Alcoholic liver disease is a major medical complication of alcohol abuse and a common liver disease in the western countries. Increasing evidence demonstrates that oxidative stress plays an important etiologic role in the development of alcoholic liver disease.Adenosylmethionine (SAMe) is a key intermediate in the hepatic transsulfuration pathway and serves as a precursor for glutathione (GSH) as well as the methyl donor in most transmethylation reactions. Although SAMe has beneficial effects on many hepatic disorders; the effects of SAMe on acute alcohol-induced liver injury are still unknown. In present study, we investigated effect and mechanism of SAMe on liver injury induced by acute alcohol administration. Our results showed that acute ethanol administration (5g/kg BW) caused prominent microvesicular steatosis with mild necrosis and an elevation of serum enzyme (ALT) activity. In association with the hepatocyte injury, acute alcohol administration induced marked decreases in both hepatic SAMe and mitochondrial GSH levels along with lipid peroxidation and mitochondrial dysfunction. SAMe (50 mg/ kg BW) treatment significantly attenuated the liver injury. Pretreatment with SAMe prevented hepatic SAMe and mitochondrial GSH depletion as well as mitochondrial dysfunction following acute alcohol exposure. These results demonstrated that SAMe protects liver from acute alcohol induced injury by preventing mitochondrial GSH depletion and mitochondrial dysfunction. (Supported by VA, NIH R01 AA01762, NIH R01 AA 10496).

946 PPAR-α ACTIVATION IS ESSENTIAL FOR DIABETES-INDUCED RESISTANCE AGAINST ACETAMINOPHEN HEPATOTOXICITY.

K. Shankar[1], V. S. Vaidya[1], J. E. Manautou[2], J. C. Corton[3], T. J. Bucci[4], J. Liu[5], M. P. Waalkes[5] and H. M. Mehendale[1]. *[1]Toxicology, University of Louisiana at Mornoe, Monroe, LA, [2]Department of Pharmacology Sciences, University of Connecticut, Storrs, CT, [3]Toxicogenomics, Toxicology Consultant, Chapel Hill, NC, [4]Pathology Associates Intl., NCTR, Jefferson, AR and [5]NCI at NIEHS, Inorganic Carcinogenesis Section, Research Triangle Park, NC.*

We recently reported a critical role for nuclear receptor, PPAR-α, in conferring resistance to acetaminophen (APAP) hepatotoxicity in diabetic (DB) mice. The present work examines the mechanisms mediating this resistance. WT-DB mice treated with APAP (600 mg/kg, LD_{100} in WT non-DB mice), showed only 30% mortality and 50% less liver injury (ALT and histopathology). In contrast, diabetic-PPAR-$\alpha^{-/-}$ mice were not protected from APAP toxicity. Pulse labeling studies and PCNA histochemical staining after injury showed earlier and robust tissue repair in WT-DB mice, but not in the PPAR-$\alpha^{-/-}$DB mice. Hepatic CYP2E1 and 1A2 protein, and APAP selective covalent binding to 58, 56 and 44 KDa acetaminophen binding proteins were similar among DB and non-DB mice. Using c-DNA microarrays we analyzed the expression of 588 genes at 12 h after APAP treatment in non-DB and DB, WT and PPAR-$\alpha^{-/-}$ mice. Hierarchical clustering (Cluster™) of genes revealed six groups of genes, with correlations among genes from similar functional families. WT-DB mice had significantly muted expression of Gadd45, Gadd153, EGR-1 and heme oxygenase-1 compared to WT non-DB mice after APAP treatment consistent with lower liver injury. WT-DB mice showed significantly greater increases in heat shock proteins 105, 25 and 70 after APAP, compared to PPAR-$\alpha^{-/-}$DB cohorts. Remarkable changes were observed in cell-cycle regulators in WT-DB selectively. Among others, WT-DB, unlike the PPAR-$\alpha^{-/-}$ DB mice revealed 10-fold increase in cyclin D1 gene expression, consistent with earlier and higher DNA synthesis. Microarray data were confirmed *via* real-time PCR analysis of 15 genes. These findings suggest enhanced p38 MAPK/cyclin D1 signaling as mechanisms underlying upregulated liver tissue repair *via* PPAR-α activation in diabetes.

947 UROPORPHYRIA CAUSED BY ETHANOL IN Hfe(-/-) MICE; ROLE OF HEPATIC IRON ACCUMULATION.

P. Sinclair[1,6,7], N. Gorman[1,6], H. Trask[1,6], W. Bement[1], J. Szakacs[3], G. Elder[1,5], D. Balestra[1], J. Sinclair[1,6,7] and G. Gerhard[1,2]. *[1]VA Med. Center, White River Junction, VT, [2]Pathology, Dartmouth Medical School, Hanover, NH, [3]Pathology, University of Utah Medical School, Salt Lake City, UT, [4]Medical Biochemistry, University of Wales Medical School, Cardiff, Wales, United Kingdom, [5]Medicine, Dartmouth Medical School, Hanover, NH, [6]Biochemistry, Dartmouth Medical School, Hanover, NH and [7]Pharmacology/Toxicology, Dartmouth Medical School, Hanover, NH.*

Two major risk factors for the development of porphyria cutanea tarda (PCT) are alcohol consumption and homozygosity for the C282Y mutation in the hereditary hemochromatosis gene (HFE). To develop an animal model, Hfe knockout and wild-type mice were treated continuously with 10 % ethanol in their drinking water. By 4 months, uroporphyrin (URO) was detected in the urine. At 6 to 7 months, hepatic URO was increased and hepatic uroporphyrinogen decarboxylase (UROD) activity was decreased. Untreated Hfe(-/-) mice, or wild-type mice treated with or without ethanol, did not display any of these biochemical changes. The ethanol treatment increased hepatic non-heme iron and hepatic 5-aminolevulinate synthase activity in Hfe(-/-), but not wild-type mice. The increases in non-heme iron in Hfe(-/-) mice were associated with diffuse increases in iron staining of parenchymal cells, but without evidence of significant liver injury. Wild-type mice treated with both high doses of iron dextran and ethanol also became uroporphyric. In conclusion, this study indicates that the uroporphyrinogenic effect of ethanol is mediated by its effects on hepatic iron metabolism and is associated with increases in hepatic 5-aminolevulinate synthase. Ethanol-treated Hfe(-/-) mice appear to be an excellent model for studies of alcohol-induced PCT. This work was supported by funds from the Department of Veterans Affairs and by grants from the National Institutes of Health ES06263 (PRS) and AG14731 (GG).

948 CARBAMOYL PHOSPHATE SYNTHETASE I: CHRONIC ETHANOL EXPOSURE AFFECTS ENZYME ACTIVITY IN HEPATOCYTES VIA A 4-HYDROXYNONENAL MECHANISM.

B. P. Sampey, M. I. Panagiotidis and D. R. Petersen. *PharmSci/Toxicology, University of Colorado Health Sciences Center, Denver, CO.*

Chronic consumption of ethanol has been demonstrated to elicit lipid peroxidation, resulting in electrophilic aldehyde by-products such as 4-hydroxynonenal (4-HNE) and malondialdehyde (MDA). These aldehydes have gained notoriety due to their long-lived ability to form adducts with proteins and nucleic acids. Although

the temporal relationship between protein-adduct formation and oxidative stress has been established, the specific proteins targeted for adduction and the resulting biomolecular perturbations have yet to be expounded. The objective of this study was to isolate and identify the proteins adducted by 4-HNE and MDA, and to evaluate the consequences that adduction impose on the normal biochemistry of hepatocytes. The novel research presented here used immunoprecipitation and western blot analysis to identify carbamoyl phosphate synthetase I (CPS-I) as a protein targeted for adduction by both 4-HNE and MDA. In animals that exhibited hepatic steatosis, CPS-I activity was decreased by as much as 33% below control levels resulting in an increase in serum ammonia levels. Although *in vivo* experiments using rats in a chronic ethanol feeding model demonstrated that both aldehydes form adducts whith CPS-I, assays using control hepatocytes treated with 4-HNE or MDA at 100μM or 1mM concentrations indicated that the inhibition of enzyme activity is associated with 4-HNE, but not MDA. Additionally, 4-HNE treatment of primary cultured hepatocytes lead to a decrease in CPS-I protein concentration, whereas MDA treatment of identical cells had no effect. To our knowledge, this is the first report that indicates the rate-limiting enzyme of the urea cycle is adducted by the ethanol-induced, lipid peroxidation products, 4-HNE and MDA, and that only 4-HNE decreases enzyme activity and concentration. (Supported by NIH/AA 09300)

949 SUBSTRATE MODIFICATION BY 4-HYDROXYNONENAL MODULATES DEGRADATION BY THE 26S PROTEASOME.

D. L. Carbone, J. A. Doorn and D. R. Petersen. *Pharmaceutical Sciences, University of Colorado HSC, Denver, CO.*

Alcoholic liver disease (ALD) is associated with the accumulation of undegraded proteins within hepatocytes. A pathway commonly employed by mammalian cells to degrade proteins involves polyubiquitination and ensuing degradation by the 26S multicatalytic protease complex (26S proteasome). Therefore, modulation of this pathway is a likely mechanism explaining altered degradation of proteins. Also associated with ALD are lipid peroxidation and the ensuing production of reactive aldehydes such as 4-hydroxynonenal (4-HNE). To test the hypothesis that 4-HNE modulates 26S proteasomal degradation through substrate modification, an *in vitro* system consisting of rabbit reticulocyte lysate (RRL) fortified with an ATP-regenerating system has been employed to monitor degradation of 4-HNE-modified alcohol dehydrogenase (ADH). This enzyme was selected as a model protein due to the likelihood it is a target for adduction because of its involvement in the metabolism of 4-HNE. Exposure of ADH to concentrations of 4-HNE ranging from 10μM to 100μM resulted in varying degrees of covalent adduct formation. The rate of RRL-mediated disappearance of ADH modified by 10μM 4-HNE was increased by approximately 30 percent over the unmodified control, while exposure to 100μM 4-HNE inhibited the degradation of ADH. Involvement of the 26S proteasome was verified using the specific proteasome inhibitor MG-132 and a non-hydrolyzable ATP analogue, both of which prevented ADH degradation. Finally, enzymatic digest of modified ADH followed by mass spectral analysis has facilitated identification of several sites of 4-HNE adduct formation. The data presented here describe a concentration-dependent ability of 4-HNE to modulate protein degradation by the 26S proteasome through substrate modification, and suggest that aldehydic products of lipid peroxidation may be involved in dysregulation of protein degradation associated with alcohol-induced liver injury. Support for this work was provided by NIH/AA09300.

950 WHY DOES INJURY PROGRESS EVEN AFTER TOXICANT IS GONE? A NOVEL MECHANISM.

P. B. Limaye[1], U. M. Apte[1], T. J. Bucci[2], A. Warbritton[2] and H. M. Mehendale[1]. [1]*Department of Toxicology, The University of Louisiana at Monroe, Monroe, LA and* [2]*Pathology Associates Inc., NCTR, Jefferson, AR.*

Liver injury induced by hepatotoxicants such as acetaminophen and CCl_4, progresses long after the chemical is eliminated from the body. We tested the hypothesis that necrotic cells dying from mechanism based events release hydrolytic enzymes, which attack the surrounding healthy cells causing progression of injury. Here we provide evidence that calpain, a cysteine protease released from dying cells, mediates progression of toxicant-inflicted injury. Therapeutic injection of a calpain inhibitor N-CBZ-VAL-PHE- methyl ester (CBZ; 60 mg/kg) 1 h after the toxicant, protects 80 % of male SW mice and 75 % of male S-D rats treated with lethal doses of acetaminophen (600 mg/kg, ip) and CCl_4 (3 ml/kg, ip), respectively. CBZ does not affect CYP2E1 (Western blot and p-nitrophenol hydroxylase), the primary bioactivating enzyme, ruling out the possibility of decreased bioactivation of these hepatotoxicants. Extracellular leakage of calpain, assessed by immunohistochemistry in liver and calpain activity in plasma was substantially lower in the necrotic area after CBZ treatment. Treatment with E64, a cell impermeable inhibitor of calpain, also reduced CCl_4-induced liver injury in S-D rats. Calpain-mediated damage of surrounding cells assessed by degradation of cytoskeletal protein α-fodrin in CCl_4-treated rat livers was substantial while it was nearly abolished in CBZ treated rats. Calpain was able to induce cell death in a Ca^{2+}-dependent manner in freshly isolated hepatocytes, which was completely blocked in the presence of CBZ (100 nm, 500 nm, and 1 μm). Hepatocytes incubated with plasma of CCl_4-treated rats (collected at 12 h when most of the CCl_4 is eliminated) induced extensive cell death, which was prevented by CBZ. These data provide substantial evidence for a novel mechanism involving calpain released from dying cells after CCl_4 and acetaminophen treatment mediates the progression of liver injury. (Supported by Kitty DeGree Endowment and LBRSP).

951 STUDIES ON THE SUSCEPTIBILITY OF TRANSPORT DEFICIENT (TR⁻) HYPERBILIRUBINEMIC RATS TO ACETAMINOPHEN HEPATOTOXICITY.

V. M. Silva[1], G. E. Hennig[3], M. S. Thibodeau[1], H. E. Whiteley[2] and J. E. Manautou[1]. [1]*Pharmaceutical Sciences, University of Connecticut, Storrs, CT,* [2]*Veterinary Medicine, University of Illinois, Urbana, IL and* [3]*Pathobiology, University of Connecticut, Storrs, CT.*

Biliary excretion of several conjugated metabolites of APAP is significantly reduced in transport deficient (TR^-) hyperbilirubinemic rats. They also have impaired biliary excretion of many organic anions and increased retention of hepatic glutathione (GSH) due to mutational deficiency of the canalicular transporter Mrp2. In these experiments, the susceptibility of TR^- rats to APAP hepatotoxicity was investigated. For this purpose, weight-matched normal male Wistar and TR^- rats were fasted overnight and treated with 1g APAP/kg, ip. Controls received vehicle only (0.2% Arabic gum). Liver toxicity was assessed 24 hrs later by plasma SDH activity and histopathology. Normal Wistar rats treated with APAP showed significant elevation in plasma SDH activity at 24 hrs. However, administration of the same dose of APAP did not increase plasma SDH activity in TR^- rats. Histopathology confirmed these findings. As expected, hepatic non-protein sulfhydryl (NPSH) content was significantly lower in normal rats treated with APAP when compared to vehicle controls. In contrast, vehicle treated TR^- rats had approximately 57% higher hepatic NPSH content than vehicle treated normal rats. No changes in NPSH content were detected at 24 hrs after APAP treatment in TR^- rats when compared to vehicle controls. To investigate the importance of higher hepatic NPSH content in TR^- rats, fasted normal and TR^- rats received buthionine sulfoximine (BSO, 0.89g/kg) three hrs before APAP (1g/kg, ip). Liver injury was determined 24 hrs after APAP. Treatment with BSO by itself decreased hepatic NPSH in TR^- rats to levels similar to those in vehicle treated normal rats. TR^- rats treated with BSO and APAP showed dramatic increases in liver injury, suggesting that increased hepatic GSH content in TR^- rats contributes to their resistance to APAP hepatotoxicity (Supported by NIH grant ES10093).

952 INCREASED HEPATOTOXICITY OF ACETAMINOPHEN IN HSP 70I KNOCKOUT MICE.

J. K. Tolson[1], D. J. Dix[2], R. W. Voellmy[3] and S. M. Roberts[1]. [1]*Center for Environmental & Human Toxicology, University of Florida, Gainesville, FL,* [2]*NHEERL, USEPA, Research Triangle Park, NC and* [3]*Department of Biochemistry, University of Miami, Miami, FL.*

The cellular stress response is characterized, in part, by the highly regulated expression of a set of proteins (heat shock proteins or Hsps). Interest in Hsps stems from numerous reports that correlate induction of Hsps to cytoprotection. For example, previous studies have found that mice subjected to transient hyperthermia (elevating all Hsps) were more resistant to acetaminophen hepatotoxicity than control mice. In these studies, the inducible form of Hsp70 (Hsp70i) was strongly upregulated in liver in response to both acetaminophen and hyperthermia. In an effort to assess the influence of Hsp70i on hepatotoxicity, acetaminophen was administered to Hsp70i knockout mice and controls. Lack of Hsp70i response in liver was verified by challenging knockout mice with hyperthermia or an acutely toxic dose of acetaminophen. Knockout animals were found to be similar to the control strain in metabolic parameters significant to acetaminophen bioactivation (CYP2E1, GST-t, and glutathione levels). Dose response studies found that the hsp70i knockout mice were more susceptible to acetaminophen induced hepatotoxicity than controls as evidenced by elevated serum ALT levels 12, 24 and 48 hours after dosing. Pretreatment with transient hyperthermia to produce a general upregulation of Hsps resulted in decreased acetaminophen hepatotoxicity in both the knockout and control strains. Residual toxicity from acetaminophen in the thermally-pretreated knockouts appeared to be greater than controls, although the differences were not statistically significant. These experiments provide evidence that hsp70i induction is partially responsible for the cytoprotective effects of transient hyperthermia. Furthermore, it suggests that endogenous levels of hsp70i produced at the time of hepatotoxic insult are cytoprotective and limit the extent of the APAP lesion. Supported by ES 07213.

953 PROTECTIVE ROLE OF KUPFFER CELLS IN ACETAMINOPHEN-INDUCED HEPATIC INJURY IN MICE.

C. Ju[1], T. Reilly[1], M. Bourdi[1], M. Radonovich[2], J. Brady[2], J. George[1] and L. Pohl[1]. *[1]NHLBI, NIH, Bethesda, MD and [2]NCI, NIH, Bethesda, MD.*

Hepatic injury induced by various toxic agents including acetaminophen (APAP) has been attributed to the production of pro-inflammatory cytokines and other mediators by resident Kupffer cells (KC) within the liver. However, evidence from our laboratory has demonstrated that hepato-protective factors, such as interleukin (IL)-10 and cyclooxygenase-derived mediators, are also upregulated in response to hepatic damage to help protect against exacerbated injury, and KC have been suggested to be a source of these modulatory factors. In other models, KC also serve important regulatory functions in pathophysiological states of the liver. Therefore, we re-evaluated the role of KC in a murine model of APAP-induced liver injury using liposome-entrapped clodronate (liposome/clodronate) as an effective KC-depleting agent. We show that in contrast to pretreatment of mice with a widely used macrophage inhibitor, GdCl3, which did not deplete KC but moderately protected against APAP-induced hepatotoxicity as reported previously, the intravenous injection of liposome/clodronate caused nearly complete elimination of KC and significantly increased susceptibility to APAP-induced liver injury as compared with mice pretreated with empty liposomes. This increased susceptibility was apparently unrelated to the metabolism of APAP since liposome/clodronate pretreatment did not alter APAP-protein adduct levels. Instead, KC depletion by liposome/clodronate led to significant decreases in the levels of hepatic mRNA expression of several hepato-regulatory cytokines and mediators, including IL-6, IL-10, IL-18 binding protein and complement 1q, suggesting that KC are a significant source for production of these mediators in this model. Our findings indicate that, in addition to their pro-toxicant activities, KC can also have an important protective function in the liver through the production of a variety of modulatory factors which may counteract inflammatory responses and/or stimulate liver regeneration.

954 INVESTIGATING THE POLYGENIC CONTROL OF SUSCEPTIBILITY TO DRUG-INDUCED LIVER DISEASE (DILD) USING VARIED STRAINS OF MICE.

K. Welch[1], T. Reilly[1], J. Brady[2], C. Pise-Masison[2], M. Radonovich[2] and L. Pohl[1]. *[1]NHLBI, NIH/HHS, Bethesda, MD and [2]NCI, NIH/HHS, Bethesda, MD.*

DILD causes significant morbidity and mortality and impairs drug development. Currently, no known criteria can predict whether a drug will cause DILD or what risk factors make an individual susceptible. Although we have discovered in mouse studies that the disruption of key regulatory factors (COX2, IL6, IL10) dramatically increased susceptibility, no single factor seems to be absolute. In order to better understand this polygenicity, we now report a genomic approach aimed at uncovering combinations of inherent differences that might more aptly mimic situations seen in patients. Susceptibility differences to the well-known analgesic/antipyretic drug, acetaminophen (APAP), were investigated using 8 common strains of mice. The rank order of liver damage following APAP treatment was C57Bl/6>C3H/HeOu>>129S6/SvEv=BALB/c>C3H/He>ICR=DBA/2>>>SJL. Lethality mimicked these rankings with noteworthy differences that included delayed lethality of C57Bl/6, ~40% deaths of ICR, and a lack of any deaths in DBA and SJL mice. Metabolic analyses of these 4 strains showed no differences in total APAP-protein adducts or CYP2E1 levels, but did reveal significantly lower levels of specific adducts in SJL mice. Using a microarray platform to monitor 36K genes and ESTs, hepatic gene expression time profiles were obtained for C57Bl/6, DBA, ICR and SJL strains in the absence and presence of APAP toxicity. The expression of >2000 known genes and ESTs including many inflammatory and stress responsive regulators, showed unique positive and negative correlations with toxicity suggesting possible mechanistic functions. A confirmed increase of heat shock proteins 40 and 70 in resistant SJL mice represents one example. Further delineation of the factors that correlate with differential toxicity profiles and analysis of ongoing F1 cross studies should facilitate our understanding of DILD and begin to uncover candidates whose altered expression might predict susceptibility.

955 SCAVENGING PEROXYNITRITE WITH GLUTATHIONE ENHANCES SURVIVAL AND PROMOTES REGENERATION AFTER ACETAMINOPHEN OVERDOSE IN MICE: ROLE OF IL-6.

M. Bajt, T. Knight and H. Jaeschke. *Pharmacology and Toxicology, University of Arkansas for Medical Sciences, Little Rock, AR.*

We recently showed that intravenous injection of glutathione (GSH) at 1.5 or 2 h after acetaminophen (AAP) treatment leads to the accelerated recovery of mitochondrial glutathione levels, which prevented AAP-induced liver injury at 6 h (Knight et al, J Pharmacol Exp Therap 303: in press, 2002). The enhanced cellular GSH content scavenged peroxynitrite but did not prevent mitochondrial dysfunction. Thus, the objective of this investigation was to evaluate the potential long-term benefits of GSH treatment. A dose of 300 mg/kg AAP induced centrilobular necrosis and increase of plasma alanine aminotransferase (ALT) activities (24 h: 3680 ± 320 University/L) in fasted C3Heb/FeJ mice. Only 56% of the animals survived for 24 h and only 5% were alive at 48 h. Although the animals were fed 9 h after AAP treatment, hepatic GSH levels were still suppressed (7.5 ± 1.2 μmol/g liver) compared to controls (19.7 ± 2.6). Glutathione disulfide (GSSG) levels were elevated (337 ± 26 nmol/g) compared to controls (74 ± 3). Treatment with GSH at 1.5 h after AAP attenuated liver injury at 24 h (1240 ± 70 University/L) and at 48 h (65 ± 10 University/L). All animals survived for 48 h. The hepatic GSH content recovered completely but an oxidant stress was still present (GSSG: 252 ± 26 nmol/g). Cyclin D1 and PCNA protein expression, as indicators of cell cycle activity and regeneration, were not detectable in controls or after AAP alone (6 to 24 h). However, in animals treated with AAP+GSH, a substantial increase in cyclin D1 (12 to 48 h) and PCNA levels (24 to 48 h) was observed by western blotting and immunohistochemistry (PCNA). Plasma IL-6 concentrations were elevated 3-5 fold in response to AAP alone (12 to 24 h). Treatment with GSH prevented IL-6 formation. Our data suggest that scavenging peroxynitrite by GSH provides a long-term hepatoprotection against AAP overdose and improves survival despite the continued mitochondrial oxidant stress. Cell cycle activation and regeneration further facilitate recovery. The regeneration response is independent of IL-6.

956 MECHANISM OF ENHANCED CCL_4-INDUCED HEPATOTOXICITY IN TYPE 2 DIABETES: ROLE OF TISSUE REPAIR.

S. P. Sawant[1], A. V. Dnyanmote[1], J. R. Latendresse[2] and H. M. Mehendale[1]. *[1]Department.of Toxicology, College of Pharmacy, The University of Louisiana at Monroe, Monroe, LA and [2]Pathology, NCTR, Jefferson, AR.*

The objective of this study was to investigate the mechanism of increased CCl_4 hepatotoxicity in type 2 diabetic rats. Type 2 diabetes was induced in male S D rats by feeding high fat diet (20% fat, 24% protein, 54% carbohydrate) and injecting streptozotocin (45 mg/kg, ip) on day 14. On day 24, blood glucose increased threefold (450 ± 66 mg/dl) with normoinsulinemia, high glycated hemoglobin, elevated triglyceride levels, and insulin resistance as measured by oral glucose tolerance test (5 mg/kg, po) confirmed type 2 diabetes. Administration of a normally nonlethal dose of CCl_4 (2 ml/kg, ip) yielded 100% mortality in the diabetic (DB) rats. A time course study with this dose of CCl_4 revealed substantially higher liver injury in DB rats as assessed by ALT and liver histopathology. Death in DB rats was due to hepatic failure as indicated by hyperammonemia and hyperbilirubinemia. Lack of any change in hepatomicrosomal CYP2E1 protein (Western blot) and activity (TBA assay) in DB rats indicated that bioactivation-based potentiation of CCl_4 hepatotoxicity could not be the reason for markedly amplified hepatotoxicity. Hepatic glutathione at 0, 6, 12 and 24 h after CCl_4 administration were unchanged in DB rats compared to non- diabetic (non-DB) rats, obviating the role of glutathione in potentiation. Tissue repair assessed by ^{3}H-T incorporation in hepatonuclear DNA and confirmed by proliferating cell nuclear antigen assay was inhibited in DB rats after CCl_4 administration due to which injury progressed and resulted in death between 24 to 48 h. In contrast, non-DB rats exhibited robust repair response resulting in complete recovery and survival. IL-6 measured in plasma of DB rats compared to non-DB rats significantly declined at 6 h after CCl_4 administration, suggesting a potential role in tissue repair. In conclusion, high fat diet yields a robust model of type 2 diabetes and CCl_4 hepatotoxicity is amplified in this model due to inhibited tissue repair. (Kitty DeGree Endowment & LBRSP)

957 MULTIPLE DRUG RESISTANCE GENE MODULATION BY STREPTOZOTOCIN.

J. M. Brady, A. L. Slitt and C. D. Klaassen. *Department of Pharmacology and Toxicology, University of Kansas Medical Center, Kansas City, KS.*

Xenobiotic transporters enable ionic and water-soluble xenobiotics to enter cells, as well as aid the excretion of these xenobiotics and/or their metabolites out of cells. Multiple drug resistance (mdr) genes encode P-glycoproteins, which are responsible for resistance to some cancer chemotherapeutic drugs and efflux of xenobiotics out of cells. Thus, mdr can protect organs from xenobiotics. In rats, there are two mdr1 genes capable of xenobiotic transport, mdr1a and mdr1b. A third gene product, mdr2, is associated with phospolipid transport and excretion of lipid into bile. Diabetes mellitus is associated with changes in the disposition of chemicals through altered biliary excretion. For example, the biliary excretion of digoxin and ouabain are significantly increased in diabetic rats. The purpose of this study was to determine whether streptozotocin (STZ)-induced diabetes regulates mdr transporters involved in biliary excretion. While mdr1a and 1b gene expression was not readily increased by microsomal enzyme inducers, in contrast to Phase I and II drug-metabolizing genes, there were specific chemicals such as STZ which induced

mdr mRNA levels. Bile flow remained normal at 5 and 10 days, but significantly increased at 20 and 30 days following STZ treatment. In a time-course study, there were modest increases in liver mdr1a mRNA levels. Liver mdr1b mRNA levels steadily increased with time more than 10 days after STZ treatment. Liver mdr2 mRNA levels tended to increase following STZ treatment, reaching statistical significance at days 10 and 30. In summary, STZ increased liver mRNA levels of mdr1a, mdr1b, and mdr2. The increase in mdr1a and 1b mRNAs may ultimately be responsible for the increased biliary excretion of cardiac glycosides, and the increase in mdr2 mRNA might be responsible for increased bile flow in STZ-induced diabetic rats. (Supported by NIH Grant ES-090716 and ES-03192)

958 INDUCTION OF FACIT COLLAGENS XII AND XIV DURING CARBON TETRACHLORIDE-INDUCED HEPATIC FIBROSIS.

D. R. Gerecke, B. Liu, L. A. Morio, P. Zhou, R. A. Hahn, J. D. Laskin, D. L. Laskin and M. K. Gordon. *Joint Graduate Program in Toxicology, Rutgers University and UMDNJ-Robert Wood Johnson Medical School, Piscataway, NJ.*

Prolonged exposure to carbon tetrachloride (CCl4) is associated with the development of hepatic fibrosis. The etiology of liver fibrosis includes the excessive accumulation of type I collagen leading to an abnormal thickening of the collagen fibrils. As a consequence, fibrotic liver has a reduced functional capacity and is unable to regenerate effectively. Collagens XII and XIV sit on the surface of collagen I fibrils and play a role in organizing collagen fibrils, assisting in the maintenance of uniform fibril size. Abnormal expression of these proteins can cause fibril thickening. In the present studies we determined if chronic carbon tetrachloride toxicity altered hepatic expression of collagen XII and XIV. Fibrosis was induced by intraperitoneal injection of CCl4 (0.3 ml/kg, twice per week for eight weeks) into female C57BL mice. Liver samples were collected 1, 3, 6, and 9 weeks after CCl4 or mineral oil control and fibrosis evaluated histologically. Hepatic expression of collagens I, XII, and XIV was quantified by immunohistochemistry and relative reverse transcription polymerase chain reaction. Increased collagen I expression in the liver was gradual, but continuous, throughout the study, beginning within one week of CCl4 exposure, reaching maximal levels by 9 weeks (a more than 15 fold increase). In contrast, expression of collagen XII was 2-4 fold greater than the controls within 3 weeks following CCl4 treatment. Unexpectedly, levels of collagen XIV remain unchanged throughout the fibrotic process. These changes in collagen levels corresponded with the increasing fibrosis of the livers over time. Increasing amount of collagen I with a constant amount of collagen XIV led to an overall dilution effect of collagen XIV. Our results are consistent with the idea that modulating the ratios of collagens I, XII and XIV play an important role in the matrix fibril organization during fibrosis.(Supported by NIH grants HL67708 and ES05022).

959 ANALYSIS OF GENDER DIFFERENCES IN EXPRESSION OF IGF-1, CYP1A2 AND CYP3A1 IN HUMAN LIVER.

S. Dial[1], A. Cromwell[2] and A. J. Harris[1]. *[1]Center for Hepatotoxicity, NCTR, Jefferson, AR and [2]Biology Department, Hendrix College, Conway, AR.* Sponsor: Y. Dragan.

Gender differences in hepatic gene expression may explain occasional differential responses to drugs or chemicals. With the advent of new genomic and proteomic analyses, it is now possible to ascertain if there are gender differences in gene expression that can be detected over inter-individual variation. In this study, the effects of gender on the mRNA or protein levels of several genes including insulin-like growth factor (IGF1), CYP1A2 and CYP3A1 were evaluated. Whole cell protein lysates were extracted from the liver of six adult male and six adult females. Western blot analysis of these samples indicated no gender differences in expression of IGF-1 or CYP3A1, however CYP1A2 protein levels were higher in males than females (P<.01). In addition, the CYP1A2 antibody reacted with a cytosolic protein, not evident in the microsomal fraction that was also expressed at higher levels in males than females (P<.05). A homology search of human protein databases using the CYP1A2 peptide used to generate the anti-CYP1A2 antibody tentatively identified this unknown protein as a methyltransferase. These results suggest there are gender differences in the expression of some hepatic proteins.

960 GLIBENCLAMIDE AND TROGLITAZONE INHIBIT THE CUMULATIVE UPTAKE AND BILIARY EXCRETION OF TAUROCHOLATE (TC) IN SANDWICH-CULTURED RAT HEPATOCYTES (SCRH).

D. C. Kemp and K. Brouwer. *Curriculum in Toxicology, University of North Carolina, Chapel Hill, NC.* Sponsor: J. lemasters.

The canalicular bile salt export pump (Bsep; Abcb11) excretes conjugated and unconjugated bile acids into bile. Inhibition of Bsep may cause hepatocellular accumulation of bile salts leading to hepatotoxicity. The SCRH model mimics extracellular matrix geometry, prolongs hepatocyte viability, preserves liver specific protein synthesis, re-establishes canalicular networks, and maintains the functional activity of basolateral and canalicular transport proteins. Freshly isolated hepatocytes from male Wistar rats were cultured for 4 days between two layers of gelled collagen. Culture media consisted of Dulbecco's Modified Eagle's Medium (DMEM), supplemented with 5% fetal bovine serum and insulin (4 mg/L) for the first 24 hrs; subsequently DMEM was supplemented with 1% ITS (insulin, transferring, selenium, linoleic acid and bovine serum albumin) replaced every 24 hrs. SCRH were used to examine alterations in the hepatic uptake and biliary excretion of TC by hepatotoxic drugs. Differential accumulation (mean+/-SEM) of [3H] TC (10mM) in Day 4 SCRH (n = 3 livers in triplicate) incubated in standard Hanks Balance Salt Solution (HBSS pH = 7.4) or Ca2+-free HBSS (disruption of tight junctions), and the biliary excretion index (BEI; percentage of accumulated substrate in canalicular networks) were quantitated. The cumulative uptake of [3H] TC in hepatocytes preincubated 10 min with glibenclamide (10 mM), or troglitazone (10 mM) in standard HBSS decreased from 523+/-124 to 375+/-11 pmol/mg protein with glibenclamide, and 324+/-78 to 159+/-24 pmol/mg protein with troglitazone. In the presence of glibenclamide or troglitazone, the BEI of TC was reduced from 60+/-16 to 40+/-10% by glibenclamide, and 53+/-17 to 25+/-5% by troglitazone. Based on data generated in SCRH, glibenclamide and troglitazone inhibited both basolateral uptake and canalicular excretion of taurocholate. Supported by NIH GM41935.

961 FIBRATES INDUCE PEROXISOMAL AND MITOCHONDRIAL PROLIFERATION IN CYNOMOLGUS MONKEYS WITHOUT CAUSING CELL CYCLE ALTERATIONS OR OXIDATIVE STRESS.

C. W. Qualls[1], D. J. Hoivik[1], M. J. Santostefano[1], H. R. Brown[1], S. P. Anderson[1], R. J. Ott[1], B. R. Oliver[1], P. N. Mudd[1], R. C. Mirabile[2], C. L. Kimbrough[1] and R. T. Miller[1]. *[1]GlaxoSmithKline, Research Triangle Park, NC and [2]GlaxoSmithKline, Upper Marion, PA.*

In mice and rats, peroxisome proliferator-activated receptor (PPAR) α agonists cause a plethora of hepatic effects including liver and hepatocellular hypertrophy, hepatocellular hyperplasia, increased β and ω oxidation of lipids, increased oxidative stress, increased hepatocellular proliferation and ultimately hepatocellular neoplasms. In these species hepatocarcinogenesis likely results from a combination of cell cycle alterations and oxidative stress. Humans and other primates are generally thought to be refractory to peroxisome proliferation (PP). PP has not been adequately evaluated at clinically relevant exposures (CRE) in primates. We treated male cynomolgus monkeys with one of two marketed hypolipidemic fibrates (PPAR α agonists). They received either fenofibrate (0, 250, 1250 or 2500mg/kg/d) or ciprofibrate (0, 3, 30, 150 or 400mg/kg/d) for 15 days. Significant hepatic (up to 2 fold weight increase) and hepatocyte (qualitative) hypertrophy, increased peroxisome numbers (up to 2.7 fold), and mitochondria numbers (up to 2.5 fold) were observed at exposures that were ~4X of CRE. Mitochondrial but not peroxisomal area was increased. In general, acyl-CoA oxidase mRNA and activity increases correlated with PP. Catalase activity and mRNA was unchanged. Cell proliferation (apoptotic/mitotic activity and Ki-67 expression) was not increased. Contemporaneously, transcriptome profiling using human oligonucleotide arrays failed to show significant evidence of cell cycle alterations, increased apoptosis, oxidative stress or DNA damage. In conclusion, numeric PP occurs at ~4X the CRE in non-human primates but is not associated with an increase in peroxisomal area. The weight of evidence reveals a lack of cell cycle alterations, DNA damage, or oxidative stress at either the cytologic or the transcriptomic level.

962 EFFECT OF ILEAL RESECTION OR CHOLESTYRAMINE TREATMENT ON SERUM TRANSAMINASES IN RATS.

R. Duan, C. Wilker, K. Gal, M. Gralinski, B. Keller, N. Napawan, E. Krul and E. Blomme. *Toxicology, Pharmacia, Skokie, IL.* Sponsor: M. Schlosser.

Most hypocholesterolemic compounds, despite acting by different mechanisms, have been associated with mild, unexplained, asymptomatic elevations of serum alanine aminotransferase (ALT) and aspartate aminotransferase (AST) in humans. In this study, using the cholestyramine-treated and ileal resection rat models, we investigated whether interruption of the enterohepatic circulation of bile acids would affect the serum levels of ALT and AST in rats. In addition, we examined the potential mechanisms for these changes in serum ALT and AST following inhibition of bile acid reabsorption. In the first model, Sprague-Dawley IGS rats were treated for 2, 4, 13 and 26 weeks with a standard diet or a standard diet containing 4% cholestyramine. In the second model, rats were subjected to a sham surgery or to an ileal resection, and sacrificed 2, 4 or 13 weeks following surgery. As anticipated, the activity and mRNA levels of cholesterol 7alpha-hydroxylase and HMG-CoA reductase increased following cholestyramine treatment or ileal resection, indicating a

disruption of the enterohepatic circulation of bile acids in both models. In both genders, there were mild, reversible increases in serum ALT and AST following cholestyramine treatment for 2, 4 and 13 weeks, although serum ALT and AST levels returned to control levels after treatment for 26 weeks. In the ileal resection model, there were also mild increases in serum ALT and AST 2 and 4 weeks after surgery. In both models, there was no histologic evidence of liver change. Furthermore, the elevations in serum ALT and AST were not due to increases in hepatic synthesis, since ALT and AST mRNA levels after cholestyramine treatment or ileal resection were similar to those of control rats. In conclusion, our results provide evidence that transient, reversible elevations of serum ALT and AST observed following ileal resection or treatment with cholestyramine or other cholesterol-lowering agents are more consistent with a pharmacologic response and are not related to hepatotoxicity.

963 ALTERED SUBCELLULAR DISTRIBUTION OF HEAT SHOCK PROTEIN 90 (HSP90) IN LIVER OF DIELDRIN-FED RAINBOW TROUT.

L. R. Curtis, D. L. Villeneuve and J. Lee. *Env. and Molec. Toxicology, Oregon State University, Corvallis, OR.*

Feeding rainbow trout 0.3 mg dieldrin/kg/day for 9-12 weeks stimulates biliary excretion of intraperitoneal challenge doses of 3 mg [^{14}C]dieldrin/ kg 5-fold and 3 mg [^{14}C]benzo[a]pyrene(BP)/kg 2-fold. This occurs without induction of the hepatic microsomal cytochrome P450 system (Fund. Appl. Toxicol. 30:187) or epoxide hydrolase. However, dieldrin increases [^{3}H]BP binding in rainbow trout hepatic cytosol from 22 to 50 pmol/mg protein. Purification of proteins from hepatic cytosol by size exclusion chromatography yields a fraction with high [^{3}H]BP binding affinity that contains a 90 kD protein. Electrospray ionization mass spectrometry identifies this protein as HSP90 (Toxicologist 66:368). The working hypothesis is that HSP90 functions as a constituent in a protein complex that traffics dieldrin and BP to intracellular sites of metabolism. If feeding dieldrin stimulates assembly and/or intracellular movement of this putative trafficking complex, subcellular distribution of HSP90 may reflect it. Western blots indicate hepatic cytosol from dieldrin-fed fish contains about 65% less HSP90 than cytosol from control fish. Hepatic microsomes from dieldrin-fed fish contain up to 3-fold more HSP90 than controls. This is consistent with the hypothesis that dieldrin stimulates trafficking of a protein complex that contains HSP90 to an intracellular site of metabolism. Supported by PHS grant P30 ES03850.

964 LATE ADMINISTRATION OF COX-2 INHIBITORS MINIMIZE HEPATIC NECROSIS IN CHLOROFORM INDUCED LIVER INJURY.

C. Begay and A. Gandolfi. *Pharmacology & Toxicology, University of Arizona, Tucson, AZ.*

Our previous studies have described the protective effects of hepatoprotective agents against liver injury elicited by chloroform even when given 24 hours after the toxicant, at a time when the liver injury is taking place and rapidly developing. However, the mechanisms involved in this protection remain unknown. The cytoprotective mechanism of these hepatoprotectants such as DMSO, may be due to a dramatic shift in the production of prostaglandins that are responsible for controlling the degree of inflammatory response that can affect blood flow in the liver. In this study, NS-398, a specific COX-2 inhibitor, and indomethacin, a COX-1 and COX-2 inhibitor, were administered 24 hr after chloroform dosing to determine their effect on liver injury in Sprague-Dawley rats. The extent of necrosis was evaluated by H&E staining, while injury to hepatocytes was evaluated by measuring plasma levels of alanine transaminase (ALT). Both COX inhibitors, indomethacin and NS-398, prevented an increase in (ALT) at 48 hr after initial toxicant insult and attenuated further liver necrosis. No changes in cellular proliferative activity occurred in all the treatment groups, which indicates that protection from the COX inhibitors did not have an effect on regeneration of cells at 32 hr and 48 hr. These results indicate COX inhibitors provide a significant protective effect on liver cells against CHCl3 injury and may provide further insight into therapeutic interventions against hepatotoxicants. (NIH ES 08414)

965 TOXICOKINETICS OF THIOACETAMIDE EXPLAINS LACK OF DOSE-RESPONSE FOR LIVER INJURY IN *AD LIBITUM* AND DIET-RESTRICTED RATS.

J. Chilakapati[1], K. Shankar[1], R. A. Hill[2] and H. M. Mehendale[1]. *[1]Toxicology, University of Louisiana at Monroe, Monroe, LA and [2]Basic Pharmaceutical Sciences, University of Louisiana at Monroe, Monroe, LA.*

Previous studies have established that thioacetamide (TA) is bioactivated by CYP2E1 to TA sulfoxide (TASO), which is further bioactivated to sulfdioxide (sulfone), an unstable ultimate reactive metabolite that initiates centrilobular hepatic necrosis. Earlier studies have shown that despite higher hepatotoxic injury of TA by enhanced bioactivation, diet restriction (DR) protected the rats from a lethal dose of TA. Low dose of TA (50 mg/kg) produced a 6-fold higher injury whereas a 12-fold higher dose of TA produced only 2.5-fold higher and delayed liver injury compared to ad libitum (AL) fed rats. The objective of present work was to determine if lack of dose response for injury in AL rats and higher injury in DR rats could be explained by toxicokinetics of TA. Male Sprague-Dawley rats were 35% diet restricted for 21 days and on the 22nd day, both AL and DR rats were administered 50 or 600 mg TA/kg ip in saline. TA and its major metabolite TASO were quantified in plasma at various time points. In the AL rats, with increasing doses (i.e., from 50 to 600 mg/kg), the half-lives of both TA (18 to 270 min) and TASO (38 to 280 min) were increased, indicating that TA bioactivation exhibits mixed kinetics: first order at low dose and zero order at high dose. Increasing TA dose resulted in a marked increase in plasma TA and TASO. The TASO/TA ratio was highest for the 50 mg/kg dose while it was the lowest for the 600 mg/kg dose. This may explain the significant liver injury seen upon administration of a low dose (50 mg/kg), and lack of appreciable increase in bioactivation-based liver injury with the high dose (600 mg/kg) in AL rats. In the DR rats, for both doses (600 and 50 mg TA/kg), there was a decrease in the half-life of TA (270 to 220 min. and 18 to 13 min) and TASO (280 to 240 min. and 38 to 31 min.) compared to AL rats suggesting that there is higher bioactivation resulting from higher CYP2E1 seen in the DR rats. 966 KAVA INDUCES HEPATOTOXICITY IN MALE B6C3F1 MICE.

D. J. Smith, L. M. Kamendulis and J. E. Klaunig. *Department of Pharmacology and Toxicology, Indiana University School of Medicine, Indianapolis, IN.*

Kava (Piper methysticum), an herbal supplement used as an anxiolytic, has been reported to cause liver injury in humans. No published studies demonstrating hepatotoxicity of Kava in other species have been located. Pharmacological activity of Kava has been associated with six major kavalactones: Dihydromethysticin (DHM), Kawain, Yangonin, Methysticin, 7, 8 Dihydrokawain (7, 8 DHK), and 5, 6 Dehydrokawain (5, 6 DHK). The present study examined the effect of Kava and each of the six-major kavalactones on toxicity (LDH release) in B6C3F1 primary mouse hepatocytes. Hepatocytes were cultured for 24 hours with Kava (0 to 0.6 mg/ml kavalactones) and toxicity measured. A dose related increase in LDH release was seen with Kava. The non water-soluble fraction of Kava (kava resin) was purified from Kava root for examination of toxicity. Hepatocytes dosed with Kava resin (0 to 500 mg/ml) for 24 hours showed an increase in LDH release at 250 and 500 mg/ml (~5.5 fold over control). Toxicity of the 6 kavalactones was also assessed (0 to 125 µg/ml). DHM was the most toxic, producing LDH release at and above 40 µg/ml (3.9 to 7.6 fold). Yangonin and 7, 8 DHK induced toxicity at and above 50 µg/ml (2.1 to 2.6 fold) and 75 µg/ml (2.55 to 3.5 fold), respectively. Methysticin was toxic at 100 and 125 µg/ml (2.8 to 3.3 fold). Kawain was toxic only at 125 µg/ml (2.7 fold). 5, 6 DHK was not toxic at the highest concentration examined. Co-treatment of DHM (10, 25, and 75 µg/ml) with aminobenzotriazole (0.1 and 0.5 mM), a P450 inhibitor, had no effect on DHM toxicity. Similarly, co-treatment of DHM (10, 25, and 75 µg/ml) with buthionine sulfoximine (1.0 and 5.0 mM), which depletes glutathione, had no effect on DHM toxicity. Kava resin (20 mg/kg, i.p.) was also administered to B6C3F1 male mice for 5 days producing slight liver toxicity as measured by elevated AST and focal hepatic necrosis. These studies provide evidence that Kava and selective kavalactone components are hepatotoxic.

967 *o*-HYDROXYPHENYLACETALDEHYDE (*O*-HPA) DETOXIFICATION IS A MAJOR DETERMINANT OF COUMARIN-INDUCED HEPATOTOXICITY.

J. D. Vassallo[1], G. P. Daston[1] and L. D. Lehman-Mckeeman[2]. *[1]Procter & Gamble, Cincinnati, OH and [2]Bristol-Myers Squibb, Wilmington, DE.*

o-HPA is a toxic metabolite formed in the absence of glutathione (GSH) following the oxidation of coumarin to coumarin 3, 4-epoxide (CE). Coumarin is toxic in rats, and formation of CE is thought to be the requisite step leading to hepatotoxicity. Metabolic formation of CE is greatest in mice, a species showing no evidence of toxicity. Since CE formation is not directly related to hepatotoxicity, and GSH conjugation of CE is similar in mice and rats, *o*-HPA detoxification is implicated as the major determinant of hepatotoxic potential. The purpose of the present work was to determine whether the detoxification reactions of *o*-HPA contribute to species differences in coumarin-induced hepatotoxicity. In F344 rat liver cytosol, *o*-HPA was oxidized to *o*-hydroxyphenylacetic acid (*o*-HPAA) with a Vmax of 1.2 nmol/min/mg protein and a Km of 7.4 µM. In contrast, the Vmax and Km for *o*-HPAA formation in B6C3F1 mouse liver cytosol were 5.4 nmol/min/mg protein and 2.2 µM, respectively yielding an intrinsic clearance through oxidation that was 15-times higher than the rat. Similarly, the Vmax and Km for oxidation were 5.2

nmol/min/mg protein and 0.5 μM, respectively in pooled human liver cytosol, representing an intrinsic clearance that was 62-times higher than the rat. All species reduced *o*-HPA to *o*-hydroxyphenylethanol (*o*-HPE), and the Km for reduction was 8.7, 65.4 and 10.5 μM in rat, mouse and human cytosol. The similar Km for oxidation and reduction in rats suggests they are equally likely to reduce or oxidize *o*-HPA, whereas mice and humans favor oxidation to non-toxic *o*-HPAA. The fate of ring-opened coumarin metabolites was evaluated in mouse liver microsomes containing mouse, rat or human hepatic cytosol. *o*-HPAA was the only metabolite formed in mouse and human cytosol, whereas the rat formed *o*-HPAA, *o*-HPE and *o*-HPA. Collectively, these data implicate *o*-HPA detoxification as the major determinant of coumarin-induced hepatotoxicity in the rat and suggests humans are unlikely to be sensitive to this toxicity.

968 EFFECTS OF STRUCTURAL MODIFICATIONS ON THE HEPATOTOXICITY OF 3-(3, 5-DICHLOROPHENYL)-2, 4-THIAZOLIDINEDIONE (DCPT) IN FISCHER 344 RATS.

N. N. Patel, R. Tchao, E. L. Kennedy and P. J. Harvison. *University of the Sciences in Philadelphia, Philadelphia, PA.*

3-(3, 5-Dichlorophenyl)-2, 4-thiazolidinedione (DCPT) is hepatotoxic in rats. The thiazolidinedione (TZD) ring is also present in the insulin-sensitizing drugs that are used for treatment of type II diabetes. These drugs have been shown to cause liver damage in some patients. To further investigate DCPT-induced hepatotoxicity, 3-phenyl-2, 4-thiazolidinedione (PTZD) and 3-(3, 5-dichlorophenyl)-5-methyl-2, 4-thiazolidinedione (DPMT) were synthesized. Male, Fischer 344 rats were administered DCPT (0.6 mmol/kg), DPMT (0.6 and 1 mmol/kg) or PTZD (0.6 and 1 mmol/kg) ip in corn oil. Control animals received corn oil (4 ml/kg) only. Liver and kidney function and morphology were assessed at 24 hrs. Compared to controls, the other treatment groups showed mild to moderate ketonuria and marked diuresis within 6 hrs. There was no change in liver or kidney weights. Serum alanine aminotransferase (ALT) levels were significantly elevated in the DCPT-, PTZD- and DPMT-treated rats compared to the controls. In contrast, blood urea nitrogen (BUN) levels were not altered by any of the compounds. Also blood glucose, urine protein and glucose levels were unaffected. The histological results showed pockets of liver necrosis with infiltration of neutrophils in the PTZD-treated animals, suggesting a possibility of widespread hepatic infarction. DCPT- and DPMT-treated animals showed no necrosis, but the hepatocytes were clearly damaged near the centrilobular vein and the cytoplasm in the cells was condensed and irregularly stained. Except for minor cellular swelling in some proximal tubules, there was no evidence of kidney damage in any of the treatment groups. In conclusion, DCPT, PTZD and DPMT produce significant liver damage, but only mild kidney damage, in rats. Our results show that DCPT-induced hepatotoxicity is not sensitive to the presence of chlorines in the phenyl ring or a methyl group in the TZD ring. This suggests that hepatotoxicity is inherent in the TZD ring itself; however, this will require further investigation.

969 RESPONSE OF LIVER SLICES TO HEPATOXICANTS ASSESSED USING TRADITIONAL CLINICAL CHEMISTRY MARKERS.

H. P. Behrsing and C. A. Tyson. *Toxicology Laboratory, SRI International, Menlo Park, CA.*

Precision-cut liver slices have long been of interest to toxicologists as a optimal model for the study of hepatotoxicity mechanisms and screening but have had limited use in such applications, in part because of their relatively short survival time in culture. Recent reports from different laboratories show progress in addressing this shortcoming, prompting reexamination of the potential this model offers. We chose to examine the method developed by Saulnier and Vickers (The Toxicologist, 2002) for this purpose. Following their modified isolation procedure, liver slices were prepared from male Sprague-Dawley rats and cultured in various media under a 70% O_2-containing atmosphere for up to 5 days. Good retention of viability (80% or higher) was obtained in Waymouths-like media based on biochemical and morphological assessments. The response to 6-mercaptopurine (6MP) and geldanamycin (GEL) compounds, which exhibit anticancer activity but different toxicity profiles in rat liver, was studied using traditional clinical chemistry markers in 3-day incubations. 6MP at 0.25 and 5.0 mM produced concentration- and time-dependent reductions in slice contents of AST, ALT and LDH and media levels increased correspondingly. Changes in slice biliary markers were more complex and inconsistent, due in part to the relatively lower levels measurable. Morphological examination of the tissues showed biliary cells to be intact and viable under conditions where hepatocyte viability had substantially degenerated. GEL in the 0.10 to 10 μM range produced analogous effects on ALT and LDH but with higher loss of alkaline phosphatase compared with 6MP. Morphologically, both liver and biliary system viability was markedly lower in concert at enzyme reductions of approximately 50% or greater. These investigations are being extended to determine the value of this improved system for discriminating different types of liver injury. This work was supported by NCI grant R21CA93262.

970 TEMPORAL EXPRESSION PATTERNS OF GENES IN THE LIVERS OF IMMATURE, OVARIECTOMIZED MICE TREATED WITH ETHYNYL ESTRADIOL.

D. R. Boverhof, K. C. Fertuck, L. D. Burgoon, R. S. Aiyar and T. R. Zacharewksi. *Biochemistry & Molecular Biology, National Food Safety & Toxicology Center, and Institute for Environmental Toxicology, Michigan State University, East Lansing, MI.*

Changes in global gene expression were examined in the livers of immature ovariectomized C57BL/6 mice treated with ethynyl estradiol (EE), a synthetic estrogen. Mice were gavaged once or 3x24hr with 0.1mg/kg EE or vehicle and livers were harvested at 0, 2, 4, 8, 12, 24 or 72 hrs. A cDNA microarray was used to assess the relative expression levels of 3068 genes using a reference design in which samples from EE treated mice were co-hybridized with samples from time-matched vehicle controls (TMV). To identify genes with significant expression changes, least squares means from a general linear mixed model of EE samples were compared to TMV samples using t-tests. Approximately 4-8% of the genes examined at each time point exhibited significant changes in expression ($p<0.01$). A gene annotation tool that interfaces with our toxicogenomic supportive relational database, dbZach (http://dbzach.fst.msu.edu), was used to associate Gene Ontology functional categories with members of the significant gene set. This identified a large number of second messenger, transcription factor and signal transduction genes (e.g. c-fos, c-jun, signal transducer and activator of transcription 5A, transcription factor 12, transglutaminase 2, and laminin 3B) and various cytochrome P450 enzymes involved in steroid and cholesterol biosynthesis that were significantly altered in response to EE. The promoters of many of these genes were retrieved from the UCSC database, screened for the presence of perfect estrogen response elements (EREs) and were found to contain this motif suggesting direct regulation by the estrogen receptor. The dramatic alteration of diverse signaling cascades illustrates the complexity of estrogen action in the liver. This, combined with the importance of the liver in metabolism and toxicity, suggests that evaluating hepatic responses will be important in future assessments of estrogen action in the intact organism. Supported by ES011271

971 PROTECTION BY NITRIC OXIDE AND CGMP AGAINST ISCHEMIA/REPERFUSION INJURY IN CULTURED RAT HEPATOCYTES.

S. Ohshima, J. Kim and J. J. Lemasters. *UNC-Chapel Hill, Chapel Hill, NC.*

BACKGROUND: Nitric oxide (NO) is an important signaling mediator involved in ischemic preconditioning, a phenomenon that confers tolerance of tissue against ischemia/reperfusion. Onset of the mitochondrial permeability transition (MPT) causes apoptotic and necrotic cell death to hepatocytes after ischemia/reperfusion. The **AIM** of this study was to investigate whether NO can block MPT-dependent ischemic hepatocellular killing after reperfusion. **METHODS:** To simulate ischemia, 1-day cultured rat hepatocytes were incubated in anoxic Krebs-Ringer-HEPES (KRH) buffer at pH 6.2 for 4 h. To simulate reperfusion, hepatocytes were then reoxygenated at pH 7.4 for 2 h. In some experiments, hepatocytes were exposed to NO from 200 μM S-nitroso-N-acetylpenicillamine (SNAP), a slow NO donor, from the beginning of reoxygenation. In other experiments, cells were incubated with 100 μM 1H-(1, 2, 4)-oxadiazolo-(4, 3) quinoxalin-1-one (ODQ, a guanylate cyclase inhibitor), 50 μM 8-Br-cGMP (a cGMP analogue), or 5 μM KT5823 (a cGMP-dependent kinase inhibitor) beginning 20 min prior to reoxygenation. Cell viability was determined by propidium iodide fluorometry. **RESULTS:** After reperfusion at pH 7.4, cell viability decreased to 36.3 ± 1.9% after 2 h of reperfusion (n=16). Viability increased to 76.5 ± 3.0% with SNAP but not with the oxidized product of SNAP. Reoxygenation at pH 6.2 led to similar protection. 8-Br-cGMP also blocked cell killing. In contrast, ODQ and KT5823 reversed cytoprotection by SNAP. ODQ and KT5823 alone did not affect cell viability. **CONCLUSION:** These results suggest that NO prevents MPT-dependent cell killing of hepatocytes after ischemia/reperfusion by a guanylate cyclase-and kinase-dependent pathway.

972 ACTIVATION OF SIGNAL TRANSDUCTION PATHWAYS IN HEPATIC PARENCHYMAL CELLS ARE REQUIRED FOR NEUTROPHIL-DEPENDENT KILLING.

B. L. Copple, B. Woolley, C. Rondelli, P. E. Ganey and R. A. Roth. *Pharmacology and Toxicology, Michigan State University, East Lansing, MI.*

Neutrophils (PMNs) are cells of the immune system which are part of the first line of defense against invading pathogens. Under certain conditions, however, these cells can damage host tissue. For example, they produce hepatic parenchymal cell

(HPC) injury after exposure of rats to bacterial lipopolysaccharide and can magnify injury during chemical hepatotoxicity. *In vitro*, proteases, such as elastase and cathepsin G, released from activated PMNs damage HPCs. These proteases activate signal transduction pathways in other cell types. Therefore, the hypothesis was tested that killing of HPCs by PMNs requires activation of signal transduction pathways in HPCs. To this end, killing of primary rat HPCs by medium isolated from activated PMNs (PMN conditioned medium) was evaluated in the presence of inhibitors of various signaling pathways. The nonspecific serine/threonine kinase inhibitors, H7 and HA-1004, completely prevented killing of hepatocytes by PMN conditioned medium; whereas, selective inhibitors of protein kinase C, A, and G did not. In addition, genistein, a nonspecific tyrosine kinase inhibitor, prevented killing of hepatocytes by PMN conditioned medium. Finally, incubation of HPCs with PMN conditioned medium caused production of reactive oxygen species (ROS) in HPCs, and desferrioxamine, an iron chelator, completely prevented killing of HPCs by PMN conditioned medium. These results suggest that reactive oxygen species and activation of serine/threonine and tyrosine kinases in HPCs are important for their killing by activated PMNs. (Supported by NIH grants ES04139)

973 NITRIC OXIDE-MEDIATED SUPPRESSION OF FLAVIN-CONTAINING MONOOXYGENASE (FMO) ACTIVITIES IN CULTURED PRIMARY RAT HEPATOCYTES BY DESTABILIZING THE MRNA AND S-NITROSYLATION OF FMO1.

S. Ryu, W. Chung, J. Kang and C. Park. *Pharmacology, National Institute of Toxicological Research, Seoul, South Korea.*

Objectives: The present work is to investigate the effect of nitric oxide (NO)-donors treated exogenously on the metabolic activities of flavin-containing monooxygenase in cultured primary rat hepatocytes. Background: Overproduction of NO by inducible NO synthase (iNOS) is a common phenomenon in inflammation. At this time, the NO has been implicated as the mediator of decreased catalytic activity and expression of drug-metabolizing enzymes such as cytochrome P450s (CYPs) and flavin-containing monooxygenases (FMOs). Previous work in our laboratory suggests that FMO activities in rat liver treated with LPS are decreased by down-regulation of FMO1 mRNA expression *in vivo* (Park et al., 1999, Mol Pharmacol). Methods: Rat hepatocytes were isolated from rat livers perfused with collagenase. The cells were then treated for 4 h with NO-donors like SNAP or SIN-1. The FMO1 mRNA expression was compared after pretreatment of actinomycin-D to examine the effect of NO on the mRNA stability. The metabolic FMO activities were determined by ranitidine N-oxidation and thiobenzamide S-oxidation estimated with HPLC and spectrophotometer, respectively, in the absence or presence of DTT, a sulfhydryl-reducing agent. Results: FMO activities determined in hepatocytes treated with NO-donors were significantly suppressed to 20-40% of those in untreated control hepatocytes. However, the expression of FMO1 mRNA was not decreased or slightly decreased. Interestingly, stability of FMO1 mRNA after pretreated with actinomycin-D was decreased significantly by exposure to NO donors. Furthermore, the inhibition of *ex vivo* and *in vitro* FMO activities estimated with microsomes exposured to NO donors was reversed completely by addition of DTT. Conclusions: These results suggest that FMO activities in hepatocytes can be decreased both by enhanced unstability of FMO1 mRNA leading to decreased FMO1 expression and by reversible S-nitrosylation of the existing FMO1.

974 INVOLVEMENT OF PHOSPHATIDYLINOSITOL 3-KINASE IN HEPATIC STELLATE CELL ACTIVATION AND ANTIOXIDANT RESPONSE ELEMENT-REGULATED GENE INDUCTION.

J. F. Reichard, M. S. Taylor and D. R. Petersen. *Pharmaceutical Sciences, UCHSC, Denver, CO.*

Liver fibrogenesis is dependant upon transdifferentiation of hepatic stellate cells (HSC) to a profibrogenic myofibroblastic phenotype. Electrophilic intermediates generated during prooxidant-induced liver injury, including 4-hydroxynonenal (4-HNE), purportedly modulate HSC gene expression and possibly HSC transdifferentiation. The extent to which 4HNE modulates HSC gene expression remains unclear. The objective of this study is to characterize the response of HSC to electrophiles, and the role of 4HNE in profibrogenic HSC activation. To this end, quiescent HSC were treated with 4HNE or tert-butylhydroquinone (tBHQ), both of which are known inducers of antioxidant response element (ARE)-regulated genes. Electrophilic agents elicit ARE-mediated gene induction through release of the cis-acting transcription factor Nrf2 from its cytoplasmic anchor protein (Keap1), allowing Nrf2 to translocate into the nucleus and participate in ARE-regulated gene induction. These studies demonstrate that both 4HNE and tBHQ induce nuclear translocation of Nrf2 and expression of GSTP1, a gene that is solely regulated by the ARE. This observation is further supported by Nrf2-mediated induction of luciferase in cultured HSC. In contrast to ARE induction, tBHQ but not 4HNE promotes myofibroblastic transdifferentiation of HSC. Pretreatment of cultured HSC with a phosphatidylinositol 3-kinase (PI3K) inhibitor blocked tBHQ-mediated ARE-dependant gene induction and HSC activation, but has no effect on HNE-mediated gene induction. These data implicate involvement of the mitogen-activated protein kinase (MAP kinase) pathway in tBHQ-mediated HSC activation and ARE gene regulation; while the trigger by which 4HNE mediates ARE-dependant gene induction is PI3K independent. We hypothesize 4HNE-mediated ARE activation may involve direct interactions between 4HNE with any of the 25 cysteine residues that compose Keap1. (This work is supported by NIH/AA05578-03 and NIH/AA09300.)

975 THE ROLE OF THE ALPHA$_1$ ADRENERGIC RECEPTOR IN THE RESTRAINT-INDUCED PHOSPHORYLATION OF STAT3.

E. A. Johnson[1], J. P. O'Callaghan[2] and D. B. Miller[1]. *[1]Chronic Stress and Neurotoxicology Laboratory, Toxicology and Molecular Biology Branch, NIOSH-CDC, Morgantown, WV and [2]Molecular Neurotoxicology Laboratory, Toxicology and Molecular Biology Branch, NIOSH-CDC, Morgantown, WV.*

Stress causes physiological changes in most organ systems in intact organisms. The Janus kinases-signal transducers and activators of transcription (JAK-STAT) signaling pathways are believed to be crucial in these changes but have received limited investigation utilizing *in vivo* stress models. We previously showed that the restraint of mice results in a substantial activation of STAT-3 in liver but the mechanism responsible for this activation is unknown. One critical component of the response to stress involves activation of the sympathetic nervous system and release of the catecholamines epinephrine and norepinephrine. In this work we used agonists and antagonists of the alpha adrenergic receptor to examine the role of the catecholamines in the activation of STAT-3 in liver. C57Bl6J mice were restrained in centrifuge tubes (2.5 cm inner diameter) for 2 or 4 hours and killed immediately afterward by focused microwave irradiation. The phosphorylation state of STAT3 was determined by western blotting and chemiluminescence detection using phospho state-specific antibodies. In confirmation of our previous work restraint produced large increases in p-STAT3. Phentolamine, an alpha-adrenegic antagonist given (10 mg/kg s.c.) 30 minutes before the start of restraint completely blocked the phosphorylation of STAT3. Further, the alpha1-adrenergic agonist phenylephrine when given (10 mg/kg s.c.) to unrestrained mice stimulates phosphorylation of STAT3 by more than 10 fold within 2 hours of the injection. Our data suggest that catecholamines acting through alpha adrenergic receptors play a crucial role in the activation of STAT3 induced by restraint.

976 15-DEOXY-PROSTAGLANDIN J2 ENHANCES ALLYL ALCOHOL-INDUCED TOXICITY IN RAT HEPATOCYTES.

J. Maddox, R. A. Roth and P. E. Ganey. *Michigan State University, East Lansing, MI.*

Allyl alcohol (AA) induces hepatotoxic responses that are potentiated by small doses of bacterial lipopolysaccharide (LPS). Previous research from this laboratory has shown that cyclooxygenase-2 is involved in the augmentation of AA liver damage by LPS *in vivo*. Studies *in vitro* showed a significant enhancement of hepatocyte (HC) killing by prostaglandin D2 (PGD2), but no effect by PGE2. In studies presented here, 15-deoxy-PGJ2 (15d-PGJ2), a non-enzymatic product of PGD2, enhanced AA cytotoxicity *in vitro* to a much greater extent than PGD2. HCs were freshly isolated from rat livers, adhered to tissue culture wells and exposed to PGs for 2 h. HCs were then exposed to various concentrations of AA for up to 90 min. HC killing was assessed from the release of alanine aminotransferase (ALT). The concentration required for half-maximal cytotoxicity by AA (EC50) was reduced by half with 15 μM 15d-PGJ2 (from 50 μM to 25 μM AA). Though 15d-PGJ2 has been identified as a peroxisome proliferator-activated receptor γ (PPARγ) agonist, it did not appear to act through PPARγ to elicit this activity because a synthetic PPARγ agonist neither augmented AA cell killing by itself nor affected the activity of 15d-PGJ2. 15d-PGJ2 has been suggested to act *via* cyclic AMP (cAMP) in macrophages, but in HCs augmentation of cAMP activity with IBMX, or inhibition of protein kinase A with HA-1004, had no effect on enhanced cell killing by 15d-PGJ2. Protein synthesis was markedly decreased by 15d-PGJ2 in HCs, but inhibition of protein synthesis did not appear to cause cell death, as shown by a lack of ALT release with treatment of cells with cyclohexamide alone. 15d-PGJ2 inhibited translocation of the p65 fragment of nuclear factor kappa B (NF kappa B) from the cytosol to the nucleus in a manner additive with AA. In addition, an inhibitor of NF kappa B enhanced AA-induced HC death. Together, these results indicate that 15d-PGJ2 augments HC killing by AA, and the mechanism may be related to the inhibition of NF kappa B activation. (Supported by NIEHS 08789)

977 MODEST INFLAMMATION RENDERS RANITIDINE HEPATOTOXIC: IS THERE A RELATIONSHIP TO DRUG IDIOSYNCRASY?

J. P. Luyendyk[1], J. F. Maddox[1], G. N. Cosma[2], P. E. Ganey[1], G. L. Cockerell[2] and R. A. Roth[1]. *[1]Department of Pharmacology and Toxicology, Institute for Environmental Toxicology, National Food Safety and Toxicology Center, Michigan State University, East Lansing, MI and [2]Investigative Toxicology, Pharmacia Corp., Kalamazoo, MI.*

Drug idiosyncrasy is an adverse event of unknown etiology that occurs in a small fraction of people taking a drug. Some idiosyncratic drug reactions may occur from episodic decreases in the threshold for drug hepatotoxicity. Previous studies in rats have shown that modest underlying inflammation caused by bacterial lipopolysaccharide (LPS) reduces the threshold for several hepatotoxicants. The H2-receptor antagonist ranitidine (RAN; ZANTAC®) causes idiosyncratic reactions in people, with liver as a frequent target. We tested the hypothesis that RAN could be rendered hepatotoxic in animals undergoing a modest inflammatory response. Male rats were treated with a nontoxic dose of LPS (44 x 10^6 EU/kg, iv) or its vehicle, then two hours later with a nontoxic dose of RAN (30 mg/kg, iv) or its vehicle. Rats were sacrificed 3, 6, 12 or 24 hours after RAN administration. The doses of RAN and LPS used were not hepatotoxic when given alone. By 6 hr, injury to hepatic parenchymal cells and bile ducts was evident only in animals treated with both RAN and LPS, as estimated by increases in serum alanine aminotransferase and γ-glutamyl transferase activities. RAN/LPS cotreatment resulted in midzonal liver lesions characterized by acute necropurulent hepatitis. Famotidine (PEPCID®) is an H2-antagonist for which the propensity for idiosyncratic reactions is far less than RAN. Rats given LPS and famotidine at a dose pharmacologically equipotent to that of RAN did not develop liver injury. The results suggest that a response resembling human RAN idiosyncrasy can be reproduced in animals experiencing a modest inflammatory response. Furthermore, they raise the possibility that concurrent inflammation precipitates idiosyncratic responses to some drugs and may lay the framework for developing a predictive animal model.

978 ENDOTOXIN, NOT OXIDATIVE STRESS, MEDIATES ACUTE ETHANOL-INDUCED HEPATIC TNF-ALPHA PRODUCTION.

Z. Zhou[1], L. Wang[1], Z. Song[1], J. C. Lambert[1,2], C. J. McClain[1,2] and J. Y. Kang[1,2,3]. *[1]Medicine, University of Louisville, Louisville, KY, [2]Pharmacology & Toxicology, University of Louisville, Louisville, KY and [3]Jewish Hospital Heart and Lung Institute, Louisville, KY.*

Tumor necrosis factor-alpha (TNF-alpha) production is a critical factor in the pathogenesis of alcoholic liver injury. Both oxidative stress and endotoxin have been implicated in the process of ethanol-induced TNF-alpha production. However, the cause-and-effect relationship between these factors has not been fully defined. The present study was undertaken to determine the mediators of ethanol-induced TNF-alpha production using a mouse model of acute alcohol hepatotoxicity. Ethanol administration *via* gavage at a dose of 6 g/kg to 129/Sv mice induced TNF-alpha production in the liver in association with increases in hepatic lipid peroxidation and plasma endotoxin. Treatment with an antioxidant N-acetyl-L-cysteine significantly inhibited ethanol-induced hepatic lipid peroxidation, but not plasma endotoxin elevation or TNF-alpha production. By contrast, treatment with an endotoxin neutralizing protein significantly suppressed ethanol-induced elevation of plasma endotoxin and inhibited TNF-alpha production, but did not reduce hepatic lipid peroxidation. Furthermore, time course analysis revealed that lipopolysaccharide (LPS) injection induced TNF-alpha production, reaching a peak value at 1.5 h. LPS also caused hepatic lipid peroxidation, but it appeared at 6 h and 12 h after treatment, a delayed time period following TNF-alpha production. This study thus systemically dissected the relationship among oxidative stress, endotoxin release, and TNF-alpha production following acute ethanol administration, and the results demonstrate that ethanol-induced hepatic TNF-alpha production is mediated by endotoxin, but not by oxidative stress. (Supported by AA13601, AA01762, AA 10496 & HL63760)

979 THE ROLE OF THE COAGULATION SYSTEM IN SYNERGISTIC LIVER INJURY CAUSED BY MONOCROTALINE AND BACTERIAL ENDOTOXIN COEXPOSURE.

S. B. Yee, P. E. Ganey and R. A. Roth. *Department of Pharmacology and Toxicology, National Food Safety and Toxicology Center, and Institute for Environmental Toxicology, Michigan State University, East Lansing, MI.*

Synergistic, acute liver injury develops in rats from the administration of a small, noninjurious dose of bacterial endotoxin (lipopolysaccharide; LPS; 7.4 x 106 EU/kg) given 4 hours after a nontoxic dose of the pyrrolizidine alkaloid, monocrotaline (MCT; 100 mg/kg). Both centrilobular (CL) and midzonal (MZ) liver lesions occur, similar to those seen from larger, toxic doses of MCT or LPS, respectively. A previous study demonstrated that coadministration of the thrombin inhibitor heparin to MCT/LPS-cotreated animals reduced hepatic parenchymal cell (HPC) injury. This suggested that the coagulation system was causally involved. To confirm that the attenuation of MCT/LPS-induced liver injury was due to the inhibition of the coagulation system, another anticoagulant, warfarin, was used. Activation of the coagulation system occurred before the onset of HPC injury. Moreover, extensive fibrin deposition, as quantified by immunohistochemistry, was evident in CL and MZ regions within 12 hours after MCT administration. Warfarin (7.5 mg/kg) given 34 and 10 hours before MCT administration in MCT/LPS-cotreated animals abrogated activation of the coagulation system, attenuated HPC injury (as marked by decreased plasma alanine aminotransferase and aspartate aminotransferase activities) and reduced sinusoidal endothelial cell injury (evident as decreased plasma hyaluronic acid concentration). Warfarin pretreatment decreased the size and frequency of CL and MZ lesions in MCT/LPS-treated rats. Collectively, these results suggest that the coagulation system plays a critical role in synergistic liver injury caused by MCT and LPS coexposure. (*Supported by NIH Grant ES 04139.*)

980 MATRIX METALLOPROTEINASES IN MONOCROTALINE-INDUCED LIVER INJURY.

U. M. Hanumegowda[1], B. L. Copple[1], M. Shibuya[2], P. E. Ganey[1] and R. A. Roth[1]. *[1]Department of Pharmacology and Toxicology, Michigan State University, East Lansing, MI and [2]Institute of Medical Science, University of Tokyo, Tokyo, Japan.*

Monocrotaline (MCT) is a pyrollizidine alkaloid that causes liver injury in animals. In rats, injury is characterized by sinusoidal endothelial cell (SEC) damage and centrilobular parenchymal cell necrosis. Endothelial dysfunction occurs as early as eight hours, and loss of SECs is seen by twelve hours after administration of MCT. Loss of endothelium is a possible outcome of the action of matrix metalloproteinases (MMPs, collagenases), specifically MMP-2 from SECs and MMP-9 from neutrophils and SECs, on basement membrane collagen. Accordingly, the dynamics of MMPs in MCT-induced sinusoidal endothelial damage was studied. Rats were treated with a single dose of MCT (300 mg/kg, ip), and livers were collected at 8, 12 and 18h. Immunofluorescence analysis of frozen sections of livers from MCT-treated rats revealed a progressive reduction in distribution of basement membrane heparan sulfate proteoglycan and collagen IV. A time-dependent increase in tissue total MMP activity and MMP-9 activity occurred in livers of MCT-treated rats, as measured by fluorescent collagenase activity assay and gelatin-zymography, respectively. Progressive neutrophil accumulation was demonstrated by an increase in myeloperoxidase (MPO) activity in liver after MCT treatment. A sinusoidal endothelial cell line, NP-26, was used for *in vitro* studies. Treatment of NP-26 cells with 0 to 0.8 mM MCT resulted in a dose-dependent release of both MMP-9 and MMP-2 from the cells as early as 4h. The results demonstrate the degradation of basement membrane collagen IV with a concurrent increase in amount and activity of MMP-2 and MMP-9, likely originating from sinusoidal endothelial cells and neutrophils. This suggests a possible role for MMPs in SEC destruction that occurs during MCT hepatotoxicity. (Supported by NIH grant ES04139)

981 S-ADENOSYL-L-METHIONINE ABSORPTION AND TRANSPORT BY CACO-2 CELLS.

J. McMillan, K. McKelvey, K. Walle and T. Walle. *Pharmacology, Medical University of South Carolina, Charleston, SC.*

S-adenosyl-L-methionine (SAMe) is a ubiquitous endogenous molecule that is known to be protective against hepatotoxic injury. Although oral SAMe appears to be absorbed across the intestinal mucosa its systemic bioavailability is very low. The reason for the low systemic bioavailability of SAMe is still unknown. Using the Caco-2 cell culture model for enterocyte absorption we determined whether SAMe could be taken up by the cells, i.e. cross the apical membrane, and whether it could be transported transcellularly as well. Caco-2 cells cultured in 6-well culture plates were used for the uptake studies. The amount of uptake of ^{14}C-carboxyl-SAMe into the cells was determined as a function of time. There was significant uptake of radioactivity into the Caco-2 cells, suggesting transport across the apical membrane. Peak levels (350 DPM/10^6 cells) occurred 1 hour after addition with a subsequent apparent decline. For transcellular transport studies, Caco-2 cells cultured on Transwell culture inserts were treated with ^{14}C-carboxyl-SAMe in the apical compartment. Apical to basolateral transport of SAMe was determined by measuring the radioactivity in the basolateral compartment over time. A time-dependent appearance of radioactivity on the basolateral side of the culture inserts was observed. The apparent permeability coefficient (Papp) for transport of SAMe was 0.5 X 10^{-6} cm/s. This Papp is similar to that observed for mannitol transport (0.5 x 10^{-6} cm/s), which is a paracellular transport process. The similarity in Papp for SAMe and

mannitol transport suggests that SAMe may be transported paracellularly. Alternatively, SAMe may be transported by an apical or basolateral efflux pump, limiting its transcellular absorption.

982 RESILIENCY OF F344 RATS TO CHLORDECONE POTENTIATED CCL_4 HEPATOTOXICITY AND LETHALITY IS AGE-DEPENDENT.

B. Murali, M. C. Korrapati, S. S. Anand and H. M. Mehendale. *Toxicology, University of Louisiana at Monroe, Monroe, LA.*

The objective of the present study was to investigate the effects of Chlordecone (CD) + CCl_4 in young adult (3 months) middle aged (14 months) and old (24 months) male F344 rats. After pretreatment with either dietary CD (10 ppm) or normal diet for 15 days, rats were challenged with a single non-toxic dose of CCl_4 (100 µl/kg, ip, 1:4 solution in corn oil) or corn oil (500 µl/kg) on 16th day. Liver injury was assessed by plasma enzymes (ALT and AST) as well as histopathology during a time course of 0 to 96 h. Liver tissue repair was measured by [^{3}H]-thymidine (^{3}H- T) incorporation into hepatic nuclear DNA. Plasma glucose and liver glycogen were measured. As expected, no mortality occurred in any age group exposed to CCl_4 injection alone. Exposure to CD + CCl_4 resulted in 50% mortality of young adult rats at 48 h followed by gradual increase, reaching 100% mortality by 96 h. However, there was no mortality in 14 and 24 month old rats. All rats exposed to CD + CCl_4 had a gradual and equal elevation of plasma transaminases regardless of age up to 36 h. Thereafter, liver injury escalated in young adults. Whereas it declined in middle and old aged rats, indicating that bioactivation-mediated liver injury did not differ between young adult and older rats. Plasma glucose did not change in any age group. Significant depletion of glycogen was observed only in young adult rats exposed to CD + CCl_4. As indicated by [^{3}H-T] assay, in aged rats liver regeneration was robust beginning at 24 h and peaking at 48 h. However, such an increase in tissue repair was not observed in young adults. Because of prompt and robust compensatory tissue repair middle aged and old rats could overcome liver injury, whereas in the young adults liver injury progressed leading to 100% lethality. These findings suggest that both middle aged and old rats are resilient to CD + CCl_4-induced hepatotoxicity by virtue of robust compensatory tissue repair. (Supported by NIH/AG19058)

983 QUANTITATION OF INDIVIDUAL BILE ACIDS IN PLASMA BY LC/MS/MS.

C. A. Fritz, C. A. Drupa, M. D. Aleo and J. Colangelo. *Drug Safety Evaluation, Pfizer Global R&D, Groton, CT.*

An increase in circulating bile acid concentrations can be an indicator of hepatobiliary diseases. Knowing how individual bile acid concentrations change with hepatotoxicity may help to understand the mechanisms behind them. This information may provide insight for further investigation, or establish a biomarker for a particular disease state. Here we describe an analytical method to profile 21 individual bile acids, including tauro conjugated, glyco conjugated, and unconjugated, in plasma as a tool in investigative studies. Plasma samples from pre-clinical studies are assayed in triplicate using solid phase extraction followed by liquid chromatography/mass spectrometry (LC/MS) analysis. Individual bile acids are separated by reverse-phase LC and monitored in negative ion mode by electrospray ionization (ESI)-MS/MS. Calibration curves are constructed from a linear regression analysis of the peak areas for samples fortified with known concentrations of analyte. Deuterated bile acids are used as internal standards for each sample, and appropriate blanks and quality controls are included in all analyses. Assay validation was conducted using control rat plasma fortified with bile acids at different concentrations. A majority of the bile acids were determined to deviate by ±30% on average from expected values for standards. The technique described has several improvements over similar methods used to quantitate bile acids. The assay is capable of measuring more individual bile acids than any other method reported in the literature. Another benefit is that sample preparation times are shorter due to the 96-well plate format and no need for sample derivitization. The assay also was more sensitive for some bile acids compared to other current methods. Further development is needed to improve overall accuracy values.

984 LEVAMISOLE ATTENUATES DICLOFENAC-INDUCED ENTEROPATHY IN RATS.

B. K. Shipp[1], L. Kaphalia[2], C. R. Atchison[3], L. R. Pohl[4], J. F. Aronson[2] and M. T. Moslen[2]. *[1]Gradient Corporation, Cambridge, MA, [2]University of Texas Medical Branch, Galveston, TX, [3]US Army Medical Research Institute of Chemical Defense, APG, MD and [4]NIH, Bethesda, MD.*

Background: Therapeutic usage of diclofenac, similar to that of other conventional NSAIDs, is frequently associated with small intestinal inflammation, ulceration and protein-losing enteropathy. Therefore, strategies are needed to minimize this complication. Objective: Based on a report of levamisole protection against the gastropathy of other NSAIDs, we investigated the effects of this agent on diclofenac enteropathy using our established rat model. Experimental Design: Fed adult male Sprague-Dawley rats were treated orally with diclofenac [0 or 50 mg/kg] with or without levamisole [100 mg/kg at - 6 hr and 50 mg at + 1 hr]. At 12 hr, extent of enteropathy was measured by counting ulcer numbers and analyzing serum for total protein and albumin concentrations. At 3 hr, a well characterized antibody was used to assess the patterns of diclofenac-protein adduction in liver and in the intestine. Results: Compared to treatment with diclofenac alone which typically produces ~ 80 intestinal ulcers and >40% leakage of serum albumin by 12 hr, animals that were co-treated with levamisole showed a 96% decrease in ulcer numbers and retention of serum proteins. At 3 hr, a pre-ulceration time point suitable for examining early events in diclofenac enteropathy, substantially less drug-protein adduction was detected in both livers and intestines of animals co-treated with levamisole. Conclusions: Our observations of attenuated enteropathy in association with a diminution in diclofenac-protein adduction support our hypothesis that adduction is a causal event in diclofenac enteropathy. The diminished adduction in the livers of animals also given levamisole suggests that the mechanism for protection by this agent stems from its influence on pre-adduction events, such as hepatic bioactivation of diclofenac to an acyl glucuronide and/or biliary secretion of this reactive metabolite. (NIH DK 56494, NIEHS T32-07254)

985 DNA DAMAGE AS A CONSEQUENCE OF CHLOROFORM-INDUCED CYTOTOXICITY IN MALE F344 RAT AND B6C3F1 MOUSE HEPATOCYTES *IN VITRO.*

Y. Zhang, H. B. Hoffman, V. A. Wong and G. L. Kedderis. *CIIT Centers for Health Research, Research Triangle Park, NC.*

Chloroform is hepatotoxic and hepatocarcinogenic in rodents but is not mutagenic. We have characterized the metabolism-dependent cytolethality of chloroform toward rodent hepatocytes at physiologically relevant exposure concentrations and times. We hypothesize that chloroform cytotoxicity produces indirect DNA damage and replication of hepatocytes, leading to mutational events involved in liver tumor development. Hepatocytes from male F-344 rats and B6C3F1 mice were incubated with chloroform (0 to 3.8 mM) for up to 3 hr. After incubation, some cells were cultured for 24 hr to determine cytotoxicity, as measured by LDH leakage. Some cells from the same incubations were used to measure cytotoxicity-related DNA damage. DNA from lysed cells was separated by centrifugation. The PicoGreen reagent was used to quantify the amount of DNA in the pellets (intact chromatin) and supernatants (fragmented DNA). DNA damage was measured as the percentage of fragmented DNA divided by total DNA. Two-parameter flow cytometry analysis of BrdU incorporation was used to evaluate cell cycle effects. Chloroform treatment produced dose- and time-dependent decreases in cell viability. Chloroform induced dose- and time-dependent DNA damage in rat hepatocytes *in vitro*, which preceded cell death. DNA damage was not evident until 2 hr of exposure. Inhibition of biotransformation by the cytochrome P450 inhibitor 1-phenylimidazole (1 mM) prevented both cytolethality and DNA damage, indicating that metabolism was required. The basal level of DNA damage in mouse cells (5.1%) was higher than that in rat (2.6%, $P<0.001$), which might contribute to species differences in susceptibility to tumor induction by chloroform. The labeling index of cells treated with 2.5 mM chloroform for 3 hr (43.1±6.4%) was significantly greater than the control (15.2±1.6%), indicating the induction of cell growth. These results show that acute exposure to chloroform induced cytotoxicity, DNA damage, and cell growth in isolated rodent hepatocytes, which are likely to be involved in the development of liver cancer.

