAS intake and clearance rates, and this information is often unavailable. Implementations of OC models rely on averages published in scientific literature for input values, which individually can vary by up to two-fold. We demonstrate that, together, these choices can have compounding (i.e., four-fold or higher) impacts on model predictions. **Conclusions:** While OC models all share a fundamental structure, the differences between models highlight the importance of careful planning when selecting which model to use. Key considerations include: 1) What is the study question that the user wants to address (e.g., characterizing exposure for a particular community vs. establishing exposure limits)? Does the study question align with the original objectives driving model development? 2) What information is available about the target population being modeled? Does this population share characteristics (e.g., age range, pregnancy history, degree of exposure) with the population that was used in model development? 3) How will the model be used to draw conclusions about exposure? Given the simplicity of OC models, they are better suited to estimate a plausible range of values (e.g., 5th-95th percentile) rather than a specific point estimate. If there are characteristics of the target population that deviate significantly from underlying model assumptions, then the model may not produce valid results. We identify here examples of invalid applications, such as: using a model developed for a community impacted by drinking water contamination to characterize a different population where water concentrations are low compared to other sources; applying central tendency physiological parameters to individuals with very high or low values; and using a steady-state model when parameters are in flux over time. Careful consideration of model design and data needs is essential to obtaining outputs that are sufficiently accurate to address the study question.

PS 4576 A Physiologically Based Pharmacokinetic Model for Tyrosine Kinase Inhibitor Zongertinib in Adults

L. Wang, and Z. Lin. University of Florida, Gainesville, FL.

Background and Purpose: Non-small cell lung cancer (NSCLC) is one of the most common cancer types, accounting for approximately 80% of all lung cancer cases in the United States. Approximately 2% - 4% of NSCLC cases have mutations in the ERBB2 gene, which encodes ErbB family receptor tyrosine kinase HER2. HER2 alteration leads to resistance to existing HER2 targeted therapies (i.e., Trastuzumab-Deruxtecan/T-DXd). Zongertinib (HERNEXEOS®/BI 1810631) is an irreversible HER2 selective tyrosine kinase inhibitor (TKI) developed by Boehringer Ingelheim. It was granted accelerated approval by the US FDA in August 2025 for HER2-mutant, unresectable or metastatic non-squamous NSCLC. It provides a selective and strong covalent binding with ATP binding sites in receptor tyrosine kinase (RTK) and a sustained inhibition of aberrant HER2-mediated signaling in HER2 mutant NSCLC. This study aimed to build a physiologically based pharmacokinetic (PBPk) model to predict the plasma concentration profiles of Zongertinib for regimen design optimization. **Methods:** The PBPk model was developed using Gastroplus® (Version 9.9.3). The development of the zongertinib PBPk model follows a pipeline of parameter calibration, model validation, and drug-drug interaction (DDI). For the model calibration, the plasma concentration data from a clinical PK study of both intravenous injection (IV) and oral tablet (PO) were used. Parameter sensitivity analysis (PSA) was conducted to assess the parameter impact. To build mechanistic clearance, CYP3A4 was introduced to the model, and enzyme kinetics parameters (V_{max} , K_m) were predicted by the AMDET predictor (Version 11.0). The model validation was performed by an independent oral tablet dose escalation PK dataset of the plasma concentration profile. The physiological system parameters were set to reflect reference human physiology reported in the baseline PK studies. **Results:** The established zongertinib PBPk model was evaluated by an independent dataset with R^2 of 0.98 in the calibration dataset, and an overall R^2 of 0.82 in the model validation datasets in human subjects. **Conclusions:** The PBPk model provides a mechanistic framework that successfully captures the observed plasma concentrations and PK profiles in the target population. It's also an analytical approach to evaluate enzyme-mediated drug-drug interactions (DDIs). However, further refinement is needed due to existing data gaps. The lack of *in vitro* experimental data for key enzymes and transporters results in the use of predicted parameters instead, which may reduce the model's prediction accuracy and sensitivity. Moreover, zongertinib exposure is not linearly proportional to the administered dose, indicating non-linear PK likely driven by saturation of certain biological processes at higher dose levels.

N. Ferguson, J. A. Areiza, G. Norman, and F. C. Fischer. University of Rhode Island, Kingston, RI.

Background and Purpose: Per- and polyfluoroalkyl substances (PFAS) are persistent organic pollutants known to accumulate in the liver, where they undergo little-to-no metabolism. Previous studies *in vitro* showed that certain PFAS can inhibit human CYP enzymes. In recombinant assays, PFOS and perfluorooctanoic acid (PFOA) inhibited CYP2D6, 2C19, 2E1, and 3A4, with half-maximal inhibitory concentration (IC_{50}) values ranging from ~5 to 100 μ M. Perfluorononanoic acid (PFNA) and perfluorodecanoic acid (PFDA) inhibited all tested CYP isoforms except CYP2E1, while short-chain PFAS showed weak to no inhibition. In immortalized HepaRG cells, PFOS and PFOA downregulated CYP1A2, 2C19, and 3A4 mRNA and activity after 48 h at ≥ 50 ng/L, whereas CYP3A4 was induced at low μ M levels in a PXR-independent manner. Short-chain PFAS ($npfc \leq 6$) such as perfluorohexanesulfonic acid (PFHxS) and 6:2 fluorotelomer alcohol (6:2 FTOH) modulated CYP1A2 activity when using β -naphthoflavone as a substrate. Interestingly, PFOS potentially inhibited CYP2C9 ($K_i = 0.04$ μ M) in human liver microsomes (HLM), an effect over two orders of magnitude stronger than in immortalized cell-based assays, underscoring the need for physiologically relevant *in vitro* models such as HLM to assess PFAS-mediated CYP inhibition. **Methods:** We assessed the reversible inhibition of seven CYP isoforms - CYP1A2, CYP2B6, CYP2C8, CYP2C9, CYP2C19, CYP2C6, and CYP3A4/5 - using selective probe substrates for each isoform. The PFAS tested as potential CYP spanned six to 12 perfluorinated carbons (n_{pfc}), including fluorotelomer and ether-substituted structures. These compounds comprised Perfluorooctanesulfonamide (FOSA), N-ethylperfluorooctanesulfonamide (EtFOSA), N-methylperfluorooctanesulfonamide (MeFOSA), PFOS, 8:2 Fluorotelomer Sulfonic Acid (8:2 FTS), perfluoroundecanoic acid (PFUnDA), Perfluorododecanoic acid (PFDoDA), PFOA, Perfluorodecanoic acid (PFDA), perfluorononanoic acid (PFNA), perfluoroheptanoic acid (PFHpA), Perfluorohexane sulfonic acid (PFHxS), Perfluoro(2-ethoxyethane) sulfonic acid (PFEESA), and an equipotent mixture of all 13 PFAS. Metabolite formation of each probe substrate was quantified and normalized to a solvent control to determine half maximal inhibitory concentration (IC_{50}) values. A C18-based solid-phase micro-extraction assay was used to determine the unbound fraction ($f_{unbound}$) of each PFAS in human liver microsomes (HLM) to derive unbound IC_{50} values. Equivalent unbound concentrations were derived from previously measured PFAS concentrations in 211 human liver samples and compared to unbound IC_{50} for individual PFAS and mixtures to evaluate potential for CYP inhibition across real-world human liver burdens. **Results:** CYP2C enzymes were most susceptible to PFAS inhibition, with IC_{50} s ranging from 23 nM ($n_{pfc} = 8$ sulfonamide) to 31 μ M ($n_{pfc} = 8$ fluorotelomer) for CYP2C9. QIVIVE compared inhibitory values to PFAS concentrations measured in 211 human livers revealed that 19% of individuals fall within 10-fold of the 10% inhibitory concentrations for PFOS, while 61% had hepatic PFAS concentrations within 100-fold of this threshold. Notably, certain sulfonamides and sulfonates exceeded the inhibitory potency of the CYP2C9 reference inhibitor sulfaphenazole, as well as several clinically relevant CYP2C9 inhibitors. The equimolar PFAS mixture yielded an unbound IC_{50} of 35 nM, with measured hepatic mixture burdens approaching these inhibitory levels. **Conclusions:** These findings indicate that PFAS can inhibit CYP2C enzymes at human-relevant exposure levels, potentially compromising both drug clearance and endogenous fatty acid metabolism. This is particularly relevant for clinical trials involving CYP2C9 substrates, where unrecognized environmental exposures may confound drug efficacy and lead to trial failure or suboptimal dosing. Incorporating PFAS and other environmental chemicals as covariates in clinical trial design or pharmacogenomic models may enhance precision medicine strategies by accounting for altered drug metabolism, exposures, and toxicity risk.

PS 4578 Access Rich Toxicokinetics Data through the Chemical Effects in Biological Systems (CEBS) Platform

M. Jackson¹, L. Hall², J. Fostel², J. Berke¹, H. Dean¹, Y. Liu², and S. Waidyanatha². ¹ASRC Federal Data Solutions, Beltsville, MD; and ²NIEHS, Research Triangle Park, NC.

Background and Purpose: Absorption, distribution, metabolism, excretion and toxicokinetics (TK) data serve as the cornerstone of understanding the systemic effects within biological systems following exposure to putative toxic substances. These data not only illuminate the toxicology profile of substances but also play a pivotal role in informing risk assessment and decision-making processes. The National Toxicology Program/Division of Translational Toxicology (DTT) at the National Institute of Environmental Health Sciences has played a significant role in generating toxicity data, using animal models, on environmental agents with potential adverse human health impacts. In support of these toxicity studies, it has conducted over 200 TK studies. Most of the study data have been annotated at both individual animal (concentration versus time data) and group (TK parameters) levels. The comprehensive TK parameters and metadata accompanying these annotated data enhance interpretability and utility of TK data and aligns with FAIR (Findable, Accessible, Interoperable, and Reusable) standards. **Methods:** Not applicable. Abstract is for non-laboratory or non-field Studies. **Results:** The original published annotated individual animal plasma or tissue concentration versus time data and group TK parameter data, as well as summary data files, are available through the Chemical Effects in

Biological Systems (CEBS, <https://doi.org/10.22427/NTP-DATA-1>), an open-source platform tailored to the needs of environmental health scientists. CEBS offers a new option for accessing TK data using the Toxicokinetics Data Collection that is presented here. This data collection boasts rich standardized metadata, such as test article, dose, dose frequency, species, strain, route, and modeling methods and has a user-friendly interface to facilitate easy data searching, filtering, and downloading that enables scientists to easily access data of interest. This dataset is also accessible through the CEBS DTT Integrated Data Resources, which offers bulk download options for both individual animal and group parameter data. Data from TK studies are also seamlessly integrated into their respective CEBS test article pages, giving researchers a comprehensive view of all studies and publication data related to a specific substance that are available in CEBS. **Conclusions:** Not applicable. Abstract is for non-laboratory or non-field Studies.

PS 4579 Beyond the kinetically derived maximum dose: a holistic view of nonlinear pharmacokinetics

C. Tan¹, D. Hoer¹, E. Mendez², and J. Leonard². ¹US Environmental Protection Agency, Research Triangle Park, NC; and ²US Environmental Protection Agency, Washington, DC.

Background and Purpose: In chemical risk assessment, an understanding of pharmacokinetics (PK) is essential for analyzing and interpreting dose-response data, as well as for effectively guiding the design of animal studies. Historically, the kinetically derived maximum dose (KMD) concept was introduced to incorporate nonlinear PK data into dose selection or response interpretation. The goal of this approach is preventing the use of excessively high doses irrelevant to human exposure. KMD has been defined as an inflection point slightly above the onset of nonlinear PK. However, this definition is both inaccurate and impractical. Nonlinear PK does not produce a distinct inflection point in the internal to external concentration (IEC) relationship. Additionally, nonlinear PK alone does not inherently signal the onset of toxic responses. The objective of this study is to compare the KMD approach with an integrated, biologically based strategy that incorporates all available PK data to elucidate the underlying shape of the IEC relationship. This approach allows for a quantitative evaluation of the presence and extent of PK nonlinearity to address risk assessment questions. **Methods:** This study illustrates the use of both animal data and new approach methods (NAMs) to investigate the impact of nonlinear pharmacokinetics (PK) on dose-response interpretation, using the pesticide afidopyropen as a case study. Uterine adenocarcinomas were identified in female rats at doses of 50 and 150 mg/kg body weight (bw)/day. To explore whether tumors occurred only at doses where afidopyropen clearance was saturated, a 28-day dietary study was conducted to measure afidopyropen concentrations in plasma at doses of 0.1, 0.5, 2.5, 12.5, 50, and 150 mg/kg bw/day. Instead of identifying a KMD based on this single dataset, our analysis used a physiologically based pharmacokinetic (PBPK) model to integrate all available PK data, such as oral absorption fraction and the absence of renal clearance. The model was then optimized against area under the curve (AUC) data from the 28-day study to determine whether the assumption of linear or nonlinear metabolism more accurately describes the data. **Results:** Although initial analysis suggested that the nonlinear metabolism assumption offered a slightly better fit to the plasma AUC data, the linear assumption also provided a reasonable fit. The linear and nonlinear models subtly diverged at the 12.5 mg/kg bw/day dose, but the absence of reliable plasma data at doses of 50 and 150 mg/kg bw/day limits further evaluation of PK linearity beyond 12.5 mg/kg bw/day. Additionally, the variability in the observed AUC data at higher doses, though problematic, is larger than the difference between the simulated linear and nonlinear curves. It is unclear whether the minor divergence of the two models reflects true nonlinear PK or is simply due to data variability. Consequently, the plasma AUC data cannot be used to exclude the relevance of the tumors observed at 50 and 150 mg/kg bw/day in rats to human exposure. This conclusion differs from the original study, which determined a KMD between 2.5 and 12.5 mg/kg bw/day and deemed the rat tumors irrelevant to human exposure. **Conclusions:** Although the KMD can indicate potential nonlinear PK that merits further examination, it overemphasizes identifying a single dose where PK transitions from linear to nonlinear. As demonstrated in the case example, such deviation is often too subtle to significantly impact dose-response interpretation. Risk assessment decisions should not depend solely on a single piece of evidence, such as a shift in PK behavior in one dataset, without understanding its biological or toxicological implications. Instead of focusing on identifying a KMD, it is essential to integrate data on exposure, PK, and hazard to guide dose selection and response interpretation, without preconceived assumptions about the impact of nonlinear PK. NAMs, such as predictive modeling, offer opportunities to bridge data and knowledge gaps without additional animal studies.

Background and Purpose: The U.S. EPA is focused on increasing the pace and reducing the cost of endocrine disruption screening for hundreds of pesticide chemicals. Quantitative *in vitro* to *in vivo* extrapolation (QIVIVE) is a New Approach Method that extrapolates *in vitro* bioactive concentrations to an external exposure level comparable to *in vivo* responses in whole organisms. Toxicokinetic (TK) models are a key component of mammalian IVIVE approaches. However, similar approaches are being developed for ecologically relevant species (e.g., fish), and species-specific differences between *in vitro* TKs are still poorly understood. Therefore, the objective of the current study is to conduct *in vitro* plasma binding and intrinsic metabolic clearance studies across 3 species (human, rat, and rainbow trout) and evaluate species-specific differences for each chemical. **Methods:** Plasma binding (fraction unbound (fUB)) was assessed using rapid equilibrium dialysis, while intrinsic metabolic clearance rates (Cl_{int}) were determined using substrate depletion assays. In the assays, mixed sex pools for human, rat, and juvenile rainbow trout plasma and hepatocytes were used. A list of reference chemicals for *in vivo* endocrine screening assays that span a diverse range of physiochemical properties were compiled. Chemicals were pre-screened for stability in the test systems to optimize test concentrations and timepoints. After preliminary evaluation, 40 chemicals were chosen for definitive testing in both assays. For the definitive plasma binding assays, the concentrations tested were between 1 and 10 µM with sampling times of 8 or 24 hours. For the definitive metabolic clearance assays, the concentrations tested were between 0.1 and 1 µM with six sampling times between 0 and up to 90 minutes. Each test chemical run included a concurrent negative control (inactive hepatocytes) replicate at the same test chemical concentration which was sampled at the same six time points.

Results: Overall, the fUB values were similar across all three species for most chemicals. Trout tended to be most different among the three species with diethylstilbestrol, estril, and fenarimol showing the highest variance of fUB across species. For example, fUB values for diethylstilbestrol were 0.008, 0.014, and 0.312, in human, rat, and trout plasma, respectively. The Cl_{int} values between species were more variable than that of the plasma binding data with the trout data commonly being different from the human and rat data. Rat or human Cl_{int} values were at least an order of magnitude or more than trout Cl_{int} values for 17β-trenbolone, diazinon, flutolanil, linuron, mifepristone, and propargite. For example, the Cl_{int} values of flutolanil were 62.1, 189, and 8.66 µL/min/106 hepatocytes for human, rat, and trout, respectively. **Conclusions:** This study has built upon previous efforts to add more empirical *in vitro* information to the endocrine relevant chemical space. The data generated in this study will be critical for developing QIVIVE approaches for endocrine disruption screening assays, such as the Hershberger assay, the female pubertal assay, and the fish short-term reproduction assay. This abstract does not necessarily reflect US EPA policy.

PS 4581 MCSimMod: Updates and Improvements to an R Package for Implementation and Application of PBPK Models

D. F. Kapraun, T. J. Zurlinden, C. M. Schacht, and P. M. Schlosser. U.S. EPA, RTP, NC.

Background and Purpose: Pharmacokinetic (PK) and physiologically based pharmacokinetic (PBPK) models, which are commonly used in human health risk assessments for chemicals, are generally implemented as computer programs. Historically, many PBPK modelers favored the programming language ACSL and its associated environment, acslX. However, in 2015, the company responsible for acslX announced it would cease support and sales of the software. Before acslX's decline, some PBPK modelers used the open-source tools R and MCSim, often separately, for computational PBPK modeling tasks. Since then, many have adopted a combined approach for implementing PBPK models using R and MCSim together. Each of these software tools has its advantages and limitations. R is a flexible and widely used language and environment for data analysis and graphics generation. However, because R is an "interpreted" language, R commands must be translated into machine code each time they are executed. This leads to slower performance for complex calculations, such as those involved in PBPK model simulations. MCSim, on the other hand, is a specialized tool for implementing and calibrating mathematical models that uses "compiled" languages to execute model simulations swiftly. To use R and MCSim together, one writes model descriptions in the MCSim model specification language, uses an MCSim utility to automatically translate and compile them, and then conducts simulations efficiently through R scripts that leverage the compiled code. Unfortunately, installing R, MCSim, and other necessary tools, and ensuring their proper integration, can be challenging, posing obstacles for many in the PBPK modeling community. To address these issues and provide a user-friendly and consistent system for implementing, applying, and sharing PBPK models, we developed the R package MCSimMod. **Methods:** The MCSimMod package, which can be easily installed using a single R command, offers an object-oriented approach for handling PBPK and other ordinary differential equation (ODE) models. MCSimMod users can create model "objects" using human-readable text descriptions written in the MCSim model specification language. These model objects allow users to directly translate the MCSim model specification text into the C programming language,

which can then be compiled into machine code. This strategy greatly increases the speed of execution of model simulations. Utilizing intuitively named class methods (functions) like "updateParams" and "runModel," users can set and update model parameters and initial conditions, as well as perform simulations. Subsequently, they can analyze simulation results and carry out necessary post-simulation calculations within the R environment. **Results:** We have created a new version of the R package MCSimMod and have made it available in a repository on the U.S. Environmental Protection Agency's (EPA) GitHub institutional account. New features include a "verbose" output option that facilitates MCSim model debugging and the additional capability of working with multiple models within the same R session. As always, the package can be used without installing the MCSim software. The package's "vignettes" provide step-by-step instructions for basic modeling tasks and include examples involving a classical PK model and a more complex PBPK model. Since the first public release of MCSimMod in April 2025, the package has been downloaded more than 2800 times. Also, the U.S. EPA PBPK Model Template software has been updated to use MCSimMod, and U.S. EPA risk assessors have used it to implement PK and PBPK models for polychlorinated biphenyls (PCBs) and ethylene dibromide (EDB). **Conclusions:** The free and open-source R package MCSimMod provides a flexible and efficient means for implementing and applying PK and PBPK models. Users can easily install MCSimMod by downloading the source code and executing a single command in an R session. Additionally, the languages required for use, R and MCSim, are already well-known to many in the PBPK modeling community. Since the initial release of MCSimMod, we have added features to facilitate debugging during preliminary model development and to allow for working with multiple models simultaneously. MCSimMod has already been used for several modeling applications by researchers and risk assessors at U.S. EPA, and we expect that it will continue to gain traction as a popular tool for the development, application, and sharing of PBPK models.

PS 4582 Evaluation of a lung microphysiological system for measuring concentrations of anti-infective drugs in epithelial lining fluid

S. Rahman, R. Geiger, M. Roni, R. DePalma, K. Wu, A. Nicasio, T. Feaster, and K. Blinova. United States Food and Drug Administration, Silver Spring, MD. Sponsor: K. Howard

Background and Purpose: Phase 1 intrapulmonary clinical studies in healthy subjects are recommended to assess anti-infective drug penetration into the alveolar epithelial lining fluid (ELF) for drugs with indications related to lung infections. While clinical intrapulmonary studies provide valuable data on lung penetration, the current practice is labor-intensive, invasive, and yields lung penetration results with high variability. New approach methodologies (NAMs), such as lung microphysiological systems (MPSs), offer a promising nonclinical alternative for modeling bronchopulmonary drug disposition by recapitulating key physiological features such as dynamic flow, cyclic stretching, and air-liquid interface culture. This study aims to evaluate whether an alveolar lung MPS can generate physiologically relevant drug concentration profiles and ultimately support or complement intrapulmonary clinical studies. **Methods:** A human lung alveolus MPS incorporating primary alveolar epithelial cells and microvascular endothelial cells was established and characterized. Model characterization included assessment of barrier integrity, alveolar type I/II cell markers, 3D morphology, surfactant activity, and barrier permeability using fluorescent tracers, along with ELF volume estimation via urea dilution method consistent with clinical bronchoalveolar lavage studies. Six anti-infective drugs with diverse physicochemical and pharmacokinetic properties (delafloxacin, azithromycin, lefamulin, omadacycline, ceftaroline, and levofloxacin) were selected for evaluation, and three compounds (delafloxacin, azithromycin, and lefamulin) have been tested to date. Following drug administration through the vascular channel, apical wash samples were collected for quantification via liquid chromatography-tandem mass spectrometry. **Results:** The alveolus MPS demonstrated structural and functional characteristics consistent with an alveolar barrier, including confluent epithelial and endothelial layers, expression of relevant markers (aquaporin 5 [AQP5] and surfactant protein B [SFTPB]) for alveolar type I/II cells, intact barrier properties determined by the expression of zonula occludens-1 (ZO-1) and vascular endothelial cadherin (VE-cadherin), and measurable surfactant activity (~484 ng/mL of SFTPB and 652 ng/mL of SFTPC). Preliminary drug studies with the first three compounds generated quantifiable concentrations in apical ELF-analog samples (1.63 µg/mL of delafloxacin at 1 hr, 0.45 µg/mL of azithromycin at 6 hr, and 0.42 µg/mL of lefamulin at 1 hr), which are broadly consistent with available clinical data. These findings support the feasibility of using the model to track drug movement across the alveolar barrier. **Conclusions:** The study demonstrates that a lung alveolus MPS can potentially evaluate bronchopulmonary drug penetration and generate ELF-like concentration data for anti-infective drugs. The model displays essential structural and functional characteristics of the human alveolar barrier and supports measurable drug transport. Continued testing with additional compounds and comparison with clinical intrapulmonary PK data will determine whether MPS-derived ELF concentrations can serve as supportive evidence or, in some cases, reduce the need for clinical intrapulmonary studies. Ongoing efforts are focused on improving experimental reproducibility, refining sampling conditions to enhance ELF-like recovery, and strengthening the robustness of drug penetration measurements. As the dataset expands, this work may help define how lung MPS approaches complement existing clinical methods and advance regulatory science initiatives aimed at integrating NAMs into drug development.

T. Yajima^{1,2}, W. Qu¹, A. Cook³, M. Rezin³, K. Aillon³, S. Waidyanatha¹, and S. S. Ferguson¹. ¹NIHES, Research Triangle Park, NC; ²The Institute of Environmental Toxicology, Ibaraki, Japan; and ³MRI Global, Kansas City, MO.

Background and Purpose: Liver microtissues from human donor tissues have emerged as New Approach Methodologies (NAMs) for evaluating xenobiotic metabolism and toxicity potential in humans as they sustain hallmarks of hepatocellular function over weeks/months in culture. However, our understanding of their proficiency to emulate metabolite profiles and predict kinetic parameters is limited, particularly for low-turnover chemicals. Primary human hepatocytes (PHH) suspension cultures, the gold-standard method, have limited longevity (i.e., ~2 hours). In this study, we established 3D liver microtissues in both single- and pooled-spheroids, alongside suspension PHH, to investigate metabolic proficiency for moderate and low-turnover chemicals. We also investigated metabolism of per- and poly fluorinated alkyl substances (PFAS) like fluorotelomers present in aqueous film-forming foams (AFFF) including 6:2-FTS, 6:2-FtSiAoS, 6:2-FtTAoS, 6:2-FTNO, and 6:2-FtSaB using spheroids. **Methods:** Suspension, single spheroid, and pooled spheroid cultures were established in 96-well plates with CELLSTAR®, Akura™, and Corning® Eplasia®, respectively. Cryopreserved PHH (single donor) were purchased from Lonza (Durham, NC). After seeding PHH to ~2,000 or ~40,000 cells/well for single- or pooled-spheroid cultures, respectively, they were equilibrated for maturation over 7 days (37°C, 5% CO₂). For suspension PHH, cells were seeded at ~2,000 cells/well and incubated with test substances (1 µM tolbutamide, phenacetin, midazolam, 6:2-FTNO, and 6:2-FtSaB; 0.1% AFFF1) for 0 and 90 min with orbital shaking, while spheroids were incubated for 0 and 24 hrs. Cells were crashed with ice-cold methanol, followed by shaking and centrifugation. An aliquot of supernatant was transferred to 96-well plates (Corning® BioCoat®) for liquid chromatography-tandem mass spectrometry analysis for parent and/or metabolite concentration. Data were analyzed statistically with GraphPad Prism (Boston, MA). **Results:** Tolbutamide, phenacetin, and midazolam reference chemicals were depleted with suspension PHH to varying degrees. The turnover rate with suspension PHH was generally more extensive than spheroid cultures, though some baseline anomalies for time-zero were evident for pooled spheroids. Suspension PHH appeared to provide faster depletion than spheroids, which may be related to enhanced accessibility through cytosolic membranes and greater media exchange surface areas in suspension form. For metabolite formation, pooled spheroids produced higher metabolite formation to acetaminophen from phenacetin and 1-OH-midazolam from midazolam compared with single spheroids or suspension PHH. Fluorotelomers 6:2-FTNO was extensively depleted over 24-hrs with single- and pooled spheroids but not significantly in PHH suspensions over 90 minutes. AFFF1 incubations containing many PFAS fluorotelomer constituents revealed extensive 6:2-FTS and 6:2-FTNO depletion in single spheroids and suspension PHH with pooled spheroids again showing baseline anomalies relative to other time-zero samples. The maximum turnover rate was >60% for 6:2-FTNO (single spheroids). There was no evidence consistent with 6:2-FTS formation from 6:2-FTNO with human hepatocytes. Depletion trends for individual PFAS 6:2-FTNO, 6:2-FtSaB were similar to those observed in their complex mixture (i.e., AFFF1). Interestingly, depletion of 6:2-FtSaB was clear for suspension PHH but not significant in spheroid systems. Further experiments are ongoing. **Conclusions:** This study has clarified the potential for fluorotelomers found in AFFF products can be metabolized by patient-derived human liver cells and demonstrates for the first time that liver microtissues are proficient in biotransformation of PFAS fluorotelomers within complex PFAS surfactant mixtures. Investigations continue to expand experimental designs to provide additional context over time and dose to enhance our understanding of PFAS metabolism and bioaccumulation with 3D liver microphysiological systems (MPS).

PS 4584 HepaSH cells as a platform to evaluate the impact of genetic polymorphisms on cytochrome P450-mediated metabolic drug clearance

S. Uehara¹, Y. Higuchi¹, N. Yoneda¹, H. Yamazaki², and H. Suemizu¹. ¹Central Institute for Experimental Medicine and Life Science, Kawasaki, Japan; and ²Showa Pharmaceutical University, Machida, Japan.

Background and Purpose: Interindividual variability in metabolic drug clearance due to genetic polymorphisms in cytochrome P450 (P450) enzymes remains a major challenge for predicting human pharmacokinetics. The drug-metabolizing activity of primary human hepatocytes is influenced by donors' lifestyle factors, such as alcohol consumption, smoking, and diet, as well as by exposure to environmental chemicals, complicating the evaluation of the impact of P450 polymorphisms. In contrast, chimeric mice with humanized livers, maintained under strictly controlled conditions, are minimally affected by interindividual differences in lifestyle- and environmental factors, allowing their hepatic enzyme activities to more accurately reflect genetic polymorphisms. This study aimed to evaluate the utility of genotyped HepaSH cells for assessing the impact of P450 polymorphisms on metabolic drug clearance. **Methods:** Genetic polymorphisms of CYP2B6, CYP2C9, CYP2C19, CYP2D6, and CYP3A5 were analyzed in three HepaSH strains (HepaSH-E, -L, and -AD) by direct DNA sequencing of the coding regions and relevant intronic/exonic variants. HepaSH cell suspensions (0.5 × 10⁶ cells/mL) were incubated with typical

P450 probe substrates. Aliquots were collected at 5, 10, 15, 20, 30, 45, 60, and 75 min and quenched in ice-cold acetonitrile. After centrifugation, drug concentrations in the supernatants were quantified by liquid chromatography-tandem mass spectrometry to calculate apparent intrinsic clearance (CL_{int}). The expression level of each P450 gene was quantified by reverse transcription-quantitative polymerase chain reaction using commercially available TaqMan assays. **Results:** CYP2D6 genotypes were *1/*1, *1/*9, and *1/*4 for HepaSH-E, -L, and -AD, respectively. CYP2D6*4 carries a splice site mutation (1846G>A) that causes abnormal mRNA splicing and produces a nonfunctional enzyme, while CYP2D6*9 is a decreased-function allele characterized by a 3-base pair deletion in exon 5 (2615-2617delAAG), resulting in the loss of one amino acid (Lys281) and reduced enzyme stability and catalytic efficiency. Accordingly, the CL_{int} of atomoxetine and propafenone, both CYP2D6 substrates, was higher in HepaSH-E than in HepaSH-L and -AD. CYP3A5 genotypes were *1/*1, *3/*3, and *3/*3 for HepaSH-E, -L, and -AD, respectively. CYP3A5*3 allele harbors a single nucleotide polymorphism in intron 3 (6986A>G) that causes a splicing defect and produces a truncated, nonfunctional protein. The CL_{int} of midazolam, a substrate for CYP3A4 and CYP3A5, was higher in HepaSH-L than in HepaSH-E and -AD. By contrast, the CL_{int} of nifedipine, a substrate primarily for CYP3A4 with minor CYP3A5 contribution, was higher in HepaSH-AD, indicating that nifedipine clearance depends mainly on CYP3A4 expression level. Thus, the individual HepaSH strains exhibited clear genotype-dependent differences in metabolic drug clearance, enabling prediction of the effects of P450 polymorphisms on human hepatic drug clearance. Analyses of CYP2B6, CYP2C9, and CYP2C19 are ongoing. **Conclusions:** Genotyped HepaSH cell strains provide a robust and practical platform for quantifying the effects of P450 genetic polymorphisms on metabolic drug clearance. These cell strains serve as a valuable tool for improving the prediction of interindividual variability in human hepatic clearance of drug candidates in drug development.

PS 4585 Single cell lung transcriptomics of low-level dietary and environmental cadmium exposure following early-life respiratory syncytial virus infection

Z. R. Jarrell¹, C. Lee¹, H. Y. Lee¹, M. L. Orr¹, K. Kim², Y. Chen³, S. Kang², D. P. Jones¹, and Y. Go¹. ¹Emory University, Atlanta, GA; ²Georgia State University, Atlanta, GA; and ³University of Oklahoma Health Sciences Center, Oklahoma City, OK.

Background and Purpose: Respiratory syncytial virus (RSV) is a major cause of severe respiratory illnesses in young children and older adults. Epidemiological evidence suggests that RSV infection can leave long-term effects on lung function over time. Cadmium (Cd) is a heavy metal for which all individuals carry some exposure risk. High-level exposures occur in occupational settings and with tobacco smoke, but low-level exposures occur through numerous dietary sources. We previously found that early-life RSV infection (eRSV) exacerbates long-term effects of Cd in the lungs. We found that inflammation, mTORC1 activation and disruption of protein palmitoylation contribute to this effect, but effects on specific lung cell populations are largely unknown. To help unravel the mechanisms at play in this combined exposure paradigm, we conducted single cell lung transcriptomics analyses to identify key cell populations, pathways and functional networks at the intersection of eRSV and Cd exposure. **Methods:** To model eRSV, C57BL/6J mice were treated intranasally with saline (vehicle control) or RSV (Line 19F in saline; 4 × 10⁴ PFU/g body weight) at 14 days old. At 35 days old, mice were treated for 16 weeks with untreated drinking water (n = 3 for control; n = 2 for eRSV only) or 3.3 mg CdCl₂/L in water (n = 3 for eRSV+Cd; n = 2 for Cd only). After treatment, mice were euthanized, and segments of the medial side of all right lung lobes were collected, with representation of the hilum and right bronchus. Segments were snap frozen and later processed using the 10x Genomics Chromium Single Cell Gene Expression Flex protocol. Samples were sequenced on a NovaSeq S4 Flow Cell. Sequencing data were initially processed for quality control and data aggregation using Cell Ranger v8.0.1. Cells were further processed for batch effect correction, cell cycle scoring and cell filtering in Seurat v5. Cell annotations were performed using the LungMap CellRef mouse lung reference, with manual adjustment using marker gene expression. Compositional analysis with false discovery rate (FDR) set to 20% was performed using scCODA. Perturbation analysis was performed using Augur. Differential expression analysis was performed using DESeq2 in Seurat, with Bonferroni correction used to maintain the aggregate Type I error rate at 5%. Gene set enrichment analysis (GSEA) was performed using differentially expressed genes (DEG) labeled by gene ontology (GO) biological process terms, with FDR adjusted to 5%. **Results:** eRSV followed by oral Cd exposure resulted in widespread effects on cell composition and gene expression. eRSV+Cd lungs had more ciliated/deuterosomal cells, while eRSV and Cd treatments alone resulted in fewer ciliated/deuterosomal cells. Ciliated/deuterosomal cells also showed the largest perturbation, with an AUC of 0.697. Interestingly, the eRSV+Cd treatment resulted in the fewest DEGs in ciliated/deuterosomal cells, 33, while eRSV and Cd resulted in 54 and 82 DEGs, respectively. The alveolar fibroblast 1 (AF1) cell population contained the highest number of DEGs by eRSV+Cd treatment, 125 genes. Gene set enrichment analysis of these genes revealed enrichment of several GO biological process terms. These included expected terms, such as collagen metabolism, leukocyte activation involved in inflammatory response, and response to toxic substances. However, previously unexplored terms such as response to pH and hormone metabolic process were also upregulated. **Conclusions:** These results provide new understanding of mechanisms which may contribute to toxicologic synergy between common eRSV infection and low-level environmental Cd exposure. Results show that AF1 cells have widespread

changes to gene expression, including disrupted processes that have not previously been explored in eRSV with Cd exposure. Furthermore, the unique sensitivity of ciliated and deuterosomal cells to the combined exposure warrants detailed study of these cell types. These findings point to new avenues for intervention which could be pursued to improve lung health outcomes post RSV infection.

PS 4586 Palmitoyltransferase zDHHC9 Regulates Fibrotic Marker Col1A1 Expression Through a Post-Transcriptional Mechanism in Human Lung Fibroblasts

C. M. Lee, H. Lee, Z. Jarrell, D. Jones, and Y. Go. Emory University, Atlanta, GA.

Background and Purpose: Environmental exposure to cadmium (Cd), a toxic metal found in food and drinking water, is associated with profibrotic responses in the lungs. We previously showed that this toxicity is potentiated by early-life respiratory syncytial virus (RSV) infection using a mouse model. This combined insult re-programmed lung metabolism and induced profibrotic signaling that was dependent on protein S-palmitoylation, a post-translational modification catalyzed by zDHHC palmitoyltransferases. While our prior integrative multi-omics analysis determined the zDHHC11 transcript as a central hub, and pan-palmitoyltransferase inhibitor (2-bromopalmitate) blocked the Cd/RSV-induced fibrotic signaling, identification and verification of specific zDHHC enzymes responsible for regulating profibrotic signaling in human lung cells are needed. Here, using CRISPR-Cas9-facilitated genetic modifications, we investigated the role of individual zDHHC enzymes in regulating components of profibrotic signaling pathway. **Methods:** We used the CRISPR-Cas9 gene editing system to generate stable knockout (KO) cell lines from human lung fibroblasts (HFL1) targeting six different palmitoyltransferases: zDHHC3, zDHHC4, zDHHC5, zDHHC7, zDHHC9, and zDHHC13. A scrambled gRNA (SCR) line was generated as a negative control. Successful protein disruption in KO lines was confirmed by Western Blot. The expression levels of fibrotic markers Col1A1 and fibronectin were then assessed at both the transcriptional level (qPCR) and the protein level (Western Blot) and compared to the SCR negative control. **Results:** All generated KO cell lines showed effective disruption in baseline expression levels of their respective target zDHHC proteins. Analysis of fibrotic markers revealed significant, enzyme-specific effects on Col1A1, while fibronectin protein levels remained similar to the negative control across all lines. The zDHHC5 KO line showed a significant reduction in Col1A1 protein, to approximately 62% of the levels seen in the SCR control. Strikingly, the zDHHC9 KO line exhibited an almost complete loss of Col1A1 protein expression, with levels decreased to less than 10% of the SCR control. Other KO lines did not show significant changes in Col1A1. Interestingly, our assessment of Col1A1 mRNA levels via qPCR in both the zDHHC5 and zDHHC9 KO lines indicated similar expression levels to that of the negative control. **Conclusions:** These findings identify specific zDHHC enzymes as critical regulators of fibrotic marker expression in human lung fibroblasts. In particular, zDHHC9 emerges as a dominant enzyme governing Col1A1 protein level. The data demonstrating a disconnect between protein and mRNA levels strongly suggest that zDHHC9 regulates Col1A1 expression via a post-transcriptional mechanism, such as influencing protein translation or stability, rather than by altering gene transcription. These results identify zDHHC9 as a novel and specific therapeutic target for lung fibrosis driven by environmental toxicants and early-life viral insults.

PS 4587 Cell death mechanism of novel indium-containing terpyridine metal complexes for breast cancer cells

A. Li¹, S. Mo¹, A. Hong², J. Chen², G. Zhang², and S. Cheng². ¹Stuyvesant High School, New York, NY; and ²John Jay College of Criminal Justice, New York, NY.

Background and Purpose: Metal complexes have long been utilized as anticancer agents, such as cisplatin which is a platinum-based drug well-known and widely used for treating various solid tumors. A major challenge in anticancer drug development is achieving high selectivity to maximize cancer cell death while minimizing toxicity to normal cells. Terpyridine (tpy) metal complexes have been extensively investigated for decades due to their broad applications in functional materials, supramolecular chemistry, catalysis, and biomedical research, including anticancer, antibacterial, and antifungal studies. Previous work from Cheng's laboratory demonstrated that indium-based tpy complexes exhibit selective cytotoxicity toward either MCF-7 breast cancer cells or MDA-MB-468 triple-negative breast cancer cells. The present study further investigates the detailed cell death signaling mechanisms of the indium-tpy (In1 and In3) complexes. **Methods:** Protein level changes in cells treated with In1 and In3 for 72 hours at their IC50 concentrations were assessed using the Full Moon Biosystems Explorer Antibody Array, which contains 656 highly specific and well-characterized antibodies targeting multiple signaling pathways. Fold changes obtained from the array were analyzed using QIAGEN Ingenuity Pathway Analysis (IPA). Western blotting was performed to validate the expression of apoptosis-related proteins, including Bad, Bax, Bak, p53, Bcl-2, and Bcl-XL. **Results:** The array data showed that treatment of MCF-7 with In1 increased the expression of Bax, Bad, and p53 (fold changes: +1.153 to +1.204), while decreasing Bak, Bcl-2, and Bcl-XL (fold changes: -1.031 to -1.372). In MDA-MB-468, In1 increased Bax, Bad, Bcl-2, and p53 (fold changes: +1.006 to +1.308) but decreased Bak and Bcl-2 (fold changes: -1.000 to -1.304). Western blot analysis validated the IPA results, showing that In1 reduced

Bcl-2 expression by 58% in MCF-7 and 42% in MDA-MB-468, and decreased Bak and Bcl-2 in MCF-7 by 40% and 58%, respectively, as well as Bcl-XL in MDA-MB-468 by 8%. Similarly, treatment of MCF-7 with In3 increased Bax, Bad, Bcl-XL, and p53 (fold changes: +1.060 to +1.549) while decreasing Bak and Bcl-2 (fold changes: -1.016 to -1.196). In MDA-MB-468, In3 increased Bak, Bcl-2, and Bcl-XL (fold changes: +1.063 to +1.126) but decreased Bax, Bad, and p53 (fold changes: -1.024 to -1.068). Western blot analysis confirmed that In3 reduced Bak and Bcl-2 in MCF-7 by 40% and 43%, respectively. However, other validated proteins did not consistently reflect the IPA findings. **Conclusions:** Both In1 and In3 modulate the expression of key apoptotic regulators in MCF-7 and MDA-MB-468 cells, indicating their potential to induce cell death via the intrinsic mitochondrial pathway. In1 consistently reduced Bcl-2 and Bak in MCF-7 and Bcl-XL in MDA-MB-468, while In3 showed a similar pattern in MCF-7 but differential effects in MDA-MB-468, suggesting cell line-specific responses. The partial discrepancies between array and protein expression highlight the complexity of post-translational regulation and pathway crosstalk. Since indium is known to bind to transferrin and can be taken up via the transferrin receptor pathway, it may influence intracellular metal homeostasis and iron-related signaling. And given the involvement of Bcl-2 family proteins in both apoptosis and oxidative stress-related cell death, future studies should explore whether In1 and In3 also induce ferroptosis by evaluating markers such as GPX4, as well as performing time- and dose-dependent analyses to better understand their mechanisms and therapeutic potential across different breast cancer subtypes.

PS 4588 Optically filtered Monochromatic portable X-ray fluorescence (MXRF) quantifies lead in wild bird bone with ICP-MS validation and defined detection limits

K. E. Adesina¹, J. A. DiNatale¹, S. S. Costa¹, B. Faber¹, T. E. Katzner², S. Cooper³, M. Martin⁴, T. R. Grier¹, and A. J. Specht^{1,5}. ¹Purdue University, West Lafayette, IN; ²U.S. Geological Survey, Forest and Rangeland Ecosystem Science Center, Boise, ID; ³Carolina Raptor Center, Huntersville, NC; ⁴North Carolina Department of Agriculture and Consumer Services, Raleigh, NC; and ⁵Harvard T.H. Chan School of Public Health, Boston, MA.

Background and Purpose: Lead (Pb) exposure threatens both wildlife and humans, causing neurological, cardiovascular, and renal damage. Conventional Pb analysis relies on costly wet-lab methods (e.g., Inductively Coupled Plasma-Mass Spectrometry, ICP-MS). Monochromatic X-ray fluorescence (MXRF) enables rapid, non-destructive, field-deployable Pb detection for environmental and biomedical use with lower detection limits than prior portable XRF systems. This study evaluated the feasibility, calibration, attenuation correction, and agreement of a doubly curved crystal (DCC) optically enhanced MXRF (X-ray Optical Systems (XOS), East Greenbush, NY) for real-time quantification of bone Pb of black vultures. **Methods:** We analyzed 38 bird bones *ex vivo* (n = 19 femur; n = 19 tarsometatarsus, TMT) with an HD Mobile MXRF (1-mm micro-spot; Mo anode; SDD, and 200s). Calibration used Pb-doped plaster phantoms (0-100 ppm) plus Lucite soft-tissue equivalents (0-5 mm). Spectra (10.0-13.6 keV) were fit with a Gaussian Pb peak on a smooth background; a Compton sideband normalized for mass/overlying tissue. Matched samples were quantified by ICP-MS. Agreement was assessed by OLS, Pearson r, Passing-Bablok, ICC (two-way, absolute), and Bland-Altman. Detection limits were derived from a blank-and-slope analytical MDL, and precision from 30 repeated measurements on two bones. **Results:** MXRF signal followed a quadratic attenuation with a restriction on measurement of bone under soft-tissue thickness less than ~3 mm, supporting reliable Pb quantification in femur, TMT, and phantoms (counts vs. ppm: R² = 0.996; phantom nominal vs. MXRF: R² = 0.994). MXRF tracked ICP-MS very closely (femur r = 0.959, ICC = 0.933; TMT r = 0.962, ICC = 0.953; combined OLS R² = 0.905). Bland-Altman mean biases were small (femur: -1.73 µg/g; TMT: -0.42 µg/g; overall: -1.07 µg/g) without proportional bias. Passing-Bablok slopes were near unity (~0.86-0.96) with small intercepts. Operational DLs were 1.79 µg/g (femur) and 0.80 µg/g (TMT); calibration-derived MDL was 0.03 µg/g at 200 seconds. **Conclusions:** A DCC-based, 1 mm-spot MXRF delivered rapid, non-destructive bone Pb estimates concordant with ICP-MS and low DLs. With attenuation correction and fixed geometry, it supports *ex vivo* Pb surveillance, carcass triage, and program evaluation in birds, advancing portable XRF for environmental health.

PS 4589 How Mercury Reshapes and Damages Neuronal Architecture: Insights from Cryo-Correlative Synchrotron-Fluorescence Imaging

I. Kellou¹, N. Pied², M. Fernandez Monreal², P. Cloetens³, A. Carmona¹, and R. Ortega¹. ¹Univ. Bordeaux, CNRS, LP2I Bordeaux, UMR 5797, Chemical Imaging and Speciation in Neurosciences, Gradignan, France; ²BIC, Bordeaux Imaging Center, Bordeaux, France; and ³ESRF, The European Synchrotron, Grenoble, France.

Background and Purpose: Mercury (Hg) is a highly neurotoxic environmental pollutant, ranked among the ten most hazardous chemicals by the World Health Organization (WHO). It has been implicated in both neurodevelopmental and neurodegenerative disorders through its capacity to disrupt redox homeostasis, interfere with intracellular trafficking, and damage organellar integrity. However, the subcellular distribution of Hg remains poorly understood, making the identification of its

intracellular targets and mechanisms of action a key challenge. Here, we aimed to determine how Hg alters the neuronal cytoskeleton architecture and organelle organization, using a novel approach of native cryo-correlative nano-imaging to directly relate metal localization to structural damages. **Methods:** We developed a cryogenic correlative imaging approach combining cryo-fluorescence light microscopy (cryo-FLM) and synchrotron-based cryo-nano X-ray fluorescence (cryo-SXRF), enabling high precision co-localization of metals with neuronal structures in native conditions. Primary rat hippocampal neurons were exposed for 24 hours to a sub-cytotoxic concentration of HgCl₂ (corresponding to Inhibitory Concentration 10%, IC₁₀). Cells were fluorescently labeled to visualize microtubules, the postsynaptic density (PSD95) and selected organelles (mitochondria and lysosomes). After rapid plunge-freezing in liquid ethane to preserve the native ultrastructure and elemental distribution, neurons were analyzed by cryo-FLM at -196 °C to map cytoskeletal architecture, postsynaptic compartments and organelles with a 350 nm spatial resolution. The same regions were subsequently examined using cryo-SXRF at the ID16A beamline (ESRF, European Synchrotron Radiation Facility), with an incident X-ray beam energy of 17 keV, achieving a spatial resolution down to 25 nm. The two datasets were correlated using the Icy software ec-CLEM plugin, allowing direct co-localization of Hg with neuronal structures at the subcellular level. These observations were supplemented by live-cell fluorescence microscopy of SiR (silicon rhodamine)-tubulin and immunofluorescence microscopy of monoclonal anti-β-tubulin and phalloidin (F-actin) in Hg-exposed and control neurons. **Results:** Live-cell fluorescence imaging revealed that Hg exposure induces progressive deformation of the microtubule network, forming bead-like tubulin varicosities along neurites. These structures were confirmed by quantitative immunofluorescence microscopy, which showed a statistically significant 1.5-fold increase ($p < 0.01$) in microtubule varicosities following Hg exposure ($n = 169$ neurons) vs controls ($n = 348$). Dual live imaging of mitochondria and lysosomes further revealed that these varicosities act as local traps for organelles, blocking their normal transport along axons and dendrites. This suggests a functional breakdown of cytoskeletal integrity and dendritic trafficking. Correlative cryo-FLM and cryo-SXRF imaging provided direct evidence that mercury accumulates within these microtubule varicosities, mainly within mitochondria. In addition, lower levels of Hg were detected all along microtubules and in postsynaptic compartments, where it appeared as small puncta (< 100 nm) associated with F-actin and PSD-95 labelling. Abnormal microtubule varicosities, disruption of mitochondrial activity and synaptic loss are common hallmarks of Alzheimer's disease (AD). **Conclusions:** Our findings demonstrate that Hg destabilizes the dendritic cytoskeleton, inducing microtubule varicosities that trap organelles and accumulate Hg mainly in the mitochondria. Hg is also present in lower content along undistorted dendrites and within postsynaptic compartments. This work demonstrates the power of cryo-correlative imaging to unveil spatial relationships between metal accumulation and neuronal structures. It provides direct evidence linking Hg-induced cytoskeletal disorganization with mitochondrial and synaptic sequestration, mechanisms that mimic AD-like neurodegeneration, suggesting that Hg exposure could be involved in the pathogenesis of AD.

PS 4590 NUPR1 Confers Protection Against Chromium Toxicity in Beas2B cells

J. Mollaneda. NYU Langone, New York, NY.

Background and Purpose: Chromium (VI) [Cr(VI)] is the product of various industrial processes and is classified as a group 1 carcinogen by IARC. Aside from the heightened risk of cancer, long term inhalation exposure to Cr(VI) decreased pulmonary function, perforation in the lung, and asthma. Earlier animal studies portend to developmental effects of chronic Cr(VI) including gross abnormalities and malignancies. In the cellular level, Cr(VI) promotes various signaling pathways and gene expression changes including increased expression of NUPR1, a stress response protein. Much of literature has described the protective role of NUPR1 in autophagy and apoptosis. However, NUPR1-mediated Cr(VI)-induced cell death has not been reported. The purpose of this study is to shed light on the role of NUPR1 in Cr(VI) induced autophagy and apoptosis in Beas2B cells, where in prolonged exposure, promotes tumorigenesis. **Methods:** Transient knockdown of NUPR1 was done using siRNA Beas2B cells and chromium-transformed Beas2B cells. Overexpression of NUPR1 was also performed with a pcDNA3.1 backbone. Beas2B cells were then exposed to 5uM of potassium chromate (K₂CrO₄) for 12 and 24 hours. Apoptosis was quantified by Annexin V FITC and PI and analyzed by flow cytometry. mRFP-GFP-LC3 puncta was also performed to analyze autophagic flux in B2B cells. Oxidative damage was assessed by using CellROX™ Green Reagent. Beas2b cells were exposed to 0.125 and 0.25uM Cr(VI) for 3 months. Then anchorage independent growth was quantified by soft agar. Chromium-transformed Beas2b cells were also subject to transient knockdown of NUPR1 and immunoblotting for autophagy and apoptosis markers. **Results:** Cr(VI) induces apoptosis and autophagy in a time dependent manner concomitant with NUPR1 upregulation in Beas2B. Endogenous NUPR1 levels were positively correlated with attenuated autophagy, apoptosis, and reactive oxygen species (ROS) mitigation in Cr(VI) exposure. NUPR1 expression is observed to be higher in chromium-transformed Beas2B cells. NUPR1 depleted Cr-T cells show elevated signs of apoptotic and autophagic activity. **Conclusions:** NUPR1, as a stress-response gene, is a master regulator of apoptosis and autophagy. Taken together, hexavalent chromium induces cell death pathways in Beas2b cells. Chromium activates autophagic and apoptotic pathways, and NUPR1 confers protection against the dysregulated activity in these pathways. Increased cell survival granted by NUPR1 expression

can promote sustained malignant transformation and tumorigenesis in prolonged exposure to Cr(VI). Further investigation of NUPR1 in Cr(VI)-induced cytotoxicity will provide insights into therapeutic approaches for chromium-associated lung cancer.

PS 4591 Correlation Between Urinary Metals and Chronic Diseases in Well-Water Users in New Mexico Border Counties

J. Zhang¹, O. Templin¹, S. Majidi¹, M. J. Campen², S. H. Munson-McGee³, and H. H. Rahman¹. ¹New Mexico State University, Las Cruces, NM; ²University of New Mexico, Albuquerque, NM; and ³Data Forward Analytics, LLC, Las Cruces, NM.

Background and Purpose: In the US, around 15% of all residents, approximately 43 million individuals, rely exclusively on private or domestic wells for their drinking water. Oversight of domestic well water safety and quality lacks state or federal regulation, placing the responsibility on consumers to monitor these factors. Due to its unique geography and the presence of the metal production industry, New Mexico (NM), including Doña Ana County, exhibits high levels of metals, including arsenic, uranium, lead, cadmium and other metals sourced from anthropogenic and naturally occurring sources. This study aimed to examine the correlation between urinary metal levels [arsenic (As), lead (Pb), antimony (Sb), uranium (U), cadmium (Cd), iron (Fe), zinc (Zn), and selenium (Se)] and chronic health conditions, including high blood pressure (HBP), diabetes, chronic obstructive pulmonary disease (COPD) and cancers in well water users. **Methods:** Data, including questionnaires and specimens, were collected from adults aged 18 and older who used well water in border counties, NM. To collect urine samples, participants were provided with a wide cup. After receiving the urine samples, the study team divided them into two 15 mL conical tubes and labeled each tube with an arbitrary number corresponding to the participant. The urine samples collected were sent to the Center for Metals in Biology and Medicine (CMBM) laboratory at the University of New Mexico (UNM). The required temperatures for all specimens were maintained from the point of collection to laboratory analysis, ensuring proper conditions for accurate analysis of the biospecimens. The analysis of metals in urine samples was performed using inductively coupled plasma mass spectrometry (ICP-MS). The laboratory analyses conducted at the UNM were supported by Grant Number P20GM13042. The survey data and urinary analysis results were all analyzed using standard statistical techniques using R software version 4.2.2. The covariate analysis was done using standard chi-square analysis. The linear logit regression analysis was done using the absence/presence of a health condition as the response factor. The primary variate was one of the well-water metal concentrations, and the remaining covariates, all treated as categorical variables, were: gender, race, education, household income, ever consumed alcohol, ever smoked, current smoker, age category, and BMI category. The estimated regression coefficients and their 95% confidence levels were converted into odds ratios prior to being reported in the results sections. **Results:** A total of 80 participants were included in this study, and urinary metals were analyzed to assess their correlation with selected chronic diseases. Higher urinary Fe levels were significantly associated with lower odds of HBP (OR = 0.94, 95% CI: 0.88-0.98), suggesting a potential protective role. In contrast, higher urinary As levels were associated with a slight increase in the odds of HBP (OR = 1.02, 95% CI: 1.00-1.05). No significant associations were observed between HBP and urinary levels of Zn, Se, Cd, Sb, Pb, or U. Fe, As, and Se demonstrated notable correlations with diabetes. Increased urinary Fe was correlated with reduced odds of diabetes (OR = 0.93, 95% CI: 0.81-1.00), and Se also showed a protective effect (OR = 0.79, 95% CI: 0.65-0.90). In contrast, higher urinary As levels were correlated with increased odds of diabetes (OR = 1.01, 95% CI: 1.00-1.03). For COPD, higher urinary Fe levels were associated with increased odds of disease (OR = 1.10, 95% CI: 1.03-1.20). No statistically significant correlations were found between urinary metals and cancer outcomes, including lung, liver, bladder, skin, prostate, or breast cancer. **Conclusions:** This is an ongoing study, and further research with larger sample sizes is essential to validate these results and determine whether the correlations of metals and chronic diseases associations can be confirmed or refuted. Research reported in this publication was supported by the National Institute of General Medical Sciences of the National Institutes of Health under award number R16GM154680.

PS 4592 Analysis of potential drivers of tungsten-enhanced breast cancer metastasis: A longitudinal study of bone marrow adipocytes

C. M. McVeigh, J. A. Tjung, J. L. Moreno, S. J. Yazzie, L. K. Heine, G. A. Picha, S. C. Helewicz, G. W. Herbert, S. Medina, and A. M. Bolt. University of New Mexico, Albuquerque, NM.

Background and Purpose: Tungsten (W) is classified as an emerging environmental toxicant due to increased human exposure and a lack of knowledge of the health risks. Epidemiological and *in vivo* studies demonstrate that exposure to W contributes to the carcinogenic process, but the molecular mechanisms are poorly defined. Due to a cohort of breast cancer patients accidentally exposed to W during intra-operative radiotherapy, our lab is investigating the effects of W on breast cancer progression and metastasis. W is known to accumulate in the bone, creating a site for long-term exposure and toxicity. Previous research in our lab has shown that in multiple triple-negative breast cancer orthotopic models, W enhances breast cancer metastasis to the bone niche. These findings suggest that W deposition in the bone

creates a favorable microenvironment to promote metastasis. Bone marrow adipocytes (BMA) play an important role in breast cancer metastasis to the bone through the secretion of adipokines/cytokines that drive tumor cells homing, colonization, and growth by changing the microenvironment. Understanding weekly changes throughout metastasis in BMA is critical to uncover adipokines/cytokines that could drive colonization and proliferation of tumor cells in the bone niche following W exposure. We aim to understand changes in BMA throughout the metastatic process to identify W mediated changes that could enhance breast cancer metastasis to the bone. **Methods:** 6-8 week old female BALB/c and C57BL/6 mice were exposed to 15ppm W in their drinking water or tap water for 4 weeks. After 4 weeks of exposure, mice underwent orthotopic injections of 4T1 (BALB/c) or E0771-Luc (C57BL/6) cells into the 4th mammary fat pad. Longitudinal time points were conducted to track changes after 4 weeks of exposure to W with no tumor cell injection (0 week; 0W), 2 weeks post-tumor cell injection (2 week; 2W), and 3 weeks post-tumor cell injection (3 week; 3W). At the end, bones were collected for multiple parameters. Femurs were used for immunohistochemistry staining of Perilipin-1+ (Plin1+) adipocytes in the bone marrow. Bone marrow from tibiae was cultured to select for mesenchymal stromal cells (MSCs), which were differentiated into BMA through media selection. Cell supernatant and RNA were collected from both MSCs and BMA to profile changes in adipokines/cytokines throughout the metastatic process. **Results:** While both models have increased metastasis to the bone following W exposure, 4T1 induced greater systemic inflammation compared to E0771-Luc. RANK L expression was significantly increased at 0W and trending at 3W in 4T1, but only a trending increase in E0771-Luc. This supports previous data showing increased osteolysis in 4T1 following W exposure at the final tumor endpoint whereas in E0771-Luc, W does not. Adiponectin levels remained unchanged in E0771-Luc, but significantly increased following W exposure at 2W and 3W in 4T1. CXCL2 expression was significantly increased following W exposure at 0W and 2W and trending at 3W in 4T1 and was significantly increased at 3W in E0771-Luc. Previous data from our research group also showed increased gene expression of CXCL2 at final tumor endpoint in 4T1. Plin-1+ staining revealed that E0771-Luc has more adipocytes compared to 4T1, regardless of exposure. **Conclusions:** Some analytes did not have changes either with W exposure or by week, suggesting that perhaps they are not the main drivers of metastasis. Analytes such as RANK L and Adiponectin showed changes following W exposure, but they were dependent upon the model used. These data suggest that there are inherent differences between models and W could be doing slightly different things in each model, including a systemic inflammation component that we observed more in the 4T1 compared to the E0771-Luc. CXCL2 was increased in both models, suggesting a common key player in enhanced metastasis to the bone. CXCL2 is known to play a role in tumorigenesis and immune escape of tumor cells. CXCL2 might be a key mediator that could be further studied in this context to provide insights. This study provides insights into adipokine/cytokines that might be critical players in W enhanced breast cancer metastasis to the bone.

PS 4593 Antibiotic Perturbation of the Gut Microbiome Increases Susceptibility to Arsenic-Induced Urothelial Cytotoxicity in the Murine Bladder

T. M. Wolfe¹, E. Dardenne-Ankringa¹, S. M. Cohen², and S. T. Walk¹. ¹Montana State University, Bozeman, MT; and ²University of Nebraska Medical Center, Omaha, NE.

Background and Purpose: Inorganic arsenic is a group 1 carcinogen and a well-known risk factor for human bladder cancer. Wild-type (WT) mice exposed to inorganic arsenic develop mild cytotoxic changes in the bladder urothelium when evaluated using scanning electron microscopy. Transgenic mice lacking normal inorganic arsenic metabolism (arsenite methyltransferase knockout, As3MT^{-/-}) develop more severe bladder cytotoxicity that increases over time compared to WT mice. The gut microbiome is an understudied modifier of arsenic toxicity, and our group demonstrated that gut bacteria protect against acute arsenic toxicity. For example, lethal toxicity in mice co-exposed to the broad-spectrum antibiotic, cefoperazone (CEF), and inorganic arsenic is four times greater than that observed in mice exposed to inorganic arsenic alone. The purpose of this study was to test the hypothesis that antibiotic perturbation of the gut microbiome accelerates and/or exacerbates arsenic-induced urothelial cytotoxicity in the murine bladder. **Methods:** Wild-type and transgenic (As3MT^{-/-}) C57BL/6 mice were exposed to one of the following treatments: 0.5 g/L CEF and 100 ppm inorganic arsenate (iAs^V); a heat-denatured CEF (0.5 g/L) and 100 ppm iAs^V (SHAM); 100 ppm iAs^V only; 0.5 g/L CEF only; and untreated (plain water) for 7 days. Following exposure, mice were put under anesthesia and the bladder was inflated with 10% buffered formalin. Following humane euthanasia, the bladder was removed and fixed with formalin for 48 hours. Following fixation, bladders were then cut in half exposing the internal urothelial lining. Bladders were then dried with increasing amounts of ethanol, critically point dried, and mounted for observation using Field Emission Scanning Electron Microscopy (FE-SEM). Micrographs from standardized anatomical regions were collected and blinded prior to histopathologic scoring by a trained pathologist. **Results:** Consistent with previous experiments, WT mice exposed to iAs^V alone showed only mild urothelial cytotoxic change and minimal to no hyperplasia. Also consistent with previous experiments, As3MT^{-/-} mice exposed to iAs^V alone exhibited increased urothelial cytotoxicity compared to WT counterparts. Both mice (WT and As3MT^{-/-}) treated with CEF+ iAs^V displayed increased urothelial cytotoxicity and frequent regions of hyperplasia compared to the same mice exposed to iAs^V alone. Notably, WT mice exposed to CEF+ iAs^V displayed urothelial necrosis and early hyperplastic changes. **Conclusions:** These results demonstrate

that antibiotic perturbation of the gut microbiome markedly increases susceptibility to arsenic-induced urothelial damage and accelerates the onset of early pathologic changes associated with bladder carcinogenesis. This is the first report of such histopathology in WT mice exposed to inorganic arsenic. Ongoing work includes additional blinded scoring of control/comparator groups (CEF alone and SHAM) and evaluations of dose- (10, 25, 50 ppm) and arsenic species-dependent effects (iAs^{III} vs. iAs^V). This study identifies the gut microbiome as a critical modifier of arsenic-induced bladder toxicity and highlights the need to consider antibiotic use and other types of microbiome perturbations in arsenic risk assessment.

PS 4594 A Lesson in Exposure Relevance: How Cr(VI) Concentrations Change Pathways of Toxicity in a C. elegans Model

S. T. Vilee¹, H. Lu¹, N. Besaw¹, L. Cai¹, M. Aschner², and J. Wise, Jr.³. ¹University of Louisville, Louisville, KY; ²Albert Einstein College of Medicine, New York City, NY; and ³University of Toledo, Toledo, OH.

Background and Purpose: Hexavalent chromium [Cr(VI)] is a ubiquitous environmental pollutant and potent toxicant, currently ranked as the #1 chemical hazard in US public drinking water. Cr(VI) toxicity is well-characterized in many tissues, with *in vitro* and *in vivo* models generating substantial amounts of mechanistic data. While the literature contains a bevy of data describing Cr(VI) toxicity, there are few reports describing how pathways of toxicity change with exposure concentration. These data limitations impair our ability to extrapolate between studies and interpret discrepancies in the literature, as failure to assess toxicity across a wide range of concentrations may lead to relevant pathways of toxicity being overlooked. We recently established a model to investigate Cr(VI) neurotoxicity in *Caenorhabditis elegans*, identifying GABAergic neurons as the most vulnerable neuronal phenotype to Cr(VI). *C. elegans* is an outstanding model to study metals toxicity, given its high-throughput nature and 60 - 80% gene homology with humans. However, no groups have reported the effects of Cr(VI) on the *C. elegans* proteome. Here, we exposed worms to Cr(VI) and performed untargeted proteomics to investigate pathways of toxicity in *C. elegans* across a wide range of Cr(VI) concentrations. We hypothesized that Cr(VI) would primarily alter DNA damage repair pathways in *C. elegans*. Here, we report Cr(VI) induced distinct pathways of toxicity across a wide range of concentrations. **Methods:** Briefly, we synchronized Bristol N2 *C. elegans* and exposed L4 worms to sodium chromate (0, 5, 50, 500, 1000 mg/L) in 85 mmol sodium chloride with 0.001% Tween-20 for 24 h. After exposure, worms were collected, washed, and freeze cracked. Total RNA and protein were extracted with TRIzol. We performed untargeted proteomics with the University of Louisville Proteomics Technology Core to investigate pathways of Cr(VI) toxicity. **Results:** Cr(VI) induced proteotoxic stress across all concentrations (e.g., impaired protein translation, altered protein folding, impaired protein degradation); however, we also report that pathways of toxicity shifted across exposure groups. Exposure to 5 and 50 mg/L increased abundance of proteins related to cholinergic signaling. Exposure to 50, 500, and 1000 mg/L altered protein abundance in a manner consistent with metabolic dysfunction. Exposure to 500 and 1000 mg/L changed protein abundance in a manner consistent with impaired chromatin remodeling and inflammation. **Conclusions:** This is the first study to consider the effects of Cr(VI) on the *C. elegans* proteome, and we report concentration-dependent changes in pathways of Cr(VI) toxicity in a *C. elegans* model. The data presented here suggest that pathways of Cr(VI) toxicity in *C. elegans* are dependent on Cr accumulation, as we previously reported internal Cr levels increased with exposure concentration. Animal models suggest sinks for Cr accumulation change with exposure concentration, possibly explaining changes in toxicity reported here if tissue Cr accumulation in *C. elegans* changed with concentration. Here, we report Cr(VI) induced proteotoxic stress across all exposure groups, suggesting proteotoxicity is a critical factor for Cr(VI) toxicity in *C. elegans*. Importantly, the data presented here demonstrate that neurotoxicity may be a primary effect in worms exposed to low concentrations of Cr(VI). Exposure to 5 or 50 mg/L increased proteins related to cholinergic function - indicating activation of compensatory mechanisms in neurotransmission. At higher concentrations, we report broader toxicity. Exposure to 50, 500, and 1000 mg/L induced metabolic stress in *C. elegans*, possibly indicating mitotoxicity. Further, exposure to 500 and 1000 mg/L decreased expression of histone proteins and increased inflammation, suggesting Cr(VI) may induce DNA damage and significant systemic toxicity in *C. elegans* at these concentrations. While highlighting how Cr(VI) toxicity shifts with exposure concentration in a *C. elegans* model, these data also emphasize the critical nature for dose selection in toxicological studies. Future experiments will consider transcriptomic data and validate proteomics data. Support from SOT GIFT (STV), T32-ES011564 (STV), LRC Voucher Program (Q3-FY2025), R01-ES10563 (MA), and R21-ES033327 (JPW).

PS 4595 Nascent Proteome is the Main Target of Toxic Protein Damage by Cadmium in Human Cells

G. Ursu, and A. Zhitkovich. Brown University, Department of Pathology and Laboratory Medicine, Providence, RI.

Background and Purpose: Cadmium (Cd) is a biopersistent toxic and carcinogenic metal that poses health risks for the general population through dietary and other sources. Long-term exposures to Cd(II) causes damage to the lungs, kidney dysfunction

tion and neurotoxic effects. Cd(II) does not react with DNA but is known to bind to proteins via their SH-groups. The purpose of this work was to investigate what proteins are preferentially damaged by Cd(II) and whether global or protein-specific damage underlies its toxicity. **Methods:** Human lung and kidney cells treated with Cd(II) were analyzed for the formation of proteolytic K48-linked polyubiquitination of proteins, protein denaturation/misfolding and the appearance of cytoplasmic aggregates. Proteotoxic activities and cytotoxicity of Cd(II) were examined under normal conditions and in cells with inactivated ubiquitin-proteasome system, protein synthesis and integrated stress response. **Results:** We found that Cd(II) induced accumulation of K48-polyubiquitinated proteins primarily in the cytosol, and nuclear protein SUMOylation was important for the optimal expression of transcriptional targets of NRF2- and HSF1-driven proteostatic responses. Global protein damage was a major cause of Cd(II) toxicity, as inhibition of ubiquitination or proteasomal activity severely impaired survival of cells at otherwise minimally or nontoxic doses, indicating the requirement for the efficient disposal of abnormal proteins. We found that newly synthesized proteins were the main group of Cd(II)-damaged cellular proteins that were undergoing proteolytic K48-polyubiquitination or became denatured as a result of Cd(II)-induced injury. Proteins with high rates of continuing synthesis such as short-lived transcriptional factors or antiapoptotic proteins were especially sensitive to denaturation by Cd(II). Activation of the integrated stress response limiting protein translation rates diminished accumulation of damaged proteins and increased Cd(II) tolerance by cells. **Conclusions:** Our findings identified damage to nascent proteins as a major cause of global proteotoxicity and cytotoxicity by Cd(II), and highlighted a high vulnerability of short-lived proteins to this metal.

PS 4596 A New Model for Studying Arsenic-induced Skin Carcinogenesis

A. N. Nail, M. Banerjee, A. P. Ferragut Cardoso, S. Thomas, J. Hwang, J. W. Park, and J. C. States. University of Louisville, Louisville, KY.