986 METALLOTHIONEIN-III PROTECTS AGAINST THE HYDROGEN PEROXIDE-INDUCED CYTOTOXIC AND DNA DAMAGE.

D. Oh [2], H. You[2] and H. Jeong[1,2]. *[1]Pharmacy, Chosun University, Kwangju, Kwangju, South Korea and [2]Research Center for Proteineous Materials, Chosun University, Kwangju, South Korea.*

Metallothionein (MT)-III, the brain specific member of MT family, is a low molecular weight, heavy-metal binding protein, in contrast to the ubiquitous MT isoforms, MT-1 and MT-2, that are found in most tissues. Results in genetically altered mice indicate that MT-III may play neuroprotective roles in the brain, but the mechanisms through which this protein functions have not been elucidated. The present study was undertaken to assess whether MT-III is able to directly protect DNA from damage and lipid peroxidation induced by hydroxyl radical and to assess its abilities to scavenge superoxide radicals. DNA damages were detected by the mobility of plasmid DNA in electrophoresis and deoxyribose degradation. Lipid

peroxidation was measured by a thiobarbituric acid reactive substance. DNA damages and lipid peroxidation were induced by ferric ion-nitrilotriacetic acid and hydrogen peroxide, which produces hydroxyl radical. DNA damages and lipid peroxidation were prevented by MT-III in a dose-dependent manner. Preincubation of MT-III with EDTA and N-ethylmaleimide, to alkylate sulfhydryl groups of MT-III, resulted in MT-III that was no longer able to prevent DNA damages. This result indicates that the cysteine thiol groups of MT-III may be involved in its protective effects of DNA from hydroxyl radical attack. MT-III scavenges superoxide radical generated from xanthine/xanthine oxidase reaction system in a dose-dependent manner. MT-III is superior in protection of DNA damages and scavenging superoxide radicals compared to MT-I and MT-II; however, there was no difference in inhibition of lipid peroxidation. These results provide direct support for an antioxidant role for MT-III that can scavenge free oxygen radicals and might be protect cells from oxidative stress.

987 STRUCTURE-ACTIVITY RELATIONSHIPS FOR GENOTOXICITY AMONG A SERIES OF SULFONIC ACID ESTERS.

L. Mueller, S. Glowienke, W. Frieauff, W. Suter and H. Martus. *Novartis Pharmacology AG, Basel, Switzerland.*

The chemical synthesis of pharmaceutical structures often involves the use of reactive starting materials or intermediates. Further, the salt/solvent matrix may generate genotoxic esters of sulfonic acid. Both characteristics may lead to the presence of genotoxic impurities in drug substances, which would have to be limited in the final product at low ppm levels. In silico structure-activity prediction can help to proactively identify structures of potential concern in drug substance syntheses. Such structure-activity prediction systems need to be trained with reliable experimental data, which are often not available. We tested a series of esters of benzyl and toluylsulfonic acid for genotoxicity in bacteria (Salmonella typhimurium TA98 and TA100) and mammalian cells (micronucleus formation in L5179Y mouse lymphoma cells). While ethylmethane sulfonate and methylmethane sulfonate are established mutagens across a variety of mutagenicity systems, little is known about the corresponding esters of benzene and toluene. Most esters tested (methyl-, ethyl-, propyl-, isobutyl-, n-butyl-esters) displayed a mutagenic activity in Salmonella. Not unexpectedly, some indications for an inverse relationship of the mutagenic potency with the side chain length was found. Similar results were obtained with the micronucleus test in mouse lymphoma cells. However, for this assay, a clear dependency of the results from distinct structural features could not be obtained. These results have implications for the use of tosylates and besylates as pharmaceutical salts.

988 CYTOTOXICITY AND GENOTOXICITY OF BENZOQUINONE IN HUMAN BONE MARROW CD34+ PROGENITOR CELLS.

D. J. Abernethy, B. Faiola, E. Kleymenova, J. Rose and L. Recio. *CIIT Centers for Health Research, Research Triangle Park, NC.* Sponsor: J. Everitt.

Benzene induces chromosome aberrations, DNA strand breaks, and a p53 response in the bone marrow of mice. Bone marrow stem cells are progenitors for leukemia and a target cell population for benzene toxicity. Benzene is metabolized to several active metabolites, including the toxic and mutagenic benzoquinone (BQ). We used human CD34+ hematopoietic stem cells (HSC) to assess the effects of BQ exposure relative to DNA damage, DNA repair, and the molecular mechanisms associated with these events. We exposed CD34+ HSC from 10 male and 10 female donors to 1, 5, 10, 15, and 20 μM BQ for 72 h. which allowed for at least one cell division. In both male and females, cell viability and apoptosis were dose-dependent with an approximate 60% viability compared to controls observed at 10 μM BQ and a two-fold increase in apoptotic cells compared to unexposed controls observed at 15 μM BQ. The percentage of micronucleated CD34+ cells observed in treated male and female donors was 4.5 and 7 times higher respectively than unexposed controls. p21 gene expression was elevated approximately 2 to 2.5-fold at 10 and 20 μM of BQ respectively for both males and females, suggesting that, similar to mice, human cells utilize the p53 pathway in response to BQ-induced DNA damage. To gain insight into the mechanism of DNA repair of BQ-induced DNA damage, expression of the DNA repair genes Rad51, APEX, Ku80, XPA, and XPC was evaluated by quantitative RT-PCR from cell populations that remained approximately 50% viable relative to unexposed controls following BQ treatment. There was no significant increase in mRNA levels for Rad51, APEX, Ku80, XPA, and XPC in either male or female donors following a 72-h treatment. Preliminary immunohistochemistry revealed the lack of Rad51 foci in BQ-exposed cells, suggesting that homologous recombination does not occur following a 72-h BQ exposure. These results indicate that BQ exposure induces cytotoxicity, apoptosis, and DNA damage in human HSC. The role and mechanism of DNA repair in BQ-induced genotoxicity require further evaluation.

989 DOES FLUMEQUINE HAVE A GENOTOXIC POTENTIAL TO THE LIVER OF MICE?

T. Watanabe[1], Y. Kashida[1], Y. Sasaki[2], A. Takahashi[1] and K. Mitsumori[1]. *[1]Laboratory of Veterinary Pathology, Tokyo University of Agriculture and Technology, Fuchu, Japan and [2]Laboratory of Genotoxicity, Faculty of Chemical and Biological Engineering, Hachinohe National College of Technology, Hachinohe, Japan.* Sponsor: M. Takahashi.

In order to elucidate the tumor initiating potential of flumequine (FL) in the liver, male C3H mice were given dietary administration of 4000 ppm FL throughout the study or for 2 weeks at the initiation stage and then received two intraperitoneal injections of D-galactosamine (Gal) at weeks 2 and 5, with or without 500 ppm phenobarbital (PB) in their drinking water for 13 weeks. In addition, an alkaline single cell gel electrophoresis (comet) assay was performed using adult, infant or partial hepatectomized male ddY mice to evaluate the potential of FL at 500 mg/kg or less to act as a DNA damaging agent. Furthermore, *in vitro* assays were conducted to investigate the potential of FL to inhibit eukaryotic topoisomerase II as well as bacterial gyrase. In the 13-week study, hepatocellular foci were observed in 2 out of 8 and 6 out of 7 animals in the FL/PB+Gal and FL/FL+Gal groups, respectively, none being evident in the other treated mice. The comet assay demonstrated FL to dose-dependently induce DNA damage in the stomach, colon, and urinary bladder of adult mice 3 h but not 24 h after its administration. Similarly, DNA damage was noted in the regenerating liver and the livers of infant mice at the 3 h time point. Inhibitory effects of FL on topoisomerase II were high relative to the influence on bacterial gyrase. The results of our studies thus strongly suggest that FL has initiating potential in the livers of mice and that this is attributable to its induction of DNA strand breaks, possibly through inhibition of topoisomerase II.

990 A COMPARISON OF *IN VITRO* TOXICITIES OF CIGARETTE SMOKE CONDENSATE FROM FOUR COMMERCIALLY AVAILABLE ULTRA LOW-TAR CIGARETTES.

J. W. Foy, B. R. Bombick, D. W. Bombick, D. J. Doolittle, A. T. Mosberg and J. E. Swauger. *R.J. Reynolds Tobacco Co., Winston-Salem, NC.*

Eclipse is a cigarette that primarily heats rather than burns tobacco. RJRT has previously reported the results of *in vitro* toxicity studies comparing Eclipse with K1R5F and K1R4F reference cigarettes. In order to characterize the differences between Eclipse and very low yielding ultra low-"tar" (vULT) cigarettes, RJRT conducted a comparative evaluation of the genotoxicity and cytotoxicity of mainstream cigarette smoke condensate (CSC) from Eclipse and three vULT tobacco-burning cigarettes (Now 85 Box, Carlton Soft Pack, and Merit Ultima) as well as the leading market ultralight brandstyle (Marlboro Ultra Lights) under four smoking regimens. These smoking regimens were: 1) FTC - (35 ml puff volume every 60 seconds for a 2 second duration [35/60/2]); 2) 50/30/2, 0% vent block); 3) Massachusetts - 45/30/2, 50% vent blocked); 4) Canadian - 55/30/2, 100% vent blocked). Ames testing indicated that Eclipse CSC was less ($p< 0.05$) mutagenic than the CSC from the four cigarettes under all smoking regimens when compared on a revertants per mg Total Particulate Matter (TPM) basis. When mutagenicity was calculated on a revertants per cigarette basis the mutagenicity of Eclipse CSC was lower ($p< 0.05$) than the mutagenicity of Carlton Soft Pack, Merit Ultima, and Marlboro Ultra Lights regardless of the puffing regimen. On a per cigarette basis, the calculated mutagenicity of Eclipse was higher ($p< 0.05$) than Now 85 Box cigarettes under the FTC and 50/30/2 regimens but lower ($p< 0.05$) under the Massachusetts and Canadian regimens. Eclipse CSC was less ($p< 0.05$) cytotoxic as measured in the Neutral Red test than the CSC from the four test cigarettes regardless of the regimen used. Collectively, these data demonstrate that the *in vitro* toxicity of CSC from Eclipse is significantly reduced relative to the activity of CSC from the vULT cigarettes and the Marlboro Ultra Lights.

991 COLLABORATIVE ASSESSMENT OF THE YEAST GENOTOXICITY SCREEN.

P. A. Weale[1], P. M. Collins[1], M. G. Barker[2], P. Cahill[2] and R. M. Walmsley[2]. *[1]MIT, Sequani Ltd, Herefordshire, United Kingdom and [2]Biomolecular Sciences, UMIST, Manchester, United Kingdom.* Sponsor: D. Mitchell.

The Yeast Genotoxicity Screen has been developed to provide a rapid genotoxicity assessment of compounds with interesting pharmacological or chemical properties. The objective of this collaborative study was to establish the reproducibility and reliability of the DNA damage reporter system in an independent laboratory. Yeast is an attractive model system for the detection and evaluation of carcinogens, as being eukaryotic, it is useful for the testing of highly bactericidal compounds, which preclude the use of the regulatory or screening Ames Test. The yeast has been genetically engineered (incorporation of reporter gene *RAD54*) to produce a fluorescent protein in proportion to the activation of their DNA repair systems. The harder its

DNA repair systems work the brighter and stronger the fluorescence. The yeast cells, serial dilution of test article solutions, genotoxic (MMS) and cytotoxic (methanol) controls and diluent (2 % DMSO) were manually mixed in 96-well microplates, then incubated overnight at 25 °C. Cell density and fluorescence measurements provided quantitative measures of cytotoxicity (positive, weak or negative, proportional to proliferation, lowered by toxic analytes) and genotoxicity (positive, weak or negative, proportional to fluorescence, increased by genotoxic analytes). The data were compared to an extensive *in vitro* and *in vivo* literature base. MMS and MNNG were confirmed genotoxins; Ampicillin and Caffeine were confirmed non-genotoxins; Urethane and Nitrosodimethylurea were confirmed Ames false negatives and 8-hydroxyquinoline was confirmed Ames false positive. The remaining compounds, Cisplatin, Phenol, Sulfamethoxazole, Bleomycin sulphate, Benzoyl chloride and Hydroxyurea required re-tests at different dose ranges, due to variable data. The test was performed with rapid end-point determination, with good concordance of results, confirming the lack of inter-laboratory and inter-personnel variation, therefore supporting the use of this screen as a useful and rapid genotoxicity assessment tool.

992 TOXIC AND MUTAGENIC EFFECTS OF BASE ANALOGS.

R. M. Schaaper, R. L. Dunn and Y. I. Pavlov. *Molecular Genetics, NIEHS, Research Triangle Park, NC.* Sponsor: J. Simmons.

Base analogs can be powerful mutagens in both eukaryotic and prokaryotic systems. Due to their similarity to normal DNA bases they may be readily incorporated in DNA; however, due to their ambivalent base-pairing properties, this results in high levels of mispairings and, hence, mutations. Base analogs can also be used as antiviral or chemotherapeutic agents, based on their toxic effects due to interference with normal nucleotide metabolism. Our laboratory has initiated a detailed study of the mutagenic and toxic mechanisms of the purine analogs N6-hydroxylaminopurine (HAP), 2-amino-N6-hydroxylaminopurine (AHAP), and 2-aminopurine (AP), using the model system Escherichia coli in which all three are powerful mutagens. Specifically we have investigated (i) the enzymatic systems that E. coli might use to protect itself against the effects of analogs, and (ii) the pathways by which the analogs are activated through conversion to the nucleotide level. Our experiments have revealed that E. coli possesses a powerful defense system acting against HAP that is dependent on the molybdenum cofactor. Strains defective in the biosynthesis of this cofactor (such as moa, moe or mod mutants) are extremely sensitive to both the toxic and mutagenic effects of HAP. None of the known E. coli molybdoenzymes tested so far is responsible for this protective effect, suggesting the operation of a novel pathway. Another class of HAP-sensitive mutants found are dam strains, which lack DNA adenine methylation. This finding suggests that DNA mismatch repair plays a role in the recognition and protection against base analogs-induced DNA mispairs. The base-analog activation experiments that we have conducted have shown that HAP can be converted to the nucleoside monophosphate (HAPMP) by any of the three E. coli purine phosphoribosyl transferases (gpt, hpt, and apt gene products), while AHAP is converted to AHAPMP by guanine phosphoribosyl transferase (gpt gene product) exclusively. In contrast, AP appears converted to APMP primarily by the serial action of purine nucleoside phosphorylase (deoD gene product) and guanosine kinase (gsk gene product).

993 TOXICITY OF CHRONIC AZATHIOPRINE ADMINISTRATION IN SOMATIC AND GERM CELLS OF C57BL/6 MICE.

S. Bendre[1,2], R. E. Patton[1], J. G. Shaddock[1], V. N. Dobrovolsky[1] and R. H. Heflich[1,2]. *[1]Genetic Toxicology, NCTR, Little Rock, AR and [2]Pharmacology and Toxicology, University of Arkansas for Medical Sciences, Little Rock, AR.*

Azathioprine (Aza), a pro-drug of the toxic purine analogue 6-mercaptopurine, is an immunosuppressant used to prevent transplant rejection and for treating autoimmune disease. Patients undergoing chronic Aza therapy can have large increases in *HPRT* lymphocyte mutant frequency (MF), presumably due to drug selection of pre-existing *HPRT* mutant lymphocytes. A similar selection of germ line *HPRT* mutations could result in an increased incidence of the Lesch-Nyhan syndrome, a devastating neurological disease, in subsequent generations. We have begun to develop a mouse model to explore the possibility of increased germ line transmission of *Hprt* mutations. Male C57Bl/6 mice were treated p.o. 3 times /wk with 0, 5, 10, 25, 50 and 100 mg/kg Aza for up to 23 wks. Mice treated with 25-100 mg/kg Aza were all dead by 14 wks of treatment. *Hprt* mutant assays performed on spleen lymphocytes indicated that most treated mice had MFs similar to control mice ($\leqq 10 \times 10^{-6}$), however, a few had clearly elevated Mfs [(e.g.), 233×10^{-6} after 10 weeks of 5mg/kg]. Measurements of testicular weight, and sperm count, viability, morphology, and motility found that 5 and 10 mg/kg Aza produced only low levels of toxicity in germ cells. The data indicate that mice chronically treated with 5 and 10 mg/kg Aza (doses comparable to those given to humans) have elevated *Hprt* MFs similar to humans. Futhermore, the results suggest that mice treated with these doses of Aza retain reasonable fertility, and will be useful for planned breeding experiments to examine the germ line transmission of *Hprt* mutations.

994 MUCOCHLORIC ACID INDUCES PARP ACTIVATION.

E. Bodes, J. Nakamura and J. A. Swenberg. *Curriculum in Toxicology, University of North Carolina, Chapel Hill, NC.*

Water chlorination generates halogenated by-products with potential public health risks. While current levels of exposure are low, chronic exposure may lead to significant risk. The halogenated hydroxyfuranones (e.g. mucochloric acid; MCA) have not been studied in detail, but may be an important source of risk. Our goal was to better understand possible mechanisms of MCA-induced genotoxicity. We used a highly sensitive slot-blot assay to characterize aldehydic DNA lesions (ADLs), which include AP sites, and to quantitate 8-oxoguanine (8oxoG; marker for direct base oxidation) by HPLC-ECD *in vivo* after MCA exposure. Five dose groups, each with 6 male F344 rats, received a single gavage dose of 0, 10, 30, 100 or 300 mg/kg MCA. Initial results indicated that there were no significant differences in ADLs and 8oxoG between control and exposed rat liver DNA. We are repeating these analyses and using a new assay where oxidized purines are excised from the DNA backbone by Ogg1, resulting in AP sites detectable by our slot-blot method. We then used a newly developed, sensitive assay which indirectly monitors the status of DNA single strand break (SSB) repair enzymes by circuitously measuring poly(ADP-ribose) polymerase (PARP) activation through depletion of intracellular NAD(P)H. PARP detects, for e.g., direct SSBs arising from sugar damage or spontaneous cleavage at AP sites. We applied this assay to XRCC1-proficient and XRCC1-deficient isogenic Chinese hamster ovary cells exposed to MCA. A water-soluble tetrazolium salt was used to monitor NAD(P)H concentrations in living cells through its reduction to a yellow dye detected spectrophotometrically. After 4h, XRCC1-deficient cells contained significantly less NAD(P)H than proficient cells. To distinguish whether the reduction of NAD(P)H was due to decreased mitochondrial function or due to NAD+ depletion by PARP activation, we co-exposed XRCC1-deficient cells to MCA and a PARP inhibitor. The MCA-induced decrease in intracellular NAD(P)H was almost completely blocked, which strongly suggests that the decrease was primarily due to PARP activation through formation of SSBs.

995 OXIDIZED GUANINE LESIONS IN THE NF-κB REGULATORY ELEMENT ARE SHIELDED FROM REPAIR BY FAPY GLYCOSYLASES WHEN THE TRANSCRIPTION FACTOR IS BOUND.

K. Morrison, B. Martin and K. D. Sugden. *Chemistry, University of Montana, Missoula, MT.* Sponsor: H. Beall.

A number of transcription factor binding sites within inducible promoter regions contain highly oxidizable sequences, namely consecutive runs of guanines. One of these regions, the NF-κB response element displays complex up or down regulation of transcription factor binding depending both upon the nature and position of the oxidized guanine product. It has been reported that the lesions we examined, 7, 8-dihydro-8-oxo-2[1]-deoxyguanosine (8-oxo-dG) and its further oxidized products, guanidinohydantoin/iminoallantoin (GH/IA) and spiroiminodihydantoin (SH) are readily repaired by the bacterial Fapy glycosylase, Fpg (MutM). Therefore we sought to examine the competition kinetics between the DNA binding protein of the NF-κB complex, p50, and bacterial Fpg or its mammalian homolog hOGG1. The terminally oxidized lesions (GH/IA and SH) were generated by the reaction of a high valent chromium compound with synthetic DNA oligonucleotides and purification by HPLC. The oligonucleotides containing a single lesion were reacted with Fpg or hOGG1 in the presence or absence of purified p50. The cleavage efficiency of Fpg was substantially greater than that of hOGG1 for all lesions and the substrate specificity for the two enzymes was also different. Fpg cleaved lesions with the efficiency 8-oxo-dG > GH/IA > SH. Of these lesions hOGG1 also cleaved 8-oxo-dG with greatest efficiency but this was followed by SH while little to no cleavage was observed for GH/IA. The NF-κB transcription factor, p50, efficiently shielded all these lesions from recognition and cleavage by both the bacterial, Fpg, and the human, OGG1, glycosylases *in vitro*. The shielding effect was enhanced with those lesions that show higher binding affinity in a p50 dose-dependent manner. As p50 is translocated to the nucleus under the same oxidative stress conditions under which these lesions can be formed, such shielding from repair may augment any misregulation of gene transcription as consequence of the changes in p50 binding affinity.

996 SYNTHESIS, CHARACTERIZATION, *IN VITRO* AND CALF THYMUS DNA IDENTIFICATION OF N^7-GUANINE ADDUCTS OF 1- AND 2-BROMOPROPANE.

E. Lee[1], Y. Moon[1], L. Zhao[1], E. Kim[1], H. Lim[1], A. Basnet[1], T. Jeong[1] and W. Chae[2]. *[1]College of Pharmacy, Yeungnam University, Kyongsan, Kyongbuk, South Korea and [2]School of Medicine, Catholic University of Daegu, Daegu, South Korea.*

It has been reported that 2-bromopropane might be a causative agent for reproductive toxicity and have immunotoxic effects. 1-Bromopropane known as an alternative to ozone depleting solvents, which has structural similarity to 2-bromopropane, has been reported to be neurotoxic to rats in long-term inhalation exposure. To elucidate mechanisms of 1- or 2-bromopropane-induced toxicities in the molecular level, formation of N^7-guanine adducts by 1- or 2-bromopropane was investigated *in vitro*. N^7-Guanine adducts of 1- and 2-bromopropane (N^7-propyl guanine and N^7-isopropyl guanine, respectively) were chemically synthesized in three steps in relatively high yields and structurally characterized by analyses of ^{1}H NMR, ^{13}C NMR, UV, HPLC and LC/MS/MS (ESI) to use as reference materials. N^7-Propyl guanine and N^7-isopropyl guanine were detected and identified by UV, HPLC and LC/MS/MS analyses after incubation of 2'-deoxyguanosine with 1- or 2-bromopropane at a physiological condition for 16 hr, followed by thermal hydrolysis. In addition, incubation of calf thymus DNA with 1- or 2-bromopropane at a physiological condition for 16 hr, followed by thermal hydrolysis, produced detectable amount of N^7-propyl guanine or N^7-isopropyl guanine by analyses of HPLC and LC/MS/MS. The present results suggest that 1- and 2-bromopropane may form a DNA adducts at N^7-position of 2'-deoxyguanosine at a physiological condition, which may be responsible for certain toxicities.

997 CONVERSION OF TRIS(8-QUINOLINOLATO-N1, O8) ALUMINUM (ALQ) TO 8-HYDROXYQUINOLINE (8OHQ) AND ACTIVITY IN BACTERIAL REVERSE MUTATION ASSAYS.

J. C. English and K. S. Roser. *Eastman Kodak Company, Rochester, NY.*

AlQ, an aluminum chelate of 8OHQ, is an important charge transfer molecule in semi-conducting imaging devices. This study was conducted to evaluate AlQ and 8OHQ for the ability to induce reverse mutations either in the presence or absence of mammalian microsomal enzymes, and to determine if AlQ decomposes or is metabolized to 8OHQ under assay conditions. The tester strains used in the mutation assay were S. typhimurium TA98, TA100, TA1535, and TA1537 and E. coli WP2uvrA(pKM101). The assays were conducted in the presence and absence of S9 mix prepared from Aroclor-induced rat liver with appropriate controls and in triplicate. Test article doses were 1 to 1000 µg per plate, and results of the initial assay were confirmed. Stability studies were carried out separately, under conditions designed to closely mimic the mutation assays. Incubation was carried out for 4 hours at 37°C and samples were collected periodically for analysis by HPLC. Analyses by LC/MS were performed to tentatively identify potential metabolites of AlQ and 8OHQ. The results of the bacterial mutagenicity assay indicate that, in the presence of S9 mix, both AlQ and 8OHQ caused positive increases in the mean number of revertants per plate with tester strains TA100 and WP2uvrA(pKM101). No positive increases were observed with any of the remaining tester strain/activation condition combinations. The stability study showed that AlQ degrades readily to 8OHQ under standard mutagenicity test conditions, and the positive test result with AlQ is due to bioactivation of 8OHQ. In the presence of S9, 8OHQ is metabolized to one detectable product with molecular weight indicative of a one-oxygen insertion. 8OHQ N-oxide and 2, 8-quinolinediol were ruled out as possible metabolites; 8OHQ epoxides and other quinolinediols were neither confirmed nor ruled out. Bacterial mutagenicity tests are not predictive of *in vivo* effects of 8OHQ; these assays are similarly expected to be poorly predictive of *in vivo* genotoxic and carcinogenic potential of AlQ.

998 EXAMINATION OF DNA DAMAGE IN ENDOTHELIAL CELLS FOLLOWING TREATMENT WITH 2-BUTOXYETHANOL USING THE SINGLE CELL GEL ELECTROPHORESIS (COMET) ASSAY.

J. M. Reed, L. M. Kamendulis and J. E. Klaunig. *Department of Pharmacology and Toxicology, Indiana University School of Medicine, Indianapolis, IN.*

2-Butoxyethanol has been shown to induce an increase in liver hemangiosarcomas selectively in the mouse following chronic treatment. While the effect for the induction of hemangiosarcomas has not been established, we have postulated that this neoplastic response is indirectly due to the activation of Kupffer cells and hemosiderin deposition subsequent to hemolysis, resulting in oxidative stress in the target endothelial cells. Oxidative stress has been implicated in the induction of DNA damage and modulation of gene expression in chemical carcinogenesis. The present study examined the effect of 2-butoxyethanol, 2-butoxyacetic acid (a major metabolite of 2-butoxyethanol) and iron on DNA damage as measured by the comet assay, in mouse endothelial cells. Treatment with 2-butoxyethanol (0 to 10mM) or 2-butoxyacetic acid (0 to 10mM) failed to induce an increase in DNA damage over control. Iron ($FeSO_4$) (0 to 10µM) and/or H_2O_2 (0 to 5µM) produced an increase in comet measured by olive tail moment and tail DNA. Coincubation of iron and/or H_2O_2 with vitamin E reduced the DNA damage observed with $FeSO_4$ and/or H_2O_2 alone. Incubation of $FeSO_4$ and/or H_2O_2 treated cells with Fpg (an enzyme that cleaves oxidized bases from duplex DNA preferentially) prior to electrophoresis revealed an increase in DNA damage suggesting that the damage was related to an oxidative insult. These data suggest that 2-butoxyethanol and 2-butoxyacetic acid do not directly induce DNA damage in endothelial cells and support our hypothesis that 2-butoxyethanol induces hepatic hemangiosarcomas indirectly, through oxidative stress mechanisms.

999 EXPOSURE OF MICE TO HC RED NO 3 DID NOT INDUCE DNA DAMAGE IN THE COMET AND MICRONUCLEUS ASSAYS.

S. Pfuhler[1], M. Vasquez[2] and R. R. Tice[2]. *[1]Wella Corp., Woodland Hills, CA and [2]ILS, Durham, NC.*

This study evaluated the potential for the hair dye HC Red No 3 to induce DNA damage in cells of the liver, urinary bladder, and peripheral blood as well as micronuclei in bone marrow polychromatic erythrocytes (PCE), after oral administration to male B6C3F1 mice. Selection of the liver was based on equivocal data indicating a possible relationship between HC Red No 3 and hepatocellular neoplasms in male mice, while evidence of nephrotoxicity predicates the evaluation of the urinary bladder. Peripheral blood was chosen to evaluate the potential for HC Red No 3 to induce systemic DNA damage. HC Red No 3, the micronucleus assay positive control (cyclophosphamide), and the vehicle control were administered by gavage once daily on four consecutive days (72, 48, 24, and 4 h prior to sacrifice/tissue sampling), while the comet assay positive control (ethylmethane sulfonate) was administered as a single intraperitoneal injection 4 h prior to sacrifice/tissue sampling. HC Red No 3 was administered at 250, 500 and 1000 mg/kg BW per day to 6 animals per dose group. The oral route of administration is the route historically used with this compound. At the time of necropsy, samples of the liver, urinary bladder, and peripheral blood were obtained from each animal for comet analysis, and bone marrow slides for micronucleus analysis were prepared from the femur of each animal. In the comet assay, 100 cells were scored per tissue for the extent of DNA migration. As an indication of the presence of necrosis or apoptosis all dose groups were checked for the frequency of cells with low molecular weight (LMW) DNA. For the MN assay, 2000 PCE were scored per animal. No evidence for apoptosis or necrosis was found using the comet LMW assay. In both assays, HC Red No 3 was negative for genotoxic activity. The values found for the positive and negative controls were within the historical database and confirm the validity of this study. The results of this study support the safety of the direct hair dye HC Red No 3.

1000 *IN VITRO* GENOTOXICITY OF FORMALDEHYDE-RELEASING BIOCIDAL AGENTS IS NOT PREDICTIVE OF *IN VIVO* GENOTOXIC POTENTIAL.

R. A. Budinsky[1], G. D. Charles[1], P. J. Spencer[1], M. Cifone[2] and B. B. Gollapudi[1]. *[1]The Dow Chemical Company, Midland, MI and [2]Covance Laboratories Inc., Vienna, VA.*

A series of formaldehyde releasing biocidal agents that produced positive genotoxic responses *in vitro* (chromosomal aberrations and increased mutation frequency in the mouse lymphoma assay) were further evaluated *in vivo* for bone marrow and liver genotoxicity. Bromonitropropane diol, 7-ethyl bicyclooxazolidine, cis-1-(3-chloroallyl)-3, 5, 7-triaza-1-azoniaadamantane chloride, 4-(2-nitrobutyl)morpholine 4, 4'-(2-ethyl-2-nitrotrimethylene)dimorpholine, dimethyl oxazolidine and tris(hydroxymethyl)nitro-methane were evaluated in both the mouse bone marrow micronucleus test (MNT) and the *in vivo*/in vitro rat unscheduled DNA synthesis (UDS) assay. For the MNT evaluation, at least 6 female and/or male CD-1 mice/dose level, at three doses and a vehicle control were treated by a single oral gavage on two consecutive days and sacrificed 24 h after the last dosing. Two thousand polychromatic erythrocytes (PCE) were evaluated from each animal and the frequencies of micronucleated PCEs (MNPCE) were recorded. There were no statistically significant increases in the frequencies of the MNPCE in the test groups relative to vehicle controls. In the UDS studies, at least five male Fischer 344 rats/dose level were given a single oral gavage at two dose levels plus a vehicle control. Livers were perfused at 2-4 and 14-16 h time-points with *in vitro* hepatocyte evaluation of nuclear cell labeling (150 nuclei per animal) after exposure to 3H-thymidine and autoradiography. None of the test materials exhibited statistically significant, compound-related increases in mean net nuclear grains or in the percent of nuclei with five or more net grains relative to vehicle controls. These results clearly demonstrate that *in vitro* genotoxicity associated with formaldehyde is unlikely to have relevance in the whole animal because of the occurrence of efficient detoxification mechanisms.

1001 LACK OF *IN VIVO* GENOTOXICITY OF A DIETARY SOY SUPPLEMENT.

B. M. Francis[2], C. A. Northcott[1] and A. Rayburn[1]. *[1]Entomology, University of Illinois at Urbana-Champaign, Urbana, IL, [2]Crop Sciences, University of Illinois at Urbana-Champaign, Urbana, IL and [3]Crop Sciences, University of Illinois at Urbana-Champaign, Urbana, IL.*

Numerous epidemiologic studies suggest that diets high in soy products reduce the risk of certain cancers, including breast and colon cancer, which are among the most common cancers in the American population. Some animal studies also suggest that soy fractions can cause deleterious effects under certain circumstances. As part of a study of the effects of diet (including contaminants, secondary plant products, and dietary supplements) on DNA, we examined the effects of two soybean fractions on DNA integrity *in vivo*, using mice and rats. The soy fractions, PCC and Novasoy, are isoflavone-rich ethanol extracts of commercial soybean processing. Outbred CD-1 mice were fed PCC as 1% of a defined, nutritionally complete, semisynthetic diet for up to 5 weeks. Three days before the end of the feeding period, a subset of mice were injected with cytosine arabinoside (ara-c) at a dose previously determined to cause significant DNA damage, to serve as positive controls. At the end of 1, 2, 3, 4 or 5 weeks of eating the defined diet ± PCC, bone marrow from all mice was extracted and examined by flow cytometry. Regardless of the length of time on the defined diet, there were no significant differences between mice given PCC-fed and control-fed mice with respect to flow cytometric measurements. As anticipated, the mice injected with ara-c showed significantly more variation in bone marrow DNA than did uninjected mice In the rat study, outbred CD-1 rats were exposed to PCC and Novasoy while on the same defined, nutritionally complete, semi-synthetic diet. At the end of the feeding period, the rats' bone marrow was extracted and examined for DNA damage. No differences were seen among any of the treatment groups.

1002 HYPOTHERMIA FOLLOWING TREATMENT OF MICE WITH PHENOL IS NOT REVERSED BY THERMOREGULATORY SUPPORT: IMPLICATIONS FOR MICRONUCLEUS (MN) FORMATION.

P. J. Spencer[1], J. G. Grundy[1], B. B. Gollapudi[1], J. M. Waechter[1], R. R. Gingell[2], S. S. Dimond[3] and B. J. Dunn[4]. *[1]The Dow Chemical Company, Midland, MI, [2]Shell Chemical Company, Houston, TX, [3]GE Plastics, Pittsfield, MA and [4]Honeywell, Morristown, NJ.*

Previous investigations revealed an association between high-dose phenol-induced MN in mouse bone marrow and prolonged hypothermia (>8°C decrements for >8 hrs). A study to test the hypothesis that MN in phenol-treated mice could be prevented by maintaining mice at normal body temperature (BT) was inconclusive due to: (a) induction of hyperthermia and MN in controls subjected to the same thermoregulatory support as phenol-treated mice, and (b) the possibility that support measures may not have fully reversed phenol-induced hypothermia. To ascertain whether thermoregulatory support was effective in maintaining phenol-treated mice at normal BT throughout 48-hr observation, frequent BTs were obtained in treated mice using a radio-telemetry device. Male mice (3/dose) were implanted with a small telemetry probe and housed singly in tubs with corncob bedding. BT of mice was sampled every 5 min in standard environmental conditions for 18-20 hrs, then moved to a room providing identical thermoregulatory support as the previous MN study (30°C with warming blankets under half the cage). Mice were dosed with a vehicle or 300 mg/kg phenol (i.p.) and BT monitored every 5-min for an additional 48 hrs. BT measurements indicated that thermoregulatory support altered the normal thermoregulatory pattern of both control and phenol-treated mice. Additionally, thermoregulatory support did not fully prevent hypothermia in phenol-treated mice. In conclusion, these data provide additional evidence for the association between hyper- and hypothermia and MN induction in mice. Attempts to distinguish the potential direct action of phenol on MN formation from the action of hypothermia alone are likely to be confounded by the fact that the maintenance of normal BT in phenol-treated hypothermic mice appears problematic. *Sponsored by the Phenol Panel of the American Chemistry Council, Arlington, VA.*

1003 STRUCTURE-DEPENDENT INCISION OF STEREOISOMERIC BPDE ADDUCTS BY *B. CALDOTENAX* UNIVERSITYvrABC EXCISION NUCLEASE.

G. Jiang[1], M. Skorvaga[2], B. van Houten[2], N. Geacintov[3] and J. States[1]. *[1]Pharmacology & Toxicology, University of Louisville, Louisville, KY, [2]NIEHS, Research Triangle Park, NC and [3]Chemistry, New York University, New York, NY.*

Benzo[*a*]pyrene is metabolized to the highly reactive and mutagenic derivative (+)-benzo[*a*]pyrene-*trans*-7, 8-dihydrodiol-9, 10-epoxide-*anti* (BPDE). BPDE forms adducts mainly on exocyclic amino groups of guanine bases (N2dG) in DNA. N2dG adducts can form in two stereoisomeric configurations, (+)-*trans* and (+)-*cis*, both repaired by nucleotide excision repair (NER). The predominant conformation of the (+)-*trans* adduct has the pyrene system lying in DNA minor groove which causing a minor helix distortion. The predominant conformation of the (+)-*cis* adduct has the pyrene system intercalated in DNA causing a major helix distortion. The (+)-*cis* is excised by human cell extracts 100-fold more efficiently than the (+)-*trans*. *E. coli* UvrABC excision nuclease incises (+)-*cis* ~1.5 fold more efficiently than (+)-*trans*. We examined the role of BPDE-adduct configuration in the recognition and excision of BPDE-adducts by thermal resistant *B. caldotenax* UvrABC excision nuclease. Site-specifically-modified oligonucleotides containing (+)-*trans*, (+)-*cis* and no adduct were ligated into 50 bp DNA fragments and used as substrates for UvrABC. Our results suggest that *B. caldotenax* UvrABC incises *cis*-BPDE- adducts more efficiently than *trans*-BPDE-adducts in the 50 bp DNA fragments (~ 1.6 fold). UvrAB-DNA complex formation was the same with (+)-*trans* and (+)-*cis* substrates suggesting that UvrAB recognizes and binds both with equal affinity and that adduct configuration modifies recognition of UvrAB-DNA complex by UvrC. Discrimination of (+)-*cis* and (+)-*trans* adducts is similar with *E. coli* and *B. caldotenax* UvrABC but much less than with human cell extracts suggesting a major difference between prokaryotic and eukaryotic NER. Stereoisomeric adduct lesions can serve as a good conformational structural tool for exploring the mechanism of DNA damage processing by NER. (Supported by NIH Grant ES06460 and the Commonwealth of Kentucky Research Challenge Trust Fund)

1004 EFFECTS OF EXTRACELLULAR AND INTRACELLULAR FACTORS ON CHROMIUM (III) AND CHROMIUM (VI) GENOTOXICITY.

Z. Kirpnick and R. Schiestl. *Pathology, UCLA, Los Angeles, CA.*

Cr (VI) is recognized as a human pulmonary carcinogen. Recently, a debate has been raised as to whether or not Cr (VI) ingestion from drinking water can lead to cancer. An argument against the role of Chromium as an oral carcinogen is that it is reduced to the non-permeable Cr (III) in biological systems. Although it has been shown that both Cr (VI) and Cr (III) have a genotoxic potential, it is still not clear how these two forms of Cr are involved in the mechanism of genotoxicity in an intact cell. In this study, a system screening for deletions was used to compare the ability of Cr (VI) and Cr (III) to induce chromosomal rearrangement in the yeast S. cerevisiae. Induction of intrachromosomal and interchromosomal recombination was measured by growth on selective media. The assay used in this study is sensitive to both oxidation states of Cr. This allows for a comparison of the genotoxic effects of both forms of Cr under identical conditions. At identical concentrations, Cr (VI) induced deletions up six times greater than Cr (III). However, Co-incubation of the test strain with microsomal fractions or N-acetylcysteine had a protective effect against Cr (VI) genotoxicity but had no protective effect against Cr (III). Also, an oxidative DNA damage repair mutant shows a much higher sensitivity to Cr (VI) than to Cr (III). These data imply that oxidative stress is greatly involved in Cr (VI) genotoxicity and not so in Cr(III). An important issue in interpreting the results of this study is the comparison of intracellular concentrations of Cr after exposure to Cr (III) or Cr (VI). This issue is being addressed by analyzing the cells using ICP-MS.

1005 COMPARISON OF DIFFERENT METHODS OF MEASURING CYTOTOXICITY FOR GENOTOXICITY TESTING IN CHL CELLS.

M. Clare[1], A. O. Asita[1], S. K. Obuya[2], M. R. Budda[2], L. Allais[1], S. R. Wilkins[1] and M. Wing[1]. *[1]Huntingdon Life Sciences, Huntingdon, Cambridgeshire, United Kingdom and [2]Science and Mathematics, Sheffied Hallam University, Sheffield, Yorkshire, United Kingdom.* Sponsor: C. Atterwill.

When substances are tested for their ability to induce structural (clastogenic) or numerical chromosome changes *in vitro* in mammalian cells, the toxicity of a test substance often determines the highest concentration to be assessed. Generally toxicity is measured either by depression in the cell count, or reduction in the mitotic index. The objective of this study was to assess the variability, and to compare the sensitivity, of alternative methods of measuring cytotoxicity. Chinese hamster lung cells (CHL) were exposed for a minimum of 3 hours to Mitomycin C in the absence of a supplemented rat liver homogenate fraction (S9 mix) or cyclophosphamide in the presence of S9 mix. Cytotoxicity was measured from 0 to 72 hours after the end of exposure. Mitochondrial function was assessed using MTT uptake and reduction. DNA synthesis was examined by tritiated thymidine uptake. Cell division was blocked either by cytochalasin B or colcemid and the percentage of either binucleate to mononucleate cells, or mitotic to interphase cells, calculated respectively. The results show considerable variability within and between different methods of measurement. Cell counts and metaphase indices were relatively variable indicators of cytotoxicity. Mitomycin C and cyclophosphamide became more toxic as time passed, as indicated by the MTT assay. It is concluded that the method and time of

measurement of cytotoxicity is likely to influence both the potency of the response and the frequency of biologically irrelevant clastogenic effects. Also, the comparison of *in vitro* micronucleus results between different cell types will be easier if the method of measuring cytotoxicity is the same for both. The MTT assay may be useful, provided that it is used at an appropriate time after the end of exposure.

1006 MINIATURIZED CHROMOSOME ABERRATION TESTING (MINICAT).

J. Lin and R. J. Proudlock. *Genetic Toxicology, CTBR, Senneville, QC, Canada.* Sponsor: L. Dostal.

In vitro genetic toxicology testing is required at an early stage of compound development. For pharmaceuticals, this usually involves a bacterial mutation and a chromosome aberration (or mammalian cell mutation) test before the compound can be administered to man. At this stage the compound is often in short supply and expensive to produce. The dose levels used are dictated by OECD guidelines so that, even for biological molecules such as growth promoters, typically 2 grams of material are used in each assay. A modification of the chromosome aberration test has been developed in this laboratory which reduces the culture volume and, therefore, the mount of test article required for a complete regulatory study to less than 70 mg. Six compounds with various modes of action (including some with a requirement for metabolic action) were evaluated in the standard and miniaturized version of the chromosome aberration test. Benzo(a)pyrene, bleomycin, cyclophosphamide, fluorouracil and mitomycin produced similar levels of chromosome aberrations at comparable doses in both test systems. The intercalating agent, 9-aminoacridine, induced polyploidy but not chromosome damage in both systems. These results show that the MINICAT can be used to meet routine regulatory requirements; it is the recommended *in vitro* mammalian genotoxicity test when test article is in short supply.

1007 PHOTOSTABILITY AND PHOTOGENOTOXICITY OF RETINYL PALMITATE.

P. P. Fu[1], Q. Xia[1], L. G. Blankenship[1], P. J. Webb[1], W. G. Wamer[2] and P. C. Howard[1]. *[1]Biochemical Toxicology Division, NCTR, Jefferson, AR and [2]Center for Food Safty and Applied Nutrition, USFDA, College Park, MD.* Sponsor: B. Delclos.

Retinyl palmitate (RP) is currently added to many cosmetic products on the US market. RP is a storage form of retinol (vitamin A) and thermally more stable than retinol, the stability of RP exposed to sunlight and the genotoxicity of RP and its photo-decomposed products have not been described. We determined the photostability and photogenotoxicity of RP and its photoreaction products under UVA, UVB, simulated sunlight (SSL), and visible light. RP photo-decomposed quickly under UVA and UVB irradiation, and at a slower rate in SSL and visible light. The rate of photo-decomposition of RP in a more polar solvent (ethanol) was much faster than that in a less polar organic solvent (hexane). Under similar conditions, retinol was more stable under photoirradiation. RP and its photo-decomposed product mixtures were neither mutagenic in *Salmonella typhimurium* TA98, TA100, and TA102 with and without S9 enzyme activation, nor capable of binding to calf thymus DNA as determined by 32P-postlabeling analysis. Anhydroretinol (AR) was formed as a product in each of the solvents using the difference radiation sources, and exists as a mixture of all-*trans*-AR, 6Z-*cis*-AR, 8Z-*cis*-AR, and 12Z-*cis*-AR, with all-*trans*-AR as a predominant component. AR is considerably stable in hexane, and decomposed photolytically and thermally into multiple products when dissolved in ethanol. It is known that retinoids exert their biological effects, such as cell differentiation and growth, through binding to the RAR and RXR nuclear receptors; however, AR has not been shown to bind to these receptors. As a result, it is possible that photochemical formation of AR from RP may result in altered biological properties when compared to RP exposure without light irradiation.

1008 GENOTOXICANT RESPONSE IN TELOMERASE IMMORTALIZED HUMAN FIBROBLASTS.

P. C. Porter and J. States. *Pharmacology & Toxicology, University of Louisville, Louisville, KY.*

Primary fibroblasts senesce after a limited number of replications. This limitation makes primary fibroblasts unusable for genetic complementation studies requiring selection and cloning. Simian virus 40 immortalization abrogates p53 dependent induction of DNA repair, cell cycle arrest, and apoptosis. Telomerase prevents senescence by maintaining telomere length. We hypothesized that telomerase immortalized cells retain normal p53 activity and provide a good model for DNA repair complementation studies. Therefore, we investigated the use of telomerase immortalized cells for nucleotide excision repair (NER) studies. Primary diploid human fibroblasts (GM00024) from the Coriell Cell Repository were transduced with a telomerase expressing and an empty retrovirus. The empty vector transduced cells senesced after a few doublings. Telomerase transduced cells were cultured continuously for over 6 months indicating immortalization had occurred. Telomerase immortalized GM00024 cells were named tGM24. Responses of tGM24 to ultraviolet light (UV) and benzo[a]pyrene-diol-epoxide (BPDE) exposure were investigated. Cell survival was dose dependent between 0 to 40 J/m^2 UVC. P53 accumulation was UV dose- and time-dependent. At 24 hours post UV, detectable levels were reached at 10 J/m^2 and reached a maximum at 20 J/m^2. At 20 J/m^2, p53 induction occurred between 4 and 8 hours and plateaued between 16 and 40 hours. Caspase-3 activation was detected above 20 J/m^2 48 hours post UV. Apoptosis, as measured by nuclear condensation 48 hours post UV, was dose dependent between 10 and 25 J/m^2. BPDE exposure induced concentration-dependent cell death and p53 accumulation. Our results are consistent with published results using primary diploid fibroblasts. Our findings suggest that the genotoxicant response is unaltered by telomerase immortalization. Telomerase immortalized cells provide an excellent permanent cell culture model for DNA repair complementation studies because they respond to genotoxicants like primary cells. (Supported by the University of Louisville and Kentucky Research Challenge Trust Fund)

1009 MUTAGENICITY AT THE *HPRT* LOCUS IN SPLENIC T-LYMPHOCYTES OF FEMALE B6C3F1 MICE AND F344 RATS AFTER INHALATION EXPOSURE TO *MESO*-1, 2, 3, 4-DIEPOXYBUTANE AND 1, 2-DIHYDROXY-3-BUTENE.

Q. Meng, L. Long, D. M. Walker, R. F. Henderson and V. E. Walker. *Lovelace Respiratory Research Institute, Albuquerque, NM.*

1, 3-butadiene (BD) is a rodent carcinogen and probable human carcinogen. To evaluate the mutagenic effects following exposure to two important BD metabolites, *meso*-1, 2, 3, 4-diepoxybutane (M-DEB) and 1, 2-dihydroxy-3-butene (DHB), B6C3F1 mice and F344 rats were exposed to 0, or 2 ppm of M-DEB for 3 weeks, or to 0, 6, or 18 ppm of DHB for 4 weeks by inhalation. M-DEB is DNA reactive, while DHB is further metabolized to DNA reactive intermediates. Exposure of mice to 2 ppm of M-DEB yields roughly similar plasma levels of DEB as in mice exposed to 62.5 ppm of BD; exposure of mice to 18 ppm of DHB yields similar plasma levels of DHB as in mice exposed to 200 ppm of BD. *Hprt* mutant frequencies (M*f*s) in splenic T-lymphocytes were determined at multiple time points after exposure using a T-cell cloning assay. M-DEB caused significantly increased *Hprt* M*f*s in both mice and rats. The highest M-DEB-induced *Hprt* M*f*s (M*f*s in exposed animals minus that in control animals) were observed at 4 week post exposure in both mice (2.14 ± 1.06, average $\pm$ SE, $P = 0.046$) and rats (6.99 ± 1.58, $P = 0.016$). The magnitude of increase in *Hprt* M*f*s over background were similar to those observed in an earlier study in mice and rats at the same age exposed to the racemic mixture of DEB under similar exposure conditions. The highest level of induced *Hprt* M*f*s in DHB-exposed mice occurred at 5.5 weeks post exposure (4.08 ± 0.59, average induced M*f*s $\pm$ SE, $P = 0.016$), while *Hprt* M*f*s were not increased in exposed rats. These data indicate that different stereoisomers of DEB have similar mutagenic efficiencies (defined as chemical-induced M*f*s/unit dose); DHB is mutagenic at the *Hprt* locus in mice and the mutagenic potency of DHB is lower than that of DEB. (Supported by the Health Effects Institute)

1010 THE LACK OF MUTAGENICITY FOR THPI (TETRAHYDROPHTHALIMIDE) IN BACTERIAL POINT MUTATION ASSAYS.

E. B. Gordon[1], J. H. Kinzell[2] and Y. Guo[1]. *[1]Scientific Affairs, Makhteshim-Agan of North America Inc., New York, NY and [2]Registration & Regulatory Affairs, Arvesta Corporation, San Francisco, CA.*

THPI (tetrahydrophthalimide) is the relatively stable degradate of captan, a fungicide that is mutagenic when assayed by *in vitro* bacterial test systems. The US Environmental Protection Agency (EPA) currently classifies captan as a "probable human carcinogen" based on the 1986 cancer guidelines and cites a possible mutagenic component in captan's mode of action (MOA) that promotes tumors in the mouse duodenum. Since captan degrades *in vivo* with a half-life of 0.97 seconds, systemic exposure after captan administration is limited to THPI and subsequent metabolites. In order to show that THPI is not mutagenic, it was tested in six bacterial systems for point mutations. THPI was administered at 0, 0.1, 0.3, 1.0, 3.3 and 10.0 mg/plate to *Salmonella typhimurium* strains TA98, TA100, TA1535, TA1537, TA102 and *Escherichia. coli* strain WP2 uvrA. Assays were conducted both with and without activation systems based on the addition of rat liver S-9 preparation. Positive controls varied by test systems and included 2-aminoanthracene, 2-nitrofluorene, sodium azide, 9-aminoacridin, danthron, mitomycin C and 1-ethyl-2-nitro-3-nitrosoguanidine. THPI was uniformly negative in these test systems while the positive controls induced mutations. These data show that THPI is not mutagenic; therefore, it cannot contribute to a "mutagenic component" of captan's MOA. In view of both captan's rapid degradation and the lack of mutagenicity for THPI *in vivo*, a non-mutagenic MOA of captan should be considered.

1011 DETECTION OF SPONTANEOUS AND CHEMICAL-INDUCED DELETION MUTATIONS IN YEAST GENOMIC DNA UNDER NON-SELECTIVE CONDITIONS.

D. E. Watson and B. Li. *Eli Lilly and Company, Greenfield, IN.* Sponsor: C. Thomas.

Mutations are rare genetic events that are difficult to measure directly within a population of wild type sequences. Established methods for detection of mutations rely on selectable loci, as in the gain of function at various his loci in the Ames test or the loss of function in the mammalian hprt assay. Use of selectable loci has been invaluable for understanding mechanisms of DNA repair and mutagenesis in many different species, but this strategy has limitations. For example, mutant frequencies in genes of biological significance cannot be determined because only selectable loci can be used for mutagenesis experiments. In addition, investigators cannot determine when mutations occur because it takes days for selective growth and observation of mutants. We present one solution to this problem and show its application in the yeast DEL assay. In these experiments we use TaqMan to make direct measurements of the yeast chromosomal DNA to detect deletion mutations. The signal/noise ratio of the assay is high, such that mutations can be observed in populations of cells grown under non-selective conditions. Using this assay, chemical-induced deletion mutants can be detected 4 hr after initiation of exposure to mutagens. Dose-response experiments using five direct-acting mutagens showed that the TaqMan assay provided data that were quantitatively similar to those observed in the plating assay, which uses selective conditions. These data therefore support this TaqMan strategy to quantitate deletion mutations in mixed populations grown under non-selective conditions. This TaqMan strategy could also be applied to a broad range of non-selectable loci in any species.

1012 DNA REPAIR AND BREAST CANCER SUSCEPTIBILITY IN PUERTO RICAN WOMEN.

J. L. Matta[1], R. Colen[1], A. Ruiz[1], J. M. Ramos[1], N. Fernandez[2] and L. Grossman[3]. *[1]Pharmacology and Toxicology, Ponce School of Medicine, Ponce, Puerto Rico, [2]Internal Medicine, St. Luke, Ponce, Puerto Rico and [3]Biochemistry, Johns Hopkins University, Baltimore, MD.*

Cancer is the second leading cause of mortality in the US. Annually more than 300, 000 women are diagnosed with breast cancer (BC) and more than 70, 000 die each year (NCI-SEER). BC represents approximately 31% of all cancers in Puerto Rican women. There is substantial evidence for the involvement of several DNA repair pathways in the carcinogenesis process. The focus of this pilot study was to examine the relationship between DNA repair capacity (DRC), tumor pathology and risk factors of Puerto Rican women with BC. It was hypothesized that a low DRC is a susceptibility factor for BC. A retrospective, case-control study design was used. Peripheral blood lymphocytes were isolated from participants with histopathologically confirmed BC in order to measure DRC using a host cell reactivation assay and a luciferase reporter gene. The age-adjusted DRC of a control group (n=101 women) without cancer was 8.9 ±4.8 (mean ± 1 SD). Participants with BC (n=23) had a mean DRC of 5.7% ±1.6. As DRC decreased, tumor aggressiveness and size and the occurrence of metastasis to axillary lymph nodes increased. Risk factors associated with BC that were statistically significant included: maternal history of BC (odds ratio=OR=11.50), pregnancy (OR= 7.33), familial history of BC or any cancer (OR=5.70 and OR=3.91, and body mass index (OR=3.59). The 36% reduction found in DRC suggests that a low DRC may be a susceptibility factor for BC. Supported by NIH-NCRR grant 2G12RR03050-17 to the PSM RCMI Program.

1013 GENETIC TOXICOLOGY OF 8-2 TELOMER B ALCOHOL.

G. L. Kennedy[1], R. Jung[2], H. Iwai[3], S. Shin-ya[4], S. Murphy[6], N. Drouot[5], C. Finlay[1], M. Donner[1], G. Erexson[7] and L. Stankowski, Jr[7]. *[1]DuPont Haskell Laboratory, Newark, DE, [2]Clariant, Frankfurt, Germany, [3]Daikin Industries, Osaka, Japan, [4]Asahi Glass, Co., Ltd.,, Tokyo, Japan, [5]Atofina Chemicals, Paris, France, [6]Atofina Chemicals, Philadelphia, PA and [7]Covance Laboratories, Vienna, VA.*

8-2 Telomer B Alcohol is a fluorinated chemical intermediate produced and used worldwide to manufacture specialty polymers and surfactants used to a) treat surfaces such as textiles to make them oil and water repellant and b) as a wetting and leveling agent in coatings and cleaning products, respectively. The global telomer producers have initiated a scientific program to develop toxicity data for this chemical. 8-2 Telomer B Alcohol was evaluated for bacterial mutagenicity, in two independent experiments, in S. typhimurium strains TA98, TA100, TA1535, and TA1537 and E coli strain WP2uvrA, at doses of 33.3 to 5, 000 µg/plate with and without metabolic activation (S9). Normal growth was observed in all strains and revertant frequencies for all doses of 8-2 Telomer B Alcohol, with and without S9, approximated vehicle controls. In a micronucleus test, male rats were given a single oral (limit) dose of 2, 000 mg/kg, and the bone marrow cells subsequently examined for the possible induction of micronucleated polychromatic erythrocytes (MN-PCE). As in earlier studies, this limit dose elicited no clinical signs of toxicity. No signs of clinical or bone marrow toxicity, and no statistically significant increases in MN-PCE frequencies were observed. Under the conditions of these tests, 8-2 Telomer B Alcohol did not induce an increase in reverse mutations in S. typhimurium or E. coli, or an increase in MN-PCEs in rat bone marrow. (Studies supported by the TRP Toxicology Program.)

1014 PREVENTION OF ARIPIPRAZOLE–INDUCED HYPOTHERMIA AND HYPOTHERMIA–RELATED MICRONUCLEUS INDUCTION IN MICE.

T. Awogi[2], T. Shiragiku[2], Y. Hirao[2], T. Osumi[2], N. Takahashi[2], K. Nagano[2], N. Browder[1], L. Yotti[4] and M. Dominick[3]. *[1]Otsuka Maryland Research Institute, Rockville, MD, [2]Otsuka Pharmaceutical Co., Ltd.,, Tokushima, Japan, [3]Bristol-Myers Squibb, Mount Vernon, IN and [4]Bristol-Myers Squibb, Syracuse, NY.*

Aripiprazole, a novel anti–psychotic agent, induced hypothermia and weak micronuclei induction in mice at 48 hours (but not 24 hours) after dosing. It has been reported that chloromazine– or reserpine–induced hypothermia and induction of micronuclei in mice were prevented by increasing the microenvironmental temperature of the housing conditions. We investigated if the micronucleus induction seen following aripiprazole administration would be observed in aripiprazole–treated hypothermia–rescued mice. Male and female mice were administered a single oral dose of 0, 100 or 200 mg/kg of aripiprazole. Each dose group was housed under different housing conditions; one consisted of housing mice individually in steel cages at 21 — 25°C, and the other consisted of housing mice on chips in a polycarbonate cage placed on a rubber mat heater with cage temperatures of 27 — 31°C. Rectal temperatures were measured. Micronucleated immature erythrocytes stained with acridine orange in the peripheral blood and bone marrow, collected 48 hours post–dosing at necropsy, were counted. Satellite groups of mice housed under the above two conditions were utilized for toxicokinetics. Minimal increases in micronucleated polychromatic erythrocytes were noted at 48 hours in bone marrow of mice rendered markedly hypothermic by treatment with aripiprazole. However, in the groups of mice administered aripiprazole and rescued from hypothermia by heating the microenvironment, no increase in micronuclei was observed. Systemic exposure to aripiprazole was similar between the mice housed under the two different conditions. These data strongly support that the minimal increases in micronuclei observed in bone marrow erythrocytes of mice treated with high toxic doses of aripiprazole were secondary to profound hypothermia.

1015 BIOACTIVATION OF NITROCOMPOUNDS BY PATHOGENIC MICROORGANISMS.

J. J. Espinosa[1,2], R. Camacho-Carranza[1], D. Escobar-García[1], V. Dorado[2], I. Pérez[2], L. Cancino-Badías[3], S. Ibarraran[1] and R. Burgos[1]. *[1]Genetic Toxicology, Instituto de Investigaciones Biomédicas, UNAM., México, Distrito Federal, Mexico, [2]Torre de Investigación Dr. Joaquín Cravioto., Instituto Nacional de Pediatría., México, Distrito Federal, Mexico and [3]CIBIOMED, ICBP "Victoria de Girón"., Universidad de la Habana, Cd. de la Habana, Cuba.* Sponsor: M. Gonsebatt.

Mutagenic nitroaromatic compounds are common environmental contaminants. They are the result of atmospheric reactions of polycyclic aromatic hydrocarbons with HNO_3 and NO_2, and of incomplete combustion processes. Their carcinogenic action and mutagenicity depend upon their enzymatic conversion to the corresponding nitroso, hydroxylamine, and amino derivatives by mammalian and bacterial nitroreductases. The objective of the present study was to explore the capacity of cellular extracts from pathogenic microorganisms to activate 1-nitropyrene (1NP) and 2-nitrofluorene (2-NF) to mutagenic derivatives detected in the Ames mutagenicity test. The following microorganisms were tested: *Salmonella typhimurium* knocked out in the main nitroreductase genes (*nfsA* and *nfnB*); *S. typhimurium* double mutant complemented with *nfsA* and *nfnB* from *Escherichia coli*; *Helicobacter pylori* and *Giardia lamblia* clinical isolated strains. Our results show that *S. typhimurium* and *E. coli nfnB* is the main gene involved in the activation of the tested nitrocompounds, although *nfsA* presents some activity. *H. pylori* lysate promoted the activation of 1NP and 2NF increasing the number of mutant colonies of YG7132 *Salmonella* nitroreductase-null tester strain. Finally, *Giardia* lysate activated both nitrocompounds in a minor extent than the observed with bacterial lysates. In summary, the data presented here demonstrate that some of the microorganisms that more frequently infect human populations, possess the enzymatic machinery to activate nitrocompounds that constitute one of the most powerful family of environmental mutagens/carcinogens.

1016 EFFECTS OF CHLOROPHYLLIN ON TRANSPORT OF DIBENZO[*A, L*]PYRENE, 2-AMINO-1-METHYL-6-PHENYLIMIDAZO-[4, 5-*B*]PYRIDINE, AND AFLATOXIN B_1 ACROSS CACO-2 CELL MONOLAYER.

J. E. Mata[1], R. J. Rodriguez[1,2], Y. Zhen[2,3], J. E. Gray[1] and D. E. Williams[2,3,4]. *[1]Pharmaceutical Sciences, Oregon State University, Corvallis, OR, [2]Environmental and Molecular Toxicology, Oregon State University, Corvallis, OR, [3]Linus Pauling Institute, Oregon State University, Corvallis, OR and [4]Marine/Freshwater Biomedical Science Center, Oregon State University, Corvallis, OR.*

Chlorophyllin (CHL) is a sodium copper derivative of chlorophyll capable of forming strong non-covalent complexes with several known carcinogens. Anticarcinogenic effects including reduced adduct and tumor formation have been demonstrated for CHL against aflatoxin B_1 (AFB_1), dibenzo[*a, l*]pyrene (DBP) and 2-amino-1-methyl-6-phenylimidazo-[4, 5-*b*]pyridine (PhIP). Alterations in uptake and/or metabolism of planar molecules with at least partial ring structure have been proposed as mechanisms of action for CHL chemoprevention. The Caco-2 cell model of intestinal epithelial transport was used to evaluate the absorption of 1 μM DBP, AFB_1 and PhIP across cell monolayers in the presence of 0, 1, 10, and 100 μM CHL. No significant differences were observed for transport from the basolateral-to-apical (BL→AP) compared to apical-to-basolateral (AP→BL) compartments for DBP and AFB_1, however, PhIP permeability (Pe) from BL→AP compartments (1.26| *times*| $10^{-5} \pm 2.10 \times 10^{-6}$ cm/sec) was significantly higher ($p < 0.001$) than AP→BL ($5.83 \times 10^{-6} \pm 7.56 \times 10^{-7}$ cm/sec) suggesting an active efflux pathway, possibly P-glycoprotein. Transport of DBP from the AP→BL compartment was significantly reduced at all CHL concentrations ($p < 0.05$). AP→BL transport of AFB_1 was significantly reduced by addition of 100 μM CHL ($p < 0.05$) while 1 or 10 μM CHL had no effect. AP→BL transport of PhIP, which has a lower binding affinity for CHL than AFB_1 or DBP, was not significantly altered by addition of CHL. These data suggest that the transport of AFB_1 and DBP can be inhibited by CHL and support a model of direct binding in the GI tract of CHL to these carcinogens as one mechanism of action as a cancer chemopreventive agent. Supported by NIH: ES03850 and ES07316.

1017 DIBENZOYLMETHANE INDUCES PHASE 2 ENZYMES VIA NRF2 ACTIVATION AND INHIBITS BENZO(a)PYRENE INDUCED DNA ADDUCTS IN MICE LUNGS.

R. K. Thimmulappa, T. Rangasamy, K. H. Mai and S. Biswal. *Environmental Health Science, Johns Hopkins University, Baltimore, MD.*

Lung cancer continues to be the leading cause of cancer death in US. Environmental tobacco smoke has been implicated as main agent in lung cancer. Overwhelming the cellular detoxication system, the carcinogens cause DNA damage that sets platform for initiation of cancer. Individual susceptibility to cancer will greatly rely on its detoxification efficacy. Hence, identifying agents that influence the detoxication of carcinogens in lungs can be of significance with respect to lung protection in high-risk population. Dibenzoylmethane (DBM), a minor constituent of licorice and β-ketone analog of curcumin was been identified as an effective blocking agent against carcinogen induced breast cancer however its mechanism is not clear. Further its potency in other organ system has not been studied. Present study reveals the potency of DBM to induce phase 2 enzymes, mechanism of induction and efficacy to inhibit the benzo(a)pyrene(B[a]P) induced DNA adducts in mice lungs. Feeding DBM (500mg/kg/bw) showed induction of phase 2 enzymes and significant inhibition of B[a]P induced DNA adducts however curcumin at a similar dose showed modest effect. To investigate whether DBM mediates phase 2 enzyme induction *via* Nrf2 activation, mouse hepa cells stably transfected with hemeoxygenase ARE luciferase vector p3XstRELuc were exposed to DBM at concentrations 5, 10 and 50 μM. A dose and time dependent increase in mRNA expression of NQO1, GST and GCS was observed. DBM at 50 μM showed a 100-fold increase in luciferase activity. Besides, co-transfection of hepa cells with dominant negative Nrf2 inhibited the reporter activity suggesting the activation of Nrf2 by DBM. EMSA showed increased DNA binding activity of Nrf2 due DBM treatment. In conclusion, DBM inhibits B[a]P induced DNA adducts through phase 2 enzyme induction *via* Nrf2 activation in lungs and thus proves to be promising chemopreventive agent. (This work was supported by the Maryland Cigarette Restitution fund and NIEHS center grant P30 ES03819).

1018 EFFECTS OF PHYTOCHEMICALS ON AFLATOXIN B_1-MEDIATED GENOTOXICITY IN HEPG2 CELLS.

K. M. Bradley, K. Gross-Steinmeyer and D. L. Eaton. *Env Health, University of Washington, Seattle, WA.*

Aflatoxin B_1 (AFB) is a fungal toxin that commonly contaminates corn, peanuts and other foodstuffs, and is an important risk factor for liver cancer in humans. A variety of phytochemicals found in certain fruits and vegetables show chemoprotective effects towards experimental carcinogenesis in rodents. The objective of this study is to identify whether the human liver-derived cell line, HepG2, can be used to screen phytochemicals for potential chemoprotective activity toward AFB, based on their ability to reduce genotoxic AFB-DNA adduct formation. The five phytochemicals examined, and the concentrations used, were: 1) curcumin (CUR; 5, 10 uM), a component of turmeric; 2) sulforaphane (SFN; 3, 5 uM), 3) phenethyl isothiocyanate (PEITC; 5, 10 uM), and 4) 3, 3-diindolylmethane (DIM; 3, 5 uM), compounds derived from cruciferous vegetables; and 5) iso-xanthohumol (IXN; 5, 10 uM), a hops flavonoid found in beer. After pretreatment of HepG2 cells with the non-cytotoxic concentrations of each phytochemical, we measured changes in AFB-DNA adduct formation using 0.2 uM [3H]-AFB. SFN, PEITC, and IXN significantly reduced AFB-DNA adduct formation in a dose-dependant manner. At the high concentration, SFN, PEITC and IXN reduced AFB-DNA adducts by 57, 69 and 58%, respectively. In contrast, 5 uM DIM significantly increased adduct levels by 121%. Thus, although chemoprotection was observed for some treatments, a modest enhancement of genotoxicity was evident for DIM, which is a known agonist for the Ah receptor and an inducer of CYP1A2. These results demonstrate that common dietary phytochemicals can modulate genotoxicity of AFB in a human liver-derived cell line, and suggest that the cell line may be of use as a screening tool to study phytochemical-induced alterations in gene expression and potential chemoprevention activity. (Supported by grants R01ES05780 and P30ES07033).

1019 EXPOSURE TO SOIL CONTAMINATED WITH AN ENVIRONMENTAL PCB/PCDD/PCDF MIXTURE INHIBITS ULTRAVIOLET RADIATION-INDUCED NON-MELANOMA SKIN CARCINOGENESIS IN THE CRL:SKH1-HRBR HAIRLESS MOUSE.

C. Morrow[2], K. Imsilp[2], J. Hartman[2], D. Schaeffer[2], L. Hansen[2] and R. B. Cope[1]. *[1]Veterinary Basic Sciences, Oregon State University, Corvalis, OR and [2]Veterinary Basic Sciences, University of Illinois, Urbana, IL.*

Chlorinated aromatic contaminants are active in carcinogenic processes within the skin and may have the potential to modulate ultraviolet radiation (UV)-induced skin carcinogenesis. Exposure to soil bedding containing a complex environmental PCB/PCDD/PCDF mixture during the irradiation phase of photocarcinogenesis was associated with significant ($p < 0.001$) reductions in papilloma incidence and squamous cell carcinoma multiplicity at irradiated skin sites. This protective effect was associated with significantly ($p < 0.0001$) reduced chronic epidermal thickening in UV and contaminant exposed mice compared with mice exposed to UV only and a significant ($p = 0.001$) increase in the amount of methanol-extractable UV-B absorbing material in the skin. This implies that part of the anti-photocarcinogenic effect of the chlorinated aromatic mixture was associated with a sunscreen-like effect. Exposure to the contaminated soil for a 4 week post-irradiation period also resulted in a significantly ($p < 0.015$) reduced tumor multiplicity. This implies that the chlorinated aromatic mixture also inhibited tumor outgrowth during the post-irradiation phase of photocarcinogenesis. Exposure to the chlorinated aromatic mixture was consistently associated with significantly ($p < 0.05$) increased body weight, thus the tumor protective effects observed in these studies cannot be directly explained on the basis of caloric restrictive effects. These results suggest that human chlorinated aromatic exposure may have significant effects on non-melanoma skin cancer development *via* multiple mechanisms.

1020 TWENTY-EIGHT DAY TOXICITY STUDY OF THE CANCER CHEMOPREVENTIVE AGENT 4-BROMOFLAVONE IN DOGS.

B. S. Levine[1], R. Krishnaraj[1], R. Morrissey[2], I. Kapetanovic[3], J. Crowell[3] and J. M. Pezzuto[1]. *[1]University of IL @ Chicago, Chicago, IL, [2]Pathology Associates, Chicago, IL and [3]NCI, Bethesda, MD.*

Toxicity of 4-Bromoflavone (4-BF), an experimental cancer chemopreventive agent, was examined after 28 days of daily oral capsule administration to 4 groups of 4 Beagle dogs/sex at 0, 15, 80 and 400 mg/kg/day. Clinical signs included dehydration, diarrhea, decreased activity and abnormally thin dogs among the high dose (400 mg/kg/day) group males. One dog in this group was anorexic, severely dehydrated and exhibited mucoid oculonasal discharge and mucoid greenish feces on day 16. Despite i.v. saline therapy initiated on day 16, the dog lost 30% weight by day 22 and was moribund sacrificed. Females in the high dose group had diarrhea and were dehydrated. Reduced weekly body weight gains were seen on days 11, 18, 25, and 29, resulting in reduced total body weight gain. Reduced food consumption was noted in all 4-BF-treated female groups on day 19. The high and mid dose group males had reduced body weight gain on days 18 and 25 and 25, respectively. Reduced food consumption was noted in these two groups on days 5 - 26. At high dose, hypercholesterolemia and hypocalcemia in males and hypoglycemia in fe-

males were noted. No hematologic changes occurred except reduced MCV in the high dose group males. Treatment-related ophthalmic lesions and changes in electrocardiograms, organ weights, plasma estradiol, testosterone and andrestenediol levels and vaginal cytology were absent. Histopathology revealed that the primary target tissues for 4-BF were liver, kidney, tonsil, epididymis, lymph nodes (mesenteric & mandibular), thymus, ileum, and bone marrow (sternum & rib). Drug-related lesions at high dose were bile duct hyperplasia, hepatic glycogen depletion, oligospermia, immature spermatocytes in epididymis, lymphoid depletion in lymph nodes, bone marrow, tonsils, and gut-associated lymphoid tissue (ileum) and thymic atrophy. (Supported by: NCI Contract No. N01-CN-15141).

1021 TOXICITY EVALUATION OF HALICHONDRIN B ANALOG IN MICE AND BEAGLE DOGS FOLLOWING MULTIPLE INTRAVENOUS EXPOSURES.

L. Bollinger[1], P. Tosca[1], M. Ryan[1], M. Brooker[1], I. Grossi[1] and A. Smith[2]. *[1]Battelle Memorial Institute, Columbus, OH and [2]National Cancer Institute, Bethesda, MD.*

Halichondrin B, a polyeher macrolide, is a tubulin-interactive, antimitotic agent that shows antitumor activity *in vitro*. Multiple (3) i.v. exposures over 9 days to halichondrin B analog produced lethality in male Fischer 344 rats and both sexes of Beagle dogs exposed to 4.43 mg/m2/day and 1.5 mg/ m2/day, respectively, with nonlethal toxicity evident in rats exposed to 2.95 and 1.48 mg/ m2/day. The focus of the current study evaluated the toxicity of halichondrin B analog in both rats and dogs using lower doses than previously studied and the multiple i.v dose exposure regimen. Fisher 344 rats were exposed over 9 days to 3 i.v. injections of 0, 0.077, 0.767 or 1.18 mg/ m2/day of halichondrin B analog. Beagle dogs were similarly exposed *via* 1-hour continuous infusions to 0, 0.08, 0.6 or 0.8 mg/ m2/day. Toxicity endpoints included clinical observations, body weights, clinical pathology, and macroscopic and microscopic pathology. Dog endpoints also included body temperature, non-compartmental serum pharmacokinetic analysis and food consumption. No remarkable clinical findings were found in either low dose rats or dogs. Clinical findings after a 3 or 26-day recovery period for the mid and high groups were limited to reversible changes in blood chemistry parameters, increased body weight (rats), thymic and bone marrow atrophy (rats), lymphoid atrophy (dogs), skeletal muscle degeneration (rats) and non-reversible testicular degeneration in high-dose rats. Analysis of low dose dog serum indicated detectable levels of halichondrin B analog only immediately post-infusion. A mean high dose peak serum concentration of approximately 34 and 39 ng/mL occurred at the end of infusion on Days 1 and 9, respectively with a mean systemic clearance of approximately 6.6 mL/min/kg on both days. The terminal half-life was approximately 6 minutes, indicating effective elimination of halichondrin B analog. Conducted under contract N01-CM-87028, Division of Cancer Treatment of the National Cancer Institute.

1022 ADMINISTRATION OF 1-O-OCTADECYL-2-0-METHYL-SN-GLYCERO-1-D-DEOXY-MYO-INOSITOL (OMDPI) IN A HYDROXYPROPYL-B-CYCLODEXTRIN VEHICLE REDUCES TOXICITY.

J. Merrill[1], M. Brooker[1], I. Grossi[1] and A. Smith[2]. *[1]Battelle Memorial Institute, Columbus, OH and [2]National Cancer Institute, Bethesda, MD.*

An aspect of cancer therapy involves inducing tumors to undergo apoptosis. OMDPI (1-*O*-octadecyl-2-*O*-methyl-*sn*-glycero-1D-deoxy-*myo*-inositol is thought to inhibit the PI-3 kinase, Akt and induce cells to undergo apoptosis. A previous study revealed that jugular catheter i.v. infusion of rats over a 1 hour period to OMDPI in a phosphate buffered saline vehicle resulted in severe localized toxicity at the dosing site after a single exposure to doses ranging from 240 to 480 mg/m^2. The current study evaluated the toxicity of OMDPI when delivered by i.v. infusion in a vehicle of 20% hydroxypropyl β-cyclodextrin (HPCD). Thirty male Fischer 344 rats were implanted with jugular catheters and exposed to daily 1-hour i.v. infusions of either 0, 60, 120, 240, 360 or 480 mg/m^2/day OMDPI in 20% HPCD for 5 days, which was followed by a 10 day recovery period. Toxicity was based on clinical observations, body weights and clinical and macroscopic pathology. No clear dose-related findings occurred over the study period. Findings attributed to possible extravasation due to catheter implantation and the dose administration procedure occurred on Study Day 3 with the death of 1 animal and the euthanasia of 2 other moribund animals in the 120 mg/m^2/day group. Localized swelling near the dosing site was noted in 2 animals in the 120 and 360 mg/m^2/day group and 1 animal in the 480 mg/m^2/day group. No remarkable clinical signs were observed in the 0, 60 or 240 mg/m^2/day dose groups. These findings indicate that localized toxicity following i.v. infusion exposure to OMDPI is greatly reduced when OMDPI is delivered in a HPCD vehicle. Conducted under contract N01-CM-87028, Division of Cancer Treatment of the National Cancer Institute.

1023 INHIBITION OF HUMAN BREAST TUMOR CELL GROWTH BY CONTROLLING MITOCHONDRIAL BIOGENESIS.

Q. H. Felty, K. P. Singh and D. Roy. *Environmental Health Sciences, University of Alabama at Birmingham, Birmingham, AL.*

Earlier studies have indicated that Ca2+ ions and mitochondrial function are involved in the regulation of a certain segment of mitosis beyond metaphase. Mitochondrial proteins such as manganese superoxide dismutase, fumarase, succinate dehydrogenase, and the peripheral benzodiazepine receptor are considered to be tumor suppressors. In mammalian cells, gene products from two physically separated genomes: one contained within an organelle and the other within the nucleus; are involved in the biogenesis of mitochondria. Although mitochondrial biogenesis is controlled by nuclear transcription activators and co-activators, the role that mitochondrial biogenesis plays in controlling nuclear gene expression and cell growth is not clear. In this study we present the data in support of our hypothesis that that the growth of breast tumor cells can be controlled through the modulation of mitochondrial biogenesis. Specific inhibitors of mitochondrial biogenesis-chloramphenicol, rhodamine 6 G, and ethidium bromide were used to study the influence of mitochondria on cell growth, cell proliferation, cell cycle progression, and cell cycle genes. Our results show that: 1) Inhibitors of mitochondrial biogenesis significantly reduced breast tumor cell growth as determined by cell counts and the sulforhodamine B assay. 2) DNA synthesis was significantly reduced (50-60%) as measured by BrdU incorporation and further verified by flow cytometry. 3) ATP assays revealed that the inhibition of S-phase was not due to a lack of ATP. 4) Super GEArray analysis of cell cycle genes revealed that the modulation of mitochondrial biogenesis significantly inhibited the expression of cell cycle genes involved in the progression from G1 to S phase. The biological significance of our findings from this study provide the basis for the development of a novel breast cancer therapy, which targets the biogenesis of mitochondria through the use of chemical or peptide inhibitors.

1024 CALORIC RESTRICTION REDUCES BODY FAT, LEAN BODY MASS, AND PALPABLE MASSES WHILE INCREASING THE 24-MONTH SURVIVAL RATE IN SPRAGUE-DAWLEY RATS.

J. F. Harriman, E. L. Padgett, D. T. Kirkpatrick, M. C. Haas, J. T. Wilkinson and C. P. Chengelis. *WIL Research Laboratories, Inc., Ashland, OH.*

Caloric Restriction (CR) has been shown to increase the life span of laboratory animals. The goals of this study were to determine the effects of CR on mortality, body weights, clinical pathology, incidence and time of onset of palpable masses, and total body composition in rats. Sixty rats/sex were fed either *ad libitum* or fed a CR diet (70 percent of age-matched *ad libitum* fed rats) and monitored for 24 months. At the end of the 24 months and prior to the scheduled necropsy, total body composition was evaluated using dual energy x-ray absorptiometry (DEXA) on 5 animals/sex/group. The survival rate at 24 months was increased from 47% to 65% for males and from 23% to 78% for females as a result of CR. Average maximum body weights were reduced in both male and female CR rats by approximately 35% compared to *ad libitum* fed rats. Serum chemistry and hematology parameters were analyzed at 12, 25, 51, 77 and 104 weeks and were unaffected by CR. The percentage of animals with palpable masses was slightly reduced in CR vs *ad libitum* animals (27% vs 33%, and 65% vs 78% for males and females, respectively). However, no age-related difference was noted in the mean number of days to the discovery of the first mass (ranged from 401 to 463 days for both groups and sexes). Correlating to the lower percent mortality in the CR group were reductions in total body fat of 57% and 92% and reductions in lean body mass of 36% and 31% for males and females, respectively. There were no discernable differences in bone mineral content or density detected for males or females. As has been noted in numerous studies, rats with CR diets have increased percent survival over 24 months. This study indicated a slight decrease in palpable masses in the CR group, but no changes in bone mineral content, bone mineral density, or clinical pathology parameters. However, the increased survival correlated with a lower body weight in CR animals, which is directly reflected by a decrease in body fat and lean body mass.

1025 COMPARISON OF ONSET AND PROGRESSION OF FOUR COMMON LESIONS/ TUMORS IN *AD LIBITUM* AND RESTRICTED FEEDING REGIMENS FOR CHRONIC STUDIES USING THE SPRAGUE-DAWLEY RAT.

S. McPherson, L. Kangas and P. Batham. *General Toxicology, CTBR, Senneville, QC, Canada.* Sponsor: L. Dostal.

Previously published research has shown that a reduction in caloric intake of 25 to 40% (of maximal caloric intake) supplemented with essential nutrients, retards the onset of aging and disease in rodents. Following these and similar findings, studies

are now being performed using restricted feeding as opposed to ad libitum feeding in an attempt to increase animal survival by improving the overall health status of the animals. Data collected at CTBR and other research facilities has shown that animals on these studies had improved survivability and had a lower body weight at the end of the dosing period (104 weeks). Analysis of the tumor data showed a reduced incidence of spontaneous and endocrine tumors for these animals when compared to ad libitum feeding. Data obtained at these laboratories for four common lesions/tumors from control animals from carcinogenicity studies using Sprague-Dawley rats from Charles River Canada were compared between restricted and ad libitum feeding regimens. The incidence of pituitary adenoma pars distalis; mammary gland fibroadenoma, mammary gland adenocarcinoma and chronic progressive nephropathy was determined from individual histopathological data. From these data the percentage incidences (number of masses/ number of rats/group) were determined for each study over the course of the 104-week dosing period. Analysis of the data showed a generalized earlier onset of the lesions and in general an increased incidence of the lesions for all four specific lesions/tumors in animals on ad libitum feeding when compared to those on a restricted diet. In conclusion, restricted feeding increased survival in the following ways each being inter dependant; 1) reduced body weight gain; 2) delayed onset of lesions and 3) reduced the overall incidence of the lesions contributing to an overall healthier animal and thus increasing the terminal data population.

1026 EFFECTS OF DIETARY GLYCINE ON THE GROWTH OF PRENEOPLASTIC HEPATIC LESIONS IN MALE F344 RATS.

P. J. Klein, L. M. Kamendulis and J. E. Klaunig. *Division of Toxicology, Department of Pharmacology and Toxicology, Indiana University School of Medicine, Indianapolis, IN.*

The Kupffer cell has the capacity to produce mitogenic factors upon activation, however its contribution to the growth of preneoplastic lesions in the liver is not clear. Phenobarbital (PB), classified as a non-genotoxic carcinogen, enhances the growth of diethylnitrosamine (DEN)-initiated preneoplastic lesions, and has also been shown to activate Kupffer cells. It has been demonstrated that glycine treatment inactivates Kupffer cells. The purpose of this study was to examine the role of Kupffer cell activation as it relates to the tumor promotional effects of PB. Following the initiation of preneoplastic lesions in male F344 rats treated with DEN, groups of 8 initiated-rats were given the following treatments: 0 and 500 mg PB/L (drinking water) for 7 and 30 days. Four rats from each treatment group received 5% GLY (diet) three days prior to additional treatments and this diet continued throughout the study. With respect to cell proliferation, PB caused significant increases in non-focal hepatocyte DNA synthesis, an effect that was not affected by GLY co-treatment. GLY alone had no effect on basal levels of hepatocyte non-focal DNA synthesis. PB also caused an increase in GSTP positive focal lesion DNA synthesis, an effect that was decreased by GLY treatment. PB also caused an increase in the volume of GSTP positive foci, however this effect was reduced by 50% with GLY treatment. GLY alone caused an approximate 40% decrease in the volume of GSTP positive foci, while no effect was seen with respect to the number of GSTP positive foci. These data demonstrate that Kupffer cell inhibition by glycine attenuates the growth of DEN-initiated GSTP positive foci. Kupffer cell inhibition also decreases the promotional properties of PB, indicating a possible growth regulatory role for the Kupffer cell. The results of this study suggest that the Kupffer cell plays an important role in modulating the selective growth of preneoplastic lesions in the liver.

1027 CHEMOTHERAPEUTIC EFFECTS OF PERILLYL ALCOHOL (POH) ON LUNG CANCER CELL LINES.

M. Xu[1], H. S. Floyd[1], S. M. Greth[1], W. L. Chang[2], J. P. Vaughn[1], K. Lohman[1], R. Stoyanova[2], G. L. Kucera[1], M. C. Willingham[1] and M. S. Miller[1]. *[1]Wake Forest University, Winston-Salem, NC and [2]Fox Chase Cancer Center, Philadelphia, PA.*

POH is being tested in clinical trials as an anti-cancer agent, though the mechanism of action has not been definitively established. We treated 2 lung cancer cell lines, H322 and H838, with POH to determine the anti-tumor properties of this agent. A sulforhodamine B cell proliferation assay was used to determine the effects of POH after 1 and 5 days of treatment with 0.25 mM, 0.5 mM, 0.75 mM, 1.0 mM, and 1.5 mM POH. After 1 day of treatment little difference could be seen between the control and highest concentrations of POH. However, after 5 days, H322 cells showed a dose-dependent decrease in cell proliferation ranging from 15%-83%. H838 cells were less responsive and showed a maximal decrease in proliferation of 70% at 1.50 mM POH. A clonogenic assay demonstrated that while there was no significant effect of POH after 1 day of exposure, a dose-dependent decrease in colony formation, ranging from 15%-97% in H322 cells and 20%-100% in H838 cells, was seen after 5 days of treatment. Using a colormetric enzymatic assay, we observed that POH activated caspase-3 activity 3-6 fold. Time-lapse video microscopy revealed that apoptotic cells were evident within 24 to 48 hr of treatment with 1.5 mM POH, with apoptosis occurring earlier in the H322 than the H838 cells by approximately 20-24 hr. At the doses employed the cells appeared to enter apoptosis in an asynchronous manner, reflecting the use of clinically relevant but not maximally toxic doses of POH. The appearance of apoptotic cells coincided with the increase in caspase-3 activity and cleavage of poly (ADP-ribose) polymerase. Nuclear staining with DAPI confirmed the classical characteristics of apoptosis in POH treated cells. RNA microarray analysis is in progress to determine alterations in expression of signaling molecules. POH may thus be an effective anti-cancer drug that stimulates apoptosis in lung tumor cells. (MX and HSF contributed equally to the work. Supported by the Vaughn-Jordon Foundation, Inc.)

1028 INHIBITION AND REVERSAL OF CELLULAR TRANSFORMATION BY THE HISTONE DEACETYLASE INHIBITOR TRICHOSTATIN A.

T. Kluz, Q. Zhang, K. Salnikow and M. Costa. *Environmental Medicine, New York University School of Medicine, Tuxedo, NY.*

The histone deacetylase inhibitor trichostatin A (TSA) inhibited the ability of nickel, chromate and benzo[a]pyrene to transform mouse embryo fibroblast (PW) cells to anchorage-independent growth. TSA to a lesser extent also inhibited the ability of these agents to transform the human osteoblastic (HOS) cells to anchorage-independent growth. Exposure of a variety of nickel or chromate-transformed clones to TSA at 5 and 25 ng/ml followed by a recovery period of 2 to 3 weeks substantially reverted the transformed phenotype from anchorage-independent growth to anchorage-dependent growth. However, TSA was not able to revert other cells as readily as the nickel or chromate-transformed cells. We have observed changes in p21 gene expression and various hypoxia inducible factor related genes such as Cap 43 and VEGF in normal and Nickel transformed cells. We have also analyzed using the gene chip the pattern of gene expression changes found in normal cells, or cells transformed by Ni or those transformed cells reverted by Trichostatin A. Further work in this area should help delineate the specific genes that are silenced by transformation and reactivated by TSA exposure during the course of its reversal of cellular transformation. Supported by grants ES 05512, ES 10344, ES 0260 and CA 16087 from NIH.

1029 CAFFEIC ACID PHENETHYL ESTER (CAPE) INHIBITS ARSENITE-INDUCED HUMAN CELL TRANSFORMATION AND INDUCES G2/M PHASE ARREST OF ARSENITE-TRANSFORMED HUMAN CELLS.

C. Yang[1,2] and K. Frenkel[2]. *[1]Center for Experimental Therapeutics and Department of Pharmacology, University of Pennsylvania School of Medicine, Philadelphia, PA and [2]Environmental Medicine, New York University, New York, NY.*

Inorganic arsenic is a common environmental and occupational pollutant and a human carcinogen, but the mechanisms of its carcinogenicity have not been well defined. Increasing evidence suggests that inflammatory factors play a pivotal role in chemical carcinogenesis. The present study was designed to investigate if CAPE, an anti-inflammatory and immunomodulatory agent, has an effect on arsenic carcinogenicity. Arsenite-induced transformation of human osteogenic sarcoma (HOS) cells, which are immortal but not tumorigenic, was determined by anchorage independent growth assay. An 8-week arsenite (Na2AsO2, 0.3 uM) exposure caused HOS cell transformation, whereas simultaneous treatment with CAPE (0.5, 1.0 or 2.5 uM) completely suppressed it. To examine the effect of CAPE on the growth of HOS cells, arsenite-transformed HOS (As-HOS) and non-transformed parent HOS (N-HOS) cells were treated with CAPE (0.5, 1.0 or 2.5 uM) for 24 h. The results showed that CAPE suppressed As-HOS cell growth dose-dependently, with no effect on growth of N-HOS. Cell cycle analysis revealed that CAPE induced As-HOS cell cycle arrest at the G2/M interphase, with the percentage of cells in G2/M increasing from 14.8% in control As-HOS to 41.8% in CAPE-treated As-HOS (2.5 uM). Western blot analysis indicated that CAPE treatment significantly inhibited the expression of cyclin B1 and cdc2 (CDK1) in As-HOS cells. It is concluded that CAPE is capable of inhibiting arsenite-induced human cell transformation and suppressing growth of arsenite-transformed cells. These results suggest that inflammatory factors may play an important role in arsenic carcinogenesis, and anti-inflammatory CAPE could be a promising preventive and therapeutic agent, particularly for human cancers resulting from arsenite exposure. [Supprted in part by ES00260 & ES10344]

1030 INDUCTION OF DIFFERENTIATION BY KAEMPHEROL IN GJIC-SUFFICIENT BUT NOT IN GJIC-DEFICIENT COLON CANCER CELLS.

Y. Nakamura[2], C. C. Chang[1], T. Mori[3], K. Sato[2], K. Ohtsuki[2], B. L. Upham[1] and J. E. Trosko[1]. *[1]Pediatrics &Human Development, Michigan State University, East Lansing, MI, [2]Food Sciences and Nutritional Health, Kyoto Prefectural University, Kyoto and [3]Nara Medical School, Kashihara, Japan.*

The consumption of flavonoids has been linked to the prevention and therapy of some human cancers. The underlying mechanisms by which the flavonoid could contribute to cancer prevention and therapy are not known. Inhibition of GJIC by oncogenes has been implicated in the removal of the suppression of growth and differentiation by neighboring cells on the initiated cells in the tumor promoting/progression steps of cancer, while upregulation of gap junctional intercellular communication (GJIC) has been correlated with anti-tumorigenicity. We determined the effects of kaempherol on the differentiation of a KNC (well-differentiated colon carcinoma; GJIC+) and a HCT116 (colon carcinoma cell line; GJIC-), as measured by changes in the activity of alkaline phosphatase (ALPase) and morphological shape of the cells. Compared to the highly malignant and GJIC—HCT116 cell line, the ALPase activity of the GJIC+-KNC cells was approximately 3x higher. Kaempherol further increased GJIC (1.3x) and ALPase activity (2.5x) and changed the morphology of the KNC cell to a more normal epithelial cell appearance but had no effect on these same parameters in the HCT116 cell line. As measured by Western blot analysis, the phospho-ERKp42 was more highly expressed than phospho-ERKp44 in the KNC cell, and decreased by 20% with kaempherol. STAT3 was also decreased by 3% in KNC with kaempherol. In conclusion, kaempherol induced further increase in GJIC of the GJIC sufficient colon cancer cell that correlated with a decrease in both ERK and STAT3 and an increase in cell differentiation, but had no affect on the GJIC-deficient cell line. Funded by the NIEHS Superfund grant #P42 ES04911-07.

1031 INHIBITION OF GAP JUNCTIONAL INTERCELLULAR COMMUNICATION BY CHLOROHYDROXYFURANONES IN BALB/C 3T3 CELLS.

P. Hakulinen[1], J. Mäki-Paakkanen[1], L. Kronberg[2] and H. Komulainen[1]. *[1]Department of Environmental Health, National Public Health Institute, Kuopio, Finland and [2]Department of Organic Chemistry, Åbo Akademi University, Turku, Finland.* Sponsor: M. Viluksela.

One of the main groups of mutagenic by-products in chlorinated drinking water is the chlorohydroxyfuranones (CHFs). Of the CHFs, MX (3-chloro-4-(dichloromethyl)-5-hydroxy-2(5H)-furanone), MCA (3, 4-dichloro-5-hydroxy-2(5H)-furanone), CMCF (3-chloro-4-(chloromethyl)-5-hydroxy-2(5H)-furanone), and MCF (3-chloro-4-methyl-5-hydroxy-2(5H)-furanone) have been shown to be genotoxic *in vitro* in bacteria and in mammalian cells. MX is genotoxic *in vivo* and a multisite carcinogen in Wistar rats. The cellular mechanisms by which MX induces tumors in rats are not known. A two-stage cell transformation assay *in vitro* suggests that MX has the potential to promote tumor development. Inhibition of gap junctional intercellular communication (GJIC) is supposed to be one mechanism in tumor-promotion. In the present study, the effects of three CHFs (MX, MCA, and CMCF) on GJIC in Balb/c 3T3 cells were measured using the scrape loading dye technique. The cells were exposed to MX (0.005, 0.05, 5, and 50 μM), MCA (0.05, 0.5, 5, and 50 μM), and CMCF (50, 75, 100, and 125 μM) for 30 minutes. The known tumor promoter, TPA (12-O-tetradecanoylphorbol-13-acetate) was used as a positive control. All three CHFs inhibited GJIC in a dose-dependent fashion in the order of potency MX⟩MCA⟩CMCF. The maximum inhibition was 50% of the control level. MX was nearly as potent (nM concentrations) as TPA, while MCA was 10 times weaker and CMCF 10 000 times weaker than MX. The results indicate that MX is a potent inhibitor of GJIC *in vitro*, while the other CHFs have a lower inhibition activity.

1032 A COX-2 INHIBITOR INHIBITS POST-INITIATION PHASE OF N-NITROSOBIS(2-OXOPROPYL)AMINE-INDUCED PANCREATIC CARCINOGENESIS IN HAMSTERS.

A. Nishikawa[1], F. Furukawa[1], T. Umemura[1], K. Kanki[1], K. Wakabayashi[2] and M. Hirose[1]. *[1]Pathology, NIHS, Tokyo, Japan and [2]Cancer Prevention, NCCRI, Tokyo, Japan.*

The modification effects of nimesulide, a cyclooxygenase (COX)-2 inhibitor, administration during the post-initiation phase of pancreatic carcinogenesis were investigated in hamsters treated with N-nitrosobis(2-oxopropyl) amine (BOP). Male Syrian hamsters were given four weekly s.c. injections of BOP at a dose of 10 mg/kg and thereafter they were administered 0, 100 or 400 ppm nimesulide in the diet for 36 weeks. Additional groups of hamsters were fed 400 ppm nimesulide without prior BOP-initiation or non-treated. At week 40 of the experiment, all surviving animals were sacrificed, and development of neoplastic and preneoplstic lesions was assessed histopathologically. The incidence of pancreatic adenocarcinomas was significantly ($p<0.05$) decreased in the BOP/400 ppm nimesulide group as compared to the BOP alone group. The multiplicity of total lesions of pancreatic adenocarcinomas plus atypical hyperplasias was also significantly ($p<0.05$) lowered. Immunohistochemically, COX-2 was expressed in pancreatic adenocarcinoma cells whereas the severity of expression was not remarkably affected by the nimesulide treatment. The incidence and multiplicity of neoplastic lesions in other organs did not significantly differ among the BOP-treated groups. No neoplastic lesions were detected in animals receiving nimesulide alone. Our results clearly indicate that nimesulide protects against BOP-induced pancreatic tumors in hamsters.

1033 COLON CANCER AND VITAMIN E SUPPLEMENTATION IN YOUNG AND OLD RATS.

E. H. South[1], J. H. Exon[1], M. W. Fariss[2] and J. G. Zhang[2]. *[1]Food Science and Toxicology, University of Idaho, Moscow, ID and [2]Pharmaceutical Science, Washington State University, Pullman, WA.*

Previous studies have reported conflicting effects of vitamin E on cancer development. In this study, we examined the effects of d-alpha tocopheryl succinate (TS) in female Sprague-Dawley rats of either 20 (OLD) or 2 mo (YNG) of age. Treatment groups from each age group were fed commercial rodent chow or the same feed supplemented with either 1 (YNG) or 2 (OLD) g/kg TS/kg diet. These animals were injected ip with the carcinogen, azoxymethane (AOM)(10 mg/kg) on days 8 and 15 of the study. After 42 days exposure the animals were sacrificed and serum and a section of colon were collected for analysis of d-alpha-tocopherol (aT) and gamma-tocopherol (gT) content. The remainder of the colons were removed and examined for the presence of aberrant crypt foci (ACF), a preneoplastic marker for colon cancer. Dietary TS supplementation significantly increased aT concentrations in the serum and colons of all rats compared to control diets. The OLD group fed the TS diets had significantly increased colonic aT and gT levels as compared to the YNG group fed similar diets. There were consistently fewer total ACF in the colons of groups treated with TS regardless of age compared to their controls. This reduction was significant in larger ACF (>3 aberrant crypt/foci) of the OLD group. It appears that the larger ACF, which are more likely to develop into tumors, are reduced by TS treatment in the OLD group and this appears to correspond with increased aT or gT levels in the colon. This data supports previous studies by others that show dietary vitamin E supplementation may be protective against the development of colon cancer. Surprisingly, our study shows that older rats retain significant levels of gT in the colons compared to young rats, even in the presence of high aT supplementation. We speculate that the retention of gT in the colons of older rats may play a chemopreventive role.

1034 EFFECT OF LOW DOSE MATERNAL DIETARY VITAMIN E ON EMBRYONIC OXIDATIVE DNA DAMAGE IN P53 KNOCKOUT MICE.

C. S. Chen[1] and P. G. Wells[1,2]. *[1]Faculty of Pharmacy, University of Toronto, Toronto, ON, Canada and [2]Pharmacology, University of Toronto, Toronto, ON, Canada.*

Reactive oxygen species (ROS) have been implicated in cancer initiation and promotion, and the embryo has limited protective antioxidative mechanisms, leaving it at potentially greater risk. We have shown that *in utero* exposure of pregnant p53 knockout mice, which exhibit spontaneous tumorigenesis, to a high level (10% [w/w]) of the antioxidant vitamin E (VE) alters conceptal DNA oxidation and enhances postnatal tumor development in the offspring. Since we previously found that low dose (0.1% [w/w]) dietary vitamin E *in utero* reduces embryonic DNA oxidation and embryopathies in outbred CD-1 mice, here we detemined the effect of this VE dose on embryonic DNA oxidation on p53 knockout mice during organogenesis (gestational day [GD] 13) to assess its potential for cancer prevention. Heterozygous (+/-) p53-deficient females were placed on either a normal or 0.1% [w/w] VE (dl-α-tocopherol-acetate)-supplemented diet for 4 weeks and mated with +/- p53-deficient males. Vitamin E supplementation continued until GD 13, when the embryos were extracted, p53-genotyped, and analyzed for DNA oxidation, reflected by 8-hydroxy-2'-deoxyguanosine formation. Unlike in CD-1 mice, 0.1% VE exposure did not alter embryonic DNA oxidation levels during organogenesis for any p53 genotype. However, since carcinogenic initiation/promotion also may occur later in gestation, it remains to be determined whether fetal DNA oxidation in the last trimester may be reduced by 0.1% VE, in which case that dose would be reasonable for attempting to inhibit tumorigenesis in p53 knockout mice. (Support: National Cancer Institute of Canada; Canadian Institutes of Health Research)

1035 SELENOMETHIONINE AND VITAMIN E IN SMOKERS: A PHASE I STUDY OF A POTENTIAL CHEMOPREVENTIVE REGIMEN.

G. Reed[1], H. Smith[1], K. Peterson[1], L. Wesselius[2], M. Plautz[2], K. Bailey[2], J. Crowell[3] and A. Hurwitz[1]. *[1]University of Kansas Medical Center, Kansas City, KS, [2]VA Medical Center, Kansas City, MO and [3]NCI, Rockville, MD.*

We have completed a Phase I study of l-selenemethionine (SeMet) and vitamin E in chronic smokers, characterizing safety and examining biomarkers for compliance and effects. Thirty-two healthy subjects with a minimum of ten pack-years of smoking were enrolled. Following a four week single-blind placebo period, each subject was examined and blood and bronchoalveolar lavage samples were obtained. Subjects then were randomized to four arms of this double-blind study: placebo, low dose SeMet (200 μg Se/day), high dose SeMet (400 μg Se/day), or high dose SeMet plus 400 I.U. vitamin E/day. All subjects also received 250 mg vitamin C/day. After 16 weeks of treatment subjects had repeat bronchoscopies and blood and lavage specimens were obtained. Markers of compliance included plasma vitamins C and E and selenium, whereas biomarkers of effect included glutathione peroxidase, catalase, and superoxide dismutase activities and PGE2 levels in bronchoalveolar lavage fluid, and DNA damage in blood mononuclear cells and in alveolar macrophages. DNA damage was determined using the single cell electrophoresis (SCE) assay. Selenium levels in alveolar macrophages also were determined for some subjects. The treatment was well tolerated, with no serious adverse effects noted. Compliance was supported by significant increases in plasma vitamin E for subjects in the fourth arm, however neither vitamin C nor selenium levels in plasma were altered by the treatments. Among the effect biomarkers, no statistically significant changes could be associated with SeMet. All groups showed some improvement in SCE scoring in alveolar macrophages, but this was not SeMet dependent. Interestingly, examination of eight high dose SeMet subjects demonstrated a significant increase in alveolar macrophage Se content. This effect in a presumed Se-replete cohort suggests that tissue-specific levels of Se may be increased by supplementation, independent of effects on Se levels in plasma. Supported by NCI-NO1-CN-65019.

1036 ARSENIC AS A DEVELOPMENTAL TOXICANT: LOW DOSE EXPOSURE *IN UTERO* INDUCES ABERRANT GENE EXPRESSION IN THE EMBRYONIC LUNG.

J. S. Petrick[1] and R. Lantz[2,3]. *[1]Pharmacology and Toxicology, The University of Arizona, Tucson, AZ, [2]Cell Biology and Anatomy, The University of Arizona, Tucson, AZ and [3]The Center for Toxicology, The University of Arizona, Tucson, AZ.*

The human health effects of low dose arsenic exposure in the drinking water remain controversial. The adult lung is a target organ for arsenic toxicity, however, the molecular effects of maternal arsenic exposure on the developing lung are poorly understood. We hypothesize that *in utero* exposure to inorganic arsenic causes altered gene expression in the lung, leading to molecular and functional changes. We exposed pregnant Sprague-Dawley rats to 500 ppb arsenic in the drinking water, in the form of sodium arsenite or sodium arsenate, from conception to embryonic day eighteen. Subtractive hybridizations of embryonic lung cDNA from control and treated day 18 embryos yielded numerous differentially expressed cDNA clones. We have sequenced 352 differentially expressed cDNA clones from these subtractive hybridizations and have spotted them on a custom cDNA microarray. Using a rat alveolar type II cell line exposed to arsenic as a model for lung gene expression effects, we have carried out a dose and time-response study of subacute, low dose arsenic exposure (10, 50, 100, and 500 ppb for 1, 7, and 14 days). Using these samples for cDNA microarray hybridizations, we have profiled gene expression changes induced by arsenic exposure. Using both subtractive hybridization and cDNA microarray, we have found differential expression of genes involved in branching morphogenesis and in formation of the extracellular matrix and cytoskeleton, thus implicating arsenic as a toxicant effecting structure and function in the developing lung. (Supported in part by the NIEHS Superfund Basic Research Program Grant P42 ES04940).

1037 ABERRANT GENE EXPRESSION IN LIVER AND LIVER TUMORS INDUCED BY TRANSPLACENTAL EXPOSURE TO INORGANIC ARSENIC.

M. P. Waalkes[1], H. Chen[1], Y. Xie[1], B. A. Diwan[2] and J. Liu[1]. *[1]Inorganic Carcinogenesis Section, LCC, NCI at NIEHS, Research Triangle Park, NC and [2]SAIC Frederick, Frederick, MD.*

Arsenic is a known human carcinogen that targets the liver. We have found exposure of pregnant mice to inorganic arsenic in the drinking water induces hepatocellular carcinoma (HCC) in the offspring. In addition, adult mice chronically exposed to inorganic arsenic in the drinking water (37.5 ppm, 48 weeks) show hepatic overexpression of the estrogen receptor-alpha (ER) and cyclin D1 genes, both of which are implicated in hepatocarcinogenesis. Thus, we examined ER and cyclin D1 expression in liver and liver tumors in adult mice that resulted from transplacental exposure to inorganic arsenite (0 or 85 ppm from gestation day 8 to 18). HCC or surrounding normal liver samples were taken at necropsy from control or arsenic-exposed mice which were typically over 1-year old. Immunohistochemistry revealed the increased expression of ER and cyclin D1 protein in HCC and normal liver of arsenic-exposed mice. Microarray and real time RT-PCR analysis confirmed the increased expression of ER (2.5- to 3.5-fold over control) and cyclin D1 (1.7- to 6.8-fold) at the RNA level in HCC and normal liver after arsenic exposure. Methylation-specific PCR of DNA from HCC and normal liver showed arsenic had induced extensive hypomethylation in the promoter region of the ER gene. To define the human significance of these data, RT-PCR analysis was applied to liver biopsy samples from a population in Guizhou, China, heavily exposed to environmental arsenic that develop HCC. ER and cyclin D1 expression was 2 to 5 times higher with arsenic exposure than in normal human livers. These data show that transplacental arsenic carcinogenesis is linked with enhanced expression of ER and cyclin D1. The overexpression of the ER gene may be due to promoter region hypomethylation. Both ER and cyclin D1 can play important roles in liver tumor formation, and their overexpression may be an important element in the hepatocarcinogenic effects of inorganic arsenic.

1038 TOXICOGENOMIC ANALYSIS OF ABERRANT GENE EXPRESSION IN LIVER AND LIVER TUMORS INDUCED BY TRANSPLACENTAL EXPOSURE TO INORGANIC ARSENIC IN MICE.

J. Liu[1], Y. Xie[1], J. M. Ward[2], B. A. Diwan[3] and M. P. Waalkes[1]. *[1]Inorganic Carcinogenesis Section, LCC, NCI at NIEHS, Research Triangle Park, NC, [2]National Cancer Institute at Frederick, Frederick, MD and [3]SAIC Frederick, Frederick, MD.*

Arsenic is a known human carcinogen. We have reported that brief exposure of pregnant mice to arsenite in the drinking water induces hepatocellular carcinoma (HCC) in the offspring. In this prior work, adult male mice, which were the offspring of dams exposed to sodium arsenite (85 ppm as arsenic) in the drinking water from gestation day 8 to 18, showed a 61% rate of HCC while control animals showed a spontaneous rate of 12%. Liver tumor or surrounding pathologically normal liver tissue samples were taken at necropsy and quick frozen for later use. In the present study, total RNA was extracted from these liver samples, and subjected to microarray and quantitative RT-PCR analysis. Among 600 genes, arsenic-induced HCC showed a higher rate of aberrant gene expression (>2 fold increase or decrease, 31% of all genes tested) than spontaneous tumors (20% of all genes tested). Overexpression of estrogen receptor-α, cyclin D1, c-*myc* and suppression of p27 was associated with arsenic exposure. Expression of α-fetoprotein and downregulation of syndecan-1, markers for aggressiveness of HCC, were seen only in arsenic-induced tumors. The non-tumorous hepatic tissue of animals transplacentally exposed to arsenic also showed various significant alterations in the expression of genes associated with cell proliferation, oxidative stress, signal transduction, DNA damage/repair, and hepatic biotransformation. Real time RT-PCR largely confirmed these findings (with a 75% accordance among 32 selected genes from microarray). These aberrantly expressed genes could be important in arsenic carcinogenesis. This genomic analysis revealed aberrant gene expression patterns associated with transplacental arsenic carcinogenesis, indicating that arsenic can alter gene expression long after a brief exposure during gestation. This study points towards the importance of protecting pregnant women in areas where arsenic exposure is common.

1039 TOXICOKINETIC AND GENOMIC ANALYSIS OF CHRONIC ARSENIC EXPOSURE IN MULTIDRUG-RESISTENCE DOUBLE KNOCKOUT MICE.

Y. Xie[1], J. Liu[1], Y. Liu[1], C. D. Klaassen[2] and M. P. Waalkes[1]. *[1]Inorganic Carcinogenesis Section, LCC, NCI at NIEHS, Research Triangle Park, NC and [2]University of Kansas Medical Center, Kansas City, KS.*

Multidrug-resistance gene double-knock out mdr1a/1b(-/-) mice, which are deficient in drug-transport type I P-glycoprotein, are more sensitive than wild-type (WT) mice to acute arsenic toxicity. This study assessed the toxic manifestations of chronic oral arsenic in mdr1a/1b(-/-) mice, including altered gene expression, and investigated altered toxicokinetics as a potential basis of enhanced arsenic toxicity. Thus, mdr1a/1b(-/-) and WT mice were exposed to sodium arsenite (0 to 80 ppm as arsenic) in the drinking water for 10 weeks at which time hepatic arsenic accumulation, redox status, lipid peroxidation (LPO) and aberrant gene expression (using cDNA microarray) were assessed. During the exposure period, all mice survived, but body weight in the highest dose (80 ppm) group was less than control in both mdr1a/1b(-/-) and WT mice. Arsenic induced pathological changes, increases in LPO and enhanced glutathione S-transferase (GST) activity in the liver, to a greater extent in mdr1a/1b(-/-) than in WT mice. Enhanced expression of hepatic

cyclin D1, a potential hepatic oncogene, was observed in arsenic-exposed mdr1a/1b (-/-) mice when compared to WT mice. The expressions of certain genes, such as those encoding GST, heat shock proteins and metabolic enzymes, were modestly altered in arsenic-exposed mice. At the highest level of exposure, the hepatic arsenic content was higher in mdr1a/1b (-/-) mice than in WT mice, suggesting that enhanced accumulation due to transport deficiency may account for the enhanced toxic manifestations observed in these double knockout mice. In summary, this study shows that chronic arsenic toxicity, including liver pathology and oxidative stress, is enhanced in mdr1a/1b(-/-) mice, possibly due to enhanced accumulation of hepatic arsenic as result of transport system deficiency.

1040 CHROMOSOME ALTERATIONS AND HYPERPROLIFERATION ASSOCIATED WITH CHRONIC ARSENIC EXPOSURE.

H. Chen and M. P. Waalkes. *Inorganic Carcinogenesis Section, LCC, NCI at NIEHS, Research Triangle Park, NC.*

Epidemiological studies link arsenic exposure to cancers of the skin, lung, liver and other sites in human, although the underlying carcinogenic mechanism remains incompletely understood. Our previous studies have shown that chronic (> 18 weeks) low level (125 to 500 nM) exposure to sodium arsenite induces malignant transformation in the TRL 1215 rat liver epithelial cell line, which is normally diploid, and non-tumorigenic. Malignant transformation was confirmed in these chronic arsenic exposed (CAsE) cells by tumor formation upon inoculation in Nude mice. Chromosomal aberrations have been linked to arsenic exposure in both epidemiological and laboratory studies. The aim of present study was to better characterize the cytogenetic effects of the arsenic during arsenite-induced transformation in CAsE cells by assessing *in vitro* changes in mitotic index (MI, related to cell proliferation), Sister-chromatid exchange (SCE, correlated with chromosome damage), and polyploidy (numerical chromosomal aberration related to tumor development). Our results showed that MI was increased a maximum of about 4-fold in a concentration dependent manner in CAsE cells compared to control cells after continuous exposure to 125, 250 or 500 nM sodium arsenite for 24 weeks. The average generation time (AGT), which is inversely related to growth rate, was reduced in CAsE cells compared to control cells after 24 weeks of arsenite exposure, but not after arsenic exposure for only 6 weeks, a time point prior to malignant transformation. Polyploid, which was typically tetraploid in nature, was increased in CAsE cells compared to control, but not changed in pretransformed cells. The frequency of the SCE was significantly increased in CAsE cells. Taken together, these results indicate chronic arsenic exposure resulting in malignant transformation induces chromosome aberrations and enhanced proliferation, factors that might be an important in arsenic carcinogenesis.

1041 MALIGNANT TRANSFORMATION AND DNA HYPOMETHYLATION IN HUMAN PROSTATE EPITHELIAL CELLS CHRONICALLY EXPOSED TO INORGANIC ARSENITE.

E. M. Brambila[1], W. E. Achanzar[2], B. A. Diwan[3], H. Chen[2], M. M. Webber[4] and M. P. Waalkes[2]. *[1]Universidad Autonoma de Puebla, Puebla, Mexico, [2]Inorganic Carcinogenesis Section, LCC, NCI at NIEHS, Research Triangle Park, NC, [3]SAIC Frederick, Frederick, MD and [4]Michigan State University, East Lansing, MI.*

Arsenic is an established human carcinogen that some epidemiological evidence suggests may target human prostate. We set out to malignantly transform the human prostate epithelial cell line RWPE-1 by chronic inorganic arsenite exposure to determine if this cell type was directly susceptible to the transforming effects of arsenic. Cells were exposed continuously to 5 mM sodium arsenite and assessed for signs of transformation, such as increase matrix metalloproteinase (MMP) secretion. After 29 weeks of exposure, the chronic arsenic-exposed human prostate epithelial cells (CAsE-PE) exhibited a 2.2-fold increase in secreted MMP-9 activity compared to passage-matched RWPE-1 cells maintained in medium only. As definitive proof of malignant transformation, the cells were inoculated into nude mice to assess tumorigenicity. Five of five mice inoculated with CAsE-PE cells developed tumors within 10 weeks of inoculation while none of the mice inoculated with passage-matched RWPE-1 cells developed tumors. CAsE-PE cells produced undifferentiated epithelial tumors that were highly invasive into the surrounding capsular muscle and adjacent normal renal parenchyme and stained positive for prostate-specific antigen, confirming their origin. We next compared the genomic DNA methylation status of CAsE-PE and passage-matched RWPE-1 cells. Our results revealed significant DNA hypomethylation in the arsenite-transformed cells, which is consistent with previous studies using rodent cell models. We are currently comparing gene expression patterns in these two lines to determine the functional consequences of this hypomethylation. The present study represents the first report of arsenite-induced malignant transformation of human epithelial cells and provides a human-based model in which to examine the mechanisms underlying arsenic carcinogenesis.

1042 ALTERED GENE EXPRESSION ASSOCIATED WITH ARSENITE-INDUCED MALIGNANT TRANSFORMATION OF HUMAN PROSTATE EPITHELIAL CELLS.

L. Benbrahim-Tallaa[1], W. E. Achanzar[1], E. M. Brambila[2], M. M. Webber[3] and M. P. Waalkes[1]. *[1]Inorganic Carcinogenesis Section, LCC, NCI at NIEHS, Research Triangle Park, NC, [2]Universidad Autonoma de Puebla, Puebla, Mexico and [3]Michigan State University, East Lansing, MI.*

Arsenic has long been known to cause cancer in humans and epidemiological studies have shown an association between long-term environmental arsenic exposure and cancer in a number of tissues, including potentially the prostate. However, the mechanisms underlying arsenic carcinogenesis remain unclear. We have recently developed an *in vitro* model of arsenic-induced prostate cancer by malignantly transforming the immortalized, non-tumorigenic human prostate epithelial cell line RWPE-1 by continuous exposure to 5 μM sodium arsenite for 29 weeks. Malignant transformation was established by the ability of the chronic arsenite-exposed prostate epithelial cells (designated CAsE-PE) to produce tumors after inoculation into nude mice. To understand the molecular mechanisms underlying arsenic carcinogenesis, we performed gene expression comparisons between CAsE-PE and passage-matched control RWPE-1 cells. Initially, we used northern blot analyses to examine expression of several oncogenes and tumor suppressor genes. Our studies revealed increases in c-*myc*, K-*ras* and *p53* mRNA in the CAsE-PE cells (1.5-fold, 2.6-fold and 2-fold, respectively, of RWPE-1 levels). As an expansion of the above studies, cDNA array experiments have been initiated in order to perform more extensive gene expression comparisons between CAsE-PE and RWPE-1 cells. The initial array studies have provided preliminary data suggesting altered expression of oncogenes as well as genes linked to apoptosis, cell cycle regulation and signal transduction in CAsE-PE cells. While these results suggest that arsenic may alter oncogene and tumor suppressor gene expression in the course of transformation, further study is clearly needed to determine the role of the observed changes in the transformation process. Further genomic analysis should provide additional clues as to the molecular changes associated with arsenic-induced malignant transformation.

1043 SPECIFIC CHANGES IN CADHERIN EXPRESSION AND LOCALIZATION ARE ASSOCIATED WITH CADMIUM-INDUCED MALIGNANT TRANSFORMATION OF HUMAN PROSTATE EPITHELIAL CELLS.

W. E. Achanzar[1], P. C. Lamar[2], W. C. Prozialeck[2], M. M. Webber[3] and M. P. Waalkes[1]. *[1]Inorganic Carcinogenesis Section, LCC, NCI at NIEHS, Research Triangle Park, NC, [2]Midwestern University, Downers Grove, IL and [3]Michigan State University, East Lansing, MI.*

Cadmium is a carcinogenic metal implicated as a human prostatic carcinogen based on epidemiological studies, rodent studies and *in vitro* experiments. However, since the evidence is still considered equivocal, identifying the molecular changes specifically associated with cadmium-induced malignant transformation of human prostate epithelial cells would help clarify the role of this metal in human prostate cancer. In order to identify cadmium-specific changes, we compared the gene expression pattern of cadmium-transformed human prostate epithelial cells to those of the parental cell line as well as Ki-*ras*- and MNU-transformants derived from the same cell line. cDNA array experiments revealed a specific increase in P-cadherin in the cadmium transformed cells that was later confirmed by western blot analyses. Surprisingly, the increase in P-cadherin resulted from overexpression of several truncated species of P-cadherin that exhibited perinuclear, rather than membrane, localization. Pan-cadherin westerns showed that these truncated molecules were missing their C-terminal regions, which explains the altered localization since the C-terminus contains the transmembrane domain. The pan-cadherin westerns also revealed specific loss of N-cadherin in the cadmium transformed cells, even though N-cadherin did not show up in the array analysis. In addition, preliminary data show that, while there are no differences in E-cadherin levels between the various cell lines, the cadmium-transformed cells showed specific alterations in E-cadherin localization. While the mechanistic implications of these changes are unclear, it is known that alterations in cadherin expression and/or localization can have profound effects on tumor cell migration and metastasis. Additionally, these alterations in cadherin expression represent potential specific biomarkers for cadmium-induced prostate cancers in men.

1044 MICROARRAY ANALYSIS OF BONE CELL GENE EXPRESSION EARLY AFTER CADMIUM GAVAGE IN MICE.

M. Bhattacharyya[1], A. Regunathan[1], D. Glesne[1] and A. Wilson[2]. [1]*Argonne National Laboratory, Argonne, IL and* [2]*Benedictine University, Lisle, IL.*

We developed an *in vivo* model for Cd-induced bone loss in which mice excrete bone mineral in feces starting 8 h after Cd gavage. In both mice and dogs, this bone response starts at 2-5 μg Cd/l blood, below current USOSHA standards for industry. Female mice of 3 strains [CF1; metallothionein-wildtype (MTN); MT1, 2-deficient (MT1, 2KO)] were placed on a low Ca diet for 2 wk. Each mouse was gavaged with 200 μg Cd or vehicle. Fecal Ca was monitored for 8 d to document the bone response. For CF1 mice, bones were taken from 4 groups: +/- Cd, 2h after Cd; +/- Cd, 4h after Cd. The MTN and MT1, 2KO strains had two groups each: +/- Cd, 4 h after Cd. PolyA+ RNA was isolated from marrow-free shafts of femura and tibiae, and each +/- Cd pair was submitted to Incyte Genomics for microarray analysis. To validate microarray results, the same CF1 4h RNA preparations were subjected to Northern analysis; probes were prepared from 18 clones of genes shown by microarray to be key to the bone cell Cd response, standard housekeeping genes, and other genes with no Cd response *via* microarray. Fecal Ca results showed that bone calcium excreted after Cd differed for the three mouse strains: CF1 0.24+0.08 mg; MTN 0.92+0.22 mg; MT1, 2KO 1.7+0.4 mg. Microarray results showed that, among the ~8500 arrayed genes, three categories were significantly induced by Cd: cell protector genes (e.g., MT1, MT2, transferrin receptor); cell signaling genes (e.g., p38 MAP kinase); and genes involved in osteoclast-mediated bone resorption (e.g., vacuolar proton pump, integrin alpha V, src-like adaptor protein). Cd also induced two genes encoding unknown proteins, one by 18-fold. No genes were clearly down-regulated by cadmium. In particular, genes for bone formation, stress response, growth factors, and signaling molecules other than p38MAPK did not change in expression in bone cells early after cadmium gavage. Results support the hypothesis that Cd increases bone demineralization *via* a p38 MAPK pathway that results in stimulation of osteoclast-mediated bone resorption.

1045 METAL RESPONSE ELEMENT BINDING TRANSCRIPTION FACTOR-1 (MTF1) IS ESSENTIAL FOR ACQUIRED RESISTANCE TO CADMIUM TOXICITY.

L. He, T. P. Dalton and D. W. Nebert. *Environmental Health, University of Cincinnati, Cincinnati, OH.*

Metallothioneins (MTs) are low-molecular-weight cysteine-rich heavy metal-binding proteins, which function to protect cells against many forms of oxidative stress including cadmium (Cd) toxicity. The four Mt genes are regulated through metal-response-element (MRE) DNA motifs, to which MRE-binding transcription factor-1 (MTF1) binds for up-regulation. The cell culture line dko7 lacks MTF1. Using these cells, MTF1 was re-introduced using a retrovirus to produce mdko7 cells. Surprisingly, mdko7 cells resist Zn, but not Cd, toxicity. When dko7 and mdko7 cells (107 cells) were cultured in 5 mM Cd, resistant mdko7 clones were observed at a frequency of 1 in 105 cells. On the other hand, resistant dko7 clones were not observed. Cd-resistant clones could be cultured in the absence of Cd for >60 population doublings, and they remain Cd-resistant. Slot-blot analysis (to detect Mt gene amplification) showed that resistance was not a result of increased Mt copy number; nevertheless, all resistant mdko7 clones had high constitutive levels of MT mRNA accumulation. These data suggest that MTF1 is essential for acquired resistance to Cd. Further, resistance to Cd may depend on activation of Mt gene expression, and this resistance, which is dependent on MTF1, is likely the result of constitutive MTF1 activation. (Supported, in part, by NIH grants P30 ES06096 and R01 ES10416)

1046 ABERRANT ONCOGENE EXPRESSION ASSOCIATED WITH CADMIUM-INDUCED MALIGNANT TRANSFORMATION IN RAT LIVER CELLS.

W. Qu[1], B. A. Diwan[2] and M. P. Waalkes[1]. [1]*Inorganic Carcinogenesis Section, LCC, NCI at NIEHS, Research Triangle Park, NC and* [2]*SAIC Frederick, Frederick, MD.*

Cadmium (Cd) is a recognized human carcinogen that potentially targets the liver, although its mechanism of action is incompletely defined. This study attempted to induce malignant transformation of normally nontumorigenic rat liver epithelial cell line TRL 1215 by chronic, low level *in vitro* Cd exposure and to define associated aberrant gene expression. Cells were cultured in 1.0 μM CdCl2 for up to 28 weeks and compared to passage-matched control cells. These chronic Cd exposed (CCE) cells were hyperproliferative with a growth rate about 3-fold higher than control cells. CCE cells showed frequent foci of cell mounding, even when subconfluent, which were absent in passage-matched control cells. CCE cells produced aggressive tumors upon inoculation into nude mice confirming malignant transformation. cDNA gene microarray showed an increase in the steady state expression of the oncogenes c-*myc* and c-*jun* in CCE cells, compared to control. To confirm the overexpression of c-*myc* and c-*jun*, northern blot analyses were performed. By this analysis, transcript levels of c-*myc* and c-*jun* were increased by over 10-fold and 2-fold, respectively, in CCE cells compared to control cells. Western blot analysis showed that the steady state level of c-Myc protein in CCE cells was increased over 10-fold compared to the control, demonstrating enhanced expression at the translational level. Further study revealed a significant increase in expression of the transcription factors AP-1 and NF-κB. Taken together, this work suggests that chronic low level Cd leading to malignant transformation triggers oncogene overexpression possibly by altering transcription factor expression. Such changes in cellular gene expression likely culminate in the loss of growth control and neoplastic transformation.

1047 INCREASED EXPRESSION OF THE ECT2 ONCOGENE IN NICKEL COMPOUND INDUCED, TRANSFORMED 10T1/2 MOUSE EMBRYO FIBROBLAST CELL LINES.

F. Clemens, J. Ramnath, R. Verma and J. Landolph. *Molecular Microbiology and Immunology, University of Southern California, Los Angeles, CA.*

Nickel is an economically important element, particularly for its presence in stainless steel. In the past, workers in specific refining operations, who were exposed to mixtures of soluble and insoluble nickel compounds, had increased incidence of nasal and lung tumors. The exact mechanism of nickel carcinogenesis is still largely unknown. In order to study the molecular mechanism of nickel carcinogenesis, we used C3H/10T1/2 (10T1/2) mouse embryo fibroblast cells and nickel oxide/nickel monosulfide induced, transformed 10T1/2 cells as a model system. To characterize the molecular events associated with nickel-induced carcinogenesis, mRNA from these cell lines was isolated and analyzed by RAP-PCR mRNA differential display. Gene fragments whose expression patterns differed between the non-transformed and transformed cell lines were isolated. One of these isolated fragments, R2-5, was a 293bp fragment that is over-expressed in nickel-induced transformed cell lines. R2-5 was subcloned, sequenced and subjected to nBLAST homology analysis. R2-5 was found to be 100% homologous to a portion of the mouse Ect2 proto-oncogene. Ect2 is known to be a GTP-exchange factor for the Rho family of GTPases. Increased expression of Ect2 keeps Rho constitutively active and results in an increased cytoskeletal remodeling and cytokinesis, which could eventually leading to morphological transformation (Miki, et al.). Southern analysis shows the presence of gene amplification of the Ect2 gene in the transformed cell lines. Multiple copies of the Ect2 gene could be responsible for its over-expression. Western analysis of Ect2 showed higher steady-state levels of Ect2 protein in the transformed cell lines. Higher steady-state levels of Ect2 may contribute to the induction of the nickel compound induced morphological transformation.

1048 ANALYSIS OF CHROMATIN STRUCTURE IN NICKEL SILENCED G12 CHINESE HAMSTER CELLS.

Y. Yan, T. Kluz, P. Zhang, H. Chen and M. Costa. *Environmental Medicine, Nelson Institute, NYU School of Medicine, Tuxedo, NY.*

We have previously reported that the gpt transgene in the G12 Chinese hamster cells could be silenced by water-insoluble nickel compounds nickel sulfide (NiS) or nickel subsulfide (Ni3S2), and showed that the transgene was silenced by de novo DNA methylation and chromatin condensation. To further understand the nature of the silencing induced by nickel, we used Chromatin immunoprecipitation (ChIP) assays to elucidate the chromatin structure in nickel-induced silenced G12 clones. We also analyzed the effects of a DNA methyltransferase inhibitor 5-azacytidine (5-AzaC) and a histone deacetylase inhibitor trichostatin A (TSA) on histone H3 and H4 acetylation and gpt gene expression in N37 cells. We observed that both histone H3 and, H4 were hypoacetylated, and methyl DNA-binding protein MeCP2 was targeted to the gpt gene locus, resulting in a localized inactive chromatin configuration in nickel silenced cell clones. The histone H3K9 was also found methylated in 3 of 4 nickel silenced cell clones, whereas the histone H3K9 was deacetylated in all 4 cell clones, indicating that the H3K9 methylation was involved in nickel induced gene silencing. The acetylation of the gpt gene could be increased by a combination of 5-AzaC and TSA treatment, but not by either 5-AzaC or TSA alone. The gpt transcript was studied by either northern blot or by semiquantitative RT-PCR, however only a slightly increase in gpt mRNA could be detected by RT-PCR. These data show that gene silencing induced by nickel in the gpt transgenic cell line involved a loss of histone acetylation and an activation of histone methylation. Both H4 and H3 histone acetylation was lost in the silenced clones and these clones exhibited an increase in the methylation of lysine 9 in histone H3. This work was supported by grant numbers ES05512, ES00260, ES10344 from the NIH/ NIEHS and CA16087 from the NIH/NCI.

1049 GENOTOXICITIES OF NICKEL SAMPLES IN C3H/10T1/2 MOUSE EMBRYO FIBROBLASTS: PREDICTIONS OF CARCINOGENIC POTENTIALS OF NICKEL CARCINOGENESIS.

R. Verma, F. M. Clemens and J. R. Landolph. *Cancer Center, Keck School of Medicine, Los Angeles, CA.*

Long-term inhalation exposures of nickel refinery workers to mixtures of specific insoluble and soluble nickel compounds in the past were associated with excess lung and nasal cancer. However, animal carcinogenicity data by relevant routes of exposure are not available for all nickel compounds, particles of elemental nickel, or nickel-containing alloys. *In vitro* studies can directly evaluate genotoxicities of nickel-containing substances relative to those nickel compounds that have been well-characterized in animal studies. Previously, we showed that two preparations of nickel subsulfide, one prepared by INCO and another one used by the National Toxicology Program in the 1990-1996 animal cancer bioassay, both induced a high, dose-dependent yield of morphological transformation in 10T1/2 cells. Nickel carbonate hydroxide ($NiCO_3$), nickelic hydroxide ($Ni(OH)_3$), small particles of nickel subsulfide (Ni_3S_2, particle size 1.35 μm), and spherical particles of 316 stainless steel powder, (SS< 3.0 μm) were subsequently studied. The effectiveness of these samples to be phagocytosed by 10T1/2 cells (based on % uptake of samples at 1.0 μg/ml and linear slope) was: Ni_3S_2 > $Ni(OH)_3$ > $NiCO_3$ > SS (<3.0 μm). The order of cytotoxic potency for this set of samples was: Ni_3S_2 > $Ni(OH)_3$ > $NiCO_3$ >>> SS (<3.0 μm). Based on percent chromosomal aberrations at 1.0 μg/ml and linear slope estimates, the effectiveness of these samples to induce chromosomal aberrations in 10T1/2 cells was: Ni_3S_2 = $NiCO_3$ > $Ni(OH)_3$ ≥ SS (<3.0 μm). Based on foci per 20 dishes at 1.0 μg/ml and linear slope estimates, the effectiveness of these samples to induce morphological transformation in 10T1/2 cells was: Ni_3S_2 > $NiCO_3$ > $Ni(OH)_3$≥ SS (<3.0μm). We predict the carcinogenic potential of these samples is Ni_3S_2 > $NiCO_3$ ≥ $Ni(OH)_3$ >> SS (<3.0μmm), and this would be the order to prioritize them for further *in vivo* testing.

1050 DIFFERENT MECHANISMS IN SUPPRESSING MTH EXPRESSION BY NICKEL CHLORIDE AND COBALT CHLORIDE.

H. Chen, Y. Yan, T. Kluz and M. Costa. *Environmental Medicine, New York University, Tuxedo, NY.*

In previous studies, carcinogenic nickel compounds were found to silence senescence gene and transgenic gene expression by epigenetic mechanisms. It is still unclear whether nickel suppresses other gene expression by the same mechanisms. Here, we studied nickel effect on the expression of MTH gene, one of the nickel-down-regulated genes selected from our GeneChip data in mouse cell. MTH (mutT homologue) encodes 8-oxodGTPase, which metabolizes 8-oxodGTP to 8-oxodGMP and thus prevents the incorporation of 8-oxodGTP into newly synthesized DNA and later subsequent mutation. Mouse cell clones, PW, HIF (+/+) and HIF (-/-), were treated with nickel chloride for 24 h. The expression of MTH gene was quantified by northern blotting method. Our data shown that nickel treatment suppresses MTH expression. Cobalt, which has similar biochemical characters as nickel, also abrogates MTH expression in a dose-dependent manner. Interestingly, the treatment of cobalt in HIF (-/-) cell does not suppress MTH gene expression, while no obvious difference on MTH gene expression was found between nickel-treated HIF (+/+) and HIF (-/-) cell. It suggests that cobalt suppress MTH expression through a HIF-dependent pathway, while nickel decrease MTH expression through other mechanisms. Currently, HIF-upstream signal transduction pathway is investigated in cobalt-treated cells. Chromatin immuno-precipitation assay will be used to test the possible change in acetylation level of histone 3 and 4 after nickel and cobalt treatment.

1051 REACTION OF URANYL ACETATE WITH ASCORBATE PRODUCES DNA STRAND BREAKS *IN VITRO.*

M. Yazzie, S. L. Gamble, D. M. Stearns and E. R. Civitello. *Department of Chemistry, Northern Arizona University, Flagstaff, AZ.* Sponsor: J. Wise.

Exposure to uranium in the mining industry has been linked to lung cancer through uranium's radioactive decay product, radon. Previous studies suggesting increased risks of pancreatic, stomach, colon and prostate cancers and birth defects in people exposed to uranium mine tailings may signal a non-radiochemical mechanism of uranium genotoxicity. We propose that hexavalent uranium (U(VI)) may have a similar chemistry to that of hexavalent chromium (Cr(VI)), which is a known human carcinogen that directly damages DNA. Chromium(VI)-induced DNA damage requires metabolism of the metal by biological reducing agents, for example ascorbate (vitamin C). The goal of our research is to measure the chemical genotoxicity of University(VI) in the presence of ascorbate. Results from experiments with plasmid DNA *in vitro* showed that reactions of University(VI) with ascorbate produced DNA single strand breaks in a time- and concentration-dependant manner. Uranyl acetate was also more cytotoxic in the Chinese hamster ovary EM9 line, which is sensitive to DNA strand breaks, than in the parental CHO AA8 line. However, the presence of catalase did not decrease DNA strand breaks *in vitro*, suggesting that a Fenton-type mechanism of free radical generation was not a significant pathway. An alternative hypothesis may be that a uranyl ascorbate complex catalyzes the hydrolysis of the DNA phosphate backbone by a mechanism similar to that known for the lanthanide metals. 1H NMR spectroscopy supported this interpretation and showed the formation of a stable uranium-ascorbate complex. These are the first experiments to demonstrate direct DNA damage induced by uranium and ascorbate. Uranium mining has a strong presence on the Navajo reservation in the Four Corners region of the United States. Understanding the metabolism of uranium and its reactivity with DNA may help to elucidate mechanisms of lung and other cancers in Native American populations exposed to uranium. Supported by NIH grant # CA96302.

1052 LEAD CHROMATE GENOTOXICITY IS MEDIATED BY PARTICLE DISSOLUTION AND NOT PARTICLE INTERNALIZATION.

H. Xie[1], S. S. Wise[1], A. L. Holmes[1], M. E. Ketterer[2], W. J. Hartsock[2] and J. P. Wise[1]. *[1]Bioscience Research Institute, University of Southern Maine, South Portland, ME and [2]Chemistry, Northern Arizona University, Flagstaff, AZ.*

Hexavalent chromium (Cr(VI)) is a well-established human lung carcinogen that is commonly encountered in occupational settings and in the environment. Water solubility has proven to be a key factor in the carcinogenicity of Cr(VI), with the water-insoluble or 'particulate' compounds the more potent carcinogens. Previous studies in rodent models indicate that extracellular particle dissolution is responsible for the genotoxicity of particulate Cr(VI) compounds in rodent cells, however, it is uncertain what roles occurs in human lung cells. We investigated the roles of particle uptake and Cr ion uptake in WTHBF-6 cells, a human lung cell line, after exposure to particulate lead chromate (PC). We found that PC was clastogenic in a concentration-dependent manner with 0.1, 0.5, and 1 ug/cm^2 PC damaging 15, 34, 42 % of metaphases respectively and a 5 ug/cm^2 concentration causing complete cell cycle arrest. We further found using ICPMS that these doses produced concentration-dependent intracellular Cr levels of 0.7, 1.6, 3.7, 7.8 and 12 uM. We investigated particle internalization using electron microscopy and found that in as little as 1 hr, PC particles were internalized in tight vacuoles after cells were exposed to the four highest concentrations. In addition, there was an apparent relative increase with concentration, however, there was no particle uptake at the lowest dose (0.1 ug/cm^2) even after 24 h. Further, we found no lysosomal association with the vacuoles containing particles suggesting that intracellular dissolution may not have occurred. These data indicate that PC clastogenesis at low doses is mediated by the dissolution of the particles and not their internalization. Further efforts are aimed at determining if dissolution is intracellular, extracellular or some combination of the two. This work was supported by NIEHS grant 1R01 ES10838-01 (J.P.W.).

1053 CHROMIUM IS THE PROXIMATE GENOTOXIC SPECIES IN LEAD CHROMATE-INDUCED GENOTOXICITY IN HUMAN BRONCHIAL CELLS.

S. S. Wise[1], A. L. Holmes[1], M. E. Ketterer[2], W. J. Hartsock[2], E. Fomchenko[1,3], S. P. Katsifis[3] and J. P. Wise[1]. *[1]Bioscience Research Institute, University of Southern Maine, South Portland, ME, [2]Chemistry, Northern Arizona University, Flagstaff, AZ and [3]Biology, University of Bridgeport, Bridgeport, CT.*

Hexavalent chromium (Cr(VI)) is a well-established human lung carcinogen with potentially widespread exposure. Solubility is a key factor in the carcinogenicity of Cr(VI), with the water-insoluble or 'particulate' compounds the more potent carcinogens. Currently data from our laboratory indicates that particle dissolution and not particle uptake is responsible for the genotoxicity of lead chromate (PC) particles in human lung cells, however, it is uncertain whether chromium (Cr), lead (Pb) or some combination of the two is the proximate clastogen. Accordingly, we compared the cytotoxicity and clastogenicity of PC (a particulate Cr(VI) compound) with sodium chromate (a soluble Cr(VI) compound) and Pb-glutamate (a soluble lead (Pb) complex) in WTHBF-6 cells, a human lung cell line. We found that 2 uM Pb was the maximal intracellular level of Pb after exposure to clastogenic concentrations of PC. However, clastogenesis was not observed after exposure to Pb-glutamate even when intracellular Pb concentrations reached 40 uM, indicating that intracellular Pb levels did not reach clastogenic levels in WTHBF-6 cells after PC treatment. By contrast, sodium chromate was clastogenic damaging 26 and 44 percent of metaphase cells at intracellular Cr doses of 0.6 and 1.9 uM respectively, which was comparable to the clastogenesis observed after PC treatment. PC damaged 10, 27 and 37 percent of metaphases at intracellular Cr doses of 1.3, 1.7 and 4.5 uM respectively. These data indicate that with respect to PC-induced genotoxicity, Cr and not Pb is the proximate genotoxic species in human lung cells. Further experiments are aimed at investigating the differences between particulate and soluble Cr(VI). This work was supported by NIEHS grant 1R01 ES10838-01 (J.P.W.).

1054 THE PHASE OF LEAD CHROMATE INDUCED CELL CYCLE ARREST IS CONCENTRATION DEPENDENT.

J. A. Moreland[1], S. S. Wise[1], A. L. Holmes[1], M. E. Ketterer[2], W. J. Hartsock[2], R. A. Thomas[3], E. Fomchenko[1,4], S. P. Katsifis[4] and J. P. Wise[1]. *[1]Bioscience Research Institute, University of Southern Maine, South Portland, ME, [2]Chemistry, Northern Arizona University, Flagstaff, AZ, [3]NPE Systems, Pembroke Pines, FL and [4]Biology, University of Bridgeport, Bridgeport, CT.*

Hexavalent chromium (Cr(VI)) is widely accepted as a human lung carcinogen that is common in the environment as a consequence of industrial pollution. A key factor in the carcinogenicity of Cr(VI) is water solubility. Water-insoluble of 'particulate' Cr(VI) compounds are more potent carcinogens than soluble compounds. However, the mechanisms that explain this difference in potency are poorly understood. One possible explanation is that the cation in the particulate compounds such as lead (Pb) may behave as a cell growth stimulant. Indeed we have found that Pb is a potent mitogen for WTHBF-6 cells (a human bronchial cell line). We found that an intracellular dose of 4 uM Pb can induce a 40% stimulation of growth. We then investigated the cell cycle effects of lead chromate (PC) itself in WTHBF-6 cells. We found a progressive change in the cell cycle arrest induced by lead chromate. At a relatively low concentration (0.5 ug/cm^2) PC induced G1 arrest increasing the number of cells in G1 by 15%. The arrest changed to a G2/M arrest when concentrations of 1.0 and 5.0 ug/cm^2 increased the number of cells in G2/M by 24 and 124% respectively. At the highest dose (10 ug/cm^2), the arrest became an S-phase arrest with an 86% increase in the cells in S-phase. We also found a concentration dependent increase in the total amount of chromosome damage at these doses suggesting that the arrest may be mediated by the amount of genetic damage that occurred. Future investigations are aimed at investigating the cell cycle effects at lower concentrations and understanding the time-course of damage formation and repair.

1055 DNA DAMAGE INDUCED BY CHROMIUM PICOLINATE.

A. M. Luke, B. E. Baker, J. A. Hager, W. K. K and D. M. Stearns. *Department of Chemistry, Northern Arizona University, Flagstaff, AZ.* Sponsor: W. John.

The dietary supplement chromium picolinate (CrPic) has previously been shown to cause chromosomal aberrations and mutations at the hprt locus, and to induce apoptosis in Chinese hamster ovary (CHO) cells. The molecular mechanism underlying this toxicity is unknown. The focus of the current work is to characterize the types of DNA lesions found in cells after exposure to CrPic. Chromium-DNA adducts were measured by ICP mass spectrometry and UV/visible spectroscopy. CrPic produced less Cr-DNA adducts in CHO cells than did chromic chloride and potassium dichromate. Results from single cell gel electrophoresis (the comet assay) suggested that DNA crosslinks were present. Comparison of the effects of MMS and proteinase K on percent DNA in tail and DNA tail length for cells exposed to CrPic, cis-platin and formaldehyde suggests that DNA-DNA crosslinks were more prevalent than DNA-protein crosslinks in CrPic treated cells. The observation of crosslinks in the comet assay was consistent with extents of cell survival in a series of CHO cells deficient in DNA repair. CrPic was most toxic in the CHO UV135 line and least toxic in the parental AA8 line with the following order observed: UV135 < UV41 < UV5 = EM9 < UV20 < AA8. The free ligand, picolinic acid, produced the opposite trend, with cell survival being greater in the repair deficient lines: AA8 < EM9 = UV20 < UV135 < UV5 < UV41. Equivalent doses of chromic chloride were non-cytotoxic in all lines tested. Understanding the mechanism behind CrPic-induced DNA damage will be necessary before genotoxicity results can be extrapolated to humans ingesting dietary supplements. Supported by NIH grant # CA75298.

1056 COMPARATIVE GENOTOXICITY OF TWO PARTICULATE HEXAVALENT CHROMIUM COMPOUNDS IN HUMAN BRONCHIAL CELLS.

A. L. Holmes[1], S. S. Wise[1], J. H. Shuler[1,3], M. E. Ketterer[2], W. J. Hartsock[2], H. Xie[1], S. P. Katsifis[3] and J. P. Wise[1]. *[1]Bioscience Research Institute, University of Southern Maine, South Portland, ME, [2]Chemistry, Northern Arizona University, Flagstaff, AZ and [3]Biology, University of Bridgeport, Bridgeport, CT.*

Particulate hexavalent chromium (Cr(VI)) compounds are well-established human lung carcinogens. However, there carcinogenic mechanisms are poorly understood as most investigators have used related soluble Cr(VI) compounds. Currently, work in our laboratory has shown that barium chromate (BC) is also cytotoxic and clastogenic. To better understand how it related to existing data on other particulate Cr(VI) compounds, we compared its cytotoxicity and clastogenicity with lead chromate (PC), which has been used as a prototypical particulate Cr(VI) compound in WTHBF-6 cells, a near-normal human lung cell line. We found that BC is more potently cytotoxic inducing 67, 12, 3, 0, and 0 % relative survival at concentrations of 0.1, 0.5, 1, 5 and 10 ug/cm^2 respectively, while PC induced only 90, 71, 43 and 15 % survival at these same concentrations respectively. We found that BC was also more potently clastogenic damaging 22 percent of metaphases cells at 0.1 ug/cm^2 and causing complete cell cycle arrest at 0.5, 1 and 5 ug/cm^2. By contrast, 0.1, 0.5, and 1.0 ug/cm^2 PC damaged 10, 27 and 37 percent of metaphase cells respectively and complete cell cycle arrest was not observed until a concentration of 5 ug/cm^2. We investigated both particle internalization and Cr ion uptake and found that BC and PC were similar with respect to particle uptake, but more Cr ions were observed in the cells treated with BC than PC. Exposure to 0.1, 0.5 and 1.0 ug/cm^2 BC produced intracellular Cr ion levels of 2.89, 5.87 and 6.44 uM respectively compared to 0.72, 1.55, and 3.69 uM respectively after PC exposure. This suggests that the difference in genotoxicity may be mediated by the difference in intracellular Cr levels. This work was supported by NIEHS grant 1R01 ES10838-01 (J.P.W.).

1057 BARIUM CHROMATE IS CYTOTOXIC AND CLASTOGENIC TO HUMAN BRONCHIAL CELLS.

J. H. Shuler[1,2], S. S. Wise[1], S. P. Katsifis[2] and J. P. Wise[1]. *[1]Bioscience Research Institute, University of Southern Maine, South Portland, ME and [2]Biology, University of Bridgeport, Bridgeport, CT.*

Particulate hexavalent chromium compounds are well-established human lung carcinogens. However, there carcinogenic mechanisms are poorly understood as most investigators have used related soluble Cr(VI) compounds. Moreover, those researchers investigating particulate chromium compounds have focused almost exclusively on lead chromate as a prototypical compound as it is the most insoluble and has been directly shown to be carcinogenic in animal models and cellular transformation assays. Almost no data exist on the carcinogenicity of other particulate Cr(VI) compounds. To begin to address this data gap, we determined the cytotoxicity and clastogenicity of barium chromate in WTHBF-6 cells, a near-normal human lung cell line. We found that the barium chromate induced concentration dependent cytotoxicity with concentrations of 0.01, 0.05, 0.1, 0.5, 1 and 5 ug/cm^2 inducing 88, 74, 67, 12, 3 and 0 percent survival respectively. Barium chromate was also clastogenic in a concentration dependent manner damaging 5, 9 and 22 percent of metaphases and inducing 5, 10 and 28 total aberrations per 100 metaphases at concentrations of 0.01, 0.05, and 0.1 ug/cm^2 respectively. The spectrum of chromosome damage induced included chromatid and isochromatid lesions and chromatid exchanges, which is consistent with mechanisms of neoplastic transformation such as deletion of tumor suppressor genes and activation of oncogenes. Overall the data clearly indicates that barium chromate is cytotoxic and genotoxic to human lung cells. This work was supported by NIEHS grant 1R01 ES10838-01 (J.P.W.).

1058 INHIBITION OF PHASE I AND PHASE II METABOLIC ENZYMES *IN VITRO* BY NICKEL CHLORIDE.

T. L. Davidson, K. Salnikow and M. Costa. *Department of Env. Med., New York University, Tuxedo, NY.*

Nickel compounds have been identified as human carcinogens/cocarcinogens using both *in vivo* studies and epidemiological evaluations. The mechanisms involved in the toxicity of nickel have not been fully elucidated. *In vitro* studies were designed to identify potential mechanisms of toxicity by analyzing transcriptional changes caused by soluble nickel. It was observed that nickel chloride can alter the transcription of several phase I and phase II metabolic enzymes, which can play a fundamental role in the detoxification and elimination of xenobiotics. For example nickel downregulated the basal and benzo(a)pyrene inducible expression of both cytochrome P450 1B1 (Cyp 1B1) and quinone reductase (NQO1). Both of these genes were involved in the biotransformation of xenobiotics. Quinone reductase was also involved in the metabolism of endogenous compounds and possibly Cyp 1b1, as well. By suppressing basal level expression of Phase I and Phase II genes, nickel can cause alterations in the metabolism of endogenous compounds. Chemicals that can bind to the aryl hydrocarbon receptor or produce oxidative stress can induce metabolic enzymes. It has been suggested that this upregulation is important to aid in the elimination of harmful compounds from the body. Nickel could block the upregulation of some detoxification enzymes and lead to a decrease in the elimination of toxic compounds. Metabolic enzymes are also important in the biotransformation of chemotherapeutic agents and insights into their regulation could prove useful in cancer treatment. In conclusion, concentrations of nickel chloride that caused low toxicity induced changes in Phase I and Phase II enzymes. This could have toxic effects by affecting the metabolism of harmful compounds in the body. These effects are relatively specific for nickel since other metals like cadmium and chromium failed to produce similar changes.

1059 CYTOTOXICITY AND CLASTOGENICITY OF ARSENIC, CADMIUM AND CHROMIUM IN HUMAN BRONCHIAL CELLS.

J. E. Little, S. S. Wise, M. J. Slotnick and J. P. Wise. *Bioscience Research Institute, University of Southern Maine, South Portland, ME.*

Metals are a significant public health concern. Several are established human lung carcinogens that pose a significant risk for both occupational and environmental exposure. Five metals are listed in the "Top 20 Hazardous Substances" by the Environmental Protection Agency (EPA) and the Agency for Toxic Substances and Disease Registry (ATSDR), and five metals are listed as "carcinogenic to humans" by the International Agency of Cancer Research (IACR). However, there is limited data concerning the effects of metals in human lung cell models. This is largely because many available human lung cell culture models are already fully transformed. Recently, we developed WTHBF-6 cells, which are a new model system of human bronchial cells that have an extended cellular life-span, but grow in culture and respond to metals similarly to primary human bronchial cells. In this model, we investigated the cytotoxicity and clastogenicity of three metals that are human lung carcinogens chromium, cadmium and arsenic. We found that chromium was the most cytotoxic of the three inducing 63, 8 and 0 percent relative survival at 1, 5 and 10 uM respectively. Arsenic was intermediate inducing 75, 33 and 8 percent survival at these concentrations, while cadmium was the least toxic with greater than 89 percent survival at each concentration. Similarly, chromium was the most clastogenic damaging 26 percent of metaphases at 1 uM and complete cell cycle arrest at 5 and 10 uM. Arsenic was again intermediate damaging 12, 28 and 36 percent of metaphases respectively at these doses, while cadmium was the least clastogenic damaging 3, 2 and 14 percent of metaphases respectively. Thus these data indicate that each of the three metals is cytotoxic and clastogenic to human lung cells with chromium more potent than arsenic; and arsenic more potent than cadmium on the basis of administered concentration. This work was supported by NIEHS grant 1R01 ES10838-01 (J.P.W.).

1060 THE MECHANISM OF RETINOL INDUCED IRRITATION AND ITS APPLICATION TO DEVELOPMENT OF ANTI-IRRITANTS.

B. Kim[1,2], Y. Sim[1] and K. Kang[2]. *[1]Pacific R&D Center, Yongin-si, Gyeonggi-do, South Korea and [2]Seoul National University, Seoul, South Korea.*

Retinoids, such as retinol and retinoic acid, have been increasingly used for topical and systemic treatment, but they induce mild erythema on the skin. It is not clear if the redness induced by retinoid is caused by the sensitization or irritation. The mechanism of dermatitis induced by retinoid is also unclear. We first clarified that retinol has no sensitization potential using IMDS, an alternative to sensitization test. we analyzed the change of mRNA expression of inflammation related cytokines, such as KC (mouse analogue of human IL-8), JE (mouse analogue of human MCP-1), TNF-a, IFN-r, IL-12p40, IL-6, IL-10, Eotaxin in mouse epidermal cell, and also examined the inflammation related cytokines in the human foreskin cell lines to understand the inflammation mechanism induced by the retinol or retinoic acid. Retinol upregulates the mRNAs of IL-8, MCP-1, TNF-a, IFN-r and IL-12p40 in mouse ear skin when measured using the RT-PCR method. Significant increases in level of IL-8 and MCP-1 protein concentration induced by retinol and retinoic acid are observed in culture supernatants of human epidermal keratinocytes, melanocytes and dermal fibroblasts. We selected several substances that have inhibitory effects against the retinol induced cytokine increase (IL-8 and MCP-1) based on the *in vitro* test using the human foreskin cell lines. These substances were used for *in vivo* test, the skin irritation test in rabbits and the human patch test, to see if those have the inhibitory effects against the retinol induced redness. Afterward, we analyzed the correlation between *in vitro* and *in vivo* data. Most of the substances which lowed the level of cytokine(MCP-1, IL-8) produced by retinol *in vitro*, showed good inhibitory effects against the retinol-induced irritation in the rabbit and human patch test. The present study showed that retinoids induced the skin irritation by the inflammation related cytokines, such as IL-8 and MCP-1. We concluded these cytokines can be applied for the good markers to screen the anti-irritants against the retinol induced irritation.

1061 PREDICTION OF THE LOCAL IRRITATION POTENTIAL OF VARIOUS PHARMACEUTICAL VEHICLES AND BUFFERS USING A NEONATAL RAT MYOCYTE ASSAY *IN VITRO*: COMPARISON WITH RESULTS OBTAINED IN PIGS *IN VIVO*.

P. A. McAnulty[1], C. N. Edwards[2], P. Glerup[2], A. Makin[2] and M. Skydsgaard[2]. *[1]Ferring International Center, Ferring Pharmaceuticals, Copenhagen S, Denmark and [2]Scantox, Lille Skensved, Denmark.*

During development of parenteral pharmaceuticals a wide range of vehicles containing the drug may need to be assessed for local irritation, and it is therefore preferable to find an alternative method of screening than use of live animals. In order to select a suitable vehicle for subcutaneous administration of a pharmaceutical, a number of routinely used vehicles and buffers have been tested in a neonatal rat myocyte assay *in vitro*, and the results compared with some of the vehicles and buffers administered subcutaneously to pigs. Pigs were chosen as the animal model because of similarities of their skin with that of humans, particularly the thickness of the subcutaneous tissues. A single cell suspension of myocytes was prepared from the skeletal muscle of 1-day old rat pups, and the cells were allowed to form a confluent layer. They were then incubated for 10 min with the following vehicles and buffers: physiological saline at pH 4.5 & 7.0, isotonic mannitol, lactose and sucrose at pH 4.5 & 7.0, and 10, 25 & 40mM acetate, citrate and succinate buffers at pH 4.3 or 4.5. 0.5% glacial acetic acid was used as a positive control. Cytotoxicity was assessed by the loss of creatine kinase activity (CK) from the cells. Saline, mannitol, lactose and sucrose showed no significant cytotoxicity, irrespective of pH. Acetate and succinate buffers caused 2 to 4 times more loss of CK activity than saline, regardless of molarity. 10 & 25mM citrate buffers caused only a slight loss of CK activity, but 40mM citrate caused a 10-fold loss of CK activity. Acetate and citrate buffers (10, 25 & 40mM) and saline have been injected subcutaneously (1 ml/day) into pigs for 28 days. There were no external signs of local irritation. The severity of pathological changes showed a similar relationship to that in the assay *in vitro*, suggesting that the myocyte model has good predictive value for local irritation.

1062 AN *IN VITRO* TECHNOLOGY FOR FAST IDENTIFICATION OF LESS ALLERGENIC PROTEIN VARIANTS.

E. L. Roggen[1], E. P. Friis[2], N. K. Soni[1] and S. Ernst[1]. *[1]Protein Screening, Novozymes A/S, Bagsvaerd, Denmark and [2]Protein Design, Novozymes A/S, Bagsvaerd, Denmark.* Sponsor: K. Sarlo.

Rationale. The use of proteins in new industrial and pharmaceutical applications is hampered by their allergenicity. Less allergenic protein variants can be obtained by protein engineering (PE) but no methods are available for fast identification of these variants in a protein library. Methods. 1) Epitope Mapping Tool(EMaT): A programme assessing experimentally defined B-cell epitope patterns on the 3D-structure of a target protein. 2) Epitope Mutation Tool(EMuT): An algorithm for identifying mutations with maximal impact on the EMaT-derived epitope profile of the target. 3) Automated screening (AS): The antibody binding capacity of the micropurified variants is assessed in an ELISA-based assay. 4) ImmunoFit: The differences in antibody binding between variants and target are quantified, and analysed statistically (Significance = >2x the standard deviation). 5) MINT study: Mice were immunised intranasally with 0.1, 1 and 10 microgram of protein, and the IgG1 and IgE levels were determined by ELISA after days 15 and 45. Results. 1: EMaT was evaluated on published B-cell epitopes. Overall, 90% of these epitopes were scored for > 50%. Linear as well as conformational epitopes for IgE and IgG antibody from human, mice, rat and rabbit were identified by this in silico method. 2: An example: EMaT revaled on Bacillus subtilisin Protease two important epitope areas. These areas were subjected to restricted site-directed mutagenesis, as predicted by EMuT. More than 90% of the epitope variants revealed a > 2x change ($p < 0.05$) in antibody-binding of rabbit anti-target IgG antibody. The 3 top-scoring variants revealed a 100x lower binding capacity. BiaCore confirmed these variants as having a > 1000x reduction in affinity for the antibody. One variant did not bind the antibody at all. Evaluation of these variants in mice revealed a > 10x reduction in IgE levels. Conclusion. This technology platform allows fast identification of less allergenic protein variants in a protein epitope library. Overall, animal experimentation is reduced with 90%.

1063 ALTBIB: ALTERNATIVES TO ANIMAL TESTING DATABASE.

V. W. Hudson, H. F. Chang and B. Mashayekhi. *National Library of Medicine, National Institute of Health, Bethesda, MD.* Sponsor: G. Fonger.

The Alternatives to Animal Testing Database is a bibliographic database whose purpose is to assit toxicologists and scientific researchers in accessing information on methods and procedures that support the development, testing, application, and validation of alternatives to the use of live vertebrates in biomedical research and toxicology testing. The database includes citations from published articles, books, book chapters, and technical reports. Content of the database are organized under subject categories, and features citations which deal with methods, tests, assays, or procedures which may prove useful in establishing alternatives to the use of intact vertebrates. Citations are selected and compiled by searching TOXLINE and MEDLINE at the National Library of Medicine (NLM). The database is updated periodically, and is available at the Specialized Information Services web site. It is searchable by using the TOXNET search engine which features a relevancy-ranked full text search capability. The content of this database is also available in a downloadable format in 23 separate issues.

1064 EXPLORATORY *IN VITRO* EYE IRRITATION STUDY OF MARKETED ALKALINE DRY LAUNDRY DETERGENTS BY BCOP ASSAY AND PH/RESERVE ALKALINITY (RA) PARAMETERS.

K. C. Cater[1], G. Mun[2], G. Moyer[2], J. Merrill[2] and J. Harbell[2]. *[1]The Dial Corporation, Scottsdale, AZ and [2]IIVS, Gaithersburg, MD.*

An exploratory *in vitro* eye irritation study of 11 currently marketed alkaline dry laundry (ADL) detergents was conducted to investigate the correlation between an *in vitro* biological endpoint and pH/reserve alkalinity (RA) ranges of ADL detergents. Marketed products can be considered "safe benchmarks", since they are produced by industry leaders and are assumed to have acceptable pH/RA characteristics. Based on performance in previous eye irritation studies with surfactants and the potential to measure depth of injury, the bovine corneal opacity and permeability (BCOP) assay was selected as an *in vitro* endpoint to evaluate biological effects. Based on preliminary studies, a 10% (w/v) aqueous suspension of each detergent was applied to the corneas for a 30-minute exposure. The degree of epithelial damage is reflected in the increase in fluorescein permeability value. Permeability values (OD_{490}) for the 11 ADL detergents ranged from 0.267 to 0.856 reflecting a moderate range of epithelial damage. The range of opacity scores was more variable (0.3 to 21.5) and showed little consistent change with the permeability values. Anionic/nonionic surfactant formulations often produce little *in vitro* opacity. The pH of each dosing suspension (10% w/v) was measured and ranged from 11.0 to 12.0. The RA was determined for a 0.2% (v/v) aqueous suspension of the supernatant from each dosing suspension (i.e., 20% dilution of supernatant from 10% dosing suspension) titrated to a target pH of 9.5. Titration values ranged from 1.7 to 5.2 ml of 1N HCl. Neither pH nor RA values correlated with the epithelial damage as measured by permeability changes. These data suggest characteristics of the formulation other than pH or RA are responsible for the epithelial damage produced in the BCOP. This protocol, using a 10% (w/v) aqueous suspension with a 30-minute exposure, the permeability endpoint (with histological confirmation) and benchmark formulations, shows promise for evaluating ADL detergents.

1065 APPROACHES TO MINIMISING DOG USE IN PHARMACEUTICAL SAFETY ASSESSMENT: AN INDUSTRY/ ANIMAL WELFARE INITIATIVE.

M. Stephan-Gueldner[1], D. Smith[2], G. Descotes[3], R. Hack[4], K. Krauser[5], R. Pfister[6], B. Phillips[7], Y. Rabemampianina[8], S. Sparrow[9], S. D. Jacobsen[10], R. Combes[11], L. Lammens[12], J. Kemkowski[13] and F. von Landenberg[14]. *[1]Non-clinical Development - Drug safety, Hoffmann-La Roche, Basel, Switzerland, [2]AstraZeneca, Cheshire, United Kingdom, [3]Servier, Courbevoie, France, [4]Aventis, Hattersheim, Germany, [5]Schering, Berlin, Germany, [6]Novartis, Basel, Switzerland, [7]RSPCA, Horsham, United Kingdom, [8]Pfizer, Amboise, France, [9]GlaxoSmithKline, Ware, United Kingdom, [10]NovoNordisk, Maaloev, Denmark, [11]FRAME, Nottingham, United Kingdom, [12]Johnson&Johnson, Beerse, Belgium, [13]Altana, Konstanz, Germany and [14]Merck, Darmstadt, Germany.*

The primary non-rodent species used in toxicology is the dog. It is widely agreed that, for ethical and economic reasons, dog use should be reduced to the minimum consistent with maintaining the scientific quality of toxicology and ensuring human safety. Dog use in toxicology has been discussed widely, both from a scientific and ethical viewpoint, and there seems to be real potential for achieving significant reductions in the number of dogs used in safety testing. An Industry/Animal Welfare Initiative was started in 2000 to evaluate and, where possible, put into practice, scientifically valid approaches to minimise dog use in regulatory toxicology. The Steering Group categorised potential approaches into three areas: industrial co-operation/data sharing, best practice in study design, and assessing the need for particular studies. Progress has been made in evaluating and/or implementing approaches in the first two areas. One way to reduce dog use would be to establish a database of effects of vehicles and other non-active ingredients used in drug formulations. Access to such a database would minimise the need for dog studies when it is intended to use a previously tested material or use it under different conditions. The possibility of establishing such a database is currently being explored. A best practice guide in aspects of study design, including appropriate group sizes, use of control animals, single sex studies and design of MTD studies, is currently being prepared and its status will be presented.

1066 EVALUATING THE IRRITANCY POTENTIAL OF SODIUM PERCARBONATE: A CASE STUDY USING THE BOVINE CORNEAL OPACITY AND PERMEABILITY (BCOP) ASSAY.

B. P. Gran[1], J. E. Swanson[1], J. C. Merrill[2] and J. W. Harbell[2]. *[1]S.C. Johnson & Son, Inc., Racine, WI and [2]Institute for In Vitro Sciences, Inc., Gaithersburg, MD.*

Sodium Percarbonate ($2Na_2CO_3{\cdot}3H_2O_2$) is a component in cleaning products but the neat powder has the potential to be highly irritating to the ocular tissue of rabbits (EPA Category I). This injury results from the chemical's reactivity and dosing method which may trap the powder against the eye. In the BCOP assay, experience has now shown that oxidizing/reactive materials often require a longer post-exposure time to fully manifest cytopathic changes. When testing reactive chemistries, the post-exposure incubation times are increased from 2 hours to 4 and 24 hours. Exposure times of 10, 20, 30 and 60 minutes were used in this study. Sodium percarbonate and percarbonate-based formulations were evaluated as 50% suspensions in water. Abattoir-derived corneas were received, mounted, exposed to test materials, and opacity, permeability and histological endpoints measured as previously reported (Harbell and Curren (1998) *In Vitro* and Mol. Biol. 11:337-341). Opacity and permeability scores increased with increasing exposure times and concentration of percarbonate. After the 10-minute exposure to percarbonate alone, the 4-hour post-exposure corneas showed focal epithelial layer changes which progressed to a loss of epithelium after 24 hours. Stromal damage included collagen matrix vacuolization and loss of basophilic components in the keratocyte cytoplasm. Exposures of 20 minutes or greater led to rapid destruction of both the epithelial and stromal cells and marked collagen matrix swelling. Tissue lesions declined rapidly with decreasing percarbonate concentration. Thus, the marked ocular damage induced by neat percarbonate in the rabbit could also be reproduced in the modified BCOP. These data suggest that the modified BCOP assay can be effectively used to evaluate the safety of percarbonate-based formulations and lead to appropriate labeling decisions.

1067 COMPARATIVE ASSESSMENT OF TWO EYE AREA COSMETIC FORMULATIONS THROUGH EVALUATION OF ALTERNATIVE EYE IRRITATION METHODS RELATIVE TO ENDPOINTS MEASURED IN A HUMAN CLINICAL SUB-ACUTE STUDY DESIGN.

J. D. Burdick[2], Y. Gao[3], B. Kanengiser[3], J. C. Merrill[1] and J. W. Harbell[1]. *[1]Institute for In Vitro Sciences, Gaithersburg, MD, [2]Bath & Body Works, Reynoldsburg, OH and [3]Clinical Research Laboratories, Piscataway, NJ.*

Evaluating ocular irritation of eye-area cosmetics is essential to their safety assessment. Although eye-area formulations are designed to be mild, subjective/objective ocular responses can limit their acceptability. This study evaluated two similar formulations by comparing alternative assays, selected for their ability to distinguish milder effects, to human objective and subjective endpoints assessed by a sub-acute human eye irritation design. Ocular irritation alternative assays included Hen's Egg Test-Choriollantoic Membrane (HETCAM) assay, Cytosensor Microphysiometer Bioassay (CMB), and EpiOcular® (EPO) tissue construct assay. HETCAM evaluates inflammatory responses in a complete tissue model. CMB uses L929 cells to evaluate cytotoxicity through metabolic rate measurements. EPO uses differentiated human epidermal keratinocytes, having stratified into a squamous epithelium similar to corneal tissue. Human ocular irritation was assessed through subjective and objective measures at post-application intervals. Ocular exams included evaluation of the area/density of fluorescein staining of all tissues utilizing Kanengiser's 13-point scale. Each formulation was assessed simultaneously by randomized, periorbital application to paired contralateral eye areas in an exaggerated use design. Clinical results indicated formulation A elicited a slightly greater magnitude and frequency of subjective and objective findings compared to formulation B. Results of alternative assays predicted both formulations were mild but were not entirely consistent in terms of rank ordering relative to the human response. This study demonstrates the need to consider a battery of alternative assays when screening formulations for distinguishing mild ocular effects and the potential of this clinical protocol in predicting differences in eye irritation potential of mild formulations.

1068 EVALUATING OXIDIZING/REACTIVE CLEANING PRODUCTS IN THE BOVINE CORNEAL OPACITY AND PERMEABILITY (BCOP) ASSAY.

J. E. Swanson[1], B. T. White[1], B. P. Gran[1], J. C. Merrill[2] and J. W. Harbell[2]. *[1]S.C. Johnson & Son, Inc., Racine, WI and [2]Institute for In Vitro Sciences, Inc., Gaithersburg, MD.*

Recent trends in household cleaners highlight enhanced cleaning with "natural" materials such as "active oxygen" and make claims such as "harnessing the natural cleaning power of..". The formulations often utilize well-known oxidizing or reactive chemistries in new, innovative ways. However, the formulations have the potential to influence the interaction of the reactive components with tissue. Thus, the irritancy potential of each formulation must be evaluated. To evaluate these formulations, the BCOP assay was selected for this study because of its range of response and capacity to exhibit depth of injury. Abattoir-derived corneas were received, mounted, exposed to test materials, and opacity and permeability endpoints measured as previously reported (Harbell and Curren (1998) *In Vitro* and Mol. Biol. 11:337-341). The BCOP assay was modified to include exposure periods of 3 to 10 minutes and extended post-exposure incubations periods of 4 and 20 hours (with controls). The assay endpoints were opacity, permeability to fluorescein and

histology. The data showed that the opacity and permeability endpoints often underestimated the degree of damage relative to the lesions observed in the corneas. Furthermore, cytopathic changes initially detected after 4 hours were more clearly manifested after 20 hours. After 4 hours, the wing and basal cells in the epithelium often showed increased cytoplasmic vacuolization and occasional nuclear pyknosis while the keratocytes of the stroma showed nuclear pyknosis and some loss of basophilic components in the cytoplasm (eosinophilia). At 20 hours, the cells in the damaged epithelial layers were lost from the corneas. In the stroma, pyknotic keratocytes were lost entirely and the full depth of injury was determined by keratocyte eosinophilia. These data suggest the importance of an extended post-exposure incubation and histological evaluation of the corneas. Understanding how these materials act in the assay enables responsible product labeling.

1069 AN IMPROVED PRIMARY SERTOLI CELL-GONOCYTE CO-CULTURE SYSTEM FROM NEONATE RAT: *IN VITRO* MODEL FOR THE ASSESSMENT OF MALE REPRODUCTIVE TOXICITY.

E. M. Faustman, X. Yu, S. Hong and J. S. Jidhu. *Environ Health, Univeristy of Washigton, Seattle, WA.*

Testicular cell growth and differentiation is essential for embryonic, prepubertal, pubertal, and adult testis function. Impairment of proliferation and differentiation of Sertoli cell and/or germ cells during the fetal or/and neonatal period can produce profound negative effects on the reproductive capacity of the adult. In this study, we established an improved *in vitro* culture system that recreates critical *in vivo* characteristics of seminiferous tubules and which will allow for improved evaluation of testicular developmental toxicants. We compared the effect of different ECM concentrations, added as an overlay, on the morphology and the expression of c-kit protein. A sequential enzymatic digestion of testicular tubules from 5-day-old rats with collagenase, DNAse I and hyaluronidase was used to obtain a cell suspension containing primarily Sertoli cells and spermatogonia. After plating, different concentrations of ECM were added directly to the culture medium. Morphological changes were monitored and photographed. For western blot analysis, cells were harvested at 72h after addition of ECM. We found that an overlay of ECM dramatically enhanced the attachment of Sertoli cells, aided in the establishment of the Sertoli cell-gonocyte communication and furthermore, increased the survival of the spermatogonia as demonstrated by c-kit protein expression levels. We also compared the MAPK, SAKP/JNK and AKT signaling and ubiquitinatin pathways in response to different concentrations of ECM. An overlay of ECM at an optimal concentration of 150 μg/ml facilitated the formation of a 3-dimensional architectural structure, and mimicked the *in vivo* testicular-like structure of the neonate testis. The expression of c-kit protein further confirmed the functional integrity of this co-culture system. This refined system will prove useful for studying the molecular mechanisms associated with developmental and reproductive environmental toxicants on Sertoli cells and/or spermatogonia. Supported by NIH ES07033, ES09601-02, USEPA R826886-01

1070 EVALUATING THE OCULAR IRRITATION POTENTIAL OF 54 TEST ARTICLES USING THE EPIOCULAR HUMAN TISSUE CONSTRUCT MODEL (OCL-200).

M. E. Blazka[1], J. W. Harbell[2], M. Klausner[3], J. C. Merrill[2], J. Kubilus[3], C. Kloos[1] and D. M. Bagley[1]. *[1]Product Safety, Colgate Palmolive, Piscataway, NJ, [2]Institute for In Vitro Sciences, Gaithersburg, MD and [3]MatTek Corp., Ashland, MA.*

Colgate-Palmolive is sponsoring a research program to validate the use of the EpiOcular model in evaluating the eye irritation potential of surfactants. Previously, in a study that demonstrated the reliability of the EpiOcular model, four laboratories using a formal and detailed study protocol tested 19 test materials. In the current study, two laboratories (Institute for *In Vitro* Sciences and MatTek Corp.) have tested 54 test articles using the same study protocol. EpiOcular is a commercially available three-dimensional *in vitro* model of the human corneal epithelium composed of normal human-derived epidermal keratinocytes. Test articles included a shampoo formulation and 30 different surfactants (10-cationic; 11-anionic; 7-nonionic; 1-amphoteric; 1-zwitterionic) which were liquids, powders or creams. Multiple concentrations of 11 of the surfactants were tested to evaluate the ability of the model to predict dose-related differences in the ocular irritation potential of test articles. Testing was conducted in compliance with FDA GLPs. The laboratories were blinded to the identities of the test articles. Test results were compared to previously published animal eye irritation studies. In terms of reliability, the results were reproducible within and between the laboratories. In terms of relevance, the EpiOcular model correctly predicted the Draize score for a majority of the samples tested. The model also correctly predicted increasing irritation potential of surfactants with increased concentrations. These data provide additional evidence that the EpiOcular model meets the validation criteria, as defined by the Interagency Coordinating Committee on the Validation of Alternative Methods (NIH Publication No. 97-3981), for assessing the ocular irritation potential of certain classes of surfactant and surfactant-based formulations.