Background and Purpose: HaCaT human keratinocytes malignantly transformed by continuous inorganic arsenic exposure (100 nM NaAsO₂, iAs), 28 weeks) serves as the gold standard model to study molecular mechanisms of iAs-induced skin carcinogenesis. However, the HaCaT cell line is inherently hypotetraploid and genomically unstable. Ker-CT cells are a non-tumorigenic near-diploid human keratinocyte cell line immortalized with hTERT and mouse CDK4 overexpression without Simian virus 40 T antigen expression. We hypothesize that chronic iAs exposure malignantly transforms Ker-CT cells, providing a genetically stable model to identify core drivers of iAs-induced skin carcinogenesis. **Methods:** To test our hypothesis, passage-matched, independent quadruplicate Ker-CT cell cultures were chronically exposed to sodium arsenite (iAs; 0 or 100 nM; 44 weeks). Longitudinal samples (DNA, RNA and whole cell lysates) were collected at 8-, 20-, and 44-week time points. Malignant transformation was evaluated through epithelial mesenchymal transition (EMT; immunoblotting), and anchorage independent growth. Longitudinal changes in iAs-induced gene expression was assessed by long-read RNA-seq (PacBio with full-length Kinnex; cutoff: $p < 0.05$, fold change $\geq \pm 30\%$). Ingenuity Pathway Analysis (IPA) was used to predict canonical pathway changes dysregulated by chronic iAs exposure. **Results:** After 44 weeks, iAs exposure concomitantly suppressed epithelial (E-cadherin) while inducing mesenchymal markers (N-cadherin and Slug), characteristic of EMT. Both iAs exposed and passage-matched unexposed cells (44 weeks) migrated to the top of soft agar, with iAs exposed cells exhibiting migration at an earlier timepoint compared to unexposed cells. Over 440 differentially expressed protein coding mRNAs were identified at each timepoint. IPA analysis revealed that 18, 33, and 48 pathways were dysregulated at 8-, 20-, 44-week timepoints, respectively. There was limited longitudinal overlap both for differentially expressed genes and dysregulated pathways highlighting the temporally dynamic nature of carcinogenesis in agreement with our published observations in the HaCaT cell line. Prominent cancer-associated pathways were dysregulated at each timepoint, elucidating the stepwise processes that promote iAs-induced skin carcinogenesis. **Conclusions:** Together, our findings support that Ker-CT cells provide a genetically stable model to study iAs-induced skin carcinogenesis.

PS 4597 Intestinal SLC30A10 suppresses manganese absorption in hereditary hemochromatosis

M. Prajapati¹, L. Chiu², J. Zhang², G. Chong², and T. Bartnikas². ¹Ferris State University, Big Rapids, MI; and ²Brown University, Providence, RI.

Background and Purpose: Iron (Fe) and manganese (Mn) are essential trace elements that must be maintained within a narrow physiological range. The export protein SLC30A10 plays a critical role in Mn homeostasis by mediating its excretion from the liver into bile and from enterocytes into the intestinal lumen. Biallelic mutations in SLC30A10 cause a rare inherited Mn overload disorder characterized by dystonia, cirrhosis, and polycythemia. Studies using Slc30a10-deficient (Slc30a10^{-/-}) mice have demonstrated impaired gastrointestinal Mn excretion and systemic Mn excess. Our prior work revealed that dietary Fe supplementation attenuates disease phenotypes in these mice, suggesting that Fe and Mn compete for absorption through shared transporters such as DMT1 and ferroportin. Interestingly, despite impaired Mn excretion, Slc30a10^{-/-} mice also exhibit increased gastrointestinal Mn absorption, a phenomenon not observed in hereditary hemochromatosis, a disease characterized by hepcidin deficiency and enhanced Fe absorption. We

therefore hypothesized that intestinal SLC30A10 suppresses dietary Mn absorption, preventing Mn overload under conditions of hepcidin deficiency. **Methods:** To test this hypothesis, we employed mice deficient in hepcidin expression. We first generated and characterized Slc30a10^{-/-}/Hjv^{-/-} double-knockout mice to assess the combined effects of both deficiencies on Mn homeostasis. Mn absorption was quantified using gastric gavage of radiolabeled ⁵²Mn. To determine the specific contribution of intestinal SLC30A10, we generated Hjv^{-/-} mice with intestinal Slc30a10 deficiency by crossing Slc30a10^{fl/fl} mice with villin-Cre (Vil) transgenic mice. Mn levels in tissues (liver, brain, bone, pancreas) and bile were quantified using inductively coupled plasma-optical emission spectrometry (ICP-OES), and ⁵²Mn absorption assays were performed to measure intestinal uptake. **Results:** Slc30a10^{-/-}/Hjv^{-/-} double-knockout mice exhibited markedly increased Mn absorption compared to single-knockout or control mice. Similarly, intestinal-specific Slc30a10 deficiency in Hjv^{-/-} mice led to significantly elevated Mn accumulation across multiple tissues, including liver, brain, bone, and pancreas, along with increased biliary Mn levels. ⁵²Mn absorption assay confirmed that intestinal loss of Slc30a10 enhances Mn absorption in Hjv^{-/-} mice. These results demonstrate that intestinal SLC30A10 actively suppresses Mn absorption, even under conditions that favor Fe hyperabsorption due to hepcidin deficiency. **Conclusions:** This study reveals that intestinal SLC30A10 serves as a critical gatekeeper preventing Mn overload during states of low hepcidin, such as hereditary hemochromatosis. In diseases of Fe excess, reduced hepcidin levels lead to increased ferroportin and compensatory upregulation of DMT1, promoting excessive Fe absorption. However, Mn absorption does not concurrently increase, due to the protective action of intestinal SLC30A10. These findings provide a mechanistic explanation for why conditions that enhance Fe absorption do not result in Mn toxicity and establish intestinal SLC30A10 as a key regulator of Mn homeostasis in iron-loading disorders.

PS 4598 Leveraging a human induced pluripotent stem cell-derived cardiomyocyte system to study the effects of inorganic arsenic exposure during cardiac development

M. K. Steiner¹, E. Tampakakis², and M. Kohr¹. ¹Johns Hopkins Bloomberg School of Public Health, Baltimore, MD; and ²Johns Hopkins School of Medicine, Baltimore, MD.

Background and Purpose: Arsenic is a naturally occurring metalloid that has been mobilized in the environment via anthropogenic processes. Exposure to inorganic arsenic (iAs) during pregnancy is associated with increased risk for congenital heart defects (CHD). CHD affects 1 in 110 infants and accounts for approximately 40% of all birth defect mortality. Disruption of transcription factors that govern the differentiation of cardiac progenitor cells has been associated with the development of CHD. Prior work from our lab found that dams exposed to iAs during gestation had altered heart structure, which may impact embryonic development. Indeed, mouse embryos from exposed dams had larger hearts and increased left ventricular internal dimensions compared to non-exposed controls. Collectively, these findings suggest that gestational iAs exposure may impair cardiac differentiation and contribute to CHD development, but additional mechanistic studies are warranted. Our study aims to examine the impact of iAs on cardiomyocyte differentiation and maturation using a human induced pluripotent stem cell (hiPSC) model. **Methods:** To model cardiogenesis *in vitro*, hiPSCs were differentiated into cardiomyocytes using sequential Wnt activation and inhibition. hiPSCs were exposed to iAs starting at differentiation day (DD) 0. An MTT viability assay was performed on hiPSCs exposed to 0-100 ppb iAs on DD3. Doses of 0, 5, and 50 ppb iAs were selected, as they did not induce excess cell death compared to higher doses. hiPSCs were exposed to the selected doses starting at DD0. Cells were analyzed at DD3, DD5, DD9, DD12, and DD21 by testing the expression of differentiation and oxidative stress genes using qPCR. Beating frequency measurements (in bpm) were also quantified. **Results:** We found a significant decrease in cell viability, even at low doses of iAs after three days of exposure. Preliminary qPCR results show that markers of early cardiomyocyte development, *Tbx5*, *Gata4*, and *Nkx2.5*, were decreased in cardiac progenitor cells exposed to 5 ppb iAs at DD5, but these markers were not statistically different in cells exposed to 50 ppb iAs compared to non-exposed controls. Cardiomyocyte maturation markers, including *Tnni3*, *Myh6*, and *Actn2*, were upregulated at DD12 in hiPSC-cardiomyocytes exposed to 50 ppb iAs; *Myh6* was still upregulated in hiPSC-cardiomyocytes at DD21, compared to non-exposed controls. Markers of oxidative stress, *Sod1* and *Gpx1*, were increased in DD21 hiPSC-cardiomyocytes exposed to 5 ppb iAs compared to non-exposed controls, but expression levels were not statistically different in cells exposed to 50 ppb iAs. Finally, beating frequency showed a dose-dependent reduction in exposed cardiomyocytes at DD12 compared to non-exposed controls, indicating a potential delay in functional maturation associated with iAs exposure during cardiac development, but this decrease was no longer seen at DD21. **Conclusions:** Our work demonstrates that exposure to iAs at environmentally relevant concentrations leads to impaired differentiation of iPSCs into cardiomyocytes, thus leading to potential diminished cardiomyocyte functionality. Our findings suggest that iAs exposure may contribute to CHD development by impairing early cardiac differentiation and interfering with cardiomyocyte maturation at later timepoints. Due to the high prevalence of CHD in the population and the increased likelihood of iAs exposure in the environment, this study is critical for understanding how iAs exposure during development impacts cardiomyocyte differentiation.

J. Peng, J. Feng, Y. Yang, and K. Lu. University of North Carolina at Chapel Hill, Chapel Hill, NC.

Background and Purpose: Inorganic arsenic (iAs) is a globally pervasive toxic metalloid, with more than 200 million individuals chronically exposed and no effective strategies available to prevent, detoxify, or eliminate it from the human body. Growing evidence indicates that the gut microbiome modulates host responses to arsenic, suggesting that targeted microbiome engineering may offer a novel detoxification approach. Although microbial arsenic metabolism has been described, it remains unclear which gut bacteria with meaningful detoxification functions can effectively reduce systemic arsenic burden *in vivo*. To address this gap, we integrated genome-scale screening with *in vitro* and *in vivo* models to identify native gut bacterial strains capable of mitigating arsenic burden. **Methods:** We conducted a genome-scale search for gut bacteria carrying key arsenic metabolism genes, including uptake genes (Pst, Pit, GlpF), the methylation gene (ArsM), and the efflux gene (ArsP). Protein sequences were queried against an in-house gut metagenome database. Isolates were cultured with 200 ppb sodium arsenite to quantify the capacity of strain-specific arsenic removal. High-performing isolates were then evaluated in human AS3MT germ-free mice and C57BL/6 hAs3mt mice exposed to 200 or 500 ppb arsenic via drinking water to determine effects on fecal elimination and systemic bioaccumulation. **Results:** *In vitro* screening revealed substantial variation across strains, with 27 isolates showing significant arsenic removal ranging from 6% to 45%. Mono-bacterial colonization markedly increased fecal arsenic elimination in both germ-free and wildtype hAs3mt mice. Importantly, single-strain supplementation in wild-type hAs3mt mice reduced arsenic accumulation in the liver and kidney, demonstrating bacterial detoxification efficacy even within a complex microbial community. **Conclusions:** Taken together, these findings establish mechanistic links between bacterial genomes, their detoxification capacity, and host arsenic burden, supporting mechanism-guided microbiome engineering as a promising strategy for mitigating risks associated with arsenic exposure.

PS 4600 Investigation into Immune Cell Dysregulation and Autoimmune Disease Mechanisms Following Exposure to Uranium Bearing Dust *in vivo*.

J. L. Moreno, M. Afaghpour-Becklund, C. McVeigh, S. Yazzie, O. Edeh, B. Baird, R. Lui, J. Cerrato, K. Zychowski, S. Blossom, and A. Bolt. University of New Mexico, Albuquerque, NM.

Background and Purpose: The western United States consists of thousands of abandoned uranium (U) mines (AUMs), many of which are present in the 4 corners region of the Southwestern United States. These AUMs are in close proximity to residential areas, many of which exist on tribal lands. Improper cleanup procedures and lack of remediation have led to significant concerns of windblown, fugitive dust blowing into these communities contributing to chronic health disease, including autoimmune diseases. Investigation into these long-term chronic health effects following exposure is critical to understand human health risk. We hypothesize that chronic inhalation exposure to AUM particulate matter (PM) will enhance autoimmunity relative to controls through immune dysregulation and chronic inflammation. **Methods:** 9 - 11 week old female MRL/MpJ mice were exposed through oropharyngeal aspiration to AUM PM from the St. Anthony mine, a former U-mine near the Pueblo of Laguna in New Mexico (St. Anthony PM), and control PM from a former coal mine in Colorado containing low heavy metal content (Colorado Red PM). Energy-dispersive X-ray spectroscopy characterization of these dusts revealed that the St. Anthony PM is rich in silica and aluminum and heavy metals U and vanadium (V), while the Colorado Red PM has negligible levels of uranium and vanadium, but does contain silica (Si) and aluminum (Al). Mice were exposed four times in total at a concentration of 50µg/µL of PM in dispersion media across the course of two weeks. Endpoint analysis were evaluated at 2 weeks, 24-hours post the final exposure and 12 weeks, 10 weeks after final exposure. Primary endpoints methodology consisted of analysis of immune cell populations in the lungs and spleen, and T-cell subpopulations within the lymph nodes by flow cytometry, cytokine analysis in the bronchoalveolar lavage fluid (BALF) and plasma using multiplex cytokine arrays, Neutrophil elastase levels in the BALF and plasma by enzyme-linked immunosorbent assay (ELISA), metal deposition within the lungs and bones by inductively coupled plasma mass spectrometry (ICP-MS), and autoantibodies in the BALF and plasma. **Results:** Our findings illustrate significant alterations in immune cell populations in the lungs following exposure to St. Anthony PM at the 2-week timepoint. In particular, we found recruitment of neutrophils after exposure to the St. Anthony PM relative to both our vehicle control, dispersion media and the environmental dust control Colorado Red PM. In order to investigate neutrophil's involvement after observing their increased recruitment to lung, we ran neutrophil elastase ELISAs which revealed a significant increase in neutrophil elastase in the BALF and plasma in the St. Anthony PM group relative to the control groups. ICP-MS analysis revealed that in the St. Anthony PM group, there was a retention of heavy metals including U, V and Al in the lungs, that are not present in the other control groups, even at the 12 week timepoint, providing evidence of long-term metal retention in the lungs that could be contributing to immune dysregulation both in the lungs and systemically. Immune dysregulations revealed by flow cytometry, show alterations to T Cell populations in the spleen via an increase in PD-1+ T Cells

in the UBD test samples. **Conclusions:** Overall, we demonstrate that inhalation exposure to St. Anthony PM caused significant alterations to the immune cell populations of the lungs. Particularly, an increase in the levels of activated neutrophils secreting neutrophil elastase, leading towards production of neutrophil extracellular traps (NETs) that could drive immune dysregulation and the development of autoimmunity through the recognition of NET components, such as modified proteins and selfDNA, by T Cells. Retention of uranium and other heavy-metals from the St. Anthony PM is a unique factor across the conditions that we hypothesize is a leading driver of the effects seen after aspiration exposure to AUM dust.

PS 4601 Zinc and Nickel Inhibit GLP-1, GIP, and Glucagon Signaling in Insulin Secreting Beta Cells

O. G. Chepurny, K. Dennehy, G. G. Holz, and M. El Muayed. SUNY Upstate Medical University, Division of Endocrinology, Syracuse, NY.

Background and Purpose: Zinc (Zn) and nickel (Ni) are reported to modulate several G-Protein Coupled Receptors (GPCRs) with resulting enhanced (β2-adrenergic) or reduced (serotonin 5-HT7, NMDA, D2 Dopamine) receptor ligand binding and activation. GLP-1, GIP, and glucagon receptors are crucial for the proper function of insulin secretion from beta cells -the cell type responsible for regulating glucose metabolism through controlled insulin secretion. Specifically, these receptors act to enhance insulin secretion in response to rising glucose. At the same time, insulin secreting beta cells within islets contain an exceptionally high concentration of the essential metal Zn -which is co-secreted with insulin into the islet milieu. They also contain a relatively high concentration of the non-essential metal Ni. Therefore, the actions of Zn and Ni on GLP-1, GIP and glucagon receptor activation and downstream signaling events were evaluated. GLP-1, GIP, and glucagon receptors are members of the B1 Class of GPCRs (B1GPCRs) that stimulate adenylyl cyclase, thereby increasing levels of the second messenger cAMP which in turn exerts multiple downstream effects, including potentiation of insulin production and secretion. **Methods:** To evaluate potential actions of Zn at B1GPCRs, we used the rat insulin secreting INS-1E cell line that expresses endogenous B1GPCRs, and that express the cAMP responsive FRET reporter H188 using an adenoviral vector. This allowed real-time kinetic measurements of cAMP production in response to GLP-1, GIP, or glucagon when cells were or were not treated with Zn (as ZnCl₂) or Ni (as NiCl₂). **Results:** A concentration dependent inhibitory action of Zn or Ni on all three B1GPCRs was found. This resulted in suppressed cAMP-elevating actions of all three hormones. This effect was observed at Zn concentrations that are expected to exist within the islet interstitial space. The IC50 for this inhibitory effect ranged from 12.0 to 15.3 µmol when testing these hormones. To test for an inhibition of GLP-1 downstream signaling, we examined changes of gene expression using a multimerized RIP1-CRE-LUC luciferase reporter that is cAMP responsive. Here, a significant and concentration dependent inhibition of GLP-1 induced luciferase expression by Zn was observed. Next, a fluorophore labeled GLP-1-[FAM-Trp31] was used to test if binding of GLP-1 to the GLP-1R is altered by Zn. In these experiments, a potent inhibition of GLP-1-[FAM-Trp31] binding by ZnCl₂ at 30 µmol/L was observed. This inhibition potentially reflects allosteric regulation of the GLP-1R by Zn. Finally, *ex vivo* assays of insulin secretion from islets isolated from C57BL/6N mice were performed. Here, a significant action by Zn to suppress the ability of GLP-1 (10 nM) to potentiate glucose-stimulated insulin secretion (GSIS) was observed. **Conclusions:** Excess Zn or Ni in insulin secreting beta cells may impair insulin secretion through inhibition of the B1GPCRs GLP-1, GIP, and glucagon.

PS 4602 Assessment of urinary metal exposure in sugarcane workers across a harvest season and their relationship to kidney health biomarkers

S. Santos¹, S. Brindley¹, J. L. Adgate², L. Krisher², J. Schaeffer³, K. A. James², L. Newman², and J. M. Brown¹. ¹University of Colorado Anschutz Medical Campus, Aurora, CO; ²Colorado School of Public Health, Aurora, CO; and ³Colorado State University, Fort Collins, CO.

Background and Purpose: Urinary metal co-exposure is hypothesized to contribute to chronic kidney disease progression in male sugarcane workers in the Pacific coastal region of Guatemala. **Methods:** Urine samples and kidney health biomarkers (estimated glomerular filtration rate [eGFR], albumin-to-creatinine ratio [ACR], and acute kidney injury estimation [AKI]) were collected across 4 time points during the 2021-2022 and 2022-2023 sugarcane harvest seasons in Guatemala. As, Cd, Co, Cu, Mn, Mo, Ni, Pb, Sb, U, W and Zn were quantified in 512 urine samples using inductively coupled plasma mass spectrometry (ICP-MS). Individual metal associations with kidney health biomarkers were evaluated, and possible synergistic effects of relevant metal mixtures were assessed using quantile g-computation. **Results:** Ni and Zn were negatively associated while Co and Mo (essential trace elements) were positively associated with eGFR. Mixture analysis showed a significant overall effect of all the metals, with Zn, Ni, and Cu contributing most to eGFR decrease, and Mo, Co, and Sb contributing most to eGFR increase. Mo was inversely associated with ACR, while As and Pb (well-known nephrotoxic metals) were positively associated with ACR both in the individual metal and mixture analysis. For AKI, Zn and Ni showed the strongest contributions, and a significant overall mixture effect was observed.

Conclusions: Overall, the findings indicate that urinary metal mixtures, particularly driven by Ni, Zn, and Mo, are associated with kidney function alterations among male sugarcane workers. Ni, found above normal urine metal reference values <4ppb, emerges as a metal of particular interest for future research in this population.

PS 4603 Uranium, Lead, and Other Toxic Metals Mapped in New Mexican Women's Triple-Negative Breast Cancer Samples

D. Aguilar Jr.¹, R. E. Holder¹, P. Zhao¹, X. Zhou², E. Erdei³, and J. A. Colacino¹.

¹University of Michigan, Ann Arbor, MI; ²Yale University, New Haven, CT; and

³University of New Mexico, Albuquerque, NM.

Background and Purpose: Triple-negative breast cancer (TNBC), the most aggressive subtype with limited therapeutical options, is diagnosed at a younger age than other forms of breast cancer. Importantly, TNBC disproportionately affects women from minority communities, who also face higher environmental toxic metal exposures. However, the molecular pathways by which these heavy metals influence the tumor microenvironment and promote Cancer Hallmarks — like inflammation and increased phenotypic plasticity — remains unclear. This problem is especially urgent in communities with well-documented heavy metal exposures. In the Southwestern United States, several communities face legacy metal and metalloids burdens arising from several sources: arsenic contamination in ground/drinking water sources, nuclear weapons development and testing, as well as uranium mining activities. These toxic exposures position people from this region as a key population for understanding the mechanistic links between heavy metal exposure and TNBC etiology and progression. **Methods:** A 20 µm resolution laser ablation inductively coupled mass spectrometry (LA-ICP-MS) assay was developed to semi-quantitatively measure several heavy metals and metalloids. This assay was applied to archived FFPE TNBC samples from 16 patients surgically treated at the University of New Mexico Comprehensive Cancer Center. All samples were stored with broad consent for future research purposes. Uranium (U), lead (Pb), vanadium (V), tungsten (W), nickel (Ni), cadmium (Cd), arsenic (As) was measured for one of these samples thus far. Phosphorous (P) was measured as a surrogate for cell/tissue density. Porcine skin gelatin-based, tissue-mimicking standards were developed to build calibration curves, with spike-in metals concentrations ranging from 10 ppb to 10 ppm. Serial tissue sections were also assayed using the Xenium spatial transcriptomics platform with a breast cancer panel supplemented with 100 empirically derived metal-responsive genes, which include genes involved in immune activation, extracellular matrix & cell structure, cell cycle, metabolic, and stress response pathways. The xenium panel was used to annotate cell types and H&E staining was used for histological reference and confirmation of tumor margins. Pixel-level Spearman's rank correlations were calculated for each element pair. **Results:** U, Pb, V, W, Cd, Ni, and Cd, were detected in the TNBC sample, with concentrations ranging from 10 ppb to over 1 ppm for some metals. While there are noticeable edge bleeding artifacts of metals, likely arising from diffusion caused by solvents used in the FFPE process, substantial hotspots of U, Pb, and Cd were observed in the cancer epithelium. Single-case results show a positive pixel-level correlation between U and P ($p=0.44$, $p\text{-value} < 0.001$), as well as weak positive correlations between U and Pb ($p=0.21$, $p\text{-value} < 0.001$), Cd and P ($p=0.21$, $p\text{-value} < 0.001$), and Ni and V ($p=0.23$, $p\text{-value} < 0.001$). **Conclusions:** The significant positive correlation between uranium and phosphorus in this pilot case provides evidence supporting the accumulation of these metals within dense tumor regions, while inter-metal correlations suggest possible mixture effects. These data establish the beginnings of critical methodological foundations advancing environmental health toward the integrated spatial omics era. Our ongoing work is generating spatial metals maps of additional TNBC tissues and integrating these maps with spatially resolved transcriptomics to discover the specific molecular pathways by which these metals may alter the tumor microenvironment and drive TNBC progression.

PS 4604 Novel Application of the EPA All Ages Lead Model (AALM) to Determine an Acute (24-hour) Inhalation Threshold for Lead Protective of Neurotoxicity in Children

S. A. Price, J. L. Bare, A. H. Verwiel, and D. M. Proctor. ToxStrategies LLC, Houston, TX.

Background and Purpose: Many state air toxics regulatory programs require inhalation reference criteria protective of acute (24-hour) exposures, which are challenging to determine for lead (Pb), as the most sensitive endpoint is neurotoxicity associated with increased blood Pb in children. One approach is to use the National Ambient Air Quality Standard (NAAQS) for Pb of 0.15 µg/m³, which was used by the Oregon Department of Environmental Quality. However, the NAAQS is intended for a 3-month average concentration, which is not well suited to characterize 24-hour exposures. An alternative approach to setting an acute threshold for Pb was developed, using the EPA's All Ages Lead Model (AALM) Version 3.1, which allows users to simulate single-day exposures (EPA 2025). Biokinetic modeling was performed to predict the air concentration for one day of exposure that would result in a blood Pb increase of 1 µg/dL. The California Office of Environmental Health Hazard Assessment (OEHHA) uses 1 µg/dL as the threshold for a source-specific incremental increase in blood lead levels (BLLs) for protection of school children and fetuses (OEHHA, 2007).

Methods: EPA's AALM was used to estimate BLLs for children each year for birth to 6 years because children are more sensitive than adults, and kinetic and exposure parameters change as children grow. First, baseline BLLs were modeled considering all exposure routes in the AALM (e.g., soil, indoor dust, food) except for air, using default model inputs (EPA, 2024). The upper tolerance limit for background Pb in Oregon soil of 79 µg/g was used for modeling soil and dust exposures. The AALM was subsequently run in an iterative process by changing the air concentration on a single day until the estimated BLLs corresponded to a BLL of 1 µg/dL above baseline. The single day of exposure (i.e., acute pulse) was simulated separately for each year from year 0 to year 6, such that there were seven different model simulations. To simulate an acute, 24-hour exposure scenario for one age group, the air concentration was assumed to be 0 µg/m³ except for the single day of exposure for the age group of interest. As shown by the magnitude of the results of the pulsed modeling, a default air concentration for Pb (0.01 µg/m³) would not contribute significantly to BLLs. The AALM uses masks to set exposures for specific repeating periods. In this case, an annual mask was set to 0 µg/m³ for days 2 through 365 of each year. Day 1 exposure was set to 0 µg/m³ for all age groups except for the specific age group with the acute 24-hour exposure. The year with acute/pulsed exposure had a non-zero air concentration on the first day. For example for year 1, the air concentrations on day 1 was modeled for three age groups: (1) age 0 at 0 µg/m³, (2) age 1 at the non-zero air concentration, and (3) age 2 and beyond at 0 µg/m³ through the end of the simulation (6.1 years). Default lung parameters from AALM 3.0 were selected (EPA 2024, 2025). These parameters represent lung kinetics for ultra-fine (approximately 0.1 µm in diameter) combustion aerosols, and relative bioavailability for inhalation exposure was assumed to be 1 (EPA, 2024). **Results:** Baseline BLLs ranged from 1.10-2.21 µg/dL. The day 1 air concentration that resulted in a predicted BLL closest to the target increased BLL ranged from 3.86 µg/m³ (year 0) to 7.64 µg/m³ (year 5). These values are all well above the NAAQS for Pb of 0.15 µg/m³. AALM predicted that the highest BLL following acute air exposures occurs two days after the 24-hour pulse exposure. The single-day air concentration for the most sensitive age group (newborn, 0-year age group) associated with a 1 µg/dL increase from the baseline BLL was 3.9 µg/m³ for the newborn age group. The estimated BLLs decreased to baseline BLLs within approximately 20 days, and the peak BLL was 3.21 µg/dL, which is lower than the CDC Pb reference level of 3.5 µg/dL. **Conclusions:** An acute 24-hour threshold for Pb in ambient air of 3.9 µg/m³ would be appropriate and protective for all ages, specifically children. This guideline is complementary to the NAAQS because a single pulsed 24-hour concentration of 3.9 µg/m³ would not exceed the NAAQS when averaged with background Pb in air concentrations over three months.

PS 4605 Scrambling the Genome: Mechanisms of Cr(VI)-induced Chromosome Instability in Lung Carcinogenesis

S. S. Diven¹, I. Meaza¹, D. Chiarugi², and J. P. Wise¹. ¹University of Louisville, Louisville, KY; and ²GeneVia Technologies, Hämeenkatu, Finland.

Background and Purpose: Hexavalent chromium [Cr(VI)] is a well-established human lung carcinogen, but the mechanisms behind how Cr(VI) induces lung cancer are poorly understood. Chromosome instability (CIN), a hallmark of lung cancer, is considered a major driving factor in Cr(VI)-induced lung cancer. Studies in cultured human lung cells show prolonged Cr(VI) exposure induces a DNA-damage repair deficiency leading to chromosome instability and neoplastic transformation. How Cr(VI) impacts the genomic sequence is not well understood. Determining the impact of Cr(VI) on the whole genome can provide insight into how chromosome instability arises to drive lung cancer. **Methods:** A clonal human lung cell line was exposed for 24 or 120 h to two particulate Cr(VI) compounds, lead chromate and zinc chromate. Following treatment, 5 subclones for each exposure were isolated. We performed karyotype analysis and compared results to the whole genome sequencing for each clone. Genomic lesions were characterized using strict thresholds. **Results:** Our karyotype analysis revealed minimal changes above control with both particulate Cr(VI) compounds after 24 h treatments, consistent with previous data. A pronounced increase in chromosome instability was observed after 120 h exposure to zinc chromate. The genomic analysis revealed both Cr(VI) compounds caused a significant number of large structural variants, including, from most abundant to least: inversions, translocations, deletions, and duplications at both time points. **Conclusions:** This study demonstrates Cr(VI) is a potent genotoxic agent that causes many genomic rearrangements not observed through traditional karyotypic analysis. The many small indels detected in the genomic analysis are predicted to cause transcription factor binding site ablation, frameshift variants, in-frame deletions, and in-frame insertions in surviving cells. These smaller genomic rearrangements can then lead to the permanent karyotypic changes observed that drive tumor development and carcinogenesis. These data can better inform risk assessment to determine safe exposure limits and provide insights for future mechanistic studies on Cr(VI)-carcinogenesis. This work was supported by NIEHS grant R35ES032876 to JPW.

B. Bennett, and M. O. Gribble. University of California, San Francisco, San Francisco, CA.

Background and Purpose: Drinking water contaminants often co-occur and are encountered as co-exposures, but there is limited research on potential toxicological interactions between drinking water contaminants. In a previous study of federally unregulated metal contaminants in US public drinking water systems surveyed over years 2013-2015 [see doi: 10.3390/ijerph18157884], geometric means were estimated for each measured metal for each drinking water system separately, and then those geometric means were compared across measured metals. The geometric means of two measures of chromium (total [Cr] and hexavalent [Cr(VI)]) were highly correlated, and both chromium geometric means were associated with vanadium (V) geometric means. Thus, there is likely to be co-exposure to chromium and vanadium in public water supplies in the United States. While the toxicity of these compounds from ingestion exposure pathway is a topic of ongoing research, inhaled Cr(VI) has been associated with lung, nasal, and sinus cancers in occupational studies, and studies of inhaled exposure to vanadium pentoxide have also suggested possible respiratory toxicity. Given the potential for both joint exposure and similar physiological impacts, this environmental genomics study sought to examine patterns of documented gene-environment interactions for chromium and vanadium to characterize potentially shared biology between these drinking water contaminant metals. **Methods:** We queried the Comparative Toxicogenomics Database (CTD) on October 17, 2025 for genes that have been previously shown to have gene-environment interactions with "chromium", "hexavalent chromium ion", or "vanadium". We then reviewed all cited studies corresponding to each gene-environment interaction indexed in CTD and returned by that query. Genes in the initial candidate list from CTD were excluded from our bioinformatic analysis if they were not human genes, if the metal of interest was not the actual exposure in the original study, if the studies were retracted, if the study could not be accessed, or if the study details were incongruent with what was reported in CTD. This resulted in a reduced gene list of confirmed-as-relevant *Homo sapiens* genes for analysis. We considered pairwise overlap of genes interacting with each metal. We then performed signaling pathway enrichment analysis using the Kyoto Encyclopedia of Genes and Genomes (KEGG) database on the Database for Annotation, Visualization, and Integrated Discovery (DAVID) platform for the confirmed-as-relevant *Homo sapiens* gene list. **Results:** This scan identified 60 genes that have been documented as having interactions with Cr, 1296 with Cr(VI), and 157 with V. The gene lists for Cr and Cr(VI) had 42 overlapping genes, Cr and V had 9 overlapping genes, and Cr(VI) and V had 25 overlapping genes. In total, 1259 unique genes were identified as having at least one documented interaction and were included in the pathway enrichment analysis. The DAVID/KEGG analysis found that 176 pathways were statistically significantly enriched (53 Bonferroni significant, 150 Benjamini-Hochberg (BH) significant, and 158 False Discovery Rate (FDR) significant). The top 10 gene-enriched KEGG pathways were cell cycle, lipid and atherosclerosis, pathways in cancer, AGE-RAGE signaling pathway in diabetic complications, apoptosis, human T-cell leukemia virus 1 infection, colorectal cancer, hepatitis B, microRNAs in cancer, and FoxO signaling pathway. **Conclusions:** Bioinformatic analysis suggests that there may be overlapping biological pathways between these metal exposures, including for genotoxic and replication stress pathways; oxidative stress, inflammatory, and immune-like signaling; and cancer pathways. There is some overlap in these KEGG gene pathways but the bioinformatic analysis suggests potential for multiple mechanisms of toxicological interaction. Given the potential for joint exposure from drinking water among other exposure pathways, toxicological studies administering doses of combined exposure to evaluate joint toxicity may be warranted.

PS 4607 Weight of Evidence Assessment for Toxicities from Retained Lead Pellet

A. Stock¹, J. Wang², C. Chan², K. Tucker², and B. Kelman². ¹JS Held LLC, New Orleans, LA; and ²JS Held LLC, Redmond, WA.

Background and Purpose: Retained bullet (RB) fragments represent a recognized but often underappreciated source of systemic lead exposure. Historically, RBs embedded in soft tissue were considered relatively benign due to presumed tissue encapsulation. However, accumulating evidence suggests that these fragments can leach lead over time, resulting in elevated blood lead levels (BLLs) and potential systemic toxicities. To address this concern, we conducted a weight-of-evidence (WOE) assessment to evaluate whether RB fragments contribute to clinically significant lead exposure and toxicity. This assessment aimed to synthesize available data on lead leaching, BLL elevation, and associated health outcomes, while critically examining the strength and limitations of the evidence base. **Methods:** A comprehensive review of human epidemiology studies and case reports was conducted, including an assessment of methodological strengths and weaknesses. Searches were performed in PubMed using free text terms: ("gunshot wound" OR gunshot* OR shot* OR bullet* OR missile* OR pellet* OR projectile* OR "retained fragment*" OR "retained lead") AND ("lead poisoning" OR "lead toxicity" OR "lead exposure" OR "blood lead" OR "serum lead"). Filters were applied to include only human studies published in English. Eligible studies were limited to epidemiology research and case reports involving adults that reported blood or serum lead levels; studies lacking

these measurements were excluded. Data were evaluated with respect to Bradford-Hill guidelines for the presence or absence of cause-effect relationship between RBs and risk of elevated BLLs and lead toxicity, including strength of association, temporality and dose-response of the relationship, replication of findings, biological plausibility, alternative explanations, specificity of the association, and consistency with other knowledge. **Results:** The search identified 342 articles published between 1946 and 2025, including 30 reviews, 1 meta-analysis, 65 case reports, 4 case-control studies, 5 cross-sectional studies, 3 prospective cohorts, and no randomized controlled trials. Epidemiology studies have shown that individuals with RB fragments exhibit elevated blood lead levels (BLLs). Anatomical location significantly influences BLLs, with fragments near bone fractures associated with higher concentrations. Increased fragment count correlates with greater BLL elevation. Numerous case reports also document delayed onset of lead toxicity symptoms, sometimes occurring years after the initial injury. Despite these findings, the evidence base is dominated by case reports and small observational studies, with few well-designed epidemiological investigations. This reliance on lower-confidence sources limits the statistical strength and generalizability of conclusions. **Conclusions:** The available evidence supports an association between retained lead fragments and elevated BLLs, with toxicity risk influenced by fragment location, number, and time since injury. However, the absence of robust epidemiological studies suggests that current assessments depend heavily on case reports and other lower-confidence sources, constraining the overall strength of inference and certainty of risk characterization. Additional high-quality, longitudinal research is needed to clarify exposure dynamics and inform clinical management guidelines.

PS 4607a Prediction of Obeticholic Acid (OCA) Liver Injury Liability in Patients with Metabolic Dysfunction-Associated Steatotic Liver Disease (MASLD) Using Quantitative Systems Toxicology

A. K. Mayo¹, J. J. Beaudoin², J. L. Woodhead², P. B. Watkins¹, and K. L. Brouwer¹.

¹The University of North Carolina at Chapel Hill, Chapel Hill, NC; and ²QSP Solutions, Simulations Plus Inc., Research Triangle Park, NC.

Background and Purpose: Obeticholic acid (OCA), a synthetic bile acid analog of chenodeoxycholic acid (CDCA), showed some promise for the treatment of metabolic dysfunction-associated steatotic liver disease (MASLD) but did not receive FDA approval for this indication, in part because of concerns about liver safety. OCA was granted accelerated approval in 2016 for treatment of primary biliary cholangitis but was recently withdrawn from the US market, also related to liver injury concerns. In clinical trials, elevated liver injury biomarkers were observed in both healthy subjects at supratherapeutic doses (100-250 mg) and in some MASLD patients at therapeutic doses (10-25 mg). MASLD patients exhibited higher plasma and predicted liver concentrations of OCA and its metabolites (glyco-OCA and tauro-OCA), particularly in advanced disease stages. We have previously used DILIsym, a quantitative systems toxicology model, to recapitulate OCA-associated liver injury in healthy subjects at supratherapeutic OCA doses. This project extended the developed DILIsym model using a virtual MASLD population to determine whether liver safety liability could have been predicted in this patient population prior to the MASLD clinical trials. We also used the model to explore mechanisms underlying the toxicity observed in this population. **Methods:** Exposure to OCA and OCA metabolites was simulated in healthy subjects using a previously developed physiologically based pharmacokinetic (PBPK) model. Concentrations of OCA and metabolites in plasma, liver, and sinusoidal compartments were increased 2-, 5-, or 10-fold at each dose level to assess the impact of increased exposure in the MASLD population. DILIsym version 8A with an extended bile acid representation (similar to version 11, commercially available since 2025) incorporated bile acid transporter inhibition (uptake, biliary and basolateral efflux) using half-maximal inhibitory concentrations. In addition, the DILIsym model incorporated mitochondrial dysfunction parameters assuming CDCA-like mitochondrial uncoupling. Liver injury biomarkers that were investigated included plasma alanine aminotransferase (ALT) and aspartate aminotransferase (AST). Predicted liver injury was reported as the percentage of virtual patients with biomarker elevations at least 2-fold from individual patient baseline values. **Results:** In the virtual MASLD population, dose-dependent increases in ALT and AST were observed at supratherapeutic OCA doses. However, susceptibility to liver injury was not increased in the virtual MASLD patients compared to healthy subjects at OCA and metabolite exposure levels typical of healthy subjects. A 2-fold increase in OCA and metabolite exposure led to ALT and AST elevations following daily OCA doses greater than 50 mg; a 5-fold increase in OCA and metabolite exposure triggered ALT and AST elevations at daily OCA doses greater than 25 mg; and a 10-fold increase in OCA and metabolite exposure predicted ALT and AST elevations at all OCA doses. At daily OCA doses of 25 mg, 5-fold and 10-fold increases in OCA and metabolite exposure resulted in ALT/AST elevations in 3.8%/4.2% and 21.3%/20.9% of virtual MASLD subjects, respectively. Mechanistic analysis revealed that bile acid transporter inhibition alone reproduced most biomarker elevations, with minimal contribution from mitochondrial uncoupling. Liver bile acid concentrations were elevated in virtual patients with increased liver injury biomarkers. **Conclusions:** Simulations in virtual MASLD patients predicted dose-dependent increases in ALT and AST at supratherapeutic OCA doses. At the clinically relevant daily OCA doses of 10 and 25 mg, biomarker elevations were observed after 10- and 5-fold increases in OCA and metabolite exposure, respectively. Bile acid transporter inhibition accounted for

most of the predicted increases in ALT and AST. Our findings indicate that DILLsym modeling would have predicted the elevations in liver injury biomarkers observed in the MASLD clinical trials. *Funded by NIH grant R35 GM122576*

PS 4608 Comparative 28-day mouse study of topically applied aryl hydrocarbon receptor ligands: microbial-derived indoles, therapeutic tapinarof, pollutants 2,3,7,8-tetrachlorodibenzo-p-dioxin and diesel exhaust particles

S. Solanki¹, S. M. Tasnim¹, L. L. Thompson¹, M. Alle¹, B. Ward¹, A. T. Slominski², Z. Janjetovic², T. Jozwicka³, P. Erdmańska³, C. H. Sutter¹, E. A. Grice⁴, and T. R. Sutter¹. ¹University of Memphis, Memphis, TN; ²University of Alabama at Birmingham, Birmingham, AL; ³Nicolaus Copernicus University, Torun, Poland; and ⁴University of Pennsylvania, Philadelphia, PA.

Background and Purpose: The aryl hydrocarbon receptor (AHR) regulates skin responses to microbial, therapeutic, and pollutant ligands in chronic inflammatory psoriasis, atopic dermatitis (AD), and chloracne diseases. While AHR activation has been linked to both cause and treatment of skin diseases, the comparative effects of distinct ligand classes remain unclear. Here, we evaluated systemic and cutaneous outcomes of topical exposure to different AHR ligands. **Methods:** Male and female C57BL/6J mice were topically treated with microbial-derived indole-3-pyruvic acid (1% IPY), indole-3-aldehyde (0.1% IAlD), therapeutic, tapinarof (1% TAP), or pollutant 2,3,7,8-tetrachlorodibenzo-p-dioxin (3E-06% or 3E-07% TCDD) or diesel exhaust particle (0.1% DEP), for 5 day/week for four consecutive weeks. Systemic effects, skin condition and atopic dermatitis- and chloracne-like outcomes were assessed. **Results:** Weight gain was largely unaffected. High-dose TCDD showed signs of limited focal hepatic changes, suggesting early hepatocellular injury, and DEP elevated serum bile acids. No consistent effects were observed on kidney histology or other serum analytes. Trans epidermal water loss, ear thickness, scratching and grooming were unchanged. DEP worsened the overall skin condition index. Both TAP and TCDD strongly induced *Cyp1a1* and *Cyp1b1*, while other treatments produced transient effects. TAP and high-dose TCDD elevated desquamation and presented with a chloracne-like pathology characterized by sebaceous gland involution, reduced numbers of sebocytes, hyperkeratosis, and cyst-formation. While these chloracne-like effects appeared to be similar, quantitative image analysis demonstrated that TCDD caused epidermal atrophy, whereas TAP resulted in epidermal hyperplasia with thickening extending into the infundibulum, along with hyperkeratosis. RNA analysis revealed that TAP selectively elevated levels of the *Nrf2* target genes, *Epgn*, *Sprr2d*, and *Slpi*, previously reported to drive the chloracne response to transgenic epidermal overexpression of *Nrf2* in mice. **Conclusions:** Overall, ligand effectiveness appears to drive compound-specific effects. Equally effective doses of TAP and TCDD elicited related effects of a chloracne-like response, yet selective differences in the modulation of *Nrf2* appear to impart unique, TAP-specific, phenotypes. These findings highlight AHR ligand-specific skin effects, in part, associated with differences in selective ligand activation of modifying signaling pathways.

PS 4609 Single-cell analysis of aryl hydrocarbon receptor-dependent effects of 2,3,7,8-tetrachlorodibenzo-p-dioxin (TCDD) on regional and cell specific changes in the pilosebaceous unit of murine skin

S. M. Tasnim¹, S. Solanki¹, J. Bhujul¹, L. Thompson², E. A. Grice³, C. H. Sutter¹, and T. R. Sutter¹. ¹University of Memphis, Memphis, TN; ²Integrated Microscopy Center, Memphis, TN; and ³University of Pennsylvania, Philadelphia, PA.

Background and Purpose: The aryl hydrocarbon receptor (AHR) is a transcription factor that is activated by 2,3,7,8 tetrachlorodibenzo-p-dioxin (TCDD), a persistent environmental pollutant. Human exposure to dioxin causes chloracne, characterized by acanthosis, hyperkeratosis, sebaceous gland involution, and hamartomas. While mice were believed to be refractory to chloracne, recent studies report similar chloracne-like phenotypes in mice. One study showed that *Lrig1*+ progenitor cells colocalized with TCDD-mediated CYP1A1 induction, indicating that TCDD may target specific cells to cause sebaceous gland (SG) involution. To better understand the effects of TCDD on the skin *in vivo*, we analyzed single cell mRNA expression in wild-type and *Ahr*-null mice. **Methods:** Wild-type (C57BL/6J) and *Ahr*-null (B6.129-*Ahr*^{tm1Bra}/J) mice were used in accordance with approved IACUC protocols. In the developmental study, dams were treated by oral gavage with vehicle (corn oil) or TCDD (5µg/kg body weight) on E12, and pups were exposed *in utero* and through lactation until P21. In the short-term dose-response study, C57BL/6J mice were treated topically once per day for 3 days with either vehicle (DMSO:Acetone, 1:9) or TCDD (3E-07%, 3E-06%, or 3E-05%), and tissues were collected 24 hours after the last treatment. Single cell analysis was performed using a RNAscope multiplex *in situ* hybridization protocol. **Results:** Histological analysis of the developmental P21 skin demonstrated that TCDD-mediated sebaceous gland atrophy was prominent, and *Ahr*-dependent. Regional analysis of *Cyp1a1* and *Cyp1b1* showed that TCDD markedly increased *Cyp1a1* in the lower part of infundibulum near the junctional zone where *Lrig1*+ stem cells reside. This increase was *Ahr*-dependent and consistent with reports of protein induction. Compared to *Cyp1a1*, expression of *Cyp1b1* was lower in this region, but significantly elevated. A second prominent region of *Cyp1a1* was present in the lower cells of the SG. Here, *Cyp1a1* was markedly induced in both sebocytes and the basal

epithelial cells of the SG, and expression was *Ahr*-dependent. Together these observations are suggestive of TCDD affecting both gland morphogenesis and sebocyte differentiation. To explore these regional effects a 3-day dose-response study was performed. The response to TCDD appeared slightly more dose-sensitive in the SG compared to the infundibulum. Within the SG, dose-dependent increases in *Cyp1a1* expression were observed in the more differentiated cells. To determine whether TCDD affected cellular differentiation in the SG, the expression of *Scd1*, a marker of sebocyte differentiation, was measured. High-dose TCDD increased the expression of *Scd1* by an area of 25%, indicating that TCDD increased cellular differentiation. This was further demonstrated by Oil Red O staining, that showed an increase in lipid levels in the epidermis. To explore SG morphogenic mechanisms, we analyzed *Lrig1*, *Myc*, and *Blimp1*. *Blimp1* is a transcriptional repressor responsible for regulating sebaceous gland size, and *Myc* is a transcription factor believed to both mark and drive SG epithelial morphogenesis and the formation of sebocytes. *Blimp1* was induced by TCDD in the cells of the lower infundibulum. Results from the P21 study demonstrated that this increase was *Ahr*-dependent. Interestingly, the epithelial cells of the junctional zone expressing *Lrig1* and *Blimp1* were apical to the cells expressing *Blimp1* and *Myc*, which were located above the cells expressing only *Myc*. In the less differentiated abapical sebocytes both *Myc* and *Blimp1* were expressed, while the terminally differentiated sebocytes expressed only *Blimp1*. TCDD appeared to increase the number of *Myc* positive cells and the levels of *Blimp1* in terminally differentiated cells. **Conclusions:** Either systemic or topical exposure to TCDD affects the sebaceous gland and infundibulum. Regional and single cell analysis of SG involution indicates an initial increase of sebocyte differentiation as an early event. Expression of *Blimp1* appears to act as an intermediary modulator of cell transitions from SG stems cells to SG epithelial cells to sebocytes. Overall, these findings provide insights into the effects of TCDD on the sebaceous gland.

PS 4610 An Investigational Study Aimed at Establishing the Respiratory Minute Volume of the Göttingen Minipig

A. Sia, W. Lee, J. Younan, and K. McNally. ITR Laboratories Canada Inc, Baie D Urfe (Montreal), QC, Canada.

Background and Purpose: An appropriate estimation of respiratory minute volume (RMV) is essential for pre-clinical inhalation toxicology research as it defines inhaled dose and enables interspecies extrapolation. Göttingen Minipigs are increasingly used as a non-rodent model due to their anatomical and physiological similarity to humans and ethical advantages over dogs and non-human primates. However, limited reference data exist for their RMV, and current equations, such as Alexander et al. 2008, and Bide et al. (2000), were developed from other species. **Methods:** Respiratory minute volumes of Göttingen Minipigs were measured and compared with predictions from established allometric equations used in inhalation toxicology. Eight naïve Göttingen Minipigs were acclimated for 14 days to the respiratory restraint system before measurement. Respiratory rate (RR), tidal volume (TV), and minute volume (MV) were recorded during the 14-day acclimation phase and then weekly over a 13-week period. No test or control items were administered. Body weight measurements were taken weekly and minute volumes were compared to the current inhalation equations. **Results:** Respiratory parameters remained consistent throughout, with growth-related shifts in tidal volume and respiratory rate producing stable minute volumes. Existing predictive equations underestimated measured RMVs, although the AIT equation aligned more closely with observed data. A short acclimation period provided reliable results, confirming the Göttingen Minipig as a suitable and stable model for inhalation studies. **Conclusions:** The difference in measured vs calculated RMV was comparable across species, including minipigs. The equation proposed by Alexander et al. resulted in smaller % differences compared to the formula proposed by Bide et al. The Alexander et al. formula is widely accepted in the industry despite differences relative to the actual/measured RMV values. As such, RMV in Minipigs can also be estimated using the Alexander et al equation.

PS 4611 Polyvinyl Chloride Nanoparticles Induce Mitochondrial Dysfunction in Human-Induced Cardiomyocytes

X. Li, and Q. Liu. Clemson University, Clemson, SC.

Background and Purpose: Polyvinyl chloride (PVC) is a highly toxic plastic that continuously releases harmful compounds throughout its lifecycle, which can bioaccumulate and pose serious cardiovascular risks. PVC plastics have been detected in multiple human organs, including the heart, liver, and lungs, as well as in carotid plaques, with their abundance positively correlating with increased mortality in patients with cardiovascular disease. These micro-plastics (MPs) and nano-plastics (NPs) can enter the body via ingestion, inhalation, or dermal exposure, accumulate in tissues, and disrupt cellular function. Experimental studies show that PVC particles damage cardiac mitochondria, inducing oxidative stress, abnormal gene expression, and apoptosis. However, the precise cellular and molecular mechanisms of PVC-NPs-induced cardiotoxicity remain unclear. This study aims to investigate these mechanisms, focusing on mitochondrial dysfunction and autophagy/mitophagy dysregulation, to provide novel insights into cardiovascular risks posed by environmental PVC particles and inform strategies for prevention and health risk

assessment. **Methods:** Cardiomyocytes derived from human stem cells were used as an alternative *in vitro* model to investigate the toxic effects of PVC-NPs. They were exposed to PVC-NPs of different sizes and concentrations to assess cell viability, intracellular ROS levels, and types of cell death (by flow cytometry). Contractile function was evaluated using live-cell imaging and calcium handling properties were assessed by Fluo-4 calcium imaging. Mitochondrial function and morphology were analyzed via Seahorse XF assays and immunofluorescence staining. Mitophagy was further assessed by p62 colocalization (immunofluorescence) and the expression of autophagy-related proteins (LC3-I/II and p62) by western blot. **Results:** PVC-NPs exhibited size- and concentration-dependent cytotoxicity in cardiomyocytes, and they caused impaired cardiac functions, such as reduced contractility, and irregular beat frequency. Moreover, PVC-NPs induced remarkable mitochondrial dysfunction and fragmentation. The PVC-NP-treated cardiomyocytes exhibited altered LC3-II/LC3-I ratios and increased p62 expression, suggesting disrupted autophagy/mitophagy. **Conclusions:** PVC-NPs significantly impair human-derived cardiomyocyte function, mitochondrial integrity, and autophagic activity. These findings provide important insights into the cardiovascular hazards posed by environmental plastic particles and offer a foundation for refined risk assessment, public health decision making, and the development of strategies to mitigate their adverse impacts on human health.

PS 4612 In The Zone: A Transcriptomics Approach To Understanding Zone-Selective Fatty Liver Disease

A. P. Gilbert, J. A. Mickel, S. Shrestha, K. Yuan, M. Y. Zahoor, and R. Nault. Michigan State University, East Lansing, MI.

Background and Purpose: Metabolic dysfunction-associated steatotic liver disease (MASLD), also known as non-alcoholic fatty liver disease, is a growing public health concern across the United States. In clinical cases and rodent models, MASLD has been shown to develop in a zone-selective manner relating to the centrilobular and periportal regions of the liver lobule. While the underlying mechanisms behind this zone-selectiveness are unknown, it is influenced by both toxicants and dietary factors. Based on previous research, it's suggested that centrilobular steatosis disrupts the hepatic packaging and transport of lipids, which is characteristic of disruption of the peroxisomal β -oxidation pathway and activation of the PPAR α receptor. It has also been shown that portal steatosis disrupts the metabolism of lipids in the liver, which corresponds to disruption of the one-carbon metabolism (OCM) pathway. This study tests our hypothesis that zone-selective steatosis is driven by distinct mechanisms either disrupting peroxisomal β -oxidation pathway or repression of rate limiting enzymes in the OCM pathway. **Methods:** To investigate the mechanisms of zone-selective steatosis, Bulk RNA sequencing (RNAseq) was performed on livers from two toxicant and two diet-induced steatosis models. Male C57BL/6J mice were treated with 0.3 or 1 mg/kg/day PFOS in drinking water (0.5% Tween-20 vehicle) or fed a high fat (GAN) diet to model centrilobular steatosis. To model periportal steatosis, mice were gavaged with 3 or 10 μ g/kg 2,3,7,8-tetrachlorodibenzo-*p*-dioxin (TCDD) every four days or fed a methionine-choline deficient (MCD) diet. **Results:** Clinical chemistry data demonstrated that serum glucose decreased significantly in the MCD and high dose TCDD periportal models. Furthermore, all three portal models significantly increased serum alanine aminotransferase (ALT) suggesting more severe hepatic injury compared to the central models. Gene expression analysis found 844 unique differentially expressed genes (DEGs) common to both periportal steatosis models, and 43 unique DEGs common to both centrilobular steatosis models. Gene set enrichment analysis (GSEA) found induction of β -oxidation pathway genes in the centrilobular models, while the portal models showed overall repression. In addition, genes *Acaa1b* and *Inmt* both showed induction in central steatosis models and repression in the portal models representing putative markers of zone-selective steatosis. While we did not see a significant overall change to OCM, portal repression of genes reliant on OCM like *Inmt*, *Bhmt*, and *Gnmt* suggests downstream metabolic disruption. **Conclusions:** Our findings suggest differences in disruption of the β -oxidation pathway between models of periportal and centrilobular steatosis, and repression of metabolic pathways reliant on OCM, reflect a putative distinguishing signature for zone-selective steatosis induced by either toxicants or dietary factors.

PS 4613 Mapping Heterogeneity of Hepatic Zonation in Genetically Diverse Mice Using Single-Nuclei Transcriptomics

M. Zahoor¹, A. P. Gilbert², J. A. Mickel², S. Shrestha³, and R. Nault^{2,4}. ¹Comparative Medicine and Integrative Biology, Michigan State University, East Lansing, MI; ²Department of Pharmacology and Toxicology, Michigan State University, East Lansing, MI; ³Genetics and Genome Sciences, Michigan State University, East Lansing, MI; and ⁴Institute for Integrative Toxicology, Michigan State University, East Lansing, MI.

Background and Purpose: The liver plays a central role in maintaining physiological homeostasis through nutrient metabolism, detoxification, and energy balance. It is a principal site of xenobiotic metabolism, and a primary target of drug and chemical induced toxicity. The liver's functions are compartmentalized across the hepatic lobule, known as zonation, which is the spatial metabolic and functional organization along periportal and pericentral regions shaped by nutrient and signaling gradients. Hepatic lipids can accumulate in zonal patterns, and previous studies indicate that

genetics plays a significant role in the development of steatotic liver disease (SLD); however, limited work has examined how genetic variation influences global portal-to-central gene-expression patterns. We hypothesized that genetic variation modulates spatial cellular heterogeneity in the liver, thereby influencing the zonation of metabolic pathways, and the susceptibility to toxicant-induced steatosis. **Methods:** To investigate the role of genetic diversity on hepatic zonation we used single-nucleus RNA sequencing (snRNA-seq) to characterize zonal expression in hepatocytes. Four genetically diverse mouse strains were used: two from the Collaborative Cross (CC) mouse diversity panel (CC005 and CC042), and two founder strains for the CC mice (A/J, C57BL/6J). Untreated mice, following 15 days acclimation with free access to water and standard chow, were used to establish zonal differences using snRNAseq. A second cohort was used to evaluate the susceptibility to toxicant-induced hepatic steatosis using the same CC strains treated with environmental contaminant and steatogenic agent perfluorooctane sulfonate (PFOS; 1 mg/kg/day) for 42 days. **Results:** A total of 10,830 cells were captured across all mice, and annotation identified most major hepatic cell types as expected primarily consisting of hepatocytes (70-80%). Differential expression analysis of hepatocytes identified 1,346 differentially expressed genes (DEGs) in A/J, 1,050 in CC005, and 1,068 in CC042 mice compared to C57BL/6J mice (lfold-change ≥ 1.5 , padj ≤ 0.05). Gene set enrichment analysis identified enrichment genes from the lipid metabolism, immune signaling, and nucleic acid processing pathways. Pseudospacial/trajectory analysis identified strain-dependent portal-to-central gradients, with genes involving immune regulation (*Tox*), extracellular matrix and adhesion (*Reln*), lipid metabolism (*Acly*), cytoskeletal and membrane architecture (*Sgcz*), and protease inhibition and the acute-phase response (*Serpina1e*). Moreover, compared to A/J and C57BL/6J, CC042 and CC005 exhibited attenuated periportal expression of *Pdzrn3* and increased pericentral expression of the regulatory lncRNA *Meg3*, both involved in *Wnt* signaling. In PFOS exposed cohort, CC042 mice showed evidence of greater liver injury compared to CC005 with increased serum ALT and hepatic lipid accumulation. **Conclusions:** Collectively, snRNAseq analysis demonstrates that genetically diverse mouse models show differences in zonal expression and PFOS injury. This heterogeneity may contribute to variation in the development and progression of hepatic steatosis.

PS 4614 Developmental TBBPA exposure exacerbated western diet-induced metabolic inflammation

J. J. Lim¹, S. M. Gibbons¹, and J. Y. Cu². ¹Institute for Systems Biology, Seattle, WA; and ²Oregon State University, Corvallis, OR.

Background and Purpose: Metabolic liver diseases are increasing in global prevalence and have traditionally been linked to nutritional imbalances, such as a high-fat western diet (HFD). However, the pathogenesis of complex metabolic disorders is rarely caused by only one risk factor. Early life exposure to environmental stressors is an emerging contributor to the delayed onset of metabolic diseases later in life. Tetrabromobisphenol A (TBBPA) is currently the most widely used brominated flame retardant worldwide. Exposure to TBBPA is associated with altered carbohydrate and lipid metabolism, and immune modulation, which are hallmarks of metabolic fatty liver diseases. The pregnane X receptor (PXR) and constitutive androstane receptor (CAR) are important liver-enriched nuclear receptors predicted to be activated by TBBPA and are involved in energy and xenobiotic metabolism through key targets, such as cytochrome P450 3A4 (CYP3A4). Little is known regarding the contribution of TBBPA in altering metabolic and immunological dysfunction in the liver. We hypothesized that early life TBBPA exposure exacerbates HFD-induced metabolic dysregulation. **Methods:** Female humanized (h) PXR/hCAR/CYP3A4/CYP3A7 (a fetal isoform of CYP3A4) dams, from 2 days before mating, were dosed with corn oil (vehicle, 10 ml/kg) or TBBPA (0.2 mg/kg) once daily until pups were weaned at postnatal day (PND) 21. Pups were placed on either a control diet or HFD until 6 months of age. Phenotypic outcomes, including body and liver weight, serum lipids, triglycerides, circulating glucose, and glucose tolerance, were measured. Single-cell RNA sequencing (scRNA-seq) of male pups was conducted to profile cell type-specific responses from early life TBBPA exposure following HFD. **Results:** TBBPA exposure exacerbated HFD-induced metabolic alterations, particularly in males, increasing body weight, liver-to-body weight ratios, and circulating cholesterol levels. ScRNA-seq showed that early life TBBPA exposure upregulated PXR transcripts in hepatocytes. Early life TBBPA exposure dysregulated intermediary metabolism and immune response in liver cell types, with a shift towards a more proinflammatory state after HFD. For example, in hepatocytes, early life TBBPA exposure upregulated genes involved in amino acid metabolism and downregulated genes related to reactive oxygen species response. Upon HFD, early life TBBPA exposure upregulated genes involved in oxidative stress and microbial influx and downregulated genes involved in drug and amino acid metabolism. Moreover, early life TBBPA exposure and upregulated genes involved in tumor necrosis factor (TNF) production, antigen presentation, and angiogenesis in non-parenchymal cells, such as Kupffer cells, monocyte-derived macrophages, endothelial cells, and dendritic cells. **Conclusions:** In summary, early life TBBPA exposure reprogrammed the hepatic immune-metabolic network in a cell type-specific manner associated with worsened HFD-induced metabolic dysfunction. Our findings highlight the metabolic toxicity of environmental toxicants, which may act as environmental contributors of complex metabolic diseases. The mechanistic insight from our results can help develop mitigation and therapeutic strategies to decrease the internal burden of environmental toxicant exposures at critical developmental timepoints.

PS 4615 Muscle-Protective Effects of *Cryptotaenia japonica* Extract Against Glucocorticoid-Induced Sarcopenia in Cellular and Animal Models

D. Choi¹, S. Heo^{1,2}, H. Lee^{1,2}, S. Cho^{1,3}, and C. Choi^{1,2,3}. ¹Well-Aging Medicare & CSU G-LAMP Project Group, Chosun University, Gwangju, Korea, Republic of; ²Integrative Biological Sciences & BK21 FOUR Educational Research Group for Age-Associated Disorder Control Technology, Chosun University, Gwangju, Korea, Republic of; and ³Biomedical Science College of Natural Science, Chosun University, Gwangju, Korea, Republic of.

Background and Purpose: Sarcopenia, a progressive loss of skeletal muscle mass and function, is frequently exacerbated by chronic glucocorticoid exposure. Although *Cryptotaenia japonica* has been traditionally used for its antioxidant, anti-inflammatory, and metabolic regulatory properties, its muscle-protective potential remains largely unexplored. Despite growing interest in botanical agents that modulate muscle homeostasis, studies evaluating *C. japonica* in the context of sarcopenia are limited. This study aimed to investigate the myoprotective effects of *C. japonica* using both *in vitro* and *in vivo* experimental models. **Methods:** Aerial parts extract of *C. japonica* (CJE) was applied to C2C12 myotubes at 10–100 µg/mL with or without dexamethasone (Dex, 10 µM). Expression of mTOR, MuRF-1, Atrogin-1 (FBX32), and FOXO1 was assessed by Western blotting and confocal microscopy. *In vivo*, Dex-induced muscle atrophy was established in ICR mice, which received oral CJE at 200 mg/kg/day. In a separate non-atrophic model, male Sprague-Dawley rats were administered CJE at 50 mg/kg/day for 5 consecutive days without Dex treatment. In both models, atrophy-related proteins including FOXO3a, MuRF-1, and Atrogin-1 were evaluated specifically in the calf muscle. Planned analyses also include histological assessment of calf muscle fiber cross-sectional area (H&E) and serum measurements of IGF-1 and GDF-8. **Results:** CJE preserved C2C12 myotube morphology and significantly attenuated Dex-induced upregulation of MuRF-1 and Atrogin-1. CJE also inhibited nuclear translocation of FOXO1, indicating suppression of FOXO-mediated catabolic signaling. *In vivo*, CJE reduced Dex-induced increases in FOXO3a, MuRF-1, and Atrogin-1 in the calf muscle, demonstrating inhibition of proteolytic pathways. Histological findings indicate that CJE contributes to the preservation of muscle fiber architecture, and serum analyses confirmed enhanced IGF-1-related anabolic activity together with reduced GDF-8 levels. **Conclusions:** The aerial parts extract of *Cryptotaenia japonica* effectively mitigates glucocorticoid-induced muscle atrophy by modulating the mTOR-FOXO signaling axis and suppressing ubiquitin-proteasome-mediated protein degradation in the calf muscle. These results support CJE as a promising natural therapeutic candidate for preventing sarcopenia and muscle-wasting conditions.

PS 4616 Comparing Models of Zone-Selective Steatosis Using Spatial Transcriptomics

S. Shrestha, A. P. Gilbert, J. A. Mickel, M. Zahoor, and R. Nault. Michigan State University, East Lansing, MI.

Background and Purpose: Environmental contaminants such as 2,3,7,8-tetrachlorodibenzo-p-dioxin (TCDD) and perfluorooctane sulfonate (PFOS) are known to induce metabolic dysfunction-associated steatotic liver disease (MASLD), characterized by lipid droplet accumulation in hepatocytes (steatosis). The liver exhibits functional and metabolic zonation along the periportal-to-centrilobular axis, and the development of steatosis shows zone selectivity dependent on the model. However, the mechanisms and consequences of this zonal development remain unclear. With increasing evidence that toxicants and dietary factors drive zone-selective disease, and the existence of multiple MASLD subtypes, we hypothesized that toxicant-induced spatially resolved gene expression patterns drives zonal selectivity of steatosis and may correspond to distinct subtypes. **Methods:** Male C57BL/6J mice were treated with PFOS (1 mg/kg/day) in 0.5% Tween-20 water, orally gavaged with TCDD (3 µg/kg) in sesame oil (every 4 days) for 84 days or fed either the Gubra Amylin NASH (GAN; 12 weeks) or control diet to represent models of zone-selective steatosis. Spatial transcriptomics was performed on liver cryosections, and sequencing data were analyzed using Python and R tools. The Robust Cell Type Decomposition (RCTD) R package was used to deconvolute cell types and annotate each spatial transcriptomics spot using a scRNAseq reference dataset. Moran's I statistic was used to assess global spatial autocorrelation and identify spatially variable genes (SVGs). STAGATE, a graph attention autoencoder framework, was used to define spatial domains based on neighbourhood similarity among spots. **Results:** An average of 120,073 on-tissue 10 µm spots were detected per tile, representing 13,345 average genes. RCTD identified 11 expected cell types, dominated by periportal (~50.7%) and centrilobular (~19.6%) hepatocytes. The proportion of central hepatocytes increased, and portal hepatocytes declined for all treatments. Moran's I identified canonical zonal marker genes for portal (*Cyp2f2*, *Ass1*, *Arg1*) and central (*Glu1*, *Cyp2e1*, *Oat*) hepatocytes as the most significant SVGs, followed by *Saa1*, *Gstm3*, and *Aldh3a2*. Comparison of pseudo-bulk differentially expressed genes (DEGs), bulk RNA-seq DEGs, and Moran's I SVGs revealed 26, 16, and 21 concordant genes for GAN, PFOS, and TCDD, respectively, reflecting spatially resolved expression of genes altered by treatment. Differential expression in STAGATE-defined central and portal neighbourhoods revealed zone-specific and treatment-dependent gene regulation including *Cyp2c50* induced in portal regions but repressed in central regions by the GAN diet, *Anxa2* with opposing central-portal patterns between PFOS and

GAN, and *Rac2* upregulated in central but downregulated in portal regions by TCDD. **Conclusions:** Altogether, these findings support the hypothesis that zone-selective steatosis results in spatially distinct changes in gene expression patterns. These zone-specific molecular signatures likely represent distinct mechanisms of disease progression, contributing to the molecular heterogeneity that may underlie MASLD subtypes.

PS 4617 Sex-Stratified Transcriptomic Analysis Identifies Cholesterol Metabolism Dysregulation in Alzheimer's Disease

M. Azaizhe, and P. Baloni. Purdue University, West Lafayette, IN.

Background and Purpose: Alzheimer's disease (AD) exhibits clear sex-specific differences in prevalence, progression, and metabolic dysfunction. Despite this distinctive pattern, clinical trials have not systematically considered sex as a confounding factor influencing therapeutic outcomes. Studies have shown that there are sex-specific lipid alterations in AD. Women with AD show greater reductions in unsaturated lipids and differential disruption of cell membrane lipids and bioactive lipids, such as phosphatidylcholine and sphingolipids. The brain contains 25% of total body cholesterol, and alterations in cholesterol homeostasis are associated with increased tau hyperphosphorylation and amyloid beta production. Therefore, cholesterol metabolism is considered a critical pathway in AD pathogenesis. The sex-specific differences in lipid and cholesterol metabolism are not fully understood and need further investigation. This study hypothesizes that AD pathogenesis involves sex-specific disturbances in lipid and cholesterol metabolism and requires different therapeutic targets for males and females to achieve optimal treatment outcomes. **Methods:** In this study, we leveraged post-mortem brain transcriptomic data from the temporal cortex comprising 148 samples (80 AD patients (49 females, 31 males) and 68 controls (33 females, 35 males)). The data was acquired from the AD Knowledge Portal. We performed differential gene expression analysis using the Limma package in R. We conducted three separate analyses: (1) AD vs Control in females, (2) AD vs Control in males, and (3) a sex-by-diagnosis interaction analysis to identify sex-specific disease effects. We stratified all differentially expressed metabolic genes ($\log_2FC > 0.2$, $FDR < 0.1$) into three categories: (1) sex-specific genes only altered in one sex; (2) sex-neutral genes altered in both sexes with no statistical difference; and (3) sex-differential genes altered in both sexes, with statistical difference. Gene-set enrichment analysis of sex-specific genes was performed using the ShinyGO tool. **Results:** Transcriptomic analysis identified 5383 and 4883 differentially expressed genes in females and males, respectively. Of these, 515 metabolic genes were significant in females, and 438 in males. Based on our defined categories, 117 metabolic genes were female-specific, and 51 were male-specific. Enrichment analysis of these sex-specific genes identified lipid metabolism enriched in both males and females, including cholesterol metabolism and steroid biosynthesis. Cholesterol metabolism genes exhibited sex-specific expression patterns: *CYP46A1* (downregulated, female-specific), *CYP27A1* (upregulated, female-specific), while *CYP7B1* and *HMGS1* were male-specific (downregulated). Efavirenz, an FDA-approved drug for HIV treatment, targets *CYP46A1*. Studies have shown that low dose of efavirenz could be used as disease-modifying therapeutic option for AD. Our transcriptomic analysis, combined with drug target identification, suggests that efavirenz can be repositioned for therapeutic intervention in female AD patients. **Conclusions:** Our results show that females exhibit greater metabolic dysregulation than males, with lipid and cholesterol metabolism identified as sex-distinguishing pathways in AD. Using a systems toxicology approach, by integrating transcriptomics and metabolic pathway analysis, we identified *CYP46A1* as a female-specific target with mechanistic implications for cholesterol regulation. The identification of efavirenz, a *CYP46A1* activator, demonstrates the application of systems toxicology in translating molecular insights into therapeutic strategies for drug repurposing and designing sex-specific treatment options in AD.