1071 ICCVAM/NICEATM EXPERT PANEL RECOMMENDATIONS FOR THE STANDARDIZATION AND VALIDATION OF *IN VITRO* ESTROGEN RECEPTOR (ER) AND ANDROGEN RECEPTOR (AR) TRANSCRIPTIONAL ACTIVATION (TA) ASSAYS.

B. S. Shane[1,2], J. Stegeman[3], E. M. Wilson[4], C. J. Inhof[1,2], R. R. Tice[1,2], E. Zeiger[5] and W. S. Stokes[2]. *[1]ILS, Inc., Research Triangle Park, NC, [2]NICEATM, NIEHS, Research Triangle Park, NC, [3]Woods Hole Oceanographic Institute, Woods Hole, MA, [4]University of N. C., Chapel Hill, NC and [5]Errol Zeiger Consulting, Chapel Hill, NC.*

A variety of natural and anthropogenic substances appear to interact with the endocrine system. As a result, the USEPA was required by legislation to develop a screening and testing program to identify substances with endocrine disruptor (ED) activity. Within the Tier 1 battery of screening test methods, *in vitro* ER and AR TA assays are proposed to identify estrogenic or androgenic agonists or antagonists. *In vitro* results would be considered together with other Tier 1 assay results in a weight-of-evidence evaluation of the need for testing in the more definitive Tier 2 *in vivo* assays. A comprehensive literature review indicated no adequately validated *in vitro* ER or AR TA assays. After considering the available data, an ICCVAM/NICEATM-sponsored Expert Panel developed recommendations for future development, standardization, and validation efforts. For ER TA assays, a mammalian cell line transfected with a human ER expression vector and a luciferase reporter containing multiple vitellogenin estrogen response elements is recommended. Pre-validation studies should be performed to determine whether transiently or stably transfected cell lines are most useful. For AR TA assays, validation of a mammalian cell line containing an endogenous human AR and transduced with an adenovirus containing a luciferase reporter plasmid is recommended. Recommendations were also developed for minimum procedural standards and substances for validation studies, which together should facilitate standardization and validation of protocols for ER and AR TA assays. Supported by NIEHS Contract N01-ES-85424.

1072 ICCVAM PROPOSED SUBSTANCES FOR THE VALIDATION OF *IN VITRO* ESTROGEN RECEPTOR (ER) AND ANDROGEN RECEPTOR (AR) BINDING AND TRANSCRIPTIONAL ACTIVATION (TA) ASSAYS.

W. S. Stokes[1], B. S. Shane[1,2], C. J. Inhof[1,2], R. R. Tice[1,2], D. Hattan[3] and M. Wind[4]. *[1]NICEATM, NIEHS, Research Triangle Park, NC, [2]ILS, Inc., Research Triangle Park, NC, [3]USFDA, Washington, DC and [4]CPSC, Washington, DC.*

The US EPAs proposed Endocrine Disruptor Screening Program (EDSP) includes a Tier 1 screening battery composed of *in vitro* and *in vivo* test methods designed to identify substances capable of interacting with the endocrine system. Prior to implementation of the EDSP, the component test methods must be adequately validated. An Interagency Coordinating Committee on the Validation of Alternative Methods (ICCVAM) and NICEATM expert panel evaluated the validation status of *in vitro* ER and AR binding and TA (agonist/antagonist) assays that might be included in the Tier 1 battery. The panel determined that none of the *in vitro* assays had been adequately validated. To facilitate the necessary validation studies, a common list of 78 proposed substances was compiled that addressed the panels recommendations. Substances were selected to ensure that reliability and accuracy of the *in vitro* assays would be adequately characterized across a broad range of chemical classes and responses. Selection criteria included quantity and quality of available data, potency, chemical class, selection for *in vivo* validation studies, and commercial availability. A minimum of 25% of the substances are known or expected to be negative in each of the different assay types. The use of a common substance list for validation will facilitate assessment of comparative assay performance, establishment of minimum performance criteria, and selection of acceptable *in vitro* test methods. Generation of both *in vivo* and *in vitro* data on many of these chemicals during future validation studies will also aid the future development of more predictive *in vitro* endocrine disruptor assays. Supported by NIEHS Contract N01-ES-85424. The views expressed above do not necessarily represent the official positions of any federal agency.

1073 A NON-ANIMAL ALTERNATIVE CARCINOGENICITY ASSAY USING FERTILIZED AVIAN EGGS: THE *IN OVO* CARCINOGENICITY ASSAY (IOCA).

D. R. Cerven[1], G. L. DeGeorge[1], M. J. Iatropoulos[2], G. M. Williams[2], C. Perrone[2] and H. Enzmann[3]. *[1]MB Research Laboratories, Spinnerstown, PA, [2]New York Medical College, Valhalla, NY and [3]Institute of Toxicology, Bayer AG, Wuppertal, Germany.*

Carcinogenicity testing of substances is currently assessed *via* costly bioassays utilizing rodents in two year studies. We have developed an alternative assay which is performed on avian embryos as a screening test for carcinogenicity. The *in ovo* carcinogenicity assay (IOCA), is conducted in fertilized turkey, chicken, or quail eggs,

and addresses the three R's (reduction, refinement and replacement) of alternatives to animal testing. *In ovo* administration of known carcinogens on day 0 to 4 of embryonic development for up to 26 days resulted in the induction of pre-neoplastic lesions in the avian liver. Liver effects included changes in liver weight, enlarged nuclei, foci of altered hepatocytes (FAH), hepatocellular reassignment from a trabecular to tubular pattern, as well as damage and breakage of mitochondrial DNA. Diethylnitrosamine, N-nitrosomorpholine, dimethylnitrosamine, and aflatoxin B_1 were all positive carcinogens in this assay. The sensitivity of this assay was similar to rodent tests; A single dose of 1.0 – 5.0 mg of DEN per 100g egg weight induced dose-dependent liver and mtDNA changes whereas 0.5 mg and below did not. Thioacetamide and all dosing vehicles were negative. The IOCA has numerous advantages over the rodent carcinogenicity bioassay, including: 1) it is a rapid test, requiring a maximum of 24 days to perform; 2) testing does not require use of any mammals; 3) testing is performed on eggs, which are kept in incubators, requiring less space and equipment than animal facilities; 4) dose amounts are small, which reduces exposure of humans to potential carcinogens; and 5) cost of analysis is greatly reduced when compared to traditional carcinogenicity testing.

1074 REGULATION OF ANGIOGENESIS FACTORS BY ULTRAVIOLET RADIATION (UVR) OR H2O2 IN THE EPIDERM *IN VITRO* HUMAN SKIN EQUIVALENT.

T. J. Last, J. Kubilus, M. Klausner, J. E. Sheasgreen and P. J. Hayden. *MatTek Corp., Ashland, MA.*

Vascular endothelial growth factors (VEGFs) released by epidermis modulate blood vessel growth (angiogenesis), a critical step in skin tumor progression and metastasis. Placenta growth factor (PlGF), an angiogenic member of the VEGF family, is also expressed in epidermis. To gain insights into the relative importance of VEGFs and PlGF in stimulating angiogenesis in epidermis, their expression was evaluated in the EpiDerm *in vitro* human skin equivalent after treatment with UVR or H_2O_2. To evaluate the role of EGR receptor (EGFr) signaling in expression of VEGF and PlGF, the EGFr ligand TGFαand the EGFr tyrosine kinase inhibitor AG1478 were used. At various times after treatment, VEGF and PlGF expression was evaluated by RT-PCR and ELISA. Message for VEGF-A, -B, -C, -D and PlGF was detected in EpiDerm, but only VEGF-A, -D and PlGF were induced by UVA or H_2O_2. These were upregulated at 1 hr and persisted for at least 8 hrs. By ELISA, VEGF-D protein was not detected and only low amounts of PlGF (~25 pg/ml) were observed. In Contrast, abundant amounts of VEGF were detected by non-specific VEGF ELISA after UVA or H_2O_2 treatment (>850 pg/ml). EGFr signaling *via* TGFα strongly induced VEGF-A and PlGF message as well as protein (2646 pg/ml and 84.5 pg/ml for VEGF and PlGF protein, respectively). AG1478 blocked TGFα effects. Induction of VEGF-A message and protein secretion by UVA or H_2O_2 was appreciably blocked by AG1478, while VEGF-D and PlGF induction were less sensitive to AG1478. Surprisingly, in contrast to UVA or H_2O_2, irradiation of EpiDerm with complete solar UVR (UVA + B) did not lead to increased expression of VEGF-A above the basal level. These results indicate that VEGF-A is the most abundant angiogenic growth factor *in vitro* human epidermis, secreted at levels on the order of >30-fold higher than PlGF. The results also indicate that exposure of skin to oxidants, or sunscreens which block UVB but not UVA, may lead to increased expression of VEGF *via* EGFr signaling and thereby promote angiogenesis in human skin.

1075 A SYNTHETIC NON-ANIMAL MODEL OF SKIN PENETRATION.

J. M. Blonder[1], B. Lin[1], S. Cook[1], R. Remington[1], L. Webster[1], M. Sarkari[1], J. Etter[1], R. Ulmer[2] and G. J. Rosenthal[1]. *[1]RxKinetix, Inc., Louisville, CO and [2]InVitro International, Irvine, CA.*

Efficacy of topical drugs depends on penetration of active into or through skin. Prior to animal and clinical studies to test topical drug efficacy, *in vitro* penetration is often evaluated to select candidate formulations that demonstrate enhanced penetration or permeation profiles, and thus, potentially enhanced topical or systemic efficacies. Although using excised human skin for penetration studies may show the best correlation to intact human skin, difficulty of procurement and lack of reproducibility among specimens limit this option. Instead, excised animal skin is often utilized. Animal skin is cost-effective and easily obtained; however, it often does not predict drug penetration in humans. Alternatively, investigators have used human-derived or synthetic skin models for penetration studies with varying results. The goal of these preliminary studies was to examine penetration of drug using a synthetic non-animal system, Corrositex® (CTX) biobarrier membranes, and to determine if penetration through this *in vitro* system correlated with *in vivo* efficacy following topical administration. Corrositex® biobarrier membranes (InVitro International, Irvine, CA) are substitute skin-like membranes approved for corrosivity testing; compounds penetrate through a skin-like membrane and participate in a colorimetric reaction in the lower chamber. CTX membranes were adapted for penetration experiments by placing various drug formulations onto the donor side and measuring drug in the receiving chamber. Drug formulations were tested for their ability to promote drug penetration through CTX membranes and for their ability to enhance efficacy against infection in an animal model. Data show that penetration through CTX membranes correlated with efficacy *in vivo*; specifically, formulations that caused greater drug penetration *in vitro* were more efficacious in reducing parameters of infection. These preliminary data point to a non-animal alternative to skin for *in vitro* penetration as well as an alternative use for CTX membranes.

1076 INSULATION AND REPAIR OF YOUR PROFESSIONAL CAREER: INTRODUCTION.

M. L. Biehl. *Pfizer Global Res. & Dev., New London, CT.*

For most SOT members, their job is primarily a vehicle to challenge themselves intellectually and scientifically in a subject matter for which they have both expertise and interest. When stability in those endeavors is threatened or even eliminated, the resulting impact on careers and personal life (e.g. financial and emotional) can be potentially devastating. In today's turbulent economy, many individuals have suddenly found their employment status and stability in jeopardy. These situations have not been localized to one SOT professional segment, but have occurred to all groups. SOT members cannot absolutely protect their job situation from this type of upheaval. However, one can learn to recognize the "warning signs", understand how to prepare for the future possibility, and how to react if it occurs so as to minimize the damage, both professionally and personally. This seminar/discussion brings together 4 experts in subjects germane to this career scenario. Subjects to be covered include: 1) current skills and training in demand by employers, 2) job search sources and "no-strength" interviewing strategies, 3) financial planning and reactions, 4) handling the emotional stress associated with job uncertainties, and 5) "personal reflections" from an SOT member who has experienced sudden job change. Following short individual presentations, the remainder of the session time will be devoted to a panel discussion. Questions (both oral and written) will be solicited from the audience.

1077 CAREER PLANNING FOR TOXICOLOGISTS. STRATEGIES FOR PREPARATION AND RESPONSE TO CHANGING CIRCUMSTANCES.

T. Leyden. *Career Marketing Associates, Greenwood Village, CO.* Sponsor: M. Biehl.

Toxicology careers have been increasingly less stable in the last few years as a result of various economic pressures across the industrial, academic and government sectors. This presentation will discuss strategies which toxicologists may employ to ensure preparedness should a staff reduction, merger, career discontent or related event occur. A number of career options and the means to explore them will be presented. Advertisements, networking and professional recruiting services will be mentioned as effective means for investigating career choices and keeping apprised of current trends in toxicology employment and compensation. A suggested plan of action to make a career change will be presented. This will include a brief review of resume and cover letter format, interview preparation and follow through.

1078 FINANCIAL STRATEGIES FOR THE UNEXPECTED CIRCUMSTANCES.

J. D. Strunk. *Salomon Smith Barney, Mystic, CT.* Sponsor: M. Biehl.

Many people struggle with the anxiety of dealing with personal financial circumstances. You can keep one step ahead of your finances by anticipating problems and taking advantage of opportunities. You can save your money and invest wisely. You can plan to ensure your long-term financial security. Financial planning can help you establish firm control over any situation. This presentation will discuss a practical means for taking stock of your present financial status. You will learn how to formulate effective strategies for building and managing your investments and finances and how to react if you are suddenly in financial difficulty.

1079 HANDLING STRESS ASSOCIATED WITH JOB UNCERTAINTIES.

R. G. Weigel. *University Counseling Center, University of Utah, Salt Lake City, UT.* Sponsor: M. Biehl.

Job termination for any reason more often than not leads to physical, cognitive, and/or emotional problems. These problems may be debilitating, but are natural reactions of normal people thrust into abnormal situations. They reflect our built-in

biological mechanism for fight or flight when threatened. Fight seldom is viable choice of behaviors. Flight from the threat may be either physical or psychological: either avoids dealing with facing up to the situation. Such avoidance, based on shame, guilt, or worries, is effective short-term to lessen anxiety, but is self-defeating over the longer haul because it inhibits the individual from seeking a new position. The longer one is out of work the more anxiety increases, and leads to further avoidance of necessary job-seeking behaviors. Thus, it is important not to succumb to such feelings, but to cope by activating oneself to mount and maintain a full-bore job search. A central component of the search is self-examination of strengths, weaknesses, needs, goals, and generalizable skills. With this increased understanding of self, the individual is better prepared to research potential employers, to consider alternative career paths, to network, and to seek possible positions. As one progresses to making contact with employers, another threat to well-being often emerges: the high risk-reward ratio of such contacts may be so stressful as to drive the job-seeker again into self-defeating avoidance of the anxiety of further rejections, and a re-escalation of debilitating physical symptoms or cognitive and emotional problems. "So, what's new?", you say. "It's predictable." Yes. However, an intellectual understanding of this process may be very difficult to bring to bear when you are the victim experiencing the shock, and sometimes the sheer terror, accompanying termination. Realistic strategies for breaking this self-destructive cycle are discussed, as are ways to prepare early and throughout one's career so as to have in place the skill sets, industry knowledge, personal hardiness, professional contacts, and search plans necessary to effectively bounce back if faced with termination.

1080 CAREER DURING CHAOS: AN INSIDERS PERSPECTIVE.

J. A. Popp. *Purdue Pharmacology L.P., Ardsley, NY.*

Change in the employment world is inevitable with the pace of change rapidly increasing. While change can be a very unsettling experience, it is important for every toxicologist to be prepared even though one's current employment appears to be stable. To be prepared the following points should be considered: 1) Every toxicologist should focus on career development all the time. It is important to have up to date skills and be able to demonstrate the ability to contribute to your current employer or to a potential new employer. 2) Rumors of pending workplace changes should be avoided since it is couterproductive. Most rumors are incorrect. You are unlikely to be able to discern the false rumors from the occassional fact. 3) Reactions of colleagues may be unpredictable. Leadership may not be demonstrated during crisis by those who demonstrate leadership during "normal" times. 4) Change is not bad. In summary, chaos in the workplace is here and it will continue. To be successful, one must be prepared, be able to demonstrate flexibility and view change as an opportunity.

1081 BEYOND GENOMICS: IMAGE ANALYSIS AND COMPUTATIONAL BIOLOGY.

K. S. Ramos[1] and C. L. Walker[2]. *[1]Center for Environmental and Rural Health, Texas A&M University, College Station, TX and [2]Department of Carcinogenesis, The University of Texas M. D. Anderson Cancer Center, Houston, TX.*

The reductionist approaches used historically in toxicology to understand the nature of cellular functions, and the processes that collectively constitute the molecular basis of the toxic response, can be overly simplistic. Instead, altered cellular structure and function must be studied in a holistic manner that embraces the immense complexity of biological networks. High-throughput genomic technologies are now allowing scientists to pave the way to a deeper understanding of biological systems and their disruption by chemical and physical agents. This symposium brings together toxicologists, engineers, and mathematicians to evaluate the usefulness of genomic and computational approaches to characterize complex biological networks in health and disease, to dissect complex toxicological responses into cogent, contextually relevant processes and to develop mathematical principals governing biological systems.

1082 EPISTEMOLOGY OF CLUSTERING.

E. R. Dougherty. *Electrical Engineering, Texas A&M University, College Station, TX.* Sponsor: K. Ramos.

Many algorithms are now available to cluster sample data points based on nearness or similarity of measure. Often the implication is that points in different clusters arise from different classes, while those within the same cluster come from the same class. Stochastically, the underlying classes represent different random processes and the inference is that clusters represent a partition of the sample points according to the process they belong to. In the present work, the validity of this assumption was tested using a model-based clustering toolbox that evaluates cluster accuracy. This method modeled each random process as its mean value plus independence noise, and generated sample points for subsequent clustering. The clustering error was then calculated, with error defined as the number of points clustered incorrectly according to the generating random processes. Various clustering algorithms were evaluated based on process variance and the key issue of the rate at which algorithmic performance improved with increasing numbers of experimental applications was demonstrated.

1083 MODELING GENETIC REGULATORY NETWORKS WITH PROBABILISTIC BOOLEAN NETWORKS: FROM INFERENCE TO INTERVENTION.

I. Shmulevich. *MD Anderson Cancer Center, Houston, TX.* Sponsor: K. Ramos.

Probabilistic Boolean Networks (PBN) constitute a class of new models of gene regulatory networks. This model class incorporates rule based dependencies between genes, allows the systematic study of global network dynamics, is able to cope with uncertainty, and permits the quantification of the relative influence and sensitivity of genes in their interactions with other genes. The dynamics of these networks, and in particular long run behavior, can be studied using Markov chain theory. We consider the general question of the potential effect of individual genes on the global dynamical network behavior, both from the view of gene perturbation as well as intervention for eliciting desired network behavior. This has great potential for the identification and discovery of potential targets for therapeutic intervention in diseases such as cancer.

1084 APPLICATION OF CLUSTERING METHODOLOGIES TO THE ANALYSIS OF ALTERED CELLULAR PHENOTYPES INDUCED BY OXIDATIVE STRESS.

K. S. Ramos[1], C. D. Johnson[1], M. H. Falahatpisheh[1], T. Thomas[1], P. Beremand[1], M. Tadesse[1], K. P. Lu[1], Y. Balagurunathan[1], C. A. Afshari[2] and . R. Dougherty[1]. *[1]Center for Environmental and Rural Health, Texas A&M University, College Station, TX and [2]Microarray Center, National Institute of Environmental Health Sciences, Research Triangle Park, NC.*

The study of complex patterns of gene expression as cells transition from normal to disease phenotypes has been facilitated by the application of Microarray technologies. The present studies were conducted to compare the transcriptome profiles of oxidatively stressed vascular and renal cells to identify critical genes that mediate acquisition of disease phenotypes. Cultured murine vascular smooth muscle cells and nephroblastema were challenged with three micromolar benzo(a)pyrene (BaP) for various times to evaluate the early adaptive global gene expression response associated with altered cellular phenotypes. Vascular and renal cytochrome P450s metabolized BaP to reactive intermediates that triggered a complex cellular response that culminated in activation/repression of overlapping signal transduction cascades involving oxidative stress and DNA damage. The largest group of responsive genes in vascular cells included lymphocyte antigen-6 complex, Histocompatibility class 1 component B and Q region, lysyl oxidase, secreted phosphoprotein, and several interferon inducible proteins; genomic changes neutralized by N-acetylcysteine (0.5 mM), a soluble antioxidant and precursor of cellular glutathione. In nephroblastemal cells, the largest group of responsive genes included glial derived neurotrophic factor, frizzled receptor, IGF receptor, synecan, Sry, oncostatin M, pinin, GATA-3, Sox-18, nrf2 and fibulin. Application of various clustering algorithms (k-means, fuzzy C means, self-organizing maps, and hierarchical) identified critical genes involved in the cellular response to oxidative stress. These data suggest that deregulation of gene expression by BaP involves disruption of redox homeostasis with several common gene targets involved in the early adaptive response to hydrocarbon injury.

1085 BAYESIAN CLASSIFICATION TOOLS IN TOXICOLOGY.

C. A. Bradfield. *McArdle Laboratory for Cancer Research, University of Wisconsin, Madison, WI.*

One of the major objectives of toxicology is to understand the adverse health effects of chemicals in humans. This understanding could be aided by the ability of group chemicals that generally act the same, or are believed to produce their toxic endpoints through similar mechanisms. In an attempt to identify these toxicologically relevant gene expression patterns, we initiated a survey of chemically induced changes in liver gene expression through the use of custom cDNA microarrays. Five broad chemical classes were selected for study. Microarray analysis was performed on various chemicals within these groups and the results analyzed using a Bayesian

analysis. Using a forward parameter selection scheme, a 'minimal' set of 5 genes was identified that allowed 100% accuracy in classifying the treatments and an 'optimal' set of 12 genes which still provided 100% accuracy but also gave more robust predictions. These results provide significant evidence that the classification of chemicals according to their gene expression profiles is possible and opens the door to a potentially new era of toxicological testing.

1086 TOXICOGENOMICS AND THE QUEST FOR PREDICTIVE TOXICOLOGY.

R. S. Paules[1], H. K. Hamadeh[1], C. A. Afshari[1], R. W. Tennant[2] and P. R. Bushel[1]. *[1]NIEHS Microarray Center, National Institute of Environmental Health Sciences, Research Triangle Park, NC and [2]National Center for Toxicogenomics, National Institute of Environmental Health Sciences, Research Triangle Park, NC.*

One of the major goals in toxicology is the ability to predict an adverse affect on human health following exposure to an environmental stress. The power and promise of genomics is to provide new tools to actually accomplish this goal. By building a robust knowledge of gene expression changes that occur in various tissues following exposures to toxicants, one can then begin to discern early changes that are informative of ensuing pathological alterations. Animals have been exposed to a variety of toxic and nontoxic agents and the gene expression patterns have been analyzed using cDNA microarray analyses. The resulting information has been subjected to a variety of analysis approaches which identify significantly differentially expressed genes within the data set, reduce the complexity of the data and allow for identification of highly informative genes that permit discrimination among classes of agents or among toxicological endpoints. These approaches include hierarchical clustering, analysis of variation (ANOVA), genetic algorithm/K-nearest neighbor (GA/KNN), linear discriminant analysis (LDA), principal component analysis (PCA), and a simplified fuzzy adaptive resonance theory map (SFAM) neural network architecture.

1087 CHILDREN'S HEALTH RISK: WHAT'S SO SPECIAL ABOUT THE DEVELOPING IMMUNE SYSTEM?

L. Burns Naas[1] and M. P. Holsapple[2]. *[1]Drug Safety Evaluation, Pfizer Global Research & Development, San Diego, CA and [2]Toxicology, Environmental Research & Consulting, The Dow Chemical Company, Midland, MI.*

In recent years, there has been increasing regulatory pressure to protect the health of children, with the basic tenet being that children differ significantly from adults in their biological and/or physiological responses to chemical exposures. In a regulatory context, this has been translated to mean a requirement for an additional 10-fold safety factor for environmental contaminants, specialized tests, or both. Much of the initial focus has been on the developing endocrine and nervous systems but increasingly the developing immune system has been identified as a potential target organ for chemically mediated toxicity. More recently, the question has been raised regarding whether the current state of the science supports the creation of developmental immunotoxicology (DIT) test guidelines. What is needed is a risk-based evaluation of the biology associated with the proposed differential sensitivity between children and adults and the impact of that assessment on additional regulatory measures to protect children in risk assessment analyses. Additionally, an understanding of whether the developing immune system shows greater susceptibility, either qualitatively or quantitatively, to chemical perturbation is critical.

1088 ASSESSING THE HAZARD TO CHILDREN OF LOW LEVEL ENVIRONMENTAL EXPOSURES.

D. J. Paustenbach. *Exponent, Boulder, CO.*

Since about 1995, there has been extraordinary interest in the possible hazard to children posed by exposure to environmental toxicants and pharmaceuticals. Passage of the Food Quality Protection Act (FQPA) in 1996 represents one of the first major national attempts to protect children from chemical exposures by requiring that pesticide residue levels be 10-fold less than would normally have been selected based on the available toxicity data. A Presidential Executive Order on the Protection of Children from Environmental Health Risks and Safety Risks and the USEPA's Office of Children's Health Protection were also established in 1997 to prioritize and coordinate research efforts on health and safety risks to children. Over the past five years, due to improved levels of detection of chemicals, it has been shown that many chemicals which are found in commercial products (carpets, wallpaper, etc.)are present in indoor air and the blood of children. In 2000, the USEPA announced the Voluntary Children's Chemical Evaluation Program (VCCEP)which is intended to provide data to enable the public to understand the potential health risks to children associated with certain chemical exposures. Recent examples of concerns over children's exposures to environmental toxicants include CCA-treated wood, pesticides in carpet from outdoor application and pthalates in toys. Two new journals have been announced which will focus on research in these areas and a dozen centers for the study of Children's Health have been formed at major universities. This presentation will review some of what is known about the enhanced susceptibility of children to low level exposure to environmental chemicals (or lack thereof), current methods for estimating exposure to children, new or proposed models for estimating the toxicological hazard, and some of the current research efforts.

1089 DIFFERENTIAL SENSITIVITY OF CHILDREN AND ADULTS TO CHEMICAL TOXICITY - BIOLOGY, RISK, AND REGULATION.

G. Charnley. *HealthRisk Strategies, Washington, DC.*

Many are questioning the extent to which methods used by regulatory agencies to assess risks from environmental toxicants are adequate to protect children. Arguments for and against an additional 10x safety factor to account for the potentially greater susceptibility of children can be made on both scientific and precautionary grounds. Insults that occur during development *in utero* or during childhood can have tragic consequences in terms of birth defects and greater likelihood of disease throughout both childhood and adulthood, placing great demands on social and emotional resources. The proportion of birth defects, developmental immunotoxicity, and other problems attributable to environmental exposures to chemical toxicants is not known, but even if that proportion is small, it would constitute a public health problem by virtue of the numbers of people affected. Children are at greater risk of chemical toxicity if their exposures are high enough to produce adverse effects whether or not they are more or less sensitive than adults, however. The question then is one of whether current regulatory approaches to limiting chemical exposures are sufficient to protect children from exposures that are toxic; or, are chemical exposures misregulated due to inadequate attention to children's sometimes greater sensitivity to particular chemicals, putting them at greater risk? The uncertainty factors that regulatory agencies use when identifying criteria for limiting chemical exposures are designed to account for differences in susceptibility within and among species and to compensate for limited data availability, when necessary. Where available, quantitative analysis of the extent of toxicodynamic and toxicokinetic variability among humans indicates that relying on a default value of 10 to compensate for variability among humans, including that due to age, and on a default value of 10 to compensate for a limited toxicity database, when necessary, are adequate to protect most of the people - including children - most of the time.

1090 THE DEVELOPING HUMAN IMMUNE SYSTEM: A CLINICAL PERSPECTIVE.

L. J. West. *Hospital for Sick Children/University of Toronto, Toronto, AB, Canada.*
Sponsor: L. Burns Naas.

Defining critical windows in the development of the immune system is needed to identify periods of specific vulnerability in the continuum of development, which may differ significantly from the mature system. Other fundamental factors must then be integrated that may further predispose the developing immune system to risk. These factors, which may vary significantly between species, include biologic parameters of the fetus, infant, child, and adolescent, such as differences in metabolism, physiology and body surface area ratios. Prenatal events can affect immune responses at birth and, depending on gestational timing, can result in widely varied outcomes. Because birth occurs at various stages of fetal maturity, the significance of parturition in terms of immune susceptibility varies from species to species. At the time of human birth, various compartments of the immune system differ in their numbers and functionality, which can contribute to a sensitivity to chemical immunosuppression. After the early neonatal period, there is continued acquisition of immune competence concomitant with increased antigen exposure throughout years one and two of childhood. However, it is important to consider the fact that attainment of immunocompetence does not necessarily mean closure of 'windows'. For comprehensive progress towards strategies aimed at the needs of the young, the following questions must be considered. Are the parameters that we extrapolate from animal models physiologically and clinically relevant to the developing human? Are the data that we extrapolate from mature individuals relevant during variable stages of immunologic immaturity? Continuing difficulties will be presented because there is inadequate data on exposure, toxic effects, pharmacokinetics and pharmacodynamics during fetal and neonatal life, infancy, childhood and adolescence. Furthermore, assays may be unvalidated for varied states of immaturity. A major collaborative effort is needed in order to facilitate design and development of better strategies to determine the potential impact of chemicals on the developing immune system.

1091 EVOLUTION OF THE SCIENCE OF DEVELOPMENTAL IMMUNOTOXICITY.

M. I. Luster. *TMBB/HELD, NIOSH/CDC, Morgantown, WV.*

The value of incorporating immunological data for the toxicological assessment of drugs, chemicals, biologicals and medical devices for human risk assessment has been increasingly accepted. Since the 1970s, experimental animal studies, and to a lesser extent human studies, have been published describing immunological effects in neonates exposed to toxic agents during the prenatal or early postnatal period . Of particular concern was that immunotoxicity often appeared more severe and/or persistent when the exposure occurred perinatally when compared to exposure in adult animals. These concerns were addressed in a 1993 report from the National Research Council (NRC) entitled Pesticides in the Diets of Infants and Children in which the immune, as well as the reproductive and nervous systems, were identified as potential targets for pesticide exposure. Efforts are presently being undertaken to identify appropriate methods and approaches to identify and study developmental immunotoxicants. In addition to immunosuppression, there is increasing evidence that transplacental priming of the immune system occurs in response to certain environmental agents which possess allergic or inflammatory properties. This subsequently results in T-helper 1 (Th1) or, more often, T-helper 2 (Th2) skewing of the immune system. Consistent with this general postulate is experimental and clinical evidence that individuals exposed early in life to these environmental agents are predispose to increased prevalence and/or severity of immune diseases

1092 SUSCEPTIBILITY OF THE DEVELOPING IMMUNE SYSTEM TO IMMUNOSUPPRESSIVE AGENTS: DIFFERENTIAL RISK ACROSS LIFE STAGES.

R. R. Dietert[1] and J. Lee[2]. *[1]Department of Microbiology, Cornell University, Ithaca, NY and [2]Institute of Comparative and Environmental Toxicology, Cornell University, Ithaca, NY.*

Recent findings from *in utero* vs. adult exposures to toxicants will be used to demonstrate the specific challenges associated with developmental immunotoxicity evaluation. Differential risk to immunotoxicants can result from life-stage-specific differences in metabolism, differential susceptibility of the developing immune system target, potential latency effects, and heterogeneous susceptibility of populations (i.e. toxicogenomics). Likewise, the challenge in selecting an appropriate age of assessment capable of revealing these comparative risks will be discussed. Data from early exposures to low-levels of the heavy metal, Pb, will be presented to support the concept of critical developmental windows of differential immunotoxic risk. Additionally, the Pb-induced immunotoxicity results are consistent with an emerging paradigm of gestationally-induced immunotoxicity. Disrupted T helper balance with the hallmark of suppressed T helper 1 (Th1) function appears to represent a common immunotoxic outcome of early chemical insults. Because Th1 function develops later in gestation than the default T helper 2 (Th2) function, the potential for impairing Th1 function with *in utero* exposure to toxicants appears to be significant. It should be noted that this type of immune alteration (elevated Th2 function with suppressed Th1 activity) would contribute to an increased risk of childhood asthma and allergic disease.

1093 TEMPORAL SPECIFIC EXPRESSION OF TOXICANT-METABOLIZING ENZYMES: IMPLICATIONS FOR LIFE-STAGE-DEPENDENT TOXICITY.

R. N. Hines. *Pediatrics & Pharmacology/Toxicology, Medical College of Wisconsin, Milwaukee, WI.*

Substantial changes in toxicokinetics and toxicodynamics occur during human development that contribute to differential susceptibility. Although certainly not the only component, the temporal-specific expression of toxicant metabolizing enzymes contribute significantly to these changes. A better knowledge of these processes and their underlying mechanisms will be required if we wish to understand and predict the dynamic dose-response relationships that occur during ontogeny and develop strategies that would prevent developmental toxicity. The objective of this symposium is to present recent advances in our understanding of how developmental, genetic, and environmental factors interact to define the risk from toxicant exposure. The symposium will cover research results on longitudinal pediatric phenotyping and present a dramatic example of the importance of phenotyping in identifying potential risk. Studies also will be presented on the characterization of both phase I and phase II developmental expression patterns in the human and animal models, explore molecular mechanisms underlying the regulation of such expression patterns, and begin to explore how genetic factors might contribute to both interindividual differences in expression as a function of age.

1094 PEDIATRIC PHARMACOGENETICS: DEVELOPMENTAL "PHENOTYPES" AND THEIR POTENTIAL CONSEQUENCES.

J. Leeder. *Developmental Pharmacology and Experimental Therapeutics, Children's Mercy Hospital, Kansas City, MO.* Sponsor: R. Hines.

Individual cytochrome P450 (CYP) isoforms have characteristic developmental profiles, and phenotypic measures of those activities change throughout maturation. Thus, in children, gene-environment interactions that contribute to the pharmacogenetic determinants of drug disposition and response are influenced by an additional variable, development. The goals of our research program are to define the ontogeny of drug biotransformation pathways *in vivo*, and to identify the pharmacogenetic basis of variation in the developmental patterns observed, a process we refer to as "developmental pharmacogenetics." To achieve these goals, we employ a longitudinal phenotyping strategy using probe compounds that are considered safe by health care professionals and perceived as safe by parents, such as dextromethorphan (DM) and acetaminophen (APAP). Phenotyping studies are coordinated with well baby visits to primary care providers. At two weeks postnatal age, CYP2D6 activity (as estimated by the ratio of DM to its *O*-demethylated metabolite, dextrorphan) is consistent with *CYP2D6* genotype (n=96). However, the data also suggest that DM *N*-demethylation activity, attributed to CYP3A, becomes quantitatively more important to overall DM biotransformation as infants mature and become toddlers. For example, the fraction of total DM and metabolites recovered as 3-hydroxymorphinan increases from 0.156 ± 0.154 at two weeks to 0.531 ± 0.157 at 12 months of age while the fraction recovered as dextrorphan decreases from 0.799 ± 0.164 to 0.450 ± 0.148 over the same period. Developmental changes in CYP activity clearly have the potential to affect dosage requirements at different ages but may have toxicologic significance as well. Following APAP dosing to two week old infants, thioether metabolites represent 10.4 ± 0.4% of recovered drug and metabolites, similar to adults. Further investigation is required to determine if developmental differences in bioactivation and detoxification processes result in periods of susceptibility that are unique to children at a specific developmental stage.

1095 MOLECULAR MECHANISMS REGULATING *FMO* TEMPORAL-SPECIFIC EXPRESSION.

R. N. Hines, S. B. Koukouritaki, K. Hopp and Z. Luo. *Pediatrics & Pharmacology/Toxicology, Medical College of Wisconsin, Milwaukee, WI.*

The flavin-containing monooxygenase genes (*FMO1-5*) encode enzymes important for the metabolism of numerous environmental toxicants. Studies to date have demonstrated temporal-, tissue-, & species-specific *FMO* expression patterns that impact susceptibility. However, a complete picture of these patterns and underlying regulatory mechanisms remain unknown. To characterize human hepatic *FMO1 & 3* developmental expression, microsomal protein levels were quantified in 240 liver samples representing ages from 8 wks gestation to 18 postnatal yrs. FMO1 expression was highest at 8-15 wks gestation (7.8 ± 5.3 pmol/mg protein) then slowly declined with complete suppression within 3 postnatal d through a mechanism tightly coupled to birth, but not gestational age. Low FMO3 levels also were detected at 8-15 wks gestation, but at no other prenatal period. Most individuals failed to express FMO3 during the first 21 postnatal days. FMO3 was detected by 10 mo & was expressed at 20% of adult values between 10 mo & 11 yr. Thus, birth is necessary, but not sufficient for the onset of FMO3 expression. A gender-independent increase in FMO3 expression was observed between 11 and 18 yrs (maximum of 26.9 ± 8.6 pmol/mg protein), although adult expression levels were not attained by the latter age. Data from transient expression studies suggest that fetal hepatic FMO1 expression is largely regulated by HNF1α, although as yet unidentified upstream-binding factors also are involved. Preliminary data implicate DBP as playing a role in regulating postnatal hepatic *FMO3* expression. Results from SNP discovery suggests a high degree of *FMO1* conservation, but did identify a functional, regulatory polymorphism in a basal promoter YY1 element that may account for up to a 2-fold variation in expression. Other novel genetic variants may partially explain interindividual variability in *FMO1 & 3*expression (Supported by PHS CA53106).

1096 HUMAN CYP2E1 DEVELOPMENTAL EXPRESSION: A ROLE IN FETAL & PEDIATRIC SUSCEPTIBILITY TO TOXICANTS?

D. McCarver, E. K. Johnsrud and S. B. Koukouritaki. *Birth Defects Research Center, Department of Pediatrics, Medical College of Wisconsin, Milwaukee, WI.*

CYP2E1 is important in the bioactivation of small molecular weight toxicants such as toluene, benzene & trichloroethylene. Developmental changes in human CYP2E1 expression likely impact susceptibility of the fetus and young child to these compounds. Two previous studies of human CYP2E1 ontogeny yielded conflicting results. To define human hepatic CYP2E1 developmental expression pattern, microsomes were prepared from human liver samples [N=72 fetal (8-37 wks);

166 postnatal (1d-18 y)]. Samples from subjects likely to have liver disease were excluded. Microsomal CYP2E1 was quantitated by western blot analysis (LOD=1.0 fmol CYP2E1). Measurable expression was seen in 18/49 2nd trimester and 12/15 3rd trimester fetal samples [medians=0.35; 6.7 pmol/mg protein, respectively]. CYP2E1 increased after birth but was relatively low in the neonatal period. CYP2E1 in neonatal samples was less than that of infants from 1-3 months of age which was less than that of older infants, children and young adults [median (range)= 8.8 (0-70); 23.8 (10-43); 41.4 (18-95), respectively; each $p<0.001$, ANOVA, post-hoc]. Beyond 3 months of age, CYP2E1 protein values did not vary by age. At every age, 4-fold or greater intersubject variation was observed. Increasing postnatal age was associated with increasing protein [N=29, $p=0.001$, linear regression], whereas the relationship with increasing GA was less striking [$p=0.07$]. These data suggest that infants < 3 months of age may have significantly lower metabolic clearance of CYP2E1 substrates compared to older age groups. This may lead to a protective effect among very young infants exposed to ubiquitous toxicants such as toluene, benzene and trichloroethylene that are bioactivated by this enzyme. We suggest that the 4-fold variation in CYP2E1 protein among all pediatric patients is consistent with either genetic differences or variable protein stabilization by an unknown endogenous substrate.

1097 DEVELOPMENTAL EXPRESSION OF HUMAN HEPATIC CYP3A AND 2B ENZYMES.

J. C. Stevens[1], S. A. Marsh[1], M. J. Zaya[1], J. R. Manro[1], S. B. Koukouritaki[2] and R. N. Hines[2]. *[1]Global Drug Metabolism, Pharmacia Corp., Kalamazoo, MI and [2]Department of Pediatrics, Medical College of Wisconsin, Milwaukee, WI.*

Within the human cytochrome P450 family, specific hepatic forms can show developmental expression patterns that may affect drug clearance, efficacy and safety. The objective of these studies was to use P450-specific enzyme activities or immunoquantitation to identify developmental expression patterns in a large (n~250) and developmentally diverse set of pediatric liver samples. CYP2B6 levels in fetal samples were found to be low, with few exceptions. Activities increased with birth, with an average activity of 0.07 nmol/min/mg observed for the birth to 3-month age category. CYP2C9-dependent activity was clearly shown in fetal samples, with a dramatic increase in activity associated with birth. CYP2C19 levels peaked at 6-12 months, with males showing a significant increase vs. females for this category. Different approaches were used to characterize changes in expression of CYP3A forms. Using an antibody specific to 3A5, protein levels showed no change in expression with age, however, ethnicity was a determinant with higher 3A5 levels observed for African American subjects in 8 of 9 age categories. The differentiation of 3A7 (fetal form) from 3A4 (primarily an adult form) within the same sample required method development. Specifically, the use of dehydroepiandrosterone (DHEA) metabolite profiles to simultaneously quantitate 3A4 and 3A7 in pediatric liver microsomes was studied. First, 7β-OH-DHEA was positively identified as the major metabolite of 3A4, based on co-chromatography and MS/MS analysis. The major metabolite of 3A7 has been reported as 16α-OH DHEA, but it is also formed by 3A4. Therefore the contributions of 3A4 and 3A7 were determined in mixtures of expressed isoforms by fitting the metabolite profiles to a multiple response model. Preliminary data suggest that DHEA metabolite profiles can differentiate 3A4 and 3A7 levels for adult and pediatric liver microsome samples.

1098 DEVELOPMENTAL CHANGES IN N-ACETYLTRANSFERASES: IMPLICATIONS FOR 4-AMINOBIPHENYL (4ABP) TOXICITY.

C. A. McQueen. *Department of Pharmacology and Toxicology, The University of Arizona, Tucson, AZ.*

Developmental changes in the expression of biotransformation enzymes affect the susceptibility of fetuses, infants and children to the therapeutic and toxic effects of chemicals. Arylamine N-acetyltransferases (NAT1 and NAT2) catalyze reactions involved in activation and detoxification of drugs and arylamine carcinogens including 4ABP. Several studies show that these enzymes are present early in human development. Interestingly, there is no apparent genotype-phenotype correlation in young children. When phenotypic determinations in children are done with the metabolic ratios used for adults, phenotype changes with age. This suggests that expression of the NAT genes is changing. Preliminary data with human postmortem samples from neonates and children show these samples have lower sulfamethazine NAT activity than that in adult liver. C57Bl/6J mice have been used to more completely assess the expression of NAT1 and NAT2 from birth to sexual maturity. Hepatic expression of NAT1 and NAT2, determined by quantitative RT PCR, increased with age. Hepatic N-acetylation of p-aminobenzoic acid, a murine NAT2 selective substrate, isoniazid, a murine NAT1 selective substrate, as well as the carcinogenic aromatic amines 2-aminofluorene and 4ABP, substrates for both isoforms, also increased with age. Toxicologic effects of this developmental pattern were evaluated with 4ABP. One reaction catalyzed by NATs is a step in the activation of 4ABP to DNA reactive products. Interaction of these products with DNA was evaluated by microarray analysis of hepatic gene expression and adduct formation in neonates and adults following exposure to 4ABP. Expression ratios of genes involved in cell cycle control were among those affected; however, the number of genes as well as the expression ratios was lower in neonates than in adults. A similar pattern was seen with 4ABP-DNA adduct levels. These results suggest that the level of expression of NAT1 and NAT2 occurring in neonates limits acetylation and contributes to decreased 4ABP toxicity compared to adults. (Supported by ES 09812 and ES 10047).

1099 OCCUPATIONAL LUNG DISEASE IN RESPONSE TO MIXED EXPOSURES: APPROACHES TO IDENTIFY THE TOXICITY OF PROCESS - DEPENDENT CONTAMINANTS.

V. Castranova and T. Gordon. *HELD, NIOSH, Morgantown, WV.*

To date, the majority of exposure limits set by OSHA or EPA have been for individual particulate agents or chemical compounds. However, modern industrial operations generate complex mixed aerosols, the components of which are often process dependent. For example, the chemical composition of welding fume varies with the type of shielding and electrode used, while microbial contamination of organic dusts or used metal working fluids can dramatically alter the biological response upon exposure to these materials. In addition, the types and amounts of organic chemicals adsorbed onto the carbon core of particles generated by diesel engines can depend on engine speed, load, and the type of fuel consumed. There is increasing awareness that the toxicity of a mixed exposure may not simply be the additive effects of its components. Indeed, synergistic effects, involving soluble metals, adsorbed organics, surface acidity, microbial contamination and particle size or surface area may occur. For this reason, NIOSH has listed "mixed exposures" as a priority area in its National Occupational Research Agenda that must be addressed to allow appropriate and complete risk assessment in complex occupational settings. The objective of this symposium is to elucidate the various interactions among components of mixed exposures that are possible and to characterize the mechanisms involved in these interactions, using real-world occupational aerosols as examples.

1100 ISSUES THAT MUST BE ADDRESSED FOR RISK ASSESSMENT OF MIXED EXPOSURES: EPA EXPERIENCE WITH AMBIENT AIR QUALITY.

D. L. Costa. *USEPA, Research Triangle Park, NC.*

Epidemiological studies have linked elevated levels of ambient particulate matter to increased morbidity and mortality from both cardiovascular and pulmonary diseases. Risk assessment efforts concerning ambient air quality must address the issue of mixed exposures, since in ambient air both gaseous and particulate fractions exhibit toxic potentials which may result in synergistic interactions. Making risk assessment even more difficult is the increasing awareness of the complex nature of ambient particulate matter itself. Recent investigations have been directed toward the elucidation of the toxic potential and adverse interactions of the various components of ambient particles. Research efforts have found several characteristics of ambient particles to be important factors for consideration. These characteristics include the unique toxic potential of soluble metals, absorbed organic chemicals, surface acidity and microbial contaminants on ambient particles. In addition, the unique toxicity of the ultrafine vs the fine fraction of ambient particles has become an issue of increasing importance. This presentation will review evidence which evaluates the relative importance of these toxic components of ambient particulate matter and mechanisms by which these components adversely affect the lungs. In addition, mechanisms by which pulmonary exposure to ambient particles can result in pathological cardiovascular reactions will be discussed.

1101 METAL WORKING FLUIDS AS COMPLEX MIXTURES.

T. Gordon. *Environmental Medicine, NYU School of Medicine, Tuxedo, NY.*

Exposure to aerosols of metal working fluids is associated with a variety of adverse respiratory effects. The identity and proportion of chemical species in these mixtures are dependent on several factors, including the manufacturer and the cooling and lubrication requirements of the machining process. In addition, a number of additives, such as biocides and anti-foaming agents, are added to the metal working fluids to enhance their operational lifespan. Also of considerable concern, an unknown number and amount of contaminants become part of the complex mixture during the machining process. These contaminants can include tramp oil, reaction products such as nitrosamines, metal fragments, and microbial products from contaminating bacteria and fungi. Only a limited amount of data in the published lit-

erature has addressed the issue of identifying the individual component(s) responsible for the adverse effect of inhaled metal working fluid aerosols. The approaches of these toxicology studies have included: 1) the comparison of used versus unused fluids, 2) the addition of individual components/contaminants to the unused fluid, 3) association studies which attempt to correlate and adverse effect with a biomarker such as specific antibodies, and 4) principal component analysis. Each of these approaches has been useful in identifying potential toxic components, but definitive answers to the complex issue of metal working fluid toxicity are still needed.

1102 PULMONARY RESPONSES TO WELDING FUMES: ROLE OF METAL CONSTITUENTS.

J. M. Antonini. *NIOSH, Morgantown, WV.*

It is estimated that more than one million workers worldwide perform some type of welding as part of their work duties. Epidemiology studies have shown that a large number of welders experience some type of respiratory illness. Respiratory effects seen in full-time welders have included bronchitis, airway irritation, lung function changes, and a possible increase in the incidence of lung cancer. Pulmonary infections are increased in terms of severity, duration, and frequency among welders. Inhalation exposure to welding fumes may vary due to differences in materials used and methods employed. The chemical properties of welding fumes can be quite complex. Most welding materials are alloy mixtures of metals characterized by different steels that may contain iron, manganese, silica, chromium, nickel, zinc, and fluorides. Animal studies have indicated that the presence and combination of different metal constituents is an important determinant in the potential pneumotoxic responses associated with welding fumes. Animal models have demonstrated that stainless steel welding fumes which contain significant levels of nickel and chromium induce more lung injury and inflammation and are retained in the lungs longer than mild steel welding fumes which contain mostly iron. In addition, stainless steel fumes generated from welding processes using fluxes to protect the resulting weld contain elevated levels of soluble metals. These soluble welding fumes have been shown to suppress lung macrophage function and significantly slow the clearance of bacterial pathogens from the lungs after infection. The presence of soluble metals, such as Cr, Ni, and Mn, and the complexes formed by these different metals, as well as fluoride compounds present in fluxes, are likely important in the pulmonary responses observed after welding fume inhalation.

1103 THE ROLE OF BACTERIAL AND FUNGAL CONTAMINANTS IN AGRICULTURAL RESPIRATORY DISEASES.

P. Thorne. *Occupational & Environmental Health, University. Iowa, Iowa City, IA.*

Farmers and other agricultural workers face a variety of respiratory diseases including organic dust toxic syndrome (ODTS), farmer's hypersensitivity pneumonitis (HP), asthma-like syndrome, asthma, and pulmonary infections. These diseases arise from complex mixtures of bioaerosols and aeroallergens including pathogenic and non-pathogenic organisms; microbial constituents such as endotoxins and glucans; and allergens from arthropods, animals, plants and molds. ODTS is an acute inflammatory response to inhalation of dusts of organic origin, such as silage, grain dust, cotton dust, and compost. It is characterized by fever, headache, chest tightness, pulmonary infiltrates, and airway obstruction. The bacterial product, endotoxin, and the fungal product, beta-glucan, have been proposed as important etiologic agents in ODTS. Farmer's HP has a similar clinical presentation to ODTS but is an allergic disease caused principally by antigens from thermophilic bacteria. However, proinflammatory constitutents in organic dust may play a role in the disease. Asthma-like syndrome may arise from work in animal confinement units, such as those for intensive poultry and swine production, or from grain handling. This syndrome is an acute non-allergic airway obstruction caused by inflammatory responses to components of the organic dust. It differs from asthma in that it rarely leads to persistent airway hyperreactivity. Pulmonary infections may be zoonotic or may arise from a variety of niche organisms. Human and animal studies elucidating the mechanisms for initiation of pulmonary reactions to organic dusts will be presented. Risk assessment strategies for these mixed exposure environments will also be addressed. Supported by NIEHS P30 ES05605.

1104 EFFECT OF DIESEL EXHAUST PARTICLES (DEP) ON IMMUNE RESPONSES: CONTRIBUTION OF THE ORGANIC COMPONENT.

P. D. Siegel[1], R. K. Saxena[1,2], Q. B. Saxena[1,3], J. Ma[4], J. Ma[1], V. Castranova[1] and D. M. Lewis[1]. *[1]HELD, NIOSH, Morgantown, WV, [2]Jawaharlal Nehru University, New Delhi, India, [3]Indian Council of Medical Research, New Delhi, India and [4]West Virginia University, Morgantown, WV.*

The effect of DEP exposure on innate, cellular and humoral pulmonary immunity has been studied using rat, mouse and cell culture models. DEP consist of a complex mixture of petrochemical-derived organics on a carbon core and are regarded as major components of particulate urban air pollution. The alveolar macrophage is considered a key cellular component in pulmonary innate immunity. DEP and DEP organic extracts have been found to suppress alveolar macrophage cytokine (IL-1, TNF-α) and reactive oxygen species (ROS) responses to lipopolysaccharide. DEP depressed clearance of *Listeria monocytogenes* and INFγ-dependent clearance of BCG in a mouse model. INFγ-stimulated nitric oxide (NO) production was suppressed by DEP and DEP organic extract *in vitro*. Further fractionation of the DEP extract suggests that this activity was predominately in polyaromatic containing and more polar (resin) fractions. Organic-stripped DEP did not alter these innate pulmonary immune responses. The contribution of the organic component of DEP is less well defined with respect to acquired and humoral immunity. Indeed, both DEP and carbon black enhanced humoral immune responses (specific IgE and IgG) in an ovalbumin sensitized rat model. It is concluded from a review of the literature and the present work that both the particulate and adsorbed organics may contribute to DEP mediated immune alterations.

1105 EVALUATION OF MCASE-ES USING A TEST PANEL OF PHARMACEUTICAL STRUCTURES.

G. Mandakas, F. M. Goodsaid and I. Y. Rosenblum. *Molecular Toxicology, Schering-Plough Research Institute, Lafayette, NJ.*

Computational models such as the MultiCASE (MCASE) predictive toxicology system are gaining widespread use in academic, industrial and regulatory organizations to assess the potential mutagenicity of new chemical entities. Expanded databases that are the foundation of the expert system (MCASE-ES) have recently become available but the majority of the chemicals within the training set are largely from non-pharmaceutical sources. This system was evaluated using a test panel of 127 structures with known mutagenicity results against the 15 mutagenicity databases available. The evaluation is based on structures within the training set that are reduced to fragments of 2 to 10 atoms in length. MCASE activity values are assigned on the basis of this training set. Predictions based upon the activity value, or CASE unit, quantify the potential activity of the test molecule. We have found the MCASE-ES system to have a sensitivity and specificity of 70% and 60%, respectively, for our test panel. There are several ways in which these results may be improved. For example, we have found that the CASE unit values from true positive predictions exhibited a normal distribution while the CASE unit values from false positive predictions had a multi-modal distribution. This suggests that changes to the logic which link mutagenic activity to the CASE unit may reduce the number of false positive predictions, therefore improving specificity. It was observed that by increasing the CASE unit value associated with mutagenic activity we were able to improve specificity to 88% but resulted in a decrease in sensitivity to 44%. Increasing the number of pharmaceutical compounds present in the training sets, both positive and negative for mutagenicity, and/or appropriately weighing their relevance may improve the sensitivity of this program. This could provide better coverage of pharmaceutical compounds and decrease the number of false predictions.

1106 A YEAST RAD54-GFP GENOTOXICITY ASSAY, IS EFFECTIVE IN IDENTIFYING DIRECT ACTING MUTAGENS IN ADDITION TO CLASTOGENS NOT DETECTED BY BACTERIAL TESTS.

R. M. Walmsley[1,3], N. Billinton[1], L. Walsh[1], M. G. Barker[1], A. W. Knight[1] and P. A. Cahill[1]. *[1]Biomolecular Sciences, UMIST, Manchester, England, United Kingdom, [2]UVL, UMIST, Manchester, England, United Kingdom and [3]Gentronix Ltd, Manchester, England, United Kingdom.* Sponsor: B. Burlinson.

A eukaroyotic (yeast) genotoxicity assay has been developed which detects increases in the activity of the DNA repair system. It uses a reporter system consisting of the DNA damage inducible promoter of the RAD54 gene fused to a GFP gene. A large study has been carried out to validate the utility of the assay in routine genotoxicity assessment. A single 96 well microplate is used to assess 4 compounds at 9 dilutions, and can be set up by a simple manual protocol for low throughput (<60 compounds/day) or with commercial robotic systems for higher throughput. There are three steps: yeast cells are added to compound dilutions, microplates are incubated overnight, spectrometric data is collected. Optical denisity is used to estimate reduced cell proliferation (toxicity). Fluorescence, normalised for cell density, is used to estimate activity of the repair system (genotoxicity). Data handling protocols are simple and transparent, leading to clear conclusions. Inspection of the data in graphical form allows direct assessment. Less than 0.5ml of compound (1mM) is required and over 250 toxic and non-toxic compounds have been tested, without S9 addition. The results to be presented include the following. Many of 'the usual suspects' are genotox positive in the test: these include EMS, MMS, NQO, MNNG, Cisplatin. Many clastogens are positive in the assay: these include phleomycin, daunorubicin, bleomycin. Expected oxidising agents (methyl viologen, hydrogen peroxide, bleomycin) and aldehydes (crotonaldehyde, benzaldehyde,

acetaldehyde) are positives. Several compounds that would require S9 in bacterial tests (benzo[a]pyrene, N-nitroso-N-ethyl urea, safrole) are also positive. There are some photomutagens (psoralen, 8-MOP) detected, though no attempt was made to exclude exposure to normal laboratory lighting. It was also interesting to detect colchicine as positive, suggesting a clastogenic as well as aneugenic mechanism for this compound.

1107 POSSIBLE ROLE FOR CHEMOTHERAPEUTIC AGENTS IN THE INDUCTION OF MITOCHONDRIAL DNA MUTATIONS AND INCREASED FREE RADICAL GENERATION.

J. Carew, Y. Zhou, M. J. Keating and P. Huang. *MD Anderson Cancer Center, Houston, TX.* Sponsor: D. McConkey.

Mitochondrial DNA (mtDNA) mutations/deletions and altered expression levels of mtDNA-encoded respiratory chain subunits have been reported in various types of solid tumors by a number of laboratories. However, the cause of mtDNA mutations and their roles in drug resistance and disease progression remain to be elucidated. We hypothesized that certain chemotherapeutic agents may cause mtDNA mutations, which contribute to drug resistance and disease progression by altering respiratory function, reactive oxygen species generation, and sensitivity to therapeutic agents. We evaluated mtDNA mutation frequency, free radical generation and clinical outcomes using chronic lymphocytic leukemia (CLL) as a model system. Primary leukemia cells were isolated from 10 untreated and 10 previously treated CLL patients. We found that CLL cells from previously treated patients had significantly higher levels of cellular superoxide than their untreated counterparts ($p = 0.0085$). Six regions of the mitochondrial genome were sequenced using DNA isolated from primary CLL cells in order to determine the mtDNA mutation frequency. We found that untreated patients had similarly low rates of heteroplasmic and homoplasmic mutations. In contrast, previously treated patients had a significantly higher heteroplasmic mutation frequency ($p = 0.0140$), but a comparable frequency of homoplasmic mutations ($p = 0.7128$). The higher mutation frequency in patients receiving prior treatment correlated with an increased number of amino acid changes in the regions we sequenced ($p = 0.0468$). Our results demonstrate that CLL patients who have been previously treated produce higher levels of cellular superoxide have a significantly higher heteroplasmic mtDNA mutation frequency, and possess more functional mtDNA sequence variations than untreated patients. Thus, we have shown for the first time a relationship between chemotherapeutic treatment and mtDNA alterations.

1108 MUTAGENICITY AT THE *HPRT* LOCUS OF T-CELLS FOLLOWING EXPOSURE OF WILD-TYPE AND CYTOCHROME P4502E1-NULL MICE TO ACRYLONITRILE.

V. Walker[1] and B. Ghanayem[2]. *[1]Lovelace Respiratory Research Institute, Albuquerque, NM and [2]NIEHS, Research Triangle Park, NC.*

Acrylonitrile (AN), an important industrial chemical, is carcinogenic in rats and mice, and CYP2E1 is the only enzyme responsible for oxidative metabolism of AN in the mouse. To investigate the potential role of CYP2E1 in AN-induced mutagenesis and carcinogenesis, we compared the relative mutagenic responses at the *Hprt* locus of T-cells isolated from spleens of female wild-type (WT) versus CYP2E1-null mice exposed (beginning at 6 wk of age) to AN at 0, 2.5 (WT mice only), 10, 20 or 60 (null mice only) mg/kg by gavage daily for 6 wk (5 days/wk) (note that 60 mg AN/kg is lethal to WT mice). The dose-response for *Hprt* MFs were determined *via* the T-cell cloning assay for cells from mice necropsied 24 h after the last day of dosing (n = 11-13/group for each genotype). In WT mice, MFs increased with increasing dose of AN [i.e., MFs were 2.3 ± 1.9 (SD) $\times 10^{-6}$, $3.1 \pm 1.2 \times 10^{-6}$, and $5.4 \pm 2.4 \times 10^{-6}$ for 2.5, 10, and 20 mg AN/kg, with respective P-values of 0.6, 0.063, and 0.016 when compared with a mean control MF value of $1.7 \pm 0.9 \times 10^{-6}$]; however, only exposures to 20 mg AN/kg led to a significant increase over the control mouse MF values. In CYP2E1-null mice, *Hprt* MFs were significantly increased over background ($1.7 \pm 0.9 \times 10^{-6}$) in the 60 mg AN/kg ($5.3 \pm 2.3 \times 10^{-6}$; $P = 0.002$) but not the 20 mg AN/kg treatment group ($1.6 \pm 0.7 \times 10^{-6}$). The occurrence of a significant mutagenic response in WT mice but not in CYP2E1-null mice exposed to 20 mg AN/kg (a carcinogenic dose-level in the cancer bioassay in WT B6C3F1 mice), suggests that the process(es) leading to mutation at the high dose level of 60 mg AN/kg in CYP2E1-null mice contribute little to the mutagenic effect measured in AN-treated WT mice. On the other hand, the significant mutagenic response in WT mice given 20 mg AN/kg, but not in CYP2E1-null mice given the same dose, indicates that oxidative metabolism, presumably to the DNA-reactive metabolite cyanoethylene oxide, is essential to AN-induced mutagenicity at dose levels leading to cancer in conventional mice.

1109 EFFECTS OF BENZENE ON HEMATOPOIETIC STEM CELLS.

B. Faiola, E. S. Fuller, V. A. Wong, D. Abernethy, L. Pluta, K. Roberts, L. Recio and J. I. Everitt. *CIIT Centers for Health Research, Research Triangle Park, NC.*

Benzene, a carcinogen that induces chromosomal breaks as a primary mode of genotoxicity in the bone marrow (BM), is associated with leukemia in humans. Genetic consequences and misrepair of DNA lesions resulting from benzene metabolites interacting with molecular targets may lead to changes in hematopoietic stem cells (HSC) that give rise to the leukemic clones. To investigate benzene-induced DNA damage responses in HSC, we studied the effects of 1, 4-benzoquinone (BQ) treatment on murine HSC *in vitro*. We also compared effects of benzene inhalation on male and female 129/Sv and 129/SvJ mice that differ at the *Prkdc* locus encoding the catalytic subunit of DNA-PK, which has a primary role in nonhomologous end joining. HSC were enriched from BM by negative selection then purified HSC were obtained by fluorescence activated cell sorting. HSC cultured in the presence of BQ for 24 h showed a dose-dependent cytotoxic response. For the inhalation study, mice were exposed to 0 or 100 ppm benzene for 6 h/day, 5 days/week for 2 weeks. Liver microsomal CYP2E1 activity was measured. Male mice of both strains had decreased white blood cell counts following exposure to benzene while female mice showed no change. Genotoxicity *in vivo* was assessed using flow cytometry to enumerate micronucleated mature normochromatic erythrocytes (MN-NCE) and micronucleated reticulocytes (MN-PCE) in blood. Comparable increases in MN-NCE and MN-PCE populations in both strains of mice following benzene exposure were seen, indicating that the difference in *Prkdc* alleles does not affect benzene-induced genotoxicity. However, male mice were significantly more susceptible to benzene-induced genotoxicity than female mice. There was no significant change in the fraction of apoptotic cells in BM or in the percentage of BM HSC from exposed mice compared to unexposed mice. RNA was isolated from BQ-treated HSC and HSC of exposed and unexposed mice for quantitative RT-PCR analysis of DNA repair genes. DNA repair pathway(s) that act on benzene-induced DNA lesions may partially explain the observed gender bias.

1110 MECHANISTIC DIFFERENCES OF BENZENE-INDUCED LEUKEMOGENESIS: GENOTOXIC IN P53-DEFICIENCY *VS.* EPIGENETIC IN THE WILD TYPE.

Y. Hirabayashi[1], B. Yoon[1], G. Li[1], Y. Kawasaki[1], Y. Kodama[1], T. Kaneko[1], J. Kanno[1], S. Aizawa[2] and T. Inoue[3]. *[1]Division of Cellular & Molecular Toxicology, NatÖl. Inst. of Health Sciences, Tokyo, Japan, [2]Lab. for Vertebrate Body Plan, Riken Center for Developmental Biology, Kobe, Japan and [3]Center for Biological Safety and Research, National Inst. of Health Sciences, Tokyo, Japan.* Sponsor: H. Ono.

The mechanistic background of benzene-induced leukemia had long been an enigma until recently, when the discovery of the peculiar cell kinetics of the stem/progenitor cells during benzene exposure was elucidated. Leukemia induction by benzene inhalation was first reported in 1887, when Le Noire described multiple cases of leukemia among Parisian cobblers. In the present study, a newly developed measure for cell-cycle of CFUs, the BUUV method, disclosed not only the underlining reason of the inconsistency but also defined the separate mechanism of leukemogenicity in wild type mice and p53 deficiency. In p53+/+ mice, p53 dependent- oscillational changes in marrow cellularity were seen during/after benzene exposure, with concurrent suppression/expression of p21. This oscillation was not observed in p53 deficient mice. cDNA micro-array examined along with the benzene exposure showed a compatible gene expressions pertinent to the cell cycle, including cyclin-dependent kinases. Taken together, our present data suggest that the leukemogenicity between mice carrying wild-type p53 and mice lacking p53 seem to differ from one another. In the case of p53 knockout mouse, DNA damage such as weak mutagenicity and or chromosomal damages are retained, and those damages participated in the induction of a consequent activation of proto-oncogenes and the like, which led cells to further neoplastic changes. In contrast, in the case of p53 knockout mice, a dramatic oscillational change in the cell cycle of the stem cell compartment seems to be an important factor for mice carrying the p53 gene.

1111 *IN VIVO* ANALYSIS OF ALACHLOR MUTAGENESIS.

D. M. Burman, K. Dixon, M. Medvedovic and M. Genter. *Environmental Health/Center for Environmental Gentetics, University of Cincinnati, Cincinnati, OH.*

Several lines of evidence suggest that the olfactory mucosal carcinogenicity of the herbicide alachlor (2-chloro-2', 6'-diethyl-N-(methoxymethyl)acetanilide [15972-60-8]) is dependent upon target tissue bioactivation to a mutagenic metabolite. To substantiate this hypothesis *in vivo*, male Big Blue rats (F344 background, Taconic) were administered alachlor at the dietary equivalent of 126 mg/kg/d for 30, 60, or 90 days, with concurrent controls receiving powdered diet only (n=7 treated and 7

control rats per time point). Following three months of alachlor exposure, the mutant frequency (ratio of confirmed mutant plaques to total plaques screened) in the olfactory mucosa of treated rats was approximately 4 times higher than that of the concurrent control (1.3E-4 vs. 3.1E-5, p=0.002; [913, 000 plaques screened]). There was similarly a trend toward an elevated olfactory mucosal mutant fraction following two months of exposure, although statistical significance was not achieved. In contrast, nasal respiratory mucosa, which is not a target tissue for alachlor carcinogenesis and is located adjacent to the olfactory mucosa in the nasal cavity, did not display an elevated mutant frequency in alachlor-treated rats compared to concurrent (3 mo) controls. DNA sequence analysis will be performed to determine the nature of alachlor-induced olfactory mucosal mutations. These observations lend further support to the hypothesis that olfactory mucosal bioactivation to a mutagenic metabolite is pivotal to the carcinogenic mechanism in this tissue.

1112 IDENTIFICATION OF CARCINOGENS USING TRP53 HETEROZYGOUS NULL MICE AND LOSS OF HETEROZYGOSITY AT THE TRP53 LOCUS.

J. E. French. *NIEHS, NIH, Research Triangle Park, NC.*

Mice heterozygous for a Trp53 null and wild type allele are p53 haploinsufficient and dysfunctional for cell cycle checkpoint control and induction of apoptosis under genotoxic stress. Exposure of p53 deficient mice to mutagenic carcinogens induced neoplasia during the period in which unexposed co-isogenic haploinsufficient and homozygous wild type mice were free from neoplasia. Maximum tolerated doses (MTD) have been, in general, effective in inducing neoplasia with reduced latency after 26-week exposure to p53 haploinsufficient mice. Latency was shortened by requiring only an additional genetic alteration(s) at the functional Trp53 locus (mutation or loss of heterozygosity) and/or inactivation of another tumor suppressor gene. Based on a chemical database of published studies, an analysis was carried out to determine the predictability of this model to identify known or suspected human carcinogens (IARC Group 1 or 2) versus those least likely to be carcinogens (IARC Group 3). Under the conditions of the short-term cancer bioassays in this model in p53 deficient mice, the model showed an accuracy of 80% (47/59 Group 1/2 vs. 3 correctly predicted). Accuracy improved to 88% (23/26) if comparison was restricted to genotoxic Group 1 and 2 carcinogens. Coupling genotoxicity and induction of loss of heterozygosity (LOH) at the Trp53 locus improved accuracy to 100% (17/17). Overall, the conventional 2-year cancer bioassay in rats and mice showed an overall accuracy of 72% (26/36) and 100% (16/16) for genotoxic carcinogens (Group 1/2 vs. 3). Interspecies extrapolation between rodents and humans is difficult due to the possibility of species differences, but demonstration of an operational mechanism similar between rodents and humans, e.g. mutation or loss of p53 function through LOH may reduce uncertainity.

1113 A PROSPECTIVE CLINICAL EVALUATION OF TYPE I SENSITIZATION AND DERMAL COMPATIBILITY OF A BACILLUS SERINE PROTEASE IN A BODY LOTION.

G. M. Adamson, L. Babcock, V. Hollis, D. B. Kirchner, J. D. Innis and K. Sarlo. *Procter & Gamble Company, Cincinnati, OH.*

A protease enzyme in a prototype beauty bar has been shown to induce allergic antibody (sensitization) in clinic subjects1. Skin compatibility and potential for protease-induced sensitization from use of enzyme in leave-on body moisturizers is not understood. This study tested potential for a body lotion containing Bacillus spp. subtilisin protease, used intermittently over 18 months to induce allergic antibody, as measured by skin prick test (SPT) and serum measurement of enzyme-specific IgE. 864 healthy atopic women, 18-60 years of age from the US, Canada, Germany and France used product that contained 100ppm of protease 5 consecutive days per month, for 18 months. Regular lotion was used the remaining days of each month. Aerosol exposures during showering averaged 0.24ng/m3 of enzyme protein, measured 12 hrs after lotion application. Previous work showed that enzyme remained on the skin for 8 to 12 hours2. Skin evaluation and SPTs were conducted every 3 months. Capacitance and TEWL measures were made in a subset of subjects at 3 month intervals: skin biopsies occurred at baseline and at the first 3-month time point. The data showed increased hydration of the skin over time. Clinical evaluation and histopathology showed no skin irritation. One subject became sensitized after 6 months product use, but exposure to a cross-reacting protease in a carpet cleaner may have contributed to this response. This subject also became sensitized to a non-cross reacting protease from exposure to another carpet cleaning product. At 15 months two subjects became sensitized. These subjects did not experience any other known exposures that may have contributed to the reactions. None of the subjects had allergic symptoms. While this study showed favorable skin compatibility of the protease containing lotion, the occurrence of allergic antibody to the enzyme was unacceptable for product commercialization. 1J. All Clin. Immun. 1998 101:179-87 2 Human Exper Toxicology 1999. 18(8): 527.

1114 EVIDENCE OF ALLERGIC ANTIBODY TO A BACILLUS SERINE PROTEASE IN ATOPIC WOMEN: A RETROSPECTIVE EVALUATION.

K. Sarlo, G. M. Adamson, R. Stachlewitz, D. B. Kirchner and J. D. Innis. *Procter & Gamble Company, Cincinnati, OH.*

There has been increasing use of enzymes in consumer products. Effective safety evaluation and exposure control has minimized the risk of enzyme-induced Type I allergy in consumers. Prevalence of allergic antibody to Bacillus spp. enzymes in a clinic population of 2500 was assessed in the early 1970's after introduction of enzyme detergents1. No subject had allergic antibody to the enzymes. In the present study, subjects were tested as part of screening for clinical studies testing skin compatibility of consumer products. From 1999 to 2002, atopic women within the ages of 18 to 60 years were tested for the presence of allergic antibody to a Bacillus spp. subtilisin protease. Subsets were tested for allergic antibody to 2 other proteases and 2 Bacillus spp. amylases. Allergic antibody was detected by skin prick test (SPT) and serology for specific IgE or IgG antibody. A total of 2549 subjects were tested: 535 in France, 1009 in Germany, 279 in Canada, and 726 in the USA. Of the 2549 subjects tested, 4 subjects were confirmed SPT (+) (wheal at least 3mm greater than the negative control + flare). Two of the 4 had IgE and/or IgG antibody to the enzyme. A fifth subject was SPT (+) on initial testing but refused follow-up tests. There was no evidence of allergic symptoms from use of cleaning products. Four of the 5 did not use laundry products that contained this enzyme and there was no clear explanation as to why any of them developed antibody that recognized the protease. Earlier studies have demonstrated that use of laundry products containing similar enzymes is unlikely to cause sensitization in consumers. Two subjects were in Canada, 1 in the USA and 2 in Germany. These data indicate that there is a prevalence of sensitization to this Bacillus protease, in comparison to the previous study1. These data indicate a need for industry to continue to monitor the population to ensure expanded uses of enzymes in consumer products do not increase the risk of Type I sensitization. 1 Clin Allergy, 1973 3:143-160

1115 EVALUATION OF THE SENSITIZATION POTENTIAL OF TWO LUBRICANT ADDITIVES, PHENYL-ALPHA-NAPHTHYLAMINE AND ALKYLATED PHENYL-ALPHA-NAPHTHYLAMINE: A COMPARISON OF DATA FROM THE LOCAL LYMPH NODE ASSAY, THE BUEHLER GUINEA PIG ASSAY, AND HUMAN REPEAT INSULT PATCH TEST.

S. Azadi[2], J. Meade[2], M. L. Kashon[2], P. T. Bailey[1] and C. L. Mann[1]. *[1]ExxonMobil Biomedical Sciences, Inc., Annandale, NJ and [2]NIOSH, Morgantown, WV.*

Phenyl-alpha-naphthylamine (PAN) and alkylated phenyl-alpha-naphthylamine (APAN), two high temperature anti-oxidants commonly used in aviation turbine lubricants have been widely used for many years with relatively few associated cases of contact allergy reported. In these studies PAN and APAN were evaluated for sensitization potential and potency using the local lymph node assay (LLNA), and these results were compared with data previously generated using a modified Buehler guinea pig test and the human repeated insult patch test (HRIPT). Chemicals were tested using female CBA mice at concentrations raging from 1-100%. Both chemicals tested positive in the LLNA inducing dose responsive and statistically significant increases in lymph node cell proliferation reaching a stimulation index (SI) of ∝3. A series of non-linear regression models were applied to the data and the model which fit the data best based on likelihood ratio tests was subsequently utilized in a bootstrap analysis to obtain an uncertainty distribution around the calculated EC3 (the chemical concentration required to induce a SI of 3). Based on this analysis, the mean EC3 values and 90 % confidence bounds were 2.29% (0.01%, 6.4%) and 11.76% (4.4%, 24.6%) respectively for PAN and APAN. This data correlated positively with the guinea pig data where induction and challenge with equal concentrations of chemicals resulted in a greater percentage of animals responding and higher severity indices for PAN versus APAN. The LLNA data also correlated positively with the human data where HRIPT showed that use levels of both PAN and APAN failed to induce sensitization when applied in lubricants at concentrations of 1.5% and 2.5%, respectively, levels lower than their calculated EC3 values.

1116 FACTORS AFFECTING BINDING OF NATURAL RUBBER LATEX (NRL) PROTEINS TO GLOVE DUSTING POWDER.

V. J. Tomazic-Jezic, A. D. Lucas and B. A. Sanchez. *Center for Devices and Radiological Heath, Food & Drug Administration, Rockville, MD.* Sponsor: T. Umbreit.

Adverse reactions to NRL proteins are caused by either topical, parenteral or respiratory exposures. NRL proteins bound to glove powder are the major source of the respiratory exposure and can cause serious reactions in frequent users of NRL

gloves. Binding of protein to glove powder has been documented in the laboratory and clinical studies. The specific factors that lead to allergen attachment and may affect the binding intensity have not been determined. We evaluated protein extracts from medical gloves with and without accompanying powder. The ratios of the amount of soluble protein in extracts and the protein remaining on powder differed among gloves tested. The ratios did not correlate with either the total protein on the glove, glove weight or total amount of powder, indicating that other factors may enhance or reduce the intensity of protein binding. To investigate the conditions that may affect the binding, we exposed several types of clean powder to NRL antigens under various conditions and evaluated protein levels on starches and respective protein solutions. Our data showed that protein binding was dose-dependent, with the saturation point at the concentrations above 0.2 mg/ml. The temperature and pH of media made no or only minor difference in the binding intensity, but marked differences were observed among the individual starch preparations. Two cross-linked corn starch powders showed a strong affinity to attach proteins, while the protein binding to cooking corn starch and oat starch was much lower. Those differences appeared more obvious if starches were exposed to NRL proteins in water than in pH-7.4 PBS. Our findings indicate that physico-chemical properties of glove dusting powder and some procedural factors may play a significant role in the protein binding affinity. With an appropriate selection of conditions and type of powder, it may be possible to reduce attachment of NRL proteins to glove powder, and consequently reduce the aeroallergen levels in hospital environments.

1117 EFFECT OF SULFUR DIOXIDE INHALATION ON THE POPULATION AND FUNCTION OF PERIPHERAL BLOOD LEUKOCYTES AND PULMONARY CELLS IN CATTLE.

L. A. Komarnisky[1], R. W. Coppock[2], A. A. Khan[3] and R. J. Christopherson[1]. *[1]Agricultural, Food and Nutritional Science, University of Alberta, Edmonton, AB, Canada, [2]Consultant, Vegreville, AB, Canada and [3]Toxicology Business Unit, Alberta Research Council, Vegreville, AB, Canada.*

Cattle production sometimes occurs in areas adjacent to oil and gas developments with potential exposure to sulfur dioxide (SO_2) as one of the components of sour gas emissions. However, effects of known concentrations of SO_2 on cattle have not been described. In a series of experiments, 24 growing calves (steers) were sequentially exposed (head-only) to air amended to contain SO_2 concentrations from 0 to 20 ppm. Steers intermittently inhaled gases for 6 hours/day over periods of 23, 9, and 8 days (experiment one) and 10, 7, and 7 days (experiment two) at the concentrations of 1, 5 and 20 ppm of SO_2 respectively. Parallel to the experimental animals a group of 22 control calves was exposed to clean filtered air designated as 0 ppm. The data obtained from experimental and control groups of steers were compared by analysis of variance to determine the effect of SO_2 on the immune function of cattle. Several immunological parameters were altered by exposure steers to various concentrations of SO_2. The CD4/CD8 ratio of T lymphocytes ($P < 0.05$) was reduced suggesting potential impairment of cell-mediated immunity. The ratio of degenerative to healthy pulmonary cells increased ($P<0.05$) in steers exposed to SO_2 gas. The number of CD14 cells (marker for monocytes) in blood increased perhaps in response to cytokine signals arising from the damaged pulmonary cells. Changes in nitric oxide (NO) production by alveolar macrophages suggesting that SO_2 gas affected their phagocytic activity. Our findings suggest that SO_2, at a concentration as low as 1 ppm, had deleterious effects on cellular functions. The altered immune responses may have implications for production efficiency and health of cattle exposed to air polluted with SO_2. In conclusion, cattle are sensitive to sulfur dioxide as previously shown for humans and other animal species.

1118 ENDOTOXIN AND ALLERGY: LPS IS A STRONG ADJUVANT FOR CAT ALLERGEN Fel d 1-SPECIFIC IgE RESPONSE IN A MOUSE SUBCUTANEOUS IMMUNIZATION MODEL.

H. Ormstad[1], E. Groeng[1], O. Duffort[2] and M. Lovik[1]. *[1]Division Environmental Medicine, Norwegian Institute of Public Health, Oslo, Norway and [2]ALK-Abello S.A., Madrid, Spain.* Sponsor: E. Dybing.

The question whether LPS is beneficial or disease-promoting in relation to asthma and allergy has been raised in several recent epidemiological studies. We asked whether LPS would increase the antibody response and give an allergic (IgE), or non-allergic (IgG2a) antibody profile after immunization with the cat allergen Fel d 1 in a mouse model. Also, when LPS and Fel d 1 are introduced to the immune system, we asked whether the timing of the two agents relative to each other is crucial. Mice were injected subcutaneously with LPS and/or Fel d 1 four times in various temporal combinations. IgE, IgG1 and IgG2a antibodies specific to Fel d 1 were measured in serum using ELISA. A greatly increased specific antibody response was observed, both for IgE, IgG1 and IgG2a, when LPS was introduced to the immune system together with the cat allergen Fel d 1, and in particular after repeated injections. No such adjuvant effect was observed when LPS was introduced alone prior to or subsequent to the allergen in the present subcutaneous immunization model. The resulting antibody response was not polarized in terms of Th1- or Th2-dependence. The adjuvant effect from endotoxin for the supposedly Th2-dependent Fel d 1-specific IgE response was strong. The so-called 'hygiene hypothesis' postulates that microbial agents protect against the development of allergy, and that the increase in allergy observed in many countries is caused by reduced exposure to microbes or microbe-derived substances such as endotoxin in the home environment. The present results do not support the 'hygiene hypothesis'.

1119 RESPIRATORY ALLERGY ASSAY IN BROWN-NORWAY RATS EXPOSED TO DIPHENYLMETHANE-4, 4'-DIISOCYANATE (MDI).

J. Pauluhn. *Toxicology, Bayer AG, Wuppertal, Germany.*

A rat bioassay has been developed for the identification and classification of respiratory allergy using trimellitic anhydride (TMA) and MDI. Emphasis was placed to study route-of-induction dependent effects and their progression upon inhalation challenge with the chemical, that included the analysis of specific and non-specific airway hyper-reactivity and pulmonary inflam-mation. Refinement of the bioassay focused on procedures to probe for changes occurring upon challenge with TMA or MDI and one day later with methacholine aerosols using physiological (Penh) and bronchoalveolar lavage endpoints, and the weights of bronchial (BLN) and auricular lymph nodes (ALN). Rats were either sensitized epicutaneously (area treated/rat: 10 cm2; TMA: day 0: 150 ul vehicle/50% TMA on each flank, day 7: booster administration to the skin of the dorsum of both ears using half the concen-tration and volume used on day 0; MDI: days 0/7: 100 ul/50 ul neat MDI as described for TMA) or by 5 x 3 hrs/day inhalation exposures (TMA: 25 and 120 mg/m3; MDI: 2 and 30 mg/m3). Following challenge with TMA, the rats sensitized to TMA elaborated marked changes in physiological endpoints and sustained pulmonary inflammation. Lung weights were significantly increased as were the weights of BLN following inhalation induction and ALN following topical induction. MDI challenged rats displayed changes in Penh when sensitized at 30 mg/m3 by inhalation. The weights of lungs and BLNs were sligthly increased in rats sensitized epicutaneously or at 30 mg/m3 whilst the ALNs were increased only following dermal induction. In summary, the findings support the conclusion that the BN rat model is suitable to identify TMA as agent causing both an immediate-type change of breathing patterns and a delayed-type, sustained pulmonary inflammatory response. The marked effects observed in rats topically sensitized to TMA could not be duplicated with MDI. It appears that endpoints originating from extrapulmonary tissues are poor substitutes for changes occurring at the pulmonary level.

1120 EXPOSURE TO 2, 3, 7, 8-TETRACHLORODIBENZO-P-DIOXIN (TCDD) IMPAIRS MAMMARY GLAND DIFFERENTIATION IN PREGNANT C57BL/6 MICE AND PREVENTS PUP SURVIVAL.

B. Lawrence[1,3,4], B. A. Vorderstrasse[1], S. E. Fenton[2] and A. A. Bohn[4]. *[1]Phar Sciences, Pharmacology/Tox Prog., Washington State University, Pullman, WA, [2]RTD, NHEERL USEPA, Research Triangle Park, NC, [3]Pharmacology/Toxicology Program, Washington State University, Pullman, WA and [4]Veterinary Clinical Sciences, Washington State University, Pullman, WA.*

While conducting experiments designed to test the immune response of mice exposed to TCDD *in utero*, we observed that pups born to dams exposed to TCDD during pregnancy all died within 24 hours of birth. This was despite the fact that the amount of TCDD given (5 ug/kg/day on gestational day 0, 7, and 14) was below that reported to cause fetal mortality. There was no gross cleft palate or severe hydronephrosis in the exposed pups. Furthermore, in a preliminary experiment, pups from a TCDD-treated dam survived when moved to a vehicle-treated dam, while pups in the converse foster did not survive. This suggested that lactation in the TCDD treated dams may be impaired. The present study was therefore conducted to test the hypothesis that mammary gland differentiation in pregnant mice is impaired by TCDD exposure. Impregnated C57Bl/6 mice were treated with vehicle or TCDD as described above. Dams (n=7/group) were sacrificed on the day of parturition, and mammary glands and plasma were collected. Glands were weighed and whole mounts of the tissue were scored, in blind, based on gland development. Glands from TCDD-treated mice were substantially less differentiated than controls, with only 10 - 70% of the branched ductal structures exhibiting lobulo-alveoli. Lobulo alveoli which did develop in the TCDD-treated mice were small and poorly formed relative to controls. Gland weights were reduced by 25% in TCDD-treated mice. Serum prolactin levels were determined to address a potential mechanism for the suppressed gland development. Prolactin levels in the TCDD-treated mice were 50% lower than in vehicle treated mice. These results demonstrate that

mammary gland differentiation is impaired in pregnant mice treated with TCDD. This novel finding suggests that exposure to TCDD may impair milk production, which could account for neonatal pup mortality.

1121 2, 3, 7, 8-TETRACHLORODIBENZO-*p*-DIOXIN (TCDD) INHIBITS PROSTATIC EPITHELIAL BUD FORMATION IN THE UROGENITAL SINUS (UGS) OF C57BL/6J MICE WITHOUT INHIBITING ANDROGEN SIGNALING.

K. Ko and R. E. Peterson. *School of Pharmacy, University of Wisconsin at Madison, Madison, WI.*

In utero and lactational TCDD exposure reduces ventral, dorsolateral, and anterior prostate weights. To elucidate the underlying mechanisms we examined the initial step in prostate development, epithelial budding from the UGS. Budding is an androgen-dependent process that TCDD inhibits both *in vivo* and *in vitro*. We tested the hypothesis that TCDD inhibits prostatic epithelial bud formation by inhibiting androgen signaling. Prostatic epithelial buds developed *in vitro* when gestation day (GD) 14 UGS was cultured for 5 days with 10^{-8} M 5α-dihydrotestosterone (DHT). DHT-dependent budding was inhibited by 10^{-5} M OH-flutamide, an androgen receptor (AR) antagonist, and by 10^{-9} M TCDD. Androgens are known to stimulate epithelial budding by binding to AR in mesenchymal cells. To determine whether TCDD inhibits the androgen signaling pathway, primary mesenchymal cells were prepared from GD 14 UGSs cultured for 3 days with 10^{-8} M DHT and either 0.1% DMSO or 10^{-9} M TCDD. Mesenchymal cells were transiently transfected with an androgen-responsive luciferase reporter, then treated with 0.1% EtOH (vehicle), 10^{-8} M DHT, 10^{-8} M DHT + 10^{-5} M OH-flutamide, or 10^{-8} M DHT + 10^{-9} M TCDD. In cells isolated from both DMSO- and TCDD-exposed UGS, 1) DHT increased luciferase activity about five-fold in comparison to vehicle-exposed cells, 2) OH-flutamide severely inhibited DHT-dependent luciferase activity, and 3) TCDD did not inhibit DHT-dependent luciferase activity. Androgen-dependent gene expression was also analyzed by real-time RT-PCR quantitation of mRNA for AR and 5α-reductase-type II. GD 14 UGSs were cultured for 3 days with 0.1% EtOH, 10^{-8} M DHT, 10^{-8} M DHT + 10^{-5} M OH-flutamide, or 10^{-8} M DHT + 10^{-9} M TCDD. OH-flutamide completely blocked the effect of DHT on both genes, whereas TCDD had no effect on mRNA expression for either. In conclusion, the inhibition of UGS prostatic epithelial bud formation by TCDD does not appear to result from an inhibition of androgen signaling. (Supported by NIH Grant ES 01332)

1122 EFFECT OF 2, 3, 7, 8-TETRACHLORODIBENZO-P-DIOXIN (TCDD) ON THE IMMUNOLOGICAL STATUS OF C57BL/6 PREGNANT MICE.

I. A. Camacho[1], M. Nagarkatti[1] and P. S. Nagarkatti[2]. *[1]Department of Microbiology and Immunology, Virginia Commonwealth University, Richmond, VA and [2]Department of Pharmacology and Toxicology, Virginia Commonwealth University, Richmond, VA.*

Whether transient immunosuppression seen during pregnancy when combined with exposure to environmental immunotoxicants could exacerbate immunosuppression leading to deleterious effects on maternal health has not been previously investigated. Therefore, the current study evaluated the immune status of C57BL/6 pregnant mice following exposure to 2, 3, 7, 8-tetrachlorodibenzo-p-dioxin (TCDD). To this end, C57BL/6 pregnant (gestational day=14) and virgin female mice were injected with a single dose of 10 μg/kg of TCDD by the intraperitoneal route. TCDD treatment caused an early immunotoxic effect in the thymus of pregnant mice with the cellularity decreasing at 48 hr of exposure, but apparent in virgin mice only after 72hr. TCDD treatment also caused more marked alterations in the thymic T cell subpopulations of pregnant mice when compared to the virgin mice, with a decrease in double-positive T cells ($CD4^+CD8^+$) and an increase in single-positive ($CD4^+$, $CD8^+$) and double-negative ($CD4^-CD8^-$) T cells. Also, the thymic but not the splenic T cell proliferative responses to mitogens were more dramatically altered in TCDD-treated pregnant mice when compared to the virgin mice. Flow cytometric analysis demonstrated that no significant changes in apoptosis and the expression of CD4, CD8, B220, NK1.1 and Mac 3 markers were observed in splenocytes from dioxin-treated virgin and pregnant mice. Immunization of mice with Staphyloccocus enterotoxin A (SEA) caused a similar immunotoxic response in dioxin-treated pregnant and virgin mice with decreased draining LN cellularity, lower percentages of SEA-responsive Vβ3+ and Vβ11+ T cells and a reduced *in vitro* proliferative response to the recall antigen. Together, our findings indicate that pregnancy augments the sensitivity to dioxin-induced immunotoxicity in the thymus, but not in secondary lymphoid organs. (Supported by NIH grants R01ES09098, F31ES11562, R21DA014885 and R01HL058641)

1123 THE EFFECTS OF 2, 3, 7, 8-TETRACHLORODIBENZO-P-DIOXIN ON TRIGGERED- AFTERDEPOLARIZATIONS IN ISOLATED RAT VENTRICULAR MYOCYTES.

A. Xie[1], N. J. Walker[2] and D. Wang[1]. *[1]Basic Pharmaceutical Sciences, College of Pharmacy University of South Carolina, Columbia, SC and [2]Environmental Toxicology Program, NIEHS, Research Triangle Park, NC.*

Dioxin TCDD (2, 3, 7, 8-Tetrachlorodibenzo-p-dioxin) exposure can cause immune system dysfunction, carcinogenesis and cardiotoxicity. The effects of TCDD on action potentials and afterdepolarizations were studied in 132 rat ventricular myocytes using Nystatin-perforated patch-clamp techniques. The animal protocol was approved by Animal Care and Use Committee of the University of South Carolina (Protocol# 1091). The action potential duration measured at 90% of repolarization (APD90) was significantly prolonged by TCDD treatment. The effects of TCDD were concentration-dependent (1 to 100 nM) and time-independent (5 to 30 min). The transpiring frequency of triggered delayed-afterdepolarizations (DADs) was increased from 12.5% (1/8 cells) in control to 75% (6/8 cells, $P<0.01$) after TCDD exposure. In the presence of either isoproterenol (Iso, 10 nM) or Kay K 8644 (1 uM), TCDD (10 nM) markedly augmented the amplitude and frequency of the triggered-DADs and initiated sustained-spontaneous action potentials in majority of the experiments. Corresponding to the increase of DADs, TCDD (10 nM) significantly enhanced the transient inward current (Iti) recorded immediately after the end of a +40 mV depolarizing pulse. In the presence of Iso or Bay K 8644, triggered-early afterdepolarizations (EADs) were observed only in cells co-exposed to TCDD (10 nM). These results indicate that TCDD itself can prolong action potential duration and cause abnormal triggered-afterdepolarizations. These effects of TCDD may lead to clinical cardiac arrhythmia especially when the susceptible subjects are stressed by elevated sympathetic activity or suffering from other cardiomyopathies coincided with Ca2+ -overload.

1124 DIOXIN INDUCES GROWTH ARREST AND REDUCES CELL CYCLE GENE EXPRESSION IN THE FETAL MURINE HEART.

M. K. Walker[1], C. D. Johnson[2], M. Tadesse[3], K. S. Ramos[2], I. D. Steele[1] and E. A. Thackaberry[1]. *[1]College of Pharmacy Toxicology Program, University of New Mexico, Albuquerque, NM, [2]Center for Environmental and Rural Health, Texas A&M University, College Station, TX and [3]Department of Statistics, Texas A&M University, College Station, TX.*

Although one of the earliest and most sensitive effects of 2, 3, 7, 8-tetrachlorodibenzo-p-dioxin (TCDD) in the avian embryo is cardiomyocyte growth arrest (Teratology 64:201 2001), little is known about TCDDs effects on the fetal murine heart. Our objectives were to determine whether TCDD induces similar effects in the fetal murine heart and whether growth arrest is associated with changes in cell cycle gene expression. Pregnant C57Bl6N mice were dosed by oral gavage with 0 (corn oil), 1.5, 3, 6, 12, or 24 ug/kg TCDD on gestation day (GD) 14.5 (n=6-16 litters/Tx). On GD17.5 fetal hearts were fixed or frozen. From the 0-6 ug/kg groups, fixed hearts were sectioned and stained with anti-proliferating cell nuclear antigen (PCNA), while RNA was isolated from frozen hearts and analyzed using microarrays. Intensity values were scaled by Affymetrix Microarray Suite 5 and normalized by GeneSpring. Fold changes in gene expression were determined using GeneSpring and dose-related changes by ANOVA ($p<0.05$). Although no maternal toxicity or fetal mortality was observed in TCDD-treated animals, dioxin treatment decreased fetal heart-to-body weight ratio in a dose-dependent manner ($p<0.008$) with a maximal reduction of 14 ± 3%, relative to controls. Of the 1.5-6 ug/kg doses analyzed, only 6 ug/kg significantly reduced the percentage of proliferating cardiomyocytes as assessed by PCNA staining (control, 26 ± 4%, 6 ug/kg, 5 ± 1%; $p<0.001$). Growth arrest was associated with reduced expression of genes involved in cardiomyocyte proliferation. TCDD induced dose-related reductions in G1/S-related, CDK2, cyclin A1; and G2/M-related, Cdc2, Cdc25C, cyclin B1. Ongoing efforts have focused on cluster analysis to determine patterns of gene expression and identify genomic networks that mediate premature cardiomyocyte growth arrest induced by TCDD. (Supported by ES09804 and 10433 to MKW and ES09106 to KSR).

1125 TCDD-INDUCED CHANGES IN GENE EXPRESSION PROFILES IN DEVELOPING PAWS OF MICE.

N. F. Alejandro, A. I. Brooks and T. A. Gasiewicz. *Department of Environmental Medicine, University of Rochester, Rochester, NY.*

The aryl-hydrocarbon receptor (AhR) is a ligand-dependent transcription factor that mediates the toxicity of halogenated aromatic hydrocarbons including 2, 3, 7, 8-tetrachlorodibenzo-p-dioxin (TCDD). These compounds are potent reproductive and developmental toxicants due to their ability to modulate gene expression and cellular differentiation/proliferation. Previous studies have identified developing paws as a putative target in embryos exposed to TCDD. In characterizing this

response, gene expression profiles by microarray genechip technology was employed. Based on preliminary studies in the developing paws, we hypothesize that TCDD induces changes in genes involved in development, cell cycle regulation and mesenchymal epithelial interactions. Pregnant C57Bl/6 mice were injected with TCDD (30 μg/kg, i.p.) on gestational day 14, and fore and hind paws collected from embryos 24 hours later. Comparisons of relative gene expression profiles were conducted between vehicle control and TCDD exposed embryos, fore and hind paws, and embryo uterine position. Genes involved in development, cell cycle regulation (i.e. apoptosis, proliferation and differentiation), and mesenchymal epithelial interactions were closely monitored. AhR responsive genes were examined and used as internal experimental controls. Microarray analysis, using GeneSpring software, identified TCDD altered expression of genes involved with development, e.g. hox genes, apoptosis, e.g. caspase 14, and mesenchymal epithelial interactions, e.g. fibroblast growth factor binding protein. AhR responsive genes, Cyp1a1 and Cyp1b1, were induced in all TCDD exposed embryos. These results indicate that TCDD-induced changes in gene expression during development may cause alterations in paw development. These findings are consistent with those in an AhR responsive reporter gene transgenic model and provide further evidence of developing paws as a target of TCDD. (Funded by NIH grant ES09430, Training grant ES07026, and Center grant ES01247).

1126 EFFECT OF TCDD AND RETINOIC ACID ON MATRIX METALLOPROTEINASE EXPRESSION IN NORMAL HUMAN KERATINOCYTES.

K. Murphy, C. M. Villano, R. Dorn, E. A. Myers and L. A. White. *Biochemistry and Microbiology, Rutgers University, New Brunswick, NJ.*

Exposure to the environmental contaminant 2, 3, 7, 8-tetrachlordibenzo-p-dioxin (TCDD) results in a number of pathological lesions that require matrix metabolism and tissue remodeling, including prostate and mammary tubule morphogenesis, palatal development, and tumor promotion. We have found that TCDD exposure of normal human keratinocytes results in increased expression and activity of several matrix metalloproteinases (MMPs). MMPs degrade the protein components of the extracellular matrix and basement membrane, and their activity is necessary for physiological processes that require tissue remodeling and cell migration. Our hypothesis is that TCDD mediates some of its biological effects by directly altering the expression of genes involved in matrix metabolism and cellular migration as well as indirectly through interactions with the retinoic acid (RA) signaling pathway. Retinoids are powerful regulators of cell growth and differentiation and are widely used in the prevention and treatment of a variety of cancers in humans. RA binds to two types of nuclear receptors, the retinoic acid receptors (RARs) and retinoic x receptors (RXRs). Using quantitative real time RT-PCR, we found that TCDD exposure of normal human keratinocytes results in increased mRNA levels of RARγ and RXRα, the predominant retinoid receptors expressed in skin. Northern analysis of mRNA isolated from TCDD, all-trans RA (atRA) and TCDD + atRA show that TCDD-induced MMP mRNA expression is further increased upon co-treatment with all-trans retinoic acid. Transient transfections using constructs containing up to 4000 bp of the MMP-1 promoter linked to the luciferase reporter suggest that TCDD and atRA induction of MMP-1 is mediated, at least in part, through transcriptional activation. Further, we find that different regions of the 5′ flanking sequences are involved in mediating TCDD and atRA activation. These data suggest that interactions between these two pathways may result in aberrant matrix remodeling and contribute to TCDD-induced phenotypes.

1127 LACTATIONAL NOT *IN UTERO* EXPOSURE TO 2, 3, 7, 8-TETRACHLORODIBENZO-*p*-DIOXIN DISRUPTS THYROID HORMONE HOMEOSTASIS IN HOLTZMAN RATS.

N. Nishimura[1], J. Yonemoto[1,2], C. Yokoi[1,2], Y. Yakeuchi[1,2], S. Ikushiro[3] and C. Tohyama[1,2]. *[1]NIES, Tsukuba, Japan, [2]CREST, JST, Japan and [3]HIT, Himeji, Japan.*

We have previously reported that even a single oral administration of low dose of 2, 3, 7, 8-tetrachlorodibenzo-*p*-dioxin (TCDD) given on gestational day 15 (GD15) caused a reduction in the serum thyroxin (T4) level in pups on postnatal days (PND)21, followed by the occurrence of thyroid hyperplasia on PND49 in Holtzman rats. Using arylhydrocarbon receptor (AhR) null mice, we have also confirmed that the T4 suppressing effect of TCDD is mediated by AhR and is due to the enhanced biliary excretion of T4-glucuronide, which is conjugated by UDP-glucuronosyltransferase (UGT)-1, a TCDD inducible enzyme. The present study was conducted to clarify a relative impact of lactational exposure on the disruption of thyroid hormone homeostasis in pups compared to *in utero* exposure by using cross-fostering protocol. Pregnant Holtzman rats were given an oral dose of 1000 ng TCDD/kg bw on GD15 or an equivalent volume of corn oil as vehicle-control. Half of the TCDD-treated litters and half of the control litters were cross-fostered on PND1, which turned out to comprise the following groups: C/C (control), T/T (perinatal exposure), T/C (prenatal exposure only), and C/T (postnatal exposure only). Male and female pups were sacrificed on PND21 (at weaning) and sera and tissues were collected. We found that serum total T4 levels of male and female pups were significantly decreased in the C/T and T/T group but not in the T/C group compared to the C/C group on PND21 (n=4-6). In addition, mRNA levels of UGT1A6, UGT1A7 and cytochrome P450 (CYP) 1A1 in the liver were highly elevated in the C/T and T/T group, but not in the T/C group compared to the C/C group. An induction of UGT1A6 and CYP1A1 in the liver of the C/T and T/T groups but only a trace in the T/C group was visualized immunohistochemically, supporting the molecular biological data on PND21. The present results led us to conclude that TCDD-induced disruption of thyroid hormone homeostasis observed in pups were mainly due to lactational exposure.

1128 SPECIES-SPECIFIC TRANSCRIPTIONAL ACTIVITY OF SYNTHETIC FLAVONOIDS IN GUINEA PIG AND MOUSE CELLS AS A RESULT OF DIFFERENTIAL INTERACTION OF ARYL HYDROCARBON RECEPTORS WITH DIOXIN RESPONSIVE ELEMENTS.

J. Zhou[1], E. C. Henry[1], C. M. Palermo[1], S. D. Dertinger[2] and T. A. Gasiewicz[1]. *[1]University of Rochester, Rochester, NY and [2]Litron Laboratory Ltd.,, Rochester, NY.*

To investigate possible species-specificity of aryl hydrocarbon receptor (AhR)-mediated signal transduction pathways, activities of TCDD and six synthetic flavonoids were evaluated in mouse hepatoma and guinea pig adenocarcinoma cells transfected with an AhR-responsive luciferase reporter. These investigations demonstrated similar rank order potency for the ability of these flavonoids to antagonize the TCDD-induced reporter gene expression in both cell lines. However, in the presence of the flavone alone, a species-specific difference in agonist activity was observed. In guinea pig cells, several flavonoids demonstrated agonist activity up to 50% of the maximum TCDD response. In mouse cells, however, no significant agonist activity was observed at the same concentrations based on luciferase enzyme activity, protein expression, and mRNA analysis. Moreover, the competitive ligand-binding assay, using [^{3}H]-TCDD in cytosolic fractions, demonstrated that 3'-methoxy-4'-nitroflavone had a similar IC_{50} in both recombinant cell lines, suggesting that the flavone has similar binding affinity to receptors from both species. However, electrophoretic mobility shift assay using the cytosolic fractions demonstrated that this flavone elicited binding to the DRE by guinea pig but not mouse AhR complex. The AhR's dependency in this differential interaction was further demonstrated using *in vitro* synthesized receptor and Arnt. Together these data suggest that the species-specific agonist/antagonist activity of these flavone derivatives is due to the efficacy of these flavonoids to elicit, in a species-specific manner, an AhR conformation that recognizes regulatory response elements. (Supported by NIH grant ES09702 and Center grant ES01247)

1129 EFFECTS OF THE DOSE OF DIMETHYLARSINIC ACID (DMA) ON THE URINARY CONCENTRATION OF DIMETHYLARSINOUS ACID (DMA^{III}).

L. L. Arnold[1], M. Cano[1], S. M. Cohen[1], X. C. Le[2] and X. Lu[2]. *[1]Path/Micro, University of Nebraska Med. Ctr., Omaha, NE and [2]University of Alberta, Edmonton, AB, Canada.*

Long-term administration of DMA in the diet causes an increase in hyperplastic lesions and tumors of the rat urinary bladder epithelium at doses of 40 and 100 ppm. There is no effect on the urinary bladder at 2 and 10 ppm. The female rat appears to be more sensitive to the effects of DMA than the male. Long-term treatment of male rats with similar doses of DMA in the drinking water is also carcinogenic to the urinary bladder. In short term studies, a dietary dose of 100 ppm DMA rapidly produces urothelial cytotoxicity followed by a regenerative hyperplasia. We have determined that the reactive intermediate DMA^{III} is present in the urine of DMA-treated rats at micromolar concentrations as early as 24 hr after the start of treatment. *In vitro* studies in our lab have shown that DMA^{III} is cytotoxic to rat (MYP3) and human (1T1) cells at 0.5-0.8 μM concentrations. To determine if the urinary concentration of DMA^{III} is affected by the dose of dietary DMA, groups of 7 female 5-week old Fischer F344 rats were treated with 0, 2, 10, 40, or 100 ppm DMA for 4 wk. Fresh void urine was collected during treatment weeks 2 and 3 and analyzed by ion pair chromatography with hydride generation atomic fluorescence (HPLC-HGAFD) detection. The results of the analyses for DMA^{III} are as follows: Wk 2, 2 ppm-0.02±0.00 μM; 10 ppm-0.05±0.01 μM; 40 ppm-0.25±0.07 μM; 100 ppm-0.92±0.15 μM. Wk 3, 2 ppm-0.03±0.01 μM; 10 ppm-0.12±0.02 μM; 40 ppm-0.28±0.09 μM; 100 ppm-0.55±0.15 μM. These results show that the concentration of urinary DMA^{III} is affected by the concentration of dietary DMA in a dose-responsive manner. Also, the concentration of urinary DMA^{III} in the 40 and 100 ppm DMA groups is similar to or above the concentrations which cause cytotoxicity *in vitro* while the urinary concentration of DMA^{III} at the no-effect doses of 2 and 10 ppm is well below the concentrations which cause *in vitro* cytotoxicity.

1130 PERSISTENT INDUCTION OF HEPATIC AND PULMONARY PHASE II ENZYME EXPRESSION BY THE CARCINOGEN 3-METHYLCHOLANTHRENE IN THE RAT.

S. R. Kondraganti, W. Jiang and B. Moorthy. *Pediatrics, Baylor College of Medicine, Houston, TX.*

Cytochromes P450 (CYP)1A1 and 1A2 enzymes play pivotal roles in the bioactivation of chemical carcinogens. We reported earlier that exposure of rats to 3-methylcholanthrene (MC) leads to persistent induction of hepatic CYP1A1/1A2 enzymes for up to 45 days after MC withdrawal. CYP1A1/1A2 and phase II enzymes of drug metabolism such as glutathione S-transferase (GST-α), NAD(P)H quinone reductase (NQO1), aldehyde dehydrogenase (ADH), and UDP glucoronosyl transferase (UDPGT) are members of the *Ah* battery and are regulated by the Ah receptor (AHR). In this investigation, we tested the hypothesis that MC treatment of rats would lead to persistent induction of these enzymes, but not epoxide hydrolase (EH), which is not a member of *Ah* battery. Adult female Sprague-Dawley rats were treated with MC (93 μmol/kg) once daily for 4 days and sacrificed at 1, 15, or 28 days after MC withdrawal. Hepatic and pulmonary expression of the AHR and phase II enzymes was studied. MC elicited increases in hepatic and pulmonary expression of the AHR mRNA at 1 day, but the induction declined by day 15. On the other hand, MC caused persistent induction of hepatic GST-α, NQO1, and EH activities for up to 15 days, with induction declining by day 28. In contrast, MC-mediated induction of ADH and UDPGT activities persisted for 28 days. In the lung, MC elicited sustained induction of ADH, NQO1, and EH, but not GST-α and UDPGT, for up to 15 days. Western blot experiments yielded data that correlated with those of enzymatic activities. Taken together, our findings indicate that MC differentially regulates the expression of hepatic and pulmonary phase II enzymes, and that AHR-independent mechanisms may have contributed to the sustained induction of these enzymes by MC. Since phase II enzymes play important roles in the detoxification of reactive electrophiles to non-carcinogenic metabolites, persistent induction of these enzymes in humans could alleviate cancer risk in individuals exposed to environmental chemicals. (Supported in part by a NIEHS grant 09132 to BM.)

1131 *IN VITRO* CHARACTERIZATION OF A RECOMBINANT ADENOVIRUS EXPRESSING UDP-GLUCURONOSYL TRANSFERASE 1A7.

L. J. Webb, F. K. Kessler and J. K. Ritter. *Pharmacology and Toxicology, Virginia Commonwealth University, Medical College of Virginia Campus, Richmond, VA.*

UDP-glucuronosyl transferase 1A7 (UGT1A7) is a phase II enzyme that usually results in increased elimination of xenobiotic substances and drugs, thereby reducing toxicity. UGT1A7 is expressed at low basal levels in the liver but is easily induced by several agents, including oltipraz, a dithiole thione, and 3-methylcholantrene, a polycylic aromatic hydrocarbon (PAH). Work in our laboratory has demonstrated that UGT1A7 has an *in vitro* substrate specificity for bulky planar and non-planar phenols, such as benzo[a]pyrene (BaP) metabolites. Therefore UGT1A7 may play an important role *in vivo* in the elimination of BaP, a PAH, thus reducing the carcinogenic effects associated with BaP exposure. A recombinant adenovirus expressing rat UGT1A7 under control of a cytomegalovirus promoter (Ad-CMV-r1A7) was developed to aid in the determination of the role of UGT1A7 *in vivo*. Western blot analysis of primary rat hepatocytes from a strain of rat devoid of UGT1A expression (Gunn) infected with Ad-CMV-r1A7 resulted in detectable UGT1A7 levels *in vitro*. Expression of UGT1A7 increased as a function of time (24-72 hours) and multiplicity of infection (MOI 0-4.0). Infection of Gunn rat hepatocytes with a β-galactosidase expressing adenovirus (Ad-CMV-βgal) served as the control. Furthermore, media analyzed by high performance liquid chormatography from Gunn rat hepatocytes infected with Ad-CMV-r1A7 and treated with acetaminophen (APAP), a substrate of UGT1A7, was found to have increased amounts of APAP-glucuronide formed as compared to control. It is concluded that Ad-CMV-r1A7 encodes for functional UGT1A7 in a time and MOI-dependent manner. Further utilization of Ad-CMV-r1A7 will allow for characterization of UGT1A7 in an *in vivo* model.(Supported by 1R01ES07763 from the National Institute of Environmental Health Sciences.)

1132 REGIOSPECIFICITY AND GLUCURONIDATING ACTIVITIES OF MAJOR RAT LIVER UGT1A FORMS TOWARD BENZO(a)PYRENE METABOLITES.

F. K. Kessler and J. K. Ritter. *Pharmacolgy and Toxicology, Virginia Commonwealth University, Medical College of Virginia Campus, Richmond, VA.*

Benzo[a]pyrene (B[a]P), a prototype polycyclic aromatic hydrocarbon (PAH) and procarcinogen, undergoes extensive metabolism to form various phenol, quinone, and diol/tetrol metabolites. These metabolites are thought to be prevented from undergoing further bioactivation by UGT-catalyzed glucuronidation. UGT1A7, a low constitutive but PAH- and oltipraz-inducible UGT in rat liver, was reported previously by our laboratory to be highly active towards B[a]P metabolites. The purpose of this study was to compare the regiospecificities and activities of UGT1A7 and the three other major UGT1 isoforms expressed in Sprague-Dawley rat liver, UGT1A1, UGT1A5, and UGT1A6, towards a panel of 14 B[a]P metabolites. Complementary DNAs coding for UGTs were expressed in HEK293 cells, and crude membrane fractions were tested for activity at 100 μM B[a]P metabolite and 1.5 mM UDP-[^{14}C]glucuronic acid. Relative glucuronidating activities were determined by normalizing the data for the level of UGT1A determined by immunoblot analysis. Of the four forms tested, UGT1A7 showed the broadest specificity and highest overall activities with 13 out of 14 substrates glucuronidated at rates $\rangle$ 0.2 nmol/mg/min (1-, 2-, 3-, 4-, 5, 6, 7, 9, 10, 11, and 12- and the 4, 5- and 7, 8-dihydrodiols). UGT1A1, the major bilirubin UGT, was the only other form with significant activities. Eleven out of 14 substrates were glucuronidated by UGT1A1 at rates $\rangle$ 0.2 nmol/mg/min) including the 3- and 9-monophenols and B[a]P-4, 5-dihydrodiol. Surprisingly, UGT1A6, a well known PAH-responsive isoform, was active towards only two minor metabolites (5- and 12-monophenols). Immunoblot analysis revealed high constitutive expression of UGT1A1 in rat liver that was not further induced by either PAHs or oltipraz. These findings suggest that UGT1A1 may be a principal constitutive UGT contributing to the detoxification and elimination of B[a]P metabolites. (Supported by 1R01ES07763 from the National Institute of Environmental Health Sciences).

1133 GLUTATHIONE REDOX POTENTIAL ALTERS CARCINOGEN METABOLISM ENZYME EXPRESSION AS MEASURED BY SELDI ANALYSIS OF TRANSCRIPTIONAL PROTEINS.

S. R. Bischoff, M. D. Powell and W. G. Kirlin. *Morehouse School of Medicine, Atlanta, GA.* Sponsor: D. Jones.

Toxicity of chemical carcinogens is dependent on expression of bioactivation and detoxification enzymes. Carcinogen metabolism and exposure to oxidative stress alters the intracellular levels of glutathione (GSH) and cysteine, which shifts the intracellular redox potential and may affect transcriptional regulation of carcinogen metabolizing enzymes. Treatment of human cell lines with N-acetyl-L-cysteine or buthionine sulfoximine reduces or oxidizes the GSH pool, respectively, and quantitative PCR indicates changes in mRNA levels of both the activating enzyme cytochrome P450 1A1 (CYP1A1) and the detoxification enzyme NAD(P)H:quinone oxidoreductase (NQO1). To determine whether these changes are due to effects on transcriptional protein interactions with DNA response elements, a strategy was developed to detect proteins bound to DNA-regulatory elements covalently coupled to an epoxide protein chip array. Protein binding to the oligonucleotide sequence is determined by surface-enhanced laser desorption/ionization (SELDI-MS). To test this technique, recombinant human c-jun was expressed in E. coli BL21:DE3 and incubated on the chip surface containing the bound activator protein 1 (AP-1) oligonucleotide sequence. SELDI analysis demonstrated that 42 pmoles c-jun (35.5 kDa) saturated 250 pmoles of AP-1 oligomer. An increase in c-jun from nuclear extracts of phorbol ester-treated HeLa and HT29 cell lines was readily detected. Regulation of NQO1expression is partially controlled by the antioxidant response element containing an AP-1 consensus sequence and is responsive to xenobiotics, antioxidants, oxidants, and environmental stresses resulting in coordinate induction of many detoxification enzymes. Similarly, CYP1A1 is regulated by protein interactions with a xenobiotic response element also affected by oxidative stress. SELDI technology can provide a powerful means to investigate protein-DNA interactions in response to induction of competing pathways for carcinogen biotransformation. (Support: RCMI RR03032; MBRS/GM-028248).

1134 ALTERED METHYLATION AS A POSSIBLE BIOMARKER OF TOXICITY.

J. M. McKim[2], R. E. Watson[1], G. L. Cockerell[2] and J. I. Goodman[1].
[1]*Pharmacology & Toxicology, Michigan State University, East Lansing, MI and* [2]*Research & Development, Pharmacia, Kalamazoo, MI.*

DNA methylation (ME) is an epigenetic mechanism that plays an important role in mammalian transcriptional regulation. Aberrant patterns of ME are implicated in carcinogenesis and in certain neurological, immune and developmental disorders. To determine if altered ME is a precursor to the toxic effects of a variety of chemicals, and if understanding ME changes might provide an enhanced assessment of the toxic potential of a chemical, preliminary experiments were conducted on the effects of model toxic compounds on global and GC-specific ME in H4IIE rat hepatoma cells. Results were compared to those generated from a "Tox Cluster" battery of *in vitro* assays (cell number, 3-(4, 5-dimethylthiazol-2-y1)-2, 5-diphenyltetrazolium bromide (MTT) for mitochondrial function, glutathione-S-transferase

leakage for cell membrane integrity, and ATP levels). Model compounds include: 5-aza-2'deoxycytitine (dAzaC), a demethylating agent; rotenone, an inhibitor of oxidative phosphorylation; staurosporine, a PKC inhibitor; and camptothecin, which causes double strand DNA breaks. Cells were treated with several doses of each compound for 24 or 72 h. Global levels of ME were decreased and GC-rich ME were altered by non-toxic doses of dAzaC. Toxic doses of camptothecin and rotenone did not alter levels of global ME at 72 h, possibly because the acute lethality of these compounds preceded any effect on ME. In contrast, 24 h treatment of a toxic dose of staurosporine led to global hypomethylation. Studies are currently being performed to more thoroughly determine dose-response relationships so that alterations in ME may be closely matched to doses shown to be toxic and non-toxic. The preliminary findings regarding dAzaC- and staurosporine-induced altered ME indicate that the incorporation of a ME assessment into toxicity testing protocols may provide a more complete picture of the toxic potential of the compound of interest and might substitute for some traditional parameters.

1135 EFFECT OF BROMODICHLOROMETHANE AND DIBROMOACETIC ACID ON THE METHYLATION OF DNA AND THE IGF-II GENE IN MICE AND RATS.

L. Tao[1], W. Wang[1], L. Li[1], A. S. Bridges[2], S. Yang[1] and M. A. Pereira[1]. *[1]Pathology, Medical College of Ohio, Toledo, OH and [2]Pathology, University of North Carolina, Chapel Hill, NC.*

The disinfection by-products (DBPs) are a diverse group of chemicals found in chlorine treated drinking water of which the trihalomethanes (THM) and haloacetic acids (HAA) are found in highest concentration. Some THM and HAA have demonstrated carcinogenic activity in the liver and kidney of rodents. DNA hypomethylation, demonstrated by a general decrease in the 5-methylcytosine (5-MeC) content of DNA, is an early event in carcinogenesis and an epigenetic mechanism for chemical carcinogens, including the THM and HAA. The ability of the THM, bromodichloromethane (BDCM) and the HAA, dibromoacetic acid (DBA) to cause DNA hypomethylation was determined in the liver and kidney. BDCM was administered in the drinking water and by oral gavage to female B6C3F1 mice and male F344 rats. DBA was administered in the drinking water to male and female mice and rats. DNA methylation was determined by high-performance liquid chromatography (HPLC), by Dot-blot analysis using a monoclonal antibody specific for 5-MeC and by bisulfite treatment of DNA followed by PCR and sequencing to determine the methylation of the insulin-like growth factor-2 (IGF-II) gene. BDCM (50-100 mg/kg by gavage and 350-700 mg/L) and DBA (1000-2000 mg/L) decreased the 5-MeC content in liver and kidney DNA by 25-46% in both mice and rats. In normal mouse liver and kidney, the region of the IGF-II gene evaluated had 14-20 of 24 CpG sites methylated. DBCM and DBA reduced the number of CpG sites that were methylated to 0-8. Hypomethylation was found after exposure to BDCM or DBA for 4 to 5 days and was maintained for 28 days. Thus, the two DBPs caused DNA hypomethylation that is consistent for an epigenetic mechanism of carcinogenesis. Supported in part by grant 1R03 ES10537 from NIEHS.

1136 CHROMATE INDUCES THE HGPRT GENE SILENCING BY DNA METHYLATION: A NEW EPIGENETIC MECHANISM FOR CHROMATE CARCINOGENESIS.

Q. Zhang, T. Kluz, K. Salnikow and M. Costa. *Department of Environmental Medicine, NYU School of Medicine, Tuxedo, NY.*

Hexvalent chromate (Cr 6+), recognized as a carcinogen by IARC, has widespread exposure both occupationally and to the general public. Epidemiological studies showed that Cr6+ compounds could induce respiratory tumors following inhalation exposure. Although a large number of studies focused on the mechanism of Cr 6+ carcinogenesis, it still remains a topic for intense research investigation. In this study, the human osteoblastic cell line (HOS) was exposed to Cr 6+, selected by 6-thioguanine (6-TG), and the HGPRT gene expression was measured by Northern blot. The results showed that the number of 6-TG resistant colonies was 7 fold higher in the cells treated with Cr 6+ 8 times than those treated only once. There was a dose-related increase in the 6-TG resistant frequency and 90% of 6-TG resistant colonies expressed the HGPRT gene when treated once. However, only 20% of the colonies expressed this gene when treated 8 times. Furthermore, when those 6-TG resistant colonies which lacked the HGPRT gene expression were treated with 5-Aza-2-deoxyctidine, then selected in HAT medium, the expression of HGPRT gene was turned on again. Additonally numerous methylation sites were found in those resistant colonies by sodium bisulfite treatment followed by sequencing. Our results demonstrate that Cr 6+ induces a high 6-TG resistant frequency and HGPRT gene silencing in HOS cells and such gene silencing is mediated by DNA methylation. Supported by grants ES 05512, ES 10344, ES 0260 and CA 16087 from NIH.

1137 THE ANALYSIS OF TRANSCRIPTIONAL REGULATION OF NICKEL-INDUCIBLE GENE CAP43.

K. Salnikow, P. Zhang and M. Costa. *Environmental Medicine, New York University School of Medicine, Tuxedo, NY.*

Cap43 gene has been cloned in our laboratory from human lung A549 cells as highly inducible by both soluble and insoluble nickel compounds (Zhou et al., 1998). Since nickel mimics hypoxic condition in cells subsequent studies have revealed that Cap43 mRNA is indeed induced by hypoxic conditions (Salnikow et al., 2000). Further, the importance of hypoxia in the induction of Cap43 was shown in studies using mouse cells with the knock-out of HIF-1α transcription factor. Thus, transcriptional upregulation of the Cap43 mRNA is highly dependent upon the HIF-1 transcription factor. In addition to hypoxia Cap43 mRNA can be induced by the elevation of intracellular calcium, however, this upregulation is dependent on another transcription factor, AP-1 (Salnikow et al., 2002). High inducibility by hypoxia makes Cap43 an important marker for cancer cells since most tumor cells experience hypoxia due to limited vasculature in the growing tumor body. Cap43 RNA and protein is remarkably stable and immunohistochemical staining have demonstrated strong overexpression of Cap43 protein in lung, breast, prostate, esophageal and melanoma cancers relative to normal tissues. Thus our preliminary studies suggest that Cap43 protein is an excellent cancer marker. In order to better understand transcriptional regulation of this new tumor marker we have cloned a 3.0 kbp fragment of the Cap43 promoter. The sequence identity was verified and a computer analysis of the predicted transcription factors binding sites has been performed. Based on the map of the predicted transcription factor binding sites we created a number of deletion fragments of the promoter. The full size promoter and all deletion fragments were inserted into a pGL3 plasmid with a Luciferase reporter gene. These constructs were used for the analyses of the transcriptional regulation of Cap43 expression in normal and transformed cells.

1138 DOWNREGULATION OF A ZINC FINGER PROTEIN-ZFP61 BY Ni IN MOUSE CELLS *IN VITRO* AND *IN VIVO.*

P. Zhang and M. Costa. *NYU Medical Center, New York, NY.*

We studied the gene expression pattern in the mouse PW cell line following nickel treatment. We found that a gene zinc finger protein 61 from a pool of downregulated genes was suppressed by Ni exposure and this effect was reversed by trichostatin A . We have confirmed that zpf61 (L28167) was downregulated by Ni, Co., and hypoxia in Northern Blot. The zfp61 RNA level was downregulated in PW cells (a mouse cell line) after Ni and Co treatment for 24 hrs, this effect was partially reverted by pretreatment with Trichostatin A (TSA) a histone deacetylase Inhibitor, which raised the overall levels of Histone acetylation in the cell. *In vivo* data also support this result, as IP injection of nickel could downregulate zfp61 transcription in various tissues as lung, liver.. Meanwhile, as Cobalt and hypoxia can induce zfp61 downregulation as well, we proposed that this parallel effect may be due to a mechanism involving the HIF dependent pathway. We further confirmed this idea by showing that in HIF defective cell lines, this zfp61 transcription depression by Ni was absent. Futher studies will reveal the possible function of this gene and the toxicological significance of its downregulation by Ni.

1139 DOWN REGULATION OF A SERINE PROTEINASE INHIBITOR BY NI AND CO IS DEPENDENT ON HYPOXIA INDUCIBLE FACTOR SIGNALLING.

J. Zhao, Y. Yan and M. Costa. *Nelson Institute of Environmental Medicine, New York University School of Medicine, Tuxedo, NY.*

We have utilized the mouse Affymetrix chip to study the gene expression pattern in mouse fibroblast cells following nickel treatment. Spi2.1, a member of the mouse Serpin (serine protease inhibitor) family, was the most down-regulated (32-fold) among all of the genes studied. We have confirmed that Serpin was down-regulated by Ni and also investigated which signalling pathways may be involved in this down-regulation of spi2.1 gene expression. PW cells (a mouse cell line) were treated with Ni and Co for 24 hrs, then total RNA was isolated and a 480 bp DNA fragment was amplified from spi2.1 full-length cDNA and used in Northern hybridization. Ni and Co exposure silenced Serpin expression, and this effect was suppressed by trichostatin A, a histone deacetylase inhibitor that raised the overall levels of histone acetylation in the cell. This down-regulation appeared to be operating *via* a hypoxia inducible factor mechanism (HIF), since exposure to hypoxia, Ni and Co caused the suppression of gene expression and the affect was greatly diminished in Hif Knock out cells. Calcium ionophore also down-regulated Serpin. We are furthering our studies of Serpin gene suppression by Ni to other species and to its role in Ni-induced carcinogenesis. (Supported by grant numbers ES05512, ES10344, ES00260 from the NIEHS).

1140 SCREENING NICKEL CARCINOGENS FOR INDUCTION OF MITOTIC RECOMBINATION IN D MELANOGASTER.

A. J. Katz, A. O. Chiu, D. X. Singh, N. Chiu, J. Beaubier and X. Shi. *NCEA, ORD, USEPA, Washington, DC.*

Nickel compounds were tested for genotoxicity in the wing spot assay of D melanogaster. Compounds assayed included nickel oxide black, nickel oxide green, nickel monosulfide and nickel arsenide. Third instar larvae were exposed to tested compounds *via* 6 hour acute feeding treatments. Both nickel oxide green and nickel monosulfide were evaluated as negative in yielding mutant clones of any type. However, nickel oxide black was found to be a positive inducer of small single spots and total spots at 80 mM. Significant ($p<0.05$) dose response relationships also existed for nickel oxide black for induction of small single spots and total spots. About 77% of single spots induced by nickel oxide black in trans-heterozygous wings involved mitotic recombination based on the inhibition in inversion heterozygous wings. Nickel oxide black was ineffective at inducing twin spots, which arise exclusively from mitotic recombination between centromere and flr gene. Uptake of nickel particles and surface zeta potential affect acetylation and condensation of histone leading to the failure of twin spot occurrence

1141 MOLECULAR PROFILING OF GENES SHOWING ALTERED EXPRESSION IN THE LIVERS OF RATS TREATED WITH NON-GENOTOXIC CARCINOGENS FOR 28 DAYS.

M. Shibutani, T. Arimura, T. Kobayashi, N. Takahashi, H. Takagi, C. Uneyama and M. Hirose. *Division Pathol., National Inst. Health Sciences., Tokyo, Japan.*
Sponsor: T. Shirai.

We performed global gene expression analysis in the rat livers to clarify common molecular events that appeared in response to repeated oral administration of representative non-genotoxic liver carcinogens for 28 days. Six-week-old male SD:IGS/DuCrj rats were fed diet containing 600 ppm-phenobarbital (PB), 600 ppm-thioacetamide (TAA), or 20, 000 ppm-di(2-ethylhexyl)phthalate (DEHP) for up to 1 year. As a negative control for carcinogenicity, a hepatotoxic dose (10, 000 ppm) of non-carcinogenic acetaminophen (APAP) was selected. After 28 days of feeding, mRNA expression analysis was performed in the livers using GeneChip Rat Genome U34A Array (Affymetrix Inc.). Among genes those expression levels were unchanged by APAP-treatment, a group of genes showing common expression patterns (up- or down-regulated) between PB, DEHP, and TAA were selected for expression analysis at 1 year of treatment by real-time RT-PCR. Among 7, 000 genes included in the chip, genes up-regulated twice or more by treatment with PB, TAA, DEHP, or APAP as compared to the control levels were 43, 477, 179, and 39, respectively. Genes down-regulated twice or less were 74, 315, 245, and 63, respectively. In every chemical examined, majority of up-regulated genes were classified into the category of Metabolism, and down-regulated genes involved diverse functional clusters including Cell signaling/Communication, Metabolism, and Cell/Organism defense. Furthermore, majority of down-regulated genes were different between chemicals, and therefore this difference may determine the phenotype of biological responses induced by each chemical. A total of 12 genes were found to show similar expression pattern (up- or down-regulated) common to the carcinogens. However, many of these genes did not follow similar expression pattern at 1 year of treatment. On the other hand, one gene (EST) showed an inverse expression pattern from 28 days to 1 year, and this change may reflect the altered cellular function caused by long-term exposure to non-genotoxic carcinogens.

1142 EXPRESSION OF MUTANT K-RASV12 IN MOUSE LUNG EPITHELIAL CELLS INCREASES GENERATION OF PEROXIDES THROUGH COX-2, RESULTING IN DNA DAMAGE.

A. E. Maciag[1], G. Sithanandam[2], K. S. Kasprzak[1] and L. M. Anderson[1].
[1]Laboratory of Comparative Carcinogenesis, National Cancer Institute at Frederick, Frederick, MD and [2]SAIC Frederick, Frederick, MD.

The K-ras gene is frequently mutated in lung adenocarcinoma. However, wild-type K-ras is a tumor suppressor in lung [1]. This raises a question: how is mutant K-ras protein so aggressively oncogenic? Several studies demonstrate that expression of a constitutively active mutant of ras leads to increase in reactive oxygen species (ROS) generation [1, 2]. Fibroblasts or keratinocytes stably transfected with a constitutively active H-ras produced large amounts of superoxide [2, 3, 4]. In this report we demonstrate that stable transfection of constitutively active human K-ras V12 into nontransformed E10 cells from peripheral mouse lung epithelium leads to increased level of peroxides, as indicated by FACS analysis of intracellular oxidation of CM-H2DCF-DA. Furthermore, we observed significant increase in DNA strand-break damage measured by Comet assay in the cells expressing K-rasV12 compared with parental line E10 and vector control. This damage was reduced by 50% by pretreatment of the cells with catalase, confirming hydrogen peroxide involvement. Both peroxide generation and DNA single strand breaks were completely blocked by pre-treatment with cyclooxygenase-2 specific inhibitor SC 58125, suggesting COX-2 as the source of reactive oxygen species. COX-2 has been repeatedly implicated in lung cancer. ROS generated as an effect of RasV12 activity through COX-2 could contribute to transformation by DNA damage and/or by alterations in intracellular signaling. This may explain the active oncogenicity of mutant K-ras. [1] Zhang Z. et al. Nature Genet 29(1): 25-33, 2001; [2] Sundaresan M, et al. Biochem. J. 318 (Pt.2): 379-382, 1996; [3] Irani K, et al. Science 275: 1649-1652, 1997; [4] Lee A.C, et al. JBC 274 (12): 7936-7940, 1999; [5] Yang, J-Q, et al. Mol. Carcinogen. 26: 180-188, 1999.

1143 ESTROGEN-INDUCED STIMULATION OF MACROPHAGES LEADING TO THE GENERATION OF REACTIVE OXYGEN SPECIES IN THE TARGET ORGAN OF CANCER.

S. Venkat, Q. Felty and D. Roy. *Environmental Health Sciences, University of Alabama at Birmingham, Birmingham, AL.*

The sex hormones-estrogen, progesterone, and testosterone have a profound influence on macrophage cell biology and function. Macrophages are located throughout the female and male reproductive tracts including the ovary, uterus, and testis. The expression of aromatase in macrophages suggests that estrogen may be produced in these cells through the conversion of androgen to estrogen. In addition, the estrogen receptor is known to be present in macrophages which suggests that estrogen may modulate the activity of these cells. It is not clear whether the growth of macrophage cells is regulated by estrogen. Recently, we reported that estrogen exposure of J744A1 cells increased the rate of BrdU incorporation. In this study, we investigated the effects of synthetic estrogen, diethylstilbestrol (DES) and natural estrogen, 17-beta-estradiol (E2) on the cell growth and rate of proliferation in the presence/absence of the antiestrogen tamoxifen. We found that J774A1 show a dose dependent increase in cell growth when treated with E2 at concentrations from 1 ug/ml up to 1 pg/ml, after 48h and 72h of treatment, with 1pg/ml showing more than a 2-fold increase in growth when compared to the control after 72 hrs. Co-treatments with E2 and tamoxifen (at doses 10 fold higher than E2) showed inhibition of E2 induced growth. Our results suggest that the growth of macrophage cells is estrogen sensitive. In addition to the immunogenic functions, macrophages play a key role in cell signaling due to their ability to produce cytokines and reactive oxygen species. Estrogen-induced stimulation of macrophages leading to the hyperproduction of the proinflammatory cytokines, such as IL-1, IL-6, and TNF, in the target organ of cancer, may be involved in the induction of instability in the genome, including oxidative damages to genes leading to gene mutations. Supported by the NIH grant ES10851.

1144 ESTROGEN REGULATES AH RESPONSIVENESS IN MCF-7 BREAST CANCER CELLS.

D. C. Spink, B. H. Katz, M. M. Hussain, B. T. Pentecost, Z. Cao and B. C. Spink. *New York State Department of Health, Wadsworth Center, Albany, NY.*

Cytochromes P450 1A1 (CYP1A1) and 1B1 (CYP1B1) catalyze the metabolic activation of numerous procarcinogens and the hydroxylation of 17beta-estradiol (E2) at the C-2 and C-4 positions, respectively. Both are under the transcriptional control of the aryl hydrocarbon (Ah) receptor, and there are indications of cross-talk between estrogen receptor-alpha- and Ah receptor-mediated signaling in breast and endometrial cells. We examined the effects of short- and long-term E2 exposure on Ah responsiveness in MCF-7 human breast cancer cells to investigate this interaction. Short-term exposure to 1 nM E2 elevated the ratio of the 4- to 2-hydroxylation pathways of E2 metabolism in 2, 3, 7, 8-tetrachlorodibenzo-p-dioxin (TCDD)-treated cells. Cells maintained long-term (9 to 12 mo.) in low-estrogen medium progressively lost Ah responsiveness as indicated by the diminution of TCDD-induced E2 metabolism and the expression of CYP1A1 and CYP1B1 mRNAs. These E2-deprived cells showed elevated levels of estrogen receptor-alpha mRNA, but depressed levels of Ah receptor mRNA. The reduction in Ah-responsiveness was reversed by culture for four passages in medium supplemented with 1 nM E2. Expression from a transiently transfected CYP1B1-promoter-luciferase reporter construct was reduced in the long-term, E2-deprived cells in a manner similar to the endogenous gene. Activity from CYP1B1 promoter-reporter construct was restored by co-transfection with an Ah receptor expression construct. This indicates that AhR expression was limiting in the estrogen-deprived MCF-7 cells. These studies suggest an additional role of estrogen in carcinogenesis may involve enhanced Ah responsiveness leading to elevated expression of the procarcinogen-bioactivating enzymes, CYP1A1 and CYP1B1.

1145 PCB METABOLITES AS INITIATING AGENTS IN HEPATOCARCINOGENESIS.

P. Espandiari, H. J. Lehmler, D. Stemm, H. P. Glauert and L. W. Robertson. *University of Kentucky, Lexington, KY.*

PCB commercial mixtures are complete rodent carcinogens. Mixtures and congeneric PCBs are efficacious promoters in rat two-stage hepatocarcinogenesis, but the question of PCB's initiating activity remains controversial. Congeneric PCBs are metabolized both *in vitro* and *in vivo* to strongly electrophilic species that bind to proteins and to DNA. We have reported previously that 4-chlorobiphenyl (PCB-3) shows initiating activity by inducing gamma-glutamyl transpeptidase (GGT)-positive foci in a modified Solt-Farber protocol. To investigate the mechanism of this activation, we examined two metabolites of PCB-3: 3-OH and 4-OH PCB-3. Fisher 344 male rats were fasted for 4 days, then 24 hrs after refeeding were injected i.p. with 400 umol/kg PCB metabolites, or injected p.o. with diethylnitrosamine (DEN) (20mg/kg) as a positive control. After a two-week recovery period, all animals were treated with selection agents: 3 daily doses of 2-acetylaminofluorene (2-AAF, 30 mg/kg), followed by a single dose of carbon tetrachloride (2 ml/kg) and by 3 additional daily doses of 2-AAF. Rats were killed two weeks after the last treatment. Although treatment with each metabolite increased the number of GGT-positive foci per cc and per liver, this increase was statistically significant only for the 4-OH-PCB-3 metabolite when compared to control rats. All DEN-treated rats developed visible nodules as well as GGT-positive foci in the liver. These data support our hypothesis that the metabolic activation of 4-chlorobiphenyl occurs *via* para hydroxylation, most likely leading to the 3, 4-catechol. (Supported by ES 07380)

1146 EFFECT OF MIXTURES OF POLYCYCLIC AROMATIC HYDROCARBONS ON HUMAN CELLS IN CULTURE.

H. Parsons[1], B. Mahadevan[1], T. Musafia[1], A. K. Sharma[2], S. Amin[2] and W. Baird[1]. *[1]Environmental and Molecular Toxicology, Oregon State University, Corvallis, OR and [2]American Health Foundation, Valhalla, NY.*

Human exposure to polycyclic aromatic hydrocarbons (PAH) occurs through complex mixtures of PAH, some of which are carcinogenic. Standard Reference Material (SRM) derived from coal tar, diesel particulate matter, and urban dust obtained from the National Institute of Standards, contained a mixture of PAH including carcinogenic, non-carcinogenic and weakly carcinogenic compounds. In order to study the effect of these PAH in complex mixtures with different levels of carcinogenicity (both weakly carcinogenic and non-carcinogenic) on DNA-binding and induction of cytochrome P450 (CYP) enzymes, artificial mixtures (1597H-coal tar, 1649H-urban dust, and 1650H-diesel exhaust) of PAH were procured in our laboratory. Human mammary carcinoma derived cell line MCF-7 was treated with the artificial mixtures of PAH, and analyzed for PAH-DNA adduct formation and induction of CYP enzymes. Results indicate that the artificial mixtures tested formed DNA adducts 24 and 48 hrs after treatment, like those treated with benzo[a]pyrene (B[a]P). Induction of CYP enzymes was also observed as measured by ethoxyresorufin O-deethylase (EROD) assay. These results demonstrate that both non-carcinogenic and weakly carcinogenic PAH in the complex mixture affect the DNA binding and the induction of CYP enzymes. Supported in part by grant CA28825, NCI, DHHS.

1147 EXPLORATION OF TOXICOLOGICAL INTERACTIONS BETWEEN JET A FUEL AND BENZO(a)PYRENE (BaP) ON MALIGNANT TRANSFORMATION OF HUMAN KERATINOCYTES.

Y. Zhang, C. Battaglia, O. Lohitnavy, J. Campain and R. Yang. *Quantitative and Computational Toxicology Group, Center for Environmental Toxicology and Technology, Department of Environmental and Radiological Health Sciences, Colorado State University, Fort Collins, CO.*

Due to its widespread use, occupational and environmental exposures to Jet A fuel have become a source of public and regulatory concern. However, it is still unclear how the interactions among the components of these complex mixtures affect their carcinogenic potential in humans. Benzo(a)pyrene (BaP) is the one of the most potent carcinogens present in petroleum mixtures. It was of interest, therefore, to evaluate how the transforming potential of BaP was affected by the presence of low levels of Jet A. To address this issue, we used the immortalized human epidermal keratinocyte cell line, RHEK-1. As a first step of this project, the toxicity of Jet A and BaP on RHEK-1 was determined by clonogenic assay. The LC10 and LC50 for Jet A were 0.004% and 0.03%, respectively; whereas the LC5 and LC50 of BaP were 0.4μM and 2.3μM, respectively. In subsequent studies, the transforming efficiency of BaP with or without Jet A in RHEK-1 cells was evaluated. RHEK-1 cells were treated repetitively (every 4 passages) with the following chemicals or controls: Culture medium, S9 alone, acetone solvent control, MNNG positive control, BaP Low (0.4μM), BaP High (2.3μM), Jet A (0.004%) alone, BaP Low + Jet A, and BaP High + Jet A. Morphological analysis, Anchorage Independent Growth (AIG), saturation density and cell cycle kinetic analysis were the endpoints studied to determine malignant progression of RHEK-1 cells following BaP and/or Jet A treatments. At passage 13, the following was observed: 1) cultures treated with BaP or MNNG showed low, but detectable, AIG as compared to negative controls and 2) cells exposed to BaP High + Jet A exhibited higher colony forming efficiency than did those exposed to BaP High alone. Although preliminary, this finding suggests that Jet A may enhance the malignant transformation of BaP. This study was supported by NIEHS R01 ES-09655.

1148 EFFECT OF 2, 2', 4, 4', 5, 5'-HEXACHLOROBIPHENYL (PCB-153) ON GENE EXPRESSION IN MICE DEFICIENT IN THE P50 SUBUNIT OF NF-κB.

Z. Lu, L. W. Robertson, B. T. Spear and H. P. Glauert. *University of Kentucky, Lexington, KY.*

Polychlorinated biphenyls have been shown to be hepatic tumor promoters and to induce liver tumors in experimental animals. The exact mechanism of the tumor promoting activity of PCBs is not well understood, but alterations in expression of genes that regulate cell proliferation and apoptosis have been proposed. Our previous studies showed that a single dose of PCB-153, a non-coplanar PCB congener, causes transient increases in the hepatic DNA binding activity of NF-κB and cell proliferation in rats and mice. Using a transgenic mouse model that is deficient in the p50 subunit of NF-κB (p50 -/-), we have demonstrated that the activation of NF-κB contributes to changes in cell proliferation and apoptosis in response to PCB-153 treatment. In the present study, we used gene microarrays to examine changes in gene expression following a single dose of PCB-153 in p50 -/- mice as well as wild type mice. Mice received a single i.p. injection of corn oil or PCB-153 (300 μmol/kg) and were euthanized 2 days later. Hepatocyte proliferation was increased by PCB-153 in wild type mice, but not in p50 -/- mice. The p50 -/- mice had more spontaneous apoptosis than wild types, and PCB-153 inhibited apoptosis in p50 -/- mice. Total RNA was collected from liver tissues and used for Affymetrix microarray analysis. Identified in the microarray analysis were 30 genes altered by PCB-153 in both wild type and p50 -/- mice, 93 genes altered by absence of p50 in both control and PCB-treated mice, 25 genes altered by PCB-153 in wild type mice, but not in p50 -/- mice, and 33 genes altered by PCB-153 only in p50 -/- mice, not in wild type mice. This study will lead to a better understanding of the mechanisms of hepatocarcinogenesis by PCBs. (Supported by ES07380)

1149 BENZO(a)PYRENE, DISTILLATE MARINE DIESEL FUEL AND A MIXTURE OF 5 POLYAROMATIC HYDROCARBONS, SINGLY AND IN COMPLEX MIXTURES, INDUCED CYTOTOXICITY AND MALIGNANT TRANSFORMATION IN HUMAN KEROTINOCYTES, RHEK-1.

O. S. Lohitnavy, C. R. Battaglia, R. S. Yang and J. A. Campain. *Environmental and Radiological Health Sciences, Colorado State University, Fort Collins, CO.*

Exposure to petroleum-based mixtures of polycyclic aromatic hydrocarbons (PAH's) has been associated with an increase in cancer incidence. However, little is currently known about the interactions among PAH components in these mixtures and risk assessment is difficult. To explore this issue, we have begun to study the effects of distillate marine diesel fuel (DMA) and a defined mixture of 5PAH's (anthracene, chrysene, fluoranthene, pyrene and phenanthrene) on the carcinogenicity of benzo(a)pyrene (BaP) in the immortalized human keratinocyte cell line, RHEK-1. Cytotoxicity analysis using the clonogenic assay was performed to determine concentration ranges for each of the chemicals/mixtures used in subsequent transformation studies. To test the carcinogenic potency of BaP alone and in the presence of either DMA or the 5PAH's, RHEK-1 cells were treated repetitively with the following: 1) BaP LC5 [0.4 and 0.5 μM in acetone or DMSO, respectively]; 2) BaP LC50 [2.3 and 2.75 μM in acetone and DMSO, respectively]; 2) BaP LC5 + LC10 DMA [0.0025% in acetone]; 3) BaP LC5 + LC10 5PAH's [2 μM in DMSO]; 4) BaP LC50 + LC10 DMA; 5) BaP LC50 + LC10 5PAH's; 6) 5PAH's alone [2 μM]; or 7) the solvent controls. All treatments were carried out in the presence of rat S9 fraction. As an indicator of malignant transformation, anchorage-independent growth (AIG) in methylcellulose (MC) was measured in each culture as a function of time. Although preliminary, the results of this analysis through passage 16-20 showed that in contrast to the control (S9, solvent, DMA, or 5PAH's alone), cultures exposed to BaP have begun to acquire slight, but detectable, AIG. Interestingly, the culture with the highest cloning efficiency in MC is currently the BaP LC5 + 5PAH mix (7.5% at passage 16). Treatment of RHEK-1 and evaluation of the cells for AIG and, eventually, tumorigenicity in mice will continue. Funded by NIEHS Grant RO1 ES09655.

1150 POLYCYCLIC AROMATIC HYDROCARBONS WITH BAY-LIKE STRUCTURES INHIBITED GAP JUNCTIONAL INTERCELLULAR COMMUNICATION IN IMMORTALIZED HUMAN PANCREATIC DUCTAL EPITHELIAL CELLS.

M. Tai, B. L. Upham and J. E. Trosko. *Pediatrics &Human Development, Michigan State University, East Lansing, MI.*

Smoking is a well-documented risk factor for the development of pancreatic adenocarcinoma. Polycyclic aromatic hydrocarbons (PAHs) are one class of compounds in this complex mixture of combusted by-products of tobacco. The most abundant PAHs in cigarette smoke are methylated anthracenes and phenanthrenes. Several reports showed that methyl- or chloro-anthracenes, which possess a bay-like structure affect epigenetic events such as an induced release of arachidonic acid, inhibition of gap junctional intercellular communication (GJIC), and induction of mitogen activated protein kinases in a pleuripotent rat liver epithelial stem cell line. Anthracenes with no bay-like structures were inactive. These biological effects are all molecular events associated with the promotional phases of cancer. To understand the epigenetic toxicity of PAHs related to pancreatic cancer, a human immortalized pancreatic ductal epithelial cell line, H6c7, was used to examine the epigenetic effects of PAHs. H6c7 cells were GJIC-incompentent and did not express detectable connexin messages when grown in medium containing hormones and growth factors. Telomerase activity was high in these immortalized H6c7 cells. In the presence of the c-AMP elevating drugs (forskolin and IBMX) in basal medium without growth factors, the cells became GJIC competent and expressed connexins. Telomerase activity was also decreased by c-AMP elevating drug treatment. After induction of c-AMP, 1-methylanthrance with bay-like structures inhibited GJIC, whereas the 2-methylanthracene lacking a bay-like structure had no effect on GJIC. Telomerase activity remained high in 1-methylanthrance treatment but not with 2-methylanthrance. These results indicate that a prominent component of cigarette smoke, namely methylantracenes with distinct structural configurations, could be a potential etiological agent contributing to the epigenetic events of pancreatic cancer. Funded by the NIEHS Superfund grant #P42 ES04911-07.

1151 EVALUATION OF EVIDENCE TO EXPLAIN THE LUNG TUMORIGENESIS IN A/J MICE INDUCED BY EXPOSURE TO AN ENVIRONMENTAL TOBACCO SMOKE SURROGATE.

C. Knoerr[1], W. Stinn[1], P. Vanscheeuwijck[2], R. Kindt[1] and H. Haussmann[1]. *[1]INBIFO GmbH, Cologne, Germany and [2]CRC B.V.B.A., Zaventem.*

Recently, lung tumors were reproducibly induced in A/J mice exposed to an experimental surrogate of environmental tobacco smoke ("ETS") using a protocol that requires a 5-month "ETS" inhalation period followed by a 4-month post-inhalation period. The present study was conducted to identify potential mechanisms underlying this tumor response. Male A/J mice were exposed to "ETS" (88% sidestream smoke, 12% mainstream smoke) at 100 mg total particulate matter/m3 or to fresh air (sham control) for 6 h/d, 5 d/w, for 5 months or were kept under one of two food restriction regimens to mimic or exceed the body weight reduction seen with "ETS" exposure. Half the mice were kept for an additional 4-month post-treatment period. At both time points, K-ras mutations in codons 12, 13, and 61 were analyzed by DNA sequencing after PCR amplification of DNA extracted from lung tumor material, and micronuclei in reticulocytes and normochromatic erythrocytes in peripheral blood were counted by a flow cytometric method. Pulmonary inflammation was assessed by differential counting of lavaged polymorphonuclear neutrophils, alveolar macrophages, and lymphocytes at the end of the treatment period. No pulmonary inflammation was observed. Urethane pre-treatment induced the signature mutation pattern in codon 61 expected from literature. At the end of the treatment period, micronuclei and mutation frequency in codon 12 were slightly higher in "ETS"-exposed mice, similar to the levels seen in food-restricted mice. These findings were not seen at the end of the post-treatment period, when "ETS"-induced tumor multiplicity was increased by approximately 2-fold over sham control. No change in the K-ras mutation pattern was detected. Thus, the mechanisms studied here did not explain the observed increase in lung tumor multiplicity by "ETS" inhalation.

1152 EFFECT OF 2, 3, 7, 8-TETRACHLORODIBENZO-P-DIOXIN (TCDD) EXPOSURE ON NORMAL HUMAN MELANOCYTES AND MELANOMA CELL LINES.

C. M. Villano, A. G. Cardoso, A. Akintobi, R. Dorn and L. A. White. *Biochemistry and Microbiology, Rutgers University, New Brunswick, NJ.*

Our hypothesis is that the environmental contaminant 2, 3, 7, 8-tetrachlordibenzo-p-dioxin (TCDD) alters tumor promotion by altering the expression of genes involved in cell-cell interactions and matrix remodeling. Although the molecular mechanisms of tumor promotion by TCDD are not clearly understood, it is believed that TCDD exerts its effects through activation of the Aryl Hydrocarbon Receptor (AhR)/Arnt transcription pathway. Studies of AhR/Arnt have focused on the heterodimers ability to activate transcription of xenobiotic metabolizing genes including members of the cytochrome (CYP450) family of monooxygenase enzymes. Our data demonstrates that TCDD treatment of normal human keratinocytes results in increased expression and activity of the matrix metalloproteinases (MMPs), enzymes that degrade the protein components of the extracellular matrix and basement membrane. The goal of this study is to characterize the TCDD-responsiveness of primary melanocytes and melanoma cell lines. We investigated TCDD-responsiveness by investigating induction of mRNA expression of two known targets for TCDD, cytochrome p450s (CYP) 1A1 and 1B1. We also examined the effect of TCDD on expression of genes involved in melanoma progression, including the MMPs, plasminogen activator inhibitor-2 (PAI-2), E-cadherin, and EMMPRIN. We used both northern analysis as well as quantitative real-time RT-PCR to examine expression of CYP1A1, CY1B1 and MMP-1 in normal human melanocytes, two invasive melanoma cell lines (A2058, HT-144) and two less invasive cell lines (Bowes, SK-Mel-2). Our data demonstrates that while normal melanocytes do not appear to be responsive to TCDD exposure, melanoma cell lines display varying degrees of TCDD-responsiveness. This suggests that responsiveness to TCDD and activation of the AhR receptor pathway is associated with melanoma, and that TCDD-activation of this pathway during melanoma progression alters expression of genes critical to metastasis.

1153 REGULATION OF EGR-1 BY TCDD IN HUMAN LUNG EPITHELIAL CELLS.

J. M. Martinez[1], S. Baek[2], T. E. Eling[2] and N. J. Walker[1]. *[1]Laboratory of Computational Biology and Risk Analysis, NIEHS, Research Triangle Park, NC and [2]Laboratory of Molecular Carcinogenesis, NIEHS, Research Triangle Park, NC.*

In humans exposed to 2, 3, 7, 8-tetrachlorodibenzo-p-dioxin (TCDD), there is an increased risk of lung cancer and development of chronic obstructive pulmonary disease. Because relatively little is known about the role of TCDD in pulmonary diseases, our objective was to investigate the mechanism of toxicity of TCDD using an *in vitro* human lung model. Using toxicogenomic analysis, we previously have shown that a plethora of genes are altered by TCDD in human lung cells. For the present study we investigated the regulation of early growth response 1 (Egr-1) gene since it was detected to be significantly altered by microarray analysis in both malignant (A549) and nonmalignant (HPL1A) cell lines exposed to TCDD for 24 hours. Egr-1 is a transcription factor that is a negative regulator of cell growth with antiapoptotic activity and can also enhance growth related to malignancy. Therefore, elevation of Egr-1 protein levels may be linked to tumor promotion activity of TCDD. To confirm that altered Egr-1 RNA levels lead to altered translation, we exposed HPL1A cells to 10 nM TCDD for 1, 3, 6, 24 or 48 hrs. By western blot analysis we found that levels of Egr-1 protein are higher in TCDD treated cells compared to vehicle treated cells at all time points tested. Using real time RT-PCR sybergreen detection, the relative fold increase of steady state mRNA for Egr-1 from TCDD treated HPL1A cells paralleled the protein expression profile. Our data show that there was a decreasing amount of both Egr-1 mRNA and protein over time, yet always higher in TCDD-treated cells. To investigate transcriptional activity of the Egr-1 promoter, cells were transfected with a plasmid containing the Egr-1 binding sites. A minimal increase in luciferase activity was detected in TCDD-treated cells. This modulation of Egr-1 expression by TCDD is likely through a post-transcriptional mechanism, such as mRNA stabilization that has previously been shown for other known TCDD altered genes.

1154 OVEREXPRESSION OF THE INTEGRIN-LINKED-KINASE PATHWAY IN HCB-TREATED FEMALE RATS.

I. Plante, D. G. Cyr and M. Charbonneau. *INRS-Institut Armand-Frappier, Montreal, QC, Canada.*

Hexachlorobenzene (HCB), a widespread environmental contaminant, causes gender-specific liver tumor promotion in the rat. Modulation of gene expression is the hallmark of epigenetic carcinogens such as HCB. We have previously shown that in female rats HCB causes significant decreases in mRNA and protein levels of the liver gap junction subunits, connexin 26 and connexin 32 (Cxs), and in gap junctional intercellular communication (GJIC). This study aim to assess the mechanistic basis for HCB-induced cell-cell changes by looking at modulation of signaling cascades. The Integrin-Linked-Kinase (ILK) phosphorylation pathway, which is overexpressed in many tumors, causes transformation of epithelial cells by disrupting cell-cell junctions. We hypothesize that HCB modulates the expression of the ILK pathway in female rats. Rats were exposed to HCB by gavage for five consecutive days and killed 45 days after the last dose, i.e. when Cxs are decreased. Western blot analysis showed a significant ($p \leq 0.05$) increase of ILK in treated rats compared to controls. Protein levels of Akt, a signaling target for ILK, and its phosphorylation

were significantly ($p \leq 0.05$) decreased; this suggests that the phosphorylation signal in HCB-treated females is relayed through another target protein, such as GSK3. ILK is known to phosphorylate GSK3 leading to translocation of beta-catenin from the cytoplasm into the nucleus. Assessment of nuclear beta-catenin showed higher levels in HCB-treated females compared to controls. In the nucleus the beta-catenin-Lef1 complex can down-regulate the expression of E-cadherin, a key cell-cell adhesion molecule. Western blot analysis showed that E-cadherin is significantly ($p \leq 0.05$) lower in HCB-treated rats compared to controls. Overall, results show that the ILK pathway is overexpressed in HCB-treated female rats. We propose that HCB promotes liver tumor formation by modulating GJIC and cell-cell junctions *via* an activation of the ILK pathway. (supported by the TSRI, Government of Canada)

1155 SPECIES DIFFERENCES IN THE INDUCTION OF HEPATOCELLULAR DNA SYNTHESIS BY DIETHANOLAMINE.

L. M. Kamendulis, D. J. Smith, Z. Jiao and J. E. Klaunig. *Department of Pharmacology and Toxicology, Indiana University School of Medicine, Indianapolis, IN.*

Diethanolamine increased the incidence and multiplicity of liver tumors in the mouse following chronic exposure. Diethanolamine inhibits cellular choline uptake. Choline deficiency produces tumors in rodents, therefore, diethanolamine, through depletion of choline, may result in tumor development in rodents. The potential for diethanolamine to function through this mode of action in humans is not known. The present study examined the effect of diethanolamine and choline depletion on DNA synthesis in primary cultured mouse, rat, and human hepatocytes. Hepatocytes were cultured with sublethal concentrations of diethanolamine (0 to 500 μg/ml) for 24 hours and DNA synthesis measured. In mouse and rat hepatocytes DNA synthesis was increased following treatment with 10 μg/ml diethanolamine and higher (3 to 4-fold over control). In contrast, diethanolamine failed to increase DNA synthesis in human hepatocytes. Incubation of hepatocytes in medium containing reduced choline (1/10 to 1/100 of normal medium; 0.898 mg/L to 0.0898 vs. 8.98 mg/L) for 24 hours increased DNA synthesis (1.6- and 1.8-fold of control in mouse and rat hepatocytes, respectively), however, choline depletion did not induce DNA synthesis in human hepatocytes. Mouse and rat hepatocytes incubated in medium supplemented with 2 to 50-fold excess choline reduced diethanolamine-induced DNA synthesis to control levels or below. In addition, gene expression analysis of mouse and rat hepatocytes following diethanolamine treatment revealed an increase in genes associated with cell growth and a decrease in expression of apoptotic genes. These results showed that the induction of DNA synthesis by diethanolamine was species specific and appears to be related to hepatocellular choline depletion. This mode of action for rodent hepatocarcinogenicity of diethanolamine may therefore not be relevant to humans.

1156 INHIBITION OF PANCREATIC CANCER CELL GROWTH BY PEROXISOME PROLIFERATOR-ACTIVATED RECEPTOR γ AGONISTS.

C. Qin[1], I. Samudio[2], J. Stewart[1], J. Lee[1] and S. Safe[1]. *[1]Veterinary Physiology & Pharmacology, Texas A&M University, College Station, TX and [2]Institute of Biosciences & Technology, Texas A&M University Health Science Center, Houston, TX.*

Peroxisome proliferator-activated receptor γ (PPARγ) is a ligand-activated nuclear receptor that belongs to the nuclear receptor superfamily of transcription factors. PPARγ is widely expressed in tumors from diverse tissue/organs, and PPARγ agonists such as prostaglandin J2 (PGJ2) inhibit growth of cancer cells through inhibition of cell cycle progression, induction of differentiation, and apoptosis. Treatment of Panc-1, Panc-3 and Panc-28 pancreatic cancer cells with 1 - 20 μM PGJ2 or the C-substituted diindolylmethane (DIM), 1, 1-bis(3'-diindolyl)-1-(*p*-trifluoromethylphenyl)methane (DIM-C-pPhCF_3) inhibited pancreatic cancer cell growth, and similar results were observed with ciglitazone. The growth-inhibitory effects observed for ciglitazone and DIM-C-pPhCF_3 were accompanied by decreased expression of cyclin D1 in Panc1 which could be inhibited by the proteasome inhibitor MG132 but not by the protease inhibitor calpain II. In contrast, PGJ2 did not affect levels of cyclin D1 protein in Panc1 cells, whereas in other cancer cell lines, all three PPARγ agonists (PGJ2, ciglitazone and DIM-C-pPhCF_3) induced proteasome-dependent degradation of cyclin D1. The mechanisms of action of these PPARγ agonists in other pancreatic cancer cell lines are currently being investigated to determine the contributions of cell context and PPARγ ligand structure on cyclin D1 expression and other pathways required for inhibition of pancreatic cancer cell growth.

1157 IPRODIONE-INDUCED RAT LEYDIG CELL TUMORS ARE MEDIATED BY TRANSIENT DECREASES IN PLASMA TESTOSTERONE.

J. Oberdoerster[1], A. Percy[2], F. Schorsch[2], P. Kennel[2] and R. Bars[2]. *[1]Toxicology, Bayer CropScience, Research Triangle Park, NC and [2]Toxicology, Bayer CropScience, Sophia-Antipolis, Alpes Maritime, France.*

Iprodione is a non-mutagenic fungicide that, following lifetime exposure at 70 mg/kg/day, is associated with benign Leydig cell (LC) tumors in the testes of rats. The rat is sensitive to the development of LC tumors by compounds that cause perturbations to the hypothalamic-pituitary-gonadal axis and so this mode of action was investigated. Following a single oral gavage administration of iprodione (0, 70, 300 mg/kg) a rapid, transient, and dose-dependent change in plasma testosterone (TST) and luteinizing hormone (LH) levels was observed. The greatest effect on TST was observed 2 h after dosing when 60 and 75% decreases in TST were detected at 70 and 300 mg/kg, respectively. The effects on LH were most marked 4 h post dosing when 36% and 55% increases in LH were noted at 70 and 300 mg/kg, respectively. TST and LH levels returned to normal 6-10 h following the acute iprodione exposure. To confirm that these effects occur following repeated exposure, iprodione was administered to male rats by oral gavage (6, 70, 300 mg/kg) for 14 days. TST levels on day 14 were significantly reduced at the high dose at up to 4 h post-dosing, as well as at 70 mg/kg/day at 2 h post-dosing. LH levels were significantly elevated in the 300 and 70 mg/kg dose groups at 4 h post-exposure. Both TST and LH levels returned to control levels within 24 h. In a separate 14-day study, assessment of LC proliferation using BrdU labeling revealed a dose-dependent increase in LC proliferation in animals treated with iprodione at 300 and 70 mg/kg/day (+74% and +36%, respectively). These data indicate that oral administration of iprodione results in a rapidly reversible hormonal imbalance that, upon repeated administration, is associated with an increase in LC proliferation. A clear threshold for hormonal change and LC proliferation occurs at 6 mg/kg/day. It is postulated that LC proliferation provoked by lifetime exposure to high levels of iprodione resulted in the tumors observed in the rat chronic study.

1158 IPRODIONE INHIBITS TESTOSTERONE BIOSYNTHESIS IN LEYDIG CELLS THROUGH A RAPID AND REVERSIBLE MECHANISM.

A. Percy[2], J. Oberdoerster[1], M. Benahmed[3] and R. Bars[2]. *[1]Toxicology, Bayer CropScience, Research Triangle Park, NC, [2]Toxicology, Bayer CropScience, Sophia-Antipolis, Alpes Maritime, France and [3]INSERM, Lyon, Rhone Alpes, France.*

Iprodione is a non-mutagenic fungicide that, following lifetime exposure, is associated with an increased incidence of benign Leydig cell (LC) tumors in the testes of male rats. Explanatory studies in the rat have demonstrated that iprodione administration results in decreased plasma testosterone (TST) and increased plasma luteinizing hormone (LH) levels. Experiments were undertaken to elucidate the mechanism of this iprodione-induced hormonal imbalance. Iprodione and its major metabolites did not bind to the androgen receptor or inhibit 5-alpha-reductase and addition of iprodione to culture media reduced TST secretion by rat testicular sections in a concentration-dependent manner. To evaluate effects on steroidogenic activity, LC were isolated from porcine testes and TST secretion evaluated following iprodione exposure. Iprodione-mediated inhibition of TST release was detected as early as 3 hours following exposure and occurred at a concentration of 1 ug/ml and above but not at lower concentrations. Two metabolites of iprodione demonstrated a similar inhibitory effect. Removal of iprodione from the culture medium reversed this effect. The iprodione-induced inhibition of TST secretion was observed when LC were stimulated with LH, agents that enhance cAMP production (i.e., cholera toxin, forskolin), or a cAMP analog. However, no effects of iprodione were observed on gonadotrophin-stimulated cAMP production indicating that the inhibition of TST secretion by iprodione is located downstream of cAMP production. The incubation of LC with 22-R hydroxycholesterol, a cholesterol substrate that does not require active transport to the mitochondria, antagonized the inhibitory effect of iprodione on TST synthesis, suggesting that iprodione prevents the active transport of cholesterol into the mitochondria. Thus, the results indicate that iprodione modulates LC steroidogenesis through a reversible inhibition of active cholesterol transport.

1159 THE EFFECTS OF THE BENZENE METABOLITES PHENOL AND CATECHOL ON C-MYB AND PIM-1 SIGNALLING IN HD-3 CELLS.

J. Wan[1] and L. M. Winn[1,2]. *[1]Pharmacology and Toxicology, Queen's University, Kingston, ON, Canada and [2]School of Environmental Studies, Queen's University, Kingston, ON, Canada.*

Exposure to the environmental toxicant benzene has been proposed to lead to carcinogenesis. Benzene is a known leukemogen and bone marrow suppressant in humans and in animals. While the mechanism of how benzene mediates leukemogen-

sis remains unknown, it is generally accepted that, in order for benzene to exert its toxicity, it first must be metabolized in the body by cytochromes P450 to metabolites such as phenol and catechol. During blood cell development the transcription factor c-Myb, plays a role in cell differentiation such that overexpression of the protein inhibits differentiation of induced erythrocytes. While little is known about the upstream activators that regulate c-Myb protein activity, c-Myb can be regulated by the serine/threonine kinase Pim-1. Mutated or overexpressed versions of the c-myb and pim-1 oncogenes are believed to play a pivotal role in the development of a wide variety of leukemias and other tumours. The objective of this study was to investigate the effects of the benzene metabolites phenol and catechol on the c-Myb and Pim-1 signalling pathway as a possible mechanism of benzene mediated leukemogenesis. To evaluate this objective, HD-3 cells were transfected with a Myb-responsive luciferase reporter plasmid derived from the chicken mim-1 promoter, along with control vector DNA or a plasmid expressing Pim-1. Cells were then exposed to phenol or catechol 1-24 hr before non-proprietary dual luciferase activities were measured in cell lysates. Results from this study revealed a time and concentration dependent increase in c-Myb activity after exposure to either phenol or catechol. Increased c-Myb activation upon exposure to catechol appeared to be Pim-1 independent, while the role of Pim-1 is currently being investigated in phenol activation of c-Myb. This study supports the hypothesis that benzene metabolites can mediate the signalling pathway involving the c-myb and pim-1 oncogenes. (Support: Canadian Institute of Health Research and Queen's University ARC)

1160 THE EFFECT OF PHENOBARBITAL ON CELL PROLIFERATION IN MICE DEFICIENT IN THE P50 SUBUNIT OF NF-κB.

J. C. Tharappel, H. P. Glauert and B. T. Spear. *Grad. Center for Nutritional Sciences, University of Kentucky, Lexington, KY.*

Phenobarbital (PB) is a nongenotoxic tumor promoter in the liver. One mechanism by which PB may exert its tumor promoting activity is by inducing oxidative stress. We previously found that PB administration increased hepatic NF-κB DNA binding activity. In this study we examined whether NF-κB is necessary for the induction of cell proliferation by PB. We used a mouse model that is deficient in the p50 subunit of NF-κB; previous studies had found that hepatic cell proliferation induced by PCBs or peroxisome proliferators was decreased in p50 -/- mice. Mice (p50 -/- and wild-type B6129) were fed a control diet or one containing 0.05% PB for 3, 10 or 34 days. At the end of the experiment, the mice were euthanized and livers removed and processed. At the 3 day time point, cell proliferation was significantly increased by PB in the p50 knockout mice but not in the wild-type mice. After 10 days, cell proliferation was significantly increased by PB in both p50 -/- and wild-type mice; genotype had no significant effect. At 34 days, cell proliferation was significantly increased in the p50 -/- mice compared to wild-type mice; phenobarbital slightly, but not significantly ($p = 0.17$), increased cell proliferation. These findings imply that the p50 subunit of NF-κB is not required for the induction of cell proliferation by PB at these time points. (Supported by ES11480)

1161 DIETHYLSTILBESTROL INDUCES CASPASE 6 ACTIVITY IN FEMALE ACI RATS.

L. R. Gued, R. D. Thomas and M. Green. *Pharmacy & Pharmaceutical Sciences, Florida A&M University, Tallahassee, FL.*

Diallyl sulfide (DAS) is a component of garlic that prevents cancer in several animal models. Its chemopreventive effects are attributed to modulation of enzymes. Diethylstilbestrol (DES) is a synthetic estrogen that causes breast cancer in female ACI rats following metabolism to reactive oxygen species (ROS). We previously showed that DAS inhibits DES-induced ROS. Caspase activation is associated with ROS in some models, yet there is little information on their role in DES-induced carcinogenesis. Caspases are aspartic acid-specific proteins constitutively expressed in the inactive form that are activated after proteolytic cleavage. Caspases 8 and 9 are upstream, and caspases 3 and 6 are downstream caspases that cleave critical cellular proteins resulting in apoptosis. Our purpose was to study the roles of caspases in the early stages of DES-induced carcinogenesis and the impact of coadministering DAS. Using female ACI rats, Group 1 was a control. Group 2 received 50 mg/kg DAS for 4 weeks. Group 3 received corn oil for 1 month with 15 mg of DES implanted after 2 weeks. Group 4 received 50 mg/kg DAS for 4 weeks with 15 mg of DES implanted after 2 weeks. 125-ug protein from breast tissue were incubated with caspase-specific fluorophores and analyzed by fluorescent assay. Relative fluorescence was measured by comparison to an uninduced control per sample. Exposure to DES resulted in a significant increase in mean caspase 6 activity relative to the controls; caspases 3, 8 and 9 activities were also significantly higher. The magnitude of caspase 6 and 8 activity was a factor of 10 greater than 3 and 9. Exposure to DAS induced caspase 3 activity and inhibited caspase 9 activity with no effects on either caspases 6 or 8. Coadministration of DAS/DES potentiated caspase 8 activation relative to the DES group. We showed for the first time that caspase 6 induction occurs early in DES-induced breast carcinogenesis in a mechanism not mediated by ROS. We conclude that manipulation of caspase 6 may provide opportunities for chemoprevention in estrogen-induced breast cancer.

1162 ALTERED RESPONSE OF TSC2-NULL RENAL EPITHELIAL CELLS TO THE PHORBOL ESTER TPA.

T. M. Kolb, L. Duan and M. A. Davis. *Pathology, University of Maryland School of Medicine, Baltimore, MD.*

Loss of tumor suppressor protein expression or function dramatically alters cellular responses to chemicals. The phorbol ester tumor promoter, 12-O-tetradecanoylphorbol 13-acetate (TPA), stimulates cell proliferation through a rapid activation of protein kinase C (PKC), followed by gradual degradation of the kinase. TPA also activates the GTPase Rap1 in some cell types. Tsc2 has a proposed GTPase activating protein (GAP) function for Rap1, and we have observed an increase in PKC expression in Tsc2-null cells. Therefore, we wanted to compare the cellular response of Tsc2-null (ERC-18) and Tsc2-competent (NRK-52E) cells to this tumor promoter. Morphologic changes in ERC-18 cells treated with 100 ng/ml TPA for 24 hours were consistent with apoptosis (shrinkage, rounding, some evidence of blebbing). NRK-52E cells showed no morphologic change after 24 hours of TPA treatment. Cyclin D1 expression and MPM2 phosphorylation were used as indicators of proliferation, and neither increased during treatment. Although no substantial increases in Rap1 activity (GTP-bound Rap1) or PKC phosphorylation were observed after 5, 15, or 60 minutes of TPA treatment in either cell type, phosphorylation of ERK, a reported downstream effector of both PKC and Rap1, was markedly increased in ERC-18 cells after 5 minutes of TPA treatment, and the increase was sustained over the first hour of treatment. ERK phosphorylation also increased in NRK-52E cells after 5 minutes, but rapidly returned to control levels within 1 hour. After 24 hours of TPA treatment, PKC phosphorylation was decreased only in ERC-18 cells. The specific PKC inhibitor bisindolylmaleimide VIII acetate also induced morphologic changes (shrinkage, rounding) in ERC-18, but not NRK-52E cells. These results imply that the response of Tsc2-null renal epithelial cells to TPA appears to be dependent on changes in PKC phosphorylation, not Rap1 activation.