PS 4618 Single-Cell Profiling of Normal Development and ATRA-induced Teratogenicity in Rat Whole Embryo Culture

L. Li, A. M. Gutierrez, J. A. Gomes, J. Chen, E. Basilio, and J. F. Robinson. University of California San Francisco, San Francisco, CA.

Background and Purpose: The rat post-implantation whole embryo culture (WEC) model enables direct assessment of environmental chemical exposures on embryogenesis during the critical windows of neurulation and early organogenesis. Gestational day (GD) 10 rat embryos are cultured *ex vivo* for 48h and evaluated for growth parameters, developmental progression, and specific anomalies. Recent advances in single-cell transcriptomic profiling now provide unprecedented resolution in defining how teratogens affect key cell populations, developmental trajectories, and underlying gene expression. **Methods:** In this study, we characterized the *ex vivo* development of rat embryos via morphological analysis and bulk and single-cell RNA sequencing under control and teratogenic conditions, using all-trans retinoic acid (ATRA) as a prototypical toxicant. **Results:** Embryos cultured under normal conditions exhibited dynamic morphological changes, recapitulating *in vivo* development, successfully completing neural tube formation and early development of multiple organs, including ear, eye, heart, and limb. These morphological changes were accompanied by global transcriptomic changes, with 731 differentially

expressed (DE) genes identified over 0-48h (561 upregulated, 170 downregulated; $p < 0.0001$, absolute fold change >1.25), enriched for nervous system development, tube formation, organ morphogenesis, embryonic patterning, and circulatory system development. At the single-cell level, embryos profiled at 0, 4, 12, 24 and 48h ($n=4$ embryos per timepoint), revealed 36 distinct cell populations representing all three germ layers. Significant shifts in cell types were evident across the time course. Prior to neural tube closure (0-12h), primitive neuroectodermal cells—neuroectoderm (NE), neuromesodermal progenitors (NMPs), rostral and caudal NE, and floor plate cells—were more abundant. By 24-48h, these progenitors transitioned toward more differentiated populations, including neural progenitor cells, post-mitotic CNS neurons, peripheral neurons/neural crest derivatives, craniofacial ectoderm and non-neural epithelium, with parallel temporal differentiation patterns observed in mesodermal and endodermal lineages. To model teratogenic perturbation, embryos were exposed to $1.7\mu\text{M}$ ATRA ($\sim 20\%$ reduction in TMS) or 0.1% DMSO and analyzed at 4 and 48h. ATRA exposure caused cell-identity shifts as early as 4h, including depletion of craniofacial ectoderm, NE and rostral NE, and expansion of neural crest, NMPs and craniofacial mesoderm. By 48h these effects intensified, with marked loss of NMPs, fore/mid/hindbrain NE, and somite populations, and increases in PNS neurons, lateral plate mesoderm, and cardiomyocytes. At the gene-expression level, ATRA altered expression of patterning and hindbrain regulators, neuroectodermal markers, and mesodermal differentiation genes, along with enzymes critical for ATRA metabolism, in a cell type-specific manner. **Conclusions:** The results identify neuroectodermal, fore/mid/hindbrain neural, and mesodermal populations as particularly vulnerable to ATRA-induced dysregulation. These findings align with ATRA's known ability to disrupt embryo patterning, neural tube and CNS morphogenesis, and craniofacial and mesodermal development, and highlight the power of single-cell approaches to pinpoint specific cell types and gene networks driving teratogenic outcomes.

PS 4619 Alcohol impairs TFEB-mediated autophagy while exacerbating inflammatory response in the aged liver

S. Williams, W. Ding, and H. Ni. University of Kansas Medical Center, Kansas City, KS.

Background and Purpose: Alcohol-associated liver disease (AALD) is a major cause of chronic liver disease. Cells protect themselves by activating protective mechanisms like autophagy. Aging is a well-known risk factor associated with AALD. Alcohol metabolism and cellular aging induce hepatic inflammation. Inflammatory signaling can be stunted by autophagic processes. Though TFEB autophagy is impaired by alcohol consumption, the role of autophagy and aging in the development of AALD is not completely understood. This study investigates changes in TFEB-regulated autophagy and its role in mitigating inflammation in alcohol-induced liver injury in aged mice. **Methods:** Young (3-month-old) and aged (22-month-old) C57BL/6N mice were subjected to chronic feeding plus acute ethanol binge model (Gao-binge model). Unbiased liver tissue RNAseq and metabolomics were performed. Tail-vein injection of adenovirus-TFEB was performed to overexpress hepatic TFEB in aged mouse livers with Gao-binge alcohol feeding. Liver injury and steatosis were determined. Western blot analysis and qPCR were performed to assess the mRNA and protein levels of autophagic machinery and inflammatory mediators. **Results:** PCA analysis of RNAseq and metabolomics showed distinct separation of four experimental groups, suggesting both aging and alcohol have specific effects on hepatic gene expression and metabolic changes. Hepatic triglycerides increased in ethanol-fed aged mice compared with the young mice fed control diet. Hepatic TFEB decreased but levels of autophagic proteins such as p62 and LC3-II increased in ethanol-fed aged mice. Protein expression of LAMP1 and ATP6v1B2 decreased in ethanol-fed aged mice compared to young, control diet-fed mice. Several inflammatory pathways and cGAS-STING genes were upregulated in aged, alcohol-fed mice. TFEB overexpression in aged, alcohol-fed mice led to decreased ALT, increased lysosomal proteins, and decreased cGAS signaling. **Conclusions:** Aging was found to exacerbate alcohol-induced hepatic steatosis despite promoting increases in liver injury markers of ALT. Additionally, aging led to further impairment of autophagy and promoted inflammatory signaling induced by alcohol consumption.

PS 4620 High-Throughput, Extraction-Free miRNA Profiling for Toxicological Applications

Z. Chen, and M. Opichka. Biospyder, Carlsbad, CA.

Background and Purpose: MicroRNAs (miRNAs) are post-transcriptional regulators of gene expression, and circulating miRNAs offer a non-invasive means to monitor tissue-specific injury. Because distinct miRNA expression patterns often reflect the tissue of origin and the nature of toxic insults, they provide valuable mechanistic insights into cellular processes such as apoptosis, inflammation, and oxidative stress. These properties make miRNAs powerful tools for monitoring safety risks in preclinical and clinical studies. Integrating miRNA expression profiles with other omics data further enhances understanding of toxicity pathways and supports the identification of potential therapeutic targets. Although small RNA-seq is used for miRNA profiling, it requires RNA purification, larger sample inputs, and incurs higher cost than TempO-Seq platform-based assays, which are target-based and do not require RNA purification. The goal of this study was to develop a targeted

miRNA assay that eliminates the need for RNA extraction, accommodates flexible sample formats, and enables rapid, cost-effective profiling of miRNAs. The simplified sample processing, combined with reduced data complexity, enables more reliable detection of cell type- or disease-specific miRNA signatures. **Methods:** The TempO-Seq Whole miRNome assay, built on established TempO-Seq technology, is a targeted platform designed to profile 2,112 human miRNA targets derived from miRBase v22.1. Because of the short length of miRNA targets, optimized probe design strategies and specialized enzymatic reactions were implemented to ensure robust performance. Initial validation was performed using purified RNA reference materials cited in benchmarking studies comparing miRNA profiling platforms. The assay was then adapted to an extraction-free workflow compatible with a wide range of sample types, including cell and FFPE lysates, plasma, and dried blood spots (DBS). To demonstrate biological and translational relevance, miRNA expression changes were characterized in two breast cancer cell lines, MCF7 and MDA-MB-231, following rapamycin treatment ($0.1\mu\text{M}$, $1\mu\text{M}$, $10\mu\text{M}$) for 24 hours, in parallel with TempO-Seq whole transcriptome analyses. Furthermore, the miRNA assay was performed on DBS samples from individuals with Alzheimer's disease and matched controls. **Results:** The TempO-Seq Whole miRNome panel is the most comprehensive set in any targeted miRNA profiling platform to date. Performance was first benchmarked using Universal Human miRNA Reference RNA, human brain RNA, and defined mixtures of the two. When compared with published data from other commercial assays (EdgeSeq, TruSeq), the TempO-Seq miRNA assay demonstrated excellent reproducibility among replicates ($R^2=0.97$) and comparable accuracy (titration response) while requiring substantially less input. The extraction-free workflow showed robust gene detection and high reproducibility across diverse and challenging sample types, including plasma, FFPE, and DBS, simplifying handling and reducing overall cost. Differential expression analysis of MCF7 and MDA-MB-231 cells treated with rapamycin revealed dose-dependent miRNA and mRNA changes consistent with mTOR pathway modulation. MCF7 cells exhibited stronger transcriptional and miRNA-level responses than MDA-MB-231 cells, aligning with known differences in rapamycin sensitivity. Finally, miRNA profiles obtained from DBS samples of individuals with Alzheimer's disease and controls demonstrated visible separation by unsupervised clustering, indicating the assay's potential for distinguishing disease states using minimally invasive specimens. **Conclusions:** The TempO-Seq miRNA assay provides a robust, extraction-free solution for high-throughput miRNA profiling across multiple sample types. The assay achieves accuracy and reproducibility comparable to established platforms (EdgeSeq, TruSeq) while requiring lower input and offering more cost-effective workflows. Combined miRNA and mRNA analyses in rapamycin-treated breast cancer cell lines confirmed expected pathway-level responses, with greater compound sensitivity observed in MCF7 cells. The distinct clustering of Alzheimer's disease DBS samples from controls further highlights its translational and diagnostic potential. Overall, this targeted miRNA assay expands the utility of TempO-Seq technology, enabling mechanistic and biomarker studies in both toxicological and disease contexts.

PS 4621 Your clues are in the proteins: enhancing toxicology insights with proteomics

S. Lao, X. Liu, and F. Fan. Johnson & Johnson, San Diego, CA.

Background and Purpose: Investigating proteome-wide changes upon treatment with therapeutic candidate(s) may provide mechanistic insights to understand adverse events (AEs). Thus, creating a proteomics workflow that captures a broad spectrum of proteins is needed. Focusing on Wistar Han rats (a predominant species used in early toxicity testing) and the liver (a key organ in drug metabolism), we developed a robust platform that generates informative proteomic data for toxicology studies. In-depth proteome-wide characterization, as well as gender differences in key pathways and enriched proteins are presented. **Methods:** For spectral library building, male and female Wistar Han (WH) rat livers ($n=3$ per gender) were prepared using S-Trap columns. Digested peptides were pooled by gender for offline fractionation to increase peptide coverage with greater sensitivity and accuracy. Data-dependent acquisition (DDA) for each fraction was performed on Bruker timsTOF and Thermo Vanquish Neo. DDA files were processed using Spectronaut to generate rat liver spectral libraries for each gender. For data-independent acquisition (DIA) method development, additional rat livers ($n=2$ per gender) were prepared using S-Trap columns. DIA methods were optimized using py_diaID to boost proteome coverage, and samples were run on the same instruments. DIA files were processed using Spectronaut for downstream protein analysis. In the case study example, female WH rats ($n=4$ per group) were dosed daily with aripiprazole (10mpk), rosiglitazone (20mpk), or vehicle (1% hydroxypropyl methylcellulose) for 28 days. Glucose tolerance test (GTT) was performed on day 27 after fasting. Livers were collected post-GTT for proteomics. **Results:** The spectral library offered in-depth comprehensive coverage for the rat liver proteome, featuring 11,388 proteins (265,024 peptides) for male and 10,144 proteins (199,846 peptides) for female. Proteins were identified across various subcellular components, including 27% membrane, 42% intracellular, 26% nuclear, and 6% extracellular proteins. Tailored DIA methods boosted protein identification, averaging over 100,000 peptides and 8,000 proteins with only 250ng of total peptides per run. Building a DDA-based spectral library is labor intensive and resource heavy. Under these circumstances, *in-silico* libraries are valuable alternatives. Our results showed that *in-silico* methods have a strong 0.9 Pearson correlation with the library-based DIA analysis, thus validating their utility when facing a pressing timeline for issue resolution. To further assess our proteomics workflow,

label-free quantification from naïve male and female rat livers identified differentially expressed proteins. Downstream pathway analysis offered insights into biological processes that may be enriched in one gender versus the other. For example, "ABC Transporters" was captured in female samples and featured four ATP-binding cassette (ABC) transporters that are liver-enriched and important for bile acid formation and detoxification [Abcb4, Abcg5, Abcc6, Abcc3]. On the opposite end, pathways enriched in males included "Retinol metabolism", which may be due to Cyp2a2 and Cyp3a18 which are known to be strongly expressed in males and are important for liver drug metabolism. This baseline analysis requires additional experimentation (such as hormonal manipulation or metabolic challenges) to further reveal potential male-female differences. As a final example on how our workflow can be applicable in safety, female Wistar Han rats were treated with rosiglitazone or aripiprazole to assess the liabilities of glucose intolerance and weight gain. Pathway enrichment analysis confirmed rosiglitazone's mechanism of action (upregulation in "PPAR Signaling Pathway"). Rats treated with aripiprazole exhibited impaired glucose tolerance, and proteomics captured downregulation of "Glycolysis/Gluconeogenesis". These insights validated the sensitivity and potential for proteomics to elucidate drug mechanisms and pathways. **Conclusions:** Our proteomics platform - from spectral library building to deep proteome profiling - achieved comprehensive coverage with high reproducibility and accuracy. Its application successfully identified differentially expressed proteins and enriched pathways, thus supporting mechanistic insights into drug effects. Ultimately, this approach offers a powerful tool to improve drug safety evaluation and hypothesis generation.

PS 4622 The Development of Gene Expression Modules from Rat Drug Response Studies Across Heart, Kidney, Liver, and Muscle

S. Denecke, A. Podtelezhnikov, J. Rogers, Z. Erdos, S. Pacchione, F. Shah, R. Gonzalez, and K. Tanis. Merck & Co. Inc., West Point, PA.

Background and Purpose: RNA expression biomarkers can be leveraged to evaluate the potential safety liabilities of preclinical candidates and to understand the molecular mechanisms of toxicities observed during development. This *toxicogenomic* approach has traditionally relied on a small, pre-defined subset of genes associated with known biological pathways. However, the rapidly falling cost of sequencing and the increasing pressure to reduce animal studies has put a premium on extracting more value from each *in vivo* sample. In this light, full transcriptome RNA sequencing has become commonplace in recent years, with modern analysis methods needed to derive comprehensive mechanistic conclusions from this data. **Methods:** Here, we use the *Weighted Gene Correlation Network Analysis* (WGCNA) framework to derive co-regulated gene expression modules in RNAseq data from heart, kidney, liver, and muscle tissues of rats treated with over 300 compounds in short term toxicity studies. Data was processed using standardized workflows and the newest version of the rat genome (GRCh8), quantifying expression changes for each gene in over 1,400 comparisons. The total number of usable genes in each tissue was filtered by applying minimum expression cutoffs. WGCNA was then applied using the eponymous R package in order to define separate sets of gene expression modules for each tissue. **Results:** >3,000 genes in each tissue were classified into one of 40-80 distinct expression modules. Comparison of the liver modules defined in this study via RNAseq with previous reports using publicly available microarray data in liver demonstrated the constancy of the module biology across platforms and laboratories. While certain modules recapitulated known toxicogenomic biomarkers (e.g., Podtelezhnikov et al. 2020), other modules are currently being annotated via a combination of pathway analysis, deconvolution of cell population changes, and association with ancillary study endpoints such as clinical chemistry and histopathology. **Conclusions:** The resultant biologically annotated expression modules will provide additional mechanistic insights into the molecular mechanisms of toxicities observed in preclinical studies. Furthermore, this analysis workflow can be applied to other species such as dogs, monkeys, or mice as standardized databases become available. Lastly, module scores based on eigengene expression in each sample may be a useful way to reduce dimensionality when using toxicogenomic data as features in machine learning models.

PS 4623 Evaluation of 2,2'-Dimorpholinodiethyl Ether (DMDEE) in Pathology, Perinatal, and Genotoxicity Studies

R. Frawley¹, S. Smith-Roe¹, H. Cunney¹, K. Stinson², and K. Cimon³. ¹NIEHS-NTP, Research Triangle Park, NC; ²Southern Research, Birmingham, AL; and ³Environmental Pathology Laboratories, Inc., Sterling, VA.

Background and Purpose: 2,2'-Dimorpholinodiethyl ether (DMDEE) is a tertiary amine catalyst used in the production of flexible and molded polyurethane foams. Human exposure occurs occupationally through inhalation of DMDEE vapors during the production process. In rat models, the fetus may be exposed through maternal transfer during gestation. DMDEE consists of two morpholine rings and may interact with nitrates to form carcinogenic products. Studies were conducted to assess subacute toxicity, genetic toxicity, and perinatal toxicity following exposure to DMDEE in rodent and *in vitro* models. **Methods:** Male and female B6C3F1/N mice (5-6 weeks old) were exposed to DMDEE (0, 62.5, 125, 250, 500, 1,000 mg DMDEE/kg) in deionized water (10 ml/kg) by oral gavage daily for 4 weeks. At necropsy, blood was collected

for hematology and for analysis of micronuclei; selected tissues were stained and analyzed for histopathology. DMDEE (500-6000 µg/tube) was also evaluated for mutagenicity using *Salmonella typhimurium* (TA98, TA100) or *Escherichia coli* (WP2 uvrA pKM101) tester strains with and without S9 activation. To evaluate reproductive toxicity, time-mated female Sprague Dawley rats (12-14 weeks old) were exposed to DMDEE (0, 31.25, 62.5, 125, 250, 500 mg DMDEE/kg) in deionized water (5 ml/kg) daily from gestation day (GD) 6 through post-natal day (PND) 27 by oral gavage. The pups were dosed by gavage at the same dose level as their dams from PND12 through PND27. Blood and tissue were collected from the dams on GD18, and from dams and pups on PND 4 and 28 for hematology, clinical chemistry and micronucleus evaluation. **Results:** No test article related effects were observed on maintenance of pregnancy or litter parameters in Sprague Dawley rats. The micronucleus test was negative in rats and B6C3F1/N mice. DMDEE was also negative in bacterial reverse mutation tests. After 4 weeks of exposure at 1000 mg /kg, DMDEE induced consistent findings of cytoplasmic vacuolization in the reproductive organs of male mice, and in the brain and kidney of 100% of male and female mice. Vacuolization of the brain choroid plexus epithelial cells in mice was accompanied by circling, repetitive head lifting, and abnormal gait in 90% of female mice and 10-30% of male mice at the highest dose. Female mice also displayed lower brain weights. Female mice treated with 500-1000 mg DMDEE/kg, and male mice treated with 1000 mg/kg, for 4 weeks exhibited vacuolization of cortical renal tubular epithelial cells. Kidney weights were higher in female B6C3F1/N mice and F0 maternal female rats at the upper dose levels. DMDEE induced modulation of clinical chemistry markers associated with kidney function (globulin, aspartate aminotransferase, albumin/globulin ratio, urea nitrogen, and creatine) in F0 female rats and in F1 pups exposed to 250 mg DMDEE/kg. Vacuolization in the epithelial cells of the coagulating gland, prostate, and epididymis, and decreased testis weight, were observed in male mice treated with 1000 mg DMDEE/kg. Hematocrit, hemoglobin, and erythrocyte counts were higher in F1 female rat pups exposed to 250 mg/DMDEE/kg but were lower in male and female B6C3F1/N mice at 1000 mg DMDEE/kg, along with a decrease in mean cell hemoglobin and mean cell volume. Lymphocytes, white blood cells, and monocytes were dysregulated in both mice and F0 and F1 rats at high doses. **Conclusions:** Mild alterations of cell populations in the blood and hemoglobin metrics in DMDEE-exposed B6C3F1/N mice and Sprague Dawley rats may be early indicators of anemia and altered immune function. The cytoplasmic vacuolization observed in mice following 4 weeks of exposure to DMDEE and the supportive behavioral observations, along with the clinical biomarkers in F0 and F1 rats exposed to DMDEE during gestation and lactation suggest potential deficits in the cellular structure and function of neurological, renal, and male reproductive tissues at higher doses. Collectively, these data suggest caution in the handling and industrial use of DMDEE in manufacturing processes.

PS 4624 Oral Toxicity of Hexanitrohexaazaisowurtzitane (CL-20) in Rats (*Rattus norvegicus*)

T. K. Brown, K. A. MacDonald, L. Crouse, and M. E. Bohannon. Defense Centers for Public Health, Aberdeen, MD. Sponsor: V. Adams

Background and Purpose: Hexanitrohexaazaisowurtzitane (CL-20) is a polycyclic nitroamine energetic that is currently being evaluated by the U.S. military for use in numerous weapons systems. CL-20 has demonstrated favorable performance characteristics, delivering 20% more power than benchmark energetics such as hexagen (RDX) or octogen (HMX). Toxicity of CL-20 is a potential concern to the warfighter and other Department of War-affiliated personnel who may handle the raw material or be exposed during training, combat, or as a result of environmental contamination. U.S. military interest in CL-20 warrants a complete toxicological test series consisting of acute (one-dose), 14-day repeated dose, and 90-day repeated dose *in vivo* exposure studies to assess toxicity. **Methods:** Oral toxicity testing was conducted in Sprague-Dawley rats via oral gavage, followed by euthanasia, via carbon dioxide, and necropsy. For the acute study, CL-20 was delivered at a limit dose of 2000 milligrams/kilogram in a methylcellulose vehicle to six male and female rats. For the subacute study, 6 rats of each sex were administered doses of 62.5, 125, 250, 500, 1000, 1500, and 2000 milligrams/kilogram daily for 14 days. For the subchronic study, 10 rats of each sex were administered doses of 0, 2.22, 6.66, 20, and 60 milligrams/kilogram daily for 90 days. All testing was performed in accordance with an approved animal use protocol in an Association for Assessment and Accreditation of Laboratory Animal Care-accredited facility. **Results:** The medial lethal dose (LD₅₀) was >2000 milligrams/kilogram based on 100% survival 14 days post-dosing with no significant body weight loss or clinical signs. For the 14-day study, noted clinical signs of morbidity included hunching, squinting, lethargy, severe weight loss, and swollen face. Nearly 100% mortality was observed among rats receiving 250 milligrams/kilogram-day (10 of 12), 500 milligrams/kilogram-day (11 of 12), and all rats receiving ≥1000 milligrams/kilogram-day. Male rats in the 125-2000 milligrams/kilogram-day dose groups experienced either decreased weight gain compared to controls or weight loss. The percent of micronucleated reticulocytes increased 3-fold and 2.5-fold in the 62.5 and 125 milligrams/kilogram-day dose groups, respectively, indicating a genotoxic effect. For the 90-day study, mortality was observed in the highest dose group, with 5 out of 10 male animals dying after an average of 75 days on the study, and 3 out of 10 female animals dying after an average of 85 days on the study. Reduced body weight was significant in female rats but also trended downward in male rats. Clinical pathology in both the subacute and subchronic studies indicated anemia and immunotoxicity. Prevalent gross pathological signs included

enlarged heart, decreased thymus, swollen or discolored lymph nodes, pale or discolored organs, dark red stomach contents, and fluid in the chest cavity. These signs, combined with indicators of anemia in the clinical pathology results, corroborate anemia as a strong toxicological effect of CL-20. Neurotoxic measurements were insignificant, indicating little or no neurotoxicity of CL-20, which is a departure from other currently-fielded energetic materials such as RDX and 1,1-diamino-2,2-dinitroethene (FOX-7), both of which cause epileptic effects. **Conclusions:** Despite low acute toxicity, CL-20 caused significant toxicological effects, including genotoxicity, after subacute and subchronic dosing. Current toxicity data for CL-20 do not demonstrate neurotoxicity. As such, given the concerns of RDX as a neurotoxin, toxicity thresholds identified in this study indicate that CL-20 has lower toxicity than that of RDX. However, identification of a critical effect and subsequent benchmark dose analysis are pending. Therefore, CL-20 exhibits mixed toxicological results that will inform its ongoing development and use in a military context for the purposes of replacing legacy energetics.

PS 4625 Assessment of the reproductive toxicity and neurotoxicity of 1,2,4-trimethylbenzene in rats following gestational and subchronic whole-body inhalation exposure

K. Ryan¹, C. Blystone¹, J. Harry¹, L. Betz², G. Roberts¹, M. Stout¹, K. R. Shockley³, and W. Gwinn¹. ¹NIEHS-DTT, Research Triangle Park, NC; ²DLH, LLC, Bethesda, MD; and ³NIEHS-Dir, Research Triangle Park, NC.

Background and Purpose: Alkylbenzenes are a chemical class produced during petroleum refining for a variety of uses including gasoline mixing and blending, industrial coatings, and combustion processes. The most abundant alkylbenzene, 1,2,4-trimethylbenzene (20-45% weight naphtha fraction), is an environmental contaminant with concerns for both developmental/reproductive toxicity and neurotoxicity. In the 2016 EPA IRIS report, confidence in the *in vivo* data to support these concerns was considered low-medium as based on study design and reporting criteria. This subchronic study was designed to investigate the toxicity of 1,2,4-trimethylbenzene (TMB) with special emphasis on assessments of reproductive and nervous system toxicity. **Methods:** Whole-body inhalation exposure of Sprague Dawley rats (0, 30, 100, 300, 600, and 1000 ppm TMB for 6 hours/day) occurred from gestation day 6-21 for the assessment of effects on maternal and fetal toxicity as well as pregnancy outcomes. Dams and offspring were monitored for toxicity on postnatal day (PND) 1-21 (without TMB exposure) and weaned offspring (n=22/sex/group) continued exposure under the same conditions as their dams for 3 months (beginning post-natal day 21). Offspring were monitored for signs of general toxicity as well as pubertal delay by time via assessment of vaginal opening (VO) and balanopreputal separation (BPS). Motor activity and auditory startle response were examined in juvenile offspring for all concentrations and again as adults for doses $\leq$ 300 ppm with additional assessment of learning and memory. Brain weight, size, and standard histopathology were assessed in a separate interim group (n=10/sex/group). Following subchronic exposure, male and female non-littermate exposed pairs were mated to assess TMB exposure effects on fertility. **Results:** Survival was not affected by TMB exposure. Gestational exposure to 1000 ppm TMB was associated with lower body weight compared to controls in dams (12% lower) and offspring (10% lower in both sexes) in the perinatal period which persisted into adulthood for both male and female rats. BPS was delayed 4-5 days in males exposed to $\geq$ 300 ppm TMB and VO was delayed 4 days in females exposed to $\geq$ 100 ppm TMB (with and without adjusting body weight at weaning). Although TMB exposure did not affect F1 pregnancy outcomes (e.g., litter size, weight, etc), mating of F1 (non-litter pairs) after subchronic exposure showed a marginal decrease in number of females mated based on sperm positivity/vaginal plug (81% 1000 ppm vs 91% in controls), but no effects on pregnancy rates were observed. Exposure-related decreases (10-24%) in both F1 corpora lutea and implantations/female was observed in TMB exposure groups $\geq$ 300 ppm. Furthermore, the number of live fetuses/litter were decreased in groups exposed to $\geq$ 300 ppm and we observed positive trends in early resorptions/litter, total resorptions/litter, and calculated post-implantation loss. Evaluation of offspring as juvenile and adults showed diminished motor activity and rearing in the 1000 ppm males and $>$ 600 ppm females. No effects were observed at either age in auditory startle response and habituation, pre-pulse startle inhibition, and in adults for Morris Water Maze learning and memory. TMB exposure did not alter brain development (e.g., weight, size) or histopathology. **Conclusions:** This study demonstrates that subchronic whole-body inhalation exposure to TMB can delay pubertal development in males ($\geq$ 300 ppm) and females ($\geq$ 100 ppm) and may reduce fertility in rats at concentrations as low as $\geq$ 300 ppm. Exposure levels $\geq$ 600 ppm suggested diminished motor function in juveniles. Lower exposure levels were not found to alter motor or sensory function or learning and memory in adults. These results build confidence in the database used to support our understanding of the human health effects associated with TMB inhalation exposure.

PS 4626 Hazard characterization of 1,2,4-trimethylbenzene in rats and mice following whole-body inhalation exposure

W. M. Gwinn¹, G. Roberts¹, M. Stout¹, S. Waidyanatha¹, J. Pierfelice², E. Mutlu³, C. Ganta⁴, M. Cesta¹, M. Cora¹, K. R. Shockley¹, M. Fyle¹, and K. Ryan¹. ¹NIEHS, Research Triangle Park, NC; ²Battelle, Columbus, OH; ³US EPA, Durham, NC; and ⁴Inotiv, Morrisville, NC.

Background and Purpose: The naphtha component of crude oil contains aromatic alkylbenzenes, including trimethylbenzenes. Alkylbenzenes are used in a variety of industrial and consumer applications. Understanding the adverse effects caused by exposure to these chemicals both occupationally and within the general population is essential to human health and safety. This 3-month exposure study investigated the toxicological hazards of the most prominent isomer, 1,2,4-trimethylbenzene (TMB), for which there have been mixed findings in both rodent studies and anecdotal reports from occupational settings. **Methods:** Male and female Hsd:Sprague Dawley rats and B6C3F1/N mice were exposed to 0, 30, 100, 300, 600, and 1000 (rat only) or 1200 (mouse only) ppm TMB via whole-body inhalation. Adult mice (n = 10/sex/group) were exposed 6 hr/day for 3 months and evaluated for exposure-related effects on survival, body and organ weights, clinical pathology, and histopathology. For rats, exposure was perinatal and initiated in pregnant dams from gestation day (GD) 6-21 to assess maternal and fetal toxicity and pregnancy outcomes. Toxicity was monitored in the dams and offspring during lactation (no TMB exposure) at postnatal day (PND) 1-21, and the weaned offspring (n=10/sex/group) were then exposed to TMB under the same conditions as their dams for 3 months to assess similar toxicity endpoints as in mice. **Results:** In mice, 1200 ppm TMB was overtly toxic. 9 males and all 10 females were found dead on the second day of exposure; the remaining male was euthanized moribund. Clinical signs following the first and prior to the second exposure included ataxia, slow/shallow or labored breathing, abnormal gait, hunched posture, hyperactivity, lethargy, or tremors. No exposure-related mortality/moribundity or adverse clinical signs were observed in mice in the remaining exposure groups throughout the study. Exposure to 600 ppm TMB was minimally toxic to males and females, and there was nominal to no exposure-related effects on clinical observations, body weights, hematology, or gross findings at necropsy. TMB exposure-related effects on organ weights were observed, but these changes were not associated with any histological findings in mice. In males, absolute and relative liver weights were increased (11 and 9%, respectively) at 600 ppm, and absolute and relative kidney weights were decreased (up to 16%) at 300 and 600 ppm. Relative liver weights were increased (9%) at 600 ppm in females. In rats, gestational exposure to 1000 ppm TMB was associated with lower body weights in the dams (decreased 12% at GD21) and in both sexes of offspring during lactation (decreased 16% at PND1 and 10% at PND21). There was no exposure-related mortality/moribundity in the dams. Pregnancy outcomes (litter size, sex ratio, and survival) were similar across all the exposure groups. Post-weaning, males exposed to $\geq$ 600 ppm TMB exhibited lower body weight gains throughout the 3-month exposure period, and terminal body weights were 12% and 10% lower in the 600 and 1000 ppm groups, respectively (at PND119). Female body weight changes were not significantly different than the controls in any of the exposure groups. There was no exposure-related mortality/moribundity in the males or females. Relative liver and kidney weights were increased 16-27% and up to 22%, respectively, at 600 and 1000 ppm in males and females. There were no hematologic changes in males or females, but there were exposure-related increases in liver enzymes and bile acids (up to 44% and 346%, respectively), and mild decreases in globulins (up to 11%). There was nominal to no exposure-related effects on histopathology. Plasma TMB concentrations measured at the end of the study correlated with increasing exposure concentrations with no apparent sex differences. **Conclusions:** This study provides valuable insight into the health hazards of TMB, which will help bridge critical data gaps needed to better assess the human health risks associated with exposure to this ubiquitous environmental chemical. These data will be interpreted in the context of a parallel study investigating the reproductive toxicity and neurotoxicity of TMB following inhalation exposure.

PS 4627 Single-Crystal Structure and Protonophoric Potential of N-(3,5-dichloro-4-hydroxyphenyl)acetamide: Implications for Mitotoxicity of Chlorinated Acetaminophen

R. M. Uppu¹, and F. R. Fronczek². ¹Southern University and A&M College, Baton Rouge, LA; and ²Louisiana State University, Baton Rouge, LA.

Background and Purpose: Under neutral and mildly oxidative conditions, HOCl/OCl⁻ (pK_a $\approx$ 7.53) chlorination of acetaminophen forms N-(3-chloro-4-hydroxyphenyl)acetamide, N-(3,5-dichloro-4-hydroxyphenyl)acetamide (DCHPA), and other transformation products in chlorine-treated waters. Although formation via the myeloperoxidase-H₂O₂-Cl⁻ pathway is likely minor, DCHPA is mechanistically important as a biomarker of chlorination and a toxicological concern. Empirically, each *ortho*-Cl reduces the phenolic pK_a by $\sim$ 1.1-1.2 units; thus, the two Cl substituents shift the pK_a of acetaminophen from $\sim$ 9.5 to $\sim$ 7.2-7.3, within the "uncoupler window" (pK_a 4.0-8.0). At physiological pH (7.4), $\sim$ 60% of DCHPA is phenoxide, with the remainder being the neutral and membrane-permeant phenol form; together these favor protonophoric cycling and potential dissipation of the mitochondrial protonmotive force. To ground these mechanistic hypotheses in definitive structure, we determined the single-crystal X-ray structure of DCHPA. **Methods:** DCHPA was synthe-

sized by acetylation of 4-amino-2,6-dichlorophenol with slightly molar excess (1.1–1.2-fold) acetic anhydride in glacial acetic acid solvent at room temperature (24–48 h) under stirring. The product was dried under vacuum and recrystallized once from water. Single crystals (colorless plates/needles) suitable for X-ray diffraction were obtained by slow cooling and evaporation of a near-saturated aqueous solution at room temperature. Diffraction data were collected at 100 K on a Bruker D8 Venture DUO equipped with a Photon III C14 detector using Cu K α radiation (λ = 1.54178 Å); a multi-scan (SADABS) absorption correction was applied. The structure was solved with SHELXT and refined on F² with SHELXL. Intermolecular interactions and graph-set motifs were analyzed using PLATON and Mercury. pK_a was estimated empirically from the *ortho* effect (~1.1–1.2 units decrease per *ortho*-Cl) rather than from *meta/para* Hammett constants. **Results:** DCHPA, C₈H₇Cl₂NO₂, crystallizes in triclinic space group P-1 with three independent molecules in the asymmetric unit. Two of them are essentially planar, with mean deviations of 13 atoms 0.029 and 0.030 Å and are nearly parallel, forming a dihedral angle of 7.5°. They differ only in the conformation of the OH hydrogen atom. The third molecule is quite nonplanar, with the CCNO acetamide plane forming a dihedral angle of 67.6° with the remainder of the molecule. C-Cl distances are in the range 1.7197(17)–1.7381(18) Å with a mean value of 1.7311 Å. C-OH distances are in the range 1.351(2)–1.359(2) Å with a mean value of 1.354 Å. The two planar molecules form antiparallel hydrogen-bonded chains through N-H...O interactions of the acetamide substituents. The NH group of the nonplanar molecule donates a bifurcated hydrogen bond to the OH and a Cl substituent of one of the planar molecules. The OH groups of all molecules form intermolecular hydrogen bonds to other OH or carbonyl oxygen atoms. N...O distances in the chains are in the range 2.913(2)–2.920(2) Å and O...O distances are in the range 2.6776(18)–2.9546(18) Å. **Conclusions:** The definitive solid-state structure (Z' = 3) and cohesive hydrogen-bond/halogen-bond network provide a robust molecular reference for DCHPA, a chlorination product of acetaminophen. The structural features (conjugation, hydrogen-bond topology, and halogen contacts) are consistent with enhanced phenoxide stabilization and the empirically expected $\Delta pK_a \approx 2.2$ –2.3 for two *ortho* Cl substituents, yielding pK_a ~7.2–7.3. These properties place DCHPA within the protonophore-active range, supporting its potential to uncouple oxidative phosphorylation and its value as a biomarker of HOCl/-OCl exposure in environmental and biological settings.

PS 4628 Single Crystal Structure of 4-Acetamido-3-chlorophenyl Acetate: An O-Acetylated Proxy for a Putative *In Vivo* N-Acetyl-1,4-benzoquinoneimine-Chloride Ion Biomarker Precursor

S. V. Bai¹, P. F. Mensah¹, G. Li², F. R. Fronczek², and R. M. Uppu¹. ¹Southern University and A&M College, Baton Rouge, LA; and ²Louisiana State University, Baton Rouge, LA.

Background and Purpose: With about 25 billion doses sold annually in the United States, acetaminophen (Tylenol) is among the most widely used analgesic and antipyretic agents. Its metabolism is dominated by sulfation, glucuronidation, and, to a lesser extent, CYP2E1 oxidation; however, nonenzymatic transformations mediated by cellular oxidants, such as, peroxytrinitrate-CO₂ and the myeloperoxidase-H₂O₂-Cl⁻ system that generates HOCl/-OCl (pK_a ≈ 7.53), also warrant consideration. While CYP2E1-mediated reactions are implicated in overdose-level formation of N-acetyl-1,4-benzoquinoneimine (NBQI), nonenzymatic biotransformations involving peroxytrinitrate-CO₂ and HOCl/-OCl may operate continuously, producing low-level *in vivo* formation of NBQI in acetaminophen users. Our focus, therefore, centers not only on overdose but also on normal exposure conditions and the identification of practical biomarkers. Given the high abundance of Cl⁻ in the cellular milieu (≈ 150 mM), we propose N-(4-hydroxy-2-chlorophenyl)acetamide (the 2-chloro isomer) as a direct, LC-MS/MS-amenable readout of endogenous NBQI-Cl⁻ chemistry. Accordingly, recognizing that O-acetylation can facilitate cellular uptake, we synthesized 4-acetamido-3-chlorophenyl acetate, the O-acetylated derivative of N-(4-hydroxy-2-chlorophenyl)acetamide, and examined its structure. **Methods:** 4-Acetamido-3-chlorophenyl acetate was synthesized by acetylation of 4-amino-3-chlorophenol with acetic anhydride following Naik *et al.* (Arkivoc, 2004, 55-63) with minor modifications. Briefly, 4-amino-3-chlorophenol hydrochloride (1.80 g, 10 mmol) was dissolved in ~50–75 mL water and adjusted to pH 1.5–1.7 with 1 N HCl. The cooled solution (ice bath) was treated with acetic anhydride (1.21 mL, 12 mmol), then NaHCO₃ (2.16–3.00 g, 25–35 mmol) was added with continuous stirring, maintaining the reaction pH between 5.5 and 6.5. The off-white precipitate was collected by filtration. Crystals were grown from a hot, near-saturated ethanolic aqueous solution by slow cooling and evaporation and subjected to single-crystal X-ray diffraction. Data were collected at 100 K on a Bruker D8 Venture DUO diffractometer with a Photon III C14 detector. Structure solution and refinement were carried out using SHELXT and SHELXL2019. Bond lengths, hydrogen-bonding patterns, and dihedral angles were analyzed to assess molecular conformation and supramolecular organization. **Results:** 4-Acetamido-3-chlorophenyl acetate, C₁₀H₉ClNO₃ (Mr = 227.64) crystallizes in monoclinic space group I 2/a and can be characterized by three planes, the phenyl plane, the acetamide plane, and the acetate plane. The phenyl and acetamide planes make a dihedral angle of 40.7°, the phenyl and acetate planes are nearly orthogonal, with a dihedral angle of 88.1°, and the acetamide and acetate planes make a dihedral angle of 51.4°. The C-Cl distance is 1.7378 (15) Å, the C(Ph)-N distance is 1.4129 (17) Å, and the C(Ph)-O distance is 1.4033 (17) Å. Molecules are linked by intermolecular hydrogen bonds involving the acetamide group, with NH as donor and carbonyl O as acceptor, forming chains along the [010] direction. The N...O distance

is 2.8335 (17) Å, and the angle about H is 157.5 (17)°. **Conclusions:** Single crystal data establish the solid-state geometry and packing of 4-acetamido-3-chlorophenyl acetate, an O-acetylated scaffold that masks the phenolic oxygen. As an acetate ester, it is expected to be more lipophilic than the free phenol and may facilitate cellular entry. It can therefore serve as a proxy for delivery and subsequent unmasking of N-(4-hydroxy-2-chlorophenyl)acetamide, the proposed readout of endogenous NBQI-Cl⁻ chemistry. This study does not demonstrate biological uptake or biomarker performance. Next steps will quantify esterase mediated O-deacetylation and formation of the amide, establish targeted LC-MS/MS detection in cells and biofluids using authentic standards, and assess stability and conversion kinetics. Finally, the proxy ester approach may provide a practical route to probe downstream signaling: after intracellular deacetylation, the liberated phenolic amide could enter conjugation pathways that generate anandamide like derivatives, enabling systematic evaluation of nociception and toxicity in cell-based and animal models.

PS 4629 Ezetimibe-Glucuronide as an exogenous biomarker probe identifies MASH

D. Farrera¹, K. L. Frost¹, J. L. Jilek¹, P. A. Sample¹, J. M. Izu¹, M. M. Alaaldin¹, P. Lindberg¹, M. M. Maloney¹, A. Rodrigues², E. Yamaguchi², S. Ryu², Y. Bib², M. West², S. Mathialagan², S. Lazzaro², B. Rabe³, D. Billheimer³, A. P. Nguyen⁴, M. F. Paine⁴, S. H. Wright³, A. O. Rahimi³, R. Akhbari³, G. Block³, I. Ghaderi³, and N. Cherrington¹, *et al.* ¹University, Tucson, AZ; ²Pfizer, Groton, CT; ³University of Arizona, Tucson, AZ; and ⁴Washington State University, Spokane, WA.

Background and Purpose: Metabolic dysfunction-associated steatohepatitis (MASH), the progressive form of metabolic dysfunction-associated steatotic liver disease (MASLD), remains underdiagnosed due to the invasiveness of liver biopsy and limited accuracy of non-invasive tests. MASH progression involves altered hepatic transporter processes that reduce biliary efflux and increase systemic retention of transporter substrates. This study aimed to determine whether ezetimibe glucuronide (EZEG), a selective substrate of three transporter pathways dysregulated in MASH, could serve as a non-invasive diagnostic biomarker. **Methods:** Biopsy-verified patients with NAFLD activity scores (NAS) ranging from 0–5 received an oral 1 mg sub-therapeutic microdose of ezetimibe (EZE). Plasma and urine EZEG levels were quantified post-dose to assess transporter-dependent disposition. Diagnostic performance was evaluated using receiver operating characteristic (ROC) analysis. **Results:** Plasma EZEG concentrations were significantly elevated in patients with MASH (NAS ≥5), showing excellent discrimination (AUROC = 0.99; 95% CI: 0.98–1.00) using the 60-minute post-dose measurement. MASH patients exhibited approximately six-fold higher plasma EZEG levels than non-MASH individuals (NAS 0–4), consistent with impaired hepatic uptake and efflux. Urinary EZEG excretion over six hours was increased but showed weaker group differentiation, likely reflecting reduced renal clearance from diminished glomerular filtration and tubular secretion. **Conclusions:** Altered hepatic transporter function in MASH leads to systemic accumulation of EZEG, providing a sensitive, mechanism-based biomarker capable of distinguishing MASH (NAS=5) from non-MASH cases. This exogenous probe drug strategy offers a non-invasive, reasonably likely surrogate endpoint to identify early-stage MASH and support disease stratification, therapeutic monitoring, and patient selection in clinical studies.

PS 4630 Copper Isotope Ratios as Biomarkers of Combined Dietary and Environmental Stressors

A. Sprague¹, D. van de Laar¹, J. Beier², F. Marcantonio¹, and N. Johnson¹. ¹Texas A&M University, College Station, TX; and ²University of Pittsburgh, Pittsburgh, PA.

Background and Purpose: Vinyl chloride (VC), an environmental pollutant and chemical of concern following the East Palestine, Ohio train derailment, is a known hepatotoxicant that directly causes liver injury at high exposure levels. The impact of lower concentrations of VC on progression of underlying liver disease remains less clear. Given the high prevalence of metabolic dysfunction-associated steatotic liver disease, (MASLD, formerly known as NAFLD) in the U.S., the potential for overlap between diet-induced liver injury and VC exposure is an important concern. Recent studies suggest that Western diet can modify VC-associated liver injury, raising the need for improved biomarkers. Isotope metallomics, an emerging field examining stable isotope distributions of essential metals, offers a novel approach to investigate such interactions. Copper (Cu) isotopes are of particular interest due to copper's role in liver metabolism and redox regulation. The objective of this study was to investigate the role of dietary background on modifying hepatic Cu isotope ratios in response to VC exposure, with the overall goal of assessing their potential as biomarkers of diet-pollutant interactions. **Methods:** Male C57/BL6 mice were fed either a control diet (CD; nutrient-balanced) or a Western diet (WD; high-fat, high-sugar) and exposed to VC (–0.85 ± 0.1 ppm) or air for 6 hours per day, 5 days per week for 12 weeks. Experimental groups included CD, CD+VC, WD, and WD+VC (n=5/group). Banked liver tissue was collected and analyzed for Cu isotope ratios (⁶⁵Cu/⁶³Cu) using multi-collector inductively coupled plasma mass spectrometry (Neptune Plus MC-ICP-MS). Results are reported in delta notation (δ⁶⁵Cu), calculated using the NIST 3114 standard, and a final correction is made to report δ⁶⁵Cu data versus NIST 976. A concentration-matched standard-sample bracketing

approach with gallium doping was used for internal normalization. Reproducibility was confirmed using an internal Cu standard (ESPI) at $n = 16$ measurements relative to the NIST 3114 standard. Yielding $\delta^{65}\text{Cu}$ relative to NIST 976 of $-0.02 \pm 0.031\%$ (2SE). **Results:** Group mean hepatic $\delta^{65}\text{Cu}$ values ($\%$) $\pm$ SEM were $\text{CD} = -0.06 \pm 0.11$, $\text{CD+VC} = -0.19 \pm 0.08$, $\text{WD} = -0.60 \pm 0.03$, and $\text{WD+VC} = -0.49 \pm 0.09$. Analysis revealed significant differences between dietary exposure groups (CD and WD, $p = 0.0040$), as well as between CD and WD+VC ($p = 0.0152$). VC exposure alone (CD vs. CD+VC) produced a modest isotopic shift that did not reach significance, and WD vs. WD+VC were not significantly different. These results suggest that diet has a dominant effect on hepatic Cu isotope ratios. **Conclusions:** This study demonstrates that hepatic Cu isotope ratios are sensitive to dietary background, with Western diet significantly shifting $\delta^{65}\text{Cu}$ toward lighter values compared to control diet. These findings support the potential of $\delta^{65}\text{Cu}$ as an innovative biomarker of nutritional status. While VC alone did not significantly alter isotopic composition in this study, the combined effects of diet and exposure underscore the importance of considering co-exposures in biomarker development. Ongoing studies will assess mechanistic endpoints, including Cu transport and oxidative stress, to better define pathways underlying isotopic fractionation.

PS 4631 Therapy-Induced Rewiring of Synovial Sarcoma Metabolism

A. Layana, and M. McBride. Rutgers, the State University of New Jersey, Piscataway, NJ.

Background and Purpose: Synovial sarcoma (SS) is one of the most common soft tissue cancers in pediatric, adolescent, and young adult patients in the world. Despite this, present treatment options are limited due to lack of targeted therapies for SS tumors. Current standard-of-care treatment depends on surgery, radiation, and cytotoxic chemotherapeutic agents such as doxorubicin. Metabolic rewiring in SS in response to treatment is poorly characterized and there are currently no metabolism-targeted interventions available for SS. Therefore, discovering treatment-induced metabolic vulnerabilities in SS tumors will guide the development of new treatment strategies for these patients. **Methods:** In this study, we aimed to characterize the metabolome changes of human synovial sarcoma cells caused by treatment with radiation and doxorubicin. We utilized liquid chromatography-mass spectrometry (LC-MS) to conduct broad targeted analysis on water-soluble metabolites in extracts from HSSYII and SYO1 cells before and after treatment with clinically relevant dosages of radiation and/or doxorubicin. Metabolomics analysis was performed to assess both their individual and combined effects in the SS cell line models. Additionally, cell proliferation was measured by an SRB assay to understand how alterations in metabolite levels correlated with growth rate. **Results:** LC-MS metabolomics quantified levels of central carbon metabolites, including amino acids, TCA cycle intermediates, and redox-related metabolites. Significant perturbations in metabolite levels were observed post-treatment within 24 hours when compared to non-treated cells. Of particular interest are alterations in levels of redox metabolites such as glutathione and its precursors following radiation treatment, indicating a metabolic response to the treatment-induced oxidative stress and potentially modulating radiosensitivity. **Conclusions:** Investigation of the efficacy of therapies targeting the unique metabolism of synovial sarcoma is ongoing and may include both dietary and pharmacological interventions to selectively disrupt tumor nutrient availability, such as for synthesis of the major antioxidant glutathione. We also aim to expand our model to better capture clinical conditions through providing multiple doses of radiation to mimic fractionated radiation therapy and expand our analysis to include measuring metabolic pathway fluxes through the use of stable isotope tracers. Continued research is crucial in translating our findings into viable treatments that can help improve outcomes for patients.

PS 4632 Combining immunocapture and microflow liquid chromatography-tandem mass spectrometry to advance bioanalysis of protein biomarkers in toxicological studies

Z. Zhou, P. Zhang, X. Yang, J. Huang, and J. Li. WuXi AppTec (Suzhou) Co., Ltd., Suzhou, China.

Background and Purpose: Biomarkers play a critical role throughout the entire drug-development lifecycle, contributing to both safety and efficacy assessments. As industrial report suggested, from 2011 to 2020, drugs developed with biomarker guidance led to 2 times higher success rate in Phase II trial and 3 times higher overall approval than those developed without. Proteins, as the functional end products of the central dogma, their expression profiles closely reflect the physiological activity, making them particularly suitable as biomarkers. So far, the Early Detection Research Network (EDRN) catalogs 627 protein biomarkers across ten organs (45% of the total entries). Nearly all clinical biomarkers approved by FDA are protein-based. Protein biomarkers are commonly measured by ligand-binding assays such as ELISA and electrochemiluminescence assay. These platforms however, have relatively limited assay ranges and rely upon specific antibody accessibility. By contrast, liquid chromatography-tandem mass spectrometry (LC-MS/MS) has emerged as an important alternative due to high specificity and methodological robustness. LC-MS/MS methods are also inherently high-throughput and can quantify multiple biomarkers in a single assay, thereby shortening laboratory turnaround time, and lowering cost.

The conventional LC-MS/MS platforms however, generally achieve lower limits of quantification (LLOQ) for proteins/peptides in the order of 1-10 ng/mL, which is insufficient for many endogenous protein biomarkers (expressed at pg/mL to fg/mL). Improving LC-MS/MS sensitivity is therefore the key to further advance protein biomarker bioanalysis. In this work, we streamlined an analytical workflow integrating immunocapture and microflow liquid chromatography (microLC), aiming to push further the protein quantitation limit, while maintaining a wide dynamic range. The established methods were validated and applied in real-world preclinical toxicology studies. **Methods:** The serum samples were incubated at room temperature overnight, with in-house prepared anti-biomarker beads based on biotin-streptavidin interaction. After repeatedly washing the beads with PBST buffer, the captured proteins were eluted with water containing 0.1% v/v TFA. Following centrifugation, dithiothreitol and iodoacetamide were added sequentially for reduction and alkylation. The proteins were digested with trypsin at 37 °C for 3 h before injection. Chromatographic separations were running at 12 $\mu\text{L}/\text{min}$ on an ACQUITY M-Class System equipped with a BEH C18 column (130Å, 1.7 μm , 300 μm * 100 mm). The chromatograms were acquired in MRM mode on a SCIEX 7500 system, with transitions of the signature peptides preselected by empirical validation accessing public databases. The endogenous protein biomarker was quantitated with external standard method using surrogate matrices. **Results:** Systematic optimization was implemented regarding immunocapture recovery, digestion efficiency, chromatographic resolution and MS detectability. Among all parameters, beads-to-protein ratio, enzyme-to-substrate ratio, signature peptide selection, and chromatographic flowrate were most impactful for sensitivity improvement, while surrogate matrices selection was critical to assure quantification precision and accuracy. The applicability and figure of merits of the developed workflow were showcased with bioanalysis of TL1A in NHP serum in general toxicology studies, to monitor the immunomodulation of DR3-TL1A pathway upon dosage. The LLOQ was achieved at 50 pg/mL with linearity across three orders of magnitude. The precision, accuracy as well as method robustness have been validated fully adhering GLP regulatory guidance. **Conclusions:** A streamlined bioanalytical workflow has been established combining immunocapture and microLC-MS/MS towards highly sensitive protein biomarker quantitation in biological matrices, with significantly reduced analytical turnaround time and reagent costs as well as improved method robustness. The applicability and advantages have been demonstrated in real-world general toxicological studies with full GLP compliance. It also suggests great potential in multiplexing, to simultaneously quantify a larger biomarker panel in "single-shot", providing in-depth physiological information towards preclinical development.

PS 4633 Arsenic & Zinc Exposure: Correlation with Diabetes and Hypertension in Doña Ana County Well-Water Users

W. R. Stokely¹, S. Majidi², S. H. Munson-McGee³, M. J. Campen⁴, and H. H. Rahman².

¹Burrell College of Osteopathic Medicine, Las Cruces, NM; ²New Mexico State University, Las Cruces, NM; ³Data Forward Analytics LLC, Las Cruces, NM; and

⁴University of New Mexico, Albuquerque, NM.

Background and Purpose: Arsenic is a toxic chemical that occurs naturally as a mineral in the earth's crust. Drinking water in New Mexico (NM) contains some of the highest levels of naturally occurring arsenic in the U.S. In NM, approximately 400,000 residents (20%) rely on private wells for their water supply. Among all counties in NM, Doña Ana has the highest average arsenic concentration at 17.3 $\mu\text{g}/\text{L}$, with 50.3% of samples exceeding the Environmental Protection Agency (EPA) Maximum Contaminant Level (MCL) of 10 $\mu\text{g}/\text{L}$. Zinc, an essential micronutrient, plays a key role in many biological processes, including immune function and protection against toxic chemicals through its antioxidant and anti-inflammatory properties. Areas with high arsenic exposure from groundwater often overlap with regions at risk of zinc deficiency. Both arsenic exposure and zinc deficiency share similar features such as increased oxidative stress and inflammation and have been linked to chronic conditions like cardiovascular disease, diabetes, and kidney disease. The biomarker 8-hydroxy-2'-deoxyguanosine (8-OHdG) is a recognized indicator of oxidative damage. The purpose of this study is to assess households with private wells and examine the presence of arsenic and zinc, as well as their correlation with diabetes and hypertension, focusing on the interaction between arsenic and zinc in Doña Ana County, NM. **Methods:** The research team recruited well-water users in Doña Ana County through online well-water data, household visits, social media, and health fairs. After obtaining informed consent, participants completed a questionnaire capturing demographics, disease history, and water-related information. Urine samples were collected in wide cups and split into two 15 mL conical tubes. One tube was stored on dry ice at -20°C for 8-OHdG analysis, while the second tube, along with a 15 mL well-water sample, was kept on ice for metal analysis. Adults (≥ 18 years) using well water in Doña Ana County, NM, were included. Urinary and well-water As and Zn were measured using inductively coupled plasma mass spectrometry (ICP-MS), and urinary 8-OHdG was analyzed using a commercial ELISA kit. Laboratory analyses were supported by P20GM130422. For statistical analysis, logistic regression was employed to examine the associations between the concentrations of these biomarkers and the prevalence of hypertension and diabetes, adjusting for relevant covariates such as age, gender, ethnicity, education, income, alcohol use, smoking status, and BMI. Statistical significance was defined as a P-value < 0.10. All statistical analyses were conducted using R software. **Results:** A total of 111 participants were analyzed, 62% of whom were women. Hypertension prevalence was 35% among women and 40% among men, and diabetes was reported in 16% of women

and 24% of men. Significant differences were observed in urinary As, Zn, well-water As, and urinary 8-OHdG levels by hypertension and diabetes status. Hypertensive smokers showed higher urinary Zn (OR = 3.15, 95% CI: 1.09-16.05), and hypertensive non-smokers had slightly elevated Zn levels (OR = 1.06, 95% CI: 1.01-1.15). Among women, hypertension was inversely associated with urinary As (OR = 0.93, 95% CI: 0.85-1.00). Hypertensive individuals with normal/low BMI were less likely to have elevated urinary 8-OHdG (OR = 0.44). Diabetic Hispanic participants had lower urinary Zn (OR = 0.56, 95% CI: 0.25-0.92). Diabetics aged ≥ 64 had higher odds of elevated well-water As exposure (OR = 1.32, 95% CI: 1.02-1.90). Diabetic males had more than twice the urinary 8-OHdG levels of non-diabetic males (OR = 2.16, 95% CI: 1.12-5.16). Diabetic college graduates also showed higher urinary 8-OHdG (OR = 1.23, 95% CI: 0.99-1.61). **Conclusions:** This cross-sectional study limits the ability to establish causal relationships between arsenic-zinc interactions and hypertension or diabetes. A larger sample size is needed to improve statistical power, and further research is warranted to confirm these findings. This project was supported by a subaward from the Mountain West Clinical and Translational Research Infrastructure Network (MW CTR-IN), funded by the National Institute of General Medical Sciences (NIGMS), NIH, under award number U54GM104944 (funded 10/27/2022).

PS 4634 Associations Between Serum PFAS Profiles and Glaucoma: Evidence for a Branched Amide PFAS Effect in U.S. Adults

J. Asowata¹, J. Roberson¹, A. Lopez-Ramirez¹, A. Bauer¹, D. Jenness¹, A. Ostrovsky², J. Cooke-Bailey¹, and T. Woodlief¹. ¹East Carolina University, Greenville, NC; and ²East Carolian Health, Greenville, NC.

Background and Purpose: Per- and polyfluoroalkyl substances (PFAS) are a diverse class of persistent chemicals with variable chain lengths, functional groups, and branching patterns that influence bioaccumulation and cellular uptake. Longer-chain PFAS (PFDeA, PFNA) exhibit higher lipophilicity, suggesting greater accumulation in lipid-rich retinal tissues. Sulfonic acid-terminated PFAS (PFOS, PFHxS) display higher plasma protein binding, potentially extending systemic exposure. Based on structure-activity relationships reported for PFAS, we hypothesize that Me-PFOA-AcOH, a branched amide PFAS, may exhibit enhanced membrane permeability and increased uptake in retinal ganglion cell (RGC)-relevant tissues. We focused on PFAS structural features to hypothesize how these chemicals may interact with ocular tissues and then evaluated their associations with glaucoma using epidemiologic data from a U.S. adult cohort. Specifically, six PFAS (PFOA, PFOS, PFHxS, Me-PFOA-AcOH, PFDeA, and PFNA) were examined. **Methods:** PFAS structural properties were compared with known toxicokinetic and bioactivity profiles from the literature, including lipophilicity, plasma protein binding, membrane permeability, and oxidative stress potential. Epidemiologic data from 1,837 adults in NHANES (2005-2007) were analyzed to identify PFAS with higher serum levels among participants with glaucoma, and weighted quantile sum (WQS) regression determined the relative contribution of each PFAS to glaucoma. **Results:** Epidemiologic analyses showed that Me-PFOA-AcOH and PFOS levels were higher in participants with glaucoma. Me-PFOA-AcOH had the strongest association with glaucoma (adjusted OR 1.67, 95% CI 1.34-2.09, $P < 0.001$) and contributed 41.4% to the overall PFAS mixture effect, while PFHxS contributed 20%. Cubic spline modeling revealed a consistent dose-dependent increase the odds of glaucoma with Me-PFOA-AcOH exposure. **Conclusions:** Branched amide PFAS such as Me-PFOA-AcOH appear to pose the greatest association, consistent with both structural predictions and observed epidemiologic associations. Our theory posits that structural features, including chain length, functional group, and branching, correlate with potential oxidative stress, mitochondrial impairment, and neuroinflammatory signaling in RGCs. These structure-activity relationships provide a framework for understanding PFAS-induced ocular toxicity and prioritizing compounds for further mechanistic studies.

PS 4635 Early GDF15 Elevation as a Predictive Biomarker in a Long-Latency Model of Doxorubicin-Induced Cardiomyopathy

A. Kumar, K. Lebarbenchon, J. Yi, and K. Gabrielson. Johns Hopkins University, Baltimore, MD.

Background and Purpose: Doxorubicin (Dox), an anthracycline chemotherapeutic, is widely used in the treatment of pediatric and adult cancers. Dox is known to cause dose-dependent cardiotoxicity that can progress to heart failure. Early detection of cardiac injury remains a major clinical problem. Growth differentiation factor-15 (GDF15) is emerging as a promising biomarker in this context. GDF15 is a stress-responsive cytokine of the TGF- β superfamily that is upregulated in the heart under oxidative stress and injury conditions. We investigated circulating and myocardial GDF15 as a predictive biomarker of Dox-induced cardiotoxicity in male and female rats across acute and chronic time-course models and examined its relationship with echocardiographic measures of cardiac function (fractional shortening, FS%). **Methods:** Male and female Sprague-Dawley rats (5-7 weeks old) were administered doxorubicin (3 mg/kg, or saline, intrajugular vein injection, 2 injections 2 weeks apart). An acute cohort was euthanized 24hr, 48hr and 72hr after doxorubicin treatment and plasma frozen. The chronic cohort (capturing the longer-latency to cardiomyopathy- up to 12 months) underwent echocardiography (Vevo 3100) until FS declined to 30% or less (50% of control values). Plasma was collected for ELISA-

based quantification of the GDF15 assay. At the time of euthanasia for our earlier pilot studies, fractional shortening data were correlated with GDF15 levels to determine biomarker sensitivity to cardiac dysfunction. Due to the pandemic, 25 rats were evaluated at euthanasia, approximately 6 months post treatment. For correlation of the last echo FS% to the last plasma GDF15, data were expressed as mean $\pm$ SD and analysed by one-way ANOVA and Pearson correlation. In a second rat study with monthly serial analysis of 54 rats (22 saline and 32 doxorubicin-treated) (done in 3 separate cohorts), blood was sampled monthly and correlated with echocardiography data. Specific data were used for predictive values from data collected from months 1 and 2 post chemotherapy using the following characteristics: early FS% decline, early GDF15 increase, sex, and weight values at the last doxorubicin treatment. Using this data logistic regression model was compared to Random Forest and XGBoost classifiers in predicting the 7-month HF outcome. Model performance was evaluated by area under the ROC curve (AUC), Brier score, calibration plots, decision curve analysis (DCA), and DeLong tests for AUC differences. Feature importance was examined via permutation testing, SHAP values, and accumulated local effects (ALE) plots. **Results:** In the first chronic cohort study, doxorubicin-treated rats exhibited a marked reduction in FS% compared to saline controls (mean FS: $\approx$ 35% vs. $\approx$ 57%, $p < 0.001$). Correspondingly, plasma GDF15 levels measured at euthanasia were significantly elevated in Dox groups, showing an inverse correlation with FS ($R^2 = 0.71$). Protein and RNA studies revealed that myocardial levels of GDF15 were higher in Dox treated rats. Ingenuity Pathway Analysis of RNA sequencing revealed activation of TP53 and other stress-response genes linked to GDF15 upregulation. In a second chronic multiple cohort study, blood collection and echocardiography were performed monthly starting one month after the last injection of doxorubicin. GDF15 increases (one month 200 pg/mL) preceded visible cardiac dysfunction, suggesting predictive potential in early sampling. Elevated GDF15 concentrations were also observed within 24hrs, 48hrs and 72hrs of treatment (800- 1000pg/mL), indicating an acute stress response. For the machine learning models, key predictors included early elevation in GDF15, early decline in FS (Δ FS), body weight, and sex. An interaction between Δ FS and GDF15 was noted, whereby rats with both an early FS drop and high GDF15 were at markedly elevated HF risk. Random Forest model showed the highest AUC at 97. **Conclusions:** In this doxorubicin cardiotoxicity animal model with a long latency to heart failure, machine learning substantially improved the early prediction of HF, highlighting the complementary value of stress biomarkers (GDF15) and functional imaging (FS) for risk stratification. Continued validation of GDF15 across sexes and timepoints will strengthen its utility for cardiotoxicity risk stratification and preclinical drug safety screening within the broader context of toxicological evaluation.

PS 4636 Red Blood Cell-Derived Extra Cellular Vesicles Serve as Biomarkers of α -Synuclein Pathology and Neuroinflammation in Neurotoxicant-Linked Parkinson's Disease

M. Samidurai, C. Janarthanam, H. Jin, G. Zenitsky, V. Anantharam, A. Kanthasamy, and A. Kanthasamy. University of Georgia, Athens, GA.

Background and Purpose: Environmental toxicants are known to induce protein misfolding, oxidative stress, and mitochondrial dysfunction, with certain herbicides strongly associated with an increased risk of Parkinson's disease (PD). Red blood cells (RBCs) are a major peripheral reservoir of α -synuclein (α Syn), can release extracellular vehicles (EVs) carrying bioactive cargo that may reflect systemic stress responses. We hypothesized that exposure to Agent Orange (AO), a dioxin-containing herbicide historically associated with Parkinsonian outcomes, promotes the release of α Syn-enriched RBC-derived EVs with enhanced aggregation propensity and proinflammatory activity. Thus, this study investigates AO-mediated alterations in RBC-EVs, evaluates their α Syn seeding capacity, and examines their contribution to microglial inflammation. Given their stability and accessibility in circulation, RBC-EVs represent a promising minimally invasive biomarker for early detecting α Syn pathology, monitoring disease-relevant processes, and elucidating mechanistic links between environmental exposures to neurodegenerative disease risk. **Methods:** RBCs from healthy individuals were obtained from GRIFOL bio supplies and exposed to acute dose of 100 μ M AO for 24 h, and EVs were isolated using differential ultracentrifugation or EXODUS nanofiltration. EV purity and concentration were verified via nanoparticle tracking analysis (NTA) and nanoflow cytometry from EV-specific dye. Total and aggregated α Syn content was quantified using Meso Scale Discovery assay and AlphaLISA assays. α Syn aggregation and seeding kinetics were assessed by Thioflavin T fluorescence assays as described in our publications. Nano-flow cytometry and super-resolution microscopy were used to characterize aggregated α Syn (α Synagg)-positive EVs. RBC-EVs isolated from AO-exposed veterans and age-matched healthy controls were analyzed in a blinded manner to quantify α Synagg-positive EV subsets and assess seeding activity. Microglial inflammatory responses to AO-exposed RBC-EVs were measured by quantifying TNF- α , IL-6, and IL-1 β levels *in vitro*. **Results:** AO exposure markedly increased the release of RBC-EVs enriched in both total and aggregated α Syn. Nano-flow cytometry and super-resolution imaging revealed elevated α Synagg-positive EVs and higher EV density in AO-treated samples. Seeding activity assays demonstrated accelerated α Syn fibrillization and potent seeding activity in EVs derived from AO-exposed RBCs, whereas control EVs failed to induce detectable aggregation. EXODUS-purified EVs exhibited stronger seeding activity than ultracentrifugation-derived EVs, indicating improved recovery of bioactive vesicles and reduced heme contamination. Blinded analyses of clinical samples revealed that $\sim$ 70% of AO-exposed individu-

als displayed an expanded α Synagg-positive EV subset (~15-22% of total EVs) and enhanced seeding activity relative to healthy controls. *In vitro*, human C20 microglia treated with AO-exposed RBC-EVs showed significant upregulation of TNF- α , IL-6, and IL-1 β , confirming that toxicant-exposed RBs release EVs capable of mediating robust proinflammatory activation. **Conclusions:** AO exposure enhances the release of RBC-EVs enriched in aggregation-competent α Syn capable of seeding pathological fibril formation and inducing microglial inflammation. EXODUS-based ultra-purification improves detection of these bioactive vesicles. Collectively, these findings identify RBC-EVs as a mechanistic link between environmental toxicant exposure and α Syn pathology. It also highlights their potential as blood-based biomarkers for early detection and monitoring of exposure-driven neurodegenerative processes.

PS 4637 Stable Copper Isotope Ratios as a Biomarker of Aflatoxin-Induced Hepatocellular Carcinoma

D. van de Laar¹, F. Marcantontio¹, N. Johnson¹, and J. Groopman². ¹Texas A&M University, College Station, TX; and ²John Hopkins University, Baltimore, MD.

Background and Purpose: This project applies isotope metallomics, the blend of geochemistry and biomedicine, to investigate Cu fractionation in the context of hepatocellular oxidative stress resulting from exposure to the known hepatocarcinogen, aflatoxin B₁ (AFB₁). Cu is transported to hepatocytes by metalloproteins (e.g., ATP7b) which are upregulated during oxidative stress. We explore differences in transport and accumulation of ⁶⁵Cu and ⁶³Cu and present results using delta notation ($\delta^{65}\text{Cu}$ (‰)) in reference to a certified Cu isotopic standard (NIST SRM 976). $\delta^{65}\text{Cu}$ values in hepatic tissue and serum may shift in response to different levels of oxidative stress, and therefore act as a prognostic biomarker of liver health. Establishing sensitive biomarkers for hepatocellular carcinoma (HCC) is crucial for early detection against a world leader in cancer mortality. **Methods:** We leveraged existing liver and serum samples from rats ranging from 43-90 weeks old, which were part of a lifetime cancer bioassay. There were two groups in this sample set; group one (AFB₁) were orally dosed with aflatoxin and a vehicle solution. Group two (AFB₁ + CDDO-Im) were dosed with aflatoxin and a potent Nrf2 activator, CDDO-Im, as a chemoprotective agent. A high percentage of rats in the AFB₁ group (22/23 rats) developed HCCs, 96% incidence. CDDO-Im provided complete protection (20/20 rats) against liver cancer. Hepatic tissue (tumor and non-tumor) and sera were digested, and Cu was purified using AG-MP1 anion exchange resin in a class 1000 clean lab. Cu isotope ratios of all samples were measured by MC-ICP-MS in triplicates, and reproducibility was additionally verified with a secondary internal standard (ESPI, $\delta^{65}\text{Cu}_{\text{NIST976}} = +0.100 \pm 0.007\text{‰}$ (2SE, n = 36)). All standards and samples were doped with a certified ⁶⁹Ga/⁷¹Ga standard (NIST SRM 994) to correct for internal fractionation. **Results:** Comparison of $\delta^{65}\text{Cu}$ values between healthy hepatic tissue samples from the CDDO-Im group (n=9) and tumorous tissue samples from the AFB₁ group (n=17) showed an enrichment of ⁶⁵Cu in tumorous tissue. We find a significant pairwise distinction between healthy tissue (avg. $\delta^{65}\text{Cu}_{\text{NIST976}} = -0.58\text{‰}$) and tumorous tissue (avg. $\delta^{65}\text{Cu}_{\text{NIST976}} = -0.33\text{‰}$) at $p = 0.021$. We additionally measured tumor-adjacent, healthy tissue from individuals with HCC and found no significant trend. **Conclusions:** Our preliminary results suggest preferential transport/accumulation of ⁶⁵Cu in the site of hepatocellular oxidative stress resulting from aflatoxin exposure. Cu fractionation may be due to redox reactions as metalloproteins use Cu to catalyze the stabilization of reactive oxygen species. We anticipate reporting the results of serum samples (work ongoing) to reflect a mass-balanced depletion of ⁶⁵Cu when individuals have HCC. This work demonstrates interdisciplinary collaboration between geochemistry, toxicology, and biomedicine and may yield a powerful new biomarker for HCC.