1163 NNK RESTORED THE CAP-DEPENDENT PROTEIN TRANSLATION BLOCKED BY RAPAMYCIN.

J. Kim[1,2] and M. Cho[1,2]. [1] *Toxicology, College of Veterinary Medicine, Seoul National University, Seoul, South Korea and* [2] *Toxicology, School of Agricultural Biotechnology, Seoul National University, Seoul, South Korea.*

Eukaryotic translation initiation factors play an important role in the control of protein translation and regulated by distinct factors. Among the regulatory factors, eIF4E and its binding protein 4E-BP1 have focused the most attention. The reversible binding between eIF4E and 4E-BP1 can be maintained through phosphorylation state of 4E-BP1. Rapamycin has shown to affect translation by changing state of phosphorylation of 4B-BP1. In this study, the effect of NNK on protein translation was examined on human bronchial epithelial cells (NL-20 cells). Following incubation with rapamycin, various concentrations of NNK were treated on NL-20 cells. The concentration of NNK was determined by MTT assay and the results showed the normal cell viability during the test period. De novo protein synthesis was measured through the incorporation of 35S-Met into NL-20 cells and the result revealed that NNK increased protein synthesis compared to rapamycin alone. In Western blot, rapamycin blocked phosphorylation of 4E-BP1, and decreased the eIF-4E protein. However, NNK restored the rapamycin-induced phosphorylation of 4E-BP1 and increased eIF4E level in a concentration-dependent manner. The alterations of the protein expression level of cyclin D1, cyclin E, cyclin A, cyclin B, cyclin G, p53, p21 and other related protein (c-myc, Erk1) were analyzed. Our results showed that cyclin D1, cyclin E, cyclin G and Erk1 were over-expressed in all groups of NNK with rapamycin, while cyclin A, cyclin B, p53, p21 and c-myc had no crucial change in NNK with and without rapamycin. Therefore, rapamycin blocked cap-dependent protein translation, decreased de novo protein synthesis, however, NNK restored phosphorylation of 4E-BP1, and increased eIF4E, cyclinD1, cyclinE, cyclinG and Erk1. These results suggest that NNK can pertubate the protein translation, and cell cycle control through cap-dependent pathway in NL-20 cells. Supported by BK21

1164 DISSOCIATION OF PRIMARY PATHOLOGIC CHANGES FROM SECONDARY INFLAMMATORY EFFECTS IN PHOSPHODIESTERASE INHIBITOR-INDUCED VASCULOPATHY.

D. Robertson , R. Slim , M. Albassam, M. D. Reily, D. Wells, J. Provost and L. A. Dethloff. *Drug Safety Evaluation and Discovery Technologies, Pfizer Global Research and Development, Ann Arbor, MI.*

This study was conducted to discern primary pathologic events from secondary inflammatory changes associated with Phosphodiesterase (PDE) inhibitor-induced vasculopathy in rats. We also aim to ascertain whether metabonomic changes associated with this vasculopathy reflect secondary inflammatory changes or primary

pathologic effects. Mesenteric vasculopathy was induced in rats by 3 daily oral doses of the PDE IV inhibitor CI-1018 at 750 mg/kg. The inflammatory component of the lesions was diminished by administration of the glucocorticoid dexamethasone or by depleting peripheral blood neutrophils with rabbit anti-rat PMN antiserum (ANS). Metabonomic analysis was conducted on urine samples and select mediators, thought to be involved in PDE inhibitor-induced vasculopathy, were assayed. Serum interleukin-6 was measured by enzyme immunoassay, plasma endothelin-1 (ET-1) was determined by radioimmunoassay, and inducible nitric oxide synthase (iNOS) and the cleaved form of caspase-3 was determined by immunohistochemistry. DEX or ANS decreased the incidence and severity of vascular lesions induced by CI-1018, but a characteristic minimal vascular lesion remained in the absence of inflammatory infiltrates. In rats given CI-1018 alone, increases in serum IL-6 were observed, accompanied by increased immunoreactivity of medial smooth muscle cell and endothelium/inflammatory cell infiltrates for caspase-3 and iNOS, respectively. Plasma levels of ET-1 were decreased. Inhibition of the inflammatory response by DEX attenuated changes in IL-6, ET-1, iNOS, and caspase-3. In metabonomic studies, principal component pattern separation between control samples and samples from rats given CI-1018 in the presence or absence of DEX or ANS were evident. These data suggest that metabonomic profile shifts induced by CI-1018 may be associated with primary pathologic changes while changes in IL-6, ET-1, iNOS, and caspase-3 reflect secondary inflammatory responses.

1165 IDENTIFICATION OF BIOMARKERS FOR WITHERING SYNDROME IN RED ABALONE USING NMR-BASED METABONOMICS.

M. R. Viant, E. S. Rosenblum and R. S. Tjeerdema. *Environmental Toxicology, University of California, Davis, CA.*

Physical, chemical and biological stressors can induce adverse biochemical effects within marine organisms, including alterations in gene expression, protein concentrations, and metabolic status. Whereas transcriptomics and proteomics have emerged as powerful tools for assessing the effects of stressors in the aquatic environment, metabonomics has yet to receive attention. High-resolution nuclear magnetic resonance (NMR) spectroscopy is particularly appropriate for investigating metabolic status, since potentially hundreds of endogenous metabolites can be quantified rapidly in tissues or biofluids, with minimal sample preparation. This approach will be illustrated by our study of withering syndrome (WS) in red abalone (*Haliotis rufescens*), an important aquaculture species along the Californian coast. Although of bacterial origin, recent studies suggest that the presence of the pathogen in combination with elevated seawater temperatures can synergistically stimulate WS pathogenesis. Before investigating the potential roles of environmental stressors, including pollutants, biomarkers of WS must first be identified. As such, one-dimensional ^{1}H NMR spectra of hemolymph, digestive juice, and perchloric acid extracts of foot muscle and digestive gland, from both healthy and diseased abalone have been recorded. Many metabolites have been identified and subsequently confirmed by two-dimensional NMR methods. Preliminary principal component analyses of the foot muscle data have revealed several differences in metabolite levels between healthy and diseased animals. These include decreased levels of valine, alanine, carnitine, glycine, tyrosine, phenylalanine and glycogen, and elevated lactate, betaine and taurine in withered abalone. Analyses of the other tissues and biofluids are underway. The identification of biomarkers will provide a powerful tool for characterizing the effects of stressors on WS pathogenesis and for determining the efficacy of feed-based antibiotics that are currently under development.

1166 GLOBAL PROTEOMICS FOR HUMAN BLOOD SERUM I: MULTIDIMENSIONAL SEPARATION OF PEPTIDES COUPLED WITH MASS SPECTROMETRY.

J. N. Adkins[1], S. P. Varnum[1], K. J. Auberry[1], R. J. Moore[1], N. H. Angell[2], D. S. Wunschel[1], R. D. Smith[1], D. L. Springer[1] and J. G. Pounds[1]. *[1]Biological Sciences, Pacific Northwest National Laboratory, Richland, WA and [2]Human Genome Science, Rockville, MD.*

The importance of early detection in many human diseases has been well documented. New methods taking advantage of the rapid advancements in mass spectrometry are now being used to identify new biomarkers linked to human disease. Proteins in human serum range in concentration over at least 7 orders of magnitude, while the most advanced mass spectrometry technologies allow measurement of proteins with concentration ranges up to about 5 orders of magnitude. One method to reduce the concentration range would be to remove or deplete high abundance proteins, such as albumin. This study uses a combination of powerful mass spectrometry technologies with improvements in sample preparation to perform a global proteomic analysis of the proteins found in human serum. This analysis can then be used as a foundation for measuring differences in protein content and concentrations of serum samples with onset and progression of disease. Two complementary sample preparation methods were compared to ascertain differences. The first method depleted immunoglobulin content from serum and used strong cation exchange chromatography (SCX) of the trypsin-digested serum peptides for analysis by capillary reversed-phase liquid chromatography (LC) with ion trap tandem mass spectrometry. This method successfully identified 500 serum proteins in about 80 fractions. A complementary second method removes immunoglobulins and albumin, and selects for cysteine containing peptides. 87 proteins were identified with this method, in a single fraction. 70% of these proteins were identified in the previous analysis.

1167 IDENTIFICATION OF DOXORUBICIN-INDUCED CHANGES IN PROTEIN FEATURES IN RAT SERA USING CLUSTER ANALYSIS AND EXPRESSION PROFILING.

P. Pine[1], E. H. Herman[1], J. Zhang[1], A. D. Knapton[1], G. Holt[2] and F. D. Sistare[1]. *[1]DAPR, CDER, USFDA, Laurel, MD and [2]Oxford Glycosciences, Ltd, Abingdon, United Kingdom.*

Two-dimensional gel electrophoresis is a powerful technology that can be used to discover biomarkers associated with drug toxicity. The present study was initiated to determine whether specific proteins associated with doxorubicin (DOX)-induced cardiotoxicity could be identified using this methodology. Serum samples were collected from male spontaneously hypertensive rats (SHR) treated with DOX, with/without pretreatment with the cardioprotectant dexrazoxane (DZR). Protein features from the 2-D gels were measured using quantitative image analysis to create protein expression maps (PEMs). To compare PEMs, the signal intensities for each feature were assigned to an index of corresponding pI and relative molecular mobility (RMM) coordinates. Principal component analysis (PCA) and hierarchical cluster analysis (HCA) were used to test the ability of the PEMs to discriminate between treatments. Expression profile matching was used to identify protein features that displayed a particular pattern of interest. Animals that were treated with either saline or DZR clustered together, indicating that the cardioprotectant had little effect on serum proteins by itself. The animals treated with DZR-DOX clustered together but fell between the controls and the DOX cluster of animals, consistent with the partial attenuation seen in the myocardial lesion scores and cardiac troponin T levels observed with DZR pretreatment. Several protein features that correlated with a pattern of complete or partial protection by DZR pretreatment could be identified using expression profile matching. Some of those features that have been identified and annotated include: alpha-1-antiproteinase, fibrinogen, anti-thrombin III, and several apolipoproteins, suggesting the presence of a chronic underlying systemic immune response to the cardiac tissue injury. These data indicate that 2-D gel analysis of serum identified a consistent set of protein features correlating with both myocardial injury and cardioprotectant activity.

1168 MEASUREMENT OF BLOOD BREVETOXIN LEVELS BY RADIOIMMUNOASSAY OF BLOOD COLLECTION CARDS AFTER ACUTE, LONG-TERM AND LOW DOSE EXPOSURE IN MICE.

J. Ramsdell[1], R. Woofter[1], M. Bottein Dechraoui[1], I. Garthwaite[2], N. R. Towers[2] and C. J. Gordon[3]. *[1]Marine Biotoxins Program, NOAA, Charleston, SC, [2]Food Science Ruakura, AgResearch, Hamilton, New Zealand and [3]NEEHRL, USEPA, Research Triangle Park, NC.* Sponsor: E. Levin.

Blood collection cards provides an efficient sample collection, storage and extraction format for biomonitoring toxins in living animals. One potential application of this method is to assess exposure to brevetoxin during red tide events. This report evaluates a radioimmunoassay (RIA) using a sheep anti-brevetoxin serum to detect brevetoxin extracted from blood dried on cotton fiber filter cards from mice treated with the brevetoxin congener (PbTx-3). The RIA has high affinity for PbTx-3 (EC50= 1.2 nM (n=10)) and recognizes both type 1 and type 2 brevetoxins. We first analyzed a sample set from an acute time course exposure, using a maximal non lethal dose (180 μg/kg) for 0.5, 1, 2, 4 and 24 h. Blood brevetoxin levels were at mean levels of 36 nM at 30 minutes and maintained levels above 25 nM during the 1-4 h time points. We next analyzed blood brevetoxin exposure after longer durations (0.5, 1, 2, 3, 4 or 7 days). Mean blood brevetoxin levels were measured at 26.0 nM at 12 h decreased to 8.2 nM at 1 day and 1.3 nM at day 2. Values at days 2-7 were higher but not significantly different from vehicle treated animals. We next determined the lowest measurable dose using increasing concentrations of PbTx-3 (10-300 μg/kg). Analysis of the blood samples at 60 min, revealed a linear relationship between external and internal dose (r2 = 0.993). All doses of brevetoxin administered were detectable at 1 h with the significant levels found for the lowest administered dose of 10 μg/kg, a dose that was ten fold lower than that which caused observable symptoms. Radioimmunoassay provided sensitive detection with minimal interference of residual matrix following extraction of dried blood from

the cards and allowed detection of brevetoxin at doses ten times lower than the lowest observable effect level and at times up to two days after exposure. This work does not necessarily reflect NOAA or EPA policy.

1169 COMPARATIVE ANALYSIS OF REACTIVE OXYGEN SPECIES IN HUMAN PLASMA AND BLOOD.

R. Sams, C. Carty, M. Schmitt, J. Inmon, S. Rhoney, E. Hudgens, R. Calderon and J. Gallagher. *Human Studies Division, USEPA, Research Triangle Park, NC.*

Reactive oxygen species (ROS) are commonly associated with diseased states (including asthma, cardiovascular disease, cancer) infections, and exposure to various toxicants in humans. It is of interest in epidemiology studies to characterize the association of oxidative stress in relation to health/exposure status to ascertain which biological media, plasma or whole blood, is a more sensitive measure of ROS. In our study we evaluated differences between plasma and whole blood in the levels of ROS-induced chemiluminescence (using lucigenin as a chemiluminescence agent) measured simultaneously from the same individuals (n=194 human subjects) over a 3-week study. Mean ROS-induced chemiluminescence measured in plasma (590.8 ± 193.6; mean ± SD; Relative Luminescence Units (RLU)) was approximately 2-fold greater (significant at $p \leq 0.001$) in comparison to whole blood (280.7 ± 204.6; RLU). Although whole blood ROS levels were less than plasma ROS levels, we did observe that the inter-individual variation was greater for whole blood compared to plasma. These data suggest that human plasma is a more sensitive biological matrix to measure the levels of ROS-induced chemiluminescence. We have an opportunity to assess associations between ROS levels and modulators of ROS including diet, age, gender, and smoking status. This abstract does not necessarily represent USEPA policy.

1170 BIOAVAILABILITY OF BISPHENOL A: PREDICTION OF ESTROGEN DISRUPTION IN HUMANS.

H. D. Luu[1], C. S. Kim[2], P. P. Sapienza[2], I. A. Ross[2], W. D. Johnson[2] and J. C. Hutter[1]. *[1]CDRH, USFDA, Rockville, MD and [2]CFSAN, USFDA, Laurel, MD.*

We are concerned over the potential low dose and long term exposure of the general population to exogenous dietary xenoestrogens like bisphenol A (4, 4' -isopropylidene-2-diphenol, BPA). BPA exposure may occur in humans since BPA is found in the lining of food cans and dental sealants. We developed a PBPK/PD model to simulate the distribution of BPA and endogenous estrogen (E2) with serum hormone binding globulins (SHBG) and albumin (ALB). The model used blood and tissues concentrations following oral low and high doses of 14C-BPA in female F-344 rats to estimate tissue distribution coefficients, metabolism and excretion parameters. The model was used subsequently to predict the plasma E2 bound to SHBG (E2-SHBG), ALB (E2 -ALB) and free fractions of E2 of British and Japanese women since we hypothesize that BPA could indirectly alter free E2 level, and a good correlation was reported to exist between estrogen bound (E2-SHBG and E2-ALB)and rates of breast cancer in these women. We propose using the model predictions with the plasma SHBG/ALB bindings as alternative tests to predict the effects of endocrine disruptors.

1171 BIOLOGICAL MONITORING OF BISPHENOL A IN A KOREAN POPULATION.

M. Yang[2], S. Park[2], C. Kim[2], S. Kim[3] and T. Kawamoto[1]. *[1]Preventive Medicine, Seoul National University, Seoul, South Korea, [2]Preventive Medicine, Eulji University, Daejon, South Korea and [3]Environmental Health, University of Occupational and Environmental Health, Kitakyushu, Japan.*

To conduct biological monitoring of environmental exposure to bisphenol A (BPA), which has potential of endocrine disruptor, we analyzed conjugated BPA in blood and urine in a Korean population (N = 60) using reverse phase- HPLC/FD (average levels of serum- and urinary BPA, 1.5 ng/ml (range, 0-36 ng/ml) and 5.63 ng/ml (range, 0-147 ng/ml), respectively). After geometric transformation of the levels, we found a positive association between serum- and urinary BPA levels (p = 0.03). The level of serum-BPA was approx. 3-fold lower than that of urinary BPA. For proper BPA biological monitoring, host susceptibility need to be investigated. For this purpose, we further studied effects of genetic polymorphism, R184S occurred in exon 1, in UDP-glucuronosyltransferase (UGT) 1A6, which are involved in BPA metabolism. Genotyping was done by real time PCR with our designed primers and probes. As results, allele frequency of wild (w) and mutant (m) was 0.83 and 0.17, respectively and followed Hardy-Weinberg's law. Average levels of serum- and urinary BPA were higher in w/w subjects (N = 40) than others (N = 20: w/m, 18; m/m, 2). However, it was not significant (p = 0.10 and 0.32 in serum- and urinary BPA, respectively). As UGT1A6 genetic polymorphism affects its activity, metabolism of BPA can be affected by UGT1A6 genetic polymorphism. Further enlarged study is required to clarify effects of UGT1A6 genetic polymorphism on BPA.

1172 PITFALLS OF BROAD-BASED CHEMICAL SCREENING OF FIRE RESPONDERS IN CALIFORNIA: A FALSE ALARM ON CYANAZINE HERBICIDE.

M. J. Fedoruk[2] and B. D. Kerger[1]. *[1]HSRI, Inc., Tallahassee, FL and [2]Center for Occupational and Environmental Health, University of California, Irvine, Irvine, CA.*

This case study describes a medical toxicology review on chemical screening tests administered to fire fighters, police, and others who responded to a 2-week long smoldering fire at a greenwaste processing facility in southern California. A few of the nearly 200 fire responders reported health complaints about 4 weeks after fire ended. Blood testing for an herbicide panel revealed presumably high amounts of blood cyanazine, a triazine herbicide that is carcinogenic in animals. Normal range data were not available on blood cyanazine due to its relatively limited applications. Based on the initial findings, other fire responders were offered screening that again revealed frequently elevated values. Several patients were advised that their elevated blood cyanazine levels may indicate appreciable risks of cancer. More focused evaluation of the cyanazine data revealed high blood cyanazine levels in control subjects and others with little or no contact with the site or fire emissions. Repeat samples in some individuals showed higher cyanazine levels weeks after initial blood sampling. No dose-response trends were apparent, even among individuals with expected high exposure duration and magnitude. Also, cyanazine was not registered for use in southern California, and would be readily destroyed by fire. Subsequent investigations revealed the cyanazine findings were anomalous; the clinical assay for this rarely tested pesticide exhibited an interference from blood caffeine (and therefore frequent false positives). Moreover, cyanazine exhibits relatively rapid excretion (within days), and hence would not be expected to remain elevated from an exposure that ended several weeks earlier. We conclude that broad-based chemical screening, in the absence of well founded study design and cautious interpretation and validation relative to exposure factors, can adversely affect the monitored population by inducing unwarranted fears and anxiety and by generating unnecessary medical screening and treatment costs.

1173 VALIDATION OF FUMONISIN BIOMARKERS IN HIGH-RISK POPULATION OF LIVER CANCER.

M. Lian[1,2], Y. Yang[1,2], J. Su[3], T. Huang[3], Z. Wei[4], Y. Liang[4], H. Luo[1,2], S. Wang[5], G. Sun[5] and J. Wang[1,2]. *[1]Environmental Toxicology, Texas Tech University, Lubbock, TX, [2]The Institute of Environmental and Human Health, Texas Tech University, Lubbock, TX, [3]Guangxi Cancer Institute, Nanning, China, [4]Fusui Liver Cancer Institute, Fusui, China and [5]Southeast University School of Public Health, Nanjing, China.*

Fumonisins (FNs), especially fumonisin B1 (FB1), are carcinogens and strong tumor promoters in animal models. Human populations in certain areas of world are exposed to higher levels of FNs through contaminated dietary components. FB1 has been linked to high incidence of primary liver cancer in certain areas of China. FB1- induced biochemical alterations in animal and human cell models, such as disruption of sphingolipids metabolism, has been proposed to serve as potential biomarkers; however, validation of these biomarkers in humans, especially in high-risk populations has not been done. In this study, we collected a total of 155 urine and blood samples from residents of three villages in Fusui County, Guangxi, China. These areas have very high liver cancer incidence and mortality rates. Metabolites of sphingolipids, sphinganine (Sa) and sphingosine (So), were measured using the method of HPLC-fluorescent detection with D-erythrosphingosine (C20) as the internal standard. The measured levels of Sa and So were normalized with the urinary creatinine level. The average ratio of Sa/So urine samples (n=155) is 0.29 with 95% of confident limit (CI) at 0.24-0.34. Female samples (n=55) had higher average ratio of Sa/So (0.37, 95% CI: 0.27-0.49) than the ratio obtained from males (n=100), which average ratio is 0.25 with 95% CI: 0.20-0.31. Dietary intake of FB1 was monitored for 1 week in a sub-study group that consisted of 19 males and 15 females from different households among the studied population. FB1 was detectable in 30 out of 34 (88.2%) food samples collected from household of study participants. Daily intake of FB1 was greatly varied among participants and ranged from 25 ug/person to 1, 083 ug/person. The association between dietary exposure to FB1 and metabolites of sphingolipids in blood and urine was further examined. (Supported by the NCI grant CA94683).

1174 ANALYSIS OF URINARY 1, 1, 2, 2-TETRACHLOROETHYLENE (PERC) METABOLITES BY HPLC ELECTROSPRAY IONIZATION TANDEM MASS SPECTROMETRY (ESI-MS/MS) AS POTENTIAL EXPOSURE BIOMARKERS.

K. L. Cheever, K. Marlow, A. Ruder, C. Forrester, L. Taylor and M. Butler. *NIOSH, Cincinnati, OH.*

The industrial solvent and dry cleaning agent, PERC (CAS 127-18-4), produces liver tumors in mice and nephrotoxicity and renal tumors in male rats. This toxicity may involve reactive intermediates which could induce similar toxicity in workers. Bioactivation of PERC is reported to occur by oxidation by CYP2E1 and GSH. Trichloroacetic acid (TCA) and dichloroacetic acid (DCA) are reported PERC urinary metabolites and the GSH conjugate is cleaved to S-(1, 2, 2-trichlorovinyl)-L-cysteine (TCVC) and acetylated to N-ac-TCVC. A biomonitoring method was developed to measure urinary levels of TCA, DCA, TCVC and N-ac-TCVC with deuterated TCVC, N-ac-TCVC and DCA as internal standards. Samples were loaded onto SPE columns and PERC metabolites were eluted with acetone, dried and diluted in MeOH for HPLC ESI-MS/MS analysis on a Phenomenex Jupiter C18 column. A 10-min linear gradient (55:45 H2O:MeOH 1% acetic acid to MeOH 1% acetic acid) at 300 µL/min eluted the compounds of interest within 12 min. The mass spectrometer was operated using ESI-MS/MS, initially in the negative ion mode for detection of TCA and DCA, and subsequently in the positive ion mode for TCVC and N-ac-TCVC. Some urine samples from laundry workers with no demonstrated PERC exposure and dry cleaning workers that were potentially exposed to PERC during loading or unloading of garments contained detectable amounts of PERC metabolites in urine collected during pre or post-shift periods. The limit of detection (LOD) was 0.47 pmol for TCVC, 0.8 pmol for N-ac-TCVC, 11.45 pmol for DCA, and 7.17 pmol for TCA. A small number of samples contained amounts of PERC metabolites that exceeded the limit of quantification (LOQ) - 4.68 pmol for TCVC, 8.03 pmol for N-ac-TCVC, 114.5 pmol for DCA, and 71.73 pmol for TCA. The analysis appears to offer significant advantages over typical extraction and derivatization procedures required for GC-MS analysis of these compounds. Thus, PERC internal exposure levels may be quantified by HPLC ESI-MS/MS analysis of these metabolites.

1175 LEVELS OF POLYCYCLIC AROMATIC HYDROCARBONS IN AMNIOTIC FLUID SAMPLES FROM SMOKERS AND NONSMOKERS.

S. R. Myers, C. Cunningham and J. Weeks. *Pharmacology and Toxicology, Center for Environmental and Occupational Health Sciences, University of Louisville, Louisville, KY.*

Previous studies from this laboratory have focused on the characterization of blood protein adducts formed *in utero* as a result of maternal smoking during pregnancy. These biological samples, obtained during the third trimester of pregnancy, at delivery, have clearly shown a correlation between maternal smoking and exposure of the fetus to tobacco smoke carcinogens, including 4-aminobiphenyl and benzo(a)pyrene. In the present study, we examined exposure of the fetus during the first trimester of development to various environmental carcinogens, particularly those found in tobacco smoke. Amniotic fluid samples were obtained from women undergoing routine amniocentesis at between 16 and 20 weeks gestational age. Amniotic fluid, produced by the fetal lungs and kidneys, is an important part of pregnancy and fetal development and this fluid surrounds the fetus throughout pregnancy. In these studies, samples of amniotic fluid were obtained from nonsmokers as well as 0.5 pk/da smokers through >2pk/da smokers. Amniotic fluid samples were extracted and analyzed by HPLC and GC/MS for the presence of polycyclic aromatic hydrocarbons (PAHs). Amniotic fluid levels of PAHs were found in almost all samples analyzed. However, there was a clear correlation between levels of maternal smoking and PAHs in the amniotic fluid. 1-hydroxypyrene levels ranged from 1.54 ± 0.12 µg/ L in nonsmokers to 11.72 ± 0.67 µg/L in women smoking >2 pks/da, indicating approximately a 10X increase over nonsmokers. Similar results were found with more widely established carcinogens, including hydroxylated benzo(a)pyrene derivatives, which ranged from 1.41 ± 0.13 µg/L in nonsmokers to 11.56 ±0.59 µg/L in >2pk/da smokers. These results indicate that exposure to harmful environmental carcinogens can occur during early gestational periods and may place the fetus at a risk of genotoxic as well as teratogenic events.

1176 HYPOURICOSURIA, A BIOMARKER OF INORGANIC ARSENIC EXPOSURE.

L. M. Del Razo[1], E. A. Garcia-Montalvo[1], O. L. Valenzuela[1] and M. B. Cruz-Gonzalez[2]. *[1] Toxicology, Cinvestav-IPN, Mexico City, Mexico and [2] Health Services, SSA, Pachuca,, Hidalgo, Mexico.*

Arsenic (As) is a human carcinogen, affecting million of people worldwide. Most ingested As is excreted in the urine within a few days, making measurements of urine As a good biomarker of recent As exposure. However, other biomarkers for assessing continue As exposure or toxic As effect are necessary. The catabolic steps that generate uric acid from nucleic acids and free purine nucleotides involve degradation through purine nucleoside intermediates to hypoxanthine and xanthine. The latter are ultimately oxidized to uric acid in man using sequential reactions catalyzed by the enzyme xanthine oxidase. In rats, the presence of uricase transforms uric acid to allantoin. Arsenite (AsIII) complexed xanthine oxidase preventing reduction of the enzyme by purines. This effect causes xanthinuria and hypouricosuria. Urine is the preferential material for screening of abnormal metabolism of purines. Three different models of arsenite (AsIII) exposure were evaluated, human or rats exposed chronically and mice exposed to 0, 3, 6 and 10mg/kg daily during 9 days. Urinary uric acid from 97 individuals chronically exposed to water naturally contaminated with As content (129 ppb) were significantly lower (2.4 mg/L) than those found in 28 control people (3.2 mg/L). Urinary levels of uric acid in rats treated daily with 1.2 mg As/kg v.o during six weeks were evaluated. A significant decrease of uric acid concentrations in the urine was observed during the first 3 weeks of As exposure. Significant dose-response decrement of urinary uric acid was observed in mice treated orally during 9 days with arsenite. These results suggest that uric acid may be a useful easy biomarker for assessing continue As exposure.

1178 ANALYSIS OF PLASMA AND URINE FOR METABOLITES FOLLOWING INHALATION EXPOSURE OF FEMALE AND MALE MICE AND RATS TO 1, 3-BUTADIENE OR 1, 2-DIHYDROXY-3-BUTENE.

D. Walker, R. Henderson, J. McDonald, D. Kracko, W. Blackwell and V. Walker. *Lovelace Respiratory Research Institute, Albuquerque, NM.*

1, 2-Dihydroxy-3-butene (ene-diol) is a marker for the flux through the hydrolysis detoxication pathway of butadiene (BD) that leads to the major human urinary metabolite, M1 (diolmercapturate). Ene-diol is also the precursor to 1, 2-dihydroxy-3, 4-epoxybutane (EBD), which is the major source of BD-induced protein and DNA adducts in all species studied. To characterize the impact of ene-diol formation during BD metabolism *in vivo*, we evaluated the levels of ene-diol as well as the urinary metabolites MI and MII (monohydroxy mercapurate) in mice and rats following inhalation exposure to BD or directly to ene-diol. Metabolites were analyzed by gas chromatography equipped with mass selection detection, with both the cis- and trans-isomers measured as total ene-diol. In mice and rats necropsied immediately after nose-only exposure to 0, 62.5, 200, or 625 BD for 6 h, the dose-response curves for ene-diol in plasma had positive curvature (e.g., in control and BD-exposed female mice, the respective plasma levels were 0, 0, 171 ± 6 ng/ml, and 10, 480 ± 3, 320 ng/ml). MI and MII in 24 h urine samples were increased above background after BD exposures, but only MI was increased after exposure of animals to 6 or 18 ppm ene-diol for either 6 h or for 4 weeks (6 h/day, 5 days/wk). Lower levels of ene-diol, compared with MI, were also detected in urine samples from animals exposed to BD or ene-diol (e.g., in female rats exposed to 200 ppm BD, the levels of ene-diol and MI were 41 ± 2 ng/mL plasma and 44 ± 20 mg/mL urine, respectively). Repeated exposures to these levels of ene-diol led to increased frequencies of *Hprt* mutations in mice and rats (see companion abstract by Q. Meng *et al.*). The study indicates that ene-diol is rapidly cleared after low-level (< 200 ppm) BD exposures but accumulates following high-level exposures. Further studies are needed to determine the fraction of ene-diol that is cleared *via* formation of the EBD compared to excretion of ene-diol and M-I.

1179 URINARY (2-METHOXYETHOXY)ACETIC ACID: AN EFFECTIVE GAS CHROMATOGRAPHIC TEST METHOD FOR QUANTIFICATION.

C. -. B'Hymer, M. Butler and K. L. Cheever. *DART, National Institute of Occupational Safety and Health, Cincinnati, OH.*

(2-Methoxyethoxy)acetic acid (MEAA) is a metabolite and biomarker for exposure to 2-(2-methoxyethoxy)ethanol (diethylene glycol monomethyl ether, DEGME, or DiEGME) and bis(2-methoxyethyl) ether (diglyme); both are glycol ethers and are of concern because of the general toxicity of these compounds. Glycol ethers have been frequently reported to damage the male reproductive system, hemaopietic system, and fetal/embryonic development. Occupational exposure by these widely used glycol ethers is likely, since they are readily absorbed through the skin. Specifically, 2-(2-methoxyethoxy)ethanol is used as an anti-icing additive to the military jet fuel JP-8, and bis(2-methoxyethyl) ether is an aprotonic solvent with industrial uses and is a component of some hydraulic fluids including brake fluid. A simple and effective general test method for MEAA in urine samples was developed to monitor any exposed population. Urine specimens were first spiked with deuterated (2-butoxy)acetic acid, which was used as a procedural internal standard. The samples were extracted with ethyl acetate, concentrated, and treated by acid catalyzed esterification to produce the corresponding ethyl esters of MEAA and the internal standard. Subsequently, the ethyl ester derivatives were extracted using meth-

ylene chloride and concentrated to produce the final solution for gas chromatographic analysis. A mass selective detector (MSD) using a 50-m X 0.20-mm (id) HP-1 capillary column and a temperature program of 50 to 230C was used for the gas chromatographic measurement. Ion m/z 59 was monitored for the ethyl ester of MEAA and ion m/z 66 was monitored for the internal standard. A recovery study using 2, 10 and 20 micrograms/mL MEAA spiked urine samples demonstrated good accuracy and precision; recovery varied between 95-103%. The limit of detection (LOD) was found to be approximately 0.1 micrograms/mL (0.8 micromoles/L) for this analysis method.

1180 DETERMINATION OF PLATELET ACTIVATION LEVELS AND TIME COURSE IN CYNOMOLGUS MONKEYS.

J. M. Gunther, S. Nechev, A. J. Jabbour, B. Lee, R. Klein, K. Okasaki, S. Meyer and K. Fukuzaki. *SNBL USA, Ltd.,, Everett, WA.*

Blood platelets are essential for normal blood clotting; however, excessive platelet activation can contribute to thromboses that can lead to disseminated intravascular coagulation, heart attacks and strokes. Evaluation of platelet activation is an important part of safety assessment of therapeutics and several markers have been described for clinical evaluation of platelet activation. This study examines platelet activation assays for potential use in preclinical safety evaluation studies performed in Cynomolgus monkeys (Macaca fascicularis). Platelet activation levels and kinetics were tested using ELISA and flow cytometry methods for measurement of plasma levels of b-thromboglobulin, P-selectin, platelet factor-4, and cell-surface expression of P-selectin (CD62P) on platelets. Essential to measurement of platelet activation was the minimization of non-specific activation during blood collection using syringes containing CTAD (citrate, theophylline, adenosine, and dipyridamole) anticoagulant. Upon determination of antibody crossreactivity in Cynomologus monkey samples, the degree and time course of platelet activation were examined. The b-thromboglobulin average baseline level in CTAD anticoagulant samples was 13.2 +/- 4.6 IU/mL (SEM, n=4). In comparison, b-thromboglobulin levels in samples obtained using 3.2% w/v sodium citrate anticoagulant had an average b-thromboglobulin level of 179.6 +/- 3.3 IU/mL (n=4). Sodium citrate plasma samples with *in vitro* platelet activation using 20 mM adenosine diphosphate (ADP) had an average b-thromboglobulin level of 175.2 +/- 3.7 IU/mL (n=4). Similar results were seen for CD62P levels detected by flow cytometry. This study should identify reliable sample collection and analytical methods to be used for the determination of platelet activation in the Cynomolgus monkey as part of safety assessment of therapeutics.

1181 SENSITIVITY OF SPECIFIC BIOCHEMICAL MARKERS TO PREDICT CATECHOLAMINE INDUCED CARDIOMYOPATHY IN CYNOMOLGUS MONKEYS.

J. C. Resendez and G. Elliott. *Toxicology, Sierra Biomedical, A Charles River Company, Sparks, NV.*

In the last 10 years relatively sensitive and specific peripheral biochemical markers of cardiomyopathy have been characterized. These biochemical markers, creatine phosphokinase (CPK) and its isoenzymes, myoglobin, and more recently, the troponin T and troponin I subunits of the troponin protein complex permit identification of cardiac injury. This study evaluated the feasibility of using of CPK and its isoenzymes, myoglobin, and troponins T and I for the detection of myocardial injury in cynomolgus monkeys (*Macaca fascicularis*). Myocardial injury was induced chemically by slow, short-term infusion of norepinephrine bitartrate. Ten animals were implanted with telemetry transmitters configured to provide lead II electrocardiograms (ECG) and measurements of central arterial pressure and body temperature. A two-hour continuous intravenous infusion of norepinephrine (0.0625 mL/kg/min) was used to induce cardiomyopathy. Cardiovascular parameters were collected by radiotelemetry, continuously between prestudy and 7 days post-dose. Blood samples for measurement of cardiac biomarkers were collected predose and at various time points, beginning 2 hours after the end of infusion and continuing until necropsy and gross and histological evaluation, 7 days after treatment. Postmortem examination confirmed cardiac injury ranging in severity from minimal to marked. The severity of myocardial lesions was well correlated with serum troponin levels and ECG abnormalities. This data indicated that, of the biochemical markers evaluated in this study, troponin T and troponin I were the most specific and sensitive indicators of cardiac muscle injury. The results of this study indicate that serum troponin levels rise quickly and persist long after cardiac injury making them a more reliable indicator of cardiac muscle injury by permitting confirmation of cardiac injury well after other biochemical markers cease to be increased. Furthermore with coexistent skeletal muscle injury, troponins were near normal while the other biochemical markers were generally increased.

1182 MECHANISM-BASED URINARY BIOMARKERS OF RENAL PHOSPHOLIPIDOSIS AND INJURY.

M. D. Aleo[1], K. A. Navetta[1], S. Emeigh Hart[2], J. M. Harrell[1], J. L. Whitman-Sherman[1], D. L. Krull[1], M. B. Wilhelms[1], G. G. Boucher[1] and A. B. Jakowski[1]. *[1]Drug Safety Evaluation, Pfizer Global R&D, Groton, CT and [2]Global Safety Assessment, AstraZeneca Pharmaceuticals LP, Wilmington, DE.*

In animals treated with aminoglycoside antibiotics renal phospholipidosis causes nephrotoxicity and limits the dose and length of drug therapy. Therefore, a biomarker that can be used to monitor phospholipidosis before the onset of nephrotoxicity would be extremely valuable for preclinical and clinical safety studies and could be used for candidate screening. Megalin, a glycoprotein receptor, is expressed in numerous tissues (renal proximal tubule (RPT), lung, testis and macrophages)that are sensitive to the development of phospholipidosis. Although the physiologic role of megalin in the RPT brush border membrane is to mediate the uptake of proteins (e.g. albumin) and receptor-vitamin complexes (e.g. retinol binding protein-retinol) from the glomerular filtrate, it also mediates the uptake of polybasic drugs such as gentamicin by the RPT, a process necessary for the development of RPT phospholipidosis, injury and cell death. In theory, toxicants that are substrates for megalin binding should decrease megalin-mediated uptake of endogenous substrates by competing for megalin binding and preventing the recycling of megalin. The result should be an increase in excretion of endogenous substrates (e.g. retinol, albumin, and cubulin) in the urine in an amount that is proportional to degree of competition. In male Sprague-Dawley rats treated with gentamicin we show that urinary retinol and albumin excretion (ca. 2-fold increase) are early and sensitive markers of renal phospholipidosis that precedes both intracellular accumulation of phospholipids (sudan black staining), formation of myeloid bodies (confirmed by electron microscopy), and histologic and serum chemistry evidence of renal injury. This work supports the usefulness of monitoring urinary retinol and albumin excretion for early detection and monitoring of renal phospholipidosis and resultant injury.

1183 ELECTROENCEPHALOGRAPHIC RESPONSE TO ACUTE 3-NITROPROPIONIC ACID (3-NPA) EXPOSURE.

Z. K. Binienda[1], R. D. Skinner[2], J. L. Summage[1], B. T. Thorn[3] and W. Slikker[1]. *[1]Neurotoxicology, NCTR/FDA, Jefferson, AR, [2]Anatomy, UAMS, Little Rock, AR and [3]ROW, Jefferson, AR.*

3-NPA is a suicide inhibitor of succinate dehydrogenase (SDH) and has been implicated in food poisoning in China following ingestion of moldy sugarcane. SDH is the TCA cycle, as well as oxidative phosphorylation Complex II, enzyme. Its inhibition leads to cellular energy deficits. Studies have shown that energy deficit in GABAergic neurons after 3-NPA exposure led to an increase in GABAergic neurotransmission. This effect may be associated with the depression of motor activity and somnolence in the acute stage of 3-NPA neurotoxicity. However, after the acute phase, interference with GABAergic neurotransmission may increase excitability and lower threshold for seizures as well. In order to assess the effect of 3-NPA on electrocerebral activity, the ECoG was recorded in conscious, adult, male Sprague-Dawley rats *via* bipolar, epidural electrodes implanted at the level of the somatosensory cortex. Following baseline recording (saline injection), rats were injected s.c. with 3-NPA at 30 mg/kg or pretreated with L-carnitine (LC), an enhancer of mitochondrial energy metabolism, administered i.p. at 100 mg/kg prior to 3-NPA. The power spectra obtained by use of Fast Fourier Transformations were divided into 1.25-4.50 Hz (delta), 4.75-6.75 Hz (theta), 7.00-9.50 Hz (alpha-1), 9.75-12.50 Hz (alpha-2), 12.75-18.50 Hz (beta-1), and 18.75-35.00 Hz (beta-2). Treatment with 3-NPA was associated with a trend toward a power decrease in the delta frequency band. Following pretreatment with LC prior to 3-NPA, ECoG power in the right hemisphere was elevated relative to the left hemisphere in all frequency bands. Results indicate dominance of inhibitory neurotransmission during the acute stage of 3-NPA-induced neurotoxicity and a stimulatory action of LC on mitochondrial energy metabolism.

1184 A COMPARATIVE RELIABILITY STUDY OF THREE TEST BATTERIES: THE BEHAVIORAL EVALUATION FOR EPIDEMIOLOGY STUDIES (BEES), THE NEUROBEHAVIORAL EVALUATION SYSTEM2 (NES2) AND THE BEHAVIORAL ASSESSMENT AND RESEARCH SYSTEM (BARS).

J. S. Woods[1,2], D. Echeverria[1,2] and N. Heyer[1]. *[1]Battelle CPHRE, Seattle, WA and [2]Enviropnmental Health, University of Washington, Seattle, WA.*

The BEES is distinguished from other batteries by its focus on re-engineering traditional tests on a touch-screen. Psychometric properties are compared with those for the NES2 and BARS. The tests include Finger Tapping, Digit, Spatial, and Auditory Span, Pattern Discrimination, Pattern Memory, Simple and Choice

Reaction Time, Switching, Tracking, Symbol-Digit, Trails A/B, and Vigilance. Adaptive vocabulary estimates pre-morbid intelligence. Test selection was based on sensitivity to insults, age, and recommendations by WHO and the ATSDR. A test-retest study was conducted among 20 subjects who were administered the three test batteries. Comparisons were based on pairwise cross-correlations, and attenuation adjusted correlations. Mean stability was evaluated using linear and non-linear components. Unadjusted cross-correlations were modest. The only test that measured the same performance across batteries was Symbol-Digit. Reaction Time was correlated between the BARS and NES, but not with the BEES. After adjustment for attenuation, the correlations were markedly stronger between the BARS and NES and between the BEES and NES, but not between the BEES and BARS. Tests from the BEES were shorter, had the highest unadjusted reliability, and had the highest 3 min. adjusted reliabilities (>.80). BEES test scores also achieved linearity with repetition and homoscedasticity of variance across trials. Six factors were identified that assess memory, decision time, hand speed, pattern analysis, and hand-eye flexibility with respective reliabilities of 0.90, 0.92, 0.90, 0.95, 0.90, and 0.89. The profile across batteries was altered by unequal reliabilities and differences in what-is-being-measured which is influenced by the interface. The psychometric properties of the BEES supports recommendation for repeated-measures assessments of pre-clinical performance where first trial stability is desired. Supported by ES04696 and ES07033.

1185 LIVER TOXICITY PREDICTION AND CLASSIFICATION USING MICROARRAY DATA: APPLICATION OF REFERENCE DATA-TRAINED MODELS TO CUSTOMERS' DATA SETS.

A. L. Castle, K. R. Johnson, B. W. Higgs, M. W. Porter, M. Elashoff, C. G. Chang and D. Mendrick. *Toxicology, Gene Logic, Gaithersburg, MD.*

The promise of toxicogenomics in identification of the general toxic response lies in its ability to assay the entire transcriptome for toxicity-related changes relative to a baseline. To that end, we have built a large reference database of gene expression data that contains thousands of liver samples from rats treated with hepatotoxicants, non-hepatotoxicants, and multiple vehicle controls. We have identified predictive gene markers and have built multiple predictive models that can discriminate general toxic responses, multiple pathologies, species specificity, and individual compounds solely based on gene expression data. These models are validated not only by cross-validation techniques, but also by using compound-treated sample data from multiple pharmaceutical companies worldwide. In some cases, these are proprietary compounds that were part of the pharmaceutical company's drug development pipeline. For the majority of the gene expression data we received from external companies, our models are insensitive to differences associated with chip processing and biological (e.g., strain) parameters. Results pertaining to the cross-validation of internal training set data and external data from pharmaceutical companies will be presented and compared. Our results show that the high success rates associated with external data are approximately the same as rates associated with our own internal data, indicating that variability across sample generation and chip processing sites does not preclude the successful identification of liver toxicity. Our models have also shown that gene expression data can be a more sensitive indicator of human-specific effects than classical measures.

1186 COMPARISON OF MICROARRAY DATA GENERATED FROM THE SAME RNA AT 15 DIFFERENT PROCESSING SITES.

M. W. Porter, A. L. Castle, K. R. Johnson, B. W. Higgs, M. Elashoff, C. G. Chang and D. Mendrick. *Toxicology, Gene Logic, Gaithersburg, MD.*

Differences in microarray processing protocols, reagent stocks, and production lots are just a few of the many parameters that cause a yet undetermined amount of process variability ultimately reflected in resultant signal intensity data. There are many components necessary to effectively characterize baseline differences in data due to these factors. One of these is the assessment of a common batch of total RNA at each site to separate processing variability from biological variability. In order to estimate data compatibility between our large reference gene expression database of over 1000 rat liver samples and data from external sources, we shipped eight total RNA samples to 15 different sites representing six pharmaceutical companies worldwide. Four biological replicates each of samples treated with chloroform and samples treated with vehicle were submitted. Each facility processed the RNA using their own protocols, reagents, QC metrics, personnel, and chip lots and ran the resultant cRNA over the Affymetrix RGU34A chip. Data sets were sent to Gene Logic for analysis. Statistical analyses such as ANOVA, PCA, correlation, and pair-wise scatterplots are being used to determine overall data compatibility. The fragment probe sets being used for the assessment include all tiled genes, genes known to be expressed in the liver, genes known to be invariant within the liver across treated samples, and predictive markers of a general toxic response in the liver. The results to date show far more gene changes due to site than toxic effects when using all tiled probe sets. However, liver-expressed genes and predictive toxicity markers characterize the toxic response over and above the site differences. In addition, the predictive markers of liver toxicity are reliable predictors across data sets from different sites of chip processing. The predictive models are able to predict vehicle controls and their toxin-treated counterparts correctly despite differences in chip processing protocols.

1187 USING GENE MARKERS IDENTIFIED FROM A LARGE DATABASE BUILT WITH PRIMARY RAT HEPATOCYTES FOR PREDICTION OF HUMAN HEPATOTOXICITY.

D. Mendrick, B. W. Higgs, M. W. Porter, A. L. Castle and M. S. Orr. *Toxicology, Gene Logic, Gaithersburg, MD.*

To prioritize lead compounds early in development, companies need an assay that requires little compound, and is higher throughput than animal studies, yet provides a prediction of a compound's potential human hepatotoxicity. To produce such an assay, we have built a large reference database of gene expression data that contains thousands of primary rat hepatocyte cultures treated with hepatotoxicants and non-hepatotoxicants. The compounds represent all types of pathologies induced in humans and/or animals, including liver necrosis, cholestasis, hepatitis, and non-genotoxic carcinogenesis. The majority of the compounds used to build this database are marketed pharmaceuticals with well-known human safety profiles, including some that induce hepatotoxicity in humans but not rats. We have identified marker genes and built predictive models that classify samples into general toxicity, species specificity, and *in vivo* pathology categories. These models predict toxicity on a biological sample by sample basis, allowing individual replicate prediction in order to provide a more accurate result. Preliminary testing has shown these models to have a high true positive rate and an acceptable false positive rate on a sample by sample and compound by compound basis. These models are validated using 1) statistical cross-validation approaches, 2) tests with data generated with new compounds at our site, and 3) customer-generated data supplied to us in a blinded fashion. Our models have shown the ability to predict drugs that induce toxicity across species as well as some that are human-specific hepatotoxicants. To date we have received one data set from a customer. Our prediction revealed no false positives on a sample by sample basis and accurate prediction of 4 peroxisome proliferators. These included WY-14643, a recognized compound, and 3 proprietary drugs, none of which had been used to build our predictive models. These preliminary results suggest that primary rat hepatocytes can be used to predict human hepatotoxicity.

1188 CHANGES OF GENE EXPRESSION PROFILES IN STABLE RENAL TUBULE EPITHELIAL CELL LINES AS BIOMARKERS OF DRUG-SPECIFIC TOXICITIES.

Y. S. Kim[1]. [1]*Cell Biology, VistaGen Therapeutics, Burlingame, CA and* [2]*School of Medicine, Mount Sinai Medical Center, New York, NY.* Sponsor: R. Snodgrass.

The therapeutic utility of many drugs is limited by their toxicity. Renal toxicity, a major reason for drug failures during development, has been observed with diverse drugs such as immunosuppressants, e.g. cyclosporine, and aminoglycoside antibiotics, e.g. gentamicin. Animal models for predicting nephrotoxicity are expensive, not very accurate. A human renal epithelial cell culture model system for evaluating drug toxicities would be highly desirable. Stable cell lines have been developed that represent the three major segments of the human renal tubule, i.e. proximal tubule (PT), thick ascending limb of Henles loop (TAL) and collecting tubule (CT). These cell lines retain their normal segment specific characteristics such as cytological structure, functional markers, characteristic responses to hormones and drugs. This study seeks to evaluate the applicability of these cell lines for identifying gene expression profiles as biomarkers of renal toxic drugs. The three cell lines were cultured in serum free, segment specific growth factor supplemented media with or without drugs with known renal toxicities *in vivo*, including cyclosporine, cisplatinum; gentamicin, tobramycin, amikacin and kanamycin. Appropriate low to high doeses of each drug were incubated with confluent cultures for 24 hours at 37oC prior to collection for RNA and protein extraction. The effect of these drugs was evaluated by gene expression microarrays using the Amersham CodeLink Expression Bioarrays. The results showed that human renal epithelia treated with these drugs responed in a dose-dependent fashion, and with the same segment-specific sensitivities (PT>TAL>CT) as seen *in vivo*. Specific gene biomarkers will be presented. These data suggest that human renal epithelia cultures represent a good model for *in vitro* testing of drugs for nephrotoxicity.

1189 MICROARRAY ANALYSIS OF NRF2 PATHWAY AND NOVEL CO-REGULATED GENES INDUCED BY ACETAMINOPHEN.

M. S. Orr, D. Fox, L. Dong and D. Mendrick. *Toxicology, Gene Logic, Gaithersburg, MD.*

Nrf2 regulates the expression of drug metabolizing enzymes and antioxidant genes essential for the detoxification of acetaminophen (APAP). Microarray analysis was employed to examine the global gene expression alterations in the Nrf2 pathway

and to discover novel co-regulated genes that may have potential functions in the Nrf2 pathway and/or APAP detoxification. Rats were treated with APAP and liver samples were collected 3, 6, and 24 hrs post dose. Gene expression changes were monitored using the Affymetrix RGU_34 GeneChip®. Data analysis revealed a cluster of phase II and glutathione pathway associated genes 24 hrs following APAP exposure. Many of these genes, such as Heme Oxygenase, UGT1A6, γ-Glutamylcysteine synthase, Aflatoxin B1 aldehyde reductase, and GSTa2, have been described as being transcriptionally regulated by Nrf2. Two interesting co-regulated genes were Protein Kinase C delta binding protein and UGT1A7, neither of which have been identified in the literature as being induced by APAP in rats and/or implicated as Nrf2-regulated at the transcription level. Clearly, the novel co-regulated genes UGT1A7 and protein kinase C delta binding protein will require further molecular characterization to determine the extent of their respective roles in APAP detoxification and/or the Nrf2 pathway. QRTPCR analysis corroborated the microarray results, indicating that APAP induced the gene expression levels of UGT1A7, Protein Kinase C delta binding protein, Heme Oxygenase, γ-Glutamylcysteine synthase, Aflatoxin B1 aldehyde reductase, and GSTa2. Furthermore, the induction of Nrf2 pathway components and phase II enzymes, such as members of the glutathione synthesis pathway were evaluated in both *in vivo* (rat) and *in vitro* (primary rat hepatocytes) models. Similarities and differences between the two models will be presented. Overall, the microarray analysis provided a comprehensive gene expression fingerprint of the changes in both the Nrf2 and glutathione pathways, allowing for the elucidation of novel co-regulated genes that may be intimately involved in APAP detoxification.

1190 IDIOSYNCRATIC DRUG REACTIONS: INVESTIGATING THE ROLE OF THE DANGER SIGNAL.

M. Popovic and J. Uetrecht. *Pharmaceutical Sciences, University of Toronto, Toronto, ON, Canada.*

BACKGROUND: Idiosyncratic drug reactions (IDR) occur rarely, but there are a great number of drugs which can induce these reactions in humans. Mechanisms of IDRs are unknown, but it is believed that most are immune-mediated. For an immune response to be induced, Poly Matzinger proposed in her Danger Hypothesis that host cells should be stressed. In an initial test of this hypothesis we treated animals with drugs known to induced IDRs and monitored two markers of cell stress. METHODS: Seventy-two female Balb/C mice were treated with one of the five drugs associated with IDRs: felbamate, clozapine, carbamazepine, phenytoin or lamotrigine. Mice were put in groups of four, and treated with the drug for 1, 3 or 5 days. Levels of NADPH quinone oxidoreductase 1 (NQO1) and glutathione-S-tranferase (GST) were analyzed in the liver and bone marrow tissues. RESULTS: NQO1 was induced in the liver by felbamate (p=0.004) and phenytoin (p=0.007) at day 1. Levels of NQO1 at day 3 and 5 remained elevated in both felbamate (p=0.001) and phenytoin (p=0.005) groups. Slight induction in hepatic NQO1 levels for mice treated with clozapine, carbamazepine or lamotrigine was also observed within five days. Hepatic GST levels increased at day 1 in phenytoin-treated animals (p=0.02), and at day 3 in the felbamate group (p=0.004) and in both groups remained elevated at day 5. GST levels in the carbamazepine group were elevated at day 1 (p=0.02) and they decreased by day 3 to control levels. In response to clozapine and lamotrigine, there was also a slight increase in GST levels. No NQO1 induction was observed in the bone marrows of any of the five different treatment groups. DISCUSSION: It appears that some drugs that cause IDRs do cause cell stress *in vivo*, but many further experiments will be required to determine if this is a characteristic feature of these drugs, and if so, what biomarkers best predict the ability of a drug to cause IDRs.

1191 ESTABLISHMENT OF BIOASSAY SYSTEM FOR ENVIRONMENTAL SAMPLES USING pERE-MCF-7 CELLS AND p1A1-HEPA I CELLS.

Y. Y. Sheen[1], K. E. Joung[1], Y. W. Kim[1] and K. H. Chung[2]. *[1]Pharmacy, Ewha Womans University, Seoul, Seoul, South Korea and [2]Sungkyunwhan University, Suwon, AL.* Sponsor: Y. Cha.

In order to establish the rapid and easy-to-perform methods using ERE-MCF-7 cells by luciferase assay. MCF-7 stable cells which are stably transfected with phERE-Luc were treated with many chemicals and then luciferase activity were determined. Estradiol (E2) and synthetic estrogen, diethylstylbesterol (DES) were induced luciferase activity in dose dependent manner ranging 20-30 folds over that of control, and their activities were blocked by Tam treatment. 29 Flavonoids and 5 curcumin derivatives were tested in this system. Their E2 equivalent concentrations (EEQs) were calculated as a concentration of E2 that resulted in the same luciferase reading of test compound from the dose response curve. These data show that these methods are valuable tools for screening estrogenic activity of chemical. We have also examined the dioxin like activites using Hepa I cells were transfected with pCYP1A1-Luc. Environmental samples were extracted using combined solid-phase extraction in static adsorption mode with soxhlet extraction. The EEQ was determined based on the luciferase activity of 17 beta-estradiol. Kumho River of Korea showed 0.77 pM EEQ in upstrean and 7.7pM EEQ in downstream. Kum River of Korea showed 3.5pM and 1.7pM EEQ in upstream and downstream respectively. Mankyung River of Korea showed 61fM and 0.41 pM EEQ in upstream and downstream respectively. Miho Stream of Korea showed 0.2pM EEQ only in the upstream. All these water samples were tested with pCYP1A1-Luc activity using Hepa I cells containing pCYP1A1-Luc as described in pERE-Luc and results showed there were more dioxin like activities in sediments than water from the river. Domestic and industrial effluents have been discharged to that they presumed to be Kumho River, Kum River, Mankyung River and Miho Stream of Korea, so contaminated with various organic compounds. [Supported by grant from the Ministry of Environment of Korea]

1192 AN ENZYMATIC TISSUE DIGESTION METHOD FOR RECOVERY OF NYLON RFP FROM THE LUNGS OF EXPOSED RATS: VALIDATION STUDIES.

T. R. Webb, K. L. Reed, G. L. Kennedy and D. B. Warheit. *Pulmonary Toxicology, DuPont Haskell Lab., Newark, DE.*

The determination of lung burden in animal biopersistence studies requires that RFP (respirable-sized, fiber-shaped particulates) be recovered without loss or damage. Preparations from digested lung tissue must also contain a minimum of lung residue, so that accurate fiber counts can be made. Numerous reagents have been used to recover fibers from lung tissue, and these include, sodium hypochlorite (bleach, hydrochloric acid, hydrogen peroxide, and potassium or sodium hydroxide). Many of these reagents are useful for inorganic fibers but are not useful for organic fiber-types such as p-aramid, which are reactive in these oxidizing agents. The current studies were conducted to provide and validate a method for recovery of Nylon RFP from the lungs of rats following a 4-week inhalation study. Using *in vitro* pilot studies, we subjected Nylon RFP to varying concentrations of Clorox hypochlorite solution at several digestion time courses. A known quantity of Nylon RFPs incubated in saline was utilized as a control sample. The numbers and dimensions of Nylon RFPs were then evaluated both by phase contrast optical microscopy (PCOM) and scanning electron microscopy (SEM). The results from these studies demonstrated that the final digestion conditions for the most effective digestions were determined to be 25% filtered Clorox hypochlorite concentration = 5.25% normal Clorox/4 = 1.31% final hypochlorite solution), shaken vigorously for 30 seconds and incubated at 60 oC for 9 minutes. The digestate was then quickly deposited on filters for analysis. Subsequently, we conducted *in vivo* studies with known quantities of instilled Nylon RFP into the lungs of rats and implemented clearance (digestion) studies 4 hrs later to validate this methodology.

1193 DETERMINANTS OF URINARY PORPHYRINS AND MERCURY AMONG DENTAL PERSONNEL.

D. Echeverria[1,2], J. S. Woods[1,2], N. Heyer[1] and C. Garabedian[1]. *[1]Battelle CPHRE, Seattle, WA and [2]Environmental Health, University of Washington, Seattle, WA.*

Assessments of mercury (Hg)exposure require the use of a biomarker that demonstrates unique specificity and sensitivity to Hg as well as identification of determinants of Hg exposure that are prevalent in human populations. We investigated potential associations between urinary Hg, porphyrin excretion patterns, medical conditions and use of medications in 89 male dentists (DDS) and 109 female dental assistants (DAs).Subjects provided a urine sample and completed a questionnaire covering demographic data, symptoms (Neuroquest), mood (Profile on Mood States), personal habits, and medical and work histories. Crude correlations were used to identify a set of potential determinants ($p<.05$) that were later tested in multiple regression models. Differences between sexes were sufficient to support separate analyses. Pooled copro-, precopro-, and penta-carboxyl porphyrin levels were strongly associated (Beta =.42 or 0.49) with urinary Hg between 0-10 ug/l. Among DDS, only urinary Hg significantly correlated with urinary porphyrins, whereas among DAs, pack-years (Beta=.29), ever having had anesthesia (Beta= -.18), and having an immune (Beta= -.20)or endocrine (Beta= -.18) disorder were also correlated. Methyl mercury exposure (#fish/week) was not associated with porphyrin excretion. The determinants of urinary mercury also differed by sex with respect to work- related factors, personal factors. There was an inverse association with alcohol consumption. These observations support the utility of urinary porphyrins as a biomarker of Hg exposure in humans and suggests their utility as a measure of altered immune and endocrine and immune function in women. Supported by ES04696 and ES07033.

1194 AN INTERVENTION ANALYSIS FOR THE REDUCTION OF EXPOSURE TO METHYLMERCURY FROM THE CONSUMPTION OF SEAFOOD.

C. D. Carrington and M. Bolger. *Center for Food Safety and Applied Nutrition, USFDA, College Park, MD.*

Previously, an exposure model was developed (Risk Analysis 22:689-699, 2002) to predict levels of methylmercury (MeHg) in blood and hair in the US population based on the frequency of seafood consumption, the amount consumed per serving, and the types of seafood consumed. Steady-state relationships that employed descriptive statistics to account for pharmacokinetic variation were used to predict levels of mercury in blood and hair. The model incorporates an uncertainty dimension that is intended to represent the range of plausible interpretations of the data. In the present analysis, the model was used to predict the impact of limitations in the amount or types of seafood consumed on predicted blood and hair MeHg levels. Specifically, simulations for three scenarios were developed: 1) limitation of the consumption of seafood to 12 oz per week, 2) elimination of the consumption of shark, swordfish and other seafood with MeHg levels exceeding 0.5 ppm., and 3) limiting the amount of seafood consumed and eliminate consumption of high MeHg species (> 0.5 ppm). In the baseline model, the median (uncertainty) estimates for the 50th, 95th, 99th, and 99.9th per capita population percentiles were 0.6, 5.4, 9.9, and 15.9 ppb MeHg in blood, and 0.2, 1.8, 3.7, and 6.4 ppm MeHg in hair. After restriction of seafood consumption to no more than 12 oz per week, the median (uncertainty) estimates for the 50th, 95th, 99th, and 99.9th per capita population percentiles were 0.6, 5.0, 8.1, and 11.5 ppb MeHg in blood, and 0.2, 1.7, 3.0, and 4.6 ppm MeHg in hair. Elimination of high MeHg species, with average concentrations above 0.5 ppm, resulted in very modest decrements in MeHg blood and hair levels, in comparison to either the baseline or the reduced consumption scenario. These results suggest that strategies to reduce MeHg exposure by reducing the amount of fish consumed are more effective at trimming the high end of the US exposure distribution than are strategies intended to change the types of fish consumed.

1195 QUANTITATIVE DISEASE PREVENTION AND COST UTILITY CONSIDERATIONS FOR A SUITE OF BIOMARKERS FOR CHRONIC BERYLLIUM DISEASE.

N. L. Judd, W. C. Griffith, T. K. Takaro and E. M. Faustman. *Institute for Risk Analysis and Risk Communication, University of Washington, Seattle, WA.*

The value of the information provided by biomarkers for exposure-associated diseases is difficult to estimate. Chronic beryllium disease (CBD) provides an exceptional example to study this problem since there are well-developed biomarkers of susceptibility and exposure/early disease. CBD continues to occur despite major reductions in occupational exposure levels. We have previously developed a model for optimization of use of the beryllium lymphocyte proliferation test (BeLPT), an indicator of beryllium sensitization, which may be detected prior to development of CBD. Our model includes assumptions based on recent studies indicating that the development of a positive BeLPT is not dose related but the development of CBD is dose related. Our model also includes per worker cost considerations such as test cost, worker retraining, and cost of illness. Our results concurred with other recommendations of annual testing. CBD is strongly associated with a genetic polymorphism in the Human Leukocyte Antigen gene variant, HLA-DPβ1*201, characterized by glutamate substitution at position 69 (Glu69+). Here we expand our original model to include consideration of genetic testing prior to Be exposure and compare the cost per worker for individuals who are Glu 69+ to those who are Glu 69-. We used estimates of Glu 69 frequency in the general population (33%) and estimates of Glu 69 frequency in diseased persons (~90%) from the literature. The cost per worker calculated from our model for Glu 69+ and Glu69- workers was $150, 000 and $20, 000 respectively for workers exposed at 0.2 μg/m3 (ACGIH and USDOE recommendations) and given the BeLPT annually. This indicates significant financial and disease reduction value for encouraging alternative occupations for susceptible individuals and the importance of careful consideration of ethical ramifications of this information. This research was supported by the CRESP II(US DOE DE-FG26-00NT40938), CEEH(NIEHS 5 P30 ES07033) and CSIR.

1196 ATSDR'S INTERMEDIATE-DURATION ORAL MINIMAL RISK LEVEL FOR COBALT.

H. Abadin[2], M. Osier[1], O. Faroon[2], C. Smith[2] and C. De Rosa[2]. *[1]Agency for Toxic Substances and Disease Registry, Atlanta, GA and [2]Environmental Science Center, Syracuse Research Corp, Syracuse, NY.*

The Agency for Toxic Substances and Disease Registry (ATSDR) recently released the Toxicological Profile for Cobalt as a draft for public comment. Developed under an interagency agreement between ATSDR and the Department of Energy, the cobalt profile updates the previous version released in 1992. The risk assessment for cobalt is interesting in that cobalt (specifically, cobalamin) is an essential component of vitamin B_{12}. Moreover, cobalt has been used in treating anemia because it stimulates the production of red blood cells in humans. Nonetheless, cardiomyopathy, gastrointestinal effects, visual disturbances, and thyroid effects following ingestion of cobalt (as cobalt sulfate in beer or as cobalt chloride as a treatment for anemia) are documented in the literature. Although no oral minimal risks levels (MRLs) were derived for cobalt in the 1992 document, a reevaluation of the toxicological database for cobalt resulted in the derivation of an intermediate-duration oral MRL of 0.01 mg/kg/day based on the study by Davis and Fields (1958). An intermediate-duration MRL is an estimate of daily exposure to a substance that is likely to be without an appreciable risk of adverse effects over a period of 15-364 days. In the Davis and Fields study, six male volunteers were exposed to 120 or 150 mg/kg/day of cobalt chloride (~1 mg Co/kg/day) for up to 22 days, resulting in polycythemia in all six subjects (16%-20% increase in pre-treatment red blood cell numbers). The implications of polycythemia observed from exposure to cobalt are unclear since the increase in red blood cells produced in this study likely produced no clinical signs. However, secondary polycythemia is clearly a biomarker of effect for cobalt exposure and a reasonable end point for the derivation of a health-based guidance value.

1197 BIOAVAILABILITY OF SILVER COMPOUNDS IN RATS.

P. J. Deisinger and J. C. English. *Health & Environment Laboratories, Eastman Kodak Company, Rochester, NY.*

Studies were undertaken to estimate the relative bioavailability in rats of several silver compounds of photo processing and environmental significance. Several indices of bioavailability were evaluated, including tissue glutathione concentrations, glutathione peroxidase activity in tissues, and serum ceruloplasmin (CP) activity. CP activity was found to be the most sensitive and reproducible biomarker of silver exposure over relatively short exposure times. CP (EC 1.16.3.1) is a plasma glycoprotein, which, in addition to its ferroxidase and radical scavenger activity, is the primary copper transport and homeostasis protein in mammals, normally carrying 6-7 copper atoms per CP molecule. Silver(I) appears to deactivate CP when it is incorporated into the protein in place of copper during *de novo* synthesis in the liver. To estimate silver bioavailability, groups of 4 female SD rats were given 14-day repeat oral doses of the reference silver compound, silver acetate, dissolved or suspended in 1% aqueous methyl cellulose. Tissues were collected on day 15 and serum CP was assayed by measurement of its diamine oxidase activity. CP activity was depleted in a dose-dependent pattern, with >98% inhibition following a 960 μmol/kg dose of silver acetate. Male SD rats showed a similar dose response, but had only about ½ the native CP oxidase activity measured in females. Subsequent experiments indicated that similar responses could be obtained with as few as 4 daily repeated doses of 960 μmol/kg silver acetate. Four-day repeated dose studies in female rats were conducted with several other silver compounds, which resulted in variable levels of CP inhibition and revealed the following relative bioreactivity of silver from these compounds; **Silver Sulfide 〈 Silver Chloride 〈 Silver Thiosulfate ≅ Silver Acetate ≅ Silver Nitrate.** Silver sulfide, the ultimate environmental form of silver from photo processing discharges, had no effect on CP oxidase activity at 960 μmol equiv. silver/kg, indicating that it is the least bioavailable and bioreactive silver species among the common photo industry/environmental forms of silver.

1198 TERATOGENICITY OF CYANOBACTERIAL EXTRACTS TO FETAX EMBRYOS.

E. O'Brien, S. Altheimer, N. Kreke and D. R. Dietrich. *Environmental Toxicology, University of Konstanz, Konstanz, Germany.*

Several species of cyanobacteria are known to produce potent toxins which have detrimental effects in wildlife, livestock and in humans. Several toxins (microcystin, saxitoxins, anatoxins etc.) may be produced simultaneously by one cyanobacterial species. The highest concentrations of these toxins, which are released upon cyanobacterial cell/filament rupture, are to be found in shallow water, which represents the primary location for aquatic early life-stage development. The effects of pure microcystin-LR (MLR) and RR (MRR) toxins on amphibian development, has been investigated. However, the effects of extracts from cultured cyanobacteria, which may contain several different toxins and hence may more accurately represent the situation in lakes and rivers, have not been assessed. Using the FETAX system, we have investigated the effects of two Planktothrix rubescens and two Microcystis aerogenosa extracts as well as pure microcystin-YR (MYR), on the development of Xenopus laevis embryos. The endpoints evaluated were mortality, malformation and growth demonstrated that neither P. rubescens extract nor MYR had any effect on embryonal survival. In contrast, M. aerogenosa extract caused a dose-dependent increase in mortality. All four extracts caused narrowing of the face in 96hr embryos. This was not observed in embryos exposed to MYR. Similarly, reduced embryonal growth, which was evident in embryos exposed to cyanobacterial extracts (M. Aerogenosa > P. rubescens), was not apparent in MYR-exposed embryos. This implies that the observed toxicity is not due to the presence of pure microcystin but rather other toxins produced by cyanobacteria.

1199 A RELIABLE SCORING SYSTEM TO ASSESS DEVELOPMENTAL TOXICITY OF ENVIRONMENTAL CONTAMINANTS USING ZEBRAFISH EMBRYOS.

C. Willett, T. Fremgen, P. McGrath and C. Zhang. *Phylonix Pharmaceuticals, Inc., Cambridge, MA.* Sponsor: P. Mayeux.

Biological testing has become an increasingly major component of ecological risk assessment and monitoring. A rapid, reproducible and inexpensive predictive vertebrate model for hazard identification would greatly contribute to ecological risk assessment. We are developing such a model using the zebrafish embryo, which has several inherent advantages: the free-living zebrafish embryo is completely transparent, facilitating experimentation and analysis, its entire body plan is established by 24 hours post-fertilization (hpf), and by 5 days post-fertilization (dpf), virtually all organs are functioning, including the liver. We have developed a simple, rapid and reliable scoring system to detect and quantify developmental toxicity. Endpoints include mortality, hatching frequency, heart rate, circulatory abnormalities and other morphological parameters. Embryos were treated by semi-static immersion in compounds diluted in fish culture medium from 24 hours post-fertilization (hpf) to 120 hpf; fresh compound was added daily. Endpoints were assessed every 12 hours until 72 hpf, and then every 24 hr until 120 hpf. Using this scoring system, we have analyzed five compounds representing different classes of environmental toxins: 2, 3, 7, 8-tetracholorodibnezo-p-dioxin (TCDD), benzene, hexachlorobutadiene (HCBD), ethanol and 2, 4-dinitrotoluene (DNT). Our results indicate that the scoring system is predictive of toxicity in other vertebrates, and that the zebrafish is a promising model for assessing environmental toxicity.

1200 DEVELOPMENTAL TOXICITY OF MIXTURES OF DI- AND TETRACHLOROETHANE AND DICHLOROPROPANE IN EMBRYO CULTURE.

J. Andrews, H. Nichols and E. Hunter. *RTD, NHEERL, ORD, USEPA, Research Triangle Park, NC.*

Drinking water chlorination results in numerous chlorinated byproducts. We evaluated the developmetal and embryo toxicity of 1, 3-dichloropropane (1, 3DP), 2, 2-dichloropropane (2, 2DP), 1, 1-dichloroethane (1, 1DE) and 1, 1, 2, 2-tetrachloroethane (TCE) in rat whole embryo culture (WEC) due to their presence in chlorinated drinking water, their structural similarities, and a lack of developmental toxicity data for these compounds. Humans could be exposed to these four chlorinated propanes and ethanes (CPEs) simultaneously in drinking water and hence we evaluated them alone and in combination. Toxicity profiles were generated by exposing gestational day (GD) 9.5 rat embryos in WEC to the CPEs for 48 hours. The individual CPEs were all dysmorphogenic in WEC and embryonic exposure resulted primarily in rotation and heart defects. The embryonic effects from exposure were compared based on developmental score (DEVSC), death and dysmorphology as the parameters of comparison. Concentrations of individual CPEs chosen for the mixture studies were predicted to produce DEVSCs 25% below control values. These equipotent mM concentrations (14.5 1, 1DE, 1.5 TCE, 16 2, 2DP, 5.5 1, 3DP) were then used to determine the toxicity of all possible combinations, based on a dose-additivity model, of the four CPEs. Eight of mixture combinations gave experimental DEVSCs which were not significantly different from the predicted scores while three of the mixtures (1, 3DP/2, 2DP;TCE/1, 3DP/2, 2DP;TCE/1, 3DP/2, 2DP/1, 1DE) gave scores which were significantly lower than predicted. Embryo mortality was additive in ten of the eleven treatment groups, with one mixture significantly more embryo toxic (27% mortality) than predicted. Dysmorphology was significantly elevated in all treatment groups compared to controls and was neither significantly different between the groups nor different from dysmorphology seen in embryos following exposure to the individual compounds. These data suggest that the developmental toxicity of these halogenated propanes and ethanes is additive. This abstract does not necessarily reflect EPA Policy.

1201 ZEBRAFISH BIOASSAYS FOR ASSESSING SUBSTANCE ABUSE.

C. Parng, N. Anderson and P. McGrath. *Phylonix Pharmaceuticals, Inc., Cambridge, MA.* Sponsor: J. McCullough.

Substance abuse often leads to clinical impairment or distress resulting profound social, occupational and medical impact. New approaches to reduce the harm caused by the use of alcohol, tobacco, prescriptive and illicit drugs are urgently needed. Due to inherent attributes including, optical clarity, rapid development, a well-defined nervous system and predictable behavior, we used the zebrafish embryo as an animal model to study substance abuse. We observed growth retardation, abnormal morphology in the heart, brain, trunk, craniofacial structure and nerve system, as well as, induced apoptosis in response to continuous administration of alcohol. These results suggest ethanol-treated zebrafish embryos exhibit clinical manifestations similar to those of human fetal alcohol syndrome and it is therefore a model for studying the impact of alcohol and other substance abuse on fetus. In addition, using subtractive hybridization, we showed that gene expression is regulated in response to alcohol treatment.

1202 TEST RESULTS WITH EIGHT CHEMICALS IN A DROSOPHILA-BASED DEVELOPMENTAL TOXICITY PRESCREEN.

D. W. Lynch. *DART, BHAB, NIOSH, Cincinnati, OH.*

To further characterize the Drosophila-based prescreen to detect developmental toxicants, the following 8 chemicals were evaluated - methyl mercury chloride (MMC), methotrexate (MTX), L-phenylalanine (LPA), sodium arsenate heptahydrate (SAH), cadmium chloride (CC), vinblastine sulfate (VBS), aminopterin (APN) and mitomycin C (MC). All of the test agents are mammalian developmental toxicants and/or teratogens. One-to-three experiments, each employing multiple concentrations and including a concurrent control, were conducted with each chemical using our published protocol (Teratogenesis, Carcinogenesis, and Mutagenesis 11:147-173, 1991). Drosophila were exposed throughout development (egg through third instar larva) in culture vials to medium containing the test chemical. A mated, untreated, Oregon-R wild-type female (Mid-American Drosophila Stock Center, BGSU, Ohio) was added to each vial and allowed to oviposit for 20 hours, then removed. Emerging offspring were collected over 10 days, and examined microscopically (25x) for bent humeral bristles and wing blade notches, morphological defects shown to occur with an increased incidence in flies exposed to developmental toxicants. In each experiment, the incidence of the two defects at each concentration was compared to the controls using chi-square. In cases where replicate data were available at a given concentration, incidence data were also pooled and compared to the pooled controls. The incidence of bent humeral bristles was statistically increased ($p<0.05$) in flies exposed to MMC, LPA, SAH, CC, VBS, and MC. VBS also statistically increased ($p<0.05$) the incidence of eye defects. The incidence of wing blade defects was statistically increased ($p<0.05$) in flies exposed to MTX and APN. These results with 8 diverse chemicals provide additional support for increased utilization of this assay as a prescreen for the detection of developmental toxicants.

1203 ZEBRAFISH AS A PREDICTIVE MODEL FOR ASSESSING TOXICITY OF CHEMOTHERAPEUTICS.

P. McGrath, T. Fremgen, C. Zhang and C. Willett. *Phylonix Pharmaceuticals, Inc., Cambridge, MA.* Sponsor: P. Mayeux.

The efficacy of many chemotherapeutics is mitigated by high toxicity. A reproducible and inexpensive predictive method for screening novel therapeutics for general toxicity would be extremely valuable. We previously demonstrated the feasibility of using zebrafish embryos to study toxicity by assessing the LC50 of 20 commercially available compounds and found good correlation between zebrafish and other mammalian models. We have further tested the model by assessing the general toxicity, including the LC50, MTD, and target organ morphology, of 15 chemotherapeutic compounds, including paclitaxel, tamoxifen, dexamethasone and actinomycin D. Embryos were treated by semi-static immersion in compounds diluted in fish culture medium from 24 hours post-fertilization (hpf) to 120 hpf. Mortality was assessed and fresh compound was added daily. MTD and organ morphology were assessed at 120 hpf. Our data correlates well with mammalian data and supports zebrafish as an alternative animal model for general toxicity testing of pharmaceutical compounds.

1204 THE TERATOGENIC EFFECTS OF ENVIRONMENTAL ETHANOL EXPOSURE.

E. J. Loucks[1,2], T. Rubenstein[2] and M. J. Carvan[1,2]. *[1]Biological Sciences, University of Milwaukee-Wisconsin, Milwaukee, WI and [2]Great Lakes WATER Institution, Milwaukee, WI.*

The long-range goal of this project is to elucidate the molecular mechanism by which ethanol perturbs embryonic and fetal development, and to identify genes that plays a role in the sensitivity to ethanol-induced teratogenesis. Maternal exposure to ethanol from alcoholic beverages and many consumer products has been linked to developmental abnormalities in human and laboratory animals. Fetal exposure to alcohol is primarily dictated by voluntary maternal behavior and societal influences. Generally, consumption of alcohol induces alterations in facial features, major organs, and bone structures and will trigger damaging effects on the brain, which will lead to learning disabilities and behavioral problems. This can have a tremendous toll on the affected individuals, their families, and society as a whole. Data from twin studies and animal models argue strongly for a robust genetic component to ethanol-induced teratogenesis. In order to take advantage of the powerful genetic capabilities of the zebrafish to identify genes that influence sensitivity,

we must first identify the effects of ethanol exposure on zebrafish development. We have identified dose-dependent changes in zebrafish embryo/larval mortality, neurocranial and craniofacial skeletal development, CNS apoptosis, expression of selected developmentally regulated genes, and cardiac development and function. This data will be discussed in relation to our mutagenic screen for genes that influence sensitivity to ethanol-induced teratogenesis.

1205 CARBONYL PROTEIN ADDUCTS AS A BIOMARKER OF CIGARETTE SMOKE EXPOSURE IN MAMMALIAN CELLS AND HUMANS.

D. W. Bombick[1], D. J. Doolittle[2] and M. W. Ogden[1]. *[1]Biological Chemistry Division, R. J. Reynolds Tobacco Company, Winston-Salem, NC and [2]Product Evaluation, R. J. Reynolds Tobacco Company, Winston-Salem, NC.*

Carbonyl protein adducts have been used as a biomarker of exposure for compounds or mixtures that can cause oxidative damage. Cigarette smoke can cause oxidative stress and contains many compounds that can cause oxidative damage. Specific examples include aldehydes (e.g., acrolein, acetaldehyde, formaldehyde) and some phenolic compounds (e.g., catechol, hydroquinone). Initial experiments to characterize the assay used a purified protein (bovine serum albumin) and a single compound (acrolein). Carbonyl protein adduct formation was linear with addition of 0-100 ug/mL of acrolein to the bovine serum albumin. A one-hour exposure of acrolein to the protein resulted in the maximum concentration of carbonyl protein adducts. The objective of subsequent experiments was to quantify the formation of carbonyl protein adducts *in vitro* and in humans after exposure to cigarette smoke. Carbonyl protein adducts were measured in Chinese hamster ovary (CHO) cells after exposure to single compounds found in cigarette smoke; cigarette smoke condensate from a reference cigarette; or the whole smoke from the same reference cigarette. Aldehydes incurred a greater amount of carbonyl protein adducts in CHO cells than phenolic compounds. CHO cells exposed to reference cigarette smoke condensate or whole reference cigarette smoke had higher levels of carbonyl protein adducts than the respective controls. The carbonyl protein adducts in a buccal wash from smokers and non-smokers indicated an approximate 4-fold increase of adducts in smokers compared to non-smokers. The measurement of carbonyl protein adducts serves as a sensitive biomarker for cigarette smoke exposure and may serve as an assay to guide the development of potential reduced risk cigarettes.

1206 HEMOGLOBIN ADDUCTS FROM *N*-METHYLOLACRYLAMIDE IN RATS: COMPARISON WITH THOSE FORMED BY ACRYLAMIDE.

T. Fennell[1], R. Snyder[1], W. Krol[1], M. A. Friedman[2] and S. C. Sumner[1]. *[1]CIIT Centers for Health Research, Research Triangle Park, NC and [2]UMDNJ, Newark, NJ.*

Acrylamide (AM) and *N*-methylolacrylamide (NMA) are used in the formulation of grouting materials. AM is metabolized to a reactive epoxide, glycidamide (GA). Both AM and GA react with hemoglobin to form adducts which can be related to exposure to AM. To evaluate whether NMA could also cause the same hemoglobin adducts as AM, *N*-(2-carbamoylethyl)valine (AAVal derived from AM) and *N*-(2-carbamoyl-2-hydroxyethyl)valine (GAVal derived from GA) were measured following a single oral dose of AM (50 mg/kg) or NMA (71 mg/kg) in male F344 rats. Blood was collected by cardiac puncture at 24 h following dosing, globin was isolated, and AAVal and GAVal were derivatized by a modified Edman degration to produce phenylthiohydantoin derivatives. The adduct derivatives were analyzed by liquid chromatography/mass spectrometry. In the AM-treated rats, AAVal was 21 ± 1.7 pmol/mg globin (mean ± SD, $n = 4$), and GAVal was 7.9 ± 0.8 pmol/mg. In the NMA-treated rats, AAVal was 41 ± 4.9 pmol/mg, and GAVal was 1.4 ± 0.1 pmol/mg. This study indicated that AAVal and GAVal can be detected following administration of NMA. Whether AAVal was derived from reaction of NMA with globin followed by loss of the hydroxymethyl group from the adduct, or loss of the hydroxymethyl group to form AM with subsequent reaction with globin is not known. However, the much higher ratio of AAVal:GAVal in the NMA-treated rats (29 vs. 2.6 in AM-treated rats) suggests that reaction of NMA with globin is the predominant route to these adducts in NMA-treated rats, rather than conversion to AM. The detection of GAVal in NMA-treated rats indicates oxidation of NMA, either directly, or following conversion to AM. The lower levels of GAVal on NMA administration suggests a much lower level of epoxide formed in these animals compared with AM treatment.

1207 CYCLIC N-TERMINAL HEMOGLOBIN ADDUCT AS A BUTADIENE DIEPOXIDE BIOMARKER.

N. I. Georgieva, K. Jayaraj, H. Koc, P. Begemann, A. Gold and J. A. Swenberg. *Environmental Sciences and Engineering, University of North Carolina, Chapel Hill, NC.*

1, 3-Butadiene (BD), a widely used industrial chemical that is carcinogenic in animals and probably humans, is oxidized by cytochrome P450 to diepoxybutane (DEB), the most mutagenic of BD metabolites. DEB can react with the N-terminal valines of hemoglobin (Hb), forming the cyclic adduct (2, 3-dihydroxypyrrolidin-1-yl)-3-methylbutanoic acid (PYRV). All three DEB metabolites (two enantiomers and one meso form) are expected to form PYRV adducts, resulting in three diastereomers. These adducts are potentially highly specific biomarkers for DEB. The aim of this study was to develop a sensitive isotope dilution mass spectrometric assay for measurement of PYRV in globin from animals and humans exposed to BD. Key to this procedure were the synthesis of alkylated terminal peptide (PYR-VLSPADKTNVK for the human α-chain) as standard and its stable isotopically labeled analog ($^2H_3$) as internal standard (IST), as well as developing a reliable procedure for concentration of the modified heptapeptide (PYR-VLSPADK) after trypsin hydrolysis. The syntheses of the standard and IST were accomplished by incorporation of PYRV (both OH groups protected by t-butylation) to the synthesized peptide sequence LSPADKTNVK. The peptides were characterized by ESI-MS/MS sequencing and exact mass measurement. The presence of all three diastereomeric peptides in the synthesized standard was established by 2D COSY ^{1}H NMR. The standard PYR-VLSPADKTNVK provided a hapten to raise polyclonal antibodies (AB) for immunoaffinity (IA) enrichment. Trypsin digested samples of standard and IST were applied on IA columns, washed extensively and eluted in 10% formic acid. Quantitation was performed by LC-ESI-MS in SIM mode, using the masses of both singly and doubly charged ions. The results showed 60-80% recovery of PYR-VLSPADK peptide after IA separation. The present limit of detection for standards was about 150 fmol (injected). PYRV is a promising biomarker for humans and animals to better understand mechanisms of carcinogenesis and more accurately predict risk.

1208 LC-ESI-MS/MS QUANTITATION OF HEXENAL-DERIVED 1, N^2-PROPANODEOXYGUANOSINE ADDUCTS.

M. D. Stout[1], R. Sangaiah[2], H. Koc[2] and J. A. Swenberg[1,2]. *[1]Curriculum in Toxicology, University of North Carolina, Chapel Hill, NC and [2]Environmental Sciences and Engineering, University of North Carolina, Chapel Hill, NC.*

E-2-Hexenal (hexenal) is an α, β-unsaturated aldehyde that is naturally formed in plants and is present in various flavorings. Hexenal has been shown to be genotoxic in a variety of *in vitro* assays and forms a pair of diastereomeric exocyclic 1, N^2-propanodeoxyguanosine adducts (H-dGuo 1 and 2) upon reaction with DNA. A sensitive and specific adduct quantitation method employing mass spectrometry is needed for measurements of adducts at low doses. To this end, we are developing and optimizing a method to quantitate H-dGuo in DNA. Analyte standards have been synthesized and characterized by UV, MS, and NMR. ESI-MS and ESI-MS/MS analysis revealed ions at the anticipated $[M + H]^+$ and [M + H − deoxyribose + H]$^+$ *m/z* for H-dGuo (*m/z* 366 and *m/z* 250, respectively). Synthesis and characterization of stable isotope internal standards ($[^{13}C_4\,^{15}N_2]$H-dGuo 1 and 2) are underway. Studies with H-dGuo spiked into DNA have shown that solid phase extraction (SPE) is an effective means of separating H-dGuo from unmodified nucleosides and other sample contaminants. LC-ESI-MS/MS was used to analyze H-dGuo spiked into DNA at varying concentrations and purified from the enzymatic DNA hydrolysate by SPE. Diversion of LC flow to waste prior to mass spectrometric analysis of H-dGuo was used to further enrich samples, and the selected reaction monitoring mode (SRM; *m/z 366→m/z 250*) was used to analyze H-dGuo. From this study, we estimated an approximate limit of quantitation of 4.2 H-dGuo 1 or 2 per 10^7 dGuo. We anticipate that utilization of an internal standard and further method optimization will allow accurate quantitation at lower concentrations of H-dGuo, allowing quantitation of H-dGuo in a variety of DNA samples. This work was supported in part by grants from the NIEHS (T32ES07126, ES11746, P30ES10126), the NCI (P30CA16086) and the Flavor and Extract Manufacturers Association (FEMA).

1209 IDENTIFICATION OF ADDUCTS FORMED BY THE REACTION OF ISOPRENE MONOEPOXIDES WITH 2'-DEOXYADENOSINE.

P. Begemann[1], N. I. Georgieva[1], R. Sangaiah[1], A. Gold[1], H. Koc[1], D. Zhang[2], B. T. Golding[2] and J. A. Swenberg[1]. *[1]Environmental Sciences and Engineering, University of North Carolina, Chapel Hill, NC and [2]Chemistry, Newcastle University, Newcastle upon Tyne, United Kingdom.*

Isoprene (IP, 2-methylbuta-1, 3-diene) is ubiquitous, since it is emitted by plants, produced by combustion processes, and is the major exhaled hydrocarbon by humans. It is also an important industrial chemical. Since IP exhibits differential tumorigenic activity in rats and mice, it is important to establish biomarkers for IP metabolites so that differences in endogenous and exogenous metabolism can be understood. These data should lead to a more accurate assessment of the risk of cancer for humans. In the present study 2'-deoxyadenosine (dAdo) and 2'-deoxyinosine (dIno) were incubated with IP monoepoxides isoprene-1, 2-oxide (IP-1, 2-O, 2-ethenyl-2-methyloxirane) and isoprene-3, 4-oxide (IP-3, 4-O, propen-2-

yloxirane). Racemic mixtures of IP-1, 2-O, as well as of IP-3, 4-O can form four adducts on each position of the nucleoside. These arise from attack of the enantiomeric epoxides with either their internal or external oxirane carbon. The adducts were separated by HPLC and identified by diode array UV detection and electrospray-mass spectrometry. NMR characterization, as well as studies with the individual epoxide stereoisomers are ongoing. HPLC-separation of the reaction mixtures of dAdo with IP-1, 2-O or IP-3, 4-O resulted in four or three N^6-dAdo adduct peaks, respectively. These were the main adducts. In addition, unstable adducts at the N1-position and their deamination products (N1-dIno adducts) were identified and characterized. Characterization of the nucleoside adducts of IP is the first step toward establishing useful DNA adducts as biomarkers of IP metabolism and exposure. N^6-adenine adducts have been used as biomarkers of exposure to butadiene in humans, however, these adducts have been shown to be non-promutagenic. Recent data suggest that N1-dIno adducts might provide a good biomarker since they are stable and potentially mutagenic.

1210 CHARACTERIZATION OF 1, N^2-PROPANODEOXYGUANOSINE ADDUCTS FORMED BY HYDROXYMETHYLVINYL KETONE.

M. W. Powley[1], K. Jayaraj[2], A. Gold[2] and J. A. Swenberg[1,2]. *[1]Pathology and Laboratory Medicine, UNC, Chapel Hill, NC and [2]Environmental Sciences and Engineering, UNC, Chapel Hill, NC.*

1, 3-Butadiene (BD) is carcinogenic in rodents and may also be a human carcinogen. While several epoxides formed during BD metabolism are mutagenic and may contribute to BD carcinogenicity, another proposed metabolite, hydroxymethylvinyl ketone (HMVK), could also play a role. By analogy with other α, β-unsaturated carbonyls, HMVK might be mutagenic *via* formation of promutagenic DNA adducts, specifically 1, N^2-propanodeoxyguanosine adducts. A significant quantity of HMVK is likely to be formed since it is a proposed intermediate in the metabolism of 3-butene-1, 2-diol (BD-diol) to 1, 2-dihydroxy-4-(*N*-acetylcysteinyl)-butane (MI), the major mercapturic acid metabolite of BD in humans. In addition, BD-diol is a major BD metabolite in rodents. Understanding potential contributions to BD carcinogenicity made by metabolites in this pathway is critical for accurate risk assessment. Since HMVK may be a significant metabolite in both humans and rodents it is necessary to determine if it is indeed able to form promutagenic DNA adducts. The hypothesis underlying this study is that HMVK forms 1, N^2-propanodeoxyguanosine adducts *in vitro*. To test this, HMVK was synthesized and incubated with 2'-deoxyguanosine at 37°C for ~24 hours under basic conditions. Adducts were separated from the unreacted nucleoside by HPLC. The resulting chromatograph showed two product peaks. Rechromatography of each collected peak yielded a chromatograph with the two original product peaks, suggesting equilibration of diastereomeric products. Full scan MS confirmed the expected molecular ion at m/z = 354 ($M + H^+$), and MS/MS gave a fragmentation pattern consistent with 1, N^2-propanodeoxyguanosine adducts. The chemical structure was definitively established by ^{1}H NMR. Proton assignments, verified by 2D NOESY and COSY experiments, confirmed the presence of the equilibrating diastereomers suggested by HPLC. The results show that HMVK is capable of forming promutagenic DNA adducts and could therefore potentially contribute to BD carcinogenicity.

1211 DEVELOPMENT OF NOVEL INTERNAL STANDARD DNA FOR DNA ADDUCT ASSAYS.

Y. Jeong and J. A. Swenberg. *University of North Carolina, Chapel Hill, NC.*

Application of stable isotope labeled internal standards (IS) dramatically enhances the accuracy of mass spectrometry analyses for DNA adducts. IS bases or nucleosides, however, cannot reflect artifacts arising during DNA hydrolysis, such as additional oxidation of unmodified nucleotides, insufficient hydrolysis of DNA to nucleosides, and reactions with other molecules, all of which hinder accurate measurement. To overcome this, we prepared high purity ^{15}N-labeled DNA from *E. coli* after culture in minimum salt medium containing $(^{15}NH_4)_2SO_4$ as a single nitrogen source for bacterial growth. The presence of ^{14}N-purines was less than 10 ppb in labeled DNA. We utilized the ^{15}N-labeled DNA to measure pyrimido[1, 2-α] purin-10(3H)-one (M_1G), the major DNA adduct induced by malondialdehyde (MDA). Under physiological conditions, M_1G is hydrolyzed to a ring-opened aldehyde form by base pairing with dC, which does not occur with M_1G base or its nucleoside under same conditions. This difference limits the use of IS M_1G or IS M_1G-dR not only due to different recoveries, but also due to competitive reaction of the aldehyde moiety toward amines, including Tris, a common buffer. The ^{15}N-DNA was treated with MDA to induce a high number of M_1G adducts in the DNA. 23ng of IS was added to sample DNA followed by mild acid hydrolysis for depurination. Depurinated M_1G and $^{15}N_5$-M_1G were selectively labeled with aldehyde reactive probe (ARP). M_1G-ARP and $^{15}N_5$-M_1G-ARP were measured using LC/MS/MS with selected reaction monitoring (*m/z* 519.3 → *m/z* 188.2 for M_1G-ARP and *m/z* 524.3 → *m/z* 193.2 for $^{15}N_5$-M_1G-ARP). Using this IS DNA, 1~3 M_1G per 10^7 nucleotides were detectable in less than 10 μg of mouse liver DNA. ^{15}N-IS DNA preparation from labeled *E. coli* is a very time and cost efficient way to produce high quality ^{15}N-IS using a simple 2~3 day bacterial culture and routine DNA isolation without any chemical or enzymatic synthesis. Such ^{15}N-labeled DNA should be suitable for most of DNA adduct assays, including multiple DNA adduct arrays. Furthermore, it is useful for the study of any artifact induced during the DNA isolation/hydrolysis process.

1212 A NOVEL ASSAY TO QUANTIFY OXIDATIVE DAMAGE USING BASE EXCISION REPAIR ENZYME 8-OXOGUANINE N-GLYCOSYLASE.

I. M. Baskerville, A. Molinelli, J. Nakamura and J. Swenberg. *Curriculum in Toxicology, University of North Carolina, Chapel Hill, NC.*

7, 8-dihydro-8-oxoguanine (8oxoG) is one of the major DNA base modifications resulting from oxidative stress. This base modification is repaired during the BER pathway by the excision of the damaged base by 8-oxoguanine-DNA glycosylase (Ogg1), which is a bi-functional enzyme with both glycosylase and AP lyase activity. Ogg1 excises oxidized purines by cleaving the N-glycosidic bond with an activated nucleophilic amino acid, which reacts with C-1′ of deoxyribose. This cleavage of the N-glycosidic bond creates a lesion known as the apurinic/apyrimidinic (AP) site, which may become mutagenic if not repaired by an AP lyase. The accurate quantitation of DNA adducts can provide us with an indication of exposure to mutagens or carcinogens and is an important tool in cancer risk assessment. Currently, there is no convenient method to measure oxidized purines in genetic material when only small amount of DNA are available. To address this limitation a new assay for oxidative DNA damage was developed. In this Ogg1-coupled Slot Blot assay, DNA (8-16$_{\mu g}$) is treated with sodium borohydride to reduce aldehydic sites. This DNA is then incubated with Ogg1 to excise oxidized purines and generate an aldehydic site. Finally, an aldehyde reactive probe (ARP) is added to the C-1′ aldehyde on the ring opened sugar resulting from the excision of the oxidized purine base from DNA, followed by application to a nitrocellulose membrane, chemiluminescence and densitometric quantitation. DNA from HeLa cells treated with submillimolar to millimolar concentrations of hydrogen peroxide was used to determine the assay's limit of detection at ~1 per 10^6 nucleotides. Further modification of this assay should lower its current limit of detection. This assay has the ability to measure 8-oxoG, its secondary products and other oxidized purines. The Ogg1-coupled slot blot assay cannot differentiate between these products, however this measurement may give a better idea of oxidative damage than the current methods for 8-oxoG.

1213 DETERMINATION OF DNA-ADDUCTS IN LIVER SAMPLES OF B6C3F1 MICE EXPOSED TO ETHYLENE OXIDE.

H. U. Käfferlein and T. R. Fennell. *CIIT Centers for Health Research, Research Triangle Park, NC.*

Ethylene oxide (EO) is an important chemical intermediate in the polymer industry and can also be formed in humans by metabolism of endogenous ethylene. EO is known to be mutagenic and carcinogenic in rodents and reacts directly with DNA to form N-7-hydroxyethylguanine (7-HEG), O^6-hydroxyethylguanine (6-HEG), and N-3-hydroxyethyladenine (3-HEA). The purpose of this investigation was to refine a method we previously developed for analysis of these adducts by HPLC and tandem mass spectrometry (HPLC-MS/MS). The sensitivity of the method was improved, and the method was validated in detail. Within-series and between-day imprecision for 3-HEA and 6- and 7-HEG was between 3.9% and 14.6% depending on the analyte and concentration, while recovery was determined to be between 84.7 and 112.6%. The limit of quantitation (LOQ, calculated, S/N 10:1) is 0.01, 0.03, and 0.02 pmol/mg DNA for 3-HEA, 6-HEG, and 7-HEG, respectively. The method was used to analyze 3-HEA and 6- and 7-HEG in liver samples from B6C3F1 mice (n = 4) exposed to 100 ppm EO by inhalation for 6 h/d and 5d/wk for 6wk. Following neutral thermal hydrolysis, 7-HEG was determined to be between 21.9 and 27.3 pmol/mg DNA, while 3-HEA was between < LOQ and 0.02 pmol/mg DNA. No 6-HEG could be analyzed. To release 6-HEG from DNA, a second clean-up, including an acidic hydrolysis of DNA, was carried out. Nevertheless, no 6-HEG could be found in liver samples of exposed mice. DNA samples from liver tissue of control mice (n = 4), which were not exposed to EO, were also analyzed for their adduct levels. Only 7-HEG could be detected in the range between 0.21 and 0.45 pmol/mg DNA. No 3-HEA and 6-HEG could be found. The results presented here are part of an on-going study of DNA adduct dosimetry in various target and nontarget tissues of B6C3F1 mice, which were exposed to EO for 0, 10, 25, 100 and 200 ppm by inhalation for up to 48 wk.

1214 FORMATION OF DHP-DERIVED DNA ADDUCTS FROM METABOLIC ACTIVATION OF CLIVORINE, A REPRESENTATIVE OTONECINE-TYPE PYRROLIZIDINE ALKALOID, AND *LIGULARIA HODGSONNII* HOOK PLANT EXTRACT.

Q. Xia[1], M. W. Chou[1], G. Lin[2] and P. P. Fu[1]. [1]*Biochemical Toxicology Division, NCTR, Jefferson, AR and* [2]*Pharmacology, The Chinese University of Hong Kong, Hong Kong, Special Administrative Region, China.* Sponsor: B. Delclos.

Plants that contain pyrrolizidine alkaloids (PAs) are widely distributed in the world. PA-containing plant extracts and pure PAs have been shown to be genotoxic and tumorigenic in experimental animals. Our recent mechanistic studies indicated that riddelliine, a tumorigenic retronecine-type PA, induced liver tumors *via* a genotoxic mechanism mediated by the formation of eight 6, 7-dihydro-7-hydroxy-1-hydroxymethyl-5H-pyrrolizine (DHP)-derived DNA adducts. To date it is not known whether this mechanism is general to PAs of other types, such as otonecine-type PAs. The *Ligularia hodgsonnii* Hook, an herbal plant used as antitussive Chinese medicine, was found to contain several otonecine-type PAs and clivorine is the predominant PA present in this plant species. Clivorine has been shown to induce tumors in rats. In this study, we report that metabolism of the PA-containing extract of this plant by F344 rat liver microsomes results in the formation of DHP. When incubation of this plant extract in the presence of calf thymus DNA, eight DHP-derived DNA adducts were formed. Similar results were obtained from metabolism of the isolated pure clivorine under similar experimental conditions. These results indicate eight DHP-derived DNA adducts were also formed from metabolic activation of otonecine-type PAs in the presence of DNA. This metabolic activation pathway involves (i) formation of the corresponding dehydropyrrolizidine (pyrrolic) derivatives through oxidative N-demethylation of the necine base followed by ring closure and dehydration; and (ii) binding of the pyrrolic metabolites to DNA leading to the DNA adduct formation and tumor initiation. The results also suggest that these eight DHP-derived DNA adducts are potential biomarkers of PA exposure and tumorigenicity.

1215 ASSESSMENT OF DNA STRAND BREAKS IN LEUKOCYTES OF WORKERS OCCUPATIONALLY EXPOSED TO 1-BROMOPROPANE.

M. Toraason[1], D. W. Lynch[1], D. G. DeBord[1], N. Singh[2] and J. Nemhauser[1]. [1]*NIOSH, Cincinnati, OH and* [2]*University of Washington, Seattle, WA.*

As part of two NIOSH Health Hazard Evaluations, the comet assay was performed on peripheral leukocytes from workers to determine if occupational exposure to 1-bromprompane (1-BP) induced DNA strand breaks. Start-of- and end-of-workweek blood and urine samples were collected from 41 and 22 workers at 2 facilities where 1-BP was used as a solvent for spray adhesives in furniture manufacturing. Exposure to 1-BP was assessed from personal breathing zone samples collected for 1-3 days up to 8 hrs per day for calculation of 8 hr time waited average (TWA) 1-BP concentrations. Bromide was measured in blood and urine as an internal biomarker of exposure. Overall, 1-BP TWA concentrations ranged from 0.2 - 271 ppm at site 1 and from 4 - 42.7 ppm at site 2. The highest exposures were in workers classified as sprayers. 1-BP TWA concentrations were statistically significantly correlated with blood and urine bromide concentrations. For estimation of DNA damage, comets were produced by alkaline microgel-electrophoresis and analyzed using VisComet image analysis software. One hundred leukocytes from each blood sample (stored at -80 oC until analysis) were evaluated for comet extent, tail extent, tail moment, and tail integrated intensity among other endpoints as a indexes of DNA single strand breaks/alkali labile sites. Start-of- and end-of-workweek comet endpoints were compared with environmental and internal exposure indices using linear regression analysis. Comet results were also stratified based on job classification. Preliminary analyses indicate that occupational exposures to 1-BP at these two facilities were not associated with the level of DNA strand breaks in leukocytes of exposed workers.

1216 THE OCCURRENCE OF SEVERE ALLERGIC REACTIONS TO FOOD IN NORWAY, BASED ON DOCTORS REPORTS TO THE NORWEGIAN REGISTER OF SEVERE ALLERGIC REACTIONS TO FOOD.

H. G. Wiker[1], M. Løvik[1], R. Kjelkevik[2], B. A. Stensby[1] and B. Gondrosen[2]. [1]*Department of Environmental Immunology, Norwegian Institute of Public Health, Oslo, Norway and* [2]*Norwegian Food Control Authority, Oslo, Norway.* Sponsor: E. Dybing.

Background: It is important to know the incidens of severe allergic reactions to Food. We have limited information about the problem in Norway, and the current register has been undertaken to obtain information about risk groups, offending foods, the circumstances under which the reactions take place, treatment and diagnostic follow-up. Methods: The reporting system became active July 1. 2000. Information material, reporting and informed consent forms were mailed to all identified first line care providers. Serum samples were analysed for specific IgE antibodies to common food allergens. Results: The first 18 months 100 cases were reported. There were 47% males and 53% females. There were marked peaks for young adults and small children. About 2/3 of cases were reported to have known allergies, and 55% had known food allergies. Asthma was reported in 26%. The location of food intake was restaurant (8%), party/visit (7%), institution (3%) home (1%) and unknown (81%). In about half of the cases some assumption could be made about the causative food, and most common were nuts, peanuts and shellfish. Of 12 food allergens used as a standard battery, seropositivity (UniCap*) was most common against peanut, hazelnut; shellfish; and celery (falling order). First symptoms were edema/swelling, urticaria, pruritus and gastrointestinal symptoms. About 50% had their reaction within 30 min after food intake. A strong correlation between seropositivity and early symptom onset was observed. The combination adrenalin/steroids/antihistamine was given in 30% of cases, 9% got adrenalin only, 34% were given various combinations without adrenalin. Bronchodilators was the main treatment in 3% of cases. No deaths were reported.

1217 REDUCTION OF FUMONISIN MYCOTOXINS IN BT. CORN.

B. Hammond[1], K. Campbell[2], T. Degooyer[2], A. Robinson[2], J. Richard[3], J. Segueira[4], C. Rubinstein[4], J. Cea[5], M. Plancke[6], L. Pinson[7], C. Radu[8], H. Esin[8], F. Tatli[9] and R. Grogna[10]. [1]*Monsanto, St. Louis, MO,* [2]*Monsanto, Monmouth, IL,* [3]*Romer Labs, Union, MO,* [4]*Monsanto, Buenas Aires, Argentina,* [5]*Lab. Tech of Uruguay, Montevideo, Uruguay,* [6]*Monsanto, Paris, France,* [7]*INRA, Paris, France,* [8]*Monsanto, Ankara, Turkey,* [9]*Adana Crop Protection Res Inst, Adana, Turkey and* [10]*Monsanto, Brussels, Belgium.*

Biotechnology has made it possible to develop corn hybrids that are protected against a major corn pest, the European corn borer (Ostrinia nubilalis). The coding sequence for Cry1Ab protein derived from Bacillus thuringiensis (Bt.) has been introduced into corn plants (event MON 810). Cry proteins are the active insecticidal ingredients of Bt. microbial insecticides that have been safely used on agricultural crops around the world for 40 years. The Cry1Ab protein is produced throughout corn plant tissues providing season-long protection against corn borers. Decreased insect damage to corn kernals reduces ports of entry for fungi that produce fumonisin mycotoxins. Fumonisins are toxic to farm animals, cause cancer in rodents and may contribute to high cancer rates in farmers in Africa and China that consume large amounts of fumonisin contaminated corn. Field trials with event MON 810 hybrids conducted in the US, France, Argentina and Turkey found generally reduced fumonisin levels in event MON 810 hybrids. In US field trials, fumonisin levels in Bt hybrids were on average 57% of levels in non transgenic controls. Many sites had a 3 fold or greater reduction in fumonisin levels. In Argentina, fumonisin levels in a Bt hybrid were on average, 39% of controls. In France, fumonisin levels were decreased several fold in Bt. hybrids. In Turkey, fumonisin levels were decreased 7 fold in a Bt. hybrid. Implications of reduction in fumonisin levels on human an animal health will be discussed. In countries where fumonisin mycotoxin contamination is high and corn is a major dietary staple, fumonisin exposures can considerably exceed the TDI of 2 ug/kg body weight/day established by Codex. Biotechnology can help improve the food security of corn grain for human and animal consumption.

1218 SAFETY EVALUATION OF AN α-AMYLASE ENZYME PREPARATION DERIVED FROM THE ARCHAEAL GENUS *THERMOCOCCALES* EXPRESSED IN *PSEUDOMONAS FLUORESCENS* BIOVAR I.

T. D. Landry[1], M. Bartels[1], L. Chew[2], J. Davis[1], N. Frawley[3], S. Stelman[4], J. Thomas[1], J. Wolt[4] and D. S. Hanselman[5]. [1]*Toxicology, Dow, Midland, MI,* [2]*Industrial Biotechnology, Dow, San Diego, CA,* [3]*Analytical, Dow, Midland, MI,* [4]*AgroSciences, Dow, Indianapolis, IN and* [5]*INNOVASE LLC, San Diego, CA.*

The engineered α-amylase, BD5088, derived from the domain *Archaea* and the genera *Thermococcus* and *Pyrococcus*, was selected based on its characteristics of low-pH optimum and high thermotolerance, properties that are suited to corn wet milling applications. The host organisms of the three α-amylases from which BD5088 was derived were isolated from marine hydrothermal systems. The recipient strain of the host that is used to produce amylase BD5088, *Pseudomonas fluorescens* DC88, was avirulent after oral administration to mice. An extensive battery of studies designed to meet FDA requirements for Generally Recognized As Safe (GRAS) substances was performed on the enzyme preparation. Analytical characterization confirmed the identity and composition. Repeat-dose oral gavage studies of the BD5088 enzyme preparation in rats, for up to 13-weeks duration, showed no systemic toxicity. Inflammation of the nasal mucosa and the lung was seen in some

rats and was attributed to regurgitation and / or aspiration of the test material that contained lipopolysaccharide from the *Pseudomonas* production strain. This interpretation was validated by administering the enzyme preparation to rats in-feed following pre-mixing in a corn oil slurry. The NOAEL was 890 mg/kg/day as Total Organic Solids. There was no genotoxic activity based on Ames (treat and plate), mouse lymphoma, mouse micronucleus and rat lymphocyte chromosome aberration tests. There was no evidence of allergic potential based on comparison with sequences contained in a database of known allergens and on a digestibility study in simulated gastric fluid. The margin of exposure (safety factor) is $>10^6$ for producing dextrose and fructose syrups by corn wet milling.

1219 CONTAMINATION RESPONSE SYSTEM AS FOOD SAFETY TOOL.

M. K. Hoffman, J. Vodela, A. M. Kadry and C. Maczka. *USDA/FSIS, Washington DC, DC.*

The Food Safety and Inspection Service (FSIS), is a public health regulatory agency of the United States. Department of Agriculture (USDA). FSIS enforces the tolerances and action levels set by FDA and EPA. FDA has statutory authority for setting tolerances and/or action levels for veterinary drugs under the FFDCA. EPA has statutory authority for setting tolerances and/or action levels for pesticides under the FIFRA and FFDCA, as modified by FQPA. The Contamination Response System (CRS) is a part of the FSIS Residue Program that is designed to monitor, detect and identify, and reduce and control residues of animal drugs, pesticides, and other chemical contaminants in meat, poultry and egg products. The CRS is activated in the event of a chemical contamination and provides rapid response to suspicion or discovery of residues or other contaminants with the potential to cause widespread adulteration of meat, poultry and egg products. The CRS includes procedures for expediting communication within and between Federal agencies, collection of information, evaluation, and decision making. In a four year period (1998-2001), we identified 42 CRS cases. Highest number of cases reported in year 1999 (20 cases) followed by year 1998 (10), 2000 (6) and 2001 (6). Bovines had highest number (17 cases) of contaminants as compared to other species of the cases such as 7 incidents in horses, 2 in sheep, 8 in goats, 7 in pigs and 1 in turkey. Polychlorinated biphenyls (45%) are the most predominantly identified environmental pollutants. Other pollutants such as benzene hexachloride (1) diphenyl dichlorotrichloroethane (4), chlordane (4), carbodax (1), endosulfan (2), famphur (3), heptachlor (1), lindane (2), methoxychlor (1), pentachloroaniline (1), poly brominated biphenyls (1), phenylbutazone (1) and toxaphen (1) constitute the remainder. USDA/FSIS CRS program in conjunction with EPA and FDA plays a pivotal role in protecting consumers from meat and poultry products that contain chemical contaminants.

1220 ANTIMICROBIAL RESIDUES IN THE UNITED STATES HORSE, SHEEP AND GOAT MEAT.

A. M. Kadry, D. Gallagher, J. Kause and C. Maczka. *Risk Assessment Division, Office of Public Health and Sciences, Food Safety and Inspection Service Department of Agriculture, Washington, DC.*

The National Residue Program of the Food Safety and Inspection Service (FSIS) of the USDA includes a comprehensive testing program for residues of pesticides, drugs and other chemical contaminants in meat and poultry. In the current investigation, nine years of data from the National Residue Monitoring Program (1992-2000) were examined. FSIS conducted 2112 analyses for antibiotics and 1369 analyses for sulfonamides in horses between 1992 and 2000. During this period only 154 and 5 violative animals for antibiotic and sulfonamides were found, respectively. Penicillin and streptomycin were the most commonly detected antibiotics in horse during the examined period (30 and 135 detection respectively). There was steady increase in the number of detections of penicillin (2 vs. 9) and streptomycin (10 vs. 58) during 1993-2000. Because there is no established tolerance for most of the examined antibiotics in horsemeat, any detected amount is considered a violation. Gentamicin and oxytetracycline residue were detected only once each during 1999 and 2000. During the 1992-2000 period, 2377, 3518, and 2586 mature sheep, lambs, and goats were tested for antibiotics respectively. During the same period, 1422, 2581, and 2361 mature sheep, lambs, and goats were tested for sulfonamides, respectively. Chlortetracycline and tetracycline were the most commonly detected antibiotics in lambs, with 8 and 6 detections respectively. Chlortetracycline was also the most commonly detected antibiotics in mature sheep. With five detections, sulfamethazine was the most commonly detected sulfonamide in goats. Only one mature sheep, eight lambs, and one goat carcass contained violative levels of antibiotics. Three lambs and seven goat carcasses contained violative levels of sulfonamides.

1221 URINARY METABOLITES OF AFLATOXIN IN DOGS AND DIETARY PROTECTION BY CLAY AGAINST CANINE AFLATOXICOSIS.

A. K. Bingham, T. D. Phillips, H. J. Huebner and J. E. Bauer. *College of Vet. Med., Texas A&M University, College Station, TX.*

Six dogs were given a single low level non-toxic dose of aflatoxin B_1. Aflatoxin M_1 detected in the urine regularly cleared the dog's system in 48 h. On average, 71.5% of this metabolite cleared in the first 6 h after dosing, increasing to 90.4% after 12 h. Aflatoxin metabolite P_1 was not found in the urine compared to large amounts of M_1 and trace levels of Q_1. In 1998, 55 dogs died in Texas from eating dog food contaminated with aflatoxin at levels ranging from 150 - 300 ppb. Corn used in the pet foods fed was contaminated with aflatoxin. NovaSil Plus (NSP) is a naturally occurring sorbent used as an anticaking agent in animal feeds. Previous research has shown that NSP is capable of tightly and selectively adsorbing aflatoxin *in vitro* and *in vivo*. Studies were conducted to investigate the ability of NSP to protect dogs from aflatoxin in the diet. In a crossover design, six dogs were randomly fed a complete and balanced diet containing no clay (control) or coated with NSP (0.5%) for a period of 7 days. On day 7, the dogs were given a low level dose of aflatoxin B_1. During the next 48 h, urine samples were collected and analyzed using HPLC. After a 5-day washout period, the diets were switched and the process repeated. Urinary metabolites were measured and compared between the controls and experimental dogs to determine the efficacy of NSP. The NSP diet provided an average decrease in urinary aflatoxin metabolites of 48.7% $\pm$ 16.6 S.D. versus the control diet. Studies incorporating NSP in the extrusion process are underway. Control and NSP-inclusion poultry and rice dog foods were extruded. Preliminary results of an eight dog crossover study indicate similar findings. In conclusion, NSP is effective in protecting dogs fed pet foods that contain aflatoxin. Despite regular screening of ingredients for aflatoxin, low levels may reach the final product undetected. NSP may provide the pet food industry further assurance of canine diet safety. (Supported by Engelhard Corp, Mark L. Morris Prof in Clin Nutr, and NIEHS P42-ESO4917)

1222 MATERNAL AND DEVELOPMENTAL ASSESSMENT OF MONTMORILLONITE CLAYS COMMONLY ADDED TO ANIMAL FEEDS: TOXICITY EVALUATION AND METAL BIOAVAILABILITY IN THE PREGNANT RAT.

M. C. Wiles, H. J. Huebner, E. Afriyie-Gyawu, R. J. Taylor, G. R. Bratton and T. D. Phillips. *Faculty of Toxicology, Veterinary Anatomy & Public Health, College of Veterinary Medicine, Texas A & M University, College Station, TX.*

A variety of common clay minerals are frequently added to animal feeds to bind and reduce the bioavailability of mycotoxins in the gastrointestinal tract. However, the safety of many of these products has not been thoroughly investigated. Those that act nonselectively may interact with nutrients, minerals, and other feedborne chemicals to pose significant hidden risks. In this study, a calcium montmorillonite clay (NovaSil Plus), that is commonly used to bind aflatoxins, and a sodium montmorillonite clay (Source Clay Minerals Repository, Columbia, MO) were examined. Clay minerals were supplemented in the diet of pregnant Sprague-Dawley rats throughout pregnancy at a level of 2%(w/w). Evaluations of toxicity were performed on day 16 and included maternal body weights, maternal feed intakes, litter weights, and embryonic resorptions. Liver, kidneys, tibia, brain, uterus, pooled placenta, and pooled embryonic mass were collected and weighed. Tissues were lyophilized and neutron activation analysis (NAA) was performed. Elements considered by NAA include: Al, Ba, Br, Ca, Ce, Co., Cr, Cs, Cu, Dy, Eu, Fe, Hf, K, La, Lu, Mg, Mn, Na, Nd, Ni, Rb, S, Sb, Sc, Se, Sm, Sr, Ta, Tb, Te, Th, Ti, Tl, University, V, Yb, Zn, and Zr. Animals supplemented with either NovaSil Plus or sodium montmorillonite clay were comparable to controls with respect to toxicity evaluations and metal analysis suggesting that these clays do not interact with mineral utilization in the pregnant rat. Although aluminum is a major component in these clays (and of particular interest), the metal was not detected above background limits in any of the tissues evaluated. Thus, this study indicates that even at high concentrations in the diet, neither clay mineral results in maternal or fetal toxicity (Supported by NIEHS P42-ES04917, TAES H6215 and USAID TAM50).

1223 ENHANCED CLAY-BASED ENTEROSORBENT FOR THE PREVENTION OF AFLATOXICOSIS: *IN VITRO* AND *IN VIVO* CHARACTERIZATION.

E. Afriyie-Gyawu, T. D. Phillips, H. J. Huebner and T. D. Phillips. *Faculty of Toxicology, Veterinary Anatomy & Public Heatlh, College of Veterinary Medicine, Texas A&M University, College Station, TX.*

Appropriate interventions that can diminish foodborne exposure to mycotoxins are high priorities. A practical approach to the aflatoxin problem has been the dietary inclusion of a calcium montmorillonite clay (NovaSil) that preferentially binds aflatoxins in the GI tract of animals. In this study our objectives were to characterize

the sorption of aflatoxin onto the surfaces of an enhanced NovaSil clay, i.e. NovaSil Plus (NSP). Equilibrium adsorption of AfB_1 to NSP was investigated using isothermal analysis. Toxin was mixed with clay at different temperatures for 24 hr; the concentration adsorbed (mol/kg) versus the equilibrium concentration in the supernatant (mol/L) was compared to standard isotherms. Data were fitted to multiple isotherm equations including: Langmuir, Freundlich, Toth, and various transforms in order to gain an insight into the molecular mechanism(s) and site(s) of AfB_1 adsorption. NSP was shown to possess a higher capacity for AfB_1 (i.e., 459 nmol/mg) versus 325 nmol/mg for NS. The enthalpy of binding was centered at -49.2 kJ/mol, suggesting chemisorption of ligand. Distribution coefficients of 2.3 $x10^5$ and 7.5 x 10^5 (for NS and NSP, respectively) confirmed high affinity binding for both clays. The sorption of AfB_1 to heat-collapsed NSP was reduced by more than 90%, suggesting that the interlayer (and calcium ions) play a key role in the mechanism of binding. The composition of matter for both clays was determined using neutron activation analysis. Oxidative metabolites in the urine of AfB_1 exposed rats were decreased in the presence of both clays. Molecular models were generated for the NSP-AfB_1 complex and support the conclusion that AfB_1 may react at multiple sites, but especially within the gallery of NSP. In summary, NSP binds aflatoxin with enhanced affinity and capacity versus NS. The mechanism appears to be similar for both clays (Supported by USAID TAM50 and NIEHS P42-ES04917).

1224 CLINICOPATHOLOGIC CHARACTERIZATION OF FUMONISIN B_1 (FB1) INDUCED HEPATO-, NEPHRO- AND NEURO-TOXICITY IN HORSES.

W. M. Haschek[1], A. L. Waggoner[1], S. Hsiao[1], G. W. Smith[2,1], M. E. Tumbleson[3], R. M. Eppley[4], J. H. Foreman[3] and P. D. Constable[3]. *[1]Veterinary Pathobiology, University of Illinois, Urbana, IL, [2]Veterinary Clinical Medicine, University of Illinois, Urbana, IL, [3]Veterinary Biosciences, University of Illinois, Urbana, IL and [4]USFDA, Washington, DC.*

Fumonisins induce hepatotoxicity in all species. In horses, FB1 induces cardiotoxicity and death due to neurotoxicity (leukoencephalomalacia) or liver failure. To investigate the pathogenesis of fumonisin toxicosis in horses and attempt to determine a NOEL, we characterized the time and dose-relationship of FB1 induced serum and urinary biochemical changes and correlated them with morphologic alterations. FB1 was administered iv at 0.20, 0.10, 0.05, 0.01 or 0 mg FB1/kg BW/day (n=3 or 4). Horses were euthanized on day 28 or when neurologic signs became severe (≥7 days, ≥0.05 mg FB1/kg). FB1 induced dose- and time-dependent increases in serum total bilirubin, bile acids and total protein concentrations (at all doses); SDH, AST, ALP, GGT activities and cholesterol (≥0.05 mg FB1/kg); and creatinine concentration (≤0.10 mg FB1/kg). In urine, GGT activity and GGT:creatinine ratio were increased at all doses. In the nervous system, a dose-dependent vasculopathy with severe proteinaceous perivascular edema, leukocytosis and hemorrhage was present in brain and spinal cord at all doses. Icterus was present at ≥0.05 mg FB1/kg with hepatocellular apoptosis (± necrosis) at all doses but especially at 0.05 mg FB1/kg. Renal lesions were not observed. Therefore, FB1-induced serum biochemical changes occurred at all doses and correlated with morphologic alterations in liver but not in kidney. A NOEL was not determined. Supported by FDA and USDA-CSREES grant # 928-39453.

1225 DETERMINATION OF ZEARALENONE IN SOME CEREALS, NUTS AND DRIED FRUITS COLLECTED FROM ALEXANDRIA MARKETS.

S. A. Soliman, N. S. Ahmed, K. A. Osman and M. S. Ibraheem. *Pesticide Chemistry, Alexandria University, Alexandria, Egypt.*

Wheat, corn and rice, of two production locations in El-beheira Governorate, and several nuts and dried fruits samples were collected from Alexandria markets and analyzed for the presence of zearalenone (ZEA). Samples were subjected for acid/base extraction and for cleanup with liquid-liquid separation. High performance liquid chromatography (HPLC) with UV detection was used for ZEA identification and quantitation. Results indicated that wheat samples collected directly after harvesting were ZEA-free, while 2 out of 3 wheat samples collected late post harvesting were positive for ZEA with concentrations of 877 and 921 ug/kg. Seven out of eleven corn and 2 out of 3 rice samples were positive for ZEA. The level of ZEA in six of the positive corn samples were in the range of 236 to 1970 ug/kg, while the level in the seventh sample sharply exceeded this range reaching unexpected value of 15703 ug/kg. This huge level could be attributed to the unacceptable storage conditions. Two out of the three tested rice samples were found to contain ZEA at levels of 254 and 476 ug/kg. Hazelnut; walnut; pistachio nut and coconut samples were positive for ZEA with ranges of 188-3838; 95-148; 84-808 and 35-768 ug/kg, respectively.Almond samples were ZEA-free and so were the tested dried fruit samples. Farmers and distributers of cereals and nuts should mentain good storage conditions for these products in order to reduce the risk to concumers by the generated mycotoxins.

1226 EFFECTS OF COOKING ON THE BIOLOGICAL ACTIVITY OF FUMONISINS.

K. A. Voss[1], W. P. Norred[1], F. I. Meredith[1], R. T. Riley[1], C. W. Bacon[1] and S. Saunders[2]. *[1]Toxicology & Mycotoxin Research Unit, USDA-Agricultural Research Service, Athens, GA and [2]Department of Food Safety, Frito-Lay Inc., Plano, TX.*

Fumonisin (FB) mycotoxins are found in corn and corn-based foods. Cooking decreases FB concentrations under some conditions, but little is known about how cooking effects its biological activity. Baked cornbread (BCB), pan-fried corn cakes (PFC), and deep fried corn fritters (DFF) were made from corn meal spiked with *Fusarium verticillioides* culture material (FCM) and fed to male rats (n=5) for 2 weeks at high (1% w/w FCM equivalents) or low (0.1 % FCM equivalents) doses. Controls were fed 1% w/w sound corn. Toxic response to BCB, PFC, DFF, and FCM included decreased body weight gain (1% diets only), decreased kidney weight, and microscopic kidney and liver lesions of the type caused by FB. FB concentration (FB_1 + FB_2) in the 1% w/w PFC diet (92.2 ppm) was slightly, but not significantly ($p<0.05$), lower than those of the 1% w/w BCB (132.2 ppm), DFF (120.3 ppm) and FCM (130.5 ppm) diets. In a second experiment, 10 g of corn containing 26 ppm FB_1, masa made from the corn, and baked and fried tortilla chips made from the masa were extracted twice with 50 ml acetonitrile/water (1:1). Extracts were combined, dried, and redissolved in 1.0 ml DMSO. Vero cells were dosed with 4 µl of the redissolved extracts for 48 hr. The corn extract inhibited ceramide synthase as indicated by significantly increased cell sphinganine (Sa) concentrations (mean=132 pmole/well), whereas Sa was unaffected by the masa, baked chip and fried chip extracts (mean Sa 14-24 pmole/well). FB_1 concentrations of the masa and chips (2.3-4.6 ppm) were likewise reduced more than 80% compared to the corn. In summary, baking and frying had no significant effect on the biological activity or concentration of FB in corn-based foods while, in contrast, nixtamalization reduced both biological activity and FB concentration in masa. Furthermore, these studies provided no evidence for the formation of unknown, biologically active FB products during cooking.

1227 FATE OF FUMONISIN IN MAIZE DURING NIXTAMALIZATION AND TORTILLA PRODUCTION BY MAYAN COMMUNITIES IN GUATEMALA.

R. T. Riley[1], E. Palencia[2], O. Torres[2], W. Hagler[3], F. Meredith[1] and L. Williams[4,1]. *[1]USDA/ARS, Athens, GA, [2]Instituto de Nutricion de Centro America y Panama, Guatemala City, Guatemala, [3]North Carolina State University, Raleigh, NC and [4]College of Agriculture and Environmental Sciences, University of Georgia, Athens, GA.*

Fumonisin B1 (FB1) is a carcinogenic mycotoxin found in maize. In the preparation of tortillas, maize is boiled in a lime solution, which hydrolyzes at least a portion of the FB1 to the aminopentol backbone (HFB1). The alkali processing of maize (nixtamalization), when conducted in a laboratory or commmercial setting, reduces the total fumonisin content. The purpose of the present study was to 1) determine if the traditional method of nixtamalization as practiced by rural Kaqchikel-speaking Mayan communities in Guatemala reduces the level of fumonisins in tortillas produced from fumonisin-contaminated maize, and 2) determine the steps in the traditional process where reduction in fumonisin levels is most likely to occur. Analysis of cooked tortillas prepared by the Mayan traditional process revealed detectable amounts of FB1, FB2 and FB3 and their hydrolyzed counterparts. There was approximately equal molar amounts of FB1 and HFB1 in the cooked tortillas but the total amount of FB1 plus HFB1 was reduced approximately 60% compared to that originally in the uncooked maize. The total FB1 plus HFB1 in the lime-water used to cook the maize and water washes of the nixtamalized maize accounted for approximately 50% of the total FB1 in the uncooked maize. The amount of HFB1 in lime-water after steeping was much greater than FB1. A total of 11% of the FB1 in the uncooked maize was accounted for in the combined water washes (3). The three fractions (tortillas, lime-water and washes) together accounted for 94% of the FB1 originally in the uncooked maize. These results show that the traditional Mayan method of nixtamalization reduces the total fumonisins in the final product and that the majority of the lost fumonisins are found in the alkali steep water; findings that are similar to that of studies conducted using commercial or non-traditional methods of nixtamalization.

1228 FUMONISIN B_1 TOXICITY IN THE BRAIN DURING COEXISTING LIPOPOLYSACCHARIDE-RELATED ENDOTOXEMIA IN BALB/C MICE.

M. F. Osuchowski, Q. He and R. P. Sharma. *Physiology and Pharmacology, The University of Georgia, Athens, GA.*

Fumonisin B_1 (FB_1) is a mycotoxin synthesized by *Fusarium verticillioides*, a widespread contaminant of corn. FB_1 is a causative agent of animal diseases including equine leukoencephalomalacia. This experiment studied the modulation of FB_1

toxicity in the brain regions after administration of endotoxin known to disrupt the blood-brain barrier (BBB). The BBB integrity after lipopolysaccharide (LPS) treatment was evaluated in female BALB/c mice (4/group) after a single intraperitoneal (i.p.) dose of LPS (3 mg/kg). After 24 and 48 hours 200 ml of 0.5% sodium fluoresceine (NaFl) was injected intravenously. Animals were sacrificed 1 hour later, brains dissected and fluorescence determined. An increase in NaFl brain levels was observed at both time points. Next, female BALB/c mice (5/group) were injected i.p. with 3 mg/kg of LPS on the first day of treatment and/or with 2.25 mg/kg of FB_1 daily subcutaneously for 3 days. Cortex, cerebellum and medulla oblongata but not midbrain indicated increased free sphinganine in the FB1 group compared to control, as determined by high performance liquid chromatography. All regions showed a greater increase in free sphinganine in LPS/FB_1 group. Reverse transcriptase polymerase chain reaction analysis assessed the expression of proinflammatory cytokines in the brain. Treatment with LPS alone induced expression of interferon γ (IFNγ), interleukin (IL)-1β, IL-6 and IL-12. Treatment with FB_1/LPS further increased expression of tumor necrosis factor a, IL-6 and IL-12, while a decrease was observed for IFNγ and IL-1β compared to LPS treatment alone. Results indicated the endotoxin-related BBB disruption was followed by inhibition of de novo synthesis of sphingolipids by FB_1 in the brain. The changes in IFNγ, IL-1β, IL-6 and IL-12 expression between LPS and LPS/FB_1 dose groups suggest interactions between endotoxin and FB_1. The exposure to FB_1 coexisting with bacterial infection may have adverse effect on the brain. (Partially supported by NIH ES09403).

1229 SUBCHRONIC TOXICITY IN RATS FED CULTURE MATERIALS OF FUMONISIN-PRODUCING AND MONILIFORMIN-PRODUCING FUNGAL ISOLATES.

J. R. Owen[1,2], R. D. Plattner[3], G. E. Rottinghaus[4], R. T. Riley[1,2], R. L. Tackett[2] and K. A. Voss[1,2]. *[1]Toxicology & Mycotoxin Research Unit, USDA-Agricultural Research Service, Athens, GA, [2]College of Pharmacy, University of Georgia, Athens, GA, [3]National Center for Agricultural Utilization Research, USDA-Agricultural Research Service, Peoria, IL and [4]University of Missouri, Columbia, MO.*

Fumonisin (FB) and moniliformin (MN) are *Fusarium* mycotoxins that co-occur in corn and foods. Their effect on human health is unclear, but both have been implicated as a factor in one or more diseases. FB is hepato- and nephrotoxic in various species and causes liver and kidney cancer in rodents. The heart is not considered a target in rodents, but FB does affect cardiac function in swine *in vivo* and in frog heart atria *in vitro*. The heart, kidney and liver are target organs of MN in poultry and rats. Additive toxicity has been found in poultry co-exposed to FB and MN. To study the effect of co-exposure in a mammalian species, male rats (2 replicate experiments; n=3/group per replicate) were fed diets spiked with FB-producing (fumonisin B_1 + B_2 + B_3) *Fusarium verticillioides* and MN-producing *F. fujikuroi* culture materials for two weeks *ad libitum*. Mycotoxin concentrations of the diets were: 0 ppm FB/0 ppm MN (control group), 400 ppm FB/0 ppm MN, 400 ppm FB/200 ppm MN, or 400 ppm FB/500 ppm MN. The replicate experiments yielded similar results. All FB-fed groups exhibited decreased body weight, decreased relative (% body weight) liver and kidney weights, and increased tissue sphinganine concentrations indicative of ceramide synthase inhibition. Apoptosis and other microscopic liver and kidney lesions were also consistent with FB toxicity and, like the other effects, were not modified by MN. Relative heart weight (% body weight) of the 400 ppm FB/500 ppm MN group was slightly increased, however, gross or microscopic heart lesions were not found in any group. In summary, MN did not significantly modify the subchronic toxicity to rats of FB-containing diets. Further investigations are needed to study the effects of chronic co-exposure to FB and MN.

1230 KINETICS OF DEOXYNIVALENOL (VOMITOXIN) DISTRIBUTION AND CLEARANCE FOLLOWING ORAL EXPOSURE IN THE MOUSE.

P. Yordanova, Z. Islam and J. J. Pestka. *Michigan State University, East Lansing, MI.*

Deoxynivalenol (DON or vomitoxin) is a trichothecene mycotoxin commonly found in cereal grains that adversely affects the gastrointestinal and immune function. Here we developed approaches to analyze for DON in tissue by immunochemical assay and used these to follow the kinetics of distribution and clearance of this mycotoxin in the mouse. Spiking studies revealed that DON in plasma could be analyzed directly using a competitive direct enzyme-linked immunosorbent assay (ELISA) providing that standard curves were prepared in human plasma as diluent. For analysis of organs, tissues were ground with a mortar and pestle in phosphate buffered saline (1:5 ratio). Resultant extracts were then heated in boiling water for 5 min, centrifuged, and supernatants analyzed by ELISA. Tissue disposition and clearance of DON were measured in B6C3F1 male mice (8 wk-old) that were orally administered 25 mg/kg BW of the toxin. Blood was collected from retroorbital plexus and organs removed after 30 min to 24 hr intervals. Maximal DON was detected at 30 min in all tissues tested with a rapid clearance following over a 24 hr period. At 30 min, DON concentrations in ng/g were 5680±1480 in kidney, 4530±1140 in heart, 4430±440 in plasma, 3900±206 in liver, 3640 ± 105 in thymus, 2990±110 in spleen and 763±61 in the brain. DON concentrations were significantly higher in all the organs tested from 30 min to 8 hr compared to untreated mice. At 24 hr, DON concentrations dropped to levels which were not significantly higher except in kidney. Taken together, the results showed that, in the mouse, DON rapidly distributed in all organs within a short time after exposure according to the rank order kidney> heart> plasma> liver> thymus> spleen> brain. (supported by NIH Grants ES 03358, ES-09521 and DK 58833).

1231 HUMAN CYTOKINE mRNA RESPONSE TO DEOXYNIVALENOL (VOMITOXIN) USING WHOLE BLOOD CULTURES.

K. M. Penner, J. S. Gray and J. J. Pestka. *Michigan State University, East Lansing, MI.*

Deoxynivalenol (DON or vomitoxin), a tricothecene mycotoxin, is a naturally occurring contaminant frequently found in grain-based foods. This toxin has adverse effects on human and animal health, with the GI tract and immune system being primary targets. A critical step in DON toxicity is action on leukocytes by activation of cytokines. Previous studies have shown an upregulation of several cytokines, in U937 cells, a cloned human macrophage model. To study the acute effects of DON on human cytokine production in peripheral mononuclear blood leukocytes, we have developed a culture approach using a 20 percent dilution of whole blood in RPMI-1640 media and a 6 hour exposure. Cultures were exposed to DON at concentrations of 0, 10, 50, 100, 250, and 500 ng/ml. RNA was then isolated and assayed using real-time PCR primer/probes, for both cytokines (IL-6, IL-8, and TNF-alpha) and 18S rRNA. Cytokine levels were normalized using 18S rRNA levels and relative expression levels determined. IL-6 was significantly induced by DON at 250 ng/ml (~9.5 fold) and 500 ng/ml (~14 fold). IL-8 was significantly induced by DON at 250 ng/ml (~8.5 fold) and 500 ng/ml (~3 fold). TNF-alpha was significantly induced by DON at 10 ng/ml (~1 fold), 250 ng/ml (~1 fold), and 500 ng/ml (~4 fold). Taken together, the capacity of DON to induce IL-8, IL-6, and TNF-alpha gene expression and the threshold doses to achieve these effects were consistent with previous findings in cloned human and mouse macrophage cultures. Interestingly, a high degree of variability was observed in blood cultures from different donors, thus raising the possibility that some individuals may have greater sensitivity to DON than others. Further research is being undertaken to clarify this possibility.

1232 INTERACTIONS BETWEEN MACROPHAGES AND NONPARENCHYMATOUS LIVER CELLS IN RESPONSE TO FUMONISIN TREAMENT *IN VITRO*

N. Sharma, Q. He and R. P. Sharma. *Physiology and Pharmacology, University of Georgia, Athens, GA.*

Fumonisin B_1 (FB_1), a common mycotoxin produced by *Fusarium verticillioides* found in corn, causes animal diseases such as equine leukoencephalomalacia and porcine pulmonary edema. It induces tumors in male rat kidney and female mouse liver, and has been associated with human esophageal cancer in areas highly contaminated with fumonisins. Liver and kidney are the target organs of fumonisin in laboratory animals, but cells from liver are resistant to fumonisin toxicity *in vitro*. We have shown that FB_1 induces localized activation of cytokine network in mouse liver. Expression of tumor necrosis factor (TNF)α, interferon (IFN) γ, and interleukin (IL) 12 in mouse liver was increased in response to FB_1. A positive amplification loop involving TNFα, IFNγ and IL-12 has been implied and involves liver macrophage (Kupffer) cells and the hepatic lymphocytes. The resistance of individual cells to the cytotoxic effects of FB_1 *in vitro* may be due to the absence of interactions between the cytokines that are produced by different types of cells. We investigated the cellular interactions in FB_1-induced toxicity using mixed cultures of macrophages (J774A.1) and nonparanchymatous liver cells (NmuLi). The results indicated that treatment of the mixed cells with 10 μM FB_1 for 48 h or 72 h produced a greater increase in lactate dehydrogenase release than either J774A.1 or NmuLi cells alone. Expression of *TNFα* and *IL-12* in mixed cultures was increased following 10 μM FB_1 treatment for 24 h, while individual types of cells were unresponsive to FB_1 treatment. Transfer of conditioned medium from J774A.1 cells treated with 10μ M FB_1 for 24 h to NmuLi cultures produced an increase in *IFNγ* expression in NmuLi after 6 h incubation. These results indicate that interactions between different types of cells are involved in hepatotoxicity and can be a contributory factor in FB_1 toxicity. (Supported in part by NIH grant ES 09403).

1233 CHRONIC DIETARY TOXICITY STUDY OF DAG (DIACYLGLYCEROL) IN BEAGLE DOGS.

C. P. Chengelis[1], J. B. Kirkpatrick[1], G. B. Marit[1], O. Morita[2], Y. Tamaki[2] and H. Suzuki[2]. *[1]WIL Research Laboratories, Inc., Ashland, OH and [2]Kao Corporation, Haga Tochigi, Japan.*

This study evaluated the possible chronic toxicologic effects of DAG, when given in the diet for 12 months to dogs. DAG is a cooking oil which contains > 80% diglycerides, < 20% triglycerides and <5 % monoglycerides. For this study, a special diet

was prepared with no dietary fat so that all of the dietary fat could be provided by DAG, at various concentrations together with a control oil. The control oil, TG (triacylglycerol), was prepared to contain > 85% triglycerides, < 10% diglycerides and <5 % monoglycerides. The fatty acid composition for DAG and TG was closely matched. Dietary concentrations of 0% DAG/9.5% TG (TG control), 1.5% DAG/8.0% TG, 5.5% DAG/4.0% TG, and 9.5% DAG/0% TG were presented daily, seven days per week, for 52 weeks. A second concurrent control group received the standard basal diet (Certified Canine LabDiet 5007, which has a fat content of 9.5%). The basal diet, control article-treated and DAG-treated groups each consisted of four males and four female dogs. Treatment was initiated in prejuvenile (2.5 months old) dogs. Statistical evaluations compared the DAG-treated groups both to the basal diet and 9.5% TG control groups. The clinical condition of the animals, body weights, body weight gains and food consumption were unaffected by DAG. Hematology and urinalysis parameters were unaffected. No serum chemistry changes indicative of a toxic effect were observed. There were no effects noted on ECG data. No test article-related gross or histopathologic findings or changes in organ weights were observed. While there were no identifiable differences between the effects of TG and DAG, both caused some changes relative to the basal diet (decreased food consumption, higher alkaline phosphatase, cholesterol and triglycerides). These changes were not toxicologically significant and were attributed to the differences in the diet. Thus, DAG at dietary concentrations up to 9.5% for one year were not toxic, and had no effect on normal canine growth and development.

1234 BISPHENOL A INTERFERES WITH MICROTUBULES IN CULTURED HUMAN FIBROBLASTS.

L. Lehmann and M. Metzler. *Institute of Food Chemistry and Toxicology, University of Karlsruhe, Karlsruhe, Germany.*

Bisphenol A (BPA) is widely used for the manufacturing of plastics, coatings and resins. In addition to being estrogenic, BPA exhibits genotoxic potential in cultured cells, e.g. by inducing micronuclei with whole chromosomes in Chinese hamster V79 cells and causing near-diploid aneuploidy and morphological transformation in Syrian hamster embryo cells. Since the induction of aneuploidy is often associated with the disruption of microtubules (MT), the ability of BPA to interfere with MT in cultured human AG01522C fibroblasts was assessed in the present study. We determined the mitotic index, the structure of the mitotic spindle and of the cytoplasmic microtubule complex (CMTC), and the number of freshly divided cells. The mitotic spindle and the CMTC were visualized by immunochemical staining of α-tubulin. Cytotoxicity or growth inhibition were assessed by electronic counting of the number of living cells. After exposure of the fibroblasts to BPA concentrations of 200 to 450 μM for half a population doubling (12 h), both the number of living and of freshly divided cells and the mitotic index declined in a concentration-dependent manner. The CMTC of BPA-treated cells contained abnormal structures resembling rings and loops (R&L), which to our knowledge have not been observed before. When fibroblasts were treated with 300-400 μM BPA for 12 h and the number of R&L determined at various time points after treatment, abnormal cells reached a maximum (30-50% of cells containing 1-3 R&L) after 1-4 h and declined steadily thereafter; control levels were reached 36 h after incubation with 300 or 350 μM BPA, whereas abnormal cells were still elevated 48 h after incubation with 400 μM BPA. The decrease of R&L did not correlate with cell growth. When cells were kept at 4°C for MT depolymerization, only about two thirds of the abnormal MT structures disappeared within a few minutes, whereas one third persisted. These data suggest that BPA interferes with MT polymerization in cultured human fibroblasts. The underlying mechanism is presently unknown and requires further studies.

1235 FUMONISIN B_1 (FB1) ALTERS SPHINGANINE (SA) AND SPHINGOSINE (SO) CONCENTRATIONS IN SERUM, TISSUE, URINE AND CEREBROSPINAL FLUID (CSF) OF HORSES.

M. E. Tumbleson[1], W. M. Haschek[2], A. L. Waggoner[2], P. D. Constable[3], G. W. Smith[3], J. H. Foreman[3] and R. M. Eppley[4]. *[1]Veterinary Biosciences, University of Illinois, Urbana, IL, [2]Veterinary Pathobiology, University of Illinois, Urbana, IL, [3]Veterinary Clinical Medicine, University of Illinois, Urbana, IL and [4]USFDA, Washington, DC.*

Fumonisins alter sphingolipid biosynthesis and induce hepatotoxicity in all species. In horses, FB1 induces cardiotoxicity and death due to neurotoxicity (leukoencephalomalacia) or liver failure. To investigate the pathogenesis of fumonisin toxicosis in horses, we evaluated the time and dose response of sphingolipids to FB1 in serum, tissue, urine and CSF and correlated with pathophysiologic findings (Haschek et al, SOT 2003 abstract; Smith, GW, et al, Am J Vet. Res 63:538-545, 2002). FB1 was administered iv at 0.20, 0.10, 0.05, 0.01 or 0 mg FB1/kg BW/day (n=3 or 4). Horses were euthanized on day 28 or when neurologic signs became severe (≥7 days, ≥0.05 mg FB1/kg). Blood, urine, CSF and selected tissues were analysed for So and Sa concentrations by HPLC. FB1 induced 1) dose- and time-dependent increases in serum Sa and So at all doses; 2) dose-dependent increases in liver and kidney Sa at ≥0.05 mg FB1/kg and So at all doses; 3) dose-dependent increases in lung Sa and So at all doses; 4) dose-dependent increases in heart and skeletal muscle Sa at all doses and So at ≥0.05 mg FB1/kg; 5) an increase in brain So at 0.10 mg FB1/kg and a decrease in spinal cord Sa at 0.01 mg FB1/kg; 6) a dose-dependent increase in urine Sa ≥0.05 mg FB1/kg and Sa:So at all doses; and 7) an increase in CSF Sa at 0.01 mg FB1/kg. Based on this and other studies, we conclude that increases in serum sphingolipid concentrations are the most sensitive and specific indicators of FB1 exposure in horses. Altered sphingolipid metabolism in liver, kidney and heart correlate with organ specific injury as determined by physiologic and pathologic evaluation, while alterations in lung and central nervous system sphingolipid metabolism do not appear directly correlated with organ specific injury. Supported by FDA and USDA-CSREES grant # 928-39453.

1236 TUMOR NECROSIS FACTOR-α INDUCTION IN FUMONISIN B_1-TREATED PORCINE RENAL EPITHELIAL CELLS IS MEDIATED VIA ACTIVATION OF PROTEIN KINASE C-α AND NUCLEAR FACTOR-κB.

N. V. Gopee and R. P. Sharma. *University of Georgia, Athens, GA.*

Fumonsin B_1 (FB_1) is a toxic metabolite produced by *Fuasrium moniliforme* (*F. verticillioides*), a fungus predominantly present in corn. FB_1 is known to be responsible for a variety of species-specific diseases including pulmonary edema in pigs and leukoencephalomalacia in horses. This mycotoxin has been reported to be a renal carcinogen in male rats, hepatocarcinogen in female mice and has been implicated as a contributing factor in human esophageal cancer. It inhibits ceramide synthase, enhances tumor necrosis factor-α (TNFα) production, and causes apoptosis. We previously showed that 1 μM FB_1 caused transient activation of protein kinase C-α (PKCα) in porcine renal epithelial cells (LLC-PK_1). It has been established that PKC activates nuclear factor-κB (NF-κB), an important transcription factor for the proinflammatory cytokine, TNFα. Therefore, this study investigated the implications of PKCα activation by 1 μM FB_1 on NF-κB activation and subsequently on TNFα gene expression in LLC-PK_1 cells. FB_1 (1 μM) induced a rapid and transient activation of PKCα and nuclear translocation of NF-κB at 5 min, followed by their down-regulation. This FB_1-induced translocation was inhibited by preincubating LLC-PK_1 cells with the PKC inhibitor, calphostin C. TNFα mRNA expression was significantly increased following 15 min exposure to FB_1. Co-exposure of cells with FB_1 with phorbol 12-myristate 13-accetate (PMA) resulted in an amplified expression of TNFα, as compared to FB_1 alone. Calphostin C abrogated the FB_1-induced increase in TNFα gene expression. This study puts forward compelling evidence that short-term activation of PKCα by FB_1 results in the activation of NF-κB, which transcribes TNFα in LLC-PK_1 cells. The PKCα-dependent induction of TNFα is one of the mechanisms involved in FB_1-induced toxicity in LLC-PK_1 cells. (Supported in part by NIH grant ES09403)

1237 90-DAY CHRONIC TOXICITY STUDY OF A NOVEL (-)-HYDROXYCITRIC ACID EXTRACT OF *GARCINIA CAMBOGIA.*

S. E. Ohia, S. J. Stohs, M. Shara, T. Yasmin, A. Chatterjee, M. Bagchi, A. Zardetto-Smith, A. Kincaid and D. Bagchi. *School of Pharmacy & Health Professions, Creighton University Medical Center, Omaha, CA.*

(-)-Hydroxycitric acid (HCA), a widely used dietary supplement for weight management, is a natural extract from the dried fruit rind of *Garcinia cambogia* . This fruit exhibits a distinctive sour taste and has been used for centuries in Southern Asia for making culinary dishes. The addition of this fruit makes meals more filling and satisfying. Previous studies demonstrated the novel beneficial effect of a novel HCA extract (HCA-SX, commercially known as Super CitriMax) in weight management, as well as its safety in acute toxicity studies. In this study, we have conducted a 90-day chronic toxicity evaluation in male and female Sprague-Dawley rats. The animals were administered 0.2%, 2.0% and 5.0% HCA-SX in their daily feed. 0.2% HCA-SX intake in feed equals 4.62 gm as a 60% HCA-SX extract (2, 770 mg HCA), which is the recommended dosage for human weight loss consumption. The animals were given Purina Lab. Chow and tap water, and sacrificed upon 30, 60 and 90 days of treatment. Changes in body weight, liver and testis weight, and serum chemistry analysis were monitored. Hepatic and testicular lipid peroxidation, and DNA fragmentation were also conducted. Histopathological examination was conducted on the major organs obtained at the time of autopsy. A time-dependent increase in animal body weight was observed in control animals, while HCA-SX administration induced a dose- and time-dependent reduction in body weight gain in both male and female rats. No significant differences in liver and testis weight were observed between the groups at 30, 60 and 90 days of treatment. No changes in hematological and biochemical variables were noted. No significant differences were observed in hepatic and testicular lipid peroxidation and

DNA fragmentation. These results demonstrate that chronic administration of HCA-SX for 90-days does not adversely affect the variables tested in these animals and is safe under the conditions studied.

1238 INDUCTION OF THE PROCARCINOGEN-ACTIVATING CYP1A2 BY A HERBAL DIETARY SUPPLEMENT IN RATS AND HUMANS.

W. Chung and S. Ryu . *Pharmacology, Inha University, Inchon, South Korea.*

Herbal dietary supplements, which are popular worldwide because they are believed to promote health, may in fact be double edge-swords. A herbal dietary supplement which contains extracts of kola nut, grape, green tea and ginkgo biloba, and is used as an agent for weight management, was administered to rats to test whether it induced CYP1A2, a procarcinogen-activating enzyme. Western blot analysis indicated that treatments with 0.5, 1 and 2 g/kg of the supplement for 3 days increased CYP1A2 expression in rat liver microsomes in a dose-dependent manner. The 0.5, 1 and 2 g/kg treatments increased rat liver microsomal CYP1A2 activity *via* the conversion of caffeine to paraxanthine to 212, 331 and 473% of normal, respectively. In humans, the intake of 2 and 4 capsules of the supplement for 3 days increased CYP1A2 activity to 194 and 203%, respectively, as assessed by the change in the urinary ratio of 1, 7-dimethylxanthine plus paraxanthine to unmetabolized caffeine. Intake of the herbal supplement increased CYP1A2 activity to levels higher than that observed from smoking (179%). This study suggests that the long-term intake of the dietary supplement inducing CYP1A2 may increase the incidence of liver, breast, bladder, prostate and colon cancers caused by procarcinogens activated by CYP1A2.

1239 SAFETY OF A NOVEL BOTANICAL EXTRACT FORMULATION FOR AMELIORATING *ALLERGIC RHINITIS.*

D. Bagchi[1], V. S. Saxena[2], N. Pratibha[2], A. Amit[2] and M. Bagchi[1]. *[1]School of Pharmacy & Health Professions, Creighton University Medical Center, Omaha, CA and [2]R & D, Natural Remedies Research Center, Bangalore, India.*

Allergic rhinitis (known as hay fever) is found to be the most frequently occurring immunological disorder affecting 40 million people in the US. Symptomatically, this is an inflammation and irritation of the nasal mucosal membrane. Allergy is defined as a state of hypersensitivity caused by exposure to a particular antigen (allergen) resulting in marked increases in reactivity to that antigen upon subsequent exposure. A novel botanical formulation (Aller-7) was developed for the treatment of *Allergic rhinitis* using a combination of 7 standardized medicinal plant extracts from *P. emblica, T. chebula, T. bellerica, A. lebbeck, P. nigrum, Z. officinale* and *P. longum.* This formulation demonstrated potent antihistaminic, antiinflammatory, antispasmodic, antioxidant and mast cell stabilization activity. This study focused on the safety and antimutagenic potential of the formula, which was tested in Swiss Albino mice at the doses of 125, 250, 500, 1000 and 1500 mg/kg. Following 15 days of feeding, the animals were sacrificed. No histopathological changes were observed in vital organs. A separate study in rats demonstrated no toxicity up to 2 gm/kg bw. Sub-acute toxicity was conducted in Albino Wistar rats at a dose of 90 mg/kg bw for 3 days, which was graduated to 180 mg/kg for the next 3 days then to 270 mg/kg for 3 weeks. After 28 days, the animals were sacrificed and tested, upon which no toxicity was observed. In a subchronic toxicity study, there was no observed effect level (NOEL) at 1 gm/kg bw in rats. In teratologic assay, at the dose of 1.8 g actives (20-times more than the recommended dose), there were no visceral or skeletal anomalies observed in the fetuses. No maternal changes were observed when Aller-7 was administered during gestation and lactation. No evidence of mutagenicity was observed at doses up to 5000 mg/plate of Aller-7 in *S. typhimurium* cells. In conclusion, these studies demonstrate the broad spectrum safety of this novel formulation for human consumption.

1240 TRANS-10, CIS-12 CONJUGATED LINOLEIC ACID INHIBITS DIFFERENTIATION IN 3T3-L1 ADIPOCYTES AND DECREASES PEROXISOME PROLIFERATOR ACTIVATED RECEPTOR γ EXPRESSION IN MICE.

K. Kang[1,2], W. Liu[2], K. J. Albright[2] and M. W. Pariza[1,2]. *[1]Food Microbiology and Toxicology, University of Wisconsin-Madison, Madison, WI and [2]Food Research Institute, Madison, WI.* Sponsor: R. Peterson.

The trans10, cis12 (t10c12) isomer of conjugated linoleic acid (CLA) has been shown to reduce body fat gain when fed to mice and inhibit lipoprotein lipase activity in cultured 3T3-L1 adipocytes. We report herein that t10c12 CLA and conjugated nonadecadienoic acid (CNA, a 19-carbon CLA cognate) block preadipocyte differentiation and nullify the differentiation enhancing effect of thiazolidinedione (TZD, a PPARγ activator). Treatment of differentiating 3T3-L1 preadipocytes with t10c12 CLA or CNA resulted in decreased intracellular triglyceride accumulation and decreased mRNA expression of the adipogenic genes fatty acid synthase, aP2, and PPARγ. T10c12 CLA also decreased PPARγ, C/EBPα protein expression with no change of C/EBPβ. Mice fed diet supplemented with 0.5% CLA mixture for 4 weeks significantly reduced body fat gain without affecting body weight or serum parameters. In accordance with cell culture study, dietary CLA treatment decreased PPARγ and its downstream lipoprotein lipase (LPL) mRNA expression. The data indicate that CLA, especially t10c12 isomer, can inhibit adipogenesis in part by its influence on the expression/activation of PPARγ.

1241 TOXICOLOGY STUDIES ON CONJUGATED LINOLEIC ACID (CLA).

S. O'Hagan. *Safety &Environmental Assurance Department, Unilever Colworth, Bedford, United Kingdom.* Sponsor: P. Hepburn.

Conjugated linoleic acid (CLA) is the term given to a group of positional and geometric isomers of the essential fatty acid linoleic acid. CLA is found naturally in foods such as dairy and meat products where the c9, t11 isomer predominates. Commercial preparations of CLA contain a mixture of isomers, with c9, t11 and t10, c12 often occurring in equal proportions. Many beneficial effects of CLA have been reported including anticarcinogenic activity. However, very little safety data are available on this material. A programme of toxicology studies was conducted to confirm the safety of a preparation containing a mixture of CLA isomers (Clarinol). Clarinol was tested in two *in vitro* mutagenicity assays, an Ames Test and an *in vitro* cytogenetics assay, and a 90-day repeat dose oral toxicity rat study. Clarinol was non-mutagenic in both *in vitro* assays. In the 90-day study, Clarinol was administered to Wistar (Crl: (WI) WU BR) rats at dose levels of 1%, 5% and 15% in a synthetic diet (AIN-93G). A high fat control diet containing 15% safflower oil was also tested in the study. A 4-week recovery period was included at the end of the study. At a dose level of 15%, Clarinol produced hepatocellular hypertrophy in female rats. This effect was reversible upon withdrawal of test material. An increase in plasma insulin levels was also observed in high dose females on study but there was no effect on plasma glucose levels. Insulin levels returned to control values at the end of the recovery period. A No Observed Adverse Effect Level of 5% was identified in the study.

1242 LACK OF ESTROGENIC OR ANTI-ESTROGENIC ACTIVITY OF THE ANTIOXIDANT NAO FOUND IN SPINACH.

L. Lomnitski[3], E. Padilla-Banks[2], W. N. Jefferson[2], A. Nyska[1], S. Grossman[3] and R. R. Newbold[2]. *[1]Laboratory of Experimental Pathology, NIEHS, Research Triangle Park, NC, [2]Laboratory of Molecular Toxicology, NIEHS, Research Triangle Park, NC and [3]Institute of Life Sciences, Bar-Ilan University, Ramat-Gan, Israel.*

The developing fetus is uniquely sensitive to perturbation by chemicals with estrogenic and/or endocrine-disrupting activity. The carcinogenic effect of developmental exposure to estrogens has been well documented in humans and experimental animals. Since some natural antioxidants and flavonoids, used increasingly in nutritional and pharmaceutical applications for infants and children, as well as adults, exhibit estrogenic activity, we investigated the estrogenic potential of the natural antioxidant NAO isolated from spinach leaves using an *in vivo* rodent uterotropic bioassay and an *in vitro* transcriptional activation assay. Outbred 17-day-old female CD-1 mice were treated with 17b-estradiol (500 mg/kg/day) as a positive control or NAO at doses ranging from 1000 to 1, 000, 000 mg/kg/day for 3 consecutive days and sacrificed on the fourth day. Body weights and uterine wet weights were determined. Mice treated with17b-estradiol showed a statistically significant increase in uterine wet weight, but mice treated with NAO did not show any increase over untreated controls at any dose tested. The estrogenic activity of NAO was also determined *in vitro* using a transcriptional activation assay in which BG1Luc4E2 cells, which express estrogen receptor, were stably transfected with a luciferase reporter gene responsive to estrogens. The positive control, 17b-estradiol, showed a dose-dependent increase in luciferase activity; however, NAO did not demonstrate any significant increase over control. NAO was also tested for anti-estrogenic activity by adding it to the cells in combination with17b-estradiol; NAO did not inhibit the effect of17b-estradiol. Together, these data suggest that NAO does not have estrogenic or anti-estrogenic activity. Additional studies using the neonatal mouse are underway to determine any potential long-term effects of NAO if exposure occurs during critical periods of early development.

1243 *IN VIVO* EXPOSURE TO AN EPHEDRA CONTAINING METABOLIC NUTRITION SYSTEM DOES NOT ALTER SERUM BIOCHEMISTRY AND HISTOPATHOLOGY OF SEVEN VITAL TARGET ORGANS OF B6C3F1 MICE.

S. Stohs[1], S. Gross[3], C. Patel[3], R. Hackman[2] and S. Ray[3]. *[1]Sch. of Pharmacology & Hlth. Profs., Creighton University, Omaha, NE, [2]Department of Nutrn., University of California, Davis, CA and [3]Toxicology Program, Coll. of Pharmacology/LIU, Brooklyn, NY.*

Although conventional biomedical research has largely focused on mechanisms of weight loss and genetic aspects of obesity, most medical solutions are plagued by side-effects and fraught with complex questions. As a consequence, consumers are

seriously considering herbal products, nutraceuticals and functional foods rather than conventional medications. This is evidently driven by a growing consumer understanding of diet/disease links, aging populations, rising health care costs, and advances in food technology and nutrition. This study investigated the effects of subchronic exposure to a metabolic nutrition system (MNS Orange-AdvoCare®) on serum biochemistry and target organ histopathology (kidney, liver, heart, brain, lung, spleen and duodenum) in mice. MNSO is a unique combination of vitamins, minerals, omega-3 fatty acids and herbal extracts designed to provide a strong foundation of nutritional support, enhance thermogenesis and boost energy levels. MNSO contains citrus, ephedra, gingko, green tea and Ocimum extracts. In this study, ♀B6C3F1 mice were fed control (-MNSO) or MNSO (1X-10X; 1X=daily human dose) diets. Animals were sacrificed after 4 mo., at which time blood was collected for serum chemistry analysis and tissue sections for H&E-staining. Food consumption and body-weight changes were also monitored throughout. MNSO exposure did not adversely affect the serum chemistry profiles(electrolyte, lipid, carbohydrate, protein), nor did it disturb normal tissue architecture. Although animals on MNSO diet consumed more food, they were relatively more lean and active compared to controls. These results suggest that long-term MNSO exposure produces normal serum chemistry and histology in mice fed up to ten times the normal human dose [Supported by AdvoCare, Carrolton, TX].

1244 A SUBCHRONIC FEEDING STUDY OF ANNATTO EXTRACT (NORBIXIN), A NATURAL FOOD COLOR EXTRACTED FROM THE SEED COAT OF ANNATTO (*BIXA ORELLANA* L.), IN SPRAGUE-DAWLEY RATS.

H. Yoshino[1,2], A. Hagiwara[1], N. Imai[1], S. Tamano[1], H. Aoki[3], K. Yasuhara[3], T. Koda[3], M. Nakamura[3] and T. Shirai[2]. *[1]Daiyu-Kai Institution of Medical Science, Ichinomiya, Japan, [2]Department of Experiment Pathology and Tumor Biology, Nagoya City University, Nagoya, Japan and [3]San-Ei Gen F.F.I. Inc.,, Toyonaka, Japan.*

A subchronic oral toxicity study of annatto extract (91.6 % as norbixin), a natural carotenoid, was conducted. Groups of 10 male and female Sprague-Dawley rats were fed annatto extract at dietary levels of 0, 0.1, 0.3 and 0.9 % for 13 weeks. There were no treatment-related adverse effects with reference to body weight, food and water consumption, and ophthalmology and hematology data. Serum biochemistry revealed changes confined to rats of the 0.9 and 0.3 % groups in both sexes, including increased alkaline phosphatase, phospholipid, total protein, albumin and the albumin/globulin ratio. Marked elevation in absolute and relative liver weights was also found in both sexes receiving 0.9 or 0.3 %, but not 0.1 %. Hepatocyte hypertrophy was evident and an additional electron microscopic examination demonstrated this to be linked to abundant mitochondria after exposure to a dietary level of 0.9 % annatto extract for 2 weeks. Thus, the No-Observed-Adverse-Effect-Level (NOAEL) was judged to be a dietary level of 0.1 % (69 mg/kg body weight/day for males, 76 mg/kg body weight/day for females) of annatto extract (norbixin) under the present experimental conditions.

1245 TRANSCRIPTIONAL RESPONSES OF AAG KNOCKOUT MOUSE EMBRYONIC STEM CELLS UPON EXPOSURE TO ME-LEX.

K. Kobayashi, L. B. Meira and L. D. Samson. *Biological Engineering, MIT, Cambridge, MA.* Sponsor: J. Sugimoto.

We have previously generated the 3-Methyladenine DNA glycosylase Aag null cells by double-targeting the Aag gene in mouse ES cells. This knockout cell line is sensitive to alkylating agent-induced p53 induction, S phase arrest, sister chromatid exchange, and apoptosis. Expression profiling of Aag null and wild type mouse ES cells treated with methyl-lexitropsin (Me-Lex), an alkylating agent that almost exclusively induces 3MeA DNA lesions, was performed using oligonucleotide microarrays (GeneChip, Affymetrix). Aag +/+ and Aag -/- cells were treated at both equitoxic and equimolar Me-Lex dose. Total RNA was isolated 0, 2, and 24 hour after treatment and used for microarray analysis. Hundreds of genes were up or down regulated at each time point for both the wild type and Aag null cells. Data analysis was focused to gene groups related to apoptosis, cell cycle, and DNA repair. Some wild type- and Aag null cell specific expression patterns identify candidate genes involved to MeLex-induced toxicity. We are now in the process of carrying out the computational analysis of the data.

1246 ROLE OF NITRIC OXIDE IN ROTENONE-INDUCED NIGRO-STRIATAL INJURY.

S. Ali[1], Y. He[2], Z. Dong[2], J. Jankovic[2], S. H. Appel[2], W. Le[2], W. Slikker, Jr[1] and S. Z. Imam[1]. *[1]Neurotoxicology, USFDA/NCTR, Jefferson, AR and [2]Department Neurology, Baylor College of Medicine, Houston, TX.*

Selective degeneration of the nigro-striatal system is the main pathology of Parkinsons' disease (PD). A deficit of mitochondrial complex I activity and increased reactive oxygen and nitrogen species have been suggested in the pathogenesis of PD. Rotenone, a widely used pesticide causes a syndrome in rats that mimics, both behaviorally and pathologically, the symptoms of PD. The present study evaluated the role of nitric oxide (NO) in the nigro-striatal injury resulting from a chronic administration of rotenone. After a 40 day administration of rotenone to adult male Sprague-Dawley rats, a relatively stable rotenone concentration was observed in the cortex and striatum. Furthermore, a significant (45%) increase in the number of nicotinamide adenine dinucleotide phosphate diaphorase(NADPH-d)-positive cells in the striatum was observed, accompanied by a 70% increase in the production of 3-nitrotyrosine, a marker for peroxynitrite generation. We also observed a highly significant increase in striatal neuronal nitric oxide synthase expression after rotenone administration. In addition, there was a 53% decrease in striatal dopamine (DA) levels and a 28% loss of substantia nigra tyrosine hydroxylase (TH) immuno-positive neurons. Moreover, the subcutaneous injection of 7-Nitroindazole (7-NI), a selective neuronal nitric oxide synthase inhibitor, provided significant protection against rotenone-induced nigro-striatal damage and attenuated the increased production of peroxynitrite. Therefore, our data suggest that chronic rotenone administration can lead to a significant damage to the nigro-striatal dopaminergic system and this damage can be mediated by the increased generation of nitric oxide and peroxynitrite.

1247 CHROMIUM EXPOSURE DISRUPTS TRANSCRIPTION FROM PAH-INDUCIBLE PROMOTERS.

Y. Wei[1], A. Puga[1] and K. Tepperman[2]. *[1]Department of Environmental Health, University of Cincinnati Medical Center, Cincinnati, OH and [2]Department of Biological Sciences, University of Cincinnati, Cincinnati, OH.*

Environmental exposures to toxic or carcinogenic compounds rarely result from the presence of a single, isolated toxicant. More frequently, the toxic agent is a complex mixture of chemical entities, often including a combination of metals, such as chromium, and PAHs, such as benzo[a]pyrene (B[a]P). Work from our laboratory has shown that chromate disrupts the coordinate induction of phase I and phase II detoxification genes by aryl hydrocarbon receptor ligands. To test the hypothesis that combined exposure to mixtures of B[a]P and chromate disrupts the regulatory mechanisms that control transcription from B[a]P-inducible gene promoters, we have used Inductively Coupled Plasma Mass Spectrometry and exposure to $^{51}CrO_4K_2$to measure the uptake, distribution and biological effects of chromium in mouse hepatoma Hepa-1 cells. In cells exposed to hexavalent chromium, conversion of Cr(VI) to Cr(III) is very rapid, with less than 5% of the input remaining as Cr(VI) after 1 hour. Twenty five percent of the total chromium is present in the nucleus and 8 - 10% of nuclear Cr(III) is found in association with chromatin. B[a]P-induced expression of a luciferase reporter driven by the mouse Cyp1a1 gene promoter stably integrated in Hepa-1 cells is almost completely repressed by chromium exposure. Overexpression of the transcriptional co-regulators SRC-1, SRC-2, p300/CBP, and RIP-140 did not reverse the chromium-mediated repression of B[a]P-dependent gene induction; however, treatment with Na butyrate, a histone deacetylase inhibitor, fully reversed the effect of chromium. These results suggest that chromium interacts with transcriptionally poised chromatin to block some feature of transcription initiation or progression from inducible promoters. *(Supported by NIH 1R01-ES10807, and NIH P42-ES04908).*

1248 ARYL HYDROCARBON RECEPTOR REGULATION AND TRANSACTIVATION DURING OSTEOBLAST DIFFERENTIATION.

E. P. Ryan[1,2], T. A. Gasiewicz[2] and J. E. Puzas[1,2]. *[1]Orthopaedics, University of Rochester, Rochester, NY and [2]Environmental Medicine, University of Rochester, Rochester, NY.*

Many toxic compounds released into the environment by fossil fuels, waste incineration and cigarette smoking exert adverse effects on the skeleton. Several metabolic bone diseases arise as a result of an imbalance in bone remodeling and these toxicants may be contributing factors in the progression of these pathological conditions. One candidate molecule that has been implicated to control the toxic effects of these exogenous compounds on bone cells is the aryl hydrocarbon receptor (AHR). The AHR is a ligand activated transcription factor that binds poly-aromatic hydrocarbons and congeners of dioxin/furan compounds. We have documented the presence of the AHR in osteoblasts and suggest that it might not only be responsible for participating in toxicity reactions but also be involved in skeletal development. We utilized cultures of osteoblasts derived from neo-natal rat calvaria as well as tissue specimens from both wild type and AHR -/- mice. AHR is expressed in primary cultures of osteoblasts that are induced to differentiate. Both the mRNA and protein levels of the receptor increase through day 15 at which point they begin to decline. This pattern of expression parallels the induction of a number of early bone-specific genes involved in the maturation of osteoblasts. We also show by immunocytochemistry that the receptor is present in calvarial osteoblasts. The AHR functions as a transactivating receptor in osteoblasts as evidenced by its ligand-de-

pendent migration to the nucleus and its association with known dioxin response elements. Dioxin exposure for 4 hours to osteoblasts in culture induces the expression of CYP1A1 and Cyclooxygenase-2 protein levels. Together these data imply that the AHR may not only mediate the effect of aromatic toxicants on bone cells but, with an as yet unidentified ligand, be involved in the differentiation pathways of the osteoblast.

1249 TEMPORAL GENE EXPRESSION CHANGES FOLLOWING TREATMENT WITH ANTHRACYCLINES IN MALE RATS.

C. I. Nduaka[1], L. T. Russell[2], L. Gallenberg[1], D. Weddle[1] and J. Waring[1]. *[1]Drug Safety Evaluation, Abbott Laboratories, Abbott Park, IL and [2]Department of Phamacology, University of Maryland, Baltimore, MD.*

Temporal gene expression changes associated with the treatment of anthracyclines in male rats were investigated. Doxorubicin was administered to rats by intravenous injection for up to 2 weeks at a dosage of 1 mg/kg/day. Daunorubicin, another anthracycline was used as a comparator drug. Evaluated parameters included clinical observation, clinical pathology, light microscopy, and ultrastructural pathology. Changes in cardiac tissue gene expression of treated rats were found to occur in the absence of downstream lesions. There were minimal changes in clinical and anatomical pathology of anthracycline treated groups when compared to control. Early changes in gene expression in the absence of any downstream lesions may be suggestive of a possible initial response (compensatory event) to the exposure to doxorubicin. The genes of interest that were up-regulated included superoxide dismutase, plasma GSH peroxidase precursor, and antioxidant protein 2. The functional relevance of the modulation observed was presumably thought to be a reflection of the roles of these genes in the antagonism of Reactive Oxygen Species. Collectively the findings suggest that additional studies will be required to better determine if the gene expression changes observed represent a reliable indicator of the early onset of toxicity or simply a compensatory event stemming from anthracycline exposure.