PS 4638 Implication of route of blood collection on rodent clinical pathology and plasma drug level output

A. Banerjee, M. Frey, M. Lindeblad, and G. Camarillo. University of Illinois at Chicago, Chicago, IL.

Background and Purpose: Blood collection in rodents is a common practice employed throughout preclinical safety and efficacy research to monitor health status and as a typical biochemical endpoint indicating systemic and organ specific changes. Historic control values of routine biochemical parameters are maintained in the laboratory as standard ranges for comparison. As a part of this study we compared the key parameters of clinical pathology, hematology and clinical chemistry, and pharmacokinetics evaluation when samples were withdrawn via retrobulbar plexus (RO) and sublingual (SL) routes (with and without clearing for saliva) blood collection. **Methods:** Standard methods for sample collection were utilized in Sprague Dawley Rats for RO blood collection under CO₂/O₂ anesthesia (followed by propacaine administration for pain management). Blood was also withdrawn from the sublingual vein without the need for anesthesia. In a separate group of rats sublingual blood collection was performed following drying of the oral cavity using a cotton swab prior to each sampling for clinical pathology parameters. For the effect on pharmacokinetics, blood was withdrawn via both routes for plasma drug level comparison at three timepoints. **Results:** Absolute and percent leucocytes, absolute lymphocyte count, hemoglobin, WBC and MCV values were significantly different between RO and SL bleeds without swabbing. However, following swabs for

saliva reduction, absolute and percent basophils and eosinophils and MCHC values were significantly ($p < 0.05$) different between RO and SL. RBC values showed statistically significant difference ($p < 0.05$) between RO and SL with or without swabbing. Glucose, total bilirubin and AST values showed statistically significant difference ($p < 0.05$) between RO bleeding and SL with and without swabbing. Albumin, globulin and total protein showed significant difference from RO levels when SL was used without swabbing. Plasma levels of the test drug (A) in samples collected from sublingual route was consistently lower in all animals tested at all timepoints (0.25, 1 and 8 hrs. post dose) and up to a 21% lower was noted following SL blood collection at the earliest time point. These samples were not collected following oral swabbing. **Conclusions:** Oral swabbing made the SL data more comparable to the RO data for both hematology and clinical chemistry. Samples collected through SL appeared with mild to moderate levels of hemolysis at most instances. AST and total bilirubin were both analyzed using assays that are impacted by hemolysis and the levels may have been falsely elevated following SL bleeds due to hemolysis. More samples will be run for comparison between the routes to choose the parameters most likely to be acceptable through SL route. The SL route was a more efficient and less invasive technique and did not require the use of anesthesia for routine analysis.

PS 4639 Analytical method performance evaluation and its application to breath analysis

O. Rivera, T. Perera, and J. Young. US Food and Drug Administration, Silver Spring, MD. Sponsor: B. Oktem

Background and Purpose: Confident identification of human breath biomarkers lacks consistency across research laboratories, which may be due to methodological differences between research groups. This difference may be due to consistency in collection procedures, collection containers, storage container and temperature as well as lack of agreement on selection of breath reference standards for analytical methods used. Therefore, an approach was developed to ensure data from disparate laboratories conducting breath research can be reliably compared and validate the chemicals being identified or missed. **Methods:** This study developed a novel framework for assessing and comparing the Gas Chromatography-Mass Spectrometry (GC-MS) detectable chemical space by integrating Abraham solubility parameters of different stationary phases. **Results:** Retention and response prediction models were established to probe the breath chemicals for a detectable space and establish method comparison and performance parameters. A breath chemical space consisting of 1164 breath related volatile organic compounds (VOC's) has been established based on an in-depth literature search. From this chemical space VOC reference standards were carefully selected to represent over 95% of the functional groups present in the breath chemical space based on cumulative representation. We have developed a DB-624 and a PEG stationary phase model which allows for detection of additional compounds using analytical methods. **Conclusions:** Our established stationary phase models may aid in establishing method performance parameters for expanding detectability of specific regions within the breath VOC space.

PS 4640 Associations Between Occupational and Environmental Metal Exposure, Genotoxic Effects, and Haematological Alterations Among Nigerian Bronze Casters-Biomarker Patterns and Health Outcomes

O. G. Igharo¹, I. H. Igbinosa¹, B. O. Eiya¹, J. O. Osakue¹, E. L. Igharo¹, J. O. Osunbor¹, I. A. Aruomaren¹, C. F. Harrington², H. B. Osadolor¹, and J. I. Anetor³. ¹University of Benin, Ugbowo, Benin City, Nigeria; ²SAS Trace Elements Centre, Surrey Research Park, Royal Surrey NHS Foundation Trust, United Kingdom; and ³University of Ibadan, Agbowo, Ibadan, Nigeria.

Background and Purpose: Nigerian bronze casters are routinely exposed to hazardous metals through traditional casting practices, particularly in underregulated environments, posing potential environmental and public health risk. While toxic metal exposure is widely recognized, its link to genotoxicity, immune suppression and haematological alterations in this population remains underexplored. This study investigates toxic metal exposure, associated biomarker changes, and potential health risks in Nigerian bronze casters. **Methods:** A cross-sectional study was conducted with 200 participants from Benin City, Nigeria, comprising 100 Benin Bronze Casters (BBC), 40 environmentally exposed individuals (EC), and 60 unexposed participants (UP). Blood samples were analyzed for toxic metal levels using Inductively Coupled Plasma Mass Spectrometry (ICP-MS). An Enzyme-Linked Immunosorbent Assay (ELISA) was employed to assess biomarkers such as mutant p53 (m-p53), 8-hydroxy-2'-deoxyguanosine (8-OHdG), DNA methyltransferase-1 (DNMT-1), and Siglec-3 (CD33), while haematological indices were analyzed using a 3-part differential analyzer. **Results:** Bronze casters exhibited significantly elevated blood levels of cadmium, lead, mercury, and arsenic compared to the control group. Genotoxic biomarker m-p53 was upregulated in BBC and EC, while DNA methyltransferase-1 (DNMT-1) activity was reduced. Elevated oxidative DNA damage marker 8-OHdG and altered haematological indices suggested potential haematotoxicity. Siglec-3 (CD33) expression was notably higher in BBC (340.20 ± 19.35 pg/mL) compared to UP (233.00 ± 14.63 pg/mL), alongside significantly reduced WBC and lymphocyte counts. **Conclusions:** These findings reveal a heightened burden

of toxic metals in Nigerian bronze casters, with evidence of genotoxic, epigenotoxic, and hematological risks. Of particular note is the elevated CD33 levels, which potentially indicate an increased risk of inflammatory stress and immune dysfunction. This study underscores the need for enhanced environmental and occupational safety measures, biomonitoring protocols, and public health interventions to mitigate these risks. This may enhance the sustainability and economic viability of the historic bronze casting vocation in Nigeria.

PS 4641 Identification of transcriptional biomarkers for major molecular initiating events in rat liver carcinogenesis

K. K. Venneman¹, M. Kotulkar¹, D. Paine-Cabrera¹, C. A. Mitchell², K. Q. Tanis³, J. C. Corton⁴, and U. Apte¹. ¹University of Kansas Medical Center, Department of Pharmacology, Toxicology, and Therapeutics, Kansas City, KS; ²Health and Environmental Sciences Institute, Washington, DC; ³Merck & Co., Inc., Rahway, NJ; and ⁴Center for Computational Toxicology and Exposure, U.S. Environmental Protection Agency, Research Triangle Park, NC.

Background and Purpose: The two-year rodent bioassay has long served as the gold standard of chemical carcinogenicity testing. However, calls are growing for reevaluation of the effectiveness of the two-year bioassay based on numerous scientific, ethical, and practical concerns. There is also mounting pressure to move away from the use of animals in research in line with the Replacement, Reduction, and Refinement (3Rs) principles and increased support for New Approach Methodologies (NAMs). Consistent with these efforts, the Health and Environmental Sciences Institute (HESI) eSTAR Carcinogenomics Workgroup has adopted an AOP framework of key hepatic molecular initiating events (MIEs) and is developing biomarkers designed to detect MIE modulation in short-term rat studies to inform on tumorigenic risk. To this end, this study focuses on identifying specific gene expression changes after activation of critical nuclear receptors in the liver for each MIE, including Aryl Hydrocarbon Receptor (AhR), Constitutive Androstane Receptor (CAR), Pregnane X Receptor (PXR), Peroxisome Proliferator-Activated Receptor Alpha (PPARα), Estrogen Receptor Alpha (ERα), and tumor suppressor protein p53 using wild type (WT) and knockout (KO) rats on a Sprague-Dawley background. **Methods:** The study included male WT and KO rats corresponding to each MIE, except for ERα, which also included female rats. Three known activators were chosen for each MIE and administered at high doses known to exceed tumorigenic activation levels. Compounds were suspended in carboxymethylcellulose sodium (CMC Na) and administered to rats (n=5 per group) by oral gavage once daily for five days. Controls were only treated with vehicle. Rats were euthanized and samples collected on the sixth day. RNA-seq was performed on total RNA extracted from liver tissue, and differentially expressed genes (DEGs) between agonist and corresponding vehicle samples were assessed. In addition, Gene Set Enrichment Analysis (GSEA) was conducted to evaluate associated pathway changes. **Results:** Comparative analyses of DEGs induced by the three activators of each MIE were conducted to identify genes consistently modulated across treatments. In addition, comparison between WT and KO treated rats identified the respective transcription factor-dependent DEGs for each MIE. GSEA further identified common pathways and leading-edge (LE) genes associated with each of the compounds in an MIE-dependent manner. **Conclusions:** For each MIE, several genes were identified as regulated by all three activators in WT but not in KO rats, suggesting these genes could serve as MIE-dependent biomarkers. The sizes and membership of these gene sets were consistent with known MIE biology, which was supported by GSEA analysis. Collectively, these analyses identify candidate genes that can be used to support the development and validation of MIE-specific biomarkers to facilitate earlier detection of liver tumorigenic risk in short-term rat studies.

PS 4642 Persistent transcriptomic changes following repeated exposure to wildfire smoke in non-human primate airway epithelial cells

E. Holmes, A. P. Brown, S. P. Elston, C. M. Royer, and H. Ji. University of California Davis, Davis, CA.

Background and Purpose: Exposure to wildfire smoke poses significant public health concerns due to its association with adverse respiratory effects. Inhalation of wildfire smoke particulate matter can lead to airway inflammation, oxidative stress-induced lung injury, impaired mucociliary clearance, and exacerbation of respiratory conditions such as asthma and chronic obstructive pulmonary disease (COPD). Despite these well-documented health risks, the molecular mechanisms underlying the respiratory effects of wildfire smoke exposure remain incompletely understood. In this study, we utilized transcriptomic and epigenomic analyses to investigate how exposure to simulated wildfire smoke influences the expression patterns of gene networks in differentiated rhesus tracheobronchial epithelial cells. **Methods:** Primary tracheobronchial epithelial cells from four adult female animals (ages 3-14yrs) were cultured under air-liquid interface conditions. They were exposed to lab-simulated wildfire smoke (WS) or filtered air (FA) 6 hours per day, either for 1 day, for 5 consecutive days, or for 5 consecutive days followed by a one-week recovery period. The PM concentration was 242.8 µg/m³ for the single-day exposure and averaged 166.66 µg/m³ over 5-day exposure. RNA sequencing was performed at all three timepoints to characterize transcriptomic alterations and differentially expressed genes (DEGs) between WS- vs FA-exposed cells were identified using

DESeq2. Gene expression data were also analyzed using WGCNA (Weighted Gene Co-expression Network Analysis, using WGCNA package in R) to identify modules of co-expressed genes and relate these modules to WS exposure. Whole-genome bisulfite sequencing was performed on the cells with 5-day exposure and differentially methylated regions (DMRs) between WS- vs FA-exposed cells were identified using DMRichR. Correlations between gene expression and DNA methylation were performed. Representation of lung disease-associated transcriptomic signatures among exposure-induced changes were evaluated. Ingenuity Pathway analysis was used to identify enriched pathways among DEGs, genes annotated to DMRs, and gene modules associated with exposures. **Results:** Our analysis identified 39, 615 and 680 WS associated DEGs at three time points, respectively. IPA revealed significant enrichment for Aryl Hydrocarbon Receptor (AHR) Signaling at the first two time points, and pulmonary healing signaling, TGF-β signaling, and regulation of the EMT by growth factors at the recovery time point. We also found three modules with significant correlations with WS exposure, with the most significantly correlated module enriched for genes in epithelial remodeling, inflammation/immune signaling, epigenetic regulation, and apoptosis/cell cycle control. 8,045 differentially methylated regions (DMRs) were detected, located proximal to genes with significant enrichment for xenobiotic metabolism, cytokine signaling, neuroinflammation signaling, pulmonary healing signaling, and regulation of the EMT by growth factors, which highlights potential regulatory mechanisms underlying the molecular response to WS exposure. While global correlations between DNA methylation and gene expression were limited, subsets of genes involved in transcriptional regulation and respiratory disease showed significant associations. Lastly, we found that exposure-induced transcriptomic signatures overlapped with those of chronic respiratory diseases, particularly COPD and idiopathic pulmonary fibrosis. **Conclusions:** Our study demonstrates that repeated wildfire smoke exposure provokes persistent transcriptional and epigenetic reprogramming in the airway epithelium involved in the disruption of pathways central to inflammation, repair, and remodeling. These findings extended our previous work on early-life exposures and highlighted the complexity of airway epithelial responses to repeated smoke inhalation. Together, these data underscored the potential for WS to leave a lasting molecular imprint on the airway epithelium, with important implications for respiratory health in populations exposed to wildfire events.

PS 4643 Ancestral Bisphenol A Exposure Resulted in Sexually Dimorphic Liver Disease, Mitochondrial Complex Suppression, and Gene-Body CpG Island Methylation

S. Anand, S. Chakraborty, and R. K. Bhandari. University of Missouri Columbia, Columbia, MO.

Background and Purpose: Environmental stressors can produce heritable phenotypes through germline-mediated epigenetic alterations, yet the underlying mechanisms through which these changes drive transgenerational disease are not well defined. Bisphenol A (BPA), a widespread endocrine disruptor, is linked to metabolic liver disease and offers a relevant model for studying inherited risks without direct exposure in descendants. Using medaka, a vertebrate model with established BPA transgenerational responses, this study examined the unexposed F2 offspring derived from BPA-exposed F0 ancestors to assess sex-specific liver disease outcomes. F2 medaka developed sexually dimorphic NAFLD/MAFLD phenotype characterized by more severe macrovesicular steatosis in females and milder microvesicular changes in males. The objective was to mechanistically define these sex-specific disease manifestations by profiling hepatic transcriptomes and epigenomes of the F2 livers, thereby linking ancestral exposure to divergent molecular programs in female versus male livers. **Methods:** Hepatic transcriptomes from F2 females and males were analyzed by RNA-seq after QC with fastp, STAR alignment to the medaka reference genome, and DESeq2 differential expression (FDR < 0.05), followed by KEGG pathway and gene-set enrichment, and comparison to a published 25-gene advanced NAFLD signature. Additionally, whole-genome bisulfite libraries were prepared with NEBNext Ultra II FS and processed via nf-core/methylseq (Bismark) to obtain CpG-level coverage and methylation profiles. Each group comprised three biological replicates from the BPA lineage and matched F2 controls derived from F0 unexposed ancestors. **Results:** In the unexposed F2 generation medaka, ancestral BPA exposure resulted in a strong female-biased liver transcriptomic response, with 5,376 DEGs in females versus 306 in males, and only female DEGs enriched for human NAFLD, including concordant changes in the markers *HSD17B14*, *AKR1B10*, and *RGS4*. Female livers showed suppression of core metabolic pathways including PPAR, AMPK, insulin signaling, cholesterol metabolism, and fatty acid degradation, while males exhibited modest downregulation centered on steroid and terpenoid backbone biosynthesis. All mitochondrially encoded subunits of oxidative phosphorylation, spanning Complex I to Complex V, were downregulated only in females, indicating impaired oxidative phosphorylation. Key metabolic transcription factors (TFs) were repressed in a sex-specific manner, with *SREBF1* silenced in males and *HNF4A* in females, accompanied by promoter hypermethylation and concordant repression of their target genes. Whole genome methylome profiling revealed a substantially larger burden of liver differentially methylated regions (DMRs) in females with only limited overlap between sexes. DMRs in both sexes were preferentially enriched in CpG islands, exons, and 3' UTRs, whereas core promoter DMRs showed little pathway signal, indicating that promoter proximal DMRs likely played a minor role in gene regulation compared with exon and 3' UTR. Liver CpG island methylation changes localized mainly to gene bodies, with a greater burden in females, pointing to regula-

tion through gene body architecture rather than promoter sites. Female DMRs were selectively enriched for liver centric metabolic and pro fibrotic programs such as TCA cycle, carbon metabolism, TGF beta, and Notch signaling, consistent with advanced liver disease, whereas males showed fewer endocrine or signaling oriented pathways, including cortisol synthesis and oxytocin signaling, that are less directly tied to hepatic metabolic injury. **Conclusions:** Ancestral BPA exposure produced sex-divergent liver disease in unexposed medaka offspring: females displayed advanced NAFLD-like transcriptional programs with suppression of core metabolic pathways and coordinated downregulation of mitochondrial OXPHOS complexes I-V, whereas males showed a muted response. Epigenomic profiling revealed substantially more DMRs in females, enriched in CpG islands within gene bodies, exons, and 3' UTRs, implicating DNA methylation in sex-specific metabolic dysregulation with minimal changes at promoters.

PS 4644 Inorganic Arsenic Reprograms a Placental miRNA-mRNA Axis Governing Structural and Stress Adaptation

V. Lyu¹, B. Qian¹, J. Ranieri¹, D. Rajasundaram¹, Y. Sadovsky², A. Barchowsky¹, and W. Tang¹. ¹University of Pittsburgh, Pittsburgh, PA; and ²Stanford University, Palo Alto, CA.

Background and Purpose: Chronic exposure to inorganic arsenic (iAs) in drinking water remains a primary global public-health concern and is linked to pregnancy complications and long-term disease risk in offspring. The placenta, a key mediator of nutrient exchange and endocrine and immune signaling, is highly sensitive to environmental insults during early development. Proper placental function depends on coordinated molecular programs governing structural maintenance, vascular remodeling, and stress adaptation. However, the mechanisms by which low iAs exposure perturbs these processes remain poorly understood. We hypothesize that the mechanisms for iAs-promoted dysfunctional reprogramming of placental development involve disruption of placental miRNA-mRNA regulatory networks that orchestrate post-transcriptional developmental regulation. **Methods:** Female C57BL/6J mice were given 10 ppb sodium arsenite in drinking water two weeks before conception through embryonic day 16. Placental miRNA and mRNA expression profiles were integrated using sparse partial least squares (sPLS) for pairwise cross-omics correlation and the DIABLO framework for supervised multi-omics integration. Correlated molecular pairs ($|r| > 0.8$) were visualized by Circos plots, and enrichment of mRNA partners was used to infer pathways represented within each miRNA module. **Results:** Multivariate integration revealed a distinct molecular signature separating iAs-exposed from control placentas, driven by coordinated downregulation of five miRNAs, miR-450a, miR-467d, miR-92a, miR-15b, and miR-295. These miRNAs formed a tightly connected repressive axis, with correlated mRNA targets enriched for adhesion, mitochondrial, and oxidative-stress pathways, suggesting coordinated alterations in placental structural integrity and stress-adaptation programs. Within this network, miR-92a and miR-15b emerged as nodal regulators negatively correlated with Itga5 and other adhesion-related genes, implicating altered placental-endothelial interactions. In parallel, miR-450a, miR-467d, and miR-295 were inversely associated with stress-responsive transcripts, including Hspa5, Hyou1, Gpx3, Ldha, and Cox5a, indicating activation of endoplasmic reticulum and oxidative stress responses. Collectively, these interactions delineate an iAs-responsive regulatory network that coordinates placental structural integrity and cellular stress adaptation, which are fundamental to maintaining placental homeostasis. **Conclusions:** iAs exposure reconfigures a placental miRNA-mRNA network that bridges structural and stress-regulatory pathways. Given that the placenta acts as a critical interface between maternal and fetal environments, perturbation of this regulatory axis provides a mechanistic basis for how early-life exposure to iAs may translate into developmental vulnerability and adult disease risk. *Supported by NIEHS grants R01ES034760 (WT) and R01ES033519-05 (AB, WT).*

PS 4645 Unraveling Benzo[a]pyrene-induced epigenetic modifications in Japanese medaka

F. Seemann, J. Selwyn, C. Bird, and L. Martin. Texas A&M University-Corpus Christi, Corpus Christi, TX.

Background and Purpose: The transmission of toxicant-induced phenotypes across generations has emerged as a critical topic in toxicology and epigenetics. Mounting evidence suggests that benzo[a]pyrene (BaP) and its metabolite BaP diol epoxide (BPDE) play a role in epigenetic regulation, potentially altering chromatin accessibility and gene expression patterns in germ cells through modification of epigenetic enzyme expression persistently affecting the offspring phenotype for three generations. Delineating epigenetic modifications in oocytes, sperm, ovary tissue and testis tissue will shed light on maternal and paternal contributions to epigenetic inheritance. It is hypothesized that epigenetic modifications in both, sperm and oocytes, contribute to the BaP-induced transgenerational phenotype. **Methods:** Ten pairs of adult medaka fish (*Oryzias latipes*; n=5) were exposed to solvent control or 1 µg/L BaP or for 21 days. Eggs were collected after the exposures ended and raised to 4 months old. This was repeated for 3 generations. Sperm, testis tissue, small oocytes, large oocytes and ovary tissue (n=5) were dissected from F3 adults and DNA extracted for 3piRAD, a refined EpiRAD/HELP single serial digestion assay with

MfeI, HpaII and MspI digestion. Libraries were sequenced with Illumina NovaSeq and data were filtered, cleaned, trimmed and mapped to the *O. latipes* reference genome. Methylation rates are calculated based on the proportion of reads mapping to methylated versus unmethylated fragments. Downstream analysis is conducted using R and Bioconductor packages, such as DSS, to identify differentially methylated regions (DMRs) between tissues or treatments. gProfiler was used for GO/KEGG pathway analyses. **Results:** Overall, ancestral BaP exposure significantly changed DNA methylation in a bi-directional manner in all tested tissues of the unexposed F₃ generation. A shift from hypermethylation to hypomethylation was particularly noted for sperm and testis tissue, while small oocytes, large oocytes and ovary tissue tended towards increased hypermethylation. These methylation profile changes were enriched for genes which were significantly associated with the human pathology pathways for abnormal skeletal morphology and abnormality of the skeletal system as well as abnormal brain morphology and abnormality of the nervous system. These pathologies have been as well identified on the phenotypic level. Distinct analyses of tissue type contrasts will shed further light on maternal and paternal contribution to BaP exposure modified epigenetic profile inheritance. **Conclusions:** The pronounced methylation differences observed in the F₃ generation indicate that ancestral BaP exposure in the F₀ lineage induced stable, heritable epigenetic alterations that persist across multiple generations in *Oryzias latipes*. Because F₃ individuals were never directly exposed to BaP, these methylation signatures represent true transgenerational epimutations, transmitted through the germline. The strong bias toward hypermethylation in sperm, contrasted with hypomethylation in oogenic and somatic gonadal tissues, suggests sex-specific epigenetic inheritance mechanisms. Similar patterns have been reported in mammalian and fish models following ancestral hydrocarbon, endocrine disruptor, or heavy-metal exposure, where F₃ progeny exhibited altered sperm methylation, differential expression of chromatin and developmental genes, and reduced fertility. The persistence of these methylation marks in the absence of direct exposure implies incomplete erasure or active maintenance during germline reprogramming, potentially via dysregulated DNA methyltransferase activity or chromatin remodeling factors. Collectively, these findings demonstrate that BaP exposure in ancestral lineages can reprogram the epigenome in a manner that is both tissue-specific and heritable, providing mechanistic evidence that environmental contaminants can drive long-term, transgenerational changes in reproductive epigenetic regulation.

PS 4646 Perinatal lead (Pb) exposure impacts on DNA methylation and hydroxymethylation in mouse hippocampus

J. Dou, R. K. Morgan, E. Matei, J. Pan, T. Ishikawa, K. Polemi, D. C. Dolinoy, J. Colacino, and K. Bakulski. University of Michigan, Ann Arbor, MI.

Background and Purpose: Environmental exposure to metals are important modifiable risk factors for neurological diseases. Epidemiological studies have found that exposure to lead (Pb) is associated with cognitive decline or Alzheimer's Disease and related dementias (ADRD). Toxicology studies have found that Pb exposure is linked to ADRD-associated molecular changes, pathology, and behavior. However, more understanding of the epigenetic consequences of Pb exposure in the brain, the specific tissue of interest for neurological outcomes, is necessary. In particular, hydroxymethylation is a less studied epigenetic modification enriched in brain tissue. **Methods:** C57BL/6J adult female mice 6-8 weeks of age were exposed to either control water or Pb acetate water (32 ppm) two weeks preconception and through weaning. At weaning (post-natal day 21), offspring were sacrificed to collect tissue, including hippocampus, and DNA was extracted from 6 control and 6 Pb exposed mice (3 male and 3 female in each group). We sequenced DNA on the Oxford Nanopore Technology PromethION platform, multiplexing two samples per flow cell. Basecalling was done in dorado software using the dna_r10.4.1_e8.2_400bps_sup@v5.2.0 basecalling model to measure methylation (5-mC) and hydroxymethylation (5-hmC) base modifications at CpG sites across the genome, and mapped to the mm10 mouse genome build. We used the dmrseq package to test for differentially methylated regions and differentially hydroxymethylated regions by Pb exposure. **Results:** We measured modifications at 14.4 million CpG sites with at least 10x coverage in all samples. Across these sites, we observed a global average of 69.3% methylation and 12.2% hydroxymethylation. Global methylation (0.35% higher in Pb exposed, p-value=0.4) and hydroxymethylation (-0.31% lower in Pb exposed, p=0.5) did not differ by treatment. Two regions were nominally associated (p-value<0.01) with Pb exposure-related DNA methylation changes in the hippocampus, in the genes *Grb10* and *Celf2*. At the *Grb10* region, Pb exposed mice had 12.9% higher DNA methylation than controls. At the *Celf2* region, Pb exposed mice had 15.7% higher DNA methylation than controls. For hydroxymethylation, 75 regions were nominally associated (p-value<0.01) with Pb exposure, including genes *Cdk12*, *Enox1*, *Crim1*, *Dlg1*, *Mir708*, *Tenm4*, *Nrg1*, *Cracd*, *Pcp4*, *Igfsf5*, *Ppip5k2*, *Pik3cb*, *Kcnma1*, *Aak1*, *Dab1*, *Rbfox1*, *Nell2*, *Syne2*, *Tbc1d9*, *Stxbp6*, *Klc1*, *D030068K23Rik*, *Plcl2*, *Eva1c*, *Chrm3*, *Rabl3*, *Rpl9*, *Lias*, *Klb*, *Sash1*, *Psen2*, *Ank2*, *Gm16958*, *Prpf18*, *Gad1l1*, *Herc2*, *Wdr7*, *Cckbr*, *Dym*, *Srrm4*, *Robo1*, *Bank1*, *Runx1t1*, *Rab3c*, *Gm5108*, *Mybbp1a*, *Ntrk2*, *Snappc3*, *Psp1*, *Gm3693*, *Slc8a3*, *Rnft2*, *Pam*, *Dock4*, *Magi1*, *Zp3*, *Slc8a1*, *2210408F21Rik*. Genes related to hydroxymethylation were enriched (FDR<0.1) in gene ontology pathways, including intracellular signal transduction, nervous system development, and ensheathment of neurons. **Conclusions:** This study identified several genes that may be epigenetically impacted in the brain by perinatal Pb exposure. These genes are involved in cell signaling and ensheathment of neurons, processes that may be disrupted by Pb exposure. Commonly used bisulfite conversion methods to measure

methylation do not allow for differentiation of 5-mC and 5-hmC, which have different biological functions and may be impacted differently by exposures. In our study, hydroxymethylation was found to be more strongly impacted, underlying the importance of its study in brain tissue and use of techniques to separately measure 5-mC and 5-hmC.

PS 4647 DNA Methylation Signatures for Fetal Alcohol Spectrum Disorder Prediction

Y. Fan¹, and F. Gao^{1,2}. ¹Department of Environmental Health Sciences, University of California, Los Angeles, Los Angeles, CA; and ²Department of Molecular and Medical Pharmacology, University of California, Los Angeles, Los Angeles, CA.

Background and Purpose: Prenatal alcohol exposure is a major preventable cause of neurodevelopmental disability and can lead to the spectrum of outcomes known as fetal alcohol spectrum disorder (FASD). Affecting 2-5% of North American children, the diagnosis of FASD remains challenging due to the lack of standardized diagnostic criteria and the wide variability in neurobehavioral manifestations. Meanwhile, prenatal alcohol exposure could induce widespread and persistent epigenetic disruption including DNA methylation (DNAm) alterations that may serve as molecular biomarkers of developmental toxicity. In this study, we developed and validated a DNAm-based prediction model to identify childhood FASD using non-invasive biospecimens, and further explored different DNAm patterns in healthy and FASD groups. **Methods:** We harmonized three public Illumina 450K datasets related to FASD through a unified pipeline. After batch correction, we constructed a buccal dataset consisting of 260 samples with 135 FASD cases. Another dataset of 134 peripheral blood samples was used as tissue-independent external validation. We first conducted feature selection using random forest model under multiple thresholds. The identified CpG features were then used to build machine learning models for FASD prediction. Model performances were evaluated through 5-fold cross validation. Metrics such as accuracy, area under the receiver operating characteristic curve (AUC-ROC), sensitivity, specificity, precision, and F1 score were used for model evaluation. Finally, we explored the co-methylation network patterns between FASD and control groups using graph learning. **Results:** Our random forest model achieved 81.1% accuracy, 89.0% AUC-ROC, 77.2% sensitivity, 85.6% specificity, 85.4% precision, and 80.7% F1 score in FASD prediction with the buccal dataset. External validation in peripheral blood yielded 77.9% accuracy, 86.3% AUC-ROC, 96.4% specificity, and 88.4% precision, while sensitivity dropped to 42.8% (F1=55.9%), potentially reflecting tissue-specific methylation differences. Preliminary network analysis demonstrated alcohol-induced alterations in coordinated methylation patterns. **Conclusions:** Our findings suggest that DNAm signatures may predict FASD using pediatric buccal samples, with preliminary evidence of cross-tissue applicability in peripheral blood. The developed model leverages DNAm data as biomarkers to complement existing behavioral and morphological criteria for FASD diagnosis. This study also contributes to molecular toxicology by exploring coordinated methylation patterns between FASD and control groups. Prospective validation in larger, clinically diverse cohorts is needed to further assess whether such methylation signatures could support early diagnosis.

PS 4648 Epigenetic alterations of histone post-translational modifications in response to alcohol

M. T. Levenson, A. Filipowicz, and P. Allard. University of California, Los Angeles, Los Angeles, CA.

Background and Purpose: Alcohol consumption prenatally is associated with various adverse reproductive health outcomes, such as fetal alcohol spectrum disorders which can span behavioral issues and developmental defects. In *Caenorhabditis elegans* it has furthermore been demonstrated with snRNA-seq that parental consumption of alcohol can alter the transcriptome in F1 and F3 generations without additional alcohol exposure, as well as promote reproductive health effects such as germline dysfunction and embryonic lethality (Truong et. al, 2023). Evidence also suggests that alcohol can directly alter histone acetylation levels (Mews et. al, 2019), potentially providing a mechanism for transmission of negative reproductive outcomes driven by ancestral alcohol exposure. This project aims to discern the mechanism through which multigenerational reproductive outcomes propagate employing the model nematode *C. elegans*. **Methods:** In this study, we cultured *C. elegans* in M9 media supplemented with OP50-1 bacteria at the L4 stage for 48 hours. Animals were exposed to USP grade ethanol at a dose of 0.5%, in accordance with previous literature. *C. elegans* are self-fertilizing, produce large broods and have a rapid generation time (~ 3 days) making them ideal for multigenerational studies. Additionally, their spatiotemporally regulated germline allows for analysis of multiple meiotic stages at one timepoint. To this end, adult P0 and F1 animals were dissected to analyze alterations in the germline to Pan H3ac, H3K9ac, H3K27ac and H3K56ac via immunofluorescent in response to ancestral alcohol. For western blotting analysis histones were enriched using an EpiQuik Total Histone extraction kit, and Pan H3ac, H3K9ac, H3K27ac and H3K56ac were analyzed quantitatively in Fiji. **Results:** Preliminary data shows that P0 animals show elevated levels of pan H3ac in response to 0.5% alcohol exposure via immunofluorescence, with differential levels also observed in the F1 generation. Western blot analysis also appears to demonstrate elevated H3K27ac in P0 animals, with differential expression also observed in

H3K9ac. **Conclusions:** Alcohol exposure appears to alter the histone PTM landscape in P0 animals, of which some of these effects can be observed over multiple generations. This potentially provides a mechanism for multigenerational phenotypes stemming from ancestral alcohol exposure.

PS 4649 Mitochondrial Dysfunction in Hemin-Induced Acute Kidney Injury is Mediated by Guanine Quadruplex Dynamics

R. J. Snyder¹, U. Shankar¹, C. K. Ganta¹, D. Cunefare¹, A. C. Telang², J. A. Beamish², K. Y. Jen³, and J. A. Watts¹. ¹National Institute of Environmental Health Sciences, Durham, NC; ²University of Michigan, Ann Arbor, MI; and ³UC Davis, Sacramento, CA. Sponsor: J. Watts, American Society for Clinical Investigation American Society for Biochemistry and Molecular Biology

Background and Purpose: Proximal tubule cells are dependent on energy from mitochondria for their transporter activity and transcription of mtDNA is essential for oxidative phosphorylation. Previously, we identified that transcription by the mitochondrial RNA polymerase (POLRMT) is regulated by formation of guanine-quadruplexes (G4) in nascent RNA. Hemin is a known endogenous G4-stabilizing ligand, and it accumulates in the kidney under conditions associated with acute kidney injury (AKI) such as sepsis, rhabdomyolysis, and ischemia-reperfusion injury (IRI). The purpose of this study is to determine whether free heme during AKI stabilizes G4 structures in the mitochondria of renal proximal tubules, impairing transcription of mtDNA and contributing to mitochondrial dysfunction following injury. **Methods:** We used circular dichroism analysis and an *in vitro* primer extension assay to measure the stability of G4s and transcriptional changes induced by the presence of hemin. In a mouse model of kidney IRI, we measured the intracellular distribution and colocalization of G4s with heme oxygenase (HMOX1) expression in proximal tubules 6 hours to 4 weeks post-IRI. Using a machine learning algorithm to delineate proximal tubules within whole slide scans of cortical kidney biopsies from 6 human donors, we measured the abundance of cytoplasmic G4s in tubular versus glomerular tissue and correlated the intensity of cytoplasmic G4s with HMOX1 expression for each donor. We also treated human proximal tubule epithelial cells (PTCs) in serum-free culture with non-cytotoxic doses of hemin for 1-24 hours. Heme-bound G4s were biotinylated in live PTCs using a peroxidase reaction and probed with streptavidin to determine the intracellular distribution of G4s stabilized by hemin with confocal microscopy. Gene expression in PTCs was analyzed by qPCR and mitochondrial function was measured using Seahorse extracellular flux assay. **Results:** Hemin stabilized RNA G4s, evidenced by increased melting temperature of RNA G4 structures and impaired transcription by POLRMT in acellular assays. Proximal tubules from mouse IRI kidneys had higher HMOX1 expression, indicating the presence of free heme, and more G4 structures at 6-48 hours post-IRI, returning to contralateral control levels within 2 weeks. Biopsies from human donor kidneys had significantly higher cytoplasmic G4 abundance in proximal tubule tissue compared to glomeruli and a positive correlation ($r > 0.7$) was found between the expression of HMOX1 in each tubule and the appearance of cytoplasmic G4 structures. Human PTCs exposed to free hemin revealed a dose-dependent increase in G4 abundance which peaked at 1-6 hours. Intracellular distribution of heme-bound G4s was primarily cytoplasmic and colocalized with mitochondrial mass (Spearman coefficient > 0.5). Mitochondrial-encoded OXPHOS genes were downregulated by hemin exposure while nuclear-encoded transcription factors TFAM and TEFM were unaffected. Uncoupled oxygen consumption rates in PTCs were significantly decreased after 24 hours of hemin exposure. **Conclusions:** These results show that hemin stabilizes G4s in proximal tubule cells and impairs mitochondrial gene transcription and function. We conclude that stabilization of G4 structures and consequent dysregulation of POLRMT transcription is an additional mechanism mediating mitochondrial dysfunction in proximal tubules during hemin-induced AKI.

PS 4650 Genome-Wide Redistribution of Newly Synthesized Histones in Human Cells Following Formaldehyde Exposure

D. Chen, P. Wu, and C. Jin. NYU School of Medicine, New York, NY.

Background and Purpose: Formaldehyde (FA), a reactive aldehyde widely present in the environment, is a known carcinogen associated with nasopharyngeal cancer and has also been implicated in myeloid leukemia and neurodegenerative disease. Recent studies indicate that exogenous FA induces only a modest increase in DNA adduct formation compared with the levels generated endogenously, suggesting that epigenetic mechanisms may play a key role in FA-mediated toxicity and disease. We previously reported that FA exposure inhibits the nuclear translocation of newly synthesized variant histone H3.3 from the cytoplasm. However, how this impairment influences the genome-wide incorporation of newly synthesized H3.3 into chromatin has remained unclear. **Methods:** To investigate the effects of FA exposure on global chromatin assembly of newly synthesized histones, we utilized a SNAP-tagged histone expression system to selectively label nascent histones. BEAS2B-SNAP-H3.3 stable cell lines were first treated with SNAP-Cell Block to quench preexisting SNAP-H3.3. After removing the blocking agent, cells underwent a "chase" period during which newly synthesized H3.3 accumulated in the presence or absence of 100 μ M FA for 24 hours. Following exposure, mono- and dinucleosomes were isolated, and nucleosomes containing newly synthesized SNAP-H3.3

were biotinylated with SNAP-Biotin ("pulse"). Biotinylated nucleosomes were then immunoprecipitated using streptavidin-conjugated beads. ChIP-seq libraries were prepared and sequenced on an Illumina NovaSeq X Plus platform to generate 2x150 bp paired-end reads. Sequencing reads were aligned to the human reference genome (hg38), and ChIP-enriched regions (peaks) were identified from deduplicated BAM files using MACS2. **Results:** The ChIP-seq analysis revealed extensive genome-wide changes in chromatin distribution of newly synthesized H3.3 following FA exposure. Occupancy analysis identified 46,548 H3.3 sites unique to controls, 139,608 unique to FA-exposed samples, and 78,992 shared loci, indicating both loss and gain of H3.3 incorporation across the genome. Differential peak analysis (DESeq2) further identified 1,603 regions with increased and 1,577 with decreased H3.3 occupancy ($p < 0.01$, $|\log_2\text{FC}| \geq 0.5$). Genomic annotation showed that sites with reduced occupancy were primarily located in distal intergenic and intronic regions, while those with increased occupancy were enriched near promoters, suggesting that FA exposure redistributes newly synthesized H3.3 from distal intergenic to promoter-proximal regions. Pathway and GO analyses linked these occupancy changes to mRNA splicing and RHO GTPase signaling, while ENCODE histone modification analysis associated the affected loci with H3K27me3, H3K27ac, and H3K79me2 marks. Notably, Ingenuity Pathway Analysis identified "cancer" as the top disease category, with head and neck carcinoma—including nasopharyngeal cancer, a known FA-related malignancy—among the most enriched terms. **Conclusions:** These results suggest that FA exposure induces a genome-wide redistribution of newly synthesized H3.3 that perturbs chromatin organization and gene regulatory pathways, potentially contributing to nasopharyngeal carcinogenesis.

PS 4651 Exploring Tissue-Specific DNA Co-Methylation Network dynamics During Human Aging

Y. Fan¹, Y. Zheng², and F. Gao^{1,3}. ¹Department of Environmental Health Sciences, University of California, Los Angeles, Los Angeles, CA; ²Division of Cancer Epidemiology and Prevention, Department of Preventive Medicine, Northwestern University Feinberg School of Medicine, Chicago, IL; and ³Department of Molecular and Medical Pharmacology, University of California, Los Angeles, Los Angeles, CA.

Background and Purpose: Aging is a complex process with widespread molecular alterations across tissues. Recent multi-omics profiling has revealed nonlinear dynamics of individual biomarkers during aging. However, how the interactions and correlations among biomarkers change over time remains understudied. Meanwhile, DNA methylation (DNAm) exhibits systematic age-associated shifts that have enabled the development of epigenetic clocks capable of estimating biological aging. DNA co-methylation networks could further capture coordinated regulatory patterns. Yet, it remains unclear whether aging involves tissue-specific dynamic changes of DNAm co-methylation networks and how these dynamics unfold during human aging. We thus investigated age-dependent changes in DNA co-methylation network structures across multiple human tissues to characterize regulatory coordination patterns complementing current studies on nonlinear aging dynamics. **Methods:** We analyzed DNA methylation of 163 samples (ages 19-70 years) profiled on Illumina MethylationEPIC v2.0 across buccal epithelium, peripheral blood mononuclear cells, saliva, and dried blood spots. Tissue-specific age-predictive CpGs were identified through Random Forest feature selection with 5-fold cross-validation and importance-threshold optimization. Weighted co-methylation networks were constructed using absolute Pearson correlations for three age groups (19-30, 31-50, 51-70 years). Network properties were quantified via mean edge weight, average weighted degree, weighted clustering coefficient, and modularity. External validation employed whole blood samples (GSE40279, n=656, ages 19-101) and combined buccal datasets (GSE50759, GSE94876, GSE113018, n=180, ages 0-60). CpGs from widely used aging clocks (e.g., Horvath pan-tissue; Hannum blood; Johnson buccal) were used for comparison. Gene ontology and KEGG pathway enrichment analysis were conducted for tissue-specific CpGs. **Results:** We identified tissue-specific CpGs that could achieve robust age prediction ($R^2=0.69-0.87$, $\text{MAE}=4.52-7.23$ years) with random forest models. Network analysis on co-methylation networks under different age groups showed diverse patterns across tissues. For instance, mean edge weight, average weighted degree, and weighted clustering coefficient of buccal co-methylation networks declined from early to mid-adulthood and then increased in late adulthood. In contrast, PBMC, saliva, and DBS showed progressive declines in mean edge weight and average weighted degree across adulthood, while weighted clustering coefficient exhibited a shallow midlife rise followed by a late-life decrease. Modularity tended to decline across tissues, indicating erosion of coordinated community structure despite divergent connectivity patterns. Validation in whole blood dataset confirmed early-to-midlife mean edge weight and average weighted degree decline with late-life stabilization across multiple CpG selection strategies. Validation in buccal dataset showed higher mean edge weight, average weighted degree, and weighted clustering coefficient in childhood, decreasing through adolescence into adulthood. Functional enrichment identified several biological pathways including mitochondrial/apoptotic regulation. **Conclusions:** Our findings suggest tissue-specific nonlinear dynamics in DNA co-methylation networks. Mean edge weight and average weighted degree, which reflecting network connectivity, showed mid-life decline and late-life increase in buccal and progressive decline in blood-derived tissues, consistent with distinct tissue-specific aging patterns. Weighted clustering coefficient, capturing local network density, exhibited similar tissue-dependent nonlinear patterns. The modularity decline across tissues indicates common loss of coordinated epigenetic structure.

PS 4652 Placental miRNA responses to prenatal cannabis, tobacco and alcohol exposure in Rhode Island, US

N. Sehgal¹, R. St. Fleur², J. Joseph², N. Belanger², A. Burt¹, K. Hermetz¹, C. J. Marsit¹, L. R. Stroud², and T. M. Everson¹. ¹Emory University, Atlanta, GA; and ²Brown University, Providence, RI.

Background and Purpose: Tobacco and alcohol use are declining while cannabis use is on the rise in the US. These substances are associated with adverse maternal-child health outcomes, although the impact of cannabis is less clear. Dysregulated placental epigenetics is a potential mechanism underlying these effects. Past epidemiological studies have mostly examined effects related to any or no use of each substance in isolation which underestimates the effects of co-use, dose and trimester-specific contributions. While many previous studies have examined the effects on placental DNA methylation or gene expression, little is known about the short-lived epigenetic regulators, miRNAs, which can block protein translation, impacting multiple biological processes. This study examines the dose- and trimester-specific placental miRNA responses to prenatal cannabis, tobacco and alcohol co-exposures. **Methods:** An ethnographically diverse sample of 133 pregnancies, 29% reporting low income, were oversampled for cannabis use from New England (the Behavior and Mood in Babies and Mothers cohort). Small RNA sequencing was performed on placental samples with 621 miRNAs passing QC and processing. Daily cannabis, tobacco, and alcohol use during and 3 months prior to pregnancy were collected via timeline follow-back interviews and biochemically verified. Latent profile analysis (LPA) was used to identify dose-based classes of prenatal cannabis exposures and secondarily to identify co-use classes of cannabis, tobacco and alcohol. Untargeted miRNA-wide associations with dose-specific profiles of cannabis only use and co-use were examined using separate negative binomial regressions. Models adjusted for infant sex, socioeconomic status, race/ethnicity, maternal age, and two surrogate variables capturing unmeasured confounding. P-values were corrected for false-discovery rate (q-value < 0.10). Sensitivity of effects to confounding by gestational age was examined. Functional effects were searched in KEGG, Reactome, and WikiPathways. **Results:** Participants reported no substance use (44%), cannabis only (29%), tobacco only (4.5%), and co-use (23%) prenatally. LPA identified three exposure profiles, that broadly reflected high, moderate, and low exposures. By itself, prenatal cannabis use had dose-specific effects on placental miRNAs while adjusting for tobacco and alcohol use. High cannabis exposures were associated with altered miR-4521 ($\log_2$ fold change (LFC) = 1.16; $q = 0.08$; 1436 mRNA targets) and miR-3925-5p (LFC = -0.85; $q = 0.08$; 119 mRNA targets) while medium cannabis exposures had no associations compared to low exposures. Cannabis, tobacco and alcohol co-exposures altered placental miRNAs in a dose-dependent manner with more changes related to moderate exposures. Compared to low exposures, high exposures perturbed miR-421 (LFC = -0.23; $q = 0.09$) which potentially targets 1436 mRNAs. Medium exposures associated with downregulation of miR-6501-3p (LFC = -0.53; $q = 0.06$) and upregulation of miR-483-5p (LFC = 0.44; $q = 0.06$); miR-1180-3p (LFC = 0.59; $q = 0.06$); and miR-365b-5p (LFC = 1.50; $q = 0.06$). These miRNAs' mRNA targets had functional effects on RNA metabolism, cell response to stimuli and stress (Reactome); VEGF signaling (WikiPathways); and spliceosome, neurodegeneration and Alzheimer disease pathways (KEGG). After gestational age adjustments, only miRNAs associated with high exposures remained significant. **Conclusions:** Using exposure profiling and untargeted small RNA-seq, this is the first study to describe the link between prenatal cannabis, tobacco and alcohol co-exposures and placental miRNAs and functioning. In a birth cohort oversampled for cannabis use, this analysis identified miRNAs associated with high cannabis exposures as well as high and moderate co-use, although these may be driven by the effects of substance use on gestational age at birth. Processes (e.g., RNA metabolism, stress, VEGF, neurodegeneration) that influence placental growth, vascular signaling and neurodevelopment, were perturbed suggesting their altered regulation could affect pregnancy outcomes.

PS 4653 Metaboloepigenetic mechanisms of transgenerational alcohol-seeking behavior

A. Filipowicz, M. Levenson, S. Kelso, and P. Allard. University of California, Los Angeles, Los Angeles, CA.

Background and Purpose: The fetal brain is particularly vulnerable to ethanol's neurotoxic effects. Exposure during fetal development can cause irreversible damage, leading to long-term cognitive and behavioral deficits that fall under the umbrella of fetal alcohol spectrum disorders (FASD). Human studies on the multi- and transgenerational effects of alcohol have suggested that neurobehavioral FASD features, including alcohol preference, can be passed across generations. However, the underlying mechanisms of transgenerational FASD inheritance remain largely unknown. **Methods:** We used the model organism *Caenorhabditis elegans* to test the hypothesis that ethanol metabolism directly leads to increased, transgenerationally stable histone acetylation that affects ethanol-related behaviors. Wild-type animals and animals carrying loss-of-function mutations in conserved ethanol metabolism genes (alcohol dehydrogenase, *adh-1*, and acetyl coenzyme A synthetase 2, *acs-19*) were exposed to physiological ethanol levels (0.05%, 0.1%, and 0.5%) and tested using behavioral and molecular assays including ethanol preference, crawling speed, food race, Western blotting, fluorescence microscopy, and mass spectrometry. **Results:** While ethanol acted as a mild aversive cue for naïve animals, 48-hour exposure to all tested doses induced attraction to ethanol. This switch from aversion

to attraction persisted to the F3 generation following a single parental exposure at the two higher doses. The ethanol preference switch was not merely a result of decreased locomotion, as crawling speed showed no decrease or increased 1 hour after exposure in P0, F1, and F3 generations. Animals tested on a more complex locomotory task (moving towards a food source) showed ethanol-dependent performance decreases at P0 and F1, though not F3, generations. Animals lacking functional *adh-1* or *acs-19* did not display an ethanol preference switch at P0, F1, or F3 generations, indicating that metabolism of ethanol into acetyl-CoA—the key molecule used to acetylate histones—is required for transgenerational ethanol-seeking behavior. Unbiased mass spectrometry of over 80 histone post-translational modifications revealed that H3K5ac, but not H3K9ac, increased in P0 and F3 generations after 0.5% ethanol exposure at P0. H3K27 modifications could not be examined due to protein sequence differences; however, preliminary Western blot and germline immunofluorescence results suggest that H3K27ac also increases upon 0.5% exposure in P0. **Conclusions:** Ongoing studies are validating the mass spectrometry results and identifying histone post-translational modifications to target for epigenomic analysis using CUT&TAG methods. We will also elucidate the epigenetic requirements, including timing and cellular distribution, that direct alcohol's effects on behavior across generations using pharmacological and RNAi-based approaches. This research will identify the metaboloeigenetic mechanisms underlying alcohol's transgenerational effects.

PS 4654 Effect of Theophylline on Respiratory and CNS Parameters in Sprague Dawley Rats

A. Javed^{1,2}, F. Zafar^{3,2}, U. Waheed², M. N. Ghayur¹, J. Liu², and J. A. Bhall². ¹Kentucky College of Osteopathic Medicine, Pikeville, KY; ²Frontage Laboratories, Concord, OH; and ³San Juan Bautista School of Medicine, Caguas, PR.

Background and Purpose: Theophylline is a bronchodilator that acts through phosphodiesterase inhibition, adenosine receptor antagonism, and anti-inflammatory mechanisms. Its respiratory and behavioral effects were assessed following overstimulation of the immune system and cascading an inflammatory response in male and female Sprague Dawley rats by administering lipopolysaccharide (LPS). **Methods:** Respiratory parameters - respiratory rate, minute volume, and tidal volume - were assessed using plethysmography chambers alongside behavioral outcomes using Functional Observational Battery (FOB) and locomotor activity tests. Animals (4/sex/group) received vehicle, LPS, theophylline, or LPS/theophylline at 0, 3, 20, or 3/20 mg/kg. When co-administered, theophylline was given 2.5 hours after LPS to allow an inflammatory response to develop. LPS was delivered intranasally (0.1 mL/animal), while vehicle and theophylline were administered intraperitoneally (10 mL/kg). **Results:** Consistent with its known stimulant effects, a significant increase in mean respiratory rate was observed in animals administered theophylline (246%) and LPS/theophylline (211%), compared to the vehicle controls. Mean minute volume rose 168% and 134% in animals administered theophylline or LPS/theophylline compared to the vehicle control group. Tidal volume was unchanged in theophylline or LPS/theophylline groups, though LPS alone caused a transient decrease. These results support the expected pharmacodynamic profile of theophylline and suggest that LPS-induced inflammation may attenuate its respiratory stimulant effects. In behavioral testing, rats treated with theophylline showed consistent increases in distance travelled, ambulation, rearing, and time active, with reduced resting time across all 5-minute intervals over a 30-minute post-dose period. These behavioral effects were observed intermittently in the LPS/theophylline group. **Conclusions:** The results showed a more agile and ambulatory CNS behavior and bronchodilation in animals administered theophylline or co-administration of LPS and theophylline. Moderately elevated effects were observed in animals administered theophylline only.

PS 4655 N-Acetylcysteine (NAC) does not prevent symptoms of acute lung injury (ALI) in acrolein-exposed mice

J. Luisi, and B. T. Ameredes. University of Texas Medical Branch, Galveston, TX.

Background and Purpose: Since Yves Alarie characterized toxicant-associated respiratory depression (RD) in a mouse model in 1966, RD has been recognized as an immediate response to lung toxicant exposures that can be associated with subsequent acute lung injury. Non-invasive whole-body plethysmography (WBP) was originally used to measure RD, but the WBP technique has been criticized in recent years, for misinterpretation of the enhanced pause (Penh) variable. NAC, typically used clinically as a mucolytic within the airways, has been proposed as a therapeutic for oxidative stress and lipid peroxidation associated with lung exposure to acrolein, specifically to counteract depletion of the antioxidant glutathione (GSH) and to reduce the subsequent oxidative stress and lipid peroxidation. In this study, we used the machine learning technique of Principal Component Analysis (PCA) to unbiasedly assess the breathing parameters measured with WBP, in testing the efficacy of NAC as a medical countermeasure against acrolein. **Methods:** Five groups of mice given intratracheal (IT) acrolein [Naïve (null), 0mg/kg(vehicle), 2mg/kg, 4mg/kg, and 4mg/kg+100mg/kg NAC, IT] were assessed for toxicity responses every 24h with WBP, body weight, and Kaplan-Meier survival analyses over 96h, followed by postmortem bronchial alveolar lavage (BAL) cell counts, and lung histology, to determine whether

NAC could alter toxic responses to acrolein. PCA of WBP data was used to determine the rank and interaction of measured variables, including breathing rate (f), minute volume (MVb), and Penh. **Results:** All acrolein exposed subjects showed RD at 3 hours post-exposure, with the 4 mg/kg group exhibiting severe RD to a level of 50% (RD₅₀) of initial breathing frequency. Furthermore, the 4 mg/kg acrolein group had 50% mortality at 96h, thereby defining the LD₅₀, in these experiments. The eigenvalue of f was 0.97 in Principal Component 1 (PC1, which explained 98% of the variance in the model). MVb had an eigenvalue of 0.94 in PC2 (which explained 1.43% of the variance in model) and was depressed from 50 ml/min to 29 ml/min in all acrolein exposure groups. Penh had a 0.96 eigenvalue in PC3 (which explained only 0.14% of the variance in the model), with median values being elevated from 0.7 to 10 (unitless) after 24h, in both 4 mg/kg acrolein exposure groups. Both 4 mg/kg acrolein exposure groups demonstrated a statistically significant increase in total airway cells (from 1.43E⁵ naïve, to 2.57E⁵ 4 mg/kg acrolein and 3.99E⁵ 4 mg/kg acrolein + NAC), with a high proportion of neutrophils observed at 96h, as compared to controls. With NAC treatment of 4 mg/kg acrolein-exposed mice, the RD₅₀ did not improve, as compared to 4 mg/kg acrolein alone. Weight loss with NAC administration was comparable to 4 mg/kg acrolein alone, both reaching a loss of 20% at 72h. The mortality rate in the NAC treatment group, as determined by the survival slope, unexpectedly accelerated, reaching LD₅₀ within 72h, as compared to the 4 mg/kg acrolein alone group, at 96h. In the NAC treated group, Penh elevations were not statistically different from 4 mg/kg acrolein, alone. BALF total cell counts of the surviving NAC treatment group mice at 96h exceeded those of the control group but were not significantly different from those observed with 4 mg/kg acrolein treatment, alone. **Conclusions:** From the PCA analysis, f, MVb, and Penh were ranked respectively as the greatest contributors to model variance. While Penh displayed a unique trendline with scalar values of 10+ within the 4 mg/kg acrolein group, as a principal component (i.e., PC3), it was not the most informative factor describing acrolein lung toxicity effects. Furthermore, 4 mg/kg acrolein + NAC, as compared with 4 mg/kg acrolein alone, did not differentiate in any statistically significant manner. Thus, NAC treatments did not mitigate any symptom of acrolein toxicity at the clinically-based dosage of 100mg/kg, suggesting that: 1) NAC was ineffective against acrolein toxicity, 2) further experiments are needed to determine possible NAC effectiveness at higher doses, and 3) the administration of NAC in the lung against acrolein toxicity may be contraindicated.

PS 4656 Noninvasive repeated sampling reveals specific respiratory cytokine signatures for individuals who use electronic-cigarettes and tobacco dual-products

J. L. Thies¹, H. J. Appleseth², N. Yamaguchi^{3,4}, P. G. Bose¹, A. M. Speen¹, C. Cobos-Urbe¹, A. A. Perryman¹, A. A. Graham¹, A. P. Tackett⁵, and M. E. Rebuli¹. ¹University of North Carolina - Chapel Hill, Chapel Hill, NC; ²Oklahoma State University, Stillwater, OK; ³University of Southern California, Los Angeles, CA; ⁴Rosalind Franklin University of Medicine and Science, Chicago, IL; and ⁵The Ohio State University, Columbus, OH.

Background and Purpose: The recommendation that electronic-cigarettes (e-cigs) can be used as a safer alternative and smoking cessation tool in most countries has led to an increase in use, despite emerging evidence suggesting use, especially in combination with other products (dual use), is associated with increased risk of long-term respiratory disease. New and attractive flavors, different device types and brands, and targeted marketing make e-cigs more appealing to young adult and youth populations, sparking increased curiosity for use. Dual use, or the use of e-cigs in combination with conventional cigarettes or other inhaled products (tobacco, CBD, THC etc.) has increased in prevalence, particularly in the youth and young adult populations, reaching concerning levels. There is limited understanding of the health effects associated with dual use, as it has not been as extensively studied as e-cigs or conventional smoking have independently. However, the combination of inhaling combustible product smoke and e-cigs aerosols could lead to increased pathological outcomes compared to either alone. Minimal longitudinal studies have been conducted to gather respiratory and immune outcomes of e-cig use. Likewise, with the emergence of dual tobacco use, limited data exists on the consequences or outcomes of such exposures, increasing the need for repeated-measure studies. **Methods:** Nasal epithelial lining fluid (NELF) was collected from a remote cohort (N = 64) of never tobacco users (n = 34), exclusive electronic cigarette users (n = 14), dual tobacco product users (n = 10), and cannabis users (n = 6), once weekly via video conferencing over four weeks, and analyzed via multiplex enzyme linked immunosorbent assays for 29 different inflammatory immune mediators. Salivary cotinine was collected to assess nicotine content between groups. Sex was added as a cofactor to determine whether main effect sex differences were present within and between groups. **Results:** Cotinine analyses showed e-cig and dual tobacco product users did not display significant differences in average cotinine but had significantly more nicotine exposure compared to never users. Moreover, dual tobacco product users displayed increased correlations between cotinine and protein concentrations. Inflammatory cytokines differed among e-cig, dual tobacco products and never users. However, inflammatory markers did not change over time. E-cig and dual product users exhibited increased proinflammatory markers compared to never users. Chemokine profiles of Eotaxin, TARC, MCP-1, and MCP-4 were specifically elevated in dual product users only compared to never users. Main effect sex was identified in 24 of 29 tested analytes. Sex differences were eliminated, introduced, and enhanced when product user status was considered compared to never users. No significant variability was observed in cytokine levels within groups when assessing differences by collection week. **Conclusions:** E-cig and dual tobacco product use

elevates inflammatory cytokines, with dual tobacco product use displaying distinct changes in chemokine profiles compared to exclusive e-cig users. Sex as a variable should be considered when analyzing data, as user status influenced the elimination and introduction of sex differences.

PS 4657 Quenching the flame: VCAM neutralizes age enhanced neuroinflammation

S. Phatak, B. Baird, M. Olewine, S. Noor, and M. Campen. University of New Mexico, Albuquerque, NM.

Background and Purpose: Ambient air pollution is recognized as the second leading risk factor for global mortality, accounting for more than 8.1 million deaths per year and contributing significantly to the global noncommunicable disease burden. Recent unprecedented heatwaves, exemplified by record-breaking temperatures and extended wildfire seasons, have further amplified ambient particulate pollution and associated health hazards, particularly in vulnerable populations such as older adults. Over 90% of the world's population lives in regions exceeding World Health Organization air quality standards, with India and China disproportionately affected, but high exposures and associated risks also persist in westernized nations where particulate matter (PM) is a prevalent contributor to disease. As our climate warms, wildfire-derived PM has become increasingly frequent and severe, affecting respiratory and extrapulmonary organ systems, leading to cardiovascular and neurological symptoms. Among the most concerning consequences is neuroinflammation, particularly in aging populations, where cumulative exposures and vascular remodeling exacerbate susceptibility. Air pollution is implicated in a spectrum of health outcomes, notably including neuroinflammatory disorders such as Alzheimer's disease, Parkinson's disease, and stroke, for which elderly cohorts appear at heightened risk due to age-associated changes in vascular and immune regulation. Mechanistically, inhaled pollutants can access and damage the central nervous system via direct and indirect pathways, provoking neuroinflammation through upregulation of pro-inflammatory mediators including tumor necrosis factor alpha (TNF) and vascular cell adhesion molecule 1 (VCAM1), a mediator of leukocyte adhesion and vascular inflammation. VCAM1, expressed primarily on endothelial cells, is of particular interest to investigate as it plays an important role at the blood-brain barrier (BBB) and the lining of the gut and is especially elevated in aged mammals. **Methods:** The present study investigated whether VCAM1 mediated immune cell trafficking contributes to neuroinflammatory responses following wildfire smoke exposure in aged animals. Eighteen-month-old female mice (human equivalent $\approx$ 60 years) were exposed to either filtered air or woodsmoke (500 μ g/m³ PM, 4 h per day, every other day for 2 weeks) while receiving intraperitoneal injections of either a VCAM1 neutralizing antibody or IgG isotype control. Tissues were harvested post-exposure for flow cytometric and molecular analyses of immune activation and inflammatory biomarkers across multiple organ systems, including the brain. Data were analyzed using two-way ANOVA to assess the interactive effects of smoke exposure and VCAM1 blockade. **Results:** Flow cytometric and immunosay analyses demonstrated that wildfire smoke exposure induced significant activation of leukocyte adhesion markers, as well as augmented neuroinflammatory profiles, specifically in animals receiving control injections. Wildfire smoke exposure upregulated VCAM1 ($p=0.0451$) and LFA ($p=0.0029$) expression on circulating leukocytes and increased the abundance of CD11b⁺ myeloid immune cells ($p=0.0007$), indicating systemic macrophage activation. VCAM1 blockade effectively attenuated these pathological immune responses and normalized organ level outcomes such as cecal hypertrophy ($p=0.0032$). **Conclusions:** These data demonstrated that VCAM1 mediated endothelial signaling contributes to wildfire smoke induced immune activation in aged animals. The unexpected observation that smoke exposure enlarged the cecum parallels clinical observations of microbiome disruption in chronically exposed human cohorts and may serve as an indicator of microbial imbalance which was normalized by VCAM1 blockade, suggesting possible gut-vascular-brain interactions in the inflammatory response. This work supports a model in which air pollution driven neuroinflammation in aging is contingent upon VCAM1 mediated leukocyte-endothelial interactions, positioning VCAM1 as a promising therapeutic target to mitigate vascular and neurological consequences of ambient particulate exposure under climate change-enhanced pollution scenarios.

PS 4658 Modelling the lung and the COPD pathophysiology in a Mechanically stimulated small airways Lung-on-Chip

R. Visone¹, M. Mondini¹, V. Fragozo Mesa², C. Pernici¹, G. Marchini³, and P. Occhetta¹. ¹BiomimX Srl, Milan, Italy; ²Politecnico di Milano, Milan, Italy; and ³Chiesi Farmaceutici SpA, Parma, Italy. Sponsor: C. Pernici, Safety Pharmacology Society

Background and Purpose: Chronic Obstructive Pulmonary Disease (COPD) remains a global health challenge in both industrialized and developing countries, with no curative therapies available. Despite cigarette smoke is recognized as one of the major risk factors for COPD, different air pollutants may contribute to the pathology onset and progression. To develop innovative treatments, it is thus fundamental to advance the understanding of disease's mechanisms, also through advanced *in vitro* models that accurately mimic COPD. In this context, organs-on-chip (OoC) have emerged as promising tools, especially to mimic alveolar structures subjected to

mechanical stimulation. However, these models lack the integration of small airways physiology with a 3D environment that can be mechanically activated to better reflect natural respiratory motion. Here we present a COPD-OoC model, generated by co-culturing human bronchial epithelial cells (HBECs) and bronchial smooth muscle cells (BSMCs) in a 3D controlled microenvironment, where a physiological-like mechanical stimulation was applied. **Methods:** BSMCs were organized as 3D microtissues, while HBECs are lined along the muscles to generate epithelial monolayers. The stromal and epithelial compartments were firstly optimized by culturing the cells for 14 days both in static and dynamic (i.e. cyclic sinusoidal 10%uniaxial strain, 16bpm) conditions. The optimized compartments were finally combined in a 5-channels device encompassing two BSMC microtissues separated by HBECs monolayer, which was subjected to air-liquid-interface. The obtained mechanically active system has been exposed to pro-inflammatory cytokines (e.g. IL-13) and/or to cigarette smoke extracts (CSE) to assess their effect in inducing COPD traits and/or impair cell viability, assessing lung toxicity. **Results:** For the stromal compartment, the optimal cell seeding density resulted a 50x10⁶cells/mL of BSMC monoculture, which led to a higher cell viability and interconnectivity. Cell elongation and expression of BSMCs markers at protein levels, such as α -SMA, β -tubulin and Collagen I were enhanced in mechanically stimulated conditions. Concerning the epithelial compartment, a seeding density of 10x10⁶cells/mL yielded optimal cell viability and barrier-like structure formation, as demonstrated by ZO-1 expression. The optimized compartments were then combined in the 5-channels device, where the model correctly developed in 10 days. BSMCs expressed α -SMA and Collagen I and exhibited increased elongation when subjected to mechanical stimulation. Epithelial cells formed structured monolayer and expressed specific markers of epithelial cells sub-populations, such as MUC5B (i.e. acinar cells), FOXJ1 (e.g. ciliated cells), and SCGB1A1 (i.e. acinar cells). The obtained mechanically active system was proven able to respond to pro-inflammatory cytokines and to cigarette smoke extracts: NHBE showed an enhanced elongation and higher α -SMA expression, especially when subjected to cigarette smoke extracts. **Conclusions:** The lung-on-chip incorporating stromal and epithelial compartments, enabled the creation of a dynamic 3D human bronchial model that mimics the active mechanical environment of the lung. BSMC and NHBE were successfully cultured within the system and exposure of the model to CSE elicited an inflammatory response characteristic of COPD. This model offers a powerful tool for assessing lung toxicity and studying disease mechanisms, to finally accelerate drug discovery.

PS 4659 Fiber Diameter Distributions of Modern Synthetic Vitreous Fibers (SVFs): Implications for Exposure and Risk Assessment

A. K. Madl¹, K. Rickabaugh², and B. Wiggins². ¹Valero Sciences LLC, Ladera Ranch, CA; and ²RJ Lee Group, Pittsburgh, PA.

Background and Purpose: Synthetic vitreous fibers (SVFs) are a class of materials that have major uses in commercial and residential insulation for thermal, fire, noise, and vibration protection, and are critical materials for energy conservation. SVFs are composed of an amorphous silicate arrangement with no discernable crystalline structure. Fiber dimension is one of the key characteristics of the 3Ds (dose, dimension, durability) of fiber toxicology, and fiber diameter is an important determinant of fiber respirability. The purpose of this analysis was to characterize the fiber diameter distribution and other physical attributes of a range of modern synthetic vitreous fibers (SVFs). **Methods:** Twenty-two samples of glass, stone/rock, and slag SVFs were selected from samples obtained from 17 different plants from eight different manufacturers. Physical characterization of SVFs included fiber diameter and size distribution by scanning electron microscopy (SEM, Tescan MIRA3), surface area by Brunauer, Emmett, and Teller (BET) analysis, and density by gas pycnometry. SVF samples were prepared by sieving fibers through a 63 μ m size mesh to reduce fiber length and remove shot. BET analysis involved degassing 0.5-1 g SVF (in duplicate) under vacuum at 45°C for 16 hours prior to analysis. The BET specific surface area (m²/g) was determined using Krypton gas (77 °K) and five relative pressures (i.e. 5-point BET) within the linear region of the adsorption isotherm. Fiber density measurements included milling and then drying $\sim$ 20 g SVF at 110°C for at least 2 hours and allowing the material to cool to room temperature in a desiccator. After insertion of a determined mass of material in the pycnometer, 50 He purges were conducted before analysis, and the average of seven measurements at 17 psi were reported. Samples for SEM analysis were prepared from subsamples of material mixed with a Turbula mixer, suspended in filtered IPA, vacuum deposited onto 0.2 μ m polycarbonate filter, and mounted on a SEM stub with colloidal graphite. Samples were then coated with a thin layer of carbon by evaporative deposition under vacuum. The lengths and widths of 700-800 individual fibers for each SVF sample were measured from an automated montage of high-resolution SEM images. **Results:** Shot ($>63 \mu$ m) was present in seven samples with masses ranging from approximately between 25-50% of the original SVF sample. Density measurements varied by SVF type and generally ranged from 2.4 to 2.9 g/cc. Surface area also differed across SVF types with an approximate range from 0.1 m²/g to slightly greater than 0.5 m²/g. Greater than 15,000 fibers were counted for fiber diameter distributions across the 22 SVF fiber samples. Fiber diameter size distribution analyses indicated that modern SVF samples were comprised of fiber diameters both less than and greater than the fiber diameter threshold of 3 μ m for respirability. **Conclusions:** A fiber diameter distribution analysis was conducted on 22 modern glass, stone/rock, and slag SVFs to evaluate fiber physical characteristics important for potential respirability. Fiber diameter distributions indicated that SVFs were comprised of both non-respirable

and respirable fiber diameter sizes. The fiber physical analyses (dimension, density, and surface area) are intended to serve as informative inputs to 1) fiber deposition/dosimetry modeling (e.g., multiple-path particle dosimetry model) and exposure/risk analysis of occupational settings involving the manufacture of different SVFs, and 2) new approach methods (NAMs) for measuring *in vitro* fiber dissolution and predicting *in vivo* fiber biopersistence.

PS 4660 Human macrophage secretory response to woodsmoke condensate exposure is dependent on polarization state, sex, and estrogen receptor activation

E. Hickman, M. Nalesnik, C. Robinette, C. Brooks, N. E. Alexis, and M. E. Rebuli. UNC Chapel Hill, Chapel Hill, NC, NC.

Background and Purpose: Wildfires have increased in frequency and severity over the past few decades, and wildfire risk is predicted to increase in the coming decades due to rising ambient temperatures and human encroachment into wildland areas. Exposure to ambient wildfire smoke (WFS) and wood smoke (WS)/WS condensate (WSC) (often used as an experimental surrogate for wildfire smoke) are associated with respiratory morbidity and mortality and can modulate inflammatory and oxidative processes in a variety of cell types and model systems. Importantly, controlled exposure studies in humans, rodents, and epithelial cells have recently demonstrated that sex can influence cellular responses to inhaled toxicant exposure. However, no studies to-date have investigated sex-specific or estrogen-dependent effects of WS on macrophages, a critical phagocytic cell type responsible for responding to infection and injury in the lungs. This study evaluated macrophage polarization state (M0, M1, M2), estrogen receptor signaling, and sex as potential sources of interindividual variability in response to WS exposure. **Methods:** Human monocyte-derived macrophages differentiated into M0, M1, and M2 polarization states were used as a model for respiratory macrophages. Monocytes were isolated from venous blood ($n = 5$ females, $n = 4$ males) and cultured for six days with M-CSF, resulting in M0 macrophages. Cells were then treated for 24 hours with interferon gamma and lipopolysaccharide to generate M1 macrophages, IL-4 to generate M2 macrophages, or no additional stimuli to maintain an M0 phenotype. A subset of macrophages were also treated with either 1 nM 17 β estradiol (E2) (an estrogen receptor alpha and beta agonist) or 1 μ M ICI 162,780 (fulvestrant, an estrogen receptor antagonist) during the differentiation process. Polarized macrophages were treated with 25 μ g/cm² smoldering red oak wood smoke condensate (WSC) for four hours followed by fresh media for two hours. Following the two-hour period with fresh media, the media was collected for cytokine/chemokine analysis, and cells were assayed for cytotoxicity and phagocytic capacity. Linear mixed effects models and principal component analysis were used to investigate the effects of sex, polarization state, and estrogen receptor treatment on macrophage responses to WSC. **Results:** WSC did not elicit significant cytotoxicity in comparison with the vehicle control, but did significantly decrease phagocytosis across macrophage polarization states, donor sexes, and estrogen receptor treatments. At baseline without WSC or estrogen treatment, M2 macrophages from male participants secreted significantly more IL-17A and TNF- β than M2 macrophages from female participants, while M0 macrophages from female participants secreted significantly more IL-7 than M0 macrophages from male participants. With estrogen treatments and no WSC, ICI treatment significantly increased expression of many secreted proteins, such as IL-6, IFN- α , and IL-1 β in all polarization states and both sexes, while estradiol had minimal effects on secreted protein concentrations. With WSC, pro-inflammatory protein secretion was significantly increased in M0 and M2 macrophages not exposed to E2 or ICI. Notably, these WSC effects were muted in E2 and ICI treated cells. **Conclusions:** Our findings demonstrate baseline differences in macrophage secretory phenotypes between males and females and that the estrogen receptor plays a role in macrophage secretory phenotype and cellular responses to WSC exposure. WSC was also found to decrease phagocytic capacity in all experimental groups, suggesting a general functional suppressive effect with exposure. Ongoing studies are focused on characterizing the transcriptional response of these cells using the same cell culture and exposure paradigm. Future studies are needed to further investigate these mechanisms and determine their impact on respiratory morbidity and mortality following inhaled toxicant exposures and ultimately inform public health and therapeutic approaches to managing health risk associated with WFS exposure.

PS 4661 *In vitro* immune off-target toxicity assessment using morph_ONE for antibody drug conjugates (ADCs).

E. Hoffman, J. Joel, R. Mahendran, E. Zequiri, A. Martin, and V. Hutter. ImmuONE, Stevenage, United Kingdom.

Background and Purpose: Antibody drug conjugates (ADCs) have revolutionized targeted cancer therapy by delivering potent cytotoxic agents directly to cancer cells. However, off-target toxicities remain a major limitation, with interstitial lung disease (ILD) emerging as one of the most serious adverse events. ILD associated with ADCs is characterized by inflammation and fibrosis of the pulmonary tissue, which can lead to progressive respiratory impairment and, in severe cases, fatal outcomes. The underlying mechanisms are not fully understood but may involve immune-mediated responses, non-specific uptake, and systemic exposure to the cytotoxic payload.

The study aimed to (i) optimise and validate human *in vitro* system (alveolar macrophages) for predicting the pulmonary toxicity observed in *in vivo* toxicity studies of ADCs, and (ii) understand the impact of the ADC vs individual components on respiratory inflammation and other potential off-target effects characterized by changes in macrophage morphology. **Methods:** ImmuPHAGE™ (alveolar macrophage-like cells, ImmuONE, UK) were exposed to ADCs of known off-target lung toxicity: trastuzumab deruxtecan, brentuximab vedotin and sacituzumab govitecan in a range of concentrations 0.001 - 100 μ g/mL for 24 h, 48 h, 72 h and 144 h. Following incubation, cells were stained with a cocktail of fluorescent dyes to identify cellular features (nucleus, cytoplasm, mitochondrial activity, membrane permeability). Images were captured using the InCell Analyser 6000 and analysed using InCell Toolbox v1.9.2. Supernatant from cell cultures was assessed for proinflammatory cytokine panel (IFN- γ , IL-1 β , IL-2, IL-4, IL-6, IL-8, IL-10, IL-12p70, IL-13, TNF- α) using MSD cytokine assay system. **Results:** Cell health deterioration, manifested by increase in membrane permeability, decrease in cell count and mitochondrial activity, was affected in a dose and time dependent manner for drugs alone but not for the ADC, indicating that drugs as a standalone treatment display cytotoxic effect on macrophages. While the ADCs did not affect cell health, individual cell data analysis showed changes in macrophage morphology, namely foamy macrophage appearance, especially following 72 h incubation. Increased area of vacuoles and increased number of vacuoles were reported in dose response manner. Cytokine analysis revealed increased secretion of proinflammatory cytokines, especially IL-6 and TNF- α . **Conclusions:** This study showed that the high content imaging assay, morph_ONE, is a suitable tool for identifying changes in macrophage health and morphology resulting from ADCs treatment. Implementing this tool in the early stages of ADC development may help to detect potential off-target toxicity in the airways before progressing to animal studies, aiding candidate selection and increasing the chances of success in the drug development process.

PS 4662 Synergistic Toxicity of E-Cigarette Flavoring Aldehydes and Nicotine in Lung Epithelial Cells

B. Dierolf, and T. Muthumalage. Purdue University, West Lafayette, IN.

Background and Purpose: Flavored ENDS aerosols contain aldehydes, ketones, and esters, as well as nicotine. The mixture toxicity of these ENDS-derived chemicals on the lungs is not well understood. We hypothesized that mixtures of flavoring aldehydes, or aldehydes with nicotine, would exert synergistic toxicity in lung epithelial cells compared to individual components. **Methods:** Bronchial epithelial cells (BEAS-2B) were treated with individual aldehydes-benzaldehyde (B), furfural (F), decanal (D), salicylaldehyde (S), citral (C), p-tolualdehyde (T), 2,5-dimethylbenzaldehyde (DB), benzaldehyde(B), cinnamaldehyde (C), and veratraldehyde(V), at 10 μ M - 2.5 mM, and in combination of two aldehydes at varying ratios (1:1- 1:49), to assess their individual and combined toxicological effects on lung epithelial cells. Effects of nicotine were determined by combining aldehyde with S-nicotine (N). Twenty-four hours post-treatment cytotoxicity was measured with MTT assays. Elicited inflammatory response was determined by a Luminex 17-plex cytokine panel. Individual chemical treatment-induced dose-response and synergism of combined chemicals were determined using CompuSyn analysis. **Results:** B:F combination showed no cytotoxicity; however, IL-6 and IL-8 levels were significantly decreased. B:D caused significant cytotoxicity, decreased IFN- γ , MCP-1, IL-5, IL-6, and IL-8, but increased GM-CSF, IFN- γ , and MCP-1. B:S showed significant cytotoxicity and a significant decrease in MCP-1, IL-6, and IL-8. B:T caused significant cytotoxicity and decreased MCP-1, IL-6, IL-7, and IL-8. B:DB caused significant cytotoxicity, increased IL-6, while decreasing TNF- α and IL-7. Combining nicotine with aldehydes, such as N:C caused significant cytotoxicity proportional to the increased cinnamaldehyde ratio in the mixture. N:C caused a decrease in MCP-1 but elevated levels of MIP-1 β , IL-6, and IL-8 with increased nicotine concentration. **Conclusions:** Binary mixtures of ENDS flavoring aldehydes, as well as aldehyde-nicotine combinations, caused synergistic and ratio-dependent cytotoxicity with differential inflammatory responses. These findings highlight the importance of mixture toxicity analysis for ENDS toxicity assessment and suggest that even low-level chemical combinations can exacerbate pulmonary toxicity. This study was funded by the National Institutes of Health R00ES033835.

PS 4663 A Comparative Analysis of Approaches for Identifying Biologically Safe Doses for Asbestos

K. Kissell, M. Stevens, T. Turla, and D. Paustenbach. TRC Strategic Health Sciences, Jackson, WY.

Background and Purpose: The fields of pharmacology and toxicology have long embraced that “the dose makes the poison”. Despite OSHA and EPA’s claim that there is “no safe dose” and reliance on the linear no-threshold (LNT) model for carcinogens, there is always a dose at which no adverse effects are reasonably expected. For years, statisticians have opined that “direct statistical confirmation of a threshold from human data is virtually impossible” due to differences in susceptibility between people (Hodgson and Darnton 2000). An understanding of the mechanism of action for asbestos carcinogenesis, in combination with the epidemiology data, supports the existence of exposure thresholds below which increased mesothelioma

and lung cancer risk are de minimis. Asbestos-induced carcinogenesis is primarily driven by chronic inflammation, with the weight of evidence indicating that asbestos is not directly DNA-reactive, immunosuppressive, or estrogenic. A biologically safe dose (BSD), below which adverse health effects are unlikely to deviate from the background incidence of disease, is generally accepted because inflammation is a reversible effect. In recent years, several approaches have been developed to identify BSDs for each asbestos fiber type. **Methods:** A targeted, non-systematic literature review was conducted to identify recent approaches for deriving asbestos BSDs. Four methodologies were reviewed: No Observable Adverse Effect Level (NOAEL) Approach, Benchmark Dose (BMD) Approach, Central Tendency Approach, and Fiber Burden Approach. The linear no-threshold (LNT) model, as applied by regulatory agencies such as the EPA and OSHA, was reviewed for comparison. **Results:** The NOAEL approach identified best-estimate NOAELs of 250-379 f/cc-years for chrysotile, 2-5 f/cc-years for amosite, and 0.6-1 f/cc-years for crocidolite (Beckett et al. 2023). Applying a safety factor of three, appropriate given the robust epidemiological and toxicological data for asbestos, yielded threshold doses of 105, 1.2, and 0.25 f/cc-years for the respective fiber types. The benchmark dose (BMD) extrapolation approach utilized updated cohort information to derive estimated doses corresponding to an observable response (Stevens et al. 2025). A theoretical 1-in-1,000 mesothelioma risk was then extrapolated below the experimental range, resulting in threshold doses of approximately 100 f/cc-years for chrysotile, 2 f/cc-years for amosite, and 0.3 f/cc-years for crocidolite. The central tendency modeling approach fit several models to available epidemiological data to estimate a central tendency threshold for chrysotile (Goodman et al. 2025). Applying potency ratios across fiber types produced cumulative thresholds of 90 f/cc-years for chrysotile, 1 f/cc-year for amosite, and 0.25 f/cc-years for crocidolite. In contrast, the fiber burden approach, as currently implemented by some experts, yielded considerably lower dose estimates: 0.015 f/cc-years for crocidolite, 0.075 f/cc-years for amosite, and 7-10 f/cc-years for chrysotile. This threshold dose is based on a risk level that “doubles” the background risk of developing mesothelioma. These values were derived based on a background rate of mesothelioma of 1 per million-years, although recent epidemiology studies suggest that a more appropriate background rate is closer to 5 per million-years. It is also noteworthy that the crocidolite-exposed cohort relied upon to derive these values (Reid et al. 2007) has limitations. Updating this approach with the latest mesothelioma background risk estimates and epidemiological data would yield BSDs that begin to approach those from the other methods. **Conclusions:** The figures derived using NOAEL/3, BMD, and Central Tendency are remarkably consistent, considering they relied on different studies and used different approaches to reach these conclusions. These three methods indicate reasonable BSDs of 100 f/cc-year, 1-2 f/cc-year, and 0.3 f/cc-year for chrysotile, amosite, and crocidolite, respectively. An updated assessment using the fiber burden approach is more consistent with these values. Given that asbestos induces mesothelioma through repeated inflammation, these approaches likely overestimate risk, suggesting a potential threshold above the derived BSDs. Significant evidence of potency differences between asbestos fiber types indicates the need for fiber-type-specific occupational exposure limits.

PS 4664 Inhaled Vitamin D as a Prophylactic Against Environmental Lung Disease and Respiratory Infection

K. D. Schichlein, G. J. Smith, and I. Jaspers. University of North Carolina at Chapel Hill, Chapel Hill, NC.

Background and Purpose: People of color are disproportionately affected by environmental lung diseases and respiratory infections, likely due in part to increased prevalence of vitamin D deficiency (VDD). In addition to health and nutritional disparities caused by socioeconomic and structural inequities, higher levels of melanin in people of color leads to decreased subcutaneous vitamin D synthesis, the primary route of vitamin D generation. VDD has been linked to increased severity and occurrence of environmental lung diseases, such as asthma and COPD, and increased risk of influenza and COVID infection, indicating that the disproportionate impact of environmental lung diseases and respiratory infections on people of color may be due in part to increased prevalence of VDD. While vitamin D has been proposed as a prophylactic treatment for environmental lung disease and respiratory infections, studies of oral vitamin D supplementation have produced mixed results. Inhalation offers the advantage of delivering vitamin D directly to the respiratory epithelium, potentially providing superior protection compared to oral supplementation. We therefore investigated the role of vitamin D inhalation as a prophylactic strategy against ozone exposure and H1N1 infection in human airway cells and evaluated potential antiviral and immunomodulatory mechanisms. **Methods:** We exposed well-differentiated, primary human bronchial epithelial cells (HBECS) at air-liquid interface to ozone or H1N1 influenza virus (A/California/07/2009), following administration of 10 µL of 10 µM vitamin D to the apical compartment. Apical treatment was delivered via aerosol in a novel multi-well *in vitro* exposure system, On-Plate Aerosol Delivery Array (OPADA). Prophylactic effects of vitamin D were evaluated through bulk RNA-sequencing, RT-qPCR, cytokine secretion, and oxidative stress endpoints. Differential expression analysis was performed along with unbiased analyses such as multi-dimensional scaling and hierarchical clustering. Gene set enrichment analysis (GSEA) and Ingenuity Pathway Analysis (IPA) were used to reveal potential mechanisms behind vitamin D's protective effects. **Results:** We found that pre-treatment with aerosolized vitamin D significantly reduced H1N1 viral load in HBECS, as measured by decreased expression of influenza genes. Vitamin D pretreatment also reduced virus-induced expression of antiviral interferon-stimulated genes (ISGs) while modulating cytokine

responses indicative of reduced inflammation. Similarly, GSEA revealed that vitamin D treatment attenuated viral inflammatory responses, immune dysfunction, and cellular damage pathways, while boosting pathways related to ciliary function. We also found that vitamin D pre-treatment attenuated ozone-induced upregulation of inflammation- and oxidative stress-related genes such as IL-8, FFAR2, COX-2, and NFKB2. Mechanistic investigation revealed that vitamin D reduced lipid peroxidation and glutathione oxidation induced by ozone, indicating that vitamin D may act as a membrane antioxidant. **Conclusions:** Here, we provide studies demonstrating that inhaled vitamin D: 1) reduces H1N1 viral load and decreases aberrant inflammatory responses, and 2) attenuates oxidative stress and inflammatory gene expression induced by oxidant pollutants such as ozone. Our data suggest inhaled vitamin D may be a feasible prophylactic strategy for protecting against influenza infection and environmental lung disease and may have utility in reducing health disparities associated with VDD in people of color. Ongoing studies aim to understand the pharmacokinetics of inhaled vitamin D, further elucidate mechanisms by which inhaled vitamin D provides protection, and explore the utility of vitamin D inhalation in humans.

PS 4665 Mast Cells Modulate Early Pulmonary Inflammatory Responses to Amorphous Silica Nanoparticles

A. N. Reinert, M. Gibb, and J. M. Brown. University of Colorado, Anschutz Medical Campus, Aurora, CO.

Background and Purpose: Amorphous silica nanoparticles (SiNP) are considered an occupational concern in both industrial and agricultural settings. While crystalline silica is well known to drive strong pulmonary inflammation, the inflammatory potential of amorphous silica is less understood. Mast cells are early responders in the lung and can influence acute inflammatory and tissue-damage responses to particle exposures. This study examined the role of mast cells in the acute pulmonary response to SiNPs using wild-type (WT) and mast cell-deficient (Kit^{W-sh}) mice. **Methods:** WT and Kit^{W-sh} mice received a single exposure to either vehicle (PBS) or SiNPs (~200 nm) at 5 mg/kg via oropharyngeal aspiration. Lung tissue and bronchoalveolar lavage fluid (BALF) were collected after 24 hours. BALF cytosins and differential cell counts were performed to assess inflammatory cell recruitment. Lung tissue was examined by H&E staining to evaluate structural injury, and flow cytometry was used to characterize immune cell populations within the lung. Lipidomic profiling was also performed on BALF samples and human mast cells (HMC-1.2) were exposed to SiNPs *in vitro* for degranulation assessment and lipidomic analysis. **Results:** SiNP exposure produced an acute inflammatory response in WT mice, characterized by shifts in BALF immune cell composition, including increased neutrophils and eosinophils accompanied by a reduction in macrophages. Similarly, innate and adaptive immune cell populations in WT lung tissue indicated a broader inflammatory recruitment compared to Kit^{W-sh} mice. In contrast, Kit^{W-sh} mice displayed a muted inflammatory profile across multiple cell types, suggesting the absence of mast cells attenuates early-stage pulmonary responses. Although SiNPs induced measurable degranulation in HMC-1.2 cells, lipidomic profiling in both BALF and HMCs revealed limited treatment-related differences, with only a few lipids showing nominal changes. **Conclusions:** Overall, the reduced responses in Kit^{W-sh} mice, together with SiNP-induced degranulation in HMCs, indicate mast cell involvement in early signaling events that may influence downstream pulmonary inflammation.

PS 4666 Tobacco-Flavored E-Cigarette Aerosol Suppresses Immune-Resolution Pathways and Initiates Early Lung Remodeling Following Sub-Chronic Inhalation Exposure

B. Dierolf, E. Kabir, C. Botero, S. Han, J. H. Park, A. Laskin, and T. Muthumalage. Purdue University, West Lafayette, IN.

Background and Purpose: Electronic nicotine delivery systems (ENDS) are widely marketed as safer alternatives to combustible cigarettes; however, toxicological data defining the chemical composition, aerosol characteristics, and biological consequences of sub-chronic flavored ENDS exposure remain limited. This study evaluated the combined pulmonary toxicity of tobacco-flavored ENDS aerosols with and without nicotine to identify early adverse outcome pathway events linked to chronic lung disease. **Hypothesis:** Sub-chronic inhalation of tobacco-flavored ENDS aerosols disrupts immune-resolution signaling and initiates ECM remodeling, with nicotine acting as a mechanistic amplifier through cholinergic suppression of inflammatory and reparative pathway. **Methods:** Male and female C57BL/6J mice were exposed to tobacco-flavored ENDS aerosols ±6 mg/mL nicotine (51 mL/puff; 2 puffs/min; 2 hr/day for 30 days). Aerosol size distributions, including number and mass concentrations, were monitored using a scanning mobility particle sizer and an optical particle sizer, while ENDS liquids were analyzed via thermal desorption DART-HRMS to characterize semi-volatile and non-volatile constituents. Post-exposure biological endpoints included lung mechanics, lung inflammatory response assessed by flow cytometry and cytokines, as well as proteomic and genomic profiling. **Results:** Tobacco and tobacco+nicotine aerosols generated significantly elevated ultrafine particle concentrations (10⁸-10⁹ particles/cm³), with dominant size modes between 30-150 nm and mass peaks at 0.1-0.3 µm, indicating strong deep-lung deposition potential. Chemical analysis revealed complex mixtures containing aldehydes, ketones, esters, alcohols, N-heterocycles, monoterpenes, sweeteners, nicotine, nico-

tine derivatives, and unidentified constituents, with tobacco-containing formulations showing the greatest chemical complexity. Both nicotine-free and nicotine-containing ENDS exposures suppressed key immune-recruitment and resolution mediators (IL-1 β , CCL3, CCR1/CCR2, PIR-A/B, LYN) and reduced fibroblast-activation markers (OSM, TNFRSF1 β). BALF exhibited increased epithelial-stress and ECM-remodeling proteins (complement D, CRP, CD26, acidic FGF, Gas6, pro-MMP9, PAI-1). Lung-tissue protease-antiprotease imbalance and impaired clearance were evident through reductions in MMP-9, MPO, CCL6, and eotaxin. Nicotine enhanced pro-MMP9 and PAI-1 elevations and increased static compliance while reducing elastance, indicating greater susceptibility to remodeling. **Conclusions:** These findings demonstrate that sub-chronic inhalation of tobacco-flavored ENDS aerosols produces early toxicological signatures of immune-resolution failure, protease imbalance, and ECM remodeling. Nicotine further amplifies these trajectories, suggesting ENDS use may predispose the lung to chronic lung disease-related outcomes even in the absence of overt inflammation. The study was supported by the National Institutes of Health, NIH/NIEHS R00ES033835.

PS 4667 Silica content-dependent epithelial injury and fibroblast activation following engineered stone particle exposure in an *in vitro* co-culture alveolar model

E. H. Choy, A. Jiménez-Chávez, D. A. Herman, M. T. Kleinman, and A. De Vizcaya-Ruiz. University of California, Irvine, Irvine, CA.

Background and Purpose: Engineered stone (ES) is widely used for kitchen and bathroom countertops. This composite material, made of ground quartz with pigments and synthetic resin, has gained popularity due to its aesthetic and lower maintenance compared to natural stones. Respirable crystalline silica from engineered stone fabrication poses a significant occupational hazard, leading to progressive and irreversible silicosis. Recent cases underscore the urgent need to elucidate its pathogenic mechanisms. When silica particles reach the alveoli, macrophages activate and initiate inflammatory signals that promote fibroblast proliferation and collagen accumulation, leading to fibrosis. ES with high silica content exacerbates these responses by increasing lung particle burden and sustaining inflammation. However, few studies have examined how the varying silica content in ES influences lung injury pathways related to silicosis. Using an *in vitro* co-culture system to model the distal lung microenvironment, we investigated how silica content affects epithelial barrier integrity, intercellular signaling, and fibroblast activation, to elucidate early events connecting ES particle exposure to silicosis progression. **Methods:** Based on established *in vitro* models, rat alveolar type II (AT II) RLE-6TN epithelial cells and NR8383 macrophages were seeded in the apical compartment, and lung fibroblast RFL-6 in the basolateral compartment, of a co-culture system to mimic alveolar microenvironment. Commercially available ES samples with high (> 40%) or low ($\leq$ 40%) silica content were tested, and a positive control pure crystalline silica (Min-U-Sil 5, diameter $\leq$ 5 μ m). With an air-liquid interface system, AT II cells and macrophages were exposed to 0, 1.0, 2.5, and 5.0 μ g/cm² ES particles, followed by incubation with fibroblasts. Cell viability and membrane integrity, and fibroblast activation were assessed at 24, 48, and 72 h post-exposure by measuring lactate dehydrogenase release, transepithelial electrical resistance (TEER), and α -smooth muscle actin (α -SMA) immunofluorescence staining, respectively. Particle size distribution of ES suspensions was characterized by dynamic light scattering (DLS). **Results:** DLS showed ES particle median diameters of 618 - 678 nm, a size range capable of reaching alveolar regions. AT II cells exposed to ES exhibited a 110%, 240%, and 290% increase in TEER at 24, 48, and 72 hours post-exposure, respectively, at the highest concentration. In comparison, control and Min-U-Sil 5 exposures produced approximately 200%, 400%, and 500% increases in TEER at the same time points. Immunofluorescence analysis of α -SMA in fibroblasts showed a dose-dependent response, with increased fluorescence intensity observed after exposure to high-silica ES. Cell viability remained within normal ranges, indicating that observed effects arose from structural and molecular alterations rather than cytotoxicity. **Conclusions:** Exposure to ES particles impaired epithelial barrier integrity in AT II cells, independent of silica content. Fibroblast activation increased with higher silica content, suggesting that particle composition influences fibrotic remodeling. While intercellular crosstalk between epithelial cells, macrophages, and fibroblasts is inferred from these responses, further studies are underway to confirm the underlying signaling mechanisms. Overall, these findings provide mechanistic insight into ES-induced disruption of alveolar homeostasis and advance understanding of the early events contributing to ES-associated silicosis, identify potential therapeutic targets, and inform exposure thresholds relevant to occupational risk.

PS 4668 Toxicity of Algal Species Associated with Florida Freshwater Cyanobacterial Blooms To Human Small Airway Epithelial Cells

C. Fisher¹, T. Jilling¹, M. Garzon-Ramirez¹, K. Kroll², S. Bisesi², M. Carolina Ferreira², J. Moretto², D. Berthold², N. Denslow², D. Laughinghouse², and T. Sabo-Attwood¹. ¹University of South Carolina, Columbia, SC; and ²University of Florida, Gainesville, FL.

Background and Purpose: Shifting climates and other environmental factors have been associated with increasing harmful cyanobacterial blooms in freshwater bodies globally, including the southeast United States. Many of these blooms are responsible for the release of an array of various cyanotoxins, including microcystins (MC), a class of cyclic peptides, that have been widely studied for their detrimental effects on aquatic organisms and humans. Microcystin-LR (MC-LR) is one of the most common congeners from this class of cyanotoxins with well-known hepatotoxicity, typically associated with oral exposure. However, the respiratory effects of MC-LR as a result of inhalation exposure are unknown, despite abundant evidence indicating aerosolization of MC-LR from bodies of water. This research gap led us to investigate the toxicity of algae with and without MC-LR on small airway epithelial cells, hypothesizing that the presence of MC-LR would produce the greatest toxicity. **Methods:** *Microcystis aeruginosa* (MA) with high levels of MC-LR and *Florianema aeruginum* (FA) with no-detectable MC-LR were isolated from freshwater bodies in Florida and are maintained in culture. Total MC production from each strain was quantified by ELISA and levels of individual MC congeners (i.e. MC-LR) were quantified by Liquid Chromatography Mass Spectrometry (LC/MS). Lyophilized cyanobacterial aliquots were lysed with three freeze-thaw cycles, particulate matter was sedimented by centrifugation and then the soluble cyanobacterial suspension supernatant was quantified and added to the growth media of cultured SAEC at increasing concentrations (120, 240 and 480 ng MC-LR/mL media) (2-3 replicates/experiment, >3 repeat experiments). As a control, purified MC-LR was also included at a concentration that mirrored what was present in the highest *Microcystis* dose (200 μ g/mL). After a 48-hour exposure, the viability of SAEC was characterized by flow cytometry using Calcein-AM (violet) to label live cells with intact membranes, CellEvent caspase 3/7 reagent (green) to label cells undergoing apoptosis and Sytox AADvanced dead cell stain to detect cells with broken membranes. Extracellular vesicles (EV) were also collected and purified from SAEC media to explore this as a unique mechanism. Extracellular vesicles were characterized by nanoCFM for number and diameter. **Results:** Quantification of MC-LR content in cyanobacterial lysates indicated 119 μ g microcystin/mg MA biomass and no detectable MC-LR in FA. SAEC post exposure to MA or to MC-LR show significant decrease of live cell count (-15.3 $\pm$ 2.3%, P=0.0085 and -21.5 $\pm$ 7.6%, P=0.0013) and increasing number of apoptotic (13.7 $\pm$ 1.8%, P=0.0002 and 19.1 $\pm$ 5.8%, P<0.0001) and dead cells (5.1 $\pm$ 1.3%, P=0.047 and 6.0 $\pm$ 2.4%, P=0.044) at 200 μ g/mL MA and 500 ng/mL MC-LR. There were no significant changes to SAECs in the presence of FA. EV size profiles showed that the spread of the diameter is seen for both MA and FA at 200 μ g/mL extract. This is interesting because MA produces MC-LR and FA does not. In a follow up experiment, the same doses were used again, but this experiment included purified MC-LR at a high dose. Again, the low dose of MA did not change the diameter, but the higher doses starting at 100 μ g/mL did increase the spread in diameters of the exosomes. Purified MC-LR also increased the diameter spread. But in this particular experiment, FA at 200 μ g/mL did not. This data suggests that the exposures to the toxins are causing the cells to put out exosomes with altered structure. **Conclusions:** This work presents some of the first characterizations of toxicity of cyanobacterial extracts and MC-LR to human small airway epithelial cells. Importantly, these data support that the toxin, MC-LR seems associated with the death of SAEC and secretion of EVs. These important observations support that the lung may be a site of toxicity of inhaled harmful algal blooms and associated toxins, and that secretion of exosomes could present as a novel mechanism of action. The results of this study add to the limited reports on how MC-LR may directly affect the respiratory system. Future work is aimed at directly understanding the mechanism of action behind MC-LR toxicity of SAECs.

PS 4669 Pulmonary Pathophysiologic Response to Acute Inhalation of Chloropicrin

S. A. Ariola, A. Arredondo, P. Venkatesh, D. X. Li, A. L. Castro, A. L. Lundberg, J. Manzano, M. C. Domanico, K. J. Bein, and L. S. Van Winkle. University of California, Davis, Davis, CA.

Background and Purpose: Chloropicrin (trichloronitromethane, CP) is a potent pulmonary irritant and soil fumigant historically used as a chemical warfare agent. Despite its continued agricultural use and potential for accidental or intentional release, the dose-response, temporal progression of lung injury, and sex dependent acute susceptibility to inhaled CP remain poorly defined. We used an acute 4 hr exposure in an inhaled CP dose response in mice to characterize the cellular targets of toxicity in the lung by sex, the LD50 and innate immune response in lung tissue. **Methods:** Male and female C57BL/6 mice were exposed via nose-only inhalation to 0.75, 1.5, 3, 6, or 12 parts per million (ppm) CP vapor for 4 hours (n=6/sex/group/timepoint) and were monitored for up to 3 days. Survival and weight loss were recorded. Regional focal intrapulmonary toxicity was assessed using histopathology in high resolution resin sections. Bronchoalveolar lavage fluid (BALF) was collected for analysis of total protein, immune cell differentials and cell death. **Results:** Weight loss was evident within 24 hours and correlated with exposure concentration and mortality.

Both sexes exhibited concentration and time dependent lethality, with females showing greater sensitivity. At 3.0ppm, mortality reached 25% in females compared with 10% in males, and at 12ppm, mortality was higher, with nearly complete lethality in females (92%) versus 56% in males. BALF protein content and total cell counts increased in a concentration dependent manner. In BALF, both sexes showed an up to a tenfold increase in total cells by 24-48 hours post exposure. Neutrophils increased in a concentration and time dependent manner. At 48 hours, neutrophils rose to $12.0 \pm 15.8\%$ and $31.2 \pm 14.4\%$ in females, and $28.6 \pm 26.7\%$ and $33.9 \pm 25.4\%$ in males at 6 and 12 ppm, respectively. By 72 hours, neutrophils increased to $12.9 \pm 7.7\%$ and $62.0 \pm 20.5\%$ in females and $18.4 \pm 13.2\%$ and $59.8 \pm 28.6\%$ in males at 6 and 12 ppm. Neutrophilic infiltration was comparable between sexes at 24 hours but trended higher in females at later timepoints and at higher doses (6 and 12 ppm). Dead epithelial cells in BALF peaked at 2 days post exposure. Histologic evaluation confirmed bronchiolar club cells as the primary targets of CP induced lung injury with pronounced vacuolization and cell loss over time post exposure. **Conclusions:** Nose only CP exposure produced reproducible, concentration dependent acute airway epithelial club cell injury in C57BL/6 mice and revealed sex differences in mortality that correspond with increased neutrophil and lavage protein levels. The selective vulnerability of bronchiolar club cells identifies a site-specific pathologic target relevant to inhalation threat scenarios that expands the current knowledge of acute cellular targets in the lung. This model establishes essential baseline data to guide both mechanistic long-term injury and repair studies being conducted in our lab, and the development of medical countermeasures for acute high dose CP exposure. Funded by: NIH grants: R01 ES034419, T32 ES007059 (to SA) T32HL007013 (to MD and JM), and with support from P30 ES023513

PS 4670 Loss of Cytochrome P450 Reductase (CPR) in Alveolar Type II Cells and Hepatocytes Exacerbates Hyperoxic Lung Injury in Mice

D. Narke, W. Jiang, and B. Moorthy. Baylor College of Medicine, Houston, TX.

Background and Purpose: Supplemental oxygen is primarily used in the management of acute respiratory distress syndrome (ARDS), a chronic lung disease affecting more than 200,000 adults and leading to 80,000 deaths in the US each year. Although supplemental oxygen is intended to treat hypoxemia (low blood oxygen) in ARDS patients, prolonged oxygen exposure (hyperoxia) alters alveolar morphology, thus causing acute lung injury (ALI). Hyperoxia has been shown to cause lung injury in humans and animal models by increasing reactive oxygen species (ROS) leading to oxidative stress, inflammation, and structural alterations to lung morphology. Our preliminary data in hyperoxia treated mice has shown significant reduction in the mRNA expression of cytochrome P450 reductase (CPR). CPR is the obligate electron donor to microsomal cytochrome P450 enzymes and is highly expressed in both lung and liver. Prior work suggests that hepatic P450 pathways mitigate hyperoxic lung injury, implicating extra-pulmonary detoxification in lung protection. We hypothesized that CPR in lungs (alveolar type II (ATII)) cells and liver is required to alleviate hyperoxia-induced lung injury and inflammation. **Methods:** Adult conditional CPR knockout mice with ATII-specific deletion (SPC promoter; lung-CPR-KO) or hepatocyte-specific deletion (albumin promoter; liver-CPR-KO), and their wild-type (WT) littermates were exposed to room air (RA) or $>95\% O_2$ for up to 72 h. Lung injury was assessed by lung weight/body weight (LW/BW) ratios and hematoxylin-eosin histopathology. Lung and liver mRNA levels of CPR, pro-inflammatory cytokines (TNF- α , IL-6) and oxidative stress response genes (NQO1, HMOX1) were quantified by qPCR, and CPR/CYP1A activity was measured enzymatically. **Results:** In WT mice, hyperoxia significantly increased LW/BW ratios (unpaired t-test; $p < 0.05$); lung TNF- α and IL-6 expression (unpaired t-test; $p < 0.05$), while significantly reducing pulmonary CPR mRNA by $\sim 35\%$ (unpaired t-test; $p < 0.05$), indicating that lung CPR is downregulated during oxygen toxicity. ATII-specific CPR deletion further exacerbated hyperoxic lung injury, with lung-CPR-KO mice displaying significantly higher LW/BW ratios (unpaired t-test; $p < 0.05$), augmented TNF- α and IL-6 expression (unpaired t-test; $p < 0.05$), and marked induction of NQO1 and HMOX1 (unpaired t-test; $p < 0.05$) compared with WT under hyperoxia, consistent with amplified inflammation and oxidative stress. Hepatocyte-specific CPR deletion similarly increased susceptibility to hyperoxic lung injury. Liver-CPR-KO mice exhibited markedly reduced hepatic CYP1A enzyme activity (unpaired t-test; $p < 0.05$), higher LW/BW ratios (unpaired t-test; $p < 0.05$), and more severe alveolar and perivascular edema and hemorrhage, along with increased pulmonary pro-inflammatory mediator expression (TNF- α and IL-6) compared with WT controls (unpaired t-test; $p < 0.05$). **Conclusions:** These data identify CPR as a critical determinant of host defense against hyperoxic lung injury in both pulmonary (ATII epithelial) and hepatic compartments. Loss of CPR in either site amplifies lung inflammation, oxidative stress, and tissue damage, supporting a dual-organ model in which local epithelial CPR and extra-pulmonary (hepatic) detoxification cooperate to constrain hyperoxic ALI. Targeting CPR-dependent pathways, or preserving CPR function in at-risk patients, may offer novel strategies to prevent or attenuate hyperoxic lung injury.

PS 4671 Transport of Airborne Asbestos Fibers in the Ambient Air: Effects of Fiber Type and Debris Binding on Fiber Dispersion

M. Stevens¹, Q. Perry², B. Deckard², A. Singhal³, and D. Paustenbach². ¹TRC Strategic Health Sciences, Denver, CO; ²TRC Strategic Health Sciences, Jackson, WY; and ³Environmental Health & Engineering, San Francisco, CA.

Background and Purpose: Mechanical cutting of asbestos cement (AC) pipe releases airborne fibers whose transport behavior is poorly characterized. This study quantified the dispersion of chrysotile and crocidolite fibers generated from high-velocity pipe cutting, using spatially resolved air sampling and scanning electron microscopy. While different methods have been proposed for estimating AED, few (if any) are able to adequately account for all the physical properties of fibers which are likely to affect transport. This study is novel in that it may be the first one to evaluate fiber transport at short distances from the source in an open environment, differentiating between chrysotile and crocidolite. **Methods:** Particulate plumes assessed in this study were generated through the cutting of a historical AC pipe containing approximately 30% chrysotile and 10% crocidolite asbestos. Six cuts were made in the pipe over a 30-minute sampling period, releasing approximately 115 g of material into the air. High velocity air sampling pumps were placed in concentric circles around the operator cutting the pipe. Samplers were placed at 28 different locations in concentric circles around the pipe cutter. Air samples were collected at distances of 8 to 95 ft from the source at a height of 4 ft above ground level. Two cassette samples were collected at each of the 28 sample locations around the point source for a total of 56 samples collected over the course of the study. **Results:** Fiber concentrations were highest (peak of 4.92 f/cc; 3.82 f/cc for chrysotile and 1.10 f/cc for crocidolite) along the visible dust plume direction (east) within 8 feet of the cutting interface and total asbestos exposure declined exponentially with distance (2.19 f/cc at 25 ft; 0.73 f/cc at 50 ft; 0.39 f/cc at 75 ft; 0.13 f/cc at 95 ft). At 90° from the plume axis, fiber concentrations at the 8-foot sampler were reduced by approximately 35%. Fiber concentrations were less than 0.7 f/cc beyond 90° from the plume axis. Aerodynamic equivalent diameter (AED) was strongly associated with deposition distance (crocidolite: $\beta = -0.046 \text{ ft}^{-1}$, $p = 3.48 \times 10^{-5}$; chrysotile: $\beta = -0.039 \text{ ft}^{-1}$, $p = 5.97 \times 10^{-4}$) while fiber length was not (crocidolite: $\beta = 0.00043 \text{ ft}^{-1}$, $p = 0.83$; chrysotile: $\beta = 0.00081 \text{ ft}^{-1}$, $p = 0.41$). Crocidolite fibers, which exhibited higher AEDs (crocidolite GM: 3.7; chrysotile GM: 2.0), settled more rapidly and were detected over shorter distances than chrysotile (crocidolite decay constant: 0.049 ft⁻¹; chrysotile decay constant: 0.044 ft⁻¹). A high proportion of fibers were bound to cement debris (chrysotile: 86%; crocidolite: 68%), and these bound fibers exhibited slightly steeper decay profiles (chrysotile: $\beta = -0.032$ vs -0.026 ; crocidolite: $\beta = -0.053$ vs -0.045). **Conclusions:** Empirical transport patterns aligned with AED-based theoretical models but diverged significantly from Gaussian plume assumptions, underscoring the limitations of traditional dispersion models for short-range, ground-level fiber emissions. These findings support the use of AED as a mechanistic predictor of fiber transport and highlight key considerations for exposure assessment in still-air environments. From an exposure perspective, the results highlight three key considerations. First, the combination of steep decay and directionality implies that short-range, directional sampling may be sufficient to characterize worst-case exposure under similar conditions. The "rule of thumb" relationship, presented in Donovan et al. (2011), between distance from a point source and fiber concentration can underestimate fiber concentrations in the plume window if the point source is directionally releasing fibers with significant velocity and significantly overestimate concentrations for locations not in that axis. Second, the predominance of debris-associated fibers—many of which settle rapidly—suggests that airborne residence time for a substantial fraction of released fibers may be limited, particularly for those with higher AED or bound to heavier debris. Finally, while crocidolite is often viewed as more hazardous due to its biopersistence and its high carcinogenic potency, its faster decay rate and shorter transport range may reduce its relative contribution to downwind exposures in similar scenarios.

PS 4672 Fluorotelomer and Perfluoro Aldehyde Lung Cell Toxicity: Implications for Indoor Exposure to Volatile PFAS

S. Horn, L. Tran, and Y. Lin. University of California, Riverside, Riverside, CA. Sponsor: J. Hoang

Background and Purpose: Fluorotelomer alcohols (FTOHs) are a volatile subclass of per and poly-fluoroalkyl substances (PFAS) that represent the largest fraction of gas-phase PFAS in indoor air. Various industrial and consumer products, like certain food contact materials, and treated textiles and upholstery, are common sources of emissions. Atmospheric oxidation of FTOHs by hydroxyl radicals produces intermediate aldehydes, mainly fluorotelomer aldehyde (FTAL) and perfluoro aldehyde (PFAL), before terminating into perfluoro carboxylic acids (PFCAs). Yet, the inhalation exposure to and toxicity of the intermediate FTOH atmospheric degradation products is not well-understood, and previous *in-vitro* studies show FTAL compounds are more toxic than their terminal PFCA products. This study aims to examine cytotoxicity in lung cells by establishing LC_{50} values for 4:1 PFAL, 4:2 FTAL, 6:1 PFAL, 6:2 FTAL, 10:1 PFAL, and 10:2 FTAL through *in-vitro* assays, and characterize their chemical reactivity with the important antioxidant biological nucleophile glutathione (GSH) to investigate its contribution to the overall mechanism of toxicity. The central hypothesis is that FTALs will exhibit the highest cytotoxicity as reflected by the lowest LC_{50} values compared to FTOH and PFAL; the cytotoxicity of the aldehydes will decrease with decreasing chain length, and will correlate with GSH adduct

formation. **Methods:** Cytotoxicity was assessed by lung cell viability after 24 hour exposures of 4:1, 6:1 and 10:1 PFAL, and 4:2, 6:2, and 10:2 FTAL on 96-well plates of BEAS-2B cells, immortalized human epithelial lung cells, using a XTT assay measuring light absorbance of metabolized salts. Cells were exposed to FTOHs, FTALs, and PFALs in cell media with less than 1% v/v DMSO or ACN depending on solubility and includes a vehicle control. To predict reactivity with biological nucleophiles, electrophilicity indexes (ω) were calculated using ionization energy and electron affinity derived from orbital energies computed at the DFT/B3LYP/6-311+G(d, p) level of theory. Calculated electrophilicity will be compared to GSH depletion via detection of adducts in chemical assays of aldehyde standards incubated with GSH. Standard aldehyde-GSH adducts will be characterized using LCMS, and exposed cells will be screened for aldehyde-GSH adducts. **Results:** 4:2 FTAL, 6:2 FTAL, and 4:1 PFAL significantly reduced lung cell viability in the micromolar range in a dose dependent manner with LC_{50} 2 μ M, 40 μ M, and 2500 μ M, respectively. The chain length of the tested aldehyde compounds influenced the cell viability, demonstrating increasing cytotoxicity with decreasing chain length, in line with previous studies on aldehydes derived from PFAS. The remaining aldehydes to be tested are expected to follow this trend. Electrophilicity indexes rank as PFAL>FTAL>FTOH and are expected to correlate positively with GSH adduct formation. **Conclusions:** 4:1 PFAL had a considerably higher LC_{50} than 4:2 FTAL, implying the alpha carbon unique to FTAL may drive cytotoxicity. Despite higher electrophilicity index ranking, 4:2 FTAL is more cytotoxic than 4:2 PFAL, showing increasing electrophilicity index does not correlate with higher toxicity. 4:2 FTAL had a lower LC_{50} than 6:2 FTAL; shorter chain lengths may allow for greater uptake and ready reaction with thiol containing biological nucleophiles such as GSH, with FTAL being attacked at the alpha carbon by thiol containing molecules, while the longer chain compounds may be sterically hindered and thus decrease their reactivity. The results from this study imply that intermediate oxidation products from atmospherically oxidized FTOHs have their own inhalation exposure risks in addition to terminal PFCAs and parent compounds, and warrants further investigation to fully elucidate inhalation risks posed by FTOHs.

PS 4673 Sex chromosome dosage as a mechanism of neonatal pulmonary oxygen toxicity

R. M. Albert, M. E. Cantu Gutierrez, A. Cantu, A. Lee, H. Chang, and K. Lingappan. Children's Hospital of Philadelphia, Philadelphia, PA.

Background and Purpose: Preterm birth (<37 weeks gestational age) affects about 10% of pregnancies globally, and premature infants are predisposed to early life mortality and a variety of long-term adverse sequelae. Premature infants often rely on therapeutic interventions such as surfactant administration, mechanical ventilation, and supplemental oxygen (hyperoxia) for survival. Although recognized as a lifesaving treatment, hyperoxia contributes to alveolar simplification and pulmonary vascular dysfunction that is pathognomonic of bronchopulmonary dysplasia (BPD). BPD is the most common lung disease of prematurity, and surviving infants are at higher risk for diseases such as reactive airway disease and emphysema. BPD has a clinically recognized male bias for disease incidence and severity, underscoring an unmet need to identify molecular mechanisms of sex-specific pathobiology. Our lab previously discovered that mice with XX chromosomes, regardless of gonadal sex, had preserved alveolarization in a BPD mouse model. It is unknown if mice with XX chromosomes were protected because they lacked a Y chromosome, or because they had twice as many X chromosomes relative to XY mice. The objective of this study is to determine the role of sex chromosome dosage on lung development and response to neonatal hyperoxic lung injury. **Methods:** To interrogate sex chromosome dosage, we used the XY* mouse line that has XX, XO, XY, and XXY genotypes. Neonatal XY* mice were exposed to hyperoxia (95% FiO₂, PND 1-5) or room air (21% FiO₂) and euthanized on PND 7 or PND 21. This exposure paradigm was chosen to parallel the sacular stage of lung development when a human preterm infant would receive supplemental oxygen in the NICU. Bulk RNA sequencing was used to assess changes in the pulmonary transcriptome, including differentially expressed genes (DEGs) and biological pathways ($\log_2FC = 0.6$; FDR = 0.05) as a function of sex chromosome dosage (n = 4 pups/genotype/treatment). **Results:** We previously characterized alveolar development at PND 21 in XY* mice and identified an interaction between the Y chromosome and treatment for radial alveolar count (P = 0.0171), and an interaction between X chromosome dosage and treatment (P = 0.0392). To interrogate the pulmonary transcriptome at PND 21, we used bulk RNA sequencing and found a subtle transcriptional response to treatment. Therefore, we sought to investigate the acute transcriptional response (PND 7) that may instead be driving our observed phenotype. We identified 216 common DEGs (15%) at PND 7 to hyperoxia. We then compared mice with a Y chromosome (XY and XXY), without a Y chromosome (XO and XX), with one X chromosome (XO and XY), and with two X chromosomes (XX and XXY). We found that mice with two X chromosomes had the most DEGs (308) under hyperoxia, followed by mice lacking a Y chromosome (148), mice with only one X chromosome (144), and mice with a Y chromosome (57). Using GSEA, we identified 78 common pathways in response to hyperoxia, including humoral immune response and positive regulation of vascular endothelial growth factor production. Mice with two X chromosomes showed unique pathways in hyperoxia response such as modulation of inflammatory response, nitric oxide pathways, and lipid metabolism. **Conclusions:** Mice with a Y chromosome had worse outcomes after neonatal hyperoxic lung injury. Ongoing works are interrogating transcriptional response at single cell resolution at PND 7 and assessing pulmonary function at

PND 21 using FlexiVent. A comprehensive investigation of sex-specific responses to respiratory exposures informs our understanding of lung development, cumulative exposures, and long-term outcomes.

PS 4674 Aerosolized Microcystin from Harmful Algal Blooms drives congener-dependent inflammation and cytotoxicity in human airway cells

B. Timalisina¹, U. Shrestha¹, J. Breidenbach², B. French¹, S. T. Haller¹, and D. Kennedy¹. ¹The University of Toledo, Toledo, OH; and ²University of Toledo, Toledo, OH.

Background and Purpose: Harmful algal blooms (HABs), primarily resulting from cyanobacterial overgrowth, are becoming more frequent and now pose serious environmental threats by releasing microcystin toxins into both water and air. Of the more than 300 identified microcystin variants, microcystin-leucine arginine (MC-LR) and leucine alanine (MC-LA) are frequently detected in both water and air during HAB events, highlighting inhalation as a significant but underappreciated route of exposure. This study investigated the physiological and inflammatory impacts of aerosolized microcystins on human airway cells. **Methods:** Primary human nasal and bronchial airway epithelial cells (hAEC) from healthy and asthmatic donors were grown at the air-liquid interface (ALI) and fully differentiated to mimic *in vivo* airway characteristics. The differentiated cells were exposed apically to aerosolized microcystins (1 μ M of MC-LR or MC-LA) or a saline control, using the expoCube targeted aerosol exposure system, which delivered a precise dose of 13 μ g/m² of each microcystin to the cell surface. Inflammatory responses were quantified at both the gene and protein levels: gene expression was measured by qRT-PCR, and protein concentrations were determined using ELISA. NF- κ B activity was assessed using A549-Dual reporter lung cells treated with 1 μ M of microcystin toxins with or without IL-1 β (0.5 ng/ml). Cytotoxicity was quantified by measuring LDH released into the conditioned media from both primary hAEC and A549 lung cells after 24-hour exposures to 1 μ M and 10 μ M of each toxin. **Results:** A 3D *in vitro* model of primary human nasal and bronchial airway epithelial cells showed full differentiation with functional cilia and mucociliary clearance. Exposure to 1 μ M MC-LR or MC-LA did not significantly alter cell morphology, while 10 μ M MC-LR caused minimal changes and 10 μ M MC-LA caused significant cell death. In healthy primary human airway cells, 1 μ M MC-LR increased *TNF- α* and *IL-6* levels (1.8-fold and 1.9-fold, respectively; p<0.001), with even greater increases observed in asthmatic cells (*TNF- α* : 3.5-fold; *IL-6*: 2.6-fold; p<0.001). In A549 cells, NF- κ B activity rose modestly (~10%, p<0.01) with MC-LR and substantially (~50%, p<0.01) with MC-LA, the latter being significantly higher than MC-LR (~40%, p<0.001). When stimulated with IL-1 β , NF- κ B activity further increased (~40% with MC-LR, ~70% with MC-LA; p<0.0001), highlighting a stronger pro-inflammatory response to MC-LA. **Conclusions:** Aerosolized microcystin exposure in human airway cells from nasal and bronchial origin induced pro-inflammatory genes, with asthmatic cells showing increased sensitivity. MC-LA triggered stronger pro-inflammatory and cytotoxic responses than MC-LR, posing higher respiratory risks for vulnerable groups. These findings highlight the potential exacerbation of airway inflammation by aerosolized MCs, particularly in vulnerable populations.

PS 4675 Hazard characterization of 2-ethyltoluene in rats and mice following whole-body inhalation exposure

M. Fyle¹, G. Roberts¹, M. Stout¹, S. Patial¹, M. Cesta¹, C. Willson², K. Shockley¹, and K. Ryan¹. ¹NIHES, Morrisville, NC; and ²Inotiv, Morrisville, NC.

Background and Purpose: Onshore crude oil production in the United States has been increasing steadily over the last decade. Production begins by removing petroleum from underground reservoirs, followed by fractional distillation to separate crude oil into useful components, such as gasoline and diesel. The naphtha component is separated at a boiling point of 60-180°C and contains aromatic alkylbenzenes, such as trimethylbenzene, ethyltoluene isomers, and xylene mixtures. These alkylbenzenes are used in a variety of products, including gasoline mixing and blending, paints, sealants, and other industrial coatings, and combustion processes. Between 5 - 10 billion pounds of naphtha was produced in the U.S. in 2019, making it a high-production volume chemical. Thus, due to its widespread use, understanding occupational and general population exposures to the chemical constituents of this crude-oil fraction is essential for protecting human health and safety. Previously, a 2-week inhalation study in Sprague-Dawley (SD) rats and B6C3F1 mice, identified 2-ethyltoluene (2-ET) as the most potent isomer, causing high mortality and prominent liver, lung, and nasal lesions. Thus, we designed a guideline sub-chronic inhalation study of 2-ET at several concentrations in mice and rats to further characterize these health effects. **Methods:** Male and female SD rats and B6C3F1/N mice (10 animals/sex/species) were exposed to 0, 3.13, 6.25, 12.5, 25, 50, and 100 ppm of 2-ET via whole-body inhalation for 6hrs/day over 13 weeks. Following exposure, survival, body and organ weights, and histopathology were assessed. **Results:** The results from this study indicated that the nose and brain might be target organs for 2-ET toxicity. In B6C3F1/N mice, there was a trend for a significant treatment-related body-weight decrease in male mice only. We observed significant decreases in terminal organ weights compared to controls that occurred in a dose-response manner across males and females, specifically at 100ppm expo-

sure levels for the liver (~12%), kidneys (~20%), and in the epididymis (~16%) and ovaries (~31%), although these changes did not manifest with histologic correlates. In SD rats, terminal body weights were significantly decreased in males and females at ≥ 12.5 ppm. Histopathology revealed test-article related lesions in the nasal cavity and the olfactory lobes of the brain, in both SD rats and B6C3F1/N mice of both sexes. Nasal lesions included olfactory epithelium atrophy, olfactory nerve atrophy, chronic active inflammation, concretions, and metaplasia of the olfactory epithelium. Respiratory epithelium hyperplasia was observed in rats but not in mice. Olfactory bulb atrophy was evident in the brain for both rats and mice. Nasal lesions were present at all doses starting from 3.13 ppm, whereas brain lesions appeared at ≥ 6.25 ppm. We were unable to identify a no observed effect level (NOEL) since changes were observed at every tested concentration of 2-ET. These findings indicate that 2-ET is a potent isomer that elicits adverse effects in the nasal cavity and olfactory lobes of the brain following inhalation exposures at concentrations of 3.13ppm or higher. **Conclusions:** This study provides valuable insights into the health effects of 2-ET, advancing potential risk assessment and read-across methodologies, as other structurally related compounds do not elicit the same potency and toxicity as 2-ET. Further studies are underway to identify a NOEL and to characterize potential bioactive metabolites of 2-ET that may contribute to nasal and brain toxicity. These insights help bridge critical data gaps needed to better assess human health risks and strengthen public health preventions against this ubiquitous environmental compound.

PS 4676 6PPD drives acute airway inflammation and macrophage shifts toward remodeling

D. Kim, G. Oh, J. Park, J. Choi, C. Park, J. Yuk, W. Jung, and M. Song. Korea Institute of Toxicology, Jeongseup, Korea, Republic of.

Background and Purpose: N-(1,3-dimethylbutyl)-N'-phenyl-p-phenylenediamine (6PPD) is a widely used rubber antioxidant, yet its respiratory toxicity and immunological mechanisms following airway exposure remain largely unclear. Macrophages play a central role in the initiation and resolution of lung inflammation, and their M1 and M2 polarizations strongly influences respiratory disease outcomes. Here, we investigated the temporal dynamics of pulmonary inflammation and macrophage polarization induced by 6PPD in both *in vivo* and *in vitro* studies. **Methods:** Mice received a single intratracheal instillation of 6PPD and were sacrificed on days 1, 4, 7, and 14. Lung weight, inflammatory cell profiles, and cytokine/chemokine levels were assessed along with histopathological evaluation. In parallel, RAW264.7 macrophages were exposed to 6PPD for 24 hours to determine polarization patterns via flow cytometry. **Results:** *In vivo*, 6PPD exposure at day 1 increased lung weight and eosinophil counts, accompanied by elevated interferon- γ (IFN- γ), interleukin-5 (IL-5), monocyte chemoattractant protein-1 (MCP-1), and vascular endothelial growth factor (VEGF). By day 4, prominent macrophage aggregation appeared in lung tissue. *In vitro*, 6PPD induced a dose-dependent shift in macrophage polarity, promoting M1 polarization at lower concentrations and M2 polarization at higher concentrations. **Conclusions:** Collectively, these findings demonstrate that 6PPD triggers acute eosinophilic inflammation with progressive macrophage recruitment, alongside a concentration-dependent polarization response. Given that M1-to-M2 transitions are associated with airway remodeling and fibrosis, repeated or high-level exposure to 6PPD may contribute to chronic respiratory pathology. These results reveal a previously unrecognized immunological mechanism of 6PPD and support its classification as a potential respiratory toxicant.

PS 4677 N-acetyltransferase 2 acetylator phenotype modifies N-acetylation, DNA damage and oxidative stress responses of 2-amino-9H-pyrido[2,3-b]indole

D. W. Hein, R. A. Salazar-González, and M. A. Doll. University of Louisville, Louisville, KY.

Background and Purpose: 2-Amino-9H-pyrido[2,3-b]indole (AaC) is a heterocyclic amine carcinogen which induces liver and blood vessel tumors and aberrant crypt foci, an early biomarker of colon cancer, in mice. (AaC) is present at high levels in tobacco smoke. Human exposure also occurs following dietary ingestion of well-done meats and exposures to diesel fumes. AaC is genotoxic in human lymphoblastoid and peripheral blood lymphocytes cells when assessed by comet and micronucleus assays and it forms high and persistent levels of DNA adducts in primary human hepatocytes. The high levels of AaC in tobacco smoke and its hepatic bioactivation may contribute to development of liver and gastrointestinal tract cancers in smokers. AaC bioactivation is catalyzed by cytochrome P450-mediated (CYP1A2) N-hydroxylation of the exocyclic amine group followed by O-acetylation catalyzed by N-acetyltransferase 2 (NAT2) to form the acetoxy derivative which binds covalently to DNA leading to mutagenesis and potentially carcinogenesis. A genetic polymorphism in NAT2 yields rapid, intermediate and slow acetylator phenotypes. Epidemiological studies suggest a role for human NAT2 genetic polymorphism in cancer risk following heterocyclic amine exposures in tobacco smoke and consumption of well-done meats. **Methods:** The role of NAT2 acetylator phenotype in AaC N-acetylation, DNA damage response and oxidative stress were investigated in rapid, intermediate, and slow acetylator cryopreserved human hepatocytes and in

nucleotide excision repair-deficient (UV5) Chinese hamster ovary (CHO) cells stably transfected with human CYP1A2 and either NAT2*4 (rapid acetylator) or NAT2*5 or NAT2*7 (slow acetylator) alleles. Cryopreserved human hepatocytes possessing two NAT2 alleles associated with rapid acetylation activity were classified as rapid acetylators, samples possessing two NAT2 alleles associated with slow acetylation activity were classified as slow acetylators. Samples possessing one allele associated with rapid acetylators and one allele associated with slow acetylators were classified as intermediate acetylators. AaC N-acetylation was quantified by separation and quantification of AaC and its N-acetyl-AaC by reverse phase high performance liquid chromatography. CHO cells treated with AaC were assessed for DNA damage response using phospho-histone H2A.X (Ser139) antibody and RedDot™2 Far-Red Nuclear Stain for normalization to cell number. CHO cells and cryopreserved human hepatocytes treated with AaC were assessed for oxidative stress response using the 2',7'-dichlorodihydrofluorescein diacetate fluorescence assay. **Results:** Levels of AaC N-acetylation and oxidative stress response were NAT2 phenotype-dependent in human cryopreserved human hepatocytes. Rates were significantly highest in rapid acetylators, lower in intermediate acetylators and lowest in slow acetylator cryopreserved human hepatocytes ($p < 0.0001$). Treatment of CHO cells with AaC resulted in dose-dependent DNA damage and oxidative stress responses that were significantly highest in CHO cells transfected with CYP1A2 and rapid acetylator NAT2*4 compared to un-transfected UV5 CHO cells, or UV5 CHO cells transfected with CYP1A2, CYP1A2/NAT2*5 or CYP1A2/NAT2*7 ($p < 0.0001$). **Conclusions:** N-acetyltransferase 2 acetylator phenotype modifies AaC N-acetylation, and DNA damage and oxidative stress responses following AaC treatment. Although N-acetylation of AaC may compete with N-hydroxylation, the O-acetylation of the N-hydroxy-AaC appears to be more impactful towards determining levels of DNA damage and oxidative stress responses. These laboratory results support epidemiological studies reporting a modifying effect of human NAT2 genetic polymorphism in cancer risk from tobacco smoke and consumption of well-done meats.

PS 4678 Effect of lead on endothelial cell viability and junctional integrity and the potential protective role of dapagliflozin

N. Ramalingam, A. Tapaswi, S. Harris, and J. A. Colacino. University of Michigan, Ann Arbor, MI.

Background and Purpose: Cancer is the second leading cause of death globally, primarily due to metastasis. Transendothelial migration of tumor cells across the vascular barrier is a key step, regulated by the integrity of endothelial cell junctions. Adherens junctions, with VE-cadherin as a crucial component, maintain vascular integrity, and disruption facilitates tumor cell migration. Environmental lead (Pb) exposure impairs endothelial function by increasing oxidative stress and reducing nitric oxide (NO) bioavailability. Dapagliflozin (DAPA), a sodium-glucose co transporter 2 (SGLT2) inhibitor, may protect endothelium from toxic insults by reducing oxidative stress, preventing cell death, and promoting survival. This study examines the impact of lead and DAPA on endothelial viability and junction integrity, addressing whether DAPA can mitigate lead's adverse effects. **Methods:** Primary human umbilical vein endothelial cells (HUVECs) were cultured in endothelial growth medium supplemented with bovine brain extract and plated in 384-well plates to ensure reproducible monolayer formation. Cells were dosed with lead acetate trihydrate at ten concentrations ranging from 0.08 to 40 μ M for time points at 48 hours and 96 hours and subsequently stained with the nuclear stain Hoechst 33342 for quantitative assessment of cell number. In parallel, a dose-response experiment measuring differences in cell number was conducted with DAPA at concentrations from 0.08 to 10 μ M, after which 10 μ M was selected as the concentration for all subsequent co-dosing assays. Three lead doses were selected—0.16 μ M, 1.25 μ M, and 10 μ M and each was tested both independently and in combination with 10 μ M DAPA. Cell number was quantified through high-content imaging using a CX5 microscope and CellProfiler 4.2.1, with cell counts normalized as percent of average control values for comparative analysis. Junctional integrity was evaluated by immunofluorescence staining for VE-cadherin, with automated measurement of edge intensity to assess changes in junction localization. Statistical analyses for the initial dose-response experiments were performed using boxplots and t-tests in R across replicates and conditions, while Wilcoxon rank-sum tests were employed for co-dosing experiments to compare cell counts and VE-cadherin edge intensity across groups. **Results:** Lead exposure reduced HUVEC cell counts in a concentration-dependent manner, with cytotoxic and anti-proliferative effects observed at 40 μ M ($p < 0.05$). DAPA alone promoted an increase in cell counts relative to untreated controls. In co-dosing experiments, DAPA exerted a marked rescue effect across all the tested doses, elevating cell counts to near-control levels at 96 hours (10 μ M $p < 2.3e-05$; 1.25 μ M $p < 2.5e-12$; 0.16 μ M $p < 0.02$). VE-cadherin immunofluorescence analysis revealed that Pb alone did not cause substantial changes in junction integrity, as edge intensity remained largely stable across different Pb doses and time points. In contrast, DAPA co-treatment led to notable increases in VE-cadherin edge intensity at both moderate and high lead exposures (1.25 μ M and 10 μ M), most significantly at 96 hours ($p < 2e-16$). **Conclusions:** DAPA confers dose-dependent protection on HUVEC viability over time, and restores VE-cadherin-mediated junction organization, especially following 96 hours of exposure. Importantly, DAPA's restorative effects on VE-cadherin organization and barrier integrity were present even in settings where total cell counts did not fully recover, underscoring the potential for pharmacological intervention to preserve junctional function under toxic stress conditions. These findings support DAPA's therapeutic potential for preserving endothelial barrier func-

tion following environmental lead exposure. Ongoing experiments are evaluating the effect of lead on endothelial cell junctions using functional transwell migration assays with breast cancer cells to directly assess whether DAPA mitigates lead-induced endothelial toxicity and limits metastatic migration, further establishing its relevance in cancer-related vascular toxicity.

PS 4679 Personalized ω -3 Fish Oil Clinical Trial Supplementation Decreases Pro-Inflammatory Adipokine Secretion and *In Vitro* Mammary Stem Cell Self-Renewal

E. M. Hill¹, J. A. Colacino¹, R. M. Esper², A. Sen², N. Polakowski¹, M. N. Aslam², Z. Djuric², M. S. Wicha², W. L. Smith², and D. E. Brenner². ¹University of Michigan Public Health, Ann Arbor, MI; and ²University of Michigan Medical School, Ann Arbor, MI.

Background and Purpose: Adipose inflammation associated with obesity is a driver of cancer risk and mortality. Adipose tissue secretes cytokines, termed adipokines, which regulate inflammation, metabolism, and other biological processes and are dysregulated during obesity. Mammary stem cells are a target of adipokines and the expansion of this stem cell population is a hypothesized driver of breast cancer risk. Dysregulated secretion of cytokines in obesity may promote the expansion of breast stem cells. Dietary ω -3 polyunsaturated fatty acids are used to alleviate symptoms of inflammatory diseases, such as rheumatoid arthritis. Thus, an ω -3 rich fish oil intervention may be an effective strategy to reduce breast cancer risk by alleviating adipose tissue inflammation and decreasing secretion of mediators that regulate breast stem cell proliferation. To test this, we conducted a clinical trial examining the impacts of a personalized fish oil intervention on adipose inflammation and breast stem cell outcomes. **Methods:** Fifteen clinically obese (BMI ≥ 30 kg/m²) women were enrolled in a clinical trial, of which 13 were able to successfully complete. Prior to fish oil dosing, blood was collected as well as subcutaneous adipose tissue via needle aspiration. Participants then received a personalized fish oil dosage designed to deliver a serum EPA: ω -3 ratio of 0.3. After 12 weeks, participants returned and blood and subcutaneous adipose were collected. Total lipids were extracted from serum and fatty acids measured by GC-MS. Adipose tissue was cultured for 48 hours and the resulting adipose conditioned media (ACM) collected. One sample was excluded due to culture contamination. Twenty-two serum cytokines and adipose-secreted adipokines were measured using Luminex or ELISA. Effects of ACM from pre- and post-treatment samples on mammary stem cells were tested using the mammosphere assay using a pool of normal human breast epithelial cells from reduction mammoplasty donors. Differences between pre- and post-treatment were determined using paired t-tests and a statistical significance cutoff of 0.05. **Results:** Twenty-eight fatty acids were detectable in most serum samples and concentrations of ω -3 fatty acids were increased after 12 weeks of fish oil supplementation. Eicosapentaenoic acid (20:5 ω -3), docosahexaenoic acid (22:6 ω -3), and docosapentaenoic acid (22:5 ω -3) were increased from 0.32 to 2.25 mol% ($p < 0.001$), 0.50 to 1.31 mol% ($p = 0.0012$), and 0.34 to 0.76 mol% ($p < 0.001$) respectively. The EPA:AA ratio also increased from 0.06 to 0.46 ($p < 0.001$). Of 17 circulating cytokines detected, 6 were significantly altered. Serum C-reactive protein decreased by 29.3% (4.65 μ g/ml to 3.27 μ g/ml, $p = 0.0016$). Circulating adiponectin, complement factor 2, and osteopontin decreased by 8.5% ($p = 0.013$), 9.1% ($p = 0.029$), and 7.68% ($p = 0.033$). Serum RBP-4 increased by 179% ($p = 0.0007$) and CCL-2 by 17.0% ($p = 0.021$). Of 16 adipokines measured in the adipose conditioned media (ACM), 2 decreased significantly, including C-reactive protein by 57.6% ($p = 0.0043$), CXCL-5 by 81.7% ($p = 0.025$). Primary mammosphere formation was not different when cultured with pre- and post-fish oil ACM (1.95% vs. 1.81%, $p = 0.38$). However, secondary mammosphere formation efficiency decreased when treated with post-fish oil ACM compared to pre-fish oil ACM (1.75% vs. 1.40%, $p = 0.03$). **Conclusions:** Personalized daily fish oil supplementation incorporated ω -3 fatty acids into blood lipids of trial participants after 12 weeks of treatment. Multiple inflammatory factors and adipokines were decreased after fish oil treatment. Secondary mammosphere formation was decreased when treated with post-fish oil ACM, suggest that altering secreted adipokines reduces breast stem cell self-renewal. Our results show that fish oil may reduce inflammatory adipokine secretion which, within the breast microenvironment, may decrease mammary stem cell expansion and thus breast cancer risk.

PS 4680 JNK Inhibition by HLN Disrupts Mitochondrial Proton Motive Force to Induce Ferroptotic Cell Death in Colorectal Cancer Therapy

M. A. Eltokhy¹, S. Gaikwad², M. Moore¹, and S. K. Srivastava¹. ¹TTUHSC, Abilene, TX; and ²Synvivo Inc., Huntsville, AL.

Background and Purpose: Mutations within MAPK signaling, including dysregulated JNK activity, promotes colorectal cancer (CRC) progression and therapy resistance. The JNK pathway is a central regulator of cellular stress and mitochondrial integrity. While its activation is associated with survival signaling and redox balance, its inhibition can dismantle metabolic homeostasis. Ferroptosis, an iron-dependent oxidative death pathway, represents an emerging strategy to overcome apoptosis resistance in CRC. In this study, we hypothesized that HLN* functions as a potent JNK inhibitor that drives ferroptotic cell death in CRC cells through disruption of mitochondrial bioenergetics and collapse of the proton motive force (PMF). **Methods:** CRC

cell lines (CT26, COLO-205, and HCT116) were treated with HLN to determine IC₅₀ values by SRB. CFA were conducted to investigate HLN's impact on the long-term proliferative potential of CRC cells. ROS generation was measured using DCFDA assay. Ferroptosis induction was assessed by lipid peroxidation MDA assay, GSH depletion and GST activity. Labile iron levels were assessed by ferro-orange assay. Mitochondrial function was evaluated via JC-1 potential assay to quantify PMF integrity as well as DiSC3(5) assay. RNA-seq and GO enrichment analyses were performed to identify pathways downstream of JNK inhibition, focusing on ferroptosis and oxidative stress. Western blotting analyzed phospho-JNK levels & other JNK pathway related proteins. To further delineate the mechanism of ferroptosis induction, key proteins were assessed using western blot such as GPX4, xCT and DMT1 expression. Mechanistic rescue assays used NaHCO₃ and NAC. For preliminary *in vivo* validation, an orthotopic CRC model was established by injecting luc-labeled CT26 cells into the cecal wall of BALB/c mice ($n = 5$ per group). After tumor establishment (day 7), mice received HLN (10 mg/kg daily oral administration) or vehicle control. Tumor growth was monitored by bioluminescence imaging. **Results:** HLN treatment exhibited potent cytotoxicity across CRC cell lines, with IC₅₀ values ranging from 1 to 4 μ M as determined by SRB assay. CFA showed a dose-dependent reduction in long-term proliferative capacity. HLN markedly increased intracellular ROS, confirming oxidative stress. This was accompanied by a significant increase in lipid peroxidation, depletion of reduced GSH, and suppression of total GST activity. Ferro-orange staining revealed a rise in labile iron pools, reinforcing the iron-dependent oxidative phenotype characteristic of ferroptosis. HLN profoundly impaired mitochondrial function. JC-1 and DiSC3(5) assays both demonstrated mitochondrial depolarization and collapse of the cytoplasmic proton-motive force (PMF), indicating bioenergetic failure. Western blot confirmed JNK pathway inhibition. Transcriptomic and GO enrichment analyses further identified enrichment in oxidative-stress and toxic-response pathways, alongside downregulation of antioxidant regulators. These transcriptional findings were corroborated at the protein level, where HLN decreased expression of GPX4, xCT, and increasing the iron transporter DMT1, implicating suppression of cystine uptake, glutathione synthesis, and iron handling. Pretreatment with N-acetylcysteine (NAC) or NaHCO₃ effectively rescued cells from ROS accumulation, restored GSH content, and mitigated HLN-induced cytotoxicity, confirming that oxidative stress downstream of JNK inhibition is central to its ferroptotic action. In the orthotopic CRC model, HLN treatment resulted in a reduction in tumor bioluminescence relative to control. No significant body-weight loss or gross toxicity was observed, underscoring tolerability. **Conclusions:** Our findings identify JNK inhibition as a novel upstream trigger for ferroptosis via mitochondrial dysfunction and PMF dissipation. By suppressing JNK-dependent antioxidant and metabolic repair pathways, HLN destabilizes mitochondrial potential, amplifies ROS accumulation, and silences the GPX4-SLC7A11 axis, driving lipid peroxidation, mediated ferroptotic death. This study defines a JNK-PMF-ferroptosis axis as a critical vulnerability in CRC and introduces HLN as a first-in-class small molecule targeting this energy-redox interface for therapeutic exploitation. *Due to Intellectual property issue, the name of the compound is not provided

PS 4682 Mechanisms of Hexavalent Chromium-Induced Carcinogenesis: DNA Double Strand Breaks and DNA Repair Inhibition in a Guinea Pig Model

I. Meaza¹, J. L. Wise², S. Diven¹, H. Lu¹, A. W. Brownell¹, J. Easley¹, J. C. Kouokam¹, J. P. Wise Jr.³, S. Vilee¹, J. T. Wise⁴, R. M. Wise¹, and J. P. Wise Sr.¹. ¹Wise Laboratory of Environmental and Genetic Toxicology, Department of Pharmacology and Toxicology, University of Louisville, Louisville, KY; ²Wise Laboratory of Liver and Environmental Health, Department of Pharmacology and Toxicology, University of Louisville, Louisville, KY; ³NeuroWise Laboratory of Environmental Toxicology, Department of Pharmacology and Experimental Therapeutics, University of Toledo, Toledo, OH; and ⁴Wise Laboratory of Nutritional Toxicology and Metabolism, Department of Human Nutrition, Food and Animal Sciences, University of Hawai'i at Mānoa, Honolulu, HI.

Background and Purpose: Hexavalent chromium [Cr(VI)] is an environmental and occupational health hazard, and a known lung carcinogen. Despite the exposure risks, it is unclear how Cr(VI) causes lung cancer. Prolonged Cr(VI) exposure induces DNA double strand breaks and inhibits their repair, leading to chromosome instability, a hallmark of lung cancer. Specifically, Cr(VI) inhibits RAD51, a key effector protein in the homologous recombination repair pathway. This mechanism has been well characterized in cell culture assays and was recently translated to a rat model. However, rats have different bronchial bifurcation patterns from humans, which is critical because Cr(VI) particles impact and form tumors at these sites in humans. In contrast, guinea pigs share these bronchial bifurcation patterns with humans, making them a more translatable model to study how Cr(VI) causes lung cancer. Our goal was to translate the mechanism of Cr(VI)-induced DNA double strand breaks and DNA repair inhibition to guinea pig lungs. We hypothesized acute Cr(VI) exposure would increase the levels of DNA double strand breaks and increase DNA repair, while subchronic exposure would increase DNA double strand breaks and inhibit their repair. **Methods:** 10-11-week-old Hartley guinea pigs were exposed to zinc chromate via oropharyngeal aspiration for an acute (24 h) or subchronic (90-day) exposure. Zinc chromate was used as a representative particulate Cr(VI) compound, as epidemiological and toxicological data show it causes lung cancer in humans. At the end of each exposure, animals were euthanized and lungs were dissected. A piece of left upper lobe lung tissue was analyzed for metal contents by

inductively coupled plasma mass spectrometry to confirm Cr reached the lungs. The right middle lobe was used for immunofluorescence staining. DNA double strand breaks were measured using the gamma-H2AX, and homologous recombination repair was assessed using RAD51. Z-stack images were obtained using a confocal microscope, and nuclear gamma-H2AX and RAD51 foci were quantified. **Results:** Cr levels increased in Cr(VI)-exposed groups, indicating our exposures reached the lungs of guinea pigs. In addition, zinc levels were also measured because we used zinc chromate as our representative Cr(VI) compound, but as expected, we did not observe significant changes in zinc levels. When comparing animals acutely and subchronically exposed to Cr(VI), acute Cr(VI) exposure induced DNA double strand breaks and DNA repair, whereas subchronic exposure also caused DNA double strand breaks but inhibited repair. This effect of increased Cr(VI)-induced increased DNA double strand breaks and inhibited repair after subchronic Cr(VI) exposure was largely observed in bronchial regions but not in alveolar regions. **Conclusions:** This study establishes a new human-relevant guinea pig model to study Cr(VI)-induced carcinogenesis and translates the mechanism of Cr(VI)-induced DNA double strand break formation and repair inhibition to guinea pig lungs. In addition, results in this study showed bronchial regions are more sensitive to this mechanism than alveoli, which is consistent with previous studies showing Cr accumulates in the bronchial regions where it forms tumors. Future studies will assess how Cr(VI) inhibits DNA repair pathways to drive lung carcinogenesis. This work was supported by the National Institute of Environmental Health Sciences grant R35ES032876 (JPWSr.) and a fellowship from "la Caixa" Foundation LCF/BQ/EU22/11930060 (IM).

PS 4683 KRAS Variant-Dependent Effects of PFOS and PFHxS Exposure in Pancreatic Ductal Adenocarcinoma Cells

S. E. Marks, K. M. Polemi, C. H. Williams, K. E. Sant, and J. D. Diedrich. Michigan State University, East Lansing, MI.

Background and Purpose: Per- and polyfluoroalkyl substances (PFAS) are known as "forever chemicals" based on their persistence in biota and the environment. Perfluorooctanesulfonate (PFOS) is one of the most prevalent PFAS, previously used to produce non-stick materials and concentrated in aqueous film-forming foams used in firefighting. PFOS was removed from many products and processes due to hazards, and it was replaced by a shorter chain (6-carbon vs. 8-carbon) analog of PFOS known as perfluorohexanesulfonate (PFHxS). PFAS have been correlated with increased risk for several cancers, but their role in pancreatic carcinogenesis remains poorly understood. Pancreatic ductal adenocarcinoma (PDAC) is among the deadliest cancers with activating KRAS mutations present in approximately 90-95% of cases. To assess the impact of PFOS and PFHxS on oncogenic and clinically relevant KRAS variants, isogenic PANC1 cells expressing KRAS G12D, KRAS G12R and KRAS Q61R mutations were exposed to a concentration range of each compound. KRAS variant-specific signaling in PDAC differentially activates effector pathways such as MAPK, PI3K, and RAL-GDS, influencing tumor cell behavior. Therefore, variant-specific differences in proliferation, gene expression, and morphology in response to PFAS were measured. **Methods:** Isogenic KRAS mutant PANC1 cells were generated using CRISPR-mediated knock-in approaches allowing for controlled interrogation of KRAS variant-specific responses to PFAS. Cells were exposed to 6.25-200 μ M of PFOS and PFHxS for 48 hours, and proliferation was measured using the PrestoBlue assay. Epithelial-to-mesenchymal (EMT) marker gene expression was quantified by quantitative PCR (qPCR). Variant-specific transcriptomic and morphological feature analyses were conducted using RNA-sequencing coupled with Cell Painting, respectively. **Results:** Both PFOS and PFHxS increased cell proliferation in a concentration-dependent manner, with cytotoxicity only observed at 200 μ M PFOS. KRAS G12R and KRAS Q61R variants displayed greater proliferative responses to PFHxS than KRAS G12D. qPCR for EMT-related genes revealed variant-specific effects, with PFOS more than doubling TWIST1 expression in KRAS G12D cells and PFHxS increasing TWIST1 in the same manner in KRAS G12R cells. **Conclusions:** These results suggest that PFOS and PFHxS promote pro-tumorigenic signaling in a KRAS variant-specific manner. Ongoing RNA sequencing and Cell Painting analyses will integrate transcriptomic and morphological responses to PFAS exposure. Collectively, these data will identify candidate biomarkers of PFAS exposure in genetically predisposed individuals, aiding early detection and risk stratification. They will also reveal molecular signatures that inform patient selection and risk modeling in environmental epidemiology. Finally, they may uncover pathways or vulnerabilities that can be targeted to mitigate the synergistic effects of PFAS exposure in KRAS-driven cancers.

PS 4684 A Mode of Action (MOA) and Human Relevance Framework (HRF) Analysis for Nasal Tumors Induced by Methyl Isothiocyanate (MITC) in Sprague Dawley Rats

M. Badding¹, B. B. Gollapudi², R. Reiss³, J. R. Harkema⁴, and S. M. Cohen⁵. ¹Biologics Consulting, Alexandria, VA; ²Toxicology Consultant, Midland, MI; ³Exponent, Alexandria, VA; ⁴Michigan State University, East Lansing, MI; and ⁵University of Nebraska Medical Center, Omaha, NE.

Background and Purpose: Methyl isothiocyanate (MITC; CAS # 556-61-6) is formed in soil following application of soil fumigants, including metam sodium and metam potassium. Exposure to MITC via inhalation following application of the fumigants has been assessed in human health risk assessments, most notably for workers and bystanders. MITC induced nasal tumors in Sprague Dawley rats exposed by inhalation to a high concentration (20 ppm), but not at 0.5 and 5 ppm. To investigate the MOA for the tumors and their relevance to humans, a study was conducted to understand the nature and severity of the acute and subacute responses to inhaled MITC in the rat nasal mucosa, at tumorigenic and non-tumorigenic concentrations. **Methods:** Seven-week-old male Crl:CD(SD) rats (8/group/time point) were exposed to filtered air (control) or MITC (0.5, 5 or 20 ppm) by whole-body inhalation for 6 hours per day for 1 day, 1 week (5 exposures per animal), or 4 weeks (5 days per week). Exposures were conducted using 1000-L stainless steel whole-body chambers. One day after the end of the last scheduled exposure, the animals were fasted overnight and sacrificed. Additional male rats (8/group) were similarly exposed for 5 days/week for 4 consecutive weeks, but sacrificed four weeks after the last exposure (recovery group). Two hours before the scheduled termination, the rats received an intraperitoneal injection of 50 mg/kg body weight bromodeoxyuridine (BrdU). Nasal tissues were taken at necropsy, fixed in 10% neutral-buffered formalin and processed for light microscopic examination of histopathology and quantitative morphometric analysis of BrdU-labelled nasal epithelial cells in regions that correlate with previously determined sites of nasal tumors. Tissue blocks were taken from four locations throughout the nasal airways (T1, T2, T3, and T4). The MITC-induced lesions identified for semiquantitative severity scoring were inflammation, epithelial hyperplasia in transitional and respiratory epithelium, squamous cell metaplasia in transitional and respiratory epithelium, epithelial degeneration and necrosis in transitional and respiratory epithelium, olfactory sensory neuron apoptosis in olfactory epithelium, olfactory sensory neuron loss resulting in atrophy of olfactory epithelium, and respiratory metaplasia of olfactory epithelium. Morphometric measurements, such as unit length BrdU labeling index in nasal epithelium (ULLI), were performed at a select anatomic site (maxilloturbinates in T1 section) that corresponded to an intranasal region with MITC-induced epithelial lesions. Data for the BrdU ULLI were statistically analyzed using a one-way ANOVA and Tukey's HSD post-hoc test. Semi-quantitative data from histopathological scoring of inflammation and epithelial hyperplasia were analyzed by the Mann-Whitney test and the Kruskal-Wallis test to compare the effects of single and multiple days of exposure. The available data on MITC toxicity were evaluated using the International Programme on Chemical Safety framework for determining MOA for the tumors and their relevance to humans. **Results:** Analysis of data from this study as well as other available toxicity data (acute and repeat dose inhalation studies in rats at various concentrations and durations) indicated that a biologically plausible MOA leading to nasal tumors at the 20 ppm exposure level involved the following key events: 1) direct cytotoxicity of MITC to the nasal mucosa (degeneration, necrosis/apoptosis); 2) consequent increased cell proliferation to compensate for MITC-induced cytotoxicity; 3) persistence of squamous cell metaplasia of the respiratory mucosa as an adaptive response to the cytotoxic insult; and 4) development of tumors, primarily squamous cell carcinomas. The analysis also examined and excluded several alternate MOAs such as genotoxicity, estrogenicity, and immunosuppression. **Conclusions:** The data informed that the tumorigenicity of MITC has exposure thresholds and is not likely to pose a carcinogenic risk to humans under normal use patterns and corresponding exposure levels.

PS 4685 Estrogenic Endocrine Disrupting Compounds Increase Cell Proliferation and Cancer Stemness in Estrogen Receptor Positive Breast Cancer Cells

C. Winz, E. Li, C. Xie, K. Lee, K. Boguszewski, S. Rohatagi, R. Hahn, R. Rancourt, P. Furmansk, and N. Suh. Rutgers University, Piscataway, NJ.

Background and Purpose: Estrogenic endocrine disrupting compounds (EDCs) found in plastics, drinking water, and food are able to bind to the estrogen receptor (ER). Excessive estrogen signaling drives proliferation, progression, and the formation of breast cancer stem cells (CSCs) in ER-positive breast cancer. Thus, we hypothesized that estrogenic EDCs mimic estrogen (E2) in breast cancer cell lines. **Methods:** Three estrogenic EDCs routinely found in human biosamples were selected for analysis: bisphenol-A (BPA), diethyl-hexyl phthalate (DEHP), and alpha-zeranol (α ZAL). We assessed proliferation, transcriptional reprogramming, and CSC formation in several breast cancer cell lines. **Results:** E2, BPA, and α ZAL significantly increased cell proliferation in ER-positive, but not in ER-negative cell lines. This was reversed with the administration of an ER-antagonist, ICI 162,780. BPA and α ZAL upregulated estrogen target genes (PGR, TFF1) and increased levels of cell cycle protein. Whole-transcriptome RNA sequencing analysis revealed that BPA and α ZAL altered the expression of genes in pathways related to cell division, DNA repair, and estrogen signaling, with a substantial transcriptional overlap between EDC and estrogen

treatments. Additionally, in the ER-positive cell line MCF-7, BPA and α ZAL increased the proportion of CSCs, defined as the CD24^{low}/CD44^{high} expressing subpopulation.

Conclusions: Overall, these data indicate that BPA and α ZAL act as functional estrogen mimics in breast cancer cells, activating canonical estrogen signaling pathways and promoting stem-like characteristics. Exposure to EDCs is nearly unavoidable; therefore, understanding their estrogenic activities is crucial for assessing environmental contributions to breast cancer risk. This work provides mechanistic insight into how environmental EDCs may influence ER-positive breast cancer biology.

PS 4686 Carcinogenicity of vinyl chloride monomer: A weight-of-evidence review by cancer sub-type

L. R. Lautermilch¹, H. L. Fairbanks¹, O. A. Adebambo¹, A. M. Urban², L. P. Marshall³, and M. L. Kreider¹. ¹Stantec, Pittsburgh, PA; ²Stantec (Formerly), San Francisco, CA; and ³Valeo Sciences, Pittsburgh, PA.

Background and Purpose: The United States Environmental Protection Agency (EPA) designated vinyl chloride monomer (VC) as a High-Priority Substance for risk evaluation under the Toxic Substances Control Act (TSCA) with cancer as a key health outcome. However, the evidence for the relationship between VC and cancer varies by sub-type. The objective of this review was to independently assess the quality of the available epidemiological and toxicological literature to determine the weight of evidence for the relationship between VC exposure and site-specific cancer risk. **Methods:** A review of English-language literature was conducted in PubMed and Scopus databases through October 7, 2024, and compared with reference lists from Agency for Toxic Substances and Disease Registry, Texas Commission on Environmental Quality, and EPA Integrated Risk Information System assessments of VC. Inclusion criteria were met when the study included relevant population (e.g., human, animal), exposure (e.g., VC via oral, inhalation, or dermal route), comparator (e.g., unexposed epidemiological controls, sham or vehicle control), and outcome (e.g., cancer, genotoxicity, carcinogenicity). The quality of each study was evaluated using the Draft Systematic Review Protocol Supporting TSCA Risk Evaluations for Chemical Substances. Studies were numerically scored from 1 to 4 (1 indicating highest quality) on methodological and analytical characteristics, including study participation, exposure characterization, outcome assessment, potential confounding, and statistical analysis for epidemiological studies, as well as test substance, test design, exposure characterization, test organisms, outcome assessment, confounding control, and data analysis for toxicological studies. Individual metric scores were averaged to provide an overall ranking of *high* ($1 \leq X < 1.7$), *medium* ($1.7 \leq X < 2.3$), *low* ($2.3 \leq X \leq 3$), or *critically deficient* (score of 4 on any metric). **Results:** A total of 96 epidemiological and 31 toxicological studies that assessed the association between VC exposure and cancer outcomes/carcinogenicity were evaluated. The 54 human incidence and mortality studies received the following ratings: 21 high-quality, 25 medium-quality, 6 low-quality and 2 critically deficient. In 13 occupational cohort studies, there was a statistically significant positive association between VC exposure and cancer of the liver or intrahepatic bile ducts. Seven high-quality occupational cohort studies and one medium-quality ecological study assessed hepatocellular carcinoma (HCC) and/or angiosarcoma of the liver (ASL). A statistically significant association with VC exposure was reported in all occupational cohorts for HCC and 5 for ASL. Overall, results were negative for cancers of the brain and central nervous system, respiratory system, hematopoietic and lymphatic, skin (including malignant melanoma), breast, and connective and soft tissues. Among 42 human genotoxicity studies, 3 were high-quality, 28 were medium-quality, 7 were low-quality, and 5 were critically deficient. Generally, high-quality studies indicated genotoxicity among workers exposed to VC for at least one year, including increased micronuclei frequency, decreased relative telomere length, and decreased expression of shelterin component genes relative to controls. Animal genotoxicity studies assessed included 7 *in vivo* studies (2 medium-quality, 3 low-quality, and 2 critically deficient), and results reinforce the observation of clastogenicity observed in humans. The 24 animal carcinogenicity studies were largely high- ($n=8$) or medium-quality ($n=10$). Animal studies similarly report common findings of liver cancers, including HCC and ASL, with less consistent observations of lung tumors. **Conclusions:** Collectively, the weight of evidence supports a positive association between VC exposure and cancers of the liver, but not other cancer types. The existing evidence is limited by the absence of occupational cohort studies at contemporary exposure levels. Additional and/or updated occupational cohort studies would provide data to address the potential for human health risk from VC exposure under current conditions.

PS 4687 A Quantitative Weight-of-Evidence Evaluation of Rodent Data Demonstrates Sufficient Evidence for a Lack of Carcinogenic Potential of Acetaminophen

M. Kovochich¹, M. D. Southall², S. Ejaz², S. K. Pitchaiyan³, N. Patel³, and D. G. Kougiou¹. ¹K2 Toxicology and Integrated Risk Assessment, LLC, Las Vegas, NV; ²Kenvue Toxicology, Medical Clinical and Safety Sciences, Summit, NJ; and ³Kenvue Toxicology, Medical Clinical and Safety Sciences, Mumbai, India.

Background and Purpose: Acetaminophen is a common antipyretic/analgesic used in the treatment of fever and minor pain, headache, myalgia, and dysmenorrhea. Although previous regulatory assessments on genotoxicity and carcinogenicity have

concluded that acetaminophen is not a carcinogenic hazard, toxicological and regulatory evaluations continue to be conducted due to new data and the widespread use of this medication. In 2024, International Agency for Research on Cancer (IARC), a specialized cancer agency of the World Health Organization, announced the intent to re-evaluate the carcinogenic hazard potential of acetaminophen. Numerous regulatory bodies have emphasized the need for a weight-of-evidence (WoE) approach toward assessing preclinical carcinogenicity data and potential relevance for human health hazard and risk evaluation. Therefore, the objective of this analysis was to inform the IARC review by performing a comprehensive quantitative weight-of-evidence (QWoE) analysis of the preclinical carcinogenicity data in rodents exposed to acetaminophen. **Methods:** We previously developed a QWoE framework using prespecified scoring criteria for preclinical acetaminophen data to characterize study outcomes with considerations for biological relevance of the response to adverse outcomes (*outcome score*) and the strength of methods and study design (*methods score*). The *outcome score* considers a potential adverse outcome based on (1) statistical significance, (2) dose-response, (3) reliability/relevance/magnitude, and (4) plausibility. Considerations for the *methods score* included (1) experimental design, (2) details/reliability of measurement(s), (3) data transparency, and (4) translational/methodological relevance. The current analysis uses this framework to characterize potential carcinogenic outcomes—specifically focused on apical endpoint measures (i.e., neoplastic lesions and tumors)—following exposure to acetaminophen in rodent studies. Following a systematic literature search, data from identified rodent studies were extracted and processed through the QWoE framework with a focus on two main carcinogenic endpoints—tumor-promoting potential and tumorigenicity (all tissues)—with additional endpoint analysis on tumorigenicity for specific tissues of interest, including liver, kidney, urinary bladder, hematopoietic tissues, and all other tissues. An entry, with an individual *outcome score* and *methods score*, was provided for each sex, species/strain, and exposure duration in an individual study for each applicable endpoint. **Results:** A total of 191 QWoE entries were documented from *in vivo* rodent studies identified in 28 publications across the carcinogenic endpoints of this QWoE analysis. For each endpoint, the mean *outcome score* and *methods score* were calculated for total entries and for entries segregated by sex to assist in determining relative data quality and potential adversity. For the tumorigenicity (all tissues) endpoint, the QWoE analysis demonstrated a mean ($\pm$ SD) *outcome score* of 0.4 ± 0.8 (out of 4)—indicating a lack of biological relevance and reliability of reported adverse effects—and a mean ($\pm$ SD) *methods score* of 2.2 ± 0.9 (out of 4)—indicating a moderate quality of evidence. Similar results were found for tumor-promoting potential and tissue-specific tumorigenicity endpoints as well as analyses segregated by sex. **Conclusions:** This QWoE analysis on the *in vivo* rodent data demonstrated no consistent evidence of carcinogenic responses in males or females following exposure to acetaminophen at a range of doses, including therapeutic/non-toxic to toxic doses. The assessment incorporated well-conducted studies, including GLP-compliant rodent carcinogenicity bioassays and more recent tumor-modulation studies employing chemically induced and tumor-implantation models, encompassing both sexes, multiple rat and mouse strains, and a range of doses. Collectively, these data provide no consistent or biologically relevant evidence that acetaminophen is carcinogenic. Accordingly, the evidence is sufficient to support the conclusion that acetaminophen is not a carcinogenic hazard in rodents.

PS 4688 Genotoxic and estrogenic exposures target distinct tissue structures in early breast carcinogenesis

J. E. Kay¹, J. T. McEneaney¹, R. Shakti¹, L. N. Vandenberg², and R. A. Rudel¹. ¹Silent Spring Institute, Newton, MA; and ²University of Massachusetts Amherst, Amherst, MA.

Background and Purpose: Breast cancer is the most common invasive cancer diagnosis in the US and worldwide, and rising rates among younger people in particular suggest that environmental exposures play a role. Genotoxic and estrogenic exposures increase risk in humans and rats, particularly during developmental windows of susceptibility such as puberty, and co-exposure may magnify effects. To describe early steps in breast carcinogenesis following exposures that are both estrogenic and genotoxic, we are assessing molecular biomarkers of effect in their spatial context in a rat model. **Methods:** In pilot studies, we exposed pubertal rats to mammary carcinogens that are genotoxic (N-nitroso-N-methylurea, NMU; acute), estrogenic (ethinylestradiol, EE2; chronic), or both (NMU during EE2; or 7,12-dimethylbenz(a)anthracene, DMBA; acute). Using immunofluorescence, H&E, and whole mounted mammary glands, we assessed DNA damage, proliferation, and tissue morphology across the mammary gland 1-day and approximately 1-week after genotoxicant exposure. **Results:** Both NMU and DMBA caused DNA damage, with the strongest γ H2AX signal in immature terminal end buds (TEBs) and little effect in mature tissue, which is consistent with the known sensitivity of the rapidly proliferating TEBs to genotoxic carcinogens. Proliferating Ki67+ cells were concentrated in TEBs in all groups, but EE2-exposed mammary glands showed increased proliferation relative to controls only in mature tissue while DMBA-exposed mammary glands exhibited a trend for increased proliferation mainly in developing regions. Consistent with estrogen-mediated proliferation, EE2-exposed mammary glands had larger TEBs and greater epithelial density in both mature and developing regions, with the most prominent differences from control in mature tissue. NMU+EE2 co-exposure resulted in patterns of DNA damage similar to those of NMU exposure alone and patterns of proliferation and tissue composition similar to those of EE2 exposure alone. Importantly, we found that since treatment-related effects occurred in specific locations (prolifera-

tive TEBs for genotoxicants, mature tissue for EE2) experimental approaches that did not separate these would have missed important biological nuances. **Conclusions:** This study lays the foundation for describing breast cancer dose-response relationships for exposures that are genotoxic and estrogenic. We found that distinct regions in the mammary gland are differentially susceptible to induction of DNA damage and proliferation by genotoxic and estrogenic agents, respectively. Our findings underscore the importance of assessing effects of chemicals with attention to their spatial context, because the mammary gland shows varying patterns of responses across the tissue. Further work will extend these experiments to include a longer 1-month timepoint to measure persistent effects of exposures, and we will use 6-plex immunofluorescence to measure DNA damage, proliferation, and cell death in various epithelial cell types. Measuring molecular effects in specific cell types *in situ* over time will allow us to identify which cells and tissue structures are most vulnerable to genotoxic and estrogenic exposures separately and together, and how those effects eventually lead to cancer.

PS 4689 Second Trimester Butanoate Metabolism in Pregnancy Linking Chemical Exposure to Incident Maternal Breast Cancer within 15 years

B. A. Cohn¹, P. M. Cirillo¹, N. Y. Krigbaum¹, S. Teeny², B. Minasenko², D. Wang², V. Tran², Y. Go², D. P. Jones², and X. Hu². ¹Public Health Institute, Oakland, CA; and ²Emory University, Atlanta, GA.

Background and Purpose: A lower ratio of estriol to the sum of estrone and estradiol (estriol ratio) in the 3rd trimester predicted maternal breast cancer within 15 years of pregnancy (DOI: 10.1210/jc.2016-3476). To further elucidate the underlying biological mechanisms, we analyzed prospective serum samples collected during the 2nd trimester and evaluated associations between the maternal metabolome and the subsequent third-trimester estriol ratio. This allows us to investigate early pregnancy metabolic pathways that may contribute to hormonal dysregulation and elevated breast cancer risk in the years following pregnancy. **Methods:** Metabolites in 2nd trimester pregnancy serum were extracted and analyzed using established untargeted metabolic profiling in 566 pregnant women residing near Oakland, California 1959-1967 (Child Health and Development Studies) of whom 36 were diagnosed with breast cancer within 15 years. High resolution mass spectrometry was performed using C18 and negative electrospray ionization. Statistical analysis and pathway enrichment screened for 2nd trimester metabolic changes associated with the 3rd trimester estriol ratio. We used Rodin for untargeted analysis (<https://rodin-meta.com>) to fit a linear regression model predicting the 3rd trimester estriol ratio moderated by subsequent breast cancer within 15 years. Conditional logistic regression estimated associations of maternal breast cancer with 2nd trimester metabolites, 3rd trimester estriol ratio and age. **Results:** We found that exposure to exogenous chemicals annotated as amino-nitrophenols and 4-nitrophenol (PNP) were inversely associated with the 3rd trimester estriol ratio in future cases ($p=0.0004$) but not in controls. Independently, metabolites in butanoate pathway, fatty acid oxidation and branched chain amino acid also predicted the 3rd trimester estriol ratio only in future cases. Succinate semialdehyde, an intermediate that connects the breakdown of the gamma-aminobutyric acid (GABA) to the butanoate metabolism and the larger tricarboxylic acid (TCA) cycle, was significantly associated with PNP. Increased level of 2nd trimester SSA significantly strengthened the association of the 3rd trimester estriol ratio with subsequent maternal breast cancer (logistic regression, $p=0.0009$). Moreover, in jointly adjusted models the 2nd trimester SSA and PNP interactions with 3rd trimester estrogens remained independent, both being significant predictors of maternal breast cancer. **Conclusions:** Exposure to amino-nitrophenols and SSA levels in 2nd trimester contributed to the link between estriol ratio and subsequent cancer, suggesting that endocrine disruption contributes to the incidence of breast cancer within 15 years of pregnancy via multiple mechanisms.

PS 4690 Consideration of Implementation for Postmarketing Carcinogenicity Studies Based on a Retrospective Analysis of Approved New Drugs by U.S. FDA in the Past Ten Years

L. Zhou, J. Ma, L. Zhang, and S. Zhang. JOINN Laboratories, Suzhou, China.

Background and Purpose: Postmarketing requirements (PMRs) refer to all mandated postmarketing studies or clinical trials. According to FDA guidance "Postmarketing Studies and Clinical Trials—Implementation of Section 505(o)(3)" and the ICH S1 guideline "Guideline on the Need for Carcinogenicity Studies of Pharmaceuticals", carcinogenicity testing is not required prior to market approval for pharmaceuticals developed to treat certain serious diseases. However, these studies are expected to be conducted after approval. Notably, the guidelines do not provide specific examples of which serious diseases warrant postmarketing carcinogenicity studies. This research aims to systematically analyze postmarketing requirements for carcinogenicity studies in the U.S., clarify how such studies are proposed, and offer insights to support pharmaceutical companies in drug development as well as regulatory agencies in drug evaluation. **Methods:** This study delved into 465 drug approvals by U.S. FDA from 2015 to 2024, either as new molecular entities (NMEs) under New Drug Applications (NDAs), or as new therapeutic biologics under Biologics License Applications (BLAs), and examined all the 25 FDA approvals that contain postmarket-

ing requirements for carcinogenicity studies in the past ten years, leveraging review documents from FDA, comprehensive data on product characteristics, all post-marketing requirements and commitments for carcinogenicity studies were extracted. **Results:** This study found that the overriding consideration for all postmarketing carcinogenicity studies were the indication of these drugs, which were life-threatening or severely debilitating diseases, and there was unmet medical need for therapies to treat these diseases, which were cystic fibrosis (CF), Duchenne muscular dystrophy (DMD), spinal muscular atrophy (SMA), carcinoid syndrome diarrhea, early stage HER-2 positive breast cancer, amyotrophic lateral sclerosis (ALS), seizures associated with Lennox-Gastaut syndrome (LGS) and Dravet syndrome (DS), hereditary transthyretin-mediated amyloidosis (hATTR amyloidosis), HIV-1 infection, Lambert-Eaton myasthenic syndrome (LEMS), extensively drug-resistant (XDR) and treatment-intolerant/nonresponsive (TI/NR) multidrug-resistant (MDR) tuberculosis, acute hepatic porphyria (AHP), primary hyperoxaluria type 1 (PH1), chronic idiopathic constipation (CIC), Alagille syndrome (ALGS), hypertrophic cardiomyopathy (HCM), epidermolysis bullosa (EB), low-grade gliomas (LGGs), and warts, hypogammaglobulinemia, infections and myelokathexis (WHIM) syndrome. For example, Alagille syndrome (ALGS) is a rare (incidence of 1 in 30,000 to 1 in 70,000), autosomal dominant, multi-organ disease. Bile duct paucity in the liver occurs in approximately 90% of patients with ALGS. The disease can progress to cirrhosis leading to liver failure. Before the approval of the drug Livmarli, there was no U.S. Food and Drug Administration (FDA)-approved medical therapy for treatment of pruritus in patients with ALGS. Additionally, the available nonclinical and clinical data for these drugs supported such a strategy, for example, besides the indication, the justification of request for deferral of carcinogenicity studies of the drug Eteplirsen was: 1) Eteplirsen was not genotoxic in the ICH standard battery of assays: *in vitro* bacterial mutation and mammalian chromosome aberration, and *in vivo* mouse bone marrow micronucleus; 2) No pre-neoplastic or other proliferative lesions were observed in the 39-week toxicity study in monkey; 3) No treatment-related clinically significant adverse events have been observed in clinical studies of > 3 years of once-weekly IV administration of eteplirsen. **Conclusions:** Postmarketing carcinogenicity studies strategy speeds the availability of pharmaceuticals for life-threatening or severely debilitating diseases, especially where no satisfactory alternative therapy exists. Our analysis of drug approvals in the U.S. FDA reveals diverse drug patterns approved for post-marketing carcinogenicity studies, and provides clear cases. This study provides valuable insights for regulatory decision-making in a dynamic pharmaceutical landscape. Balancing the risks and rewards of conditional approvals is crucial in ensuring both patient safety and timely access to innovative treatments.

PS 4691 Readaddiction to deaddiction drug A case study on Buprenorphine Poisoning

R. Kaushik, and A. Pathak. All India Institute of Medical Sciences Bathinda Punjab, Bathinda, India.

Background and Purpose: Opioid substitution therapy is the predominant measure in the National Drug De-addiction programme in India, and Buprenorphine is the key drug used in the therapy, which itself is an opioid and has less tendency to abuse and physical dependence. This drug is used in agonist substitution treatment—a method for addressing addiction by substituting a more potent full agonist opioid, such as heroin, with a less potent opioid, i.e., Buprenorphine. **Methods:** Patients who have been brought to the emergency department of AIIMS Bathinda in Altered Mental status and with a history of drug abuse were considered in the study. The Blood toxicological analysis was advised. Quantification was achieved by selected ion monitoring of m/z 468.4 (BUP), 414.3 (NBUP) and LC-MS/MS method was developed for the simultaneous quantification of BUP and NBUP in serum. For reference, the median (maximum) concentration in BUP dependent OST based patients is 4.2 µg/L (102 µg/L) for BUP, 74.7 µg/L (580 µg/L) for NBUP. **Results:** Personal history of the patients revealed addiction to a drug being distributed at the hospital. 24 per cent of the total subjects considered were found addicted to Buprenorphine-Naloxone fixed drug combination. The toxicology analysis result shows positive for norbuprenorphine with average levels of 1200 microgram/L. The patients were stabilised and the average duration of stay in the hospital was found to be one week. **Conclusions:** Buprenorphine misuse and diversion is a complex issue. Research indicates that though diversion of buprenorphine does take place at times, the possibility of harms is substantially reduced with the Buprenorphine-Naloxone formulation. It must also be noted that wider and easier availability of treatment would reduce the risk of diversion. Research also indicates that much of the diverted use of medications takes place for therapeutic purposes (easing withdrawal and controlling craving). No specified time limit for substitution is one of the major cause of drug diversion and misuse. However, treatment providers need to be vigilant regarding misuse and diversion, ascertain the reasons for the same and take steps to minimize it.

B. Andresano¹, T. M. Cahill¹, M. Grommes², and M. Leung¹. ¹Arizona State University, Glendale, AZ; and ²Desert Tox, LLC, Scottsdale, AZ.

Background and Purpose: The contamination level of cannabis in the illicit market - including unlicensed production (i.e., black market cannabis) within a legalized state and products that failed compliance testing in the gray market - is largely unknown. Our objectives were to i.) develop an analytical method to quantify a panel of common illicit drugs in cannabis and ii.) characterize the scale and type of illicit drug contaminants in the cannabis. To the authors' knowledge, this is the largest study of illicit drug contaminants in black- and gray-market cannabis in the Southwestern U.S. to date. **Methods:** We surveyed the production environment and contaminant sources of illicit cannabis. Maricopa County Sheriff's Office (MCSO)'s High Intensity Drug Trafficking Areas Task Force conducted 37 seizures and collected 79 cannabis dried flower samples between 2023 and 2024. While 90% of seized cannabis in Arizona was estimated to come from California, a few grow operations were discovered locally in Arizona. Additionally, U.S. Postal Inspection Services (USPIS) seized 39 cannabis dried flower samples between 2023 and 2024. The prepared samples were analyzed for the 17 analytes using an Agilent 6495 LC-MS-MS, including amphetamine, benzoylecgonine, cocaine, codeine, fentanyl, hydrocodone, hydromorphone, LSD, methamphetamine (MAMP), 3,4-methylenedioxymethamphetamine (MDMA/Ecstasy), morphine, oxycodone, oxycodone, phenylcyclohexyl piperidine, psilocin, psilocybin, 3,4-methylenedioxymethamphetamine. **Results:** Twenty-five (21.2%) out of 118 cannabis flower samples had detectable concentrations of illicit drugs. Only four of the 17 analytes tested were detected. The most commonly detected drug was cocaine (20.3%), followed by MAMP (3.4%) and MDMA (0.9%). Benzoylecgonine, the breakdown product of cocaine, was found in four samples containing cocaine. Three MAMP and one MDMA samples were also found to contain cocaine. The highest concentration of illicit drugs was cocaine at 15,200 ppm (or 1.5 % by weight). Only one positive seized sample (2.6%) was collected by the USPIS, while the remaining 24 positive samples were all collected by the MCSO at a detection rate of 27.8%. Notably, fentanyl was not detected in any of the 118 samples. This is consistent with a 2021 study in Connecticut that found fentanyl in illicit cannabis as a standalone case of unintentional contamination (Connecticut Overdose Response Strategy, 2021; Besthoff, 2022, NBC Connecticut. June 24). **Conclusions:** The presence of illicit drugs in black and grey market products highlights the contamination of the product being distributed. This research focused on illicit drugs, but other types of contamination are also likely to occur given the poor product preparation areas. Further research is needed to characterize the biological and chemical contaminants in illicit cannabis and their health risk to cannabis consumers.

T. Shamblin¹, M. Burnett¹, C. Thornton², E. Carter¹, L. Seid², B. Dunaway², K. Martin², K. Willett², and N. Ashpole¹. ¹Mississippi State University, Mississippi State, MS; and ²University of Mississippi, University, MS.

Background and Purpose: Consumer access to cannabinoids has increased significantly in recent years, thereby increasing the risk of developmental exposure to Δ^9 -tetrahydrocannabinol (Δ^9 -THC) and other cannabinoids. The goal of this study is to evaluate the impact of developmental cannabinoid exposure and determine the potential mechanism of action of behavioral and morphological deficits observed, using the zebrafish (*Danio rerio*) model. **Methods:** Wildtype (5D), *cnr1*^{-/-}, and *cnr2*^{-/-} embryos were exposed to increasing concentrations (0-2 μ M) of eight widely available cannabinoids from 6-96 hours post fertilization (hpf). Cannabinoids of interest included: Δ^9 -THC, Δ^{10} -THC, Δ^8 -THC, tetrahydrocannabinol (THCV), hexahydrocannabinol (HHC), cannabidiol (CBD), cannabigerol (CBG), and cannabinol (CBN). At 120 hpf, larval photolocomotor response and morphology, including body length, eye diameter, and the presence of edemas were evaluated. **Results:** Wild-type larvae exposed to Δ^9 -THC, Δ^8 -THC, THCV, HHC, CBD, and CBG showed dose-dependent reductions in photolocomotion. Body length and eye diameter were also reduced with higher exposure concentrations. The *cnr1*^{-/-} and *cnr2*^{-/-} fish showed lower baseline levels of activity than wild-type zebrafish. Nevertheless, several of the cannabinoids still caused a significant reduction in locomotor activity within the knock-outs, suggesting an alternative mechanism of action outside CB1 and CB2 for Δ^9 -THC, CBG, and HHC. Surprisingly, CBD and THCV did not reduce locomotion in *cnr1*^{-/-} fish, suggesting potential activity through CB1. THCV also failed to reduce locomotion in *cnr2*^{-/-} fish, suggesting potential activity through CB2. Minimal toxicity was observed with Δ^{10} -THC and CBN exposure, across all three genotypes. **Conclusions:** Together, these data highlight cannabinoid-specific neurodevelopmental toxicities. Most of the cannabinoids tested resulted in behavioral and morphological toxicities in the days following early embryonic exposure. Further work is needed to delineate the mechanism of toxicity and persistence of neurodevelopmental effects after early-life exposure to these consumer products.

H. C. Gonzalez¹, B. R. Deaton¹, T. T. Mendenhall¹, K. L. Gordon², and J. H. Hartman¹. ¹Medical University of South Carolina, Charleston, SC; and ²University of North Carolina at Chapel Hill, Chapel Hill, NC.

Background and Purpose: Ethanol is first metabolized to the toxic intermediate acetaldehyde and then converted to acetate by aldehyde dehydrogenase. One of the three enzymes involved in ethanol metabolism, cytochrome P450 2E1 (CYP2E1), exists in both endoplasmic reticulum (ER) and mitochondrial isoforms. ER localized CYP2E1 is well studied in alcohol metabolism, but far less is known about the function of mitochondrial CYP2E1. In rats, alcohol exposure increases CYP2E1 levels in brain mitochondria, yet the contribution of mitochondrial CYP2E1 to ethanol toxicity is unclear. This study aimed to determine how mitochondrial CYP2E1 influences organismal and mitochondrial responses to ethanol and its metabolites. **Methods:** Transgenic *Caenorhabditis elegans* were generated using CRISPR/Cas9 knock in to introduce human CYP2E1 and the human ER or mitochondrial cofactor required to direct CYP2E1 activity to that compartment. Wild-type N2 worms were used as a negative control, as they lack CYP2E1 expression. Worms were exposed for four hours to increasing concentrations of ethanol (0 to 500 mM), acetaldehyde (0 to 100 mM), or acetate (0 to 100 mM). Locomotion and lethality were quantified, and oxygen consumption rates (OCRs) were measured using the Resipher system. Additional assays included hydrogen peroxide lethality and initial glutathione measurements. **Results:** Ethanol caused dose dependent inhibition of motility in all strains, with mitochondrial CYP2E1 worms showing greater inhibition at 250 mM. Acetaldehyde exposure reduced motility more strongly in CYP2E1 expressing strains than in wild type worms, although LD50 values were similar across strains (24 to 49 mM). Acetaldehyde caused a dose dependent inhibition of respiration, with mitochondrial CYP2E1 worms showing the greatest reduction at 25 mM ($p < 0.0001$) and 50 mM ($p < 0.05$). Hydrogen peroxide lethality was similar across strains (LD50 values 2.7 to 4.5 mM), suggesting reactive oxygen species are not the sole drivers of acetaldehyde toxicity. Acetate impaired motility in both CYP2E1 strains at intermediate doses, with mitochondrial CYP2E1 worms showing significantly reduced movement at higher concentrations. Acetate increased OCR in most strains, but mitochondrial CYP2E1 suppressed this increase. **Conclusions:** These findings indicate that mitochondrial CYP2E1 increases sensitivity to ethanol and its metabolites in ways that extend beyond the initial oxidation of ethanol. Preliminary data suggest that CYP2E1 expressing worms have elevated baseline glutathione levels, and ongoing work is focused on defining oxidative stress responses and metabolomic changes to further clarify the role of mitochondrial CYP2E1 in alcohol related toxicity.

E. Passini, M. Blee, and F. Sewell. NC3Rs, London, United Kingdom.

Background and Purpose: Two species (a rodent and a non-rodent) are generally used to support clinical development and licensing of new medicines. Whilst there are opportunities to reduce to a single species in later-development studies for biologics that follow the ICH S6(R1) guideline (e.g. if toxicities in earlier studies are "similar") two species are currently required for small molecules and other drug modalities that are developed according to the ICH M3(R2) guideline. Following on from previous work to support wider uptake of opportunities to use a single species within ICH S6(R1), the UK National Centre for the Replacement, Refinement and Reduction of Animals in Research (NC3Rs) has recently initiated a project to determine whether there are cases where a single species could also be sufficient for later-development studies for molecules following ICH M3(R2), without compromising human safety. **Methods:** An international working group consisting of 44 experts from various pharmaceutical companies, contract research organisations and regulatory agencies was convened, and a survey designed to collect detailed information on studies conducted to support first-in-human (FIH) trials and later development for molecules developed under ICH M3(R2). Survey respondents were asked to provide details on the study designs and the toxicities observed (including severity, monitorability, reversibility, and their impact on decision-making and/or clinical programme). They were also asked for information on the similarity of toxicity findings across the two species and the two study phases, and to provide their opinion on whether - in hindsight - the same decisions could have been made using only one species for later development studies. **Results:** Data were collected from 17 companies for 75 molecules, covering various therapeutic areas including nervous system (23), anti-infectives (11) and oncology (10). Of these, 33 molecules were active in development, 16 marketed and 26 stopped during development (mainly for strategic and/or business reasons). For each molecule, data on at least two first-in-human enabling and two later-development studies was provided (one rodent and one non-rodent for each study phase). Species used were mainly rat (74) as rodent, and dog (50) as non-rodent. Toxicity findings occurred in ~90% of the studies. However, only ~30% were considered a concern for human safety and <20% had an impact on the clinical programme. Looking retrospectively at the study data, survey respondents indicated that the same decisions could have been made using only one species for later-development studies for 75% of the molecules, almost equally split between the choice of rodent only and non-rodent only. A series of blinded exercises were conducted

within the working group to assess if/when/how these decisions could be taken prospectively and revealed that the choice of using a single species for later-development studies could have been made prospectively for at least 60% of the molecules, without missing toxicities of concern for humans. **Conclusions:** The data analysis suggests there may be opportunities where using a single species for later development studies could be appropriate also for molecules developed following ICH M3(R2), without compromising human safety. Ongoing work aims now to identify the common factors driving the choice of a single species / two species approach, in order to develop recommendations and create an evidence base to inform regulatory guidance.

PS 4696 Pharmaceutical Safety Considerations for Cereblon-Recruiting Targeted Protein Degraders

R. Roberts¹, H. Garside¹, J. Sidaway¹, L. Jones², N. Vargesson³, and C. Targeted Protein Degradation Safety Committee⁴. ¹Apconix, Alderley Edge, United Kingdom; ²Dana-Farber Cancer Institute, Boston, MA; ³University of Aberdeen, Aberdeen, United Kingdom; and ⁴Health and Environmental Sciences Institute, Washington, DC.

Background and Purpose: Cereblon (CRBN)-recruiting molecular glue degraders (MGDs) and proteolysis-targeting chimeras (PROTACs), collectively referred to as CRBN-recruiting targeted protein degraders (CRBN-TPDs), have shown great promise for exploring previously intractable drug targets across a range of indications. However, this class of drugs poses unique challenges related to off-target neosubstrate identification and risk-assessment. Hence, there is a need for a scientific consensus on rigorous, consistent, and effective methods for the assessment of the safety of CRBN-TPDs. Here, we provide an overview of the endogenous functions of CRBN and key learnings on potential organ toxicities and translational considerations for off-target neosubstrate degradation based on data from immunomodulatory imide drugs, next-generation MGDs and PROTACs. **Methods:** An extensive literature review was performed to assess CRBN-TPD safety testing strategies, and key considerations for CRBN-TPD development and recommendations for safety testing were identified. RNA-Seq expression data from nonclinical species were obtained (NCBI accession number: PRJNA516470). Human data were curated from the Genotype-Tissue Expression project. **Results:** Key challenges include species-specific sequence differences in CRBN and its neosubstrates, variability in neosubstrate expression patterns, and the off-target effects associated with diverse CRBN-TPD structures. Based on this assessment, we suggest best practices for monitoring on-target versus off-target degradation from CRBN-TPDs, such as profiling on- and off-target degradation using proteomics, assessing *in vivo* relevance across toxicology species, and applying predictive *in vitro* models for teratogenicity and other toxicities. Furthermore, we highlight gaps in the understanding of CRBN's full biological role and potential unintended consequences such as proteasome saturation, neosubstrate sequestration, and an altered immunopeptidome. **Conclusions:** Standardized safety assessment strategies and deeper mechanistic insights will support the development of CRBN-TPDs as well as novel E3 ligases and other degradation modalities.

PS 4697 In Vitro Hemolytic Potential of Cyclodextrins: A Species Comparison

B. Morrison¹, Z. Dewald¹, R. Prince¹, A. Sen¹, M. Andracki¹, and J. Kapeghian². ¹Frontage Laboratories, Inc., Chicago, IL; and ²Preclinical Safety Associates, LLC, Reno, NV.

Background and Purpose: Cyclodextrins—including HP- β -CD, HP- γ -CD, RM- β -CD, and SBE- β -CD—are widely used as excipients in nonclinical formulations due to their ability to enhance solubility and stability of poorly soluble compounds. However, since their potential to induce hemolysis may vary by species and concentration, a rapid *in vitro* evaluation of hemolytic potential was conducted across several commonly used species in nonclinical safety testing. **Methods:** *In vitro* hemolysis assays were performed using fresh whole blood collected from fasted rats, rabbits, minipigs, and dogs. Pooled heparinized blood samples were exposed to increasing concentrations of several commercially available cyclodextrins including the following: random methylated β cyclodextrin (RM- β -CD), hydroxypropyl γ cyclodextrin (HP- γ -CD), sulfobutylether β cyclodextrin (SBE- β -CD), and hydroxypropyl β cyclodextrin (HP- β -CD). RM- β -CD was tested at 13.3, 23.3, and 33.3 mg/mL, while HP- β -CD, HP- γ -CD, and SBE- β -CD were evaluated at 23.3, 40.8, and 58.3 mg/mL. Triton X-100 (8.3 mg/mL) served as a positive control, and 0.9% saline was the negative control. For each assay, 100 μ L of the test formulation was added to 500 μ L of whole blood, followed by incubation for 30 minutes at room temperature. Hemolysis was quantified via spectrophotometric analysis of plasma hemoglobin using a Beckman Coulter AU480 clinical chemistry analyzer. **Results:** RM- β -CD induced significant hemolysis at 13.3 mg/mL in whole blood from rats, minipigs, dogs, and rabbits. HP- β -CD induced hemolysis at 23.3 mg/mL in rat and rabbit blood, and at 40.8 mg/mL in blood from minipigs and dogs. SBE- β -CD caused hemolysis at 40.8 mg/mL in rats and at 58.3 mg/mL in rabbits but did not induce hemolysis in minipigs or dogs at any concentration tested. HP- γ -CD did not induce hemolysis in any species at the concentrations evaluated. Across all species tested, rat-derived whole blood consistently was more sensitive to cyclodextrin-induced hemolysis. The findings with HP- β -CD are consistent with prior studies

showing hemolysis in rats following exposure to 35% HP- β -CD both *in vitro* (50 μ L added to 500 μ L whole blood) and *in vivo* (10 mL administered via short IV infusion). **Conclusions:** HP- β -CD and related cyclodextrins exhibit species- and concentration-dependent hemolytic potential *in vitro*, with rats demonstrating heightened sensitivity across common laboratory species tested. Species-related differences in hemolytic response highlight the need for tailored formulation strategies with cyclodextrins to ensure tolerability and study integrity.

PS 4698 Monitoring Muscle Fiber Toxicity with Transcriptional Biomarkers

A. A. Podtelezchnikov, K. Vlasakova, P. Lane, Z. Erdos, S. Pacchione, A. Aslamkhan, W. Glaab, K. Tanis, and R. Gonzalez. Merck and Co., Inc., West Point, PA.

Background and Purpose: Drug-induced myopathies can be caused by different medications, such as statins and fibrates, and may originate from the energy metabolism perturbations. Muscle tissue that requires significant energy supply is particularly sensitive to these effects, and as fibers of type I and type II rely on differential metabolic pathways, they can have different susceptibility to the injury. **Methods:** In this study, we performed RNA sequencing on archived quadriceps samples from dogs treated for 9 months with a discontinued development compound with histopathological evidence of muscle degeneration. **Results:** Differential gene expression analysis revealed consistent changes in gene markers of type I and type II fibers in opposite directions, suggesting underlying changes in muscle fiber type composition. To confirm these findings, a single-nuclei RNA-Seq study was performed, with more than 17,000 nuclei isolated and sequenced. All major muscle cell types were identified in this study based on their established corresponding gene markers. Particularly, separate type I and type II myocyte nuclei were detected, and markers of the corresponding slow and fast fibers were confirmed. In addition, we observed upregulation of synaptic markers in regenerating myocytes in the injured tissue samples, which might be attributed to newly forming neuromuscular junctions. **Conclusions:** These RNA markers can be used for detection and monitoring of fiber type-specific myopathies in future drug development.

PS 4699 A 3D Heart-on-Chip For Cardiotoxicity Screening: Assessing Drug-Induced Alterations In Cardiac Electrophysiology and Contractility

C. Pernici¹, R. Visone¹, M. Mondini¹, E. Vermersch², M. Rasponi³, E. Ferrari¹, A. Garry², and P. Occhetta¹. ¹BiomimX Srl, Milan, Italy; ²Sanofi, Vitry, France; and ³Politecnico di Milano, Milan, Italy. Sponsor: C. Pernici, Safety Pharmacology Society

Background and Purpose: Cardiotoxicity detection remains a critical step in the drug development pipeline (DDP). To enable more predictive preclinical *in vitro* studies, the combined use of advanced technologies such as Organs-on-Chip (OoCs) and human induced pluripotent stem cell-derived cardiomyocytes (hiPSC-CMs) holds great promise. This approach offers the opportunity to generate physiologically relevant, human-based data that better translate to clinical outcomes. By using animal models indeed, cardiovascular adverse effects that go undetected can result in cardiotoxic compounds reaching the market, while findings of cardiac issues in animals often lead to the premature discontinuation of promising drug candidates without confirmation of their true clinical risk. In this scenario, we present uHeart, a 3D cardiac *in vitro* model developed by integrating human iPSC-CMs within a beating OoC platform equipped with multiparametric readouts for cardiotoxicity assessment. uHeart has been applied in pharmacological studies to demonstrate its applicability in different contexts of use (CoUs) in cardiac safety, demonstrating its capability in detecting drug-induced changes in electrophysiology and contractility. **Methods:** uHeart microtissues are developed by using hiPSC-CMs and human fibroblasts (Fs) embedded in fibrin hydrogel at a density of 100x10⁶ cells/ml (75%-25%, CMs-Fs ratio) and cultured in uBeat® Stretch platforms for 7 days. The system provides to the obtained microtissues a physiological mechanical stimulation that mimics the heart-beat (i.e. 10% strain, 1Hz). uHeart was qualified for QT-prolongation and pro-arrhythmia detection by following the ICH S7B guidelines, using 11 drugs listed in the Comprehensive *in vitro* Proarrhythmia Assay (CiPA). Drug-induced alterations were evaluated at incremental doses, by analysing the field potential (FP) morphology (i.e., beating period-BP, spike amplitude-AMP, FP duration-FPD) and arrhythmic events. The model was further exploited for evaluating the effect of 19 reference compounds that affect contractility by acting on calcium homeostasis, on sodium channel and on the sarcomere. Drug-induced changes were evaluated at incremental doses by analysing contractility parameters from video analysis by means of MuscleMotion (e.g., beating period-BP, contraction time-CT, relaxation time-RT, contraction amplitude-CA, contraction velocity-CV). **Results:** The mechanical stimulation promoted the formation of microtissues exhibiting spontaneous and synchronized beating (coefficient of variation of the beating period-BP < 25%; ~85% yield). The analyses on field potential (FP) (i.e., BP, spike amplitude, FP duration) revealed that the microtissues responded to drugs acting on single (i.e. Nifedipine, Mexiletine and Dofetilide) and multiple (e.g. Quinidine, Terfenadine, Sotalol, Ranolazine) ion channel. Overall, uHeart demonstrates 83.3% sensitivity and 100% specificity in predicting QT-prolongation. Moreover, uHeart showed a superior outcome with respect to 2D models in detecting arrhythmic events and detect toxicities of molecules that resulted false-negative in animal models. The analyses on contractile parameters (e.g., beating period-BP,

contraction time-CT, relaxation time-RT, contraction amplitude-CA, contraction velocity-CV) highlighted that uHeart has 65% sensitivity and 100% specificity in predicting inotropic effects. Notably, uHeart outperformed traditional 2D models in detecting the effects of drugs targeting the sarcomere, underscoring the importance of using a 3D model to tackle effect of specific group of compounds. These results highlight uHeart enhanced relevance and potential for application in more specific CoUs. **Conclusions:** uHeart is a highly functional 3D human cardiac model, developed in accordance with the 3Rs principles, designed to advance preclinical cardiac safety assessment. Extensive pharmacological testing has demonstrated the model's robust suitability for cardiotoxicity evaluation across a range of CoU. This positions uHeart as a promising preclinical tool for predictive cardiac toxicity screening in drug development.

PS 4700 Development of a Guinea Pig Telemetry Model for Early QT Prolongation Screening in Compliance with ICH S7B Best Practices

R. Fujii, K. Sampei, H. Saito, M. Yoshii, A. Kanno, A. Fujiwara, and T. Kadota. CMIC Pharma Science Co., Ltd., Yamanashi, Japan.

Background and Purpose: Nonclinical evaluation of drug-induced QT interval prolongation is essential for predicting proarrhythmic risk in humans. Regulatory guidelines, including ICH S7B, recommend *in vivo* QT studies using non-rodent species such as dogs or monkeys. However, these models present challenges in early drug development due to high costs, ethical considerations, and operational complexity. Guinea pigs offer a promising alternative because of their manageable size, ease of handling, and cardiac ion channel expression profiles that closely resemble those of humans. Although *ex vivo* studies using guinea pig hearts have demonstrated their utility in QT assessment, *in vivo* telemetry-based models remain insufficiently developed and lack standardization for early screening. In this study, we aimed to establish a telemetry-based QT assessment model in guinea pigs in accordance with the best practices outlined in the ICH S7B Q&A document. Furthermore, we evaluated strategies to improve screening sensitivity and efficiency in guinea pig QT prolongation assays by incorporating best-practice concepts. Developing a physiologically relevant and cost-effective model is expected to enhance both sensitivity and operational efficiency in early-phase cardiac safety screening. **Methods:** Four male SPF Hartley guinea pigs aged 7 to 9 weeks were administered moxifloxacin orally at doses of 10, 30, and 100 mg/kg, following a Williams Latin square design. Electrocardiographic parameters (RR, PR, QRS, QT, QTc) were continuously recorded under conscious conditions using telemetry. Comparative analysis was performed using ECG data from dogs treated with the same compound to explore interspecies differences in pharmacodynamic response. **Results:** QT interval prolongation was not observed at the low (10 mg/kg) or medium (30 mg/kg) doses of moxifloxacin. However, a trend toward QT prolongation was noted at the high dose (100 mg/kg). Compared to canine data, guinea pigs did not exhibit a clear dose-dependent QT response, suggesting potential species-specific differences in cardiac sensitivity to moxifloxacin. **Conclusions:** These findings indicate that guinea pig telemetry may serve as a practical and physiologically relevant model for early QT assessment, offering a viable alternative to conventional non-rodent species. From a toxicological standpoint, the ability to detect drug-induced electrophysiological changes such as QT prolongation at an early stage may facilitate the identification of proarrhythmic risk prior to progression into later-phase studies. Looking ahead, the application of individualized QT correction (QTc_{adj}) based on the slope (β) derived from QT-RR relationships, along with the estimation of the minimum detectable difference (MDD), may enhance the model's quantitative capabilities and contribute to improved sensitivity and screening precision in early drug development.

PS 4701 Differentiating Pure hERG from Multi-Ion Channel Blockers Using a New Proarrhythmic Risk Biomarker: a Study Evaluating the Effects of QT-positive drugs on the JTpeak interval in Telemetered Dogs

J. Valentin¹, A. Betat², A. Delaunois¹, M. Loiseau², A. Maurin², C. Drieu La Rochelle², E. Martel³, and E. Delpy². ¹UCB Biopharma SRL, Braine-l'Alleud, Belgium; ²Biotrial Pharmacology, Rennes, France; and ³Boehringer Ingelheim Pharma, Biberach/Riss, Germany.

Background and Purpose: The JTpeak (JT_p) and Tpeak-to-Tend intervals (TpTe), representing cardiac ventricular early and late repolarization, respectively, have been proposed as a complementary, sensitive, and more specific biomarkers than the QT interval for assessing proarrhythmic risk in drug development. It aims to improve the differentiation between drugs that selectively inhibit hERG channels (associated with high proarrhythmic risk) and those that affect multiple cardiac ion channels (associated with minimal to no risk). As previously reported by Darpo et al. (2019) in human, the present study aimed to evaluate the effects of five QT-prolonging reference drugs, namely moxifloxacin, dofetilide, dolasetron, ondansetron and quinine, on JT_p interval in telemetered conscious dogs. TpTe interval, together with PR and QRS intervals reflecting, the effects on other cardiac ion channels, were also measured. Levocetirizine, a QT-negative control drug, was included for comparison. **Methods:** The study was performed in conscious male dogs (n=7) previously instrumented

with a telemetry implant for the measurement of arterial blood pressure and ECG. Each compound was administered orally at two dose levels using a crossover study design, with ECG monitored over a 24-hour period post-dosing. Dedicated pharmacokinetic sessions were performed to determine corresponding drug plasma exposures, and sensitivity parameters were calculated. JT_p and TpTe intervals were individually corrected (c) for heart rate variations, as it is done with QT. **Results:** Compared to vehicle, dofetilide (0.03 and 0.15 mg/kg), moxifloxacin (30 and 100 mg/kg), and ondansetron (10 and 30 mg/kg) produced dose-dependent increases in JT_p interval, consistent with predominant hERG channel blockade. However, no effect was observed on TpTe-c interval with moxifloxacin and dofetilide, whereas a slight increase was noted with ondansetron. In contrast, dolasetron (6 and 20 mg/kg) and quinine (20 mg/kg) did not affect the JT_p interval. Interestingly, dolasetron slightly and transiently increased TpTe-c at the highest dose, and also increased both QRS and PR intervals, reflecting its inhibitory effects on sodium and calcium currents. With quinine, a slight increase in QRS interval was observed. As expected, levocetirizine (2 and 10 mg/kg) showed no effect on ECG intervals, at any dose or timepoint. Total plasma drug concentrations for each compound increased dose-proportionally. In this study, the residual mean standard error (RMSE) for JT_p-c ranged between 2.3 and 4.4 msec, thus suggesting a very well-powered study. **Conclusions:** The JT_p interval was confirmed as a sensitive biomarker to differentiate between purported selective hERG blockers (moxifloxacin, dofetilide, ondansetron) and compounds with multi-ion channel activity (dolasetron, quinine). In dogs, additional endpoints such as TpTe interval may further complement classification, although further assessment remains to be performed. These findings support the relevance of JT_p interval assessment as a valuable parameter to complement QT interval measurements in cardiovascular safety pharmacology studies, enhancing the specificity and sensitivity of proarrhythmic risk evaluation.

PS 4702 Non-Drug Induced Spontaneous Convulsions in Different Nonclinical Laboratory Animals Used for Non-Clinical Drug Safety Evaluation

Z. Wang, and R. Zhang. WuXi AppTec (Suzhou) Co., Ltd., Suzhou, China.

Background and Purpose: Convulsions are occasionally observed during long-term toxicity and carcinogenicity studies in laboratory animals, but distinguishing whether these events are related to the test article or are spontaneous/procedural is crucial for accurate data interpretation. This review aimed to summarize the incidence and characteristics of convulsions in various commonly used laboratory animal species at the Suzhou testing facility, and to provide a reference for toxicologists and pathologists in differentiating test article-related effects from procedural or spontaneous findings. **Methods:** A retrospective review was conducted of studies performed at the Suzhou testing facility between 2018 and 2025. The analyzed studies included 7-day to 2-year carcinogenicity and toxicity studies on Sprague-Dawley (SD) rats, CD-1 mice, Tg.rasH2 mice, Beagle dogs, non-human primates (NHPs), Bama minipigs, Hartley guinea pigs, and New Zealand white rabbits. The occurrence, timing, and circumstances of convulsions were recorded and analyzed, with attention to study duration, sex, procedures (e.g., blood collection, dosing), and histopathological findings. **Results:** The results indicated that convulsions were most frequently observed in rats, particularly in the 2-year studies, with a highest incidence of spontaneous convulsions at 5.9% (males) and 4.41% (females). The percentages of convulsions in the 26-week and 13-week studies were 2.99% and 2.63%, respectively, with no significant sex differences. In the 4-week studies, symptoms were noted in only one male rat. In CD-1 mice and Tg.rasH2 mice during the 26-week studies, convulsions occurred mainly during blood collection or formulation administration procedures, suggesting procedural-related. In NHPs, convulsions were noted once each in a 2-month and a 6-month Intravenous Infusion study, while no occurrences were observed in Beagle dogs, guinea pigs, rabbits, or minipigs. Convulsions first appeared at 20 weeks in males and 14 weeks in females, with an average onset age of approximately 51 weeks across all animals during 2-Year Carcinogenicity study. Some animals had convulsions only once, while others experienced multiple episodes. No deaths were related to convulsions, and no related histopathological abnormalities were found in the brain upon examination. **Conclusions:** SD rats exhibited a higher frequency of convulsions compared to other species, especially in longer-duration studies. The convulsions observed in mice were mostly procedural, and other species showed minimal or no occurrences. No convulsion-related deaths or brain pathology were detected. The increased frequency of convulsions in SD rats may be influenced by environmental factors, age, and handling frequency. The compiled database will support toxicologists and pathologists in distinguishing between test article-related effects and spontaneous or procedural findings in future studies.

R. M. Nandre¹, M. Pape², T. L. Horn², A. Maximov³, B. Davletov⁴, and P. S. Terse¹.

¹NCATS, Rockville, MD; ²ITRI, Chicago, IL; ³Scripps Research, La Jolla, CA; and ⁴The University of Sheffield, Sheffield, United Kingdom.

Background and Purpose: Bi-Tox, a new molecular entity is formed by combining the two botulinum domains (Spytag and Spycatcher), which is being developed for chronic peripheral neuropathy. As per the CDC guideline, a mouse bioassay was performed to determine whether Bi-Tox can be excluded from the select agent list. **Methods:** Acute lethality (LD₅₀) of a single intraperitoneal administration of Bi-Tox and wild type Botulinum Neurotoxin A (WT BoNT/A) following a seven-day observation period was determined in CD-1 Mice (4 wk old, 15-30 g body weight) using 0.5% Human Serum Albumin in sterile water as a vehicle. Dose formulations were analyzed by SDS-PAGE for Bi-Tox concentration. **Results:** WT BoNT/A at 40 or 24 ng/kg resulted in 100% mortality within 1 or 2 days of administration, respectively. Administration of WT BoNT/A at 4, 0.8, or 0.6 ng/kg resulted in 100%, 80%, or 100% mortality/morbidity, respectively. However, no clinical signs were observed in animals dosed with 0.4 ng/kg of WT BoNT/A. In the formulation analysis of Bi-Tox, the band in the SDS-PAGE predicted to be Bi-Tox was correlated to an average of 43.8 µg/mL for the expected concentration of 82.8 µg/mL. Bi-Tox at 2120 or 212 ng/kg resulted in 100% or 90% mortality within 1 or 2 days of dose administration. In addition, 52.9 ng/kg or 26.5 ng/kg Bi-Tox exhibited 70% or 40% mortality, respectively, with all deaths reported within 3 days of administration. Bi-Tox associated clinical signs of ataxia, labored breathing, and wasp waist were observed in these dose groups. Further, 30% or 10% mortalities were reported in animals administered 13.2 ng/kg or 10.6 ng/kg of Bi-Tox, respectively. Animals administered Bi-Tox at 7.94 ng/kg exhibited clinical signs of rapid breathing (all mice) and wasp waist (3 of 10 mice). Following administration of Bi-Tox at 5.29 ng/kg, mice exhibited rough coat (4 of 10 mice), slight rapid breathing (7 of 10 mice) and slight wasp waist (3 of 10 mice), which were mild and inconsistent with botulism progression. Therefore, no further groups were administered with Bi-Tox. **Conclusions:** Based on this bioassay, the Lethal Dose 50 (LD₅₀) of Bi-Tox was determined to be 35.15 ng/kg, and the LD₅₀ of WT BoNT/A was 0.692 ng/kg. This observed LD₅₀ of Bi-Tox was approximately 51-fold higher than that of WT BoNT/A under the conditions employed in this study, which was not adequate enough for CDC to exclude Bi-Tox from the select agent list. (Supported by Contract No HHSN2712017000161 under HEAL/NCATS program).

PS 4704 Preclinical Toxicology Assessment of VT-109, a Novel Agent for Treatment of Acute Respiratory Distress Syndrome

A. Lyubimov, Y. Komarova, M. Lindeblad, A. Zakharov, R. Kwok, and K. Kabirov. University of Illinois at Chicago, Chicago, IL.

Background and Purpose: Acute Respiratory Distress Syndrome (ARDS) is marked by non-cardiogenic pulmonary edema, hypoxemia, and respiratory failure, leading to high mortality. The COVID-19 pandemic has underscored the urgent need for effective ARDS therapies. To address this, we developed VT-109, a synthetic cyclic peptide to reduce pulmonary vascular leakage by modulating pathological calcium signaling in endothelial cells. Our studies evaluated the toxicity and pharmacokinetics of VT-109 following intravenous administration in Crl:CD (SD) rats and Beagle dogs. **Methods:** Rat Study: VT-109 was administered at dose levels of 0, 3.75, 7 (7.5 in the PK cohort), and 15 mg/kg. The test article and vehicle (5% DMA, 10% PEG400, 1% Polysorbate 80) were delivered via tail vein injection once daily for seven consecutive days. Crl:CD (SD) rats were obtained from Charles River Laboratories. Evaluations included mortality, clinical observations, physical examinations, body weight, clinical pathology, plasma and lung drug concentration analyses, pharmacokinetic assessments, and gross necropsy. Dog Study: VT-109 was administered at dose levels of 0.25 and 1.25 mg/kg. The test article and vehicle (0.42% DMA, 0.83% PEG400) were delivered via cephalic vein injection once daily for seven consecutive days. Beagle dogs were obtained from Marshall BioResources. Evaluations included mortality, clinical observations, physical examinations, body weight, food consumption, clinical pathology, and plasma drug concentration analysis. **Results:** Rat Study: Repeated administration of VT-109 at 3.75, 7, and 15 mg/kg for seven consecutive days produced clinical signs in the high-dose group, along with changes in hematology parameters and fibrinogen levels across all dose groups. No gross lesions were observed at necropsy. Plasma VT-109 concentrations increased proportionally with dose, with peak levels (C_{max}) observed within 2 minutes post-dosing. On Day 1, the terminal elimination half-life (t_{1/2-λz}) ranged from 5.87 to 6.92 hours across the 3.75, 7.5, and 15 mg/kg groups. Systemic exposure was higher in males than in females at all dose levels. On Day 7, t_{1/2-λz} ranged from 6.19 to 8.51 hours, with males showing higher exposure at 7.5 and 15 mg/kg, but lower exposure at 3.75 mg/kg compared to females. VT-109 concentrations in lung tissue also increased with dose, with C_{max} occurring approximately 2 hours after the final administration. The terminal half-life in the lungs ranged from 8.01 to 125.88 hours in males (3.75 and 15 mg/kg) and from 6.31 to 15.50 hours in females (7.5 and 15 mg/kg). Overall, lung exposure was lower in males compared with females at the 7.5 and 15 mg/kg dose levels. Dog Study: There were no mortalities or clinical signs in any dose group. No significant changes were observed in body weight, food consumption, or clinical pathology parameters in male or female dogs. VT-109 had no effect on food consumption at any dose level. Plasma VT-109 concentrations increased proportionally with dose.

On Days 1 and 7, C_{max} was reached at varying time points (15 minutes, 30 minutes, or 1 hour) depending on dose level and sex. Plasma concentrations were measurable up to 6 hours post-dose. **Conclusions:** The no-observed-adverse-effect level (NOAEL) in rats was not established. The lowest-observed-adverse-effect level (LOAEL) was established at the VT-109 dose level of 3.75 mg/kg. The test article at doses of 0.25 and 1.25 mg/kg was well tolerated by Beagle dogs. The results of these dose-range-finding studies were used in the ongoing pivotal VT-109 studies. The U.S. Army Medical Research Acquisition Activity, 808 Schreider Street, Fort Detrick MD 21702-5014 is the awarding and administering acquisition office. This work was supported by the Assistant Secretary of Defense for Health Affairs, endorsed by the Department of Defense, in the amount of \$5,860,641, through the Peer Reviewed Medical Research Program under Award No. W81XWH-21-1-0639. PS 4705 Risk Assessment of Lens Opacities Observed in a 39-Week Toxicity Study of SNG-30 in Dogs

C. Nekomoto¹, E. Kashiwagi¹, K. Kin², Y. Asaoka¹, and T. Fukushima¹. ¹Shionogi & Co., Ltd., Osaka, Japan; and ²Shionogi TechnoAdvance Research Co., Ltd, Osaka, Japan.

Background and Purpose: In nonclinical safety evaluation of drug candidates, repeated-dose toxicity studies with durations exceeding the anticipated clinical dosing period are essential. Unexpected toxicities that cannot be detected in subacute repeated-dose toxicity studies can sometimes be revealed for the first time in chronic repeated-dose toxicity studies. For the compound SNG-30 developed by SHIONOGI, lens opacities were observed at the end of a 39-week repeated oral dose toxicity study in dogs, which were not detected in a 4-week repeated oral dose toxicity study. Therefore, to assess the human risk and development feasibility of this toxicity, additional tests were conducted during the 39-week repeated dose toxicity study, as well as additional *in vitro* studies to investigate the mechanism. These results were compared with toxicity information from other drugs known to cause lens opacities. **Methods:** SNG-30 was orally administered to male and female beagle dogs at doses of 0, 3, 20, and 1000 mg/kg/day for 39 weeks. Ophthalmological examinations were conducted at multiple time points (pre-dose, week 19, week 38, and 4, 8, and 12 weeks after withdrawal), followed by necropsy and histopathological examinations (week 39, 13 weeks after withdrawal). As an additional investigation, plasma concentrations of cholesterol precursors were measured at various time points (pre-dose, weeks 13, 27, 39, and 4 and 13 weeks after withdrawal). In addition, multiple tissues were isolated from untreated beagle dogs, and mRNA expression levels of the pharmacological target gene M were analyzed by real-time PCR. Furthermore, the effects of SNG-30 on various cellular function markers were evaluated in human cultured lens epithelial-like cells (B-3 cells) after 24 hours of treatment. **Results:** In the high-dose group of the 39-week repeated-dose study in dogs, no abnormalities were observed at the 19-week ophthalmoscopic examination, but lens opacities were detected at week 38. Histopathological examination also revealed degeneration of lens fibers in this group. During the 13-week withdrawal period, no recovery was observed, but there was no further progression of lens fiber degeneration. The exposure margin between the dose at which no lens opacity was observed and the estimated human therapeutic dose was approximately 20-fold. Mechanistically, the pattern of lens opacity observed in this study was relatively similar to changes reported for compounds with cholesterol synthesis inhibitory activity, and increases in plasma cholesterol precursors were observed at weeks 27 and 39 in the high-dose SNG-30 group. Furthermore, there was no information on the relationship between the pharmacological target and lens opacities, and target gene expression was not detected in the canine lens. Additional data from human lens epithelial cells and other studies did not confirm any effects on oxidative damage, glucose metabolism abnormalities, or membrane dysfunction, which have been reported as causes of lens opacities for other compounds. **Conclusions:** Lens opacities caused by SNG-30, which first became apparent in the 39-week repeated-dose oral toxicity study in dogs, resembled those caused by other drugs known to induce lens opacities through inhibition of cholesterol synthesis and were accompanied by changes in plasma cholesterol precursors. These changes were considered to be due to an off-target effect on cholesterol synthesis. In the middle-dose group, where no lens opacities were observed, there were no changes in plasma cholesterol precursors or other toxicity-related findings. Based on clinical information for drugs with the potential to cause lens opacities, it is possible to estimate the risk in clinical trials of SNG-30 and to set monitoring parameters. Taking the safety margin into account, it was determined that the development of SNG-30 was feasible.

J. W. Davis II, L. O. Whiteley, D. Froim, A. Burdick, T. Picariello, C. A. Desjardins, T. Natoli, S. Zanotti, B. Basiri, R. Batra, and O. Beskrovnya. Dyne Therapeutics, Waltham, MA.

Background and Purpose: Oligonucleotides (ONTs) are a class of promising therapeutics for the treatment of genetic neuromuscular diseases. However, achieving efficacious concentrations in muscles and central nervous system (CNS) has hindered progress to success in the clinic. To overcome this limitation, we developed the FORCE platform, which consists of an antigen-binding fragment (Fab) highly specific for the human transferrin receptor 1 (TfR1), to which ONT payloads can be conjugated via a cleavable valine-citrulline linker. The platform was designed to allow for conjugation of either neutral or charged payloads to enable the flexibility to match payload to mechanism of disease. TfR1 plays an important role in iron trafficking and erythropoiesis, and anemia has been reported nonclinically and clinically for biologics that leverage TfR1 to enable therapeutic delivery of payloads to muscle and CNS. **Methods:** To understand the impact of FORCE platform on erythropoiesis, cynomolgus monkeys were administered FORCE conjugates harboring either a phosphorodiamidate morpholino (Fab-PMO), a negatively charged gapmer (Fab-ASO), or a small interfering RNA (Fab-siRNA) for 13 weeks at 3- to 4-week intervals followed by 8-week recovery periods. The concentration of the test article in bone marrow was determined at necropsy using a qualified method developed for each test article and red cell mass endpoints were measured 24 to 48 hrs after the first dose and at necropsy. **Results:** In these studies, all Fab conjugates were well-tolerated and exposure of bone marrow to each payload increased in a dose-responsive manner. Reticulocytes were transiently decreased 24-48 hrs after administration of either Fab-PMO or Fab-ASO in a dose-dependent manner and returned to pre-study values prior to the next dose administered while hematologic endpoints were unchanged after administration of Fab-siRNA. Red blood cells, hemoglobin as well as hematocrit remained unchanged for all FORCE conjugates. Given the importance of iron on erythropoiesis, iron trafficking was also characterized. Fab-PMO caused a reversible, minimal, but non-dose responsive increase in serum iron 48 hrs after the fourth dose. Neither transferrin nor ferritin serum levels were changed after repeated administration with Fab-PMO. Fab-ASO, at a similar dose range, did not alter serum iron nor transferrin, although there was a transient increase in circulating ferritin, which was interpreted to be an indication of a minimal inflammatory response, a known effect of phosphorothioate ASOs in non-clinical species. Fab-siRNA had no impact on any iron parameter tested. **Conclusions:** The totality of the data indicates that despite exposure to the bone marrow and minimal transient alterations in serum iron levels and resultant decreased reticulocytes, repeat administration of FORCE conjugates to cynomolgus monkeys does not result in anemia. Further the lack of consistent effects on transferrin or ferritin indicates the FORCE platform does not compete with endogenous TfR1 ligands.

PS 4707 Summary of three toxicity study of repeated intravenous infusion of exatecan derivative-ADCs to cynomolgus monkey

J. Zou¹, L. Zhang², J. Ma², and Y. Zhang¹. ¹JOINN Laboratories, Beijing, China; and ²JOINN Laboratories, Suzhou, China.

Background and Purpose: Test articles A, B and C were three ADCs containing different targets of exatecan. This study summarizes the toxic reactions after repeated intravenous infusion of three exatecan ADCs of A, B and C, in cynomolgus monkey conducted in JOINN Laboratories, providing some toxicity references for the development of similar drugs. **Methods:** 40 cynomolgus monkeys (20 animals/sex) were used and divided into 4 groups (5 animals/sex/group) and treated with vehicle control article and low-, middle-, and high-dose group in each study. The dosages of the test article A were 10, 30 and 45 mg/kg. The administration doses of test article B were 7.5, 15 and 30/20 mg/kg (30 mg/kg for the first administration and 20 mg/kg for the second and third administrations). The dosages of the test article C were 10, 30 and 50 mg/kg. All animals were administered by intravenous infusion once every 3 weeks for a total of 2 or 3 times. During the study, clinical signs, body weight, clinical pathology, immune-related indicators, and histopathological examination etc. were performed. **Results:** The highest non-severely toxic dose (HNSTD) was 45 mg/kg for test article A, 15 mg/kg for B, and 50 mg/kg for C. Mortality occurred in 4/10 animals at 30 mg/kg of B, primarily due to malnutrition secondary to persistent diarrhea and general deterioration; no deaths or moribundity were observed with A or C. All compounds caused transient loose stools. Systemic exposure to exatecan was significantly higher for B than A or C, correlating with its lower tolerated dose. Drug-to-antibody ratios (DAR) were 4 for A and 8 for B and C; exposure differences were attributed to linker and target variations rather than DAR. Thus, tolerated dose was inversely related to exatecan exposure. The predominant toxicity for all compounds involved the hematopoietic and immune systems, evidenced by reductions in RBC indices (RBC, HGB, HCT, Retic), thymic lymphocytes, bone marrow hematopoietic cells, and lymphocytes in spleen and lymph nodes. Test article B also induced gastrointestinal, skin, and renal lesions, including intestinal mucosal necrosis, hemorrhage, villous atrophy, lamina propria edema, epithelial detachment; skin inflammation, ulceration, necrosis; and renal tubular casts, dilation, and vacuolation. Exposure to total antibody, ADC, and exatecan increased dose-dependently without accumulation. Anti-drug antibodies (ADA) were detected in A and C without affecting exposure;

none were observed in B. No significant dose-related changes were noted in food consumption, cardiovascular, respiratory, ophthalmic, or other systemic parameters. Consistent with literature, exatecan toxicity primarily affects rapidly proliferating tissues, with noncumulative myelosuppression—especially neutropenia—as the principal dose-limiting effect. Compared to exatecan alone, ADC derivatives markedly reduced hematologic toxicity and eliminated reproductive tissue toxicity. **Conclusions:** The tolerated dose of exatecan derivative ADCs given to cynomolgus monkeys was related to the systemic exposure to exatecan after administration. The administration of exatecan derivative ADCs significantly reduced hematological toxicity. The main toxicities were bone marrow hematopoietic inhibition and immunosuppression.

PS 4708 Safety and Pharmacokinetic Evaluation of MAM01, a Monoclonal Antibody for Malaria infection caused by *Plasmodium falciparum*

N. Sharma¹, U. Argikar¹, J. Huleatt¹, J. White², and M. Otieno¹. ¹Gates Medical Research Institute, Cambridge, MA; and ²BioData Solutions, Lawrence, KS.

Background and Purpose: Malaria is a life-threatening disease caused by *Plasmodium* parasites, transmitted through bites from infected female *Anopheles* mosquitoes. Of the five species that infect humans, *Plasmodium falciparum* is responsible for over 95% of global malaria cases and 96% of malaria-related deaths in the WHO African Region. In 2022, approximately 608,000 deaths were attributed to malaria, primarily in children in sub-Saharan Africa. MAM01 is an extended half-life IgG1 monoclonal antibody currently in clinical development for passive immunoprevention of malaria in children 3 months to <60 months of age, by targeting *Plasmodium falciparum* circumsporozoite protein. Extensive pharmacokinetics (PK) characterization of MAM01 was conducted in mice and rats, along with safety evaluation in nonhuman primates. These studies were aimed at supporting Phase 1 first in human studies, based on safety and toxicology evaluation. **Methods:** Single intravenous doses up to 100mg/kg were administered in non-GLP studies in rats and monkeys, with long-term post-dose evaluations for 3 months in rats and 6 months in monkeys. A 4-week repeat-dose GLP study in monkeys evaluated systemic toxicity following four weekly administrations of up to 300 mg/kg via intravenous (IV) injection, and 152.1 mg/dose via subcutaneous (SC) or intramuscular (IM) routes. Additionally, a GLP tissue cross-reactivity study was performed using normal adult human tissues to identify potential off-target binding and species selection for the GLP study. A mathematical model was developed using mouse, rat, and monkey pharmacokinetics and mouse efficacy data to project human PK. Simulations were then performed to determine the predicted concentration of MAM01 corresponding to 95% protection in humans. **Results:** In single dose studies conducted in rats and monkeys, MAM01 had an extended half-life of up to 309 hours (~13 days) in rats or 618 hours (~26 days) in monkeys, respectively, following IV administration, and up to 691 hours (~29 days) in monkeys after SC injection, at the low dose of 10 mg/kg. A 4-week repeat-dose GLP study in monkeys identified a no observed adverse effect level of 300 mg/kg IV, providing a 9.3-fold exposure margin over estimated human exposures. A GLP tissue cross-reactivity study in normal adult human tissues revealed no off-target binding. MAM01 demonstrated extended half-life (up to 691 hours SC in monkeys) and consistent pharmacokinetic profiles without evidence of anti-drug antibody interference. No test article-related toxicity, organ-specific effects, or adverse reactions were observed across all doses and routes. The simulations of MAM01 treatment from the mathematical model suggested that prophylactic efficacy may be observed for doses over a range of 1.5 - 40 mg/kg. **Conclusions:** Overall, the nonclinical safety profile of MAM01 supported dosing of humans in a Phase 1 clinical setting.

PS 4709 Non-Clinical Development of the Monoclonal Antibody Zanidatamab for the Treatment of HER2-Expressing Cancers

G. R. Paul¹, G. Rowse², R. Davies², N. Weisser², A. Kyakulaga³, K. Vaidya³, and D. Manca³. ¹Jazz Pharmaceuticals, Cambridge, United Kingdom; ²Zymeworks, Vancouver, BC, Canada; and ³Jazz Pharmaceuticals, Palo Alto, CA. Sponsor: G. Paul, EUROTOX

Background and Purpose: Zanidatamab is a bispecific antibody that targets human epidermal growth factor receptor 2 (HER2), leading to receptor downregulation and effector-mediated cytotoxicity with consequent antitumor activity in HER2-expressing cancers. A comprehensive non-clinical programme consistent with the International Council for Harmonisation of Technical Requirements for Pharmaceuticals for Human Use (ICH) and other jurisdictional requirements was required to support the marketing application of zanidatamab. **Methods:** All *in vivo* toxicology studies were conducted in cynomolgus macaques, since zanidatamab binds with similar sub-nanomolar affinities to both human and macaque HER2, but not other species. Zanidatamab was administered intravenously (1-hour infusion) to monkeys (n ≤ 4/sex/group) at 0, 5, 50, or 150 mg/kg once weekly (QW) for up to 13 weeks and assessed for toxicology, toxicokinetics, immunogenicity (antidrug antibodies) and safety pharmacology endpoints. Additional animals (n ≤ 3/sex/group; 0 and 150 mg/kg QW) were similarly dosed and then maintained for an off-dose period of 8 weeks to evaluate the reversibility or progression of any findings. Doses were selected with reference to a preliminary 4-week, dose range-finding study performed in the same species. Cross-reactivity studies were also performed, in

vitro, to investigate membranous immunostaining of zanidatamab in human tissues. Assessment of mutagenicity and reproductive toxicology studies were not warranted for zanidatamab, in accordance with ICH-S9. An antibody binding to the extracellular domain of HER2 is not expected to interact directly with chromosomal material; thus, zanidatamab was not considered to present a mutagenic liability. On the basis of a weight of evidence analysis, zanidatamab was considered an embryo-fetal toxicant, since the critical role of HER2 in fetal development is well established and the potential for embryo-fetal toxicity by HER2-blocking antibodies has been documented. **Results:** Human tissue cross-reactivity studies demonstrated membranous staining of zanidatamab consistent with HER2 expression reported in the literature (Press, 1990; Liu, 2001). Although the spinal cord also exhibited membrane staining, the existence of the blood-spinal cord barrier should limit *in vivo* exposure of this tissue to zanidatamab (Rossi, 2013). Zanidatamab exposure (in terms of area under the curve) in cynomolgus macaques increased approximately dose-proportionately, with a mean terminal elimination half-life of 2.73 to 8.95 days. Zanidatamab-related effects in monkeys were minimal and included a non-dose-dependent increase in the incidence of diarrhoea. Mild increases in blood urea nitrogen and/or decreases in serum albumin levels were not dose-related and were within historical control ranges but were correlated with an increased incidence of diarrhoea for some animals and considered a consequence of mild subclinical dehydration. The no observed adverse effect level (NOAEL) was thus 150 mg/kg QW, the highest dose evaluated. There were no effects of zanidatamab on neurobehavioral, respiratory and cardiovascular functions in macaques. **Conclusions:** In summary, this programme characterised the non-clinical safety of zanidatamab and successfully supported its marketing application. The NOAEL in cynomolgus macaques was 150 mg/kg QW, the highest dose evaluated. **References:** Liu et al, (2001). PS 4710 Standardizing Immunomodulatory Dosing of Sirolimus in Non-Human Primates for Gene Therapy: A Data-Driven Review

J. Forget, A. Hunnerdorse, N. Makori, and W. Davis. Altasciences Preclinical Seattle, Seattle, WA.

Background and Purpose: Gene therapy continues to progress as a viable therapeutic intervention for genetic disorders. These therapeutic interventions often use viral vectors (eg, adeno-associated virus) and lipid nanoparticles as a platform which may illicit severe immunogenic responses. Immunomodulatory agents such as Sirolimus, an mTOR inhibitor, improve tolerability due to the immunosuppressive effects, including modulation of T-cell activity and reduction of inflammatory responses. In clinical practice, recommended human dosages of Sirolimus vary based on indication, body weight, and immunologic risk, with target trough blood concentrations generally ranging from 5 to 15 ng/mL. The purpose of this abstract is to establish a nonclinical reference range for Sirolimus dosing in mg/kg to facilitate therapeutic dose calculations (ease of study conduct and improve reproducibility in nonclinical studies) in non-human primates. **Methods:** Across multiple safety assessment studies conducted over the past two years, a total of 35 cynomolgus monkeys were identified as receiving Sirolimus treatment, either as a monotherapy or in combination with other immunosuppressive agents, as part of the study design, involving either once- or twice-daily administration, with or without weekly dose adjustments. Of these, 21 animals were selected for evaluation of target dose level vs corresponding blood concentrations. Whole blood samples were collected weekly, using K2EDTA tubes, and Sirolimus concentrations were quantified via high-performance liquid chromatography with tandem mass spectrometry (LC-MS/MS). For each animal, the Sirolimus dose was calculated based on initial level (mg/m²), most recent body weight, and body surface area (BSA) conversion methodology. This value was then converted into a practical dosing unit of mg/kg. **Results:** Sirolimus treatment typically began 2 to 3 days prior to the gene therapy administration and continued daily for a duration ranging from 5 days to 2 months following the gene therapy dose. In general, incremental increases in mg/kg dosing were associated with higher trough and peak Sirolimus blood concentrations; however, individual animal responses varied considerably throughout the study periods. A review of non-clinical gene therapy study designs indicated an intended target therapeutic blood concentration between 2 and 10 ng/mL per day. Measured blood concentrations across studies ranged from 1.2 to 8.5 ng/mL, with corresponding calculated dose levels between 0.15 and 0.57 mg/kg/day. Notably, inter-animal variability was observed even at similar levels. Additionally, dose adjustments generally resulted in changes to blood concentrations within $\pm 10\%$ of prior levels. Based on the cumulative data review, a Sirolimus dose range of 0.2 to 0.5 mg/kg/day is proposed to achieve the intended target therapeutic trough blood levels. **Conclusions:** Sirolimus dosing regimens in non-human primate gene therapy studies varied in schedule and duration, with some adjustments along the way requiring blood sample collection to confirm blood concentration levels. While higher mg/kg doses generally led to increased blood concentrations, individual animal variability was significant. The proposed dose range of 0.2 to 0.5 mg/kg/day establishes a foundational framework for achieving therapeutic Sirolimus levels in non-human primates, reduce the frequency of blood collections required for monitoring, while also enabling more consistent comparisons across nonclinical studies.

PS 4711 A Retrospective Study of Nonclinical Safety Data for siRNAs

Y. Zhang, L. Guo, and R. Zhang. WuXi AppTec (Suzhou) Co., Ltd., Suzhou, China.

Background and Purpose: Small interfering RNA (siRNA) therapeutics represent a promising class of drugs. This poster aims to summarize the toxicological findings from a retrospective analysis to identify common patterns and assess overall safety. **Methods:** A retrospective analysis was conducted on a database of 46 GLP-compliant, repeated-dose toxicity studies. The database encompassed 23 different siRNA molecules in preclinical development. Details on therapeutic areas, experimental design (species, duration, route), and extensive data collections were analyzed. The data included toxicokinetic parameters, clinical and anatomic pathology, immunological profiles (cytokines, complement, immunophenotyping), and immunogenicity assessments. **Results: Study Distribution:** The studies covered therapeutic areas including metabolic (35%), cardiovascular (22%), and liver diseases (17%). Test species were primarily nonhuman primates (NHPs, 48%) and rats (39%), with fewer studies in dogs (2%) and mice (11%). **Administration & Exposure:** Most siRNAs utilized the GalNAc delivery system and were administered subcutaneously at doses of 10-600 mg/kg. The time to maximum concentration (T_{max}) was 0.5-2.0 hours in rodents and 1.0-8.0 hours in NHPs, with no observed accumulation. Higher drug exposure was noted in the liver and followed by the kidneys. **Toxicological Findings:** Mild to moderate changes were common in hematology, hepatic parameters, and pharmacological markers, while immunological effects were rare. The primary target organs were the liver, kidneys, lymph nodes, and injection sites, with occasional involvement of the spleen, thymus, and thyroid. Most findings were minimal to moderate in severity and were either reversible or showed partial recovery. **Immunogenicity:** Anti-drug antibodies (ADAs) were rarely detected and had no impact on systemic exposure. **Conclusions:** This retrospective analysis demonstrates a generally favorable and predictable safety profile for siRNA therapeutics in preclinical development. Toxicological findings were primarily confined to expected target organs, were typically mild to moderate, and often reversible. The establishment of a No Observed Adverse Effect Level (NOAEL) in 98% of the studies, coupled with rare and non-impactful immunogenicity, supports the continued development of siRNA drugs.

PS 4712 Acute Acceptable Exposure Levels for Impurities in an Infant Intrathecal Drug Product

A. Jee, and J. Gould. SafeBridge Consultants, Inc., New York, NY.

Background and Purpose: Permitted daily exposure limits (PDEs) represent a dose of a substance that is unlikely to cause adverse effects if an individual is exposed, by specified routes, at or below this dose every day over a lifetime. In certain circumstances, such as in less-than-lifetime exposure scenarios, higher doses of the chemical may be safe. Here, we propose an Acute Acceptable Exposure Level (AAEL) for infant exposure to an impurity present in a drug product administered via the intrathecal route. This is illustrated through two case studies for erucamide and ethanol, both of which have published limits set forth by the International Council for Harmonisation (ICH). **Methods:** AAELs were derived based on the adult parenteral PDE approach following ICH Q3C, Q3D, and draft Q3E guidelines, which generally involves understanding the critical effect, selection of a point-of-departure (POD) from a robust study, and the application of the appropriate adjustment factors. To develop the AAEL for the intrathecal route for a 7.6 kg (6-month-old) infant, modifications for this assessment include specific examination for the potential for central nervous system (CNS) as the critical effect, utilization of an acute study where possible, and the omission of a subchronic-to-chronic extrapolation factor. If necessary, a modifying factor was added to account for sensitivity of the developing infant CNS. The resulting dose was then adjusted to a concentration utilizing a 7.6 kg infant blood volume and cerebrospinal fluid (CSF) volume to ultimately identify a safe acute intrathecal dose. **Results:** AAELs for exposure by the intrathecal route for a 7.6 kg (6-month-old) infant were derived for two impurities. First, based on the ICH Q3E draft PDE for erucamide, a POD was selected from a 13-week rat study in which no effects were noted, and was adjusted for a 7.6 kg patient, a modifying factor for potential direct infant CNS effects, and the CSF volume of a 7.6 kg infant. This resulted in an AAEL for erucamide of 150 mcg. Secondly, the threshold of effect of a predicted embryonic ethanol concentration associated with maternal consumption of one alcoholic beverage per day was selected as the POD, and was adjusted for a 7.6 kg patient, inter-individual variability, extrapolation from a LOAEL to a NOAEL, and the CSF volume of a 7.6 kg infant, resulting in an AAEL for ethanol of 40 mcg/day. **Conclusions:** While PDEs are routinely derived for impurities in many drug products, acute exposures for infants via the intrathecal route are rarely encountered. The scientifically plausible approach presented here demonstrates the use of less-than-lifetime exposure, sensitive population (infant) CNS effects, unusual route extrapolation, and concentration at the sensitive tissue to provide a safe dose for inadvertently exposed infants.

K. J. Sadko¹, A. VandenBussche¹, M. Baillie², and A. Lauver¹. ¹Michigan State University, East Lansing, MI; and ²Certara Inc., Radnor, PA.

Background and Purpose: In early 2025, the FDA and NIH announced initiatives to reduce mandatory animal testing and expand the use of new approach methodologies (NAMs) in grant applications and preclinical drug development. Among these NAMs is Simcyp®, a physiology-based pharmacokinetic (PBPK) modeling platform that incorporates both human and animal simulation modules. These modules draw on compound-specific physicochemical properties as well as training datasets generated from validated reference compounds. Although the human simulator has undergone substantial validation across key ADME processes, the animal modules lack similar depth. In 2022, the FDA issued draft clinical guidance on assessing the pressor effects of investigational drugs, explicitly highlighting rofecoxib and torcetrapib as recommended positive controls. Validating model-based predictions of these drugs is essential for reducing animal use by establishing PK modules suitable for quantitative systems pharmacology applications. This study compares PK predictions generated with the Simcyp® rat model against *in vivo* and literature PK data. We hypothesize that the Simcyp® rat model will reliably capture the PK profiles of both compounds. **Methods:** A PK study was conducted on eight Sprague-Dawley (SD) rats (four females and four males), the strain on which the validated rat model is based. Animals received torcetrapib (100 mg/kg, PO), followed by a one-week wash-out period and then were administered rofecoxib (100 mg/kg, PO). Venous blood samples were collected from the lateral tail vein at baseline and at 0.5, 1, 2, 4, 8, and 24 hours after dosing and analyzed using LC-MS. Noncompartmental PK parameters were generated with Phoenix WinNonlin®. Literature-derived physicochemical data were used in the Simcyp® rat simulator to generate predicted PK profiles for both drugs. Simulated results were compared with *in vivo* data and published PK values, and any discrepancies in key parameters were quantified. Experimental PK data were used to refine drug profiles within the simulator as needed. **Results:** *In vivo* PK studies are currently underway. For rofecoxib, which has more comprehensive published physicochemical information, Simcyp® generated reasonably accurate predictions of key pharmacokinetic parameters. In contrast, predictions for torcetrapib were less accurate, particularly for exposure-related metrics, reflecting the limited preclinical data available. For rofecoxib, $t_{1/2}$ and t_{max} were accurately predicted compared to values in the literature (5.2h vs 5.0h and 2.7h vs 2.3h, respectively), AUC was underpredicted by approximately 2-fold (16.00 mg*L/h vs 29.63mg*L/h), and C_{max} was overpredicted by 3.8-fold (1.55mg/L and 0.40mg/L). Available literature PK data for torcetrapib are based on a 20 mg/kg dose, whereas our *in vivo* study uses a 100 mg/kg dose to produce a human-relevant pressor response. Despite this dose difference, both the simulated and literature values demonstrated comparable $t_{1/2}$ and T_{max} . Half-lives were predicted at 3.07h, which approximates the literature $t_{1/2}$ values of 3.50h. Similarly, t_{max} was well predicted at 2.40h compared to the literature value of 2.70h. However, AUC and C_{max} were severely underpredicted. Literature values of AUC and C_{max} were reported as 95.8 mg*L/h and 19.1 mg/L. The simulation predicted an AUC of 25 mg* h and C_{max} of 3.32 mg/L, a 5.75-fold and 3.8-fold underprediction. **Conclusions:** The Simcyp® rat model accurately predicts absorption-related pharmacokinetic parameters such as t_{max} and $t_{1/2}$. However, the lack of complete ADME data limits its ability to forecast exposure-related metrics like C_{max} and AUC, which are key for exposure-related toxicology outcomes. Ongoing *in vivo* studies will help refine these drug profiles, supporting the development of validated PBPK modules for use as NAM-based positive controls in evaluating drug-induced hypertension risk. Better PK predictions in rats will improve model-informed toxicological assessments, particularly for exposure-dependent effects, and reduce the dependence on animal testing.

PS 4714 Off target toxicity and efficacy testing of a novel stress reliever in a multi-organ microphysiological system

R. Brighton, and C. McAleer. Hesperos, Orlando, FL.

Background and Purpose: *Echinacea purpurea*, a known immunomodulator and pain reliever, has shown potential benefits on anxiety-like behavior in animal models. *E. purpurea* contains alkalimides, which can selectively bind and activate cannabinoid 1 (CB1) and cannabinoid 2 (CB2) receptors. One of the main active alkalimide, dodeca-2E,4E,8Z,10E/Z-tetraenoic acid isobutylamide (dodeca) is reported to have a significant positive relationship with CB1 receptor, but the safety and efficacy of *E. purpurea* and its components as a stress reliever in humans is not well understood. **Methods:** This study used an *in vitro* single-organ central nervous system (CNS) and a multi-organ microphysiological system (MPS) with human cells-based gut, liver, blood-brain-barrier (BBB) and CNS to investigate the efficacy and potential off-target toxicity of oral delivery of *E. purpurea* extract and dodeca in its pure form to ameliorate cortisol-induced stress on the CNS. Cannabidiol (CBD) and diazepam with known stress relieving properties were used as control drugs. A five-point dose range of pure dodeca (1 uM, 3 uM, 10 uM, 30 uM and 100 uM) was utilized to capture the dose-dependent response. The function and health of the constructs was measured by long-term potential (LTP) maintenance (CNS), albumin synthesis and P450 cytochrome activity (liver), and transendothelial electrical resistance (TEER) (BBB and gut) over a 48-hour exposure period to the drugs followed by a cell viability assess-

ment. The transport kinetics of dodeca across BBB and gut were used to create a pharmacokinetic-pharmacodynamic (PKPD) model to predict efficacy of dodeca *in vivo*. **Results:** *E. purpurea* extract showed a dramatic dose-dependent increase in LTP maintenance within both single- and multi-organ MPS, with the effect sustained for a duration of several hours and a significant induction of CYP1A1 activity in the liver without compromising cellular health. The observed fleeting effect aligned with the clinical dosing of *E. purpurea* tinctures as an anti-inflammatory medication. The multi-organ MPS showed a more enhanced rescue effect on LTP compared to the single organ, suggesting the contribution of drug metabolites in the stress relieving process. The extract showed more enhanced effects than its equivalent concentration of pure dodeca showing the contribution of other components within the extract. The PKPD modeling approach predicted dodeca would produce amelioration of stress-induced LTP deficits *in vivo*, consistent with clinical reports of reduced stress. **Conclusions:** Compared to single-organ CNS, inclusion of barrier tissues and liver in the multi-organ MPS showed contribution of drug transport and metabolism creating a more representative system for studying the pharmacokinetics and pharmacodynamics of compounds and metabolites. With the lack of human relevant data and models to study therapeutics, MPS presents a potentially beneficial platform for studying drug-drug interactions with other common therapeutics for both efficacy and off-target toxicity. Additionally, MPS provides supplementary information on the dosing concentrations and strategy based on human-cell response *in vitro*.

PS 4715 Assessing the data landscape of extractables and leachables (E&L) and implementing strategies to fill data gaps

C. Johnson¹, A. Bassan², M. Pavan², D. Palazzotti², and K. Cross¹. ¹Instem, Conshohocken, PA; and ²Innovatune, Padova, Italy.

Background and Purpose: Extractables and leachables (E&Ls) are chemical substances that can migrate into drug products from closed container systems, packaging materials, or medical devices, under exaggerated, manufacturing or storage conditions. As leachables are observed under normal storage conditions, it is important to assess the safety of those leachables which exceed safety thresholds. Where sufficient data are available to assess safety, a permitted daily exposure (PDE) value is calculated to communicate safe levels. However, where data are lacking for PDE derivation, data from a surrogate compound is assessed for its suitability to fill data gaps using read-across strategies. Read-across includes an assessment of data availability, and data suitability, while also ensuring overall analog fitness through an evaluation of similarity. The objective of the current study was to survey the availability of data to support read-across strategies for E&Ls. Additionally, where data are lacking, we discuss considerations for the derivation of a PDE value through a read-across case study using 1,9-Dimethyl nonanedioate as an example. **Methods:** A dataset of ~1200 E&L chemicals was compiled from ELSIE, PQRI and proprietary sources. Each chemical was assigned to a chemical cluster using hierarchical agglomerative clustering. Manual review was used to refine the chemical class assignments. A two-tier system of clusters was established to define the E&L chemical space. The second tier was based on stricter classification rules than the first tier. Each of the chemicals was mapped to data sources that are commonly referenced for safety assessments including the Leadscape (sub) chronic databases, EFSA OpenFoodTox, ECHA, IRIS, ToxRefDB, CPDB as well as established ICH PDEs. An assessment of data availability across the second tier was performed and reported. A case study involving a data poor member of the Aliphatic esters (Di-esters/Straight chain) cluster was used to highlight considerations for PDE derivation using read-across. **Results:** Approximately half of the E&L chemicals mapped to experimental data, with an additional 10% of chemicals having limited experimental data. Second tier clusters meet stricter structural requirements and therefore availability of data within these clusters provides a preliminary indication of the number of clusters where read-across could be considered. More specifically, 37% of clusters were populated by members, which were all data rich, while 80% of clusters were populated by at least one data rich member. For those clusters populated by data-poor members, it is important to find potential analogs with data to support read-across methodologies. 1,9-Dimethyl nonanedioate is a data-poor member of the Aliphatic esters (Di-esters/Straight chain) class with 6 data-rich and 2 data-poor members. The data-rich members together with additional analogs from the Leadscape database were evaluated as potential sources for read-across. Similarity was assessed across multiple domains including examination of experimental and predicted toxicological profiles. Positive Ames test results for 1,9-dimethyl nonanedioate were a key toxicological difference compared to a potential analog dimethyl decanedioate, which is assessed as negative in the Ames test. Such toxicological differences require resolution prior to reading across data from dimethyl decanedioate (analog) to 1,9-dimethyl nonanedioate (target). In the case of 1,9-dimethyl nonanedioate, the positive Ames result is traceable to a metabolite with antimicrobial activity. Whereas a negative mouse lymphoma study and a negative *in vivo* mouse micronucleus assay support the negative assessment of genotoxicity for the dimethyl decanedioate analog. **Conclusions:** The distribution of data across clusters indicates strong potential for applying read-across to support data-poor members, while recognizing that a case-by-case evaluation would still be required. *In silico* profiling reveals that even structurally close analogs within some second-tier clusters may exhibit divergent toxicological features, and such differences must be resolved to support any read-across rationale. The study provides insights into the data landscape for E&L. It is important to identify those chemical classes for which read-across could be applied, and where defaulting to threshold values would be appropriate.

S. An, and N. Liu. Wuxi Aptec (Suzhou) Co., Ltd., Jiangsu, China. Sponsor: R. Zhang

Background and Purpose: With the rapid advancement of the medical aesthetics industry, an increasing variety of aesthetic products are being widely utilized for skin beautification. However, this trend has also led to a rising incidence of adverse events, including skin necrosis, nodules, alopecia, and even life-threatening complications. Numerous studies have demonstrated that the injection of hyaluronic acid (HA) or similar products may result in tissue hypoxia or necrosis due to vascular compromise. To facilitate the safety evaluation of such aesthetic products, a study was conducted to establish an induced vascular occlusion model and assess both the potential risk of vascular embolism following a single arterial injection of HA and the efficacy of the recommended HA rescue protocol (HA-HYAL). **Methods:** Eight male rabbits were randomly assigned to 4 groups, with 4 rabbit ears in each group. During the Occlusion Phase: Groups 1-2: The single ear of each rabbit received a single injection of equal amounts of HA via the central ear artery. During the Rescue Phase: Groups 3-4: Rabbit auricular arteries were first occluded with HA and subsequently treated with hyalase, administered either intra-arterially (IA) or subcutaneously (SC). Hyalase was injected at the occlusion site 5 minutes after HA administration, based on observed blood flow interruption. For the SC rescue group, a second hyalase injection was performed 30 minutes after the initial HA injection to facilitate embolus dissolution. The formation of transparent emboli was monitored post-injection, and photographs of vascular embolism in the rabbit ear were taken at various time points under strong illumination. A 14-day observation period was conducted to evaluate vascular recanalization and tissue necrosis. The injection rate was controlled at approximately 0.2 mL/min. All animals were necropsied on Day 15, and gross lesion assessment and histopathological examination were performed. **Results:** **Occlusion Phase:** Immediately after HA injection, all treated rabbit ears exhibited transparent emboli, visible in both the main trunk and branches of the central ear artery. Partial recanalization of the central artery was observed in all HA-injected ears by Day 14. On Day 14, two out of four ears showed mild skin damage, while the remaining two demonstrated moderate to severe skin damage. Focal/multifocal to coalescing scabs (3/4 ears) and locally extensive dark red discoloration (4/4 ears) were noted, corresponding microscopically to crust formation, skin necrosis, and chronic/acute subcutaneous inflammation. Multiple emboli were detected in the vasculature at proximal, middle, and distal injection sites in all ears. In some arteries, the vessel wall was infiltrated by multinucleated giant cells and other inflammatory cells. The mean maximum diameter of embolus-containing vessels in the HA group was 704.54 μm . **Rescue Phase:** Immediately after HA injection, all treated rabbit ears exhibited transparent emboli in the central ear artery. Complete recanalization of the central artery was achieved by 24 hours in the HA/IA rescue group and by Day 7 in the HA/SC rescue group. By Day 14, both ears in each rescue group showed only mild skin damage. Focal/multifocal scabs (1/2 ears in each rescue group) and locally extensive dark red discoloration (2/2 ears in each rescue group) were observed, correlating microscopically with crust, skin necrosis, and chronic/acute subcutaneous inflammation. Multiple emboli were present in the vasculature at all injection sites. The mean maximum diameter of embolus-containing vessels in the rescue groups (512.18 μm) was markedly smaller than in the occlusion phase. In the occlusion phase, pathological findings indicated that HA induced multiple vascular emboli and tissue necrosis at the injection sites. **Conclusions:** This study demonstrates: 1 Successful establishment of a standardized vascular occlusion model. 2 Significant therapeutic efficacy of hyaluronidase rescue therapy. 3 Critical importance of early intervention in mitigating irreversible ischemic injury. 4 Validation of a translatable preclinical platform for evaluating vascular safety profiles of aesthetic products, featuring quantifiable occlusion parameters and clinically relevant rescue endpoints.

PS 4717 Immunogenicity and Toxicity of rAAV Gene Therapies in Non-human Primates in Preclinical Safety Evaluation

C. Wu, L. Zhang, and J. Ma. JOINN Laboratories, Suzhou, China.

Background and Purpose: Recombinant Adeno-associated virus (rAAV) is among the most widely used vectors for gene delivery, yet its clinical application is challenged by severe immune-mediated toxicities. This study aimed to define a core set of parameters for preclinical assessment of rAAV immunogenicity and toxicity. **Methods:** We conducted a pooled analysis of 16 non-human primate (NHP) toxicity studies over the past five years, evaluating a multidimensional dataset: pre-existing immunity, innate immunity (cytokines, complement), adaptive immunity (antibody/T-cell responses), clinical pathology, and histopathology of key organs. **Results:** A pooled analysis across the 16 studies included a total of 538 NHPs administered with rAAV via subretinal, intravitreal, intravenous, or intrathecal injection. By study count, ocular indication was the majority (68.75%), followed by central nervous system (12.5%), hemophilia (12.5%), and cardiac (6.25%) indications. The vectors of AAV2, 5, 8, and 9 were selected based on their distinct tissue tropism. Toxicity profiles were influenced by administration route and vector tropism. As anticipated, ocular delivery was associated with local inflammation, while systemic administration resulted in hepatotoxicity, consistent with the underlying biology of target tissues. To exclude animals with high pre-existing immunity, all studies implemented rigorous serological screening (87.5% used neutralizing antibody (NAb) assay with titer cut-off $\leq 1:4$ to 1:20 and 12.5% used binding antibody (BAB) assay with an OD value of <0.5). Anti-

AAV2 NAb was most prevalent (28.2%-87.4%), followed by AAV5 and AAV9 (~30%), and AAV8 (~5%). Innate immune activation is a recognized trigger of adverse events in clinical rAAV trials. To investigate this, we monitored early post-dosing biomarkers, including a broad panel of cytokines and complement factors, with sampling within the 24-hour window. Notably, across all studies evaluated, no significant innate immune activation was detected. Adaptive immune response is a pivotal determinant of the safety and efficacy profile. Humoral immunity was assessed by measuring serum and local neutralizing antibody against AAV capsid, as well as binding antibody against transgene product. Cellular immunity was evaluated via IFN- γ ELISpot in response to capsid or transgene product. In these studies, both humoral and cellular immune were evaluated prior to dosing, at 2 to 4 weeks post-dosing, and over prolonged periods (months). After dosing, high-titer serum NAb (1:256-1:8000) developed in 70%-100% of animals, while lower-frequency (20%-40%) and lower-titer (1:4-1:256) local NAb and infrequent anti-transgene antibody (10%-30%) were detected. Critically, cellular immune response was minimal, with positive IFN- γ ELISpot signals detected in only 2 of 13 studies. Clinical trials of rAAV products have reported hepatotoxicity, thrombotic microangiopathy and dorsal root ganglia toxicity. To evaluate these potential toxicities, key parameters were monitored, including liver enzymes (ALT, AST and GGT) and kidney function (UREA and Cre), histopathology of liver, kidney, and dorsal root ganglia. In the present review, most studies showed no evidence of treatment-related liver toxicity. An elevation of ALT without corresponding microscopic findings was observed in only one study, affecting 2 out of 10 animals. And hepatocellular vacuolation was noted in three studies from the same sponsor, but confirmed to be fatty granules via Oil Red O staining. It is noteworthy that the only study to report elevated ALT level was one of the two studies with a positive T-cell response, suggesting a potential association between cellular immunity and hepatocellular injury in that specific context. Kidney function, histopathology of kidney and dorsal root ganglia were normal across all studies. **Conclusions:** This analysis confirms immunogenicity as a critical safety concern for rAAV therapy. While robust anti-capsid antibody responses were prevalent, cellular immunity and transgene-specific responses were minimal. Observed toxicities were mild, including transient ALT elevation and steatosis. A comprehensive panel assessing humoral/cellular immunity, clinical pathology, and histopathology characterized these events, supporting its essential role in the preclinical risk assessment framework to ensure the safe progression of rAAV-based gene therapy.

PS 4718 Multiwalled Carbon Nanotubes Modulate Lipid Rafts Assembly and Hippo Signaling.

M. Thakur, and S. Batra. Southern University and A&M College, Baton Rouge, LA.

Background and Purpose: Multiwalled carbon nanotubes (MWCNTs) are widely used innovative nanomaterials with potential liver toxicity. This study explores how MWCNTs alter lipid rafts (cholesterol-rich membrane microdomains) that are critical for immune signaling and trigger inflammation and Hippo pathway, offering novel insights into nanotoxicology. **Methods:** Human lung epithelial (A549) cells and full-thickness airway microtissues (MatTek EpiAirwayFT) were exposed to 25 $\mu\text{g}/\text{ml}$ MWCNTs for 24 h to quantify cytokines and chemokines by ELISA, and transcription factors by qRT-PCR and immunoblotting. Isolated lipid raft fractions were characterized using immunoblotting, hybrid ELISA or immunofluorescence imaging. Electron microscopy was used to visualize morphological changes in A549 cells. Lipid rafts were modulated using docosahexaenoic acid (DHA), polyunsaturated fatty acids (PUFA), or caveolin-1 (CAV1) neutralization in our cellular study model. **Results:** MWCNTs increased IL-6, IL-8, CCL2, CCL5 at mRNA and/or protein levels and boosted inflammatory drivers (NF- κB , STAT3), but not receptors (TLR4 and RAGE) protein expression, suggesting post-transcriptional regulation in A549 cells and microtissues. Hippo signaling components (YAP/TAZ) were induced, linking to inflammation. MWCNTs altered CAV-1/2, but not flotillin 1/2 expression. Electron microscopy showed membrane distortion and needle-shaped MWCNT internalization. DHA (omega-3 PUFA) pretreatment abrogated raft markers, while general PUFA enrichment had no significant effect on our cellular model. CAV-1 neutralization altered inflammation and Hippo components. **Conclusions:** This study reveals MWCNTs disrupt lipid rafts driving inflammation and Hippo signaling, advancing mechanistic understanding of nanomaterial toxicity. It informs safer nanomaterial design and toxicology research. Future lipidomic study will map membrane changes to develop protective strategies.

PS 4719 Construction of an *in vitro* TDAR alternative model to mimic T-cell-dependent antibody response (TDAR) assay

K. Zhang^{1,2}, J. Chen^{1,2}, and L. Gong^{1,2,3}. ¹Nanjing University of Chinese Medicine, Nanjing, China; ²Shanghai Institute of Materia Medica, Chinese Academy of Sciences, Shanghai, China; and ³Zhongshan Institute for Drug Discovery, Shanghai Institute of Materia Medica, Chinese Academy of Sciences, Zhongshan, China.

Background and Purpose: T-cell-dependent antibody response (TDAR) assay is a gold standard for assessing the effects of chemicals on adaptive humoral immunity, which usually employed to evaluate immunotoxicity of chemical substances and efficacy of immune adjuvants. However, the classic TDAR is conducted on animal models, which have limitations such as time-consuming (at least 4 weeks) and differ-

ent immune responses between humans and animals. Therefore, it is necessary to develop *in vitro* alternative models. **Methods:** Human peripheral blood mononuclear cells (PBMCs) from healthy donors were stimulated with candidates for 10 consecutive days in an environment containing antigens (Keyhole Limpet Hemocyanin, KLH, 20 µg/mL), IL-2 (100 U/mL), and Staphylococcal protein A (SPA, 10 µg/mL), then the KLH-specific IgM/IgG in the supernatants were measured by ELISA. **Results:** We observed PBMCs stimulated with KLH, IL-2, and SPA were able to produce KLH-specific IgM/IgG antibodies, demonstrating the detectability and sensitivity of the *in vitro* TDAR platform. Furthermore, after adding resiquimod (R848) and the candidate (LG01) in this system, we observed a significant increase in the secretion of anti-KLH IgM/IgG antibodies compared to the KLH-only stimulated group. **Conclusions:** The TDAR alternative model was successfully constructed *in vitro* based on PBMCs, which can be applied to high-throughput adjuvants screening and provide more accurate risk assessments of immunotoxicity.

PS 4720 The effects of direct addition of lead(ii) acetate to a human *in vitro* model of hematopoiesis recapitulates exposure to lead *in utero*

K. N. Cross¹, J. W. Zagorski¹, N. E. Kaminski¹, A. Goodyke², E. Siegwald², and M. Cordoba Munoz². ¹Michigan State University, East Lansing, MI; and ²Corewell Health, Grand Rapids, MI.

Background and Purpose: Exposure to heavy metals during pregnancy and early immune development is a significant public health concern. Lead, a known developmental immunotoxicant capable of crossing the placental barrier, remains a persistent environmental threat. Michigan's aging infrastructure has contributed to notable disparities in exposure; although Flint drew national attention, Kent County (Grand Rapids, MI) reports the highest childhood lead levels in the state. While prenatal lead exposure has been linked to adverse outcomes, its impact on the developing human immune system remains poorly characterized. Traditional rodent-based immunotoxicity models often fail to fully recapitulate human immune development, underscoring the need for more human-relevant approaches as regulatory agencies adopt new approach methodologies (NAMs). To address this, we applied a human *in vitro* NAM that differentiates CD34⁺ hematopoietic stem cells toward myeloid and lymphoid lineages to assess the effects of lead on immune cell lineage commitment and compared these results with *ex vivo* umbilical cord PBMCs with documented *in utero* exposure. Together, this approach evaluates developmental immunotoxicity in a human-relevant system and benchmarks outcomes against real-world exposure. **Methods:** **Cell culture:** Human CD34⁺ hematopoietic stem cells isolated from umbilical cord blood were cultured for 28 days in complete RPMI containing human serum and antibiotics. Cells were seeded at 5 × 10⁴ cells/mL and exposed to vehicle or lead (ii) acetate (31.25-250 nM) on days 0, 7, 14, and 21. Hematopoietic differentiation was supported by SCF, FLT3L, and IL-6 supplementation on day 0, followed by SCF, FLT3L, and IL-7 on day 7. Half-media changes were performed on days 14 and 21 using cytokine-free media. **Flow cytometry:** Cells were collected on days 0, 7, 14, 21, and 28 to assess viability and lineage-specific differentiation. Samples were stained with a viability dye, surface markers identifying myeloid and B-cell subsets, and intracellular CD79a. After fixation and permeabilization, samples were analyzed on a Cytex Northern Lights cytometer. Compensation was performed using single-stain controls, and consistent gating strategies were applied across time points in FlowJo to quantify changes in developing immune cell populations. **Results:** Lead exposure during hematopoietic differentiation significantly altered human immune lineage development in a cell type specific manner. *In vitro* treatment of CD34⁺ cord-blood-derived stem cells with increasing concentrations of lead (ii) acetate over 28 days revealed dynamic effects on myeloid populations: CD14⁺CD1c⁺ monocytes were transiently suppressed at early time points, CD14⁺CD66b⁺ granulocytes were consistently reduced, CD206⁺ macrophages trended upward, and CD1c⁺ dendritic cells remained unaffected. Lymphoid lineage analysis demonstrated a potentiation in the development of B-cell precursors, with a significant increase in the pre-B cell marker CD79a at day 21 and trends toward elevated CD10⁺ and CD19⁺ cells. These *in vitro* findings were validated in a clinical cohort, where umbilical cord blood from infants with documented *in utero* lead exposure demonstrated reduced circulating monocytes and a significant enrichment of CD10⁺CD79a⁺ early pre-B cells, while total B-cell precursors were unchanged. Together, these results indicate the utilization of a human-based model of hematopoiesis recapitulates the effects of *in utero* lead exposure on the developing immune system. **Conclusions:** Traditionally, developmental immunotoxicology has relied on animal models due to limited access to human samples and a lack of suitable *in vitro* systems. Here, we demonstrate that a human umbilical cord blood-derived CD34⁺ stem cell assay can model hematopoiesis over four weeks and generate nearly all immune cell types. Lead exposure during differentiation selectively suppressed myeloid populations while promoting B-cell lineage commitment, particularly CD79a⁺ pre-B cells. In summary, our *in vitro* findings were confirmed in umbilical cord blood from infants with documented *in utero* lead exposure, demonstrating reduced circulating monocytes and increased early pre-B cells. (This work was funded by the Michigan State University Corewell Health Alliance Grant).

PS 4721 Δ⁹-tetrahydrocannabinol (THC) and cannabidiol (CBD) attenuate CD16⁺ monocyte-induced inflammatory responses by astrocytes in a primary human co-culture system

S. Sermet^{1,2}, R. Crawford^{1,3}, and N. E. Kaminski^{1,2,3}. ¹Michigan State University, East Lansing, MI; ²Department of Pharmacology and Toxicology, East Lansing, MI; and ³Institute for Integrative Toxicology, East Lansing, MI.

Background and Purpose: CD16⁺ monocytes represent a minor subset of the total monocyte population (~15%) yet play a disproportionate role in driving neuroinflammation related to human immunodeficiency virus (HIV)- associated neurocognitive disorders (HAND), largely due to their enhanced transmigration across the blood-brain barrier. CD16⁺ monocytes can be activated by HIV ssRNAs via toll-like receptor (TLR) 7 and subsequently interact with brain-resident cells, including astrocytes. Interactions between CD16⁺ monocytes and astrocytes can amplify inflammatory signaling in the brain. Previous work from our laboratory has identified monocyte-derived IL-1β as a driving factor for astrocyte production of neuroinflammatory factors. Despite cannabis use among the HIV community, the mechanisms by which known immune-modulating cannabinoids, Δ⁹-tetrahydrocannabinol (THC) and cannabidiol (CBD), affect human immune responses remain elusive. The objective of this study was to determine how THC and CBD influence virally activated CD16⁺ monocyte-driven astrocyte cytokine production, and monocyte chemotaxis in HIV- and HIV+ subjects. **Methods:** For this study, we employed a primary human CD16⁺ monocyte-astrocyte co-culture system. Co-cultures were stimulated with the TLR7 agonist R837 and treated with increasing concentrations of THC or CBD (0.5, 1, 5, 10 µM). Supernatants were quantified for soluble IL-6, MCP-1, IL-8, and IL-1β by ELISA. To further assess functional outcomes, an image-based chemotaxis assay was performed to evaluate how cannabinoid pre-treatments influence HIV- and HIV-monocyte migration towards conditioned media from recombinant IL-1β-treated astrocytes. In addition, flow cytometry was used to determine how THC and CBD modulate the expression of f-actin, open conformation LFA-1, and open conformation MAC-1, key proteins involved in monocyte chemotaxis. **Results:** Production of inflammatory mediators, IL-6, MCP-1, and IL-8 in CD16⁺ monocyte-astrocyte co-cultures were suppressed by THC and CBD in a concentration-dependent manner. Furthermore, THC and CBD reduced IL-1β secretion by CD16⁺ monocytes, providing a putative explanation for the suppression of inflammatory mediator production in co-cultures. Additionally, monocytes from HIV+ subjects exhibited enhanced migration compared to monocytes from HIV- subjects, which was suppressed only by THC treatment and not by CBD. This effect was associated with reduced expression of F-actin, open conformation LFA-1, and open conformation MAC-1. **Conclusions:** THC and CBD attenuate CD16⁺ monocyte-driven astrocyte production of neuroinflammatory mediators. In addition, monocytes isolated from HIV+ subjects exhibit enhanced chemotaxis compared to those from HIV- subjects, an effect that is selectively suppressed by THC. Collectively, these findings suggest that THC and, to a lesser extent, CBD may have therapeutic potential for mitigating inflammation associated with neuroinflammatory conditions involving CD16⁺ monocytes. (Supported in part by NIH R01 DA047180 and NIH R01 DA053047).

PS 4722 Glucocorticoid drugs suppress neutrophil control of the opportunistic pathogen *Aspergillus fumigatus*

S. U. Thrikawala¹, and E. E. Rosowski². ¹Eastern Washington University, Cheney, WA; and ²Clemson University, Clemson, SC. Sponsor: M. Bondesson

Background and Purpose: Even in the absence of an allergic reaction, pharmaceuticals can elicit adverse immune effects in patients undergoing drug therapy. A prime example of that is glucocorticoid-mediated increase of infection susceptibility. Patients undergo prolonged glucocorticoid therapy after bone marrow or organ transplant surgery to prevent rejection. This immunosuppression increases patient susceptibility to opportunistic pathogens. In healthy individuals, innate immunity consisting primarily of macrophages and neutrophils, is sufficient to prevent opportunistic pathogens causing disease. Glucocorticoids suppress this frontline defense increasing patient susceptibility to opportunistic infections. However, the innate immune mechanisms altered by glucocorticoid exposure causing this adverse effect are not fully understood. **Methods:** To investigate this question, we used a zebrafish larva infection model to visualize how glucocorticoids alter host immune cell-pathogen interactions in a live organism. We injected spores of *Aspergillus fumigatus*, one of the most common fungal pathogens infecting glucocorticoid-treated patients, into the hindbrain ventricle of zebrafish larvae. Immediately after infection, larvae were exposed to a common glucocorticoid drug, dexamethasone. We used high-resolution live imaging to visualize the effects of glucocorticoids on macrophage and neutrophil control of *A. fumigatus* pathogenesis. **Results:** Using this zebrafish larva-*A. fumigatus* infection model, we have previously shown that dexamethasone primarily affects neutrophils by suppressing the pro-inflammatory transcription factor NF-κB. We find that neutrophils fail to control invasive growth of *A. fumigatus* extracellular hyphae when larvae are exposed to dexamethasone as compared to vehicle control. We therefore hypothesized that neutrophil extracellular killing mechanisms that target *A. fumigatus* hyphae are inhibited by dexamethasone exposure. We first tested if neutrophils release granules around *A. fumigatus* hyphae. Through live imaging in combination with Sudan Black B staining of fixed larvae, we find extracellular granular material at the site of hyphal growth. However, dexamethasone treatment of larvae does not significantly inhibit neutrophil degranulation. In

addition to granular content, neutrophils also release nuclear content to form neutrophil extracellular traps (NETs). To visualize extracellular nuclear material in a live organism, we used zebrafish larvae expressing histone H2B tagged with a fluorescent marker in neutrophils, that also express a different fluorescent marker that localizes to the neutrophil cytoplasm. Through confocal fluorescence microscopy of these larvae, we find that extracellular H2B puncta are able to trap and break *A. fumigatus* hyphae. We are currently investigating if dexamethasone treatment of larvae inhibits this process. Thirdly, we tested if neutrophil production of reactive oxygen species (ROS) promotes control of hyphae and is affected by dexamethasone treatment. To test the significance of neutrophil ROS production in *A. fumigatus* pathogenesis, we used CRISPR/Cas9 to target the p22 subunit of the ROS-producing Nox2 complex. Larvae injected with Cas9 and guide RNAs targeting the p22 gene *cyba* succumb to the infection at a similar rate to larvae injected with control gRNAs. This suggests that neutrophil ROS does not play a major protective role against *A. fumigatus* and staining for ROS production with H2DCFDA dye demonstrates that dexamethasone treatment does not affect ROS production by neutrophils in response to *A. fumigatus*. **Conclusions:** Overall, it is still unclear how dexamethasone suppresses neutrophil ability to control *A. fumigatus*. However, we have optimized the techniques to visualize that *in vivo*, neutrophils degranulate, generate extracellular nuclear material, and produce ROS against the fungal pathogen *A. fumigatus*, which can be used to test the effects of other pharmaceutical immunosuppressants and neutrophil defense against other opportunistic pathogens.

PS 4723 Development of an *in vitro* human T-cell activation assay to evaluate the potential hypersensitivity to small molecule drug candidates

M. O. Ogese, B. Bhatt, B. Vega, A. Varone, J. J. Monroe, M. A. Oropallo, and R. J. Gonzalez. Department of Investigative Toxicology, Nonclinical Drug Safety, Merck & Co., Inc., Rahway, NJ.

Background and Purpose: Immune-mediated drug hypersensitivity reactions (iDHRs) can be life-threatening, but their idiosyncratic nature and inadequate mechanistic understanding make them challenging to derisk during pre-clinical drug development. Significant gaps exist with respect to the immunoregulatory mechanisms and susceptibility factors that predispose specific individuals to iDHRs and uncovering this information could help prevent these adverse events. **Methods:** To better understand the role of immune cell stimulation in the development of DHRs, we established a dendritic cell/T-cell priming assay using immune cells isolated from four HLA-typed human donors. Immune cells were treated with the allergenic protein reactive metabolite of p-Phenylenediamine (Bandrowski's Base (BB)). We additionally sought to characterize T-cell subsets that may play a critical role in the development of DHRs. Autologous CD14⁺ monocyte-derived dendritic cells were cultured with naïve T-cells (CD3+CD45RA+CD45RO-CD197+) and BB (10 μ M) for 2 weeks. On day 15, cells were restimulated with BB (0-20 μ M) for 48 hours and T-cell activation was assessed by evaluating proliferation (CFSE), activation markers (CD25, CD69 and CD71) and immunoregulatory markers (FoxP3 and CTLA4) via flow cytometry. **Results:** Our results demonstrated that naïve T-cells primed with BB showed significant expansion of a drug-specific CD4⁺ T-cell population expressing CD25, CD69, CD71 and CTLA-4, alongside the secretion of IL-4. In addition, a substantial decrease in non-BB-specific CD8⁺ T-cells was observed. Primed T-cells from all donors proliferated and displayed a concentration-dependent increase in the expression of CD25, CD69, CD71 and CTLA-4. Also, the stimulation of BB-specific T-cells occurred in a time-dependent manner. The optimum T-cell proliferation and activation was observed when primed cells were restimulated for 24-48 hours. Furthermore, priming induced significant expansion of CD4⁺CD25⁺FoxP3⁺CTLA4⁺ Treg population. **Conclusions:** This study identifies potential immuno-biomarkers of drug-specific T-cell activation and provides mechanistic insights into the role of various T-cell subsets involved in DHRs. Investigations are ongoing to characterize the nature of BB antigenic determinants responsible for T-cell activation and to delineate BB-induced changes in T-cell gene expression. In addition, experiments to test an expanded list of commercial drugs implicated in clinical drug hypersensitivity have been planned. Finally, integrating the various endpoints from this study will be vital for the development of *in vitro* and *in silico* human predictive models important for drug hypersensitivity risk assessment during preclinical drug development.

PS 4724 Investigating Potential Immunotoxicity of Understudied PFAS Found In North Carolina Waters (perfluoro-3,5,7,9-butaaxadecanoic acid; perfluoro-3,6,-dioxo-4-methyl-7-octensulfonic acid; 2-[difluoro(trifluoromethoxy)methoxy]-2,2-difluoroacetic acid)

M. Carroll¹, T. Woodlief², A. Ahmed², and J. DeWitt¹. ¹Oregon State University, Corvallis, OR; and ²East Carolina University, Greenville, NC.

Background and Purpose: Per- and polyfluoroalkyl substances (PFAS) are a large class of nearly 15,000 synthetic compounds with myriad applications across industry and consumer goods, of which many members are understudied. Perfluorooctanoic acid and perfluorooctane sulfonic acid, two well studied members of the PFAS class, are classified as presumed immune hazards to humans. This raises the

question of the ability of other PFAS to induce immunotoxicity, especially those that are under-examined and thus toxicologically data poor. PFAS are widespread and many of the understudied PFAS are in water sources (drinking, surface, and ground waters) across the country. North Carolina, in particular, has extensive PFAS water contamination. Three compounds found in North Carolina waters are perfluoro-3,5,7,9-butaaxadecanoic acid (PFO4DANA; CAS 1035377-21-9), perfluoro-3,6,-dioxo-4-methyl-7-octensulfonic acid (Nafion byproduct 1; CAS 29311-67-9), and 2-[difluoro(trifluoromethoxy)methoxy]-2,2-difluoroacetic acid (PFO2HxA; CAS 39492-88-1). These three compounds, despite being found in North Carolina waters, have only been studied minimally for their toxicity. **Methods:** Based on previous work from our laboratory, which indicated exposure to individual PFAS can induce effects on the immune system, three immunotoxicity studies were conducted, one for each compound. In each study, adult male and female C57BL/6 mice (6-8 weeks old) were exposed by gavage once/day for 30 days with their respective compound at 0, 0.05, 0.5, or 5 mg/kg. Five days before study terminus, mice were injected with sheep red blood cells (SRBC) to induce T-cell dependent antibody responses (TDAR). Spleens were collected one day after exposure ended and immunophenotyping and evaluation of various markers for B cell maturation and differentiation were conducted through flow cytometry. **Results:** Analysis of B cells for PFO4DANA demonstrated statistical differences in plasmablast and marginal B cell numbers in females between controls (0 mg/kg PFO4DANA) and the 0.5 mg/kg PFO4DANA dose group, and between controls and the 5 mg/kg PFO4DANA dose group. There were also statistical differences in plasmablast, follicular, and memory B cell numbers by sex. The TDAR for PFO4DANA did not vary statistically by dose, however there were statistical differences by sex. Analysis of B cells for Nafion byproduct 1 (NBP1) revealed statistical differences in naïve, follicular, and memory B cell numbers in males between controls (0 mg/kg NBP1) and the 0.05 mg/kg NBP1 dose group. The TDAR did not vary statistically by dose, however there were statistical differences by sex. Analysis of B cells for PFO2HxA demonstrated statistical differences in marginal B cell numbers in females between controls (0 mg/kg PFO2HxA) and all other dose groups (0.05, 0.5, and 5 mg/kg PFO2HxA). There were also statistical differences in memory B cell numbers in females between controls and all other dose groups. The TDAR for PFO2HxA varied statistically by dose, between controls (0 mg/kg PFO2HxA) and the 0.05 mg/kg PFO2HxA dose group in females, and there were also statistical differences by sex. **Conclusions:** These PFAS, chosen for their lack of toxicological data and relevance to the people of North Carolina, showcased shifts in important subpopulations of B cells. Despite that these shifts did not always lead to changes in the TDAR by dose, it is still important to understand potential implications of altered B cell subsets. These three compounds are merely a snapshot of novel PFAS found in North Carolina waters and other water sources, globally. Further investigation is needed to understand potential immunological health risks, to investigate other understudied PFAS, and to confirm these findings.

PS 4725 Effects of indium tin oxide nanoparticles on human T helper cells: mitochondrial dysfunction and suppression of cytokine gene expressions

Y. Nishimura¹, N. Maruo², M. Eitoku², K. Kobiro³, A. Kamezaki¹, T. Ito¹, and N. Suganuma². ¹Kawasaki Medical School, Kurashiki, Japan; ²Kochi Medical School, Kochi, Japan; and ³Kochi University of Technology, Kochi, Japan.

Background and Purpose: Indium is a rare metal with high electrical conductivity, which has led to its widespread industrial use. Especially, indium tin oxide (ITO) is used in flat panel displays and solar power generation systems, and its global market is expected to continue expanding, which is making its toxicity of concern. Inhalation exposure to ITO causes pulmonary fibrosis similar to other mineral particles, but is accompanied by characteristic pathologies such as emphysematous lesions and pulmonary alveolar proteinosis (PAP). ITO accumulates in draining lymph nodes as well as in the lungs, but the effects of ITO exposure on lymphocyte function have not received much attention ever. In particular, the effect on CD4⁺ T helper cell function may be involved in ITO toxicity through the homeostatic machinery of lung function with alveolar macrophages. The human CD4⁺ T cell line MT-2 is a useful tool to build an *in vitro* model for immunotoxicological study, by which we previously unveiled much knowledge. Therefore, we performed experiments with MT-2 cells to examine the uptake of ITO nanoparticles into intracellular vesicles and their effects on mitochondrial function and cytokine production. **Methods:** The two types of ITO nanoparticles (Sigma ITO-S, specific surface area A = 33.86 m²g⁻¹ or Thermo ITO-T, A = 2.96 m²g⁻¹) were used. MT-2 cells were cultured for two or three days under exposure to ITO-S, ITO-T or titanium dioxide (TiO₂, A = 47.56 m²g⁻¹). Cell viability after culture was quantified colorimetrically using WST-1 reagent. Total RNA was extracted from the cells recovered after culture, and relative mRNA levels of the genes were quantified by RT-qPCR using the SYBR Green method. After culture, cells were stained with the fluorescent reagent JC-1 to examine changes in mitochondrial membrane potential ($\Delta\psi$ m). Furthermore, SEM-EDX and TEM were used to examine the uptake of ITO particles and abnormalities in mitochondrial morphology. In addition, PMA-induced THP-1 macrophages were cultured with several cytokines produced by Th cells and then analyzed for expression of lipid metabolism genes. **Results:** In MT-2 cells cultured for three days, ITO-S exposure clearly reduced cell viability, with significantly lower levels at concentrations of over 50 and 100 μ g/ml compared to ITO-T and TiO₂ respectively, and then the dose of 100 μ g/ml were used for the subsequent experiments. While no significant differences were observed in mRNA levels of the ER stress response or the autophagy-related genes, ITO-S exposure significantly

increased mRNA levels of several proteostasis genes as well as p-eIF2 α cells an indicator of translational arrest. SEM-EDX confirmed ITO uptake into intracellular vesicles. TEM images revealed abnormal mitochondrial morphology in ITO-S and TiO₂-exposed groups, with numerous cristae with aberrantly enlarged intermembrane spaces, that's more marked in the ITO-S group. Furthermore, when $\Delta\psi_m$ were examined using JC-1 staining, low $\Delta\psi_m$ cells (%) significantly increased only in the ITO-S exposure group, meaning mitochondrial damage. These findings suggested possible dysfunction in energy-driven cytokine production. When the cells isolated from culture with ITO-S were stimulated with PMA and ionomycin, they showed significant decreases in IL-4, IL-13, IFN- γ and TNF- α mRNAs, where that in IL-4 was remarkable, while no changes in IL-10 and TGF- β 1. Moreover, the addition with IL-4 induced increases in PPARY, FABP4 and LIPA mRNAs in the culture of THP-1 macrophages, indicating increase in lipid metabolism. **Conclusions:** These results indicate that 1) ITO nanoparticles are internalized in vesicles by human T helper cells, 2) they interfere with intracellular proteostasis and cause mitochondrial dysfunction and 3) ITO-exposed Th cells show dysfunction in stimulation-induced expression of cytokine genes, in particular IL-4, which functions in lipid metabolism of macrophages. The mitochondrial dysfunction might contribute to impairment in expression of cytokine genes after activation. In addition, it is known that impaired lipid metabolism of alveolar macrophages causes PAP. These findings suggest immunotoxic effects of ITO exposure on Th cell function via mitochondrial dysfunction, which might be a link between ITO exposure and the related disease.

PS 4726 Preclinical De-Risking of Cell Therapy Products

B. Quist¹, H. Leonard², L. Francois¹, M. Hazenoot¹, M. Hiller¹, R. Shea³, L. Schewitz-Bowers², D. Rocca², L. Nunan², L. Brackenbury², M. Aspinall O'Dea³, R. Redis¹, S. de Munnik¹, G. Moiset¹, and P. I. Rac². ¹Charles River Laboratories, Leiden, Netherlands; ²Charles River Laboratories, Portishead, United Kingdom; and ³Charles River Laboratories, High Peak, United Kingdom.

Background and Purpose: Engineered T cell therapies such as Chimeric Antigen Receptor (CAR) T cells have emerged as promising therapies but also suffer from severe safety risks. One major concern is that (low) target antigen expression in healthy cells or non-specific antigen recognition could potentially result in off-disease toxicities. Another safety concern is that the random integration of the CAR-encoded DNA cassettes in the host genome can potentially cause insertional mutagenesis and may contribute to oncogenic transformation of the T-cells. The lack of pharmacologically relevant animal models emphasizes the need to evaluate the safety of CAR-T cell therapy products *in vitro*. **Methods:** The human epidermal growth factor receptor 2 (HER2) is a well-established therapeutic target for various cancer types. To explore potential off-disease effects of HER2-targeting CAR-T cells, the Retrogenix™ cell microarray screening technology was used to assess off target binding against a panel of >6500 proteins. In addition, HER2 CAR-T cells were co-cultured with primary or iPSC-derived cells to evaluate any unwanted cytotoxicity against healthy cells. To de-risk the CAR-T cells for potential insertional mutagenesis after stably introducing the CAR cassette, HER2 CAR-T cells were assessed for their potential uncontrolled and cytokine-independent growth, and the CAR vector copy number (VCN) was determined by droplet digital PCR (ddPCR). Finally, lipid nanoparticles (LNP) were explored as an alternative and non-integrating delivery method for the generation of mRNA-encoding CAR-T cells. **Results:** Although the Retrogenix™ screen only identified on-target and CAR-independent interactions and no off-target binding, HER2 CAR-T cells showed activation and cytotoxicity towards several primary cell types, most likely due to on-target off-disease effects. A clear decrease in viability and cell numbers was observed when HER2 CAR-T cells were cultured in the absence of cytokines and these results are further supported by the relatively low VCN of 3 (a VCN of less than 5 is recommended to minimize the risk of oncogenesis), indicating low risk of CAR-T cell transformation under the conditions tested. Finally, LNP mRNA CAR-T cells showed HER2 CAR expression in the majority of T cells and cytotoxicity towards a HER2-expressing tumor cell line. **Conclusions:** In conclusion, HER2 CAR-T cells were evaluated using several *in vitro* safety assays. Although no off-targets were identified and no cytokine-independent growth was observed, the HER2 CAR-T cells showed cytotoxicity towards several tested primary cell types, highlighting the importance of evaluating the safety of CAR T-cell therapies and de-risking them early in their development. Furthermore, functional efficacy studies show a huge potential for LNP-mRNA as a non-viral and non-integrating delivery method for CAR-T cell generation, shaping the future of the cell therapy landscape.

PS 4727 Characterizing Effects of Non-Toxic Aryl Hydrocarbon Receptor (AHR) Ligands on IgG1 antibody production in Human Peripheral Blood Mononuclear Cells

A. Deb, A. Venugopalan, and B. Kaplan. Mississippi State University, Mississippi State, MS.

Background and Purpose: Multiple sclerosis (MS) is an autoimmune disorder characterized by the demyelination of neurons in the central nervous system, which is due in part to pathogenic antibodies such as IgGs. Previous epidemiological studies have reported decreased serum IgG1 levels in individuals exposed to the aryl hydrocarbon receptor (AHR) ligand 2,3,7,8-tetrachlorodibenzo-p-dioxin (TCDD). Consistent

with this, our lab found that TCDD suppressed IgG1 production in the experimental autoimmune encephalomyelitis (EAE) mouse model of MS. To determine the potential for non-toxic AHR ligands to suppress antibody production in humans and eventually MS, our objective was to examine effects on IgG1 production in human peripheral blood mononuclear cells (PBMCs). **Methods:** PBMCs were isolated from leukopaks obtained from 24 healthy donors using Histopaque 1077 density gradient centrifugation. Cells were pretreated overnight with vehicle (0.01% DMSO) or AHR ligands; TCDD (30 nM), ITE (1 μ M), FICZ (0.1 μ M), or I3C (2 μ M). After overnight treatment, cells were then stimulated with pokeweed mitogen (PWM, 5 μ g/mL) to induce IgG1 production. Cells were incubated for 2 days or 5 days following PWM treatment. Cells after 2-day stimulation were used for *IL6* and *IL1B* gene analysis via RT-PCR and RNA sequencing. Supernatants after 5-day stimulation were analyzed for IgG1 antibody production. **Results:** Our PCR results revealed that PWM significantly upregulated the expression of proinflammatory cytokine genes *IL6* and *IL1B* at day 3. Our ELISA results demonstrated that PWM induced the human PBMC to produce IgG1 after 6 days. IgG1 antibody production was modestly suppressed by pretreatment with AHR ligands, with I3C showing the most consistent inhibitory effect across most of the donors. Transcriptomic analysis revealed a greater number of downregulated genes relative to upregulated ones following I3C exposure. KEGG pathway analysis identified several signaling pathways including oxidative phosphorylation, T cell receptor signaling, Th17 cell differentiation, PI3K-Akt signaling, MAPK signaling, and NF-kappa B signaling, that were suppressed with I3C treatment in PWM-stimulated PBMC, many of which also contribute to the pathogenesis of MS. **Conclusions:** These findings demonstrate that AHR activation, particularly by I3C, suppressed human IgG1 antibody production and downregulated multiple proinflammatory signaling pathways in PBMCs. This study will help us address the gaps in our understanding of the mechanistic pathways involved in immune suppression by AHR ligands in human cells and their possible use for MS treatment.

PS 4728 Investigating how per- and polyfluoroalkyl substances (PFAS) affect neutrophil function

V. E. Resh, and J. A. Yoder. North Carolina State University, Raleigh, NC.

Background and Purpose: The term per- and polyfluoroalkyl substances (PFAS) denotes a collection of highly stable, synthetic chemicals used in consumer products such as nonstick cookware, food packaging, stain repellent materials, and fire fighting foams. Their resistance to most forms of degradation has allowed them to become nearly omnipresent, posing a threat to environmental and human health. Concerningly, exposure to select PFAS has been shown to impair the immune system, cause developmental delays, increase the risk of cancer, dysregulate hormonal balance, and induce disorders of the liver, kidney, and thyroid in humans. Despite these observations, our knowledge of the health risks posed by PFAS remains lacking due to a limited understanding of how different PFAS alter the cellular functions that culminate in the aforementioned outcomes, as well as the sheer number of PFAS that still require testing. Previous work has shown that certain PFAS suppress the ability of neutrophils to release antimicrobial stores of reactive oxygen species in a process known as the respiratory burst. This work aims to better isolate this interaction and understand how these chemicals may be interfering with neutrophil biology. **Methods:** Neutrophil-like HL-60 cells were stimulated with phorbol myristate acetate (PMA) and a measure of reactive oxygen species (ROS) with dihydrorhodamine (DHR) is used as a proxy of respiratory burst output. To limit excessive sequestration of PFAS by serum albumin, cells underwent a serum-free pulse (SFP) for the first hour in which cells were exposed to PFAS. Cells were exposed to perfluorohexanoic acid (PFHxA) or hexafluoropropylene oxide dimer acid (HFPO-DA or GenX). **Results:** Initial experiments demonstrate a significant reduction in ROS production in the SFP group compared to the control. Importantly, these findings do not correlate with any significant changes in cell viability. **Conclusions:** These results will inform future experimental methodologies designed to uncover the molecular mechanism by which PFAS suppress neutrophil function, and ultimately bridge existing knowledge gaps concerning PFAS exposure and immune function.

PS 4729 Development of rat immunogenicity assays to evaluate the immunostimulatory potential of peptides prior to nonclinical safety studies

B. A. Vega, B. Bhatt, N. Li, M. A. Oropallo, and R. J. Gonzalez. Merck & Co., Inc., West Point, PA.

Background and Purpose: Biologics and peptide therapeutics offer enhanced target selectivity over other modalities (ie, small molecules); however, immunogenicity of these therapeutics can present an obstacle to their development. Human-based therapeutics are often highly immunogenic in nonclinical animals, and can have a significant impact on pharmacodynamics, pharmacokinetics, toxicity profiles, and ultimately study interpretation. Screening assays to predict immunogenicity of human-based therapeutics in rats are currently unavailable, and thus impacts to program development may not be known until completion of repeat-dose toxicity studies. To improve screening for immunogenicity risk in rats, we aimed to develop an *in vitro* assay analogous to those established for predicting human immunogenicity. **Methods:** Splenocytes from naive rats were harvested and cultured with test

articles for 7 days, and immune stimulation was evaluated via interferon- γ (IFN γ) fluorospot. **Results:** Our results demonstrate that the assay was sensitive to pan-T cell activating agents Concanavalin A (ConA) and Phorbol 12-Myristate 13-Acetate (PMA) and showed positive correlation to *in vivo* observations of immunogenicity when tested with keyhole limpet hemocyanin (KLH) or 3 internal Merck compounds. **Conclusions:** The assay demonstrated limited sensitivity, reducing its ability to reliably predict *in vivo* immunogenicity outcomes. Further work is ongoing to enhance the assay sensitivity and explore additional endpoints including T cell proliferation, immunophenotyping, serum biomarkers, and transcriptional signatures of immune stimulation.

PS 4730 Antimicrobial cetylpyridinium chloride suppresses mast cell degranulation and cytokine production by targeting tyrosine phosphorylation of Syk kinase and key substrates Linker for Activation of T-Cells (LAT) and Vav1

M. K. Lorenger, B. Obeng, E. R. Morrison, D. J. Wagner, E. Ledue, and J. A. Gosse. University of Maine, Orono, ME.

Background and Purpose: Cetylpyridinium chloride (CPC) is a quaternary ammonium antimicrobial used in numerous personal care products, human food, cosmetic products, and cleaning solutions. Mast cells (MC) are ubiquitous in the human body and play many roles in the immune and nervous systems. Previously we showed that exposure-relevant, non-cytotoxic doses of CPC inhibit key MC functions, both degranulation (in both rat and human MCs), by inhibiting antigen (Ag)-stimulated Ca²⁺ mobilization and thus microtubule polymerization. With the goal of determining the underlying biochemical mechanisms, we hypothesized that CPC shuts down Ca²⁺ signaling by affecting specific phospho-tyrosines on key early signaling kinases via electrostatic disruption. We also predict that CPC's shut down of the activation of the critical transcription factor Nuclear Factor of Activated T-cells (NFAT) and specific players within the MAPK pathway leads to loss of TNF- α production. **Methods:** Using biochemical techniques such as western blotting and RT-qPCR, as well as confocal microscopy, we demonstrate how CPC affects these specific proteins. **Results:** Here we show that CPC inhibits tyrosine phosphorylation of the specific key players Syk kinase and its substrates Vav1 and LAT, though not all tyrosine-phosphorylated proteins, such as Gab2, are affected by CPC. We also show that CPC inhibits the MC function of cytokine production, specifically the key inflammatory cytokine TNF- α . **Conclusions:** Our findings reveal the mechanisms of action of this ubiquitous chemical, with relevance to human health, and predictions of CPC effects on related cell types like T-cells which share signaling machinery with MC. Work is underway to examine whether CPC directly targets the key activation residues, Y519/520, within Syk kinase. We also are currently investigating the path by which CPC's inhibition of LAT and Vav1 links to its dampening of TNF- α expression, with a focus on NFAT translocation to the nucleus and the MAPK pathway.

PS 4731 Effects of arsenic, cadmium, and lead on macrophage cytokine production

L. Y. Middleton, M. R. Rea, A. Tapaswi, J. Gbadegoye, E. Shah, S. M. Harris, and J. A. Colacino. University of Michigan, Ann Arbor, MI.

Background and Purpose: Arsenic, cadmium, and lead are common exposures with immunotoxic effects. Cytokine signaling plays a key role in the tumor microenvironment where it promotes cancer cell death or alternatively, progression and metastasis of the tumor. For example, IL-1 β is a pro-inflammatory cytokine that can regulate both pro- and anti-tumor effects. IL-4 promotes breast cancer cell proliferation. IL-8 attracts other immune cells to sites of tissue damage and promotes angiogenesis. CCL-2 and CXCL-1 both promote breast cancer metastasis, while CXCL-2 also plays a role in the epithelial to mesenchymal transition. MMP-1 is elevated in multiple tumors, is correlated with metastasis, and is necessary for macrophage infiltration. All three heavy metals/metalloids are known to dysregulate cytokine production, but their effects at low doses relevant to human population exposures have not been systematically characterized in human macrophages. **Methods:** THP-1 monocytes were differentiated into macrophages using 100nM phorbol 12-myristate 13-acetate (PMA) for 24 hours then exposed to sodium arsenite (0.12 μ M and 5 μ M), cadmium chloride (35nM and 3.5 μ M), and lead acetate trihydrate (0.17 μ M and 5 μ M) or control for 48 hours in three technical replicates. All doses were confirmed by Hoechst and DEAD green staining to have no impact on cellular viability. To assess migration, macrophages were scratched with a pipette tip, dosed with heavy metals, and imaged for 48 hours. Scratch closure was analyzed using ImageJ and R, comparing percent change in wound area from time zero and 48 hours. Conditioned media was collected and the cytokines IL-1 β , IL-4, IL-8, IL-23, TGF- β , TNF- α , CCL-2, CXCL-1, and MMP-1 were measured by enzyme-linked immunosorbent assay. Cytokine levels were compared by analysis of variance and post-hoc Tukey testing. **Results:** Exposure to the three heavy metals did not impact rates of THP-1 derived macrophage scratch closure. Heavy metal exposure resulted in altered levels in seven out of nine measured cytokines. CCL-2 levels decreased following exposure to 5 μ M arsenic, from 115.0 pg/mL in the control to 64.3 pg/mL ($p=0.002$), but cadmium significantly increased levels from 113.3 pg/mL in the control to 206.7 pg/mL in 3.5 μ M ($p=0.0001$). Levels of IL-8 and CXCL-1 displayed dose-dependent increases in

response to each of the three chemicals except between control and 35nM cadmium ($p<0.05$). Levels of IL-4 increased from 0.3 pg/mL in control and 11.3 pg/mL in 5 μ M lead to 53.0 pg/mL in 0.17 μ M lead ($p<0.001$), while arsenic and cadmium had no effect. Levels of MMP-1 were decreased in the 5 μ M groups compared to control and low doses for arsenic and lead ($p<0.05$). Low dose arsenic and lead had increased TGF- β levels compared to control and high doses ($p<0.05$). Lead increased TNF- α from 2.3 pg/mL in control to 25.3 pg/mL in 0.17 μ M lead ($p=0.02$). **Conclusions:** Arsenic, cadmium, and lead have effects on macrophage cytokine production at physiologically relevant doses. The effects of arsenic show a pattern of decreased CCL-2, increased CXCL-1, decreased MMP-1, and increased IL-8. Increased levels of CCL-2 and CXCL-1 are associated with breast cancer progression and metastasis. MMP-1 helps macrophages migrate through tissue, so lower levels may impair macrophage infiltration into tumors while IL-8 increases angiogenesis, overall leading to worse prognosis. Cadmium exposure resulted in increased CCL-2, CXCL-1, and IL-8 which could promote breast cancer metastasis and angiogenesis. Lead exposure increased CXCL-1, IL-8, and TNF- α while decreasing MMP-1. These results suggest that heavy metal exposure dysregulates cytokine production by macrophages. Further experiments are in progress to assess effects of heavy metals on RNA expression in the macrophages as well as measuring the impact of macrophage-conditioned media on triple negative breast cancer cell migration.

PS 4732 Evaluating the immunotoxicity of a bispecific antibody (glofitamab) using an ex vivo circulating human whole blood assay

H. Harlin Laven¹, L. Nilsson¹, M. Pettersson¹, G. Törnqvist¹, E. Fletcher¹, S. Ponandai-Srinivasan¹, and S. Mangsbo². ¹Immuned, 753 41 Uppsala, Sweden; and ²Uppsala University, 753 10 Uppsala, Sweden. Sponsor: S. Mangsbo, American Association for Cancer Research

Background and Purpose: Since the advent of targeted antibody therapy, there has been interest in developing bispecific antibodies (BsAbs), but the necessary technology was not available until more recently. Only in the last few years have several BsAbs been approved for clinical use. However, many of the BsAbs are associated with a high risk of cytokine release syndrome and other adverse events. Since many bispecific antibodies target antigens unique to humans and given the need for new approach methodologies (NAMs) that comply with the 3Rs, it would be valuable to have an *in vitro* system for predicting immunotoxicity during preclinical development of BsAbs. **Methods:** ID.Flow is an *ex vivo* system using circulating human whole blood at 37 °C previously evaluated for predicting infusion reactions of monoclonal antibodies and oligonucleotide drugs. The system allows for simultaneous evaluation of multiple immune responses, such as cytokine release, complement activation, activation or depletion of platelets and white blood cells, and coagulation. By using clinically relevant controls, the relative levels of immunotoxicity can be assessed. ID.Flow was used here to evaluate glofitamab, a bispecific T cell engager approved for the treatment of diffuse large B cell lymphoma. Glofitamab is associated with cytokine release syndrome (CRS) including serious or fatal reactions. **Results:** The efficacy and immunotoxicity of glofitamab were investigated in ID.Flow at concentrations similar to the reported C_{max}. As controls, the monoclonal antibodies obinutuzumab and alemtuzumab were used, both of which are associated with manageable CRS in the clinic. Glofitamab resulted in B cell depletion with live B cell counts significantly reduced by 6 hours (60%) and most B cells (90%) depleted by 24 hours. In comparison, B cell depletion using obinutuzumab or alemtuzumab occurred with slightly faster kinetics (80-90% depletion by 6 hours). Correlating with clinical observations, inflammatory cytokines assessed (IFN- γ , IL-2, IL-6, IL-8 and TNF- α) were present at very high levels in circulating whole blood treated with glofitamab for 6 hours. IL-6 and IL-8 were induced to similar levels as those seen using alemtuzumab at C_{max}, and for IFN- γ and TNF- α , the levels were even higher than those seen with alemtuzumab. IL-2 was, as expected, not produced in response to either obinutuzumab or alemtuzumab, but was induced to high levels (similar to an agonistic anti-CD28 antibody) in the presence of glofitamab. Neither obinutuzumab nor glofitamab had any effect on complement activation in ID.Flow, whereas alemtuzumab induced increased levels of C3a and C5a. Interestingly, using flow cytometry, a population of double-positive CD3⁺ CD22⁺ events was observed in samples treated with glofitamab correlating with the mechanism of action of the drug. **Conclusions:** In conclusion, ID.Flow can be used to assess the immunotoxicity and potentially the efficacy of bispecific antibodies with glofitamab as a relevant clinical control.

PS 4733 Detection of circulating immune complexes as a biomarker of immunogenicity

R. B. Johnson, B. Vega, M. A. Oropallo, and R. J. Gonzalez. Merck, West Point, PA.

Background and Purpose: Development of anti-drug antibodies (ADAs) can limit drug efficacy, reduce exposure, and lead to downstream adverse events. ADA binding to drug can lead to the formation of circulating immune complexes (CICs), which can accumulate in blood and slow drug clearance, activate endothelial cells, platelets, and neutrophils, initiate a complement cascade through binding to C1q, or deposit in perivascular tissues of various organs (e.g., kidney, blood vessels, liver, etc) resulting in inflammatory cellular infiltrates. While ADA measurement is a common endpoint in

nonclinical toxicology and clinical studies, measurement of CICs are not commonly examined. **Methods:** Here, we sought to establish methods for detection of CICs in serum or plasma from human, primate, and rat. We established a method for generation of positive control CICs *in vitro* via heat inactivation of serum and show that CICs from these controls, or sera from patients with systemic lupus erythematosus, can be robustly detected using a C1q capture ELISA. **Results:** Moreover, we show that the human C1q ELISA has the capability to bind rhesus CICs, but not rat CICs, with little loss in sensitivity. CIC formation and CIC-C1q assay activity were unaffected by using human or NHP serum or EDTA plasma. Assay performance was also comparable following a single freeze/thaw cycle, suggesting the assay can be used with archived samples. **Conclusions:** We conclude that these assays may be informative as a diagnostic tool of ADA formation and trigger for immunohistochemistry assessments evaluating immune complex deposition, providing additional weight of evidence to understand a drug's immunogenicity risk.

PS 4734 Differential activation of canonical and non-canonical IL-1 β maturation pathways in monocyte subsets in the context of HIV

B. M. Finn^{1,2,3}, R. B. Crawford^{1,3}, P. Gulick^{1,4}, and N. E. Kaminski^{1,2,5,3}. ¹Michigan State University, East Lansing, MI; ²Department of Pharmacology and Toxicology, East Lansing, MI; ³Institute for Integrative Toxicology, East Lansing, MI; ⁴Department of Osteopathic Medicine, East Lansing, MI; and ⁵Center for Research on Ingredient Safety, East Lansing, MI.

Background and Purpose: Despite the success of combination antiretroviral therapy (cART), chronic inflammation persists in people living with HIV (PLWH), contributing to comorbidities such as HIV-associated neurocognitive disorder (HAND). Microbial translocation from the gastrointestinal tract, a major HIV reservoir, exposes peripheral monocytes to toll-like receptor 4 (TLR4) agonists like lipopolysaccharide (LPS), driving the release of proinflammatory cytokines such as interleukin-1 β (IL-1 β). IL-1 β maturation typically depends on inflammasome-mediated caspase-1 activation, which requires the apoptosis-associated speck-like protein containing a caspase recruitment domain (ASC). Previous research has shown that ASC-dependent inflammasome formation is significantly reduced in HIV+ monocytes in response to LPS stimulation, despite a 2-fold increase in IL-1 β secretion, suggesting ASC-independent mechanisms of IL-1 β maturation. Alternative ASC-independent mechanisms involving caspases-4/5, caspase-8, and NLR family CARD-containing (NLRC) sensors can also cleave pro-IL-1 β . The contribution of these non-canonical pathways to persistent inflammation in HIV infection remains poorly understood. While pan monocytes were utilized to evaluate ASC-dependent inflammasome formation in the HIV+ population, CD16+ monocytes are considered the more inflammatory phenotype compared to CD16- monocytes and have been shown to be upregulated in HIV+ individuals. The purpose of this study was to define the relative contributions of canonical versus non-canonical IL-1 β activation pathways in monocytes from HIV+ donors and to assess how these mechanisms differ between monocyte subsets. **Methods:** Peripheral blood monocytes from HIV-negative (HIV-) and HIV-positive (HIV+) donors were isolated and stimulated with LPS (TLR4 agonist). IL-1 β secretion was measured by ELISA. Inflammasome activation was evaluated via flow cytometry tracking ASC speck formation. Expression of inflammasome-related genes (NLRC family members) was quantified by qPCR. Pharmacologic inhibitors targeting caspase-1, caspases-4/5, and caspase-8 were used to dissect pathway-specific IL-1 β responses in pan, CD16+, and CD16- monocyte subsets. **Results:** IL-1 β secretion in both HIV- and HIV+ monocytes was comparably suppressed by caspase-1 and caspase-4/5 inhibitors, supporting involvement of both canonical and non-canonical caspases in IL-1 β activation. Among ASC-independent NLRs, *NOD1* mRNA was significantly upregulated in HIV+ monocytes compared to HIV- monocytes, identifying it as a potential alternative sensor protein driving IL-1 β maturation. Both caspase-1 and caspase-4/5 inhibitors suppressed IL-1 β secretion in CD16+ and CD16- monocytes. However, caspase-8 inhibition selectively reduced IL-1 β in CD16- monocytes, indicating subset-specific utilization of caspase-8-dependent signaling. **Conclusions:** These data reveal that monocytes from HIV+ donors rely on both canonical ASC-dependent IL-1 β maturation as well as non-canonical ASC-independent IL-1 β activation pathways. Upregulation of *NOD1* in HIV+ monocytes and differential caspase usage between CD16+ and CD16- monocytes highlight the complexity of inflammasome-independent cytokine processing during HIV infection. Understanding these alternative pathways could identify new targets to mitigate chronic inflammation in PLWH. (Supported by NIH R01 DA053047 and T32 ES007255).

PS 4735 The effects of BPA on murine IL-17A regulation in naïve CD4⁺ T cells *in vitro*.

L. K. Blevins^{1,2}, R. B. Crawford^{1,2}, and N. E. Kaminski^{1,2,3}. ¹Michigan State University, East Lansing, MI; ²Institute for Integrative Toxicology, East Lansing, MI; and ³Department of Pharmacology and Toxicology, East Lansing, MI.

Background and Purpose: In a previous study it was reported that prenatal exposure through treatment of dams to BPA increased the frequency of splenic Th17 cells in murine offspring. Based on these findings, the objective of this study was to investigate whether direct addition of BPA to cultured naïve CD4⁺ T cells from mouse spleens promoted IL-17A secretion. **Methods:** Naïve CD4⁺ T cells were puri-

fied from single cell suspensions of splenocytes isolated from female C57BL/6 mice by magnetic assisted cell sorting. Naïve CD4⁺ T cells were then activated with plate bound anti-CD3 and soluble anti-CD28 antibodies under both normal and Th17 polarizing culture conditions for 5 days to establish the kinetics of IL-17A secretion. In addition, IL-22 secretion and intracellular ROR γ t, a transcription factor associated with IL-17 production were also measured. At the time of activation, cells were treated with either 10nM TCDD, increasing concentrations of FICZ, and 10 μ M AHR antagonist, CH223191, as positive and negative controls of IL-17 induction, respectively. For studies examining BPA (0.05, 5, 500, 5000, and 50000nM), naïve CD4⁺ T cells were isolated and activated as above in normal and polarizing conditions with 50nM FICZ and 10 μ M CH223191 as positive and negative controls, respectively, for 4 days. On days 3 and 4 post activation, IL-17A and IL-22 secretion were quantified by ELISA and the frequencies of IL-17⁺, IL-22⁺, and ROR γ t⁺ cells was quantified by flow cytometry. **Results:** The initial studies to establish the kinetics of IL-17A secretion showed that IL-17 concentrations peaked by day 4 post activation in both Th17 polarizing and non-polarizing conditions. Moreover, on day 4, AHR activation by either TCDD or FICZ promoted significant IL-17 and IL-22 secretion compared to vehicle treated controls under non-Th17 polarizing conditions. FICZ also resulted in increased frequency of IL-17⁺ cells, while TCDD-mediated effects were not statistically significant, suggesting that FICZ is an appropriate positive control for IL-17A induction. Treatment of CD4⁺ T cells with BPA did not result in any significant increase in cells positive for IL-17A or increased secretion of IL-17, while 50nM FICZ induced significant increases in IL-17A under polarizing conditions and IL-22 under both polarizing and non-polarizing culture conditions. It is noteworthy that the highest concentration of BPA (50000nM) utilized resulted in altered cellular morphology and decreased cytokine secretion, characteristics of reduced T cell activation. None of the aforementioned changes in IL-17A⁺ cells or IL-17A secretion corresponded to changes in ROR γ t positivity in any treatment group. **Conclusions:** These studies suggest that treatment of mature, naïve CD4⁺ T cells with BPA does not induce IL-17A or IL-22 secretion while AHR ligand FICZ promotes IL-17A and IL-22. Interestingly, FICZ-mediated induction of IL-17A and IL-22 was independent of changes in the percentage of cells expressing ROR γ t. In contrast to exposure to BPA *in utero*, direct addition of BPA to mature CD4⁺ T cells had no effect on IL-17A regulation. These results suggest a need for additional investigations of the effects of BPA on IL-17A.

PS 4736 Developmental Immunotoxicity of Five Understudied Per and Polyfluoroalkyl Substances (PFAS) that Contaminate Drinking Water

S. Streeter, M. Carroll, E. Hass, and J. DeWitt. Oregon State University, Corvallis, OR.

Background and Purpose: Per- and polyfluoroalkyl substances (PFAS) are a large class of environmentally persistent contaminants, characterized by long half-lives in organisms and the potential for bioaccumulation due to their resistance to degradation and metabolism. The PFAS studied are detectable in drinking water across the United States. PFAS exposure has been linked to numerous negative health outcomes, including cancers, thyroid disease, immunotoxicity, and developmental toxicity. Despite the commonality of these chemicals, their effects on the developing immune system are not well understood, which is a critical point for public health. **Methods:** Five PFAS were evaluated for this study; Perfluoro-2-methoxyacetic acid (PFMOAA), Nafion Byproduct 2 (NBP2), Perfluoropentane sulfonic acid (PFPeS), Sodium-Perfluoro-3,5,7,9,11-Pentafluorododecanoic Acid (NA-PFO5DoA), and Hexafluoropropylene Oxide Dimer Acid (HFPO-DA or GenX). C57BL/6 female mice were impregnated by C3H male mice. Dams received daily gavage doses of vehicle control, or one of three concentrations from gestational day (GD) 1 through GD17. Administered doses were based on the ability of legacy PFAS, such as perfluorooctanoic acid, to induce developmental toxicity at 5 mg/kg during this period of exposure. On postnatal day 1 (PND1, day of birth), litters were culled to six offspring and were kept with dams until weaning at PND21. Two subsets of pups had organs and sera collected on PND21 to assess body burden and on PND28 to assess basic immunophenotype. Offspring were not directly dosed to focus on effects of gestational exposure. At PND51, offspring were immunized with sheep red blood cells (SRBCs) to elicit T cell-dependent antibody responses (TDAR). At peak IgM antibody production five days post immunization, offspring were humanely euthanized. Blood, spleen, thymus, kidney, brain, heart, and liver were collected for immunophenotyping, immunohistochemistry, and further analyses. Anti-SRBC IgM antibodies were measured by enzyme-linked immunosorbent assay (ELISA), and liver peroxisome proliferation was measured via Acyl-CoA oxidase activity, the first step in peroxisomal β -oxidation. **Results:** Gestational exposure to NA-PFO5DoA and GenX resulted in statistically elevated liver somatic indices in the higher dose groups. NA-PFO5DoA exposed groups also had statistically decreased spleen weights at PND28 and PND56. At PND 28 PFMOAA exposed groups had statistically increased thymus cellularity in the highest dose group, and statistically decreased spleen cellularity. No statistical alterations in the TDAR were observed in this model for any of the five chemicals. Future analysis will include assessment of peroxisome proliferation across these five PFAS. **Conclusions:** Increased liver somatic indices indicate that liver hypertrophy, a common effect of legacy and novel PFAS, can occur and persist following gestational exposure to NA-PFO5DoA and GenX. Decreased spleen weights from NA-PFO5DoA exposure possibly indicate this as well. The absence of overt effects on the TDAR suggests that mechanisms for developmental suppression of the humoral immune response are not observable in this model. Thus, while the immune system does

not appear to be the most sensitive developmental endpoint in this mouse model, persistent effects of developmental exposure were still evident for some of these understudied PFAS with human exposure potential.

PS 4737 Immune Cell Clearance and Acetaminophen Induced Acute Liver Failure

D. K. Chavez, A. Venkatraman, H. Jaeschke, and A. Ramachandran. University of Kansas Medical Center, Kansas City, KS.

Background and Purpose: Acetaminophen (APAP) overdose remains the leading cause of acute liver failure (ALF) in the United States and a major clinical concern worldwide. The pathophysiology of APAP-induced liver injury involves hepatocellular necrosis initiated by the formation of the reactive metabolite N-acetyl-p-benzoquinone imine, which depletes glutathione and causes oxidative stress and mitochondrial dysfunction. While numerous studies have investigated the mechanisms of hepatocyte injury and regeneration, the contribution of immune cell clearance to hepatic recovery is less understood. Following the resolution of necrosis, infiltrating immune cells such as macrophages and neutrophils play essential roles in debris removal, cytokine modulation, and restoration of homeostasis. However, their prolonged retention can perpetuate inflammation and delay tissue repair. Previous work from our laboratory demonstrated that apoptotic signaling in macrophages is critical for their clearance by newly regenerated hepatocytes, facilitating proper termination of inflammation. In contrast, mechanisms governing neutrophil removal from injured liver tissue remain unclear. Given that neutrophils exit through lymphatics in other organs, hepatic lymphatics may similarly support their egress and inflammation resolution after APAP overdose. Understanding this process could identify novel therapeutic targets for enhancing liver repair and preventing progression to ALF. **Methods:** Male C57BL/6J mice (8-10 weeks old) were fasted overnight and administered acetaminophen (300 mg/kg, intraperitoneally) to induce moderate hepatotoxicity. To investigate the role of hepatic lymphangiogenesis in immune cell clearance, a subset of mice received SAR131675 (SAR), a potent and selective inhibitor of VEGFR3-mediated lymphangiogenesis, administered 6 hours post-APAP to target the regenerative phase without affecting the initial injury. Liver injury and recovery were assessed between 12-48 hours post-dose. Serum alanine aminotransferase (ALT) activity was quantified as a marker of hepatocellular damage. Liver sections were examined by hematoxylin and eosin staining for necrosis and regeneration, while immunohistochemistry and immunofluorescence were used to evaluate lymphatic (LYVE-1), neutrophil (Ly6G), and proliferation (PCNA) markers. Immune cell infiltration and hepatocyte proliferation were quantified in QuPath and compared between groups. **Results:** Moderate APAP overdose caused extensive centrilobular necrosis and marked elevation in serum ALT, consistent with acute liver injury at 12-24h. Treatment with SAR did not significantly alter the extent of injury or ALT release, confirming that VEGFR3 inhibition did not influence hepatotoxicity initiation. However, inhibition of lymphangiogenesis markedly altered the inflammatory landscape during recovery. Compared to vehicle controls, SAR-treated livers exhibited persistent, spatially confined neutrophil accumulation, particularly within necrotic and peri-necrotic regions at 24-48 h post-APAP. This retention of neutrophils was accompanied by reduced PCNA expression in peri-necrotic hepatocytes, suggesting impaired proliferative recovery. Vehicle-treated animals showed normal neutrophil clearance and strong hepatocyte proliferation, reflecting a normal shift from inflammation to regeneration. These findings suggest that lymphatic vessel formation and function are essential for neutrophil emigration from the injured parenchyma, likely through VEGFR3-dependent mechanisms. **Conclusions:** Our findings identify hepatic lymphangiogenesis as a previously unrecognized component of the immune resolution process following APAP-induced liver injury. By facilitating neutrophil clearance through hepatic lymphatics, the liver promotes timely resolution of inflammation and supports regeneration. Pharmacologic inhibition of lymphangiogenesis disrupts this process, leading to sustained neutrophil retention, diminished hepatocyte proliferation, and impaired tissue repair. These results provide novel mechanistic insight into how lymphatic remodeling influences immune cell dynamics during drug-induced liver injury. Understanding these interactions may open new therapeutic avenues aimed at promoting immune resolution and preventing the progression from acute injury to acute liver failure in patients with APAP overdose.

PS 4738 Metabolic Reprogramming of CD4⁺ T Cells in Autoimmune-Prone Mice Exposed to Trichloroethylene

H. Wondra. University of New Mexico, Albuquerque, NM.

Background and Purpose: Autoimmune disorders have been on the rise, and while the causes are not known, studies suggest that environmental factors contribute largely. One of these environmental factors, Trichloroethylene, an industrial degreaser, has been studied and linked to immunotoxicity and T-cell-driven autoimmunity. Preliminary data have shown that TCE exposure *in vivo* promotes autoimmune disease pathology by increasing the number of proinflammatory cytokine-secreting Th1-like CD4⁺ T cells in autoimmune-prone MRL-MpJ mice (MRL). To better understand the mechanism, RNA sequencing was conducted on CD4⁺ T cells to determine the direct effects of TCE metabolite, trichloroacetaldehyde hydrate (TCAH) *in vitro*, revealing alterations in metabolic pathways, some of which are

related to glycolysis. We hypothesize that TCAH promotes autoimmunity by modulating T-cell imbalance through metabolic reprogramming. **Methods:** RNA was isolated, and sequencing was conducted to determine the direct effects of trichloroacetaldehyde hydrate (TCAH) on gene expression in polarized Th1 and activated CD4⁺ T cells from MRL mice *ex vivo*. Th1 cells were compared with anti-CD3/anti-CD28-activated CD4⁺ cells (activated but non-polarized) to analyze and compare TCAH-altered gene expression in male and female MRL mice between these subsets. Gene expression profiles revealed TCAH-mediated metabolic changes. Consequently, extracellular flux assays (Agilent Seahorse assays) were conducted to confirm and further investigate functional metabolic alterations in TCAH-treated CD4⁺ cells. Naive CD4⁺ T cells were isolated and purified from MRL/MpJ mice and cultured +/- TCAH over time to capture activation (1,2 days) and differentiation (3-4 days). Agilent Seahorse T cell metabolic rate assays were undertaken to assess the metabolic function of these cells in the presence or absence of TCAH across various concentrations to establish a dose response (0, 0.25, 0.50, 0.75 mM). Non-autoimmune C57BL/6 mice were also examined to establish a comparison of genetic susceptibility to TCAH exposure. BCA assays for quantification of protein content were utilized for normalization of Seahorse metabolic assays. **Results:** RNA-sequencing results revealed key sex-dependent differences in activated CD4⁺ T cells treated with TCAH in MRL mice. Females exhibited reduced expression of genes involved in glycolysis, the TCA cycle, and the HIF-1 pathway, alongside upregulation of genes associated with one-carbon metabolism and glutaminolysis. Using Seahorse T cell metabolic assays on C57/BL6 CD4⁺ T cells, 96 hours of TCAH exposure led to decreased OCR at higher TCAH concentrations and an increase in the percentage of ATP produced via glycolysis. In MRL mice, Seahorse glycolytic rate assays showed a trend in a decrease in basal and compensatory glycolysis in TCAH-treated cells at 24 hours, followed by an increase at later time points compared to controls in female MRL mice CD4⁺ T cells. **Conclusions:** Our findings suggest that disruption of metabolic programming by TCE may represent one mechanism by which TCE promotes autoimmunity in human populations. Investigating how TCE affects metabolic pathways mechanistically may enhance our understanding of how environmental factors are associated with autoimmune disease.

PS 4739 Histone Variant-Specific Epigenetic Remodeling in Activated CD4⁺ T Cells Following Exposure to a Trichloroethylene Metabolite

L. V. Santos-Medina¹, S. R. Choudhury², and S. J. Blossom¹. ¹University of New Mexico Health Sciences Center, Albuquerque, NM; and ²University of Arkansas for Medical Sciences, Little Rock, AR.

Background and Purpose: Environmental toxicants such as trichloroethylene (TCE) contribute to immune dysregulation and autoimmune disease, yet the mechanisms of these effects including epigenetic pathways involved remain unclear. Prior work identified DNA methylation changes in CD4⁺ T cells at histone-related genes and Polycomb targets after TCE/ trichloroacetaldehyde hydrate (TCAH) exposure, suggesting additional epigenetic mechanisms may be involved. **Methods:** Naive CD4⁺ T cells from autoimmune-prone MRL/MpJ mice were activated +/- 0.5 mM TCAH for four days. Histone post translational modifications (PTM)s were quantified by high-resolution mass spectrometry, and DNA methylation at heterochromatin-associated repeats (D4Z4, NBL2) was assessed using pyrosequencing. Cell-cycle dynamics and proliferation was measured to determine whether PTM alterations correspond with TCAH-induced checkpoint or replication defects. **Results:** TCAH caused widespread remodeling of histone PTMs. Replication-dependent H3.1 regions maintained repressive stability, whereas replication-independent H3.3 domains showed marked dysregulation, including reduced H3K27me2 and increased H3K36me2/3, patterns consistent with enhanced transcriptional elongation. DNA methylation analysis revealed site-specific hypomethylation at D4Z4 and hypermethylation at NBL2, indicating region-dependent chromatin instability. Preliminary cell-cycle analysis suggest possible S-phase disruption, consistent with altered PTMs affecting replication-associated chromatin states. **Conclusions:** TCAH disrupts multiple epigenetic layers in a histone-variant- and locus-specific manner, potentially priming activated CD4⁺ T cells for transcriptional and cell-cycle dysregulation. These findings highlight the importance of histone variant context in environmental epigenetics and provide mechanistic insight into how chlorinated solvents may influence immune function and autoimmunity risk.

PS 4740 Short Libby Amphibole fibers induce pulmonary inflammation in mice up to 21 days post-exposure

K. M. Serve, U. Adhikari, L. McOmber, S. Madrigal Nunez, J. Nielson, D. Stevens, V. Wallace, and D. Pradhan. Idaho State University, Pocatello, ID.

Background and Purpose: Short asbestos fibers (SAF), <5µm in length and <1µm in width, comprise the majority of commercial and environmental exposures but are assumed to have negligible health impacts due to their rapid clearance from the lungs. However, due to their small size, SAF can penetrate deeply into the lungs and cross into the pleural space, where they can remain for years. Since the pleural cavity is a key site of asbestos related disease development, we assessed the effects of SAF on early immune responses in mouse lungs, comparing responses in the inter-

stitial and pleural spaces. **Methods:** Wild-type C57/Bl6 or Ccr2-null mice (deficient in monocyte recruitment) were exposed to a single small dose of SAF or vehicle control administered via oropharyngeal aspiration. Fibers used in this experiment were elutriated Libby amphibole (LA; mean length $1.9 \pm 2.1 \mu\text{m}$, mean width of $0.39 \pm 0.2 \mu\text{m}$). All groups consisted of equal numbers of male and female mice, and all animal experiments were approved and monitored by IACUC. Immune responses in wild-type mice were assessed at 7-, 14-, and 21-days post-exposure. Bronchoalveolar lavage fluid (BALF) and pleural wash (PW) were collected and immune cells were identified using flow cytometry. Pro-inflammatory and pro-resolving lipid mediators and TGF-beta were quantified in washes and lung tissue, and histological analyses of lung tissues were performed to measure collagen and assess structural changes. **Results:** Compared to vehicle, LA exposure resulted in significantly reduced macrophage and neutrophil numbers but increased B and T cells in both the PW and BALF at early time points. Monocytes were increased in the PW on day 7, suggesting recruitment of these cells. Concentration of the pro-inflammatory mediators leukotriene B4 (LTB4) and prostaglandin E2 (PGE2) were increased in BALF on day 21, as were concentrations of active TGF-beta, a pro-fibrotic cytokine, with no differences were noted in the PW. Interestingly, pro-resolving lipoxin A4 (LXA4) was also significantly elevated on day 21 in both PW and lung, suggesting a shift from inflammation to resolution. No significant sex effects were noted. On day 21, histological analyses showed thickened pleural tissue and increased lung protein citrullination. Since monocytes were a key component of early cell influx and have been associated with pro-inflammatory responses, we repeated the experiment using Ccr2-null mice and examined responses at 21 days post-exposure. Interestingly, LA induced increased LTB4 and LXA4 in these mice at day 21, as seen with wild-type only, but the saline control Ccr2-null mice also showed significant increases in these lipid mediators. Additionally, histological alterations consistent with fibrosis were noted in both the saline and LA treated Ccr2-null mice, similar to LA-treated wild-type mice, suggesting that lung recruitment of monocytes may be critical for resolving fibrotic activity. **Conclusions:** Together, these data suggest that even a single exposure to a small dose of short amphibole fibers induces protracted inflammatory response. Further, measured responses did differ between the pleural and interstitial spaces, though these responses did not appear to be driven by monocyte recruitment. Overall, these findings suggest that the unique cellular composition and immune responses within different pulmonary cavities may drive different responses to inhaled toxicants.

PS 4741 Improved cryopreservation of human Precision-Cut Lung Slices supports tissue integrity

H. Obernolte¹, K. Grieger¹, S. Metzger², V. Neuhaus¹, F. Ihmig², F. Sonntag³, F. Schmieder³, J. Neubauer², I. Meiser², and K. Sewald¹. ¹Fraunhofer Institute for Toxicology and Experimental Medicine ITEM, Hannover, Germany; ²Fraunhofer Institute for Biomedical Engineering IBMT, Sulzbach, Germany; and ³Fraunhofer Institute for Material and Beam Technology IWS, Dresden, Germany. Sponsor: S. Escher

Background and Purpose: Maintaining the integrity of complex and immunocompetent tissue models poses significant obstacles in biomedical research, particularly in toxicity assessments. The development of effective cryopreservation techniques is crucial for securing a consistent supply of standardized tissue models, decreasing reliance on freshly obtained samples, and facilitating long-term storage for both research and clinical uses. Traditional slow freezing methods frequently result in cellular stress and modifications in immune responses, necessitating the exploration of enhanced preservation strategies. **Methods:** In this investigation, we employed a novel rapid freezing technique for cryopreservation of human precision-cut lung slices (PCLS) and compared it against the established slow freezing method. PCLS were derived from agarose-inflated human lung tissue and were subjected to the respective freezing protocols one day after preparation. Subsequent evaluations included assessments of metabolic activity (WST-1 assay), cytotoxicity (LDH release), live/dead staining, RNA quality and integrity, as well as cytokine production in response to pro-inflammatory stimulation. **Results:** Both freezing methods resulted in diminished viability of PCLS compared to fresh samples. However, the rapid freezing technique exhibited markedly better preservation, with viability rates of approximately 70% immediately post-thaw and 85% after 24 hours, in contrast to 50% and 60% for the slow freezing method. Cytotoxicity levels were also significantly reduced in the rapid freezing group, with 10% and 20% at the respective time points, compared to 40% and 45% observed in slowly frozen slices. RNA quality remained stable across both methods, with RIN values consistently exceeding 7.9. To evaluate immune functionality, PCLS were subjected to lipopolysaccharide (LPS) stimulation for 24 hours, followed by measurements of pro-inflammatory cytokine secretion. The freezing process influenced baseline cytokine production, with increased levels of interleukins, such as IL-8 immediately after thawing. A notable decrease in IL-8 responsiveness was solely present in PCLS subjected to slow freezing. Both methods demonstrated a recovery of cytokine responsiveness over one and three days, with the rapid freezing technique facilitating a quicker and more complete recovery. **Conclusions:** In conclusion, the innovative rapid freezing method significantly enhances the preservation of PCLS viability, RNA integrity, and immune functionality compared to traditional slow freezing. This method represents a promising advance for the long-term storage and standardized use of complex human tissue models in toxicity-focused biomedical research.

PS 4742 Can IGH Variants Drive Antibody Regulation and Environmental Response?

M. Bhakta-Yadav, and C. Sulentic. Wright State University, Dayton, OH.

Background and Purpose: The immunoglobulin heavy chain (IGH) gene encodes all antibody isotypes (IgM, IgD, IgG, IgE, IgA), which are critical for immune defense. Environmental or genetic alterations affecting IGH expression can significantly impact human health. Toxicants that activate the aryl hydrocarbon receptor (AhR), such as TCDD, are known to suppress IGH expression and antibody levels; however, AhR's role in human IGH regulation remains poorly defined. This knowledge gap is compounded by species differences, as rodent-based models do not fully reflect human IGH complexity, including a genetic variation within the hs1.2 enhancer that consists of a one to four ~53 bp repeat. Variation in the hs1.2 enhancer has been associated with hypersensitivity and autoimmune disorders. We hypothesize that hs1.2 variants modulate IGH expression and sensitivity to AhR ligands. **Methods:** Using a human B-cell line (CL-01), CRISPR-Cas9 was used to generate clones with distinct hs1.2 variants (one to four ~53 bp repeats). Sanger sequencing confirmed variant-specific changes in putative transcription factor binding sites. IGH expression and antibody secretion were assessed under basal and stimulated conditions. Preliminary experiments evaluated the effects of the AhR ligand TCDD on these variants. **Results:** The hs1.2 variants exhibited altered IGH expression profiles and antibody secretion compared to wild-type cells. Variant-specific differences in putative transcription factor binding sites correlated with functional changes. Preliminary data indicate differential sensitivity to TCDD among hs1.2 variants. **Conclusions:** Genetic variation in the hs1.2 enhancer influences IGH regulation and antibody production, potentially modifying susceptibility to AhR ligands. Given AhR's role as an environmental sensor for dietary and microbial metabolites, persistent ligands may disrupt homeostatic signaling, increasing risk for immune dysfunction. These findings highlight the importance of human-specific genetic variation in assessing xenobiotic impacts on B-cell function.

PS 4743 Airway Antimicrobial Proteins (AMPs) Orchestrate Defense Against Environmental Fungal Exposures

V. Romero¹, R. Y. Chen¹, M. Cai¹, L. Zhu¹, H. Mou², H. Ding¹, Y. Chen¹, and Y. P. Di³.

¹University of Arizona, Tucson, AZ; ²Massachusetts General Hospital, Harvard Medical School, Boston, MA; and ³Florida International University, Port St Lucie, FL.

Background and Purpose: Humans are continuously exposed to airborne fungal species such as *Alternaria* and *Aspergillus*, and in the endemic regions of the Southwest, *Coccidioides* represents an additional major environmental exposure that is expanding across the western United States. These fungi can induce epithelial injury, dysregulated inflammation, and, in some cases, granuloma formation. However, the epithelial-derived factors that coordinate early antifungal immunity remain poorly defined. Our prior work identified several airway AMPs—particularly BPIFA1—as among the earliest epithelial proteins induced following exposure to environmental fungal spores. Although AMPs are well recognized for their antibacterial activities, their antifungal functions and their roles in shaping granulomatous versus non-granulomatous responses remain largely unexplored. We hypothesized that BPIFA1 and related AMPs act as central epithelial mediators that translate fungal exposure into coordinated innate immune responses required for early fungal containment. **Methods:** BPIFA1-derived peptides (BDPs) were screened for antifungal activity alone or in combination with clinically used antifungal agents. Plasmon-waveguide resonance (PWR) spectroscopy and light/electron microscopy (LM/EM) were used to define the biophysical mechanisms of fungal killing. BPIFA1-deficient (KO) mice were intranasally exposed to fungal spores, and outcomes were assessed by survival, lung fungal burden, histopathology, and granuloma architecture (only in the relevant model). Bronchoalveolar lavage (BAL) fluid was analyzed for cytokines and inflammatory mediators. **Results:** BDPs exhibited potent, broad-spectrum antifungal activity. Notably, BDPs synergized with both first-line (azoles) and second-line (amphotericin B) antifungal drugs, with synergy varying by fungal species. Mechanistically, BDPs may compromise fungal membrane integrity and/or inhibit hyphal growth. *In vivo*, BPIFA1 KO mice were markedly more susceptible to fungal exposure, demonstrating accelerated mortality, increased fungal burden, and exaggerated airway inflammation. **Conclusions:** Airway AMPs—exemplified by BPIFA1—represent previously unrecognized, epithelial-derived regulators of host defense against diverse environmental fungi. These proteins appear essential for shaping early antifungal immunity and influencing host resilience to fungal exposure. Our findings identify a unifying epithelial-innate immune mechanism activated by multiple airborne fungal species and highlight BPI-family-regulated pathways as promising targets for mitigating pulmonary diseases caused or exacerbated by environmental fungal exposures.

S. Salukuti, R. Kondati, and S. Batra. Southern University and A&M College, Baton Rouge, LA.

Background and Purpose: Persistent organic pollutants (POPs), including pentachlorophenol (PCP), its metabolite tetrachlorohydroquinone (TCHQ), and hexachlorobenzene (HCB), are widespread environmental toxicants noted for their persistence, hydrophobicity, and bioaccumulation potential. These chemicals disrupt intracellular proteostasis and redox homeostasis processes essential to effective MHC Class I antigen presentation. PCP undergoes metabolic conversion to TCHQ, a reactive hydroquinone that generates reactive oxygen species (ROS) and forms thiol adducts, resulting in oxidative stress and impairment of proteasome function. The protonophoric activity of PCP and mitochondrial dysfunction induced by HCB further deplete cellular ATP pools, compromising the energy-dependent ubiquitin-proteasome system and peptide processing crucial for antigen presentation. **Methods:** To explore potential molecular-level interactions, *in silico* molecular docking studies were performed using AutoDock Vina to evaluate the binding of PCP, TCHQ, and HCB with key components of the MHC Class I pathway. The crystal structures of HLA-A (PDB ID: 1AKJ), HLA-B (PDB ID: 1HSA), and the transporter associated with antigen processing TAP1/2 (PDB ID: 5U1D) were selected as receptor models. Ligand-protein docking was conducted to estimate binding affinities, identify active site interactions, and assess the likelihood of each pollutant interfering with peptide binding or transport. **Results:** All three POPs exhibited moderate binding affinities with MHC I and TAP complexes. For HLA-A, the lowest binding energies were PCP -5.9, TCHQ -6.0, and HCB -5.6 kcal/mol; for HLA-B, PCP -5.6, TCHQ -5.3, and HCB -5.3 kcal/mol; and for TAP1/2, PCP -5.5, TCHQ -5.8, and HCB -5.4 kcal/mol. Docking poses indicated stable interactions within the peptide-binding and transporter domains, suggesting that these pollutants may directly interfere with antigen processing and presentation, an effect that may compromise immune function and contribute to the toxicological risk of POP exposure. **Conclusions:** The observed molecular interactions provide strong evidence that persistent organic pollutants (POPs) such as PCP, TCHQ, and HCB can compromise immune recognition by directly modulating MHC Class I molecules and TAP transporters. These alterations may disrupt peptide loading, trafficking, and antigen presentation, potentially weakening cellular immune surveillance and increasing susceptibility to infection or immune dysregulation. Our findings emphasize the toxicological significance of these compounds in altering adaptive and innate immune pathways, warranting further *in vitro* validation studies using *in vitro* models to confirm these effects at the cellular level.

PS 4745 Comparative Autoimmune and Neuronal Zoomer Antibody Profiling across three Heavy-Metal-Exposed Cohorts from Italy: Adolescents, Ferroalloy Workers, and Elderly Patients with Parkinsonism

S. Azmoun¹, F. Lewis¹, D. Shioeb², R. Marquez¹, M. Ali¹, V. Sundar¹, E. Colicchio³, I. Mhatre-Winters⁴, H. Krishnamurthy⁵, J. R. Richardson⁴, D. Placidi², L. Lambertini³, and R. G. Lucchini¹. ¹Florida International University, Miami, FL; ²University of Brescia, Brescia, Italy; ³Cahn School of Medicine at Mount Sinai, New York, NY; ⁴University of Georgia, Athens, GA; and ⁵Vibrant Sciences LLC, San Carlos, CA.

Background and Purpose: Heavy-metal exposure (e.g., Mn, As, Cr) contributes to both neurodevelopmental and neurodegenerative outcomes, yet biomarkers that bridge early-life vulnerability to later-life disease remain poorly defined. While systemic immune activation is increasingly recognized as a mechanistic contributor to metal-associated neurotoxicity, comparative immune-neural antibody dysregulation across the lifespan has not been evaluated. Identifying shared immune-neural signatures across developmental stages could elucidate mechanisms consistent with the Developmental Origins of Health and Disease (DOHaD) framework and help uncover biomarkers linking neurodevelopment to neurodegeneration. This study aimed to characterize overlapping autoimmune and neuronal antibody dysregulation across three multi-age metal-exposed cohorts: (1) adolescents exposed to ambient steel emissions, (2) metal-exposed ferroalloy workers, and (3) parkinsonian patients exposed to ambient ferroalloy emissions. **Methods:** Blood samples were analyzed using a combined Protein microarray platform, containing 106 autoimmune and 64 neuronal-associated antibodies in Vibrant Sciences, LLC (Santa Clara, CA, USA). Comparisons were defined as: exposed vs. control (adolescents, n=132), occupationally exposed vs. control (workers, n=11), parkinsonian patients vs. healthy controls (elderly, n=97). In adolescents, cognitive and behavioral function scores and blood metal concentrations differed significantly between exposed and control groups, and similar case-control differences in metal levels were also observed in workers and elderly cohorts. For each antibody, log₂-transformed mean differences were estimated, and significance was assessed using Analysis of Covariance (ANCOVA) adjusted for age and sex. Antibodies dysregulated in at least two of the three cohorts were defined as "shared markers". Directionality (up- or down-regulation) and effect magnitude were compared using standardized mean differences. **Results:** Across 170 antibodies, five markers exhibited consistent and statistically significant dysregulation in all three cohorts, indicating shared immune-neural perturbations across the exposure spectrum. These included AP3B2, Beta-Amyloid (Aβ), DBH, GFAP, and Human Brain Cerebellum Protein. Parkinsonian cases exhibited the strongest elevations, with AP3B2, DBH, GFAP, and Human Brain Cerebellum Protein signifi-

cantly up-regulated (FDR<0.05), while Aβ was significantly decreased (FDR<0.05). The Ferroalloy Workers showed more moderate but directionally similar increases for all five markers, suggesting early immune activation in occupational exposure. In contrast, children displayed significant inverse regulation for these antibodies, highlighting distinct developmental immune responses. Despite differing life stages and exposure sources, the same antibody clusters mapped to neuronal integrity, synaptic trafficking, astrocytic injury, and catecholaminergic signaling, and pathways implicated in mood and depression, indicating biologically convergent pathways. **Conclusions:** This multi-age cross-cohort comparative analysis identifies a consistent set of immune-neural antibody alterations linked to heavy-metal exposure and neurobehavioral dysfunction. The shared dysregulated markers (AP3B2, Aβ, DBH, GFAP, cerebellar proteins) suggest that metal-associated immune activation may operate along a continuum - from early-life vulnerability to occupational exposure to later-life neurodegeneration. These findings highlight the potential translational value of antibody-based signatures for exposure surveillance, early detection of neurotoxicity, and mechanistic understanding of environmentally driven neurodegenerative processes.

PS 4746 Unregulated Alternative Cannabinoid Vaping Products Cause Significant Pulmonary Toxicity and Immune Dysfunction against Respiratory Pathogens

E. Kabir¹, B. Dierolf¹, B. Andersano², T. M. Cahill², M. C. Leung², and T. Muthumalage¹. ¹Purdue University, West Lafayette, IN; and ²Arizona State University, Phoenix, AZ.

Background and Purpose: Alternative cannabinoid vaping products (e.g., Δ⁸-THC, Δ¹⁰-THC, HHC, THCP, THCA) have rapidly emerged in the U.S. market, circumventing regulatory oversight. These products are widely available in smoke shops and gas stations, often flavored to appeal to youth. Despite increasing use, little is known about their pulmonary or immunotoxicological risks, and their impact on antiviral host defense remains poorly understood. **Hypothesis:** Vaping products containing alternative THC analogs exhibit greater pulmonary toxicity and impair host immune responses to influenza A virus (IAV) infection. **Methods:** Eight commercial cartridges labeled as Δ⁸-THC, Δ¹⁰-THC, HHC, THCP, and THCA were analyzed via GC-MS for cannabinoid composition. Bubble extracts in DMSO were evaluated for cytotoxicity and cellular ROS in BEAS-2B bronchial epithelial cells. HHC-induced inflammatory response was assessed by measuring IL-8 cytokine levels. Diversity outbred J: DO mice were exposed to whole-body inhalation exposure to HHC aerosols for 30 min/day over 7 days (51 mL, 2 puffs/min), followed by challenge with mouse-adapted influenza IAV/PR8. Three days post-infection, BALF and lung tissues were analyzed via flow cytometry and inflammatory mediator profiling. **Results:** Chemical analysis revealed widespread mislabeling, with only 4/8 cartridges matched labeled contents. Three were labeled as "THCP" but were predominantly Δ⁸-THC or HHC. All HHC-containing cartridges exhibited racemic R/S mixtures. *In vitro* treatments with HHC-containing extracts produced significant ROS generation and cytotoxicity, and HHC elicited a robust, concentration-dependent IL-8 response ($p < 0.001$). Consistently, *n vivo* exposure to HHC increased BALF cellular infiltration but decreased total lung immune cell counts. IAV infection significantly increased BALF infiltrates, but HHC/THC + IAV co-exposure significantly blunted this recruitment, indicating impaired antiviral immune response. **Conclusions:** Misrepresented alternative cannabinoid vape products, such as those of HHC, elicit significant pulmonary toxicity and suppress host antiviral defenses. These findings suggest that repeated exposure may heighten susceptibility to respiratory pathogens and underscore the urgent need for inhalation toxicology assessment and regulatory oversight of emerging cannabinoid vaping products. This study was supported by the Ralph W. and Grace M. Showalter Research Trust Award at Purdue University.

PS 4747 Redefining Developmental Immunotoxicity Testing: Transitioning From Animal Models to Human-Relevant Frameworks

F. C. Sillé¹, and M. Collinge². ¹Center for Alternatives to Animal Testing (CAAT), Department of Environmental Health and Engineering, Johns Hopkins Bloomberg School of Public Health, Baltimore, MD; and ²Pfizer Inc., Groton, CT.

Background and Purpose: The developing immune system is uniquely vulnerable to environmental and pharmacological perturbations that can lead to lifelong immune dysfunction. Despite growing evidence linking early-life exposures to allergy, autoimmunity, and impaired host defense, developmental immunotoxicity (DIT) testing remains largely dependent on animal models with limited translatability to human immune ontogeny. The *International Working Group towards Alternatives to In Vivo Developmental Immunotoxicity Testing* is advancing a roadmap to modernize DIT assessment through human-relevant, mechanistic approaches aligned with regulatory needs. **Methods:** We integrated current evidence on age-specific immune vulnerabilities with advances in developmental immunology and systems toxicology. New Approach Methodologies (NAMs)—including iPSC-derived immune models, organoid and microphysiological systems, and single-cell and spatial transcriptomics—were assessed for their applicability to early immune development. A tiered testing framework was constructed that incorporates reference chemicals, defined validation criteria, and key mechanistic markers to support assay qualification. In parallel, initial efforts were made to outline a putative adverse outcome pathway (AOP) linking

early perturbations in immune cell differentiation to impaired immune competence. **Results:** Recent advances in high-dimensional profiling have revealed conserved and human-specific molecular programs driving immune maturation and their disruption by environmental agents. *In vitro* systems now recapitulate essential developmental transitions of hematopoietic and lymphoid lineages, enabling functional evaluation of immune perturbation with improved mechanistic clarity. Integration of these models into tiered testing strategies supports the identification of early key events predictive of adverse immune outcomes, providing a scalable and ethically sound alternative to current *in vivo* methods. **Conclusions:** DIT testing is entering a new era defined by human relevance, mechanistic precision, and translational value. The development and validation of NAM-based DIT frameworks—anchored by reference chemicals, clear qualification criteria, and mechanistically grounded AOPs—will enable more predictive, ethical, and policy-relevant assessment of immune developmental hazards. These advances redefine how we identify, characterize, and ultimately prevent immune disruption across the life course.

PS 4748 Sex-Dependent Immune Reprogramming Following Developmental PFOS Exposure in an ASD mouse model

D. Jiang, F. Eldefrawy, and T. L. Guo. University of Georgia, Athens, GA.

Background and Purpose: Perfluorooctane sulfonate (PFOS) is a globally persistent perfluoroalkyl substance (PFAS) with immunomodulatory and endocrine-disrupting effects. However, its long-term impact on immune development and homeostasis in autism spectrum disorder (ASD) remains unclear. As immune dysregulation plays a critical role in the pathogenesis of ASD, it was hypothesized that the combined gestational and early postnatal PFOS exposure at environmental relevant levels could have dose- and sex-dependent effects on splenic leukocyte profiles in adult BTBR-mt⁸⁶ offspring, an ASD mouse model. **Methods:** Timely mated pregnant dams received vehicle or PFOS (0.2 or 1.0 mg/kg/day; *n* = 6) by gavage from conception to postnatal day 21. Adult male and female offspring were euthanized at 14-15 weeks of age, and single-cell splenocyte suspensions were analyzed by flow cytometry for B-cell, T-cell, myeloid, and regulatory markers populations (%) as well as mean fluorescence intensity (MFI). **Results:** In males, PFOS exposure increased both terminal body and spleen weights, with significant effects observed at the low dose. Immunologically, PFOS induced heightened B-cell activations at both doses, as evidenced by elevated CD40L expression (B220⁺CD40L⁺), and showed a trend towards decreased populations of T-cell associated activation markers (CD40⁺CD44⁺CD4⁺). The expressions of myeloid activation markers (GR1⁺F4/80⁺) were elevated at low dose, while cytotoxic T-cell markers (CD3⁺CD8⁺) and regulatory markers (CD25⁺) primarily elevated at high dose, suggesting heightened inflammatory priming and immune responsiveness in males. In contrast, females exhibited predominantly immunosuppressive profiles, particularly at high dose, with decreased myeloid (Mac-3⁺) population and reduced expression of B-cell (B220⁺), T-cell (CD4⁺, CD8⁺), myeloid (F4/80⁺) and regulatory markers (CD25⁺), reflecting compromised adaptive and innate immune cell activation. **Conclusions:** These findings demonstrate that developmental PFOS exposure durably reprograms immune homeostasis in a sex- and dose-dependent manner. The bias of males toward immune activation while females toward immunosuppression highlights the vulnerability of the developing immune system to PFAS exposure and underscores the importance of considering sex-specific risk in assessing long-term immunotoxic outcomes.

PS 4749 Cytokine Profiling for Immunotoxicity Assessment: Comparison of MSD®, Luminex®, and CBA Multiplex Platforms in Preclinical Matrices

Q. Gu, J. Li, T. Yu, W. Sheng, B. Wei, Y. Zong, X. Guo, C. Zhu, M. Wang, X. Jin, and X. Li. WuXi AppTec (Suzhou) Co., Ltd, Suzhou, China.

Background and Purpose: Cytokines mediate critical immunological activities, reflect immune activation, and indicate disease status. Cytokine profiling is central to immunotoxicity assessment during drug development. Ligand binding assays are routinely employed to detect cytokine release at the protein level. Multiplex cytokine analysis methods are widely adopted for capturing complex cytokine profiles, offering advantages over singleplex methods by reducing sample handling and minimizing total sample volume requirements. Among these platforms, cytometric bead array (CBA), Meso Scale Discovery (MSD®) and Luminex® provide high-throughput analysis for preclinical risk assessment. Despite their popularity, choosing the right platform and interpreting results across different platforms remains challenging. In this study, we directly compare cytokine profiles generated by three multiplex platforms (MSD®, CBA, and Luminex®) using identical sample sets. **Methods:** Cytokine production was stimulated with in-house positive control mixes. Cytokine release was subsequently measured in serum samples from non-human primates (NHPs) and in supernatants from stimulated human peripheral blood mononuclear cells (PBMCs). The cytokines IL-2, IL-6, TNF-α, and IFN-γ were quantified in all samples using three multiplex platforms: ECL platform (MSD® U-plex), Luminex® platform (ThermoFisher ProcartaPlex) and CBA platform (Biolegend LEGENDplex for NHP serum and BD Flex set for human supernatant). Additional analytes were measured on specific platforms: IP-10 was quantified in NHP serum in MSD® and Luminex® panel. IL-10 was quantified in human PBMC supernatant using MSD® and CBA. All animal research was approved

by the Institutional Animal Care and Use Committee. All assays were performed according to the manufacturers' protocols. Selectivity/ parallelism was performed to determine MRD. Accuracy and precision run was also evaluated. Results from the same sample group were compared across the three platforms. Data values below the lower limit of quantification (LLOQ) were substituted with zero for comparative analysis. Statistical comparisons were performed using ANOVA followed by pairwise t-tests. **Results:** Our results demonstrated a relatively consistent cytokine trend following stimulation as assessed across all three platforms. In pre-stimulation samples, baseline was comparable across all three platforms (MSD®, Luminex®, CBA), with analytes IL-2, IL-6, TNF-α, IFN-γ below the LLOQ. Platform-specific differences was observed during IL-2 and IL-10 detection in NHP serum and during IL-10 detection in human PBMC supernatant. All platforms detected the peak IL-2 release post-stimulation at comparable levels. However, only the MSD® platform consistently detected IL-2 in serum samples at the 6-hour time point, despite the results exceeding the LLOQ of all three assays, suggesting potential differences in the antibody binding of the respective IL-2 assays. Additionally, IP-10 in stimulated NHP serum was detectable only by MSD®, not Luminex®. Detected IL-10 levels in stimulated human PBMC supernatant were significantly higher using CBA versus MSD®, though both platforms showed consistent trends. While IL-6, TNF-α, and IFN-γ showed no significant statistical differences across platforms, absolute concentrations varied by over 3-fold in pairwise comparisons. Consequently, these platforms are suitable for relative quantification looking for trends, but direct comparison of data values is not recommended. **Conclusions:** Our data demonstrated that selecting a multiplex cytokine platform (MSD®, Luminex®, or CBA) for preclinical immunotoxicity assessment requires a fit-for-purpose approach. When comparison between data set is expected, trend rather than data point values may be comparable for data generated across platforms. However, when direct comparison of absolute cytokine levels is crucial, data set from same platform may be required.