1250 EXPRESSION AND REGULATION OF THE PLANT STEROL HALF TRANSPORTER GENES ABCG5 AND ABCG8 IN RATS.

M. Z. Dieter and C. D. Klaassen. *University of Kansas Medical Center, Kansas City, KS.*

The Abcg5 and Abcg8 genes encode half-transporter proteins that heterodimerize to form a transporter of plant sterols and cholesterol. Mutations in these genes result in the human condition sitosterolemia, characterized by the accumulation of plant sterols in the blood, leading to premature arteriosclerosis and coronary artery disease. While the expression and regulation of these genes has been studied in mice and to a lesser extent in humans, it has been largely ignored in rats. Therefore, the purpose of this study was to examine the expression and regulation of Abcg5 and Abcg8 at the mRNA level in the Sprague-Dawley rat. Both Abcg5 and Abcg8 mRNA were expressed primarily in rat small intestine, with the highest levels in jejunum and lower levels in the duodenum and ileum. Both genes were also highly expressed in rat liver, but were minimal in all other tissues examined (brain, kidney, large intestine, lung, and stomach). There were no significant gender differences in the expression of these genes. The effects of a 1% cholesterol diet on the regulation of Abcg5 and Abcg8 were also examined, and compared with those seen in C57BL/6 mice. In mice, a 1% cholesterol diet caused a 3.5-fold increase in the expression of liver Abcg5 mRNA, and a 5-fold increase in liver Abcg8 mRNA, compared to liver mRNA levels in mice fed a standard diet. However, in rats, the 1% cholesterol diet suppressed liver Abcg5 mRNA levels by 75%, and suppressed liver Abcg8 mRNA levels by 88%, in comparison to levels seen in rats fed a standard diet. In mouse small intestine, Abcg5 and Abcg8 mRNA levels were only modestly induced by the 1% cholesterol diet, with similar results observed in rat small intestine. However, compared to mouse, a more robust increase was seen in rat ileum, where both genes were induced 2.5-fold. These results suggest variation between rats and mice in regulatory mechanisms controlling Abcg5 and Abcg8 expression, and may explain some differences in lipid metabolism observed between these two species. (Supported by NIH grants ES-09716 and ES-07079)

1251 TISSUE AND GENDER-SPECIFIC EXPRESSION OF THE MULTIDRUG RESISTANCE-ASSOCIATED PROTEINS 1-6 IN MICE.

J. M. Maher, N. J. Cherrington and C. D. Klaassen. *Pharmacology, KU Medical Center, Kansas City, KS.*

The family of Multidrug resistance-associated proteins (Mrps) are a class of ATP-dependent transporters that are important in the export of various conjugated and unconjugated organic anions out of cells. The tissue distribution of these transporters has been thoroughly conducted in rats, but similar characterization of the Mrp family in mice is incomplete. Therefore, the purpose of this study was to quantitatively determine relative mRNA levels of the Mrp family in nine mouse tissues (liver, kidney, lung, stomach, duodenum, jejunum, ileum, large intestine, and whole brain) and to determine whether there are gender variations in expression of Mrps in the C57BL/6 mouse. Mrp1 was present in all tissues examined, with highest expression in stomach and large intestine. Mrp2 mRNA levels were highest in small intestine, followed by liver and kidney. Mrp3 was ubiquitous, with highest levels in large intestine. Mrp4 message levels were predominant in kidney, with relatively minimal expression elsewhere. Mrp5 had a unique pattern of expression with high mRNA levels in brain, lung and stomach. Finally, Mrp6 message was primarily observed in liver and small intestine. Female-predominant expression was observed in kidney (Mrp3 and Mrp4) as well as liver (Mrp1, Mrp4 and Mrp6), suggesting possible endocrine regulation of these transporters. In general, the tissue expression correlates well with that in rat, with only minor differences observed. However, some gender differences in Mrps seem to be species-specific (Mrp3, Mrp4, and Mrp6), and differ from results seen in rat. (Supported by NIH grants ES-09716 and ES-07079)

1252 TISSUE DISTRIBUTION OF MOUSE ORGANIC ANION TRANSPORTING POLYPEPTIDES.

X. Cheng, N. J. Cherrington and C. D. Klaassen. *University of Kansas Medical Center, Kansas City, KS.*

Organic anion transporting polypeptides (Oatps), which belong to the Slc21a family of solute carrier transporters, mediate Na+-independent transport of xenobiotics and endogenous compounds. The purpose of this study was to determine the tissue-specific distribution of eight known members of the Oatp family, namely Oatp1-5, 9, 12 and prostaglandin transporter (PGT) in mice, as well as to determine potential gender differences in their expression. The mRNA levels of each Oatp in liver, kidney, lung, stomach, duodenum, jejunum, ileum, large intestine, and whole brain, were quantified with the branched DNA signal amplification assay. Oatp1 mRNA was mostly detected in liver and kidney, but with substantially higher levels in male than female mice in both tissues. Oatp2 mRNA levels were highest in liver and brain. Furthermore, female mice had 2.5-fold more Oatp2 gene transcripts in liver than males. Oatp3 mRNA levels were low in all tissues examined, with the highest of these levels in lung. Oatp4, also named liver-specific transporter (lst), was almost exclusively detected in liver, whereas Oatp5 mRNA was only found in kidney. Oatp9 mRNA was ubiquitous, with the highest concentration in liver and all three parts of the small intestine. Oatp12 mRNA was found at similar concentration in all tissues examined, with the lowest levels in liver. PGT mRNA levels had the highest abundance in lung and stomach. Additionally, there was no gender difference found in Oatp3-5, 9, 12 or PGT mRNA. In conclusion, these data indicate that the tissue distribution of each mouse Oatp is unique. However, the tissue distribution of these mouse Oatps correlates well with corresponding rat Oatps, suggesting the functions in both species may be similar. Gender differences only in Oatp1 and Oatp2 mRNA suggest that endocrine hormones may influence the regulation of these two genes, but not other Oatps. (Supported by NIH grant ES-09649)

1253 *TERT*-BUTYL HYDROQUINONE (TBHQ) PROTECTS AGAINST ARSENITE-INDUCED CYTOTOXICITY.

S. Kann, M. Huang, Y. Yang, Y. Chen, T. P. Dalton and A. Puga. *Department of Environmental Health, University of Cincinnati Medical Center, Cincinnati, OH.*

The carcinogenic metaloid arsenic and benzo(a)pyrene (B[a]P) are among the top 20 hazardous substances in the environment and they are often found as co-contaminants, including in a full 50% of the 1, 200 Superfund sites in the National Priority List. The long-range goal of this research is to develop an understanding of the mechanisms underlying the adverse health effects of complex mixtures of B[a]P and arsenic. We are exploring the hypothesis that combined exposure to a mixture of B[a]P and arsenite will disrupt the regulatory mechanisms that control transcription from B[a]P-inducible gene promoters, and will cause an uncoupling of phase I and phase II gene expression with a concomitant imbalance in B[a]P metabolism. In embryo fibroblasts (MEF) from C57BL/6J mice, low doses of arsenite (1 - 2 μM) synergize with B[a]P, but not with tBHQ, in the induction of the phase II quinone oxidoreductase gene, NQO1. Global profiling experiments indicate that tBHQ inhibits the induction by arsenite of a large number of genes, suggesting that tBHQ could protect against oxidative damage induced by arsenite. To test this hypothesis, be used MEF's from GCLM knock-out mice, lacking the modifier subunit of glutamylcysteinyl ligase, which have been shown to be extremely susceptible to killing by oxidants. In GCLM-KO MEFs, tBHQ was fully protective of the cytotoxicity induced by arsenite. These data suggest that a major component in the

cytotoxic effects of arsenite is the inability to adapt quickly to an oxidative challenge and synthesize glutathione *de novo* and that tBHQ protects against this challenge. *(Supported by NIH 1R01-ES10807, and NIH P42-ES04908).*

1254 INDUCTION OF UDP-GLUCURONOSYLTRANSFERASE 1A AND 2B mRNA LEVELS IN RAT LIVER AND DUODENUM BY CLASSES OF MICROSOMAL ENZYME INDUCERS THAT ACTIVATE VARIOUS TRANSCRIPTIONAL PATHWAYS.

M. K. Shelby and C. D. Klaassen. *University of Kansas Medical Center, Kansas City, KS.*

Microsomal enzyme inducers (MEIs) upregulate Phase I biotransformation enzymes, most notably the cytochrome P450s (CYPs). Transcriptional upregulation by MEIs occurs by at least four different nuclear receptor mechanisms: aryl hydrocarbon receptor (AhR; CYP1A inducers), constitutive androstane receptor (CAR; CYP2B inducers), pregnane-X receptor (PXR; CYP3A inducers), and peroxisomal proliferator activating receptor-α (PPARα; CYP4A inducers). Other mechanisms include the antioxidant/electrophile response element (ARE/EpRE; quinone reductase inducers) and CYP2E inducers which upregulate enzymes through post-transcriptional mechanisms including mRNA stabilization. UDP-glucuronosyltransferases (UGTs) are Phase II biotransformation enzymes, most of which are expressed in liver, but some are primarily expressed in intestine. MEIs are known to increase UGT activity; however, information concerning transcriptional regulation of individual UGT isoforms is incomplete. Therefore, the purpose of this study was to examine effects of MEIs on UGT1A and 2B isoform mRNA levels in rat liver and duodenum. All three AhR ligands induced UGT1A6 and 1A7 mRNA levels in liver, but not duodenum. Two AhR ligands induced UGT1A3 mRNA in liver only. All four CAR activators induced UGT2B1 mRNA in liver but not duodenum. Similarly, three CAR activators induced UGT1A1 and 1A6 mRNA levels in liver only. Two of the three PXR ligands induced UGT1A2 mRNA in duodenum, but not liver. Two of the three PPARα ligands induced UGT1A1 and UGT1A3 mRNA levels in liver only. Two EpRE ligands induced UGT2B12 mRNA in liver and duodenum, and UGT1A6, 1A7, 2B1, and 2B3 mRNA in liver only. All three CYP2E inducers upregulated UGT1A3 mRNA levels in liver only. In summary, some UGTs, like CYPs, are upregulated by MEIs, though MEIs had minimal effects on UGT expression in duodenum. Additionally, several UGT isoforms are induced by the various mechanisms responsible for CYP regulation. (Supported by NIH grants ES-03192 and ES-07079)

1255 ROLE OF TRANSCRIPTION FACTORS IN LPS-INDUCED DECREASE OF MOUSE ORGANIC ANION TRANSPORTING POLYPEPTIDE (OATP) 4 EXPRESSION.

N. Li, M. Z. Dieter and C. D. Klaassen. *University of Kansas Medical Center, Kansas City, KS.*

Previous studies indicate that lipopolysaccharide (LPS) causes a time- and dose-dependent decrease in mouse oatp4 mRNA levels. Oatp4 mRNA levels were lowest at 12 hr after LPS treatment. Because LPS is reported to transcriptionally down-regulate Ntcp and Mrp2, the purpose of the present study was to determine the effect of LPS on the binding activities of seven transcription factors predicted to bind to the regulatory sequence of oatp4, namely HNF-1α, C/EBP, HNF-3β, CHOP-C, HFH-1 and HFH-2, and RARα:RXRα, using electrophoretic mobility shift assays (EMSAs). Nuclear extracts were prepared from livers of C3H/OuJ mice excised at 0, 1.5, 3, 6, 12, 16, 24, and 48 hr after treatment with LPS (5 mg/kg). CHOP-C, HFH-1 and HFH-2 showed no indication of binding to the oatp4 regulatory sequence in EMSAs. However, the binding to the putative binding sequences of HNF-1α, C/EBP, HNF3β, and RARα:RXRα was detected in mouse liver by EMSAs. Their lowest levels were observed at 1.5, 1.5 to 3, 1.5, and 1.5 to 3 hr after LPS treatment, respectively, then subsequently increased to control values. Specific unlabeled oligonucleotides (100- to 500-fold molar excess) abolished the complex recognized by ^{32}P-labeled oligonucleotides specific to HNF-1α, C/EBP, HNF3β, and RARα:RXRα. Anti-HNF-1α antibody caused a supershift with HNF-1α putative binding sequence, but anti-HNF-1β antibody did not. To further address the function of HNF-1α in the regulation of mouse oatp4 expression, oatp4 mRNA levels were determined with the branched DNA signal amplification assay in livers of HNF-1α-null (*Tcf*$^{-/-}$) and wild-type mice. Mouse oatp4 mRNA levels in HNF-1α-null mice were markedly lower than that in wild-type mice. Therefore, these data suggest that HNF-1α, C/EBP, HNF3β and RARα:RXRα might be involved in the down-regulation of mouse oatp4 by LPS, but CHOP-C, HFH-1 and HFH-2 do not seem to be involved. Moreover, these data also suggest that HNF-1α plays a critical role in the constitutive expression of mouse oatp4. (Supported by NIH grant ES-09649)

1256 ROLE OF THE TGF-BETA PATHWAY IN THE PATHOGENESIS OF STREPTOZOTOCIN-INDUCED DIABETIC NEPHROPATHY.

J. Yan[1], L. Song[2], M. Brej[1], J. Kachur[2], Z. Guan[2] and E. A. Blomme[1]. *[1]Global Toxicology, Pharmacia Corp., Skokie, IL and [2]Skokie Discovery Biology, Pharmacia Corp., Skokie, IL.*

Diabetic nephropathy, a major complication of diabetes, is characterized histologically by thickening of the glomerular basement membrane, glomerular hypertrophy, mesangial matrix accumulation, and interstitial fibrosis. These changes correlate well with the loss of renal function. The molecular pathogenesis of diabetic nephropathy, however, has not been fully elucidated. To determine the molecular mechanisms involved in this condition, we have studied changes in gene expression in the kidneys of streptozotocin (STZ)-treated mice, a well-characterized model of diabetes. Male CD-1 mice (3 per group and per time point) were treated with a single intraperitoneal injection of STZ (200 mg/kg) or vehicle, sacrificed 2 and 6 months after treatment, and the kidneys were collected for histologic and molecular evaluation. GEArray, real-time quantitative RT-PCR and Western blot analysis revealed many changes in gene expression, in particular in the TGF-beta pathway. We also localized these changes in gene expression in the different compartments of the kidney by using laser capture microdissection (LCM) to isolate glomeruli and cortical tubules, respectively. By real-time quantitative RT-PCR, TGF-beta and SREBP-1 gene expression were increased in both glomeruli and cortical tubules, while cdkn1a (p21/Waf1/Cip1) expression was mainly increased in cortical tubules. In addition, although not detected in the RNA extracted from whole STZ-diabetic kidneys, nephrin expression was dramatically increased in isolated glomeruli. Collectively, these data confirmed that genes in the TGF-beta pathway are involved in the pathogenesis of diabetic nephropathy and indicated the potential value of LCM in transcriptomics studies.

1257 CONSTITUTIVE EXPRESSION OF VARIOUS XENOBIOTIC AND ENDOBIOTIC TRANSPORTER mRNAS IN THE CHOROID PLEXUS OF ADULT SPRAGUE-DAWLEY RATS.

S. Choudhuri[2,1], N. Cherrington[1], N. Li[1] and C. D. Klaassen[1]. *[1]Pharmacology Toxicology and Therapeutics, University of Kansas Medical Center, Kansas City, KS and [2]USFDA, College Park, MD.*

A major function of xenobiotic and endobiotic transporters is to move a wide range of organic substances and metals across cell membranes. The choroid plexus plays an important role in regulating the exchange of materials between blood and cerebrospinal fluid, thereby protecting the brain from various toxic insults. Therefore, choroid plexus is one of the most toxicologically important tissues of the central nervous system. The aim of this study was to quantitatively determine the constitutive expression of various transporters in the choroid plexus of adult Sprague-Dawley rats. The mRNA levels of 39 genes (Mrp1, 2, 3, 4, 5, and 6; Mdr1a, 1b and 2; Oatp1, 2, 3, 4, 5, 9 and 12; Oat1, 2, 3, and K; Oct1, 2, 3, N1 and N2; Ntcp, Bsep, Ibat; Dmt1, Menke's and Wilson's; Ent1 and 2, Cnt1 and 2; Pept1 and 2; as well as Abcg5 and 8) were measured in choroid plexus by the branched DNA signal amplification method. The mRNA levels of these genes were also determined in liver, kidney and ileum in order to compare relative expression levels. The expression of 8 genes (Mrp1, 4, and 5, Oatp3, Menke's, Dmt1, Ent1, and Pept2) was higher in choroid plexus than in liver, kidney and ileum. An additional 7 genes (OctN1 and N2, Oatp2, Oat2 and 3, and Cnt1 and 2) were all significantly expressed in choroid plexus, but choroid plexus was not the tissue with the highest expression. The remaining 24 transporters were expressed at low levels in choroid plexus as compared to other tissues. The constitutive expression levels of different transporters in choroid plexus may provide insight into the range of xenobiotics that can potentially be transported by the choroid plexus, thereby providing a means to protect the brain from toxicity. (Supported by NIH grants ES-09716, ES-09649, and ES-07079)

1258 INDUCTION OF MULTIDRUG RESISTANCE PROTEIN 3 (Mrp3) *IN VIVO* IS INDEPENDENT OF CONSTITUTIVE ANDROSTANE RECEPTOR.

N. Cherrington[1], A. L. Slitt[1], J. M. Maher[1], Y. Y. Wan[2], J. Zhang[3], W. Huang[3], D. M. Moore[3] and C. D. Klaassen[1]. *[1]Pharmacology Toxicology and Therapeutics, University of Kansas Medical Center, Kansas City, KS, [2]Harbor-UCLA Medical Center, Torrance, CA and [3]Baylor College of Medicine, Houston, TX.*

Previous studies demonstrated that the organic anion transporter Mrp3 is induced in rat liver by phenobarbital (PB) and several other microsomal enzyme inducers that induce cytochrome P450 2B (CYP2B). CYP2B is known to be induced by constitutive androstane receptor (CAR)-retinoid X receptor (RXR) heterodimer binding to a PB-responsive promoter element. Hepatic mRNA levels of CYP2B

and Mrp3 were measured in three models of altered CAR activity (Wistar Kyoto rats, RXRα$^{-/-}$ and CAR$^{-/-}$ mice) in order to determine the involvement of CAR in the induction of Mrp3. In Wistar Kyoto rats, a strain in which females express very little CAR protein, the induction of CYP2B1/2 mRNA by PB, diallyl sulfide, and trans-stilbene oxide, but not by oltipraz, was significantly higher in males than in females. In contrast, Mrp3 mRNA was induced by each of these treatments to an equal level in males and females. In hepatocyte-specific RXRα$^{-/-}$ mice, CYP2B10 mRNA was not induced by diallyl sulfide or oltipraz, and the induction by PB and trans-stilbene oxide was diminished as compared to wild-type mice. Mrp3 however, was induced by PB, diallyl sulfide, trans-stilbene oxide and oltipraz in both wild-type and RXRα$^{-/-}$ mice. Additionally, the constitutive expression of Mrp3 was significantly reduced in the RXRα$^{-/-}$ mice. In CAR$^{-/-}$ mice, the robust induction of CYP2B10 by PB seen in wild-type mice was completely absent. However, Mrp3 mRNA was equally induced by PB in both wild-type and CAR$^{-/-}$ mice. These data clearly demonstrate that induction of hepatic Mrp3 is CAR-independent and implies a role for RXRα in the constitutive expression of Mrp3. (Supported by NIH grants ES-09716, ES-09649, and ES-07079)

1259 SPECIES AND GENDER DIFFERENCES IN ORGANIC ANION TRANSPORTER mRNA.

S. C. Buist and C. D. Klaassen. *University of Kansas Medical Center, Kansas City, KS.*

Significant gender differences in organic anion transporter (Oat) mRNA levels are known in rat kidney and liver. Oats are uptake transporters that facilitate the initial steps of excretion. Mechanisms by which Oat gender differences occur could be revealed using mouse knockout (KO) models, but similar expression patterns between species must first be determined. Thus, the aim of this study was to determine whether oat1, oat2 and oat3 mRNA levels in mouse tissues exhibit similar gender-specific patterns observed in rat. Tissues were collected from male and female 129J and C57BL/6 mice, two strains used in KO development. Oat mRNA levels were determined by branched DNA and compared with rat Oat mRNA levels. Rat Oat1 mRNA was prevalent in kidney, where male levels exceeded female levels. Mouse oat1 in both strains was analogous to rat levels. Rat Oat2 mRNA was highest in female kidney, and markedly higher than in male kidney. Although oat2 was highest in kidney of both mouse strains, 129J female levels were only slightly higher than male; no gender difference was evident in C57 kidneys. Additionally, rat Oat2 mRNA in males was highest in liver at only 1/3 of female kidney levels. Conversely, highest oat2 levels in male mice were in kidney. Oat3 mRNA was highest in kidney for both species. However, female predominance was only observed in 129J kidney. Oat3 mRNA levels in rat liver were low compared with kidney and were male-specific. Similarly, oat3 mRNA was low in liver of both mouse strains, with male levels higher than female levels. However, oat3 mRNA in mouse liver was notably lower relative to kidney than was observed in rat. Overall, species differences regarding gender-specific mRNA levels were evident for oat2 and oat3, but oat1 mRNA levels were similar between species. Therefore, the use of mouse KO models may not be appropriate to study the mechanisms of Oat2 and Oat3 gender differences. Moreover, characterizing Oat mRNA species differences may aid interpretation of anion toxicity or clearance discrepancies if mRNA and protein trends coincide. (Supported by NIH grants ES-09716 and ES-07079)

1260 COACTIVATION OF ESTROGEN RECEPTOR α BY DRIP 205 IN HUMAN BREAST CANCER CELLS.

Q. Wu and S. Safe. *Veterinary Physiology & Pharmacology, Texas A&M University, College Station, TX.*

Vitamin D interacting protein 205 (DRIP 205) has been characterized as a component of the mediator complex of transcription factors which interact with multiple transcription factors including nuclear receptors. Previous studies in this laboratory have demonstrated that DRIP 205 coactivates estrogen receptor α (ERα)-mediated transactivation in cells cotransfected with constructs containing three tandem estrogen response elements (pERE$_3$) or GC-rich motifs (pSp1$_3$) that bind ERα and ERα/Sp1, respectively. DRIP 205 mutants containing C-terminal (aa 714-1566) and N-terminal (aa 1-516) deletions also coactivate ERα- or ERα/Sp1-mediated transactivation in ZR-75 breast cancer cells, and both of these mutants contain LXXLL box motifs that interact with activation function 2 (AF2) of ERα. Therefore, a DRIP 205 mutant (DRIP 205 Δ588-635, DRIP 205m3) that did not contain the LXXLL boxes was generated to investigate contributions of these motifs on coactivation. In cells transfected with pERE$_3$ or pSp1$_3$, DRIP 205m3 significantly coactivated both ERα- and ERα/Sp1-mediated transactivation, respectively. Coactivation of ERα by DRIP 205m3 was further investigated in ZR-75 cells transfected with pERE$_3$ and increasing concentrations of expression plasmids encoding the AF1 domain of ERα (ERα-AF1) and the LXXLL motifs in steroid receptor coactivators (GRIP1-NR box). Expression of both ERα-AF1 and GRIP1-NR box peptides decreased transactivation coactivated by DRIP 205m3. These results suggest that DRIP 205 can coactivate ERα- and ERα/Sp1-mediated transactivation in breast cancer cells, and this response is LXXLL box-independent. Based on results of competitive peptide inhibition studies, coactivation of ERα by DRIP is complex and may involve both AF1 and AF2 domains of ERα. Current studies are focused on identifying functional interacting domains of ERα and DRIP 205. (Supported by ES09106 and CA76636)

1261 CELL CONTEXT-DEPENDENT DIFFERENCES IN THE MECHANISM OF HORMONAL ACTIVATION OF E2F1 IN BREAST CANCER CELLS.

S. Ngwenya and S. Safe. *Veterinary Physiology & Pharmacology, Texas A&M University, College Station, TX.*

17β-Estradiol (E2) induces E2F1 gene expression in MCF-7 breast cancer cells, and deletion analysis of the E2F1 gene promoter showed that the -146 to -54 region was the minimal estrogen-responsive sequence. Subsequent analysis of this promoter in MCF-7 cells indicated that E2-induced transactivation was dependent on both upstream GC-rich and downstream CCAAT motifs that bound estrogen receptor α (ERα)/Sp1 and NFYA, respectively. Moreover, the resulting ERα/Sp1/NFYA complex was required for enhanced gene expression. E2 also induces E2F1 gene expression in ER-positive ZR-75 breast cancer cells, and deletion analysis of the E2F1 gene promoter also demonstrated that the -146 to -54 region was the minimal E2-responsive sequence. Subsequent mutation/deletion analysis of the E2F1 promoter showed that both the upstream GC-rich and downstream CCAAT sites were independently E2-responsive, and this was in direct contrast to results obtained in MCF-7 cells where both motifs were required for transactivation. Further analysis showed that the upstream GC-rich sites (-169 to -111) were hormonally-activated by genomic ERα/Sp1 in which ER induced transactivation through protein-protein (ERα/Sp1) and not protein-DNA (promoter) interactions. In contrast, the downstream (-122 to -54) CCAAT motif binds NFY proteins, and hormone-induced transactivation is associated with activation of cAMP/PKA which in turns activates NFYA in ZR-75 cells. These results demonstrate the importance of cell context in the molecular mechanisms of E2F1 activation and illustrate significant differences even among ER-positive breast cancer cells. (Supported by NIH ES09106 and ES09253).

1262 ESTROGEN RECEPTOR/Sp1 COMPLEXES ARE REQUIRED FOR INDUCTION OF *CAD* GENE EXPRESSION BY 17β-ESTRADIOL IN BREAST CANCER CELLS.

S. Khan, M. Abdelrahim, I. Samudio and S. Safe. *Veterinary Physiology & Pharmacology, Texas A&M University, College Station, TX.*

The *cad* gene is trifunctional and expresses carbamoylphosphate synthetase/aspartate carbamyltransferase/dihydroorotase which are required for pyrimidine biosynthesis. *Cad* gene activities are induced in MCF-7 human breast cancer cells, and treatment of MCF-7 or ZR-75 cells with 10 nM 17β-estradiol (E2) resulted in a 3- to 5-fold increase in cad mRNA levels in both cell lines. The mechanism of hormone-induced *cad* gene expression was further investigated using constructs containing the growth-responsive -90 to +115 (pCAD1) region of the *cad* gene promoter. E2 induced reporter gene (luciferase) activity in MCF-7 and ZR-75 cells transfected with pCAD1 which contains three upstream GC-rich and two downstream E-box motifs. Deletion and mutation analysis of the *cad* gene promoter demonstrated that only the GC-boxes which bind Sp1 protein were required for E2-responsiveness. In many cell lines, interaction of c-*myc* with the E-box motifs is required for *cad* expression. Although E2 induces c-*myc* in breast cancer cells, high endogenous expression of USF1/2 which is bound to the E-box sequences in gel mobility shift assays precludes *myc* binding. Results of electrophoretic mobility shift and chromatin immunoprecipitation assays show that both Sp1 and estrogen receptor α (ERα) interact with the GC-rich region of the *cad* gene promoter. Moreover, in transactivation assays with pCAD1, hormone-induced transactivation was inhibited by cotransfection with dominant negative Sp1 expression plasmid and small inhibitory RNA for Sp1 which silences Sp1 expression in the cells. These results demonstrate that, in common with many other genes involved in E2-induced cell proliferation, the *cad* gene is also regulated by a non-classical ERα/Sp1-mediated pathway. (Supported by NIH ES09106 and CA76636)

1263 TRANSCRIPTIONAL REGULATION OF HUMAN *CYP2F1* LUNG SPECIFIC EXPRESSION.

J. Wan, B. Carr and G. Yost. *Pharmacology & Toxicology, University of Utah, Salt Lake City, UT.*

CYP2F1 is expressed preferentially in human lung and is believed to play important roles in bioactivating pulmonary toxicants. DNAse I footprinting analysis with nuclear extracts from human lung revealed a single protected region (−152 to −182) in

the proximal promoter of the *CYP2F1* gene. This region contains two E–box regulatory motifs that normally bind deltaEF1, E12, E47 and AP4 transcription factors. The entire promoter region from +106 to −1685 was scanned, but no additional protected regions were identified. In EMSA assays, performed with a 31bp probe corresponding to the region from −152 to −182, prominent protein DNA complexes were detected with nuclear extracts from human lung tissue but not from liver and heart tissue. Binding of nuclear proteins was abolished by addition of non–radiolabeled specific probe but not by adding nonspecific probe. Supershift EMSA analysis did not identify the protein involved in binding this 31bp probe, all antibodies (deltaEF1, AP4, E2A, HEB, TAL1) used in this study failed to yield a supershift. In addition, supershift EMSA assays identified three Sp1/Sp3 binding sites with BEAS–2B and A549 lung cell nuclear extracts; one partially overlapped the DNAse protected region (−164 to −193), and another two were located at −49 to −72 and −103 to −125. Luciferase reporter assay shows that the later two Sp1/Sp3 binding sites drive the transcription activity of *CYP2F1* in human lung A594 and BEAS–2B cells. (Supported by PHS Grant #HL60143).

1264 MECHANISMS OF ARYL HYDROCARBON RECEPTOR-MEDIATED DISRUPTION OF ANDROGEN RECEPTOR FUNCTION IN LNCAP CELLS.

S. J. Barnes, C. Tomlinson, M. Sartor, M. Medvedovic and A. Puga. *Department of Environmental Health, University of Cincinnati Medical Center, Cincinnati, OH.*

2, 3, 7, 8, Tetrachlorodibenzo-p-dioxin (TCDD) blocks androgen-induced responses in male rats exposed *in utero* and lactationally, and to a lesser extent in adult rats. In experimental animals, reduced fertility following TCDD exposure has been attributed to decreased growth of the testis, epididymis, and accessory sex organs, and decreased daily and ejaculated sperm numbers. Several studies have shown the prostate to be most sensitive to TCDD treatment. Proposed mechanisms of the anti-androgenic effects of TCDD and other aryl hydrocarbon receptor (AHR) ligands include: (1) enhanced ligand metabolism; (2) altered hormone synthesis; (3) down-regulation of receptor levels; and (4) interference with hormone-induced gene transcription and cell proliferation in hormone-responsive tissues. In the present study we utilized androgen-dependent human Lymph Node Cancer of the Prostate (LNCaP) cells to determine the effect of TCDD on androgen receptor-(AR) mediated gene expression and DNA binding. Luciferase reporter assays indicate that TCDD-activated AHR inhibits induction by dihydrotestosterone (DHT) of AR-mediated gene transactivation. Electrophoretic mobility shifts assays reveal that TCDD blocks binding of the DHT-activated AR to its cognate sequence, but does not interfere with nuclear translocation of the activated AR. Global gene profiling using microarray analysis shows that TCDD blocks expression of several androgen responsive genes, including several members of the kallikrein gene family, which includes PSA, the androgen-inducible marker of prostate cancer. These results point to a role of the AHR in disruption of androgen-mediated responses through interference with AR promoter binding. *(Supported by NIH Grants RO1 ES06273 and P30 ES06096).*

1265 REGULATION OF CYCLOOXYGENASE 2 BY 2, 3, 7, 8-TETRACHLORODIBENZO-*p*-DIOXIN.

C. J. Broccardo, M. E. Legare and W. H. Hanneman. *Environmental and Radiological Health Sciences, Colorado State University, Fort Collins, CO.*

TCDD (2, 3, 7, 8 tetrachlorodibenzo-p-dioxin) is a ubiquitous environmental contaminant that has been shown to cause carcinogenic, reproductive, developmental, immunological, hepatic, and neurotoxic responses in animals. Many actions of TCDD are mediated by binding to the cytosolic arylhydrocarbon receptor (AhR) and induction of the classical dioxin-inducible gene battery. However, little is known about the complex molecular actions of TCDD beyond those associated with the AhR and it is likely that specific toxic effects of TCDD are mediated independent of the AhR. TCDD has been shown to induce *COX2* (cyclooxygenase 2) in rat liver and repress *COX2* in rat ovary; these responses may be AhR dependent. Physiologically, *COX2* is induced by a host of stimuli associated with inflammation, cytokines, and tumor necrosis factor-α. TCDD may regulate the *COX2* gene *via* CYP1A1 (cyctochrome P450 1A1) mediated arachidonic acid oxidation and activation of the NF-kB (nuclear factor kappa beta) pathway. Using large scale gene arrays we have previously shown that 50 nM TCDD x 8 h upregulates *COX2* 2.5 fold in C6 rat glioma cells. In order to further study this effect we have treated MO59K human glioma and H42E rat hepatoma cells with 50 nM TCDD for 4, 8, 24 h. Using quantitative real-time RT-PCR our data shows a cell line and time-specific regulation of *COX2* and *CYP1A1*, which is measured as a positive indicator of AhR activity. In conclusion, TCDD mediated dysregulation of *COX2* and *CYP1A1* may contribute to the toxicity of TCDD.

1266 STEROIDOGENIC ACUTE REGULATORY PROTEIN (STAR PROTEIN) ACTIVITY IN FISH.

J. Kocerha[1], K. K. Kroll[2] and N. D. Denslow[1,2]. *[1]Biochemistry and Molecular Biology, University of Florida, Gainesville, FL and [2]Interdisciplinary Center for Biotechnology Research, University of Florida, Gainesville, FL.*

The steroidogenic pathway is targeted by some environmental contaminants, resulting in reduced levels of steroid hormone synthesis. Alterations in steroid production can lead to severe reproductive abnormalities and other physiological dysfunction. The Steroidogenic Acute Regulatory (StAR) Protein transports cholesterol across the mitochondrial membrane, which is a rate-limiting step in steroidogenesis. Using largemouth bass (LMB) as a model, we have begun to examine the molecular mechanism(s) involved in the regulation of StAR. We have cloned the entire coding region of LMB StAR and have used this sequence to develop a real-time PCR assay to measure changes in StAR mRNA levels in ovarian tissue cultures. Preliminary data shows significant induction of StAR mRNA levels in LMB ovarian tissue cultures by 1mM dbcAMP after 4 hours, which suggests that mammalian and fish StAR may be similarly regulated. A 3 kb portion of the LMB StAR promoter was also cloned to further understand the transcriptional regulation of StAR in LMB. The transcriptional start site for the LMB promoter was located using RACE and the sequence upstream of the start site has been analyzed for consensus sites. A putative consensus binding site for SF-1 (sterol factor 1) has been identified close to the transcriptional start site. This suggests that SF-1, like in mammalian systems, may be involved in the regulation of LMB StAR. Elucidating the molecular pathway and determining sites for steroidogenic regulation provides crucial information to the understanding of normal cellular functioning.

1267 EFFECT OF SYNTHETIC ANTIOXIDANTS ON ALPHA CLASS GLUTATHIONE S-TRANSFERASE GENE EXPRESSION AND GLUTATHIONE BIOSYNTHESIS IN HUMAN LIVER SLICES.

C. M. Huisden[1], R. L. Fisher[2] and E. P. Gallagher[1]. *[1]Physiological Sciences, University of Florida, Gainesville, FL and [2]Vitron Inc., Tucson, AZ.*

The human glutathione S-transferases (hGSTs) comprise a multigenic family involved in a variety of detoxification reactions. The alpha classes GSTs (hGSTA1, hGSTA2, and hGSTA4), in particular, exhibit catalytic activities toward reactive aldehydes as well as peroxidase activities toward hydroperoxides. In the current study, we examined the effect of exposure to known rodent GST inducers on alpha class GST expression and glutathione biosynthesis in cultured human liver slices. Precision human liver slices were incubated up to 24 hours in the presence of *tert*-butyl-hydroquinone (TBHQ), ethoxyquin (EQ), and butylated hydroxyanisole (BHA). Cultured liver slices generally remained viable throughout the exposures, with the exception of high does of EQ (640 uM) and TBHQ (200 uM) which triggered losses in slice potassium concentrations at 24 h of exposure. In slices prepared from one donor, 40 uM EQ elicited a 40% increase in hepatic GSH, whereas exposure to 640 uM EQ elicited a modest (1.8-fold) increase in hGSTA4 mRNA expression but decreased the levels of hGSTA1 and hGSTA2 mRNAs. In a second experminent, the treatments were generally unaffective with regards to alpha GST gene expression, although some transient increases (<25%) in hGSTA1 mRNA expression were observed on exposure to 10 uM BHA. In summary, our results suggest that the expression of mRNAs encoding the alpha GST isozymes hGSTA1, hGSTA2, and hGSTA4 are not strongly modulated by certain synthetic antioxidants in cultured human liver slices. These results may be reflection of 1) an overall poor induction response of human alpha GST by antioxidants relative to rodents, 2) a limited responsiveness of these genes to inducing agents in cultured human liver slices, or 3) variability in inducibility among liver donors. Supported by NIH ES09427 and USEPA STAR 827441.

1268 EXAMINATION OF THE ROLE OF P53-ASSOCIATED CELL CYCLE GENE EXPRESSION INDUCED BY METHYLMERCURY IN MOUSE EMBRYONAL FIBROBLASTS.

C. C. Tin, J. S. Sidhu, S. Hong, E. Kim and E. M. Faustman. *Environmental Health, University of Washington, Seattle, WA.*

Exposure to methylmercury (MeHg) in the environment poses a risk of impaired function and death to human neurons, with the developing brain being more susceptible. Our lab has hypothesized that MeHg damage can be characterized by changes in cell cycle progression—namely G_2 M arrest. P53, acting as a transcription factor in response to genotoxic stress, serves as a cell cycle checkpoint and thus may play a role in mercury toxicity. We have employed cultures of p53 transgenic mouse embryonal fibroblasts to examine differential sensitivity to MeHg, and specifically the pathways induced by p53. Of particular interest for their promotion and inhibition of cyclin dependent kinases were cyclin B1 and p21, respectively.

Fibroblasts were exposed to 0.75, 2, and 4μM MeHg, and total RNA harvested from cells at 8, 24, and 48 hours post-exposure. Since we speculated that MeHg induced alteration of various genes related to the inhibition of the proteasomal pathway, lactacystin, a specific proteasomal inhibitor, was used as an additional control. By preventing ubiquitination and degradation of proteins, lactacystin would thereby increase endogenous p53. Experiments which assayed for changes in mRNA expression by semi-quantitative RT-PCR demonstrated that cyclin B1 was downregulated by treatments for up to 24 hours in the $p53^{+/+}$ cells, while in $p53^{-/-}$ cultures cyclin B1 expression was only initially depressed by lactacystin. Basal expression of p21 was higher in the wildtype compared to the null, but all samples expressed p21 suggesting p53-independent regulation. GADD153, another transcription factor capable of causing cell cycle arrest, increased with MeHg dose in $p53^{+/+}$ cells but not in the $p53^{-/-}$ and not as a result of lactacystin exposure. Given the responses of 3 representative p53-inducible genes, MeHg toxicity is associated with changes in expression of cell cycle genes determined in part by p53 status and proteasomal activity. Supported by NIH Grants ES10613-01, ES11387-01, ES09601-02, and ES07033.

1269 INTERACTION BETWEEN THE ARYL HYDROCARBON RECEPTOR AND TRANSCRIPTION FACTOR E2F LEADS TO GENE REPRESSION.

J. Marlowe, X. Chang, Y. Wei and A. Puga. *Department of Environmental Health, University of Cincinnati Medical Center, Cincinnati, OH.*

The molecular basis of the biological effects of 2, 3, 7, 8-tetrachlorodibenzo-p-dioxin (TCDD) is largely unknown. TCDD mediates the transactivation of the CYP1 family of cytochrome P450 monooxygenases, but activation of the CYP1A1, CYP1A2 and CYP1B1 genes does not adequately explain the diversity of TCDD effects. Complexes formed between the activated AHR, the retinoblastoma protein RB and the transcription factor E2F at E2F binding sites of natural promoters, are important in repression of S-phase-specific genes and cell cycle arrest. Gene expression profiling has shown that more genes are repressed by TCDD treatment than they are induced, even when secondary effects of exposure are blocked by protein synthesis inhibitors. Transactivation by the activated AHR can explain gene induction, but not gene repression, which constitutes a major effect of dioxin exposure that has not been characterized at the molecular level. Based on preliminary evidence, we hypothesized that AHR can also cause gene repression by forming complexes with the transcription factor E2F independently of RB and interfering with E2F-dependent transcription. To test this hypothesis, we analyzed protein interactions between AHR and E2F in pull-down and gel retardation assays. In pull-down assays using GST-E2F fusions as bait we found that AHR binds directly to GST-E2F, forming stable protein complexes. Using gel retardation assays, we show that AHR can specifically displace RB from its interaction with E2F at E2F binding sites occupied by RB(p105)/E2F/DP1 complexes, generating a novel complex containing E2F and AHR. We also used transient expression of a luciferase reporter driven by the promoter of the DHFR gene in RB-negative mouse hepatoma Hepa-1 cells to show that direct AHR-E2F interactions lead to gene repression. These data suggest that AHR not only establishes active repression interactions with RB, but that it can also bind to E2F and down-regulate gene expression possibly through a mechanism of E2F sequestration. *(Supported by NIH R01 ES06273).*

1270 TRAPPING GENES ASSOCIATED WITH TOBACCO USE.

A. F. Flint, C. T. French, J. M. Brzeziski, M. E. Legare and W. H. Hanneman. *Environmental and Radiological Health Science, Colorado State University, Fort Collins, CO.*

Data from epidemiological studies have strongly linked the development of squamous cell carcinomas of the upper aerodigestive tract to consumption of tobacco, particularly when combined with alcohol. The exact mechanisms leading from tobacco use to disease are not well understood, but for tumorigenesis those mechanisms are surely genetic. Understanding how carcinogens induce tumor formation ultimately relies on identifying and characterizing the genes that are targeted for mutation and/or dysregulation by those carcinogens. To this end, many mutations have been found in cancer cells from tobacco users, but not all mutations have been associated with specific genes. Thus, the goal of this project is to identify, mutate and characterize those genes. This goal is part of the long-term objective of understanding the genetic mechanisms underlying the development of cancer. To address this goal, we have deployed a gene-trapping strategy to identify tobacco-sensitive genes. Briefly, mouse embryonic stem (ES) cells are transfected with a promoterless reporter gene construct. Successful transfection of an ES cell will knockout an endogenous gene, but the reporter gene will be active and under the control of the endogenous promoter. Large numbers of unique gene-trapped ES cell clones are then screened in the presence or absence of cigarette smoke condensate (CSC), and altered reporter gene expression is identified and recorded. The reporter gene itself is then used as the starting point for sequencing of the endogenous genes. Sequences are then compared to those in the GenBank database to identify novel genes as well as previously known genes that were unknown to be altered/dysregulated by tobacco. In addition, mutant ES cells created as described above can be used to generate knockout mice. Those mice in turn will then be studied to understand the role of each gene relative to the development of cancer and disease.

1271 HEPATOBILIARY TRANSPORTER INDUCTION IN ALTERED THYROID HORMONE HOMEOSTASIS: A MICROARRAY ANALYSIS.

G. Falls, B. Gemzik, B. D. Car and L. D. Lehman-McKeeman. *Discovery Toxicology, Bristol-Myers Squibb Co., Wilmington, DE.*

The mechanism by which UDPGT inducers alter hepatic clearance of thyroid hormones in rodents has been well established. DPC 904 (a pyrazolopyrimidine) reduced serum T4 and T3 and increased TSH, and caused thyroid follicular cell hypertrophy and hyperplasia, increased liver weights, and hepatocellular hypertrophy with increased mitoses in rats given ≥200 mg/kg/day for 5 days. The biliary clearance of both T4-glucuronide and unconjugated T4 was increased with treatment; however, the majority of excreted T4 was unconjugated. We hypothesized that the reduction in serum T4 was related to increased hepatobiliary transport of both conjugated and unconjugated T4. The aim of this study was to determine whether expression of genes involved in thyroid hormone homeostasis (e.g. hepatic enzymes and transporters) is altered following treatment with DPC 904. Mature male Sprague-Dawley rats were given a single 200 mg/kg dosage of DPC 904, and serum and livers were collected at 3, 6, 10, 24, or 48 hours. Serum T4 and T3 levels were decreased (0.6× and 0.7×, respectively) at 10 hours, and TSH was increased (1.9×) by 24 hours and remained elevated. Hepatic gene expression profiles were generated using Affymetrix Rat Genome U34A arrays and Rosetta Resolver software. Induction of oatp2 (Slc21a5) mRNA was evident at 3 hours, coinciding with a strong and sustained increase in CYP3A expression. There was also a dramatic increase in CYP2B expression at 3 hours. Mrp2 was induced at 6 hours, and UGT1A1, 1A2, 1A5, 1A6, and 2B1 expression was increased by 10 hours. Generally, peak gene expression changes were observed at 24 hours. In support of the microarray results, oatp2 protein levels were markedly increased in treated rats. Based on these results, hepatic uptake of T4 is likely increased by induction of oatp2, whereas increased biliary excretion correlates with increased UGT and mrp2 expression. Cluster analysis supports the conclusion that DPC 904 regulates hepatic gene expression through both PXR and CAR activation.

1272 GENE EXPRESSION IN RAT SKIN FOLLOWING DERMAL EXPOSURE TO JP-8 JET FUEL.

C. M. Garrett[1,2], J. Rogers[1,2] and J. N. McDougal[3]. *[1]Geo-Centers, Inc., Wright-Patterson AFB, OH, [2]Wright-Patterson, AFB, Wright-Patterson AFB, OH and [3]Wright State University, Dayton, OH.*

Dermal irritation resulting from occupational exposure of Air Force personnel to jet fuels continues to be an important occupational health issue. Irritant contact dermatitis, the most common occupational skin disease, costs the government millions of dollars each year. Gene array technology can serve as a tool for assessing chemical irritancy potential. To determine the transcriptional response to jet fuel, male Fisher 344 rat skins were exposed to JP-8 for 1 hour *in vivo*. Total skin RNA was then isolated at 0 h (control), 1 and 4 hrs following the beginning of the exposure to monitor transcriptomic profiles using the Affymetrix RatTox U34 array. Our results indicate dermal exposure to JP-8 causes significant change in gene expression: 187 transcripts changed at 1 hour and 216 genes changed at 4 hours when compared to controls. Of the 187 genes showing differential expression at 1 hour, 67 were expressed sequence tags (EST). Of the remaining 120 transcripts, 33 showed increased expression and 67 had decreased expression with respect to controls. At 4 hours there were 73 ESTs, 64 increases and 55 decreases. Genes were grouped according to the following functional categories: metabolism, cell structure, extracellular matrix, differentiation and cell division, signal transduction, transporters and ligands, cellular and oxidative stress, cytokines/growth factors/receptors, and miscellaneous. A strong temporal change of gene expression was observed in the skin following exposure to JP-8. Characterization and analysis of the transcriptomic response of skin to jet fuel may enhance the risk assessment of JP-8-induced dermal irritation.

1273 UNRAVELLING THE MOLECULAR MECHANISMS UNDERLYING HYDROXYUREA GENOTOXICITY IN MOUSE LYMPHOMA L5178Y CELLS USING TOXICOGENOMICS.

E. Boitier, J. Marchandeau, M. Flor, R. A. Roberts, J. Gautier and V. Thybaud. *Drug Safety Evaluation, Aventis Pharmacology SA, Vitry sur Seine, France.*

The application of gene expression profiling technology to genetic toxicology is expected to allow a significant advance in understanding toxic mechanisms of DNA reactive genotoxins versus non-DNA reactive genotoxins such as Hydroxyurea

(HU), and should ultimately aid in a better risk assessment. The main objectives of the study were to (1) examine the relative sensitivity of DNA microarray technologies using HU as a model compound, (2) investigate the relationship between gene expression changes and traditional genetic toxicology endpoints and (3) better characterize the molecular mechanisms of HU genotoxicity. Mouse lymphoma L5178Y cells were treated for 4 hrs with increasing doses of HU (from 0.1mM to 1mM) and harvested immediately or left for a 20hr-recovery period (n = 3 independent biological experiments). Cytotoxicity was evaluated by cell count and genotoxicity by *in vitro* micronucleus assay at 24hrs. Gene expression profiling of HU-treated L5178Y cells was performed using Affymetrix mouse MG-U74A GeneChips (Affymetrix, USA). Data analysis showed a dose-dependent increase in the number of genes modulated, 75% of which was significantly down-regulated, whatever the doses or the time-points. Hierarchical clustering analysis of the gene expression profiles allowed a better discrimination of the genotoxicity data at 4 hrs as compared to 24 hrs, suggesting a putative link between gene expression modulation at 4hrs and the observed genotoxicity. The modulated genes at 4 hrs were involved in cell cycle, chromosome assembly, nucleotide metabolism and DNA repair pathway (less clear gene expression patterns at 24hrs). Therefore, the gene expression modulation observed at 4hrs could represent HU molecular signature, most probably linked to its non-DNA reactive genotoxic properties. Additional experiments with other non-DNA reactive genotoxins should help determine whether the observed HU gene expression fingerprint is compound- or chemical class-specific.

1274 LIVER-TARGETING PRODRUG OF PMEA INDUCES A MUCH MORE FAVORABLE KIDNEY AND LIVER TOXICOLOGICAL GENE EXPRESSION IN RATS COMPARED TO BISPOM-PMEA.

C. Fang, C. Lim, P. Srivastava, J. Y. Lau and C. Lin. *Research and Development, Ribapharm Inc., Costa Mesa, CA.*

Background: PMEA is an acyclic nucleotide phosphonate analog with potent anti-hepatitis B virus (HBV) activity. However it has low oral bioavailability and accumulated at high levels in kidney. Two prodrugs of PMEA are being developed. BisPOM-PMEA is an orally bioavailable esterase-activated prodrug, whereas hepavir B is a liver-targeting cytochrome P450 (CYP) 3A4-activated prodrug. **Aim:** To profile and compare the renal and hepatic toxicological gene expression in rats in response to prolonged treatment of BisPOM-PMEA and hepavir B. **Methods:** Five male rats per group were dosed orally for 8 days with 40 and 300 mg/kg/day of BisPOM-PMEA and hepavir B, respectively. Affymetrix Rat Toxicology Arrays were employed. 3-fold difference of gene expression compared to controls is taken as cutoff. Changes in expression of selected genes were confirmed by competitive RT-PCR analyses. **Results:** *Gene Expression Profile in Kidney:* Both BisPOM-PMEA and hepavir B treatments markedly increased the mRNA levels of multidrug resistance gene (mdr1b, >20 folds) as well as cell cycle genes (cyclin B and G, and GADD153, 3-5 folds). In addition, hepavir B at 300 mg/kg/day also induced other genes including stearyl-CoA desaturase (>25 folds) and fatty acid synthetase (25 folds). In contrast, BisPOM-PMEA at 40 mg/kg/day down-regulated more than 50 genes including canalicular multispecific organic anion transporter (cMOAT, 3.2 folds, specific for the adefovir excretion), and a large number of drug metabolizing enzymes (CYP1A, 2A, 2B, 2C, 3A, GST and UDPGT, 5-40 folds). *In Liver:* Only minor changes in gene expression were observed, except that hepavir B at 300 mg/kg/day down-regulated stearyl-CoA desaturase (9.6 folds) but up-regulated mdr1b (>40 folds). **Conclusion:** BisPOM-PMEA (at 40 mg/kg/day) dramatically down-regulated many more toxicological genes in kidney compared to hepavir B (at 300 mg/kg/day). The data suggested that hepavir B may have less nephrotoxicity potential compared to BisPOM-PMEA.

1275 THE EFFECT OF GLUTATHIONE REGULATION ON GENE EXPRESSION IN RAT PRIMARY HEPATOCYTES.

N. Kelley-Loughnane[1], A. Soto[2], S. M. Hussain[2], V. Chan[2], D. C. Rudnicki[3] and J. M. Frazier[3]. [1]*Geo-Centers, Inc., Wright-Patterson Air Force Base, OH,* [2]*ManTech Environmental Technology, Inc., Wright-Patterson AFB, OH and* [3]*Operational Toxicology Branch, AFRL/HEST, Wright-Patterson AFB, OH.*

Evaluation of the cellular response to chemical or environmental changes has led to utilization of microarray technology. Toxicologists are investigating this technology as a way to monitor changes in thousands of genes in order to find more sensitive predictive methods for drug and chemical safety analyses. Genomic modeling research shows the potential of using genomic data for predictive models. Glutathione (GSH) plays an important role in modulating the toxicity of chemicals and is often measured as an indicator of xenobiotic metabolism. The rate-limiting step of GSH synthesis is controlled by the enzyme γ-glutamylcysteine synthetase (GCS) that is feedback inhibited by GSH. L-Buthionine sulfoximine (BSO) is a potent inhibitor of GCS. This research investigated the effect of GSH depletion on the transcriptome of primary rat hepatocytes. To determine the gene expression profiles for normal (0 μM BSO) and those GSH-depleted hepatocytes, total RNA from these cultures were harvested at several time points (0h, 2h, 4h, 6h, 12h, and 24h) during treatment with 0 μM, 50 μM, and 200μM BSO. These samples were analyzed with the Affymetrix rat genome U34A arrays. These studies create a baseline of gene expression in naïve and GSH-depleted primary rat hepatocytes in the presence and absence of a GSH synthesis inhibitor. Both the metabolism and function of GSH involves many interconnected biochemical pathways, such as protein synthesis, regulation of enzyme activity, amino acid transport, catabolism of reactive oxygen species, and coenzyme activity for synthesis of endogenous compounds. This research establishes the groundwork for modeling the GSH pathway in primary rat hepatocytes.

1276 DEVELOPMENT OF A GENE-EXPRESSION ARRAY FOCUSING ON THE HYPOTHALAMUS-PITUITARY-THYROID AXIS IN XENOPUS LAEVIS.

J. Korte, S. J. Degitz and J. E. Tietge. *MED, NHEERL, ORD, USEPA, Duluth, MN.* Sponsor: J. Nichols.

As recommended by the Endocrine Disrupter Screening and Testing Program Advisory Committee (EDSTAC), the USEPA has been developing a screening test capable of detecting effects of Endocrine Disrupting Chemicals (EDCs) on the hypothalamus-pituitary-thyroid (HPT) axis in *Xenopus laevis*. As part of this, we developed an oligonucleotide array to assess changes in expression of important thyroid-axis genes, allowing comparison of the results with morphometric and biochemical information. The method consists of hybridizing amplified, biotinylated RNA from test organisms with membrane-bound synthetic DNA oligomers of 65 to 70 bases. The biotin label is detected by chemiluminescence and quantified. Currently, there are two different oligos for each of the 70 different genes represented on the array, and each oligo is spotted twice. When tested on samples from stage 53 to 56 tadpoles, the system shows robust responses from housekeeping genes (actin, elongation factor 1-α, ribosomal protein L8, etc.), as well as strong responses from genes important to the HPT axis (thyroid stimulating hormone, thyroid hormone receptor, corticotropin releasing factor, proopiomelanocortin, prohormone convertase, growth hormones A and B, etc.) The method has numerous attractive features: 1) very sensitive, surpassing radioactive methods 2) system does not require complete sequence information, useful in species such as *X. laevis* where complete genomic information is not available 3) high flexibility, allowing genes to be added as new sequences become available. 4) does not require robotics or other highly specialized/expensive equipment 5) potential to detect hundreds of genes at once 6) fast, the results are available a few hours after the hybridization step. The array has been run successfully with RNA from whole tadpoles, tail sections, and even on individual brains weighing only a few milligrams. *This abstract does not necessarily reflect EPA policy.*

1277 IDENTIFYING NOVEL DIOXIN-INDUCIBLE GENE TARGETS IN NEURONAL CELL LINES.

M. S. von Maier, M. E. Legare and W. H. Hanneman. *Department of Environmental & Radiological Health Sciences, Colorado State University, Fort Collins, CO.*

A great deal of concern exists that even low levels of dioxins transferred to a developing fetus across the placenta can induce neurological injury. A first step to understanding mechanisms of dioxin injury is to identify modifications in neuronal gene expression resulting from dioxin exposure. Using human glioma (MO59K) and neuroblastoma (SH-SY5Y) cells we identified dioxin-inducible genes by suppression subtractive hybridization (SSH) and serial analysis of gene expression (SAGE). Of particular interest is the aryl hydrocarbon receptor (AhR) nuclear translocator II (ARNT2) protein which is a basic helix-loop-helix (bHLH) transcription factor that is highly expressed in neurons and is thought to play an integral role in neuronal AhR-mediated responses to dioxin. In cDNA libraries enriched for dioxin-induced genes from human glioma and neuroblastoma cells we have identified individual dioxin-induced genes in subtracted libraries and compared expression in the two cell types. Identification of dioxin responsive genes, that include a combination of Ahr, Arnt, Arnt2 and hypoxia inducible factors (Hif), among others, provides a foundation from which to examine cross-talk and signaling between the identified dioxin responsive genes and their gene products.

1278 TRANSCRIPTIONAL CHANGES IN NORMAL HUMAN LIVER CELLS EXPOSED TO TETRACHLOROETHYLENE METABOLITE USING MICROARRAY ANALYSIS.

N. Keshava and T. Ong. *Toxicology and Molecular Biology Branch, National Institute for Occupational Safety and Health, Morgantown, WV.* Sponsor: P. Joseph.

Trichloroacetic acid (TCA) is a major metabolite of tetrachloroethylene (TCE) in both humans and experimental animals. Occupational exposure to TCE can occur through inhalation, skin contact or ingestion during its use in dry cleaning and de-

greasing. TCE is converted to TCA mediated through cytochrome P450 pathway. Although TCE is classified as a probable carcinogen to humans by International Agency for Research on Cancer, inadequate evidence limits classifying TCA as a probable carcinogen. Studies have been conducted in our laboratory to determine whether exposure to TCA causes alterations in expression of cancer related genes in cultured human cells. Exponentially growing normal human liver cells were exposed to 200 and 400 uM concentration of TCA for 12h. Total RNA was used for the preparation of double stranded cDNA. Biotin labeled cRNA transcript was synthesized using cDNA, fragmented and hybridized to HuGeneFL GeneChip probe arrays representing more than 6800 human genes and expressed sequence tags. The arrays were stained with streptavidin-phycoerythrin and biotinylated anti-streptavidin antibodies. The differential gene expression data analysis was performed using GeneChip 4.0 software. The 3'/5' cRNA transcript ratios for both GAPDH and b-actin were found to be consistent between control and treatment groups over a period of 12h exposure. Altered gene expression patterns were observed in 133 RNA transcripts with at least a 2 fold change. Alterations in expression include metabolic genes (CYP11B1, MGMT), cell cycle control and DNA repair genes (GADD45, Cyclin G2, Cyclin D3, Cyclin A) and transcription factors (IF2, IF3). Whether alterations in the expression pattern of these genes, particularly transcriptional factors, is associated with carcinogenic potential of TCA needs to be elucidated.

1279 SPERM RNA AMPLIFICATION FOR GENE EXPRESSION PROFILING BY DNA MICROARRAY TECHNOLOGY.

H. Ren, K. E. Thompson, J. E. Schmid and D. J. Dix. *Reproductive Toxicology Division, NHEERL, Office of Research and Development, USEPA, Research Triangle Park, NC.*

DNA microarray technology has been widely used to detect differential gene expression and to generate gene expression profiles useful for studying drug or environmental effects on animals or humans. In order to establish methods for monitoring effects of environmental chemicals on the male reproductive system, we have collected rat (pool of ten 75-90 day Sprague-Dawley rats) epididymal sperm and isolated total RNA. Due to the limited number of sperm from individual animals, the amount of total RNA purified from rat sperm was not sufficient for microarray probe labeling. Therefore, RNA amplification was used to generate sufficient quantities of antisense RNA (aRNA) for array hybridization. Two rounds amplification of 200ng rat sperm RNA generated 25 to 35ug aRNA. Only one round of amplification was necessary to obtain similar amounts of aRNA from 200ng testis RNA. After indirect labeling with Cy3 or Cy5, aRNAs were hybridized to glass-slide microarrays with 70-mer oligonucleotides probes for 4, 370 rat genes. Preliminary analysis identified hundreds of genes/mRNAs in both the testis and sperm samples (e.g., SP22 sperm protein). These results indicate that RNA amplification can be used to generate gene expression profiles from tissue samples with limited amounts of RNA. More detailed studies of sperm RNA profiles from rats following chemical exposure are underway. Results from these toxicology studies promise to complement studies of sperm RNA profiles in humans. This is an abstract of a proposed presentation and does not necessarily reflect EPA policy.

1280 A PRACTICAL EXPERIMENTAL DESIGN TO CORRECT FOR DYE BIAS IN DUAL-LABELED CDNA MICROARRAY EXPERIMENTS WITHOUT SACRIFICING PRECISION.

B. A. Rosenzweig[1], P. S. Pine[1], O. E. Domon[2], S. Morris[2] and F. D. Sistare[1]. *[1]CDER, USFDA, Laurel, MD and [2]NCTR, Jefferson, AR.*

A significant limitation to the use of dual-labeled spotted cDNA microarrays is the introduction of signal variance by dye bias presumably due to sample incorporation of two distinctly different chemical dyes. Several approaches were used to assess and minimize the effects of dye bias on fluorescent signal hybridizations. Human TK6 cells were exposed to vehicle or (0.01 to 1.0 uM) benzo[a]pyrene diol epoxide (BPDE) for 4 or 24h and total RNA was isolated, labeled with Cy3 or Cy5, and hybridized to Human 350 Microarrays (Phase-1, Santa Fe, NM). Dye bias alone accounted for a significant component of measured differences and introduced unacceptably high numbers of both false positive and false negative statistically significant signals. However, we have found that within a given set of concurrently processed hybridizations, the bias is remarkably consistent and, therefore, measurable and correctable. Paired replicate dye-swap corrections are commonly performed to eliminate dye bias but can be costly to end-users, can introduce statistical error, and may therefore generate false negative signals when statistical criteria are used to identify gene expression alterations. We demonstrate a practical experimental design to measure and mathematically eliminate this dye bias for each set of concurrently processed microarrays by including split control sample hybridizations (Control Cy3 vs. Control Cy5). The number of replicate hybridizations required for confidence in data interpretation can thus be minimized. We show that approximately 25 - 30% of the genes identified as statistically significantly (paired t-test, $p<0.001$) altered by BPDE treatment on a pair of microarrays can differ depending on the approach chosen to eliminate dye-bias effects. Incorporating split control microarrays within a set of concurrently processed hybridizations to measure dye bias specifically can eliminate the need for dye-swaps and improve experimental precision.

1281 EVOLUTIONARILY CONSERVED RESPONSES TO ARSENIC IN YEAST AND HUMAN CELLS.

A. Haugen[1], H. K. Hamadeh[2], J. Collins[1], P. Bushel[1], J. Miller[1], C. J. Tucker[1], D. A. Gordenin[1], G. Karthikeyan[1], C. Afshari[2] and B. Van Houten[1]. *[1]Laboratory of Mol.Gen., NIEHS, Research Triangle Park, NC and [2]Amgen Inc., Thousand Oaks, CA.*

Human exposure to arsenic in the drinking water is associated with an increased incidence of neoplasia including skin cancer. However, the mechanisms in arsenite-mediated toxicity and carcinogenesis remain elusive, due in part to the lack of an appropriate animal model. Microarrays have provided important information about the response to environmental toxicants. Previous gene expression studies in normal human epidermal keratinocytes (NHEK) suggested that arsenite (AsIII) was associated with oxidative stress, altered DNA repair, and increased proliferation (Hamadeh et al, 2002). To investigate the importance of arsenite-modulated genes in the etiology of arsenic-related effects, we are comparing gene expression profiles in yeast and human cells. Our hypothesis is that arsenic will lead to a conserved response in all eukaryotic cells. Yeast is an excellent model for characterizing and interpreting genomic expression data because of extensive understanding of its biology and genome. Our goal is to assess whether a yeast model for AsIII toxicity can identify human-yeast orthologs modulated by arsenite. Preliminary results of multiple biological experiments with four hybes/experiment and analysis of statistically validated outlier genes at 99% confidence show stress response genes (e.g. heat shock proteins, thioredoxins, metallothioneins, glutathione transferase) are induced in both yeast and human cells after non-toxic doses of AsIII. Additional candidate human genes are being discovered through the analysis of yeast orthologs, using the 6200 gene set. AsIII treated NHEK RNA will be subjected to RT-PCR to quantify the levels of target genes identified using yeast gene expression and deletion analysis, and help discover new genes involved in human arsenite-mediated toxicity and carcinogenesis.

1282 TEMPORAL GENE EXPRFESSION PROFILIES OF HUMAN FETAL ASTROCYTE SVG CELLS TREATED WITH A NEUROTOXICANT, 6-AMINONICOTINAMIDE.

T. Yamada[1,2], L. D. Burgoon[1,3], K. Y. Kwan[1,2], M. R. Fielden[1,2], J. E. Trosko[2,4] and T. R. Zacharewski[1,2]. *[1]Biochemistry and Molecular Biology, Michigan State University, East Lansing, MI, [2]National Food Safety and Toxicology Center, Michigan State University, East Lansing, MI, [3]Pharmacology and Toxicology, Michigan State University, East Lansing, MI and [4]Pediatrics and Human Development, Michigan State University, East Lansing, MI.*

6-Aminonicotinamide is a nicotinamide analogue that is known to induce severe neurotoxic effects to both developing and adult animals. Several histopathological and biochemical analyses suggest that astrocytes are its major targets. This chemical is considered to affect the pentose phosphate pathway, resulting in the inhibition of NADPH production. However, the molecular mechanism leading to brain disorders remains unknown. In this study, the effects of 6-aminonicotinamide on global gene expression were examined in SVG, an immortalized human fetal astrocyte cell line. Cells were treated with 6-aminonicotinamide at doses ranging from 0.1 to 10 μM for 24h. After treatment, RNA was isolated from each treatment and vehicle-treated control group and the temporal changes in gene expression were measured using a custom, SVG-specific cDNA microarray (3, 372 genes). Data were background corrected, and subsequently normalized by z-score normalization using the GenePix Post Processing (GP3) script. Data were filtered using a General Linear Mixed Model to model the microarray data, followed by pairwise comparisons using a t-test. The expression of numerous genes were affected following treatment, including a series of genes known to be responsive to oxidative stress as well as apoptosis-related genes. The temporal gene expression profiles suggest that 6-aminonicotinamide induces oxidative stress, followed by adaptive responses and events leading to apoptosis of SVG cells. Supported by ES 04911-12.

1283 ALTERATIONS IN GENE EXPRESSION BY TRIVALENT CHROMIUM IN HEPG2 CELLS AND MOUSE LIVER.

W. Baldwin, L. Bain and B. Romero. *Biological Sciences, University of Texas at El Paso, El Paso, TX.*

Trivalent chromium [Cr(III)] is used as a dietary supplement to lose weight and is the dominant toxicant at several Superfund sites around the United States, including an estuarine site in South Carolina. However, the effects of Cr(III) are not well

understood and studied because of its low bioavailability. Therefore, we have attempted to characterize the effects of Cr(III) on gene expression in male mouse liver and HepG2 cells. HepG2 cells were exposed to Cr(III), as chromium chloride hexahydrate to determine their toxicity. Cr(III) did not cause cell death at any dose tested, but significantly decreased growth at 100uM. Cells were treated with 20uM Cr(III) for 6 hours or five days, RNA was extracted and Clontech™ arrays were incubated and analyzed. ResGen Pathways Universal Microarray Analysis Software™ was used for microarray analysis and alterations in gene expression were considered statistically significant by the Chen Test at $p<0.05$. Several genes involved in protein turnover showed altered expression due to Cr(III) in HepG2 cells, including α-1 antichymotrypsin, cathepsin D, apoptotic protease activating factor 1, and ACl proteasome subunit a3. Furthermore, several genes that have previously been shown to be altered by oxidative stress were changed in HepG2 cells, as were some growth related genes (IGF-BP1). RT-PCR was performed to confirm differential expression of some of these genes. In comparison, mice were treated with Cr(III) in their drinking water at a concentration of 200mg/L for two weeks. Mouse liver arrays also demonstrated changes in gene expression in oxidative stress and protein turnover related genes. However, most of the alterations in gene expression in mouse liver were in either growth related genes (Erbb2, IGFBP-1, STAT6, Myc) or genes involved in the immune system (TDAG51, IL6R). Many of the genes altered are involved in tumor progression and metastasis and some are involved in Alzheimers disease. A thorough comparison of changes between short and long-term exposure to cells and treatment of mice will be presented.

1284 CHARACTERIZATION OF TCDD-RESPONSIVE GENES IDENTIFIED BY CDNA MICROARRAY ANALYSIS.

H. M. Handley[1], J. J. Stegeman[1] and M. C. Fishman[2,3]. [1]*Biology, Woods Hole Oceanographic Institution, Woods Hole, MA,* [2]*Cardiovascular Research Center, Massachusetts General Hospital, Charlestown, MA and* [3]*Novartis Institute for Biomedical Research, Inc., Cambridge, MA.*

2, 3, 7, 8-tetrachlorodibenzo-*p*-dioxin (TCDD) is a powerful teratogen capable of disrupting development of the cardiovascular system, kidney, brain, craniofacial structures, and endocrine system. The molecular mechanisms of TCDD embryotoxicity are poorly understood, but likely involve AHR-mediated transcriptional regulation. Previously, we have reported the use of cardiovascular-specific cDNA microarrays to identify alterations in gene expression in zebrafish embryos exposed to TCDD. Here we present more detailed analyses of genes of interest identified by these studies. cDNA clones manifesting 2-fold or greater differential regulation by TCDD were sequenced and found to represent 12 genes of known function, as well as 21 ESTs. The normal roles of the known genes include xenobiotic metabolism, cardiovascular function, hormone synthesis, and fatty acid binding. In order to better understand their roles in embryotoxic processes, we have used RT-PCR to characterize the dose- and developmental time- dependence of TCDD-regulated changes in expression of these genes. In addition, a combination of *in situ* hybridization, RT-PCR, and morpholino knock-down is being utilized to begin functionally characterizing novel TCDD-responsive ESTs. This work promises to provide important insights into the molecular pathways affected during TCDD-induced embryotoxicity. NIH #P42-ES07381

1285 DIFFERENTIATION BETWEEN SENSITIZERS AND IRRITANTS IN THE LOCAL LYMPH NODE ASSAY USING A MINIMAL TRANSCRIPT SET.

C. M. Glatt[1], C. Smith[1], W. Foster[2] and G. Ladics[1]. [1]*Haskell Laboratory, DuPont, Newark, DE and* [2]*Bristol Myers Squibb Co., Wilmington, DE.*

Previous studies utilized the LLNA in conjunction with DNA microarrays to evaluate expression profiling as a method to distinguish between structurally diverse sensitizers and irritants and to identify potential transcript biomarkers specific for each compound class. Eight transcript discriminators were identified: mucin 10 (Muc10); T-cell death associated gene (Tdag); T-cell receptor gamma V4, (Tcrg-V4); gap junction membrane channel protein β2; lymphocyte-activation gene 3 (Lag3); RAB4A; and kallikreins 9 and 26 (KIK9 and KLK26). The objective of this study was to confirm and/or refine the 8 potential transcript biomarkers using real-time PCR. Analyses were performed on auricular lymph node total RNA isolated from 8-week-old female CBA/JHsd mice (n=10-15/group) dosed with either 4:1 acetone/olive oil (vehicle) or one of three dermal sensitizers (0.25% dinitrochlorobenzene, DNCB; 0.05% oxazolone, OX; 25% α-hexylcinnamaldehyde, HCA) or one of four irritants (25% chlorobenzene, CB; 5% phenol, PH; 20% benzoic acid, BA; 0.5, 1, or 2% benzalkonium chloride, BAC) according to standard LLNA protocol. Experiments were performed using the TaqMan® technology and primer/probe sets of each specific biomarker. Consistent with the array results, Lag3 was upregulated in mice treated with the sensitizers and unchanged in mice from the irritant groups. Evaluation of sensitizer-specific signatures revealed a strong induction of cell cycle and inflammatory response transcripts that are unaltered by irritant treatment. These clusters of potential biomarkers effectively confirm proliferation-based scoring in the LLNA. Expression profiling performed on higher doses of BAC that typically score positive in the LLNA, revealed a similar induction of many of these transcripts, as well as the proinflammatory serine protease, kallikrein 6 providing a molecular basis for high-dose irritant scoring in the LLNA. These results revealed a minimal transcript biomarker set that has the potential to distinguish sensitizers from irritants in the LLNA.

1286 COMPARATIVE GENE EXPRESSION PROFILING IN FEMALE RATS TREATED SUBCHRONICALLY AND CHRONICALLY WITH PCB126, PCB153, AND TCDD.

C. Vezina[1], R. L. Malek[2], H. Sajadi[2], D. A. Brazeau[3] and J. R. Olson[1]. [1]*Pharmacology and Toxicology, University at Buffalo, Buffalo, NY,* [2]*The Institute for Genomic Research, Rockville, MD and* [3]*Pharmaceutics, University at Buffalo, Buffalo, NY.*

PCB126 (3, 4, 5, 3', 4'), PCB153 (2, 4, 5, 2', 4', 5'), and 2, 3, 7, 8-tetrachlorodibenzo-p-dioxin (TCDD) represent persistent environmental contaminants that elicit a variety of toxicological responses. Disparate affinities for the Aryl Hydrocarbon Receptor (AhR) partially explains differences in the toxicology of PCB126 (high affinity), TCDD (high affinity) and PCB153 (little or no affinity), but little is known about how these chemicals influence other molecular pathways. The purpose of the present study was to characterize global gene expression profiles in female Sprague-Dawley rats treated with vehicle, 100 ng/kg/day TCDD, 1000 ng/kg/day PCB126, or 1000 ug/kg/day PCB153 for 13 or 52 weeks (NTP cancer bioassay). Total RNA from toxin treated and time matched, vehicle treated liver tissue was reverse transcribed in the presence of amino-allyl dUTP and subsequently coupled to Cy5 or Cy3 esters, respectively. Triplicate labeling reactions were applied to cDNA microarrays fabricated at the Institute for Genomic Research (TIGR, http://pga.tigr.org/RatText.shtml). Each array contained over 26 k genes from 13 different tissue libraries. Poor quality spots were removed from further analysis and the remaining datasets were normalized by lowess and subjected to cluster analysis to identify dose, time and toxicant-related patterns in gene expression. Additionally, Sprague-Dawley rat tissue slices were incubated for 24 hr in dynamic organ culture containing either 10 nM dioxin or vehicle and analyzed by microarray in order to identify biomarkers for acute exposure. We discovered a number of genes exhibiting time and/or compound-specific alterations in expression and selected changes were validated by RT-PCR. These data may provide new biomarkers for exposure to PCBs and TCDD and elucidate new biological mechanisms for their toxicity. (Supported in part by NIEHS ES09440, SOT, and University at Buffalo).

1287 ESTROGEN INCREASES DOPAMINE BETA HYDROXYLASE ACTIVITY AND PROTEIN EXPRESSION IN CATH.A CELLS.

H. L. Rincavage and C. M. Kuhn. *Pharmacology, Duke University, Durham, NC.* Sponsor: T. Slotkin.

We have previously found that the locus coeruleus-derived cell line Cath.a expresses Estrogen receptor (ER) beta protein, but does not express ER alpha protein. The expression of ER beta in this cell line may have important ramifications for the regulation of estrogen-dependent genes involved in noradrenergic function. To test the possibility that estrogen modulates noradrenergic function, we investigated the effects of estrogen on two enzymes involved in norepinephrine synthesis, dopamine beta hydroxylase (DBH) and tyrosine hydroxylase (TH). In order to assess the effects of estrogen on DBH activity, cells were treated with estrogen (10 pM and 100 nM) for 24 hrs, then lysed and freeze-thawed to release DBH. DBH was semi-purified by adsorption onto concavalin A Sepharose 4B beads. Enzyme activity was assayed in the presence of a saturating dopamine concentration (3 mM). Norepinephrine was extracted with alumina and detected by HPLC. Estrogen increased the activity of DBH in a concentration-dependent manner. Western blot analysis showed that DBH protein expression increased with estrogen treatment as well. Protein expression of tyrosine hydroxylase (TH) did not change with estrogen treatment. These findings indicate that estrogen may regulate mood by affecting central noradrenergic mechanisms. Supported by MH-65093

1288 USE OF A PLANAR MICROELECTRODE ARRAY SYSTEM TO MEASURE TOXICANT INDUCED CHANGES IN THE ELECTRICAL ACTIVITY OF ACUTE BRAIN SLICES FROM BLUEGILL SUNFISH (*LEPOMIS MACROCHIRUS*).

J. Rossi III, S. M. McInturf, F. J. McDougle, M. Y. Bekkedal and G. D. Ritchie. *Neurobehavioral Effects Laboratory, Naval Health Research Center Detachment-Toxicology, Wright-Patterson AFB, OH.* Sponsor: R. Carpenter.

Existing electro-chemical water monitoring systems recognize only specific threats or categories of threats. The present study used a commercially available, planar microelectrode array system (Panasonic MED64) to develop a flexible system for

water supply monitoring. It was first necessary to determine that fish brain would provide viable slices for use with the MED64 System, previously demonstrated to work only with mammalian brain slices. Initially, thirty two 500 uM slices obtained from the optic tectum of bluegill sunfish were attached to 64-electrode microelectrode arrays and bathed in continuous perfusion of fish artificial cerebrospinal fluid (F-CSF). The brain slices were attached to the array so that it maximally covered the areas believed to be the most active for sensory input integration. Electrode sites were successively stimulated with 50 uA biphasic pulses with a pulse duration of 100 uS. The presence of evoked response activity was then assessed at each of the 63 remaining electrode sites. This process was repeated until the entire array was mapped. Test electrode pairs were then chosen for each brain slice. The gain in evoked response amplitude averaged 5-10x for all of the slices. The biological nature of the responses was tested by treatment with 20 uMol of the sodium channel blocker tetrodotoxin (TTX). TTX reversibly eliminateed the evoked responses. Subsequently, slices were treated with ethanol (20-80 uMol), and dose dependent reductions in evoked response amplitude were observed. Slices treated with the GABA-A chloride channel suppressor (TMPP) (10-30 uMol) exhibited dose related increases in the amplitude of the evoked responses, as did slices treated with the GABA-B agonist baclofen (10-20 uMol). Phaclofen, a GABA-B antagonist, was found to reduce the amplitude of the responses.

1289 USE OF A PLANAR MICROELECTRODE ARRAY SYSTEM TO MEASURE EFFECTS OF CHEMICAL CHALLENGES ON AN ACUTE TISSUE SLICE PREPARATION FROM MOUSE CEREBELLUM.

G. D. Ritchie, J. Rossi III, F. J. McDougle, S. M. McInturf and M. Y. Bekkedal. *Neurobehavioral Effects Laboratory, Naval Health Research Center Detachment-Toxicology, Wright-Patterson AFB, OH.* Sponsor: R. Carpenter.

To date, several publications have reported use of acute tissue slice preparations mounted on 8-64 electrode microarrays to evaluate neurotoxicant or pharmaceutical challenges. These experiments have utilized hippocampal, cortical or suprachiasmatic nucleus (SCN) preparations dissected from rat brain. To date, no published research has used either acute tissue slice preparations from mouse brain, or cerebellar preparations from any species. Because the cerebellum subserves important fine motor control and associative learning functions, development of a cerebellar preparation is of obvious importance to military toxicology. The present experiment used cerebellar slices from young adult mice and typically included the interpositus and other deep cerebellar nuclei. Slices were mounted for up to 6 hr on MED64 (Panasonic) microarrays perfused with mouse ACSF. Slices were challenged with one of four compounds active at the GABA-A receptor [TMPP (5-15 uMol), PTZ (20-80 uMol), picrotoxin (25 uMol), or ethanol (50 uMol)] or with either a GABA-B agonist [baclofen (15 uMol)] or antagonist [phaclofen (20 uMol)]. Each chemical challenge provided a "response profile" to electrical stimulation, as compared to baseline, that was unique to that chemical. It is suggested such "profiles" can be used to identify chemical challenges with unknown compounds whose mechanism of neural action is identical or similar.

1290 POLYCHLORINATED BIPHENYLS INHIBIT DOPAMINE UPTAKE IN HUMAN NEUROBLASTOMA CELLS STABLY EXPRESSING THE HUMAN DOPAMINE TRANSPORTER.

J. R. Richardson and G. W. Miller. *Center for Neurodegenerative Disease and Department of Occupational and Environmental Health, Rollins School of Public Health, Emory University, Atlanta, GA.*

Polychlorinated biphenyls (PCB) are persistent environmental contaminants that have been reported to produce neurological dysfunction in both humans and laboratory animals. Studies by Seegal and co-workers have shown that sub-chronic or chronic exposure of non-human primates and rodents to the PCB mixtures Aroclor 1016 or 1254 results in long-term depletion of dopamine levels in the striatum and substantia nigra. Recently, Mariussen and Fonnum reported that the PCB mixtures Aroclor 1242 and 1254 inhibited dopamine uptake into whole rat brain synaptosomes. To determine if inhibition of dopamine uptake observed in rat brain synaptosomes was due to direct inhibition of the dopamine transporter (DAT), we generated a human neuroblastoma line stably expressing the human dopamine transporter. Human DAT cDNA was inserted into the plasmid pcDNA 3.1 and transfected into SK-N-MC neuroblastoma cells using Lipofectamine. Cells were cultured in growth medium containing G418, resistant colonies screened by western immunoblotting and dopamine uptake, and a stable cell line expressing high levels of DAT was used for further study. Cells were plated in 24-well trays at a density of 100, 000 cells per well and assays conducted two days later. For determination of IC_{50} values, cells were incubated with various concentrations of Aroclor 1016 or 1254 for 15 min. Dopamine uptake was initiated and allowed to proceed for 10 min. Non-specific uptake was determined in the presence of 10 μM GBR12935, a specific inhibitor of DAT, and IC_{50} values were estimated by nonlinear regression. Aroclor 1016 and 1254 inhibited dopamine uptake with IC_{50} values of 7.9 and 8.6 μM, respectively. These concentrations are in the same range as those shown to elicit dopamine release and deplete dopamine levels in striatal slices. Therefore, these results suggest that a possible mechanism for depletion of dopamine levels by PCBs may be inhibition of DAT mediated reuptake of released dopamine.

1291 THE INDUCTION OF MITOCHONDRIAL SP60 IN RAT HIPPOCAMPAL ASTROCYTES BY DIETHYLDITHIOCARBAMATE.

A. Almiroudis and L. D. Trombetta. *St John's University, Jamaica, NY.*

Diethyldithiocarbamate (DDC) and its parent compound Disulfiram have been shown to cause alterations in mitochondria. These include alterations in their outer membrane and cristae, the formation of myelin whorls and the accumulation of electron dense material and condensation of material within the mitochondrial matrix. Mitochondrial SP60 and SP10 belong to a family of highly conserved proteins, termed chaperonins, that occur in prokaryotes and in mitochondria and chloroplasts of eukaryotic cells. They function in the biogenesis of mitochondria and their constitutive role is the assembly of newly imported, matrix localized proteins. They are also involved in the assembly of proteins of that are encoded by the mitochondrial genome and translated on the mitochondrial ribosomes. In conditions of stress, SP60 and SP10 act as molecular chaperones by binding to hydrophobic protein surfaces that are transiently exposed during various denaturing processes. This binding may inhibit incorrect interactions that may lead to protein aggregation, misfolding, or the production of any non-functional structures. The present report investigated the effects of DDC on the induction of SP60 and SP10 in rat hippocampal astrocytes. Cultures of rat hippocampal astrocytes were treated with 150 μM DDC for one hour and samples were collected at 0, 4, and 6hrs post-DDC treatment. Immunoblot analysis revealed significant increase in SP60 at 0 and 6 hrs. post-DDC treatment. Preliminary investigation of SP10 induction did not show any changes.

1292 INTERLEUKIN-1β ENHANCES NMDA RECEPTOR-MEDIATED $[CA^{2+}]_I$ INCREASE IN PRIMARY RAT HIPPOCAMPAL NEURONS: ROLE IN NEUROTOXICITY.

B. Viviani[1], S. Bartesaghi[1], A. Vezzani[2], M. Binaglia[1], C. L. Galli[1] and M. Marinovich[1]. *[1]Department of Pharmacological Sciences, University of Milan, Milan, Italy and [2]Department of Neuroscience, Mario Negri Inst for Pharmacology Res, Milan, Italy.*

Interleukin (IL)-1β and the over-activation of NMDA receptor have often been implicated in several cases of neurotoxicity and in the pathogenesis of various CNS diseases. In this study, we investigated the effect of IL-1 βon NMDA-induced intracellular Ca^{2+} ($[Ca^{2+}]_i$) increase in primary rat hippocampal neurons. We found that 0.025-0.1ng/ml IL1b rapidly and dose-dependently enhances 10 μM NMDA-induced increases of $[Cal^{2+}]_i$ by 50% on average thus suggesting a facilitation of NMDA-receptor function. This effect occurred only when neurons were pretreated with IL-1β while it was absent if IL-1β and NMDA were simultaneously applied. The effect of IL-1β was mediated by IL-1 type I receptors since it was abolished by 1μg/ml IL-1 receptor antagonist. Facilitation of NMDA-induced $[Cal^{2+}]_i$ increase by IL-1β was prevented by 500 nM staurosporin and 500nM levendustin A, suggesting an involvement of src tyrosine kinase. These data suggest that IL-1β increases NMDA receptor function. Since over-activation of this receptor increases $[Ca^{2+}]_i$, that can activate downstream signaling pathways leading to cell death, the observed effect may play a role in glutamate-mediated neurodegeneration.

1293 ACCUMULATION OF THE PERSISTENT ENVIRONMENTAL TOXICANTS METHYLMERCURY OR POLYCHLORINATED BIPHENYLS IN *IN VITRO* MODELS OF RAT NEURONAL TISSUE.

C. A. Meacham[1], T. M. Freudenrich[1], W. L. Anderson[1], L. Sui[2], S. Barone Jr[1], M. E. Gilbert[1], W. R. Mundy[1] and T. J. Shafer[1]. *[1]Neurotoxicology Division, NHEERL, ORD, USEPA, Research Triangle Park, NC and [2]National Research Council, Research Triangle Park, NC.*

Polychlorinated biphenyls (PCBs) and methylmercury ($CH3Hg^+$) are known toxicants which persist in the environment and accumulate in tissue. Studies to identify mechanisms of action associated with these toxicants have largely been conducted *in vitro*, and dosimetry comparisons across *in vitro* preparations and *in vivo* dosing conditions have not been well defined. The present study examined the accumulation of

the PCB mixture Aroclor 1254 (A1254) or CH_3Hg^+ in commonly used *in vitro* neuronal models: primary cultures of rat neocortical cells and nerve growth factor differentiated pheochromocytoma (PC12) cells. Cells were exposed to A1254 (0, 3 μM) or to CH_3Hg^+ (0, 10, 100, 1000 nM) in serum-free media for 1 or 24 hr. In addition, cells were exposed to 3 μM A1254 in double the media (2x) volume for 1 hr. After each exposure cells were washed, centrifuged, cell pellet weighed, and total PCB or Hg^+ content measured by dual column gas chromatography with electron capture detection or by cold vapor atomic absorption, respectively. Neocortical cells exposed to A1254 contained 20.6, 24.1, and 55.4 ppm PCB after 1 hr, 24 hr, and 2x volume respectively. PC12 cells exposed to A1254 contained 66.7, 103.8, and 103.9 ppm for 1 hr, 24 hr, and 2x volume. Neocortical cells exposed to 0, 10, 100, 1000 nM CH_3Hg^+ contained 0.023, 0.149, 1.206, and 11.498 ppm and 0.032, 0.136, 1.177, and 7.708 ppm after 1 and 24 hr. PC12 cells exposed to CH_3Hg^+ incorporated 0.128, 0.266, 2.171, 17.473 ppm after 1 hr and 0.086, 0.408, 2.806, 21.855 ppm after 24 hr at 0, 10, 100, and 1000 nM, respectively. These results demonstrate that these neurotoxicants readily accumulate in neuronal tissue *in vitro*. These results will help to facilitate comparison of *in vitro* exposures to these compounds with tissue levels observed following *in vivo* exposure. (This abstract does not necessarily reflect USEPA policy).

1294 PERCHLOROETHYLENE (PERC) INHIBITS FUNCTION OF VOLTAGE-GATED CALCIUM CHANNELS IN PHEOCHROMOCYTOMA CELLS.

T. J. Shafer. *Neurotoxicology Division, NHEERL, ORD, USEPA, Research Triangle Park, NC.*

The industrial solvent perchloroethylene (PERC) is listed as a hazardous air pollutant in the 1990 Ammendments to Clean Air Act and is a known neurotoxicant. However, the mechanisms by which PERC alters nervous system function are poorly understood. In recent years, it has been demonstrated that volatile organic solvents such as toluene and trichloroethylene disrupt the function of ligand and voltage-gated ion channels in neurons, including voltage-gated calcium channels (VGCC). The present experiments examined the hypothesis that PERC also disrupts ion channel function by examining PERC effects on Ca^{2+} currents (I_{Ca}) in nerve growth factor differientiated pheochromocytoma (PC12) cells using whole cell patch clamp techniques. PERC (100-1000 μM) inhibited I_{Ca} rapidly in a concentration-dependent and reversible manner; 1000 μM PERC completely suppressed I_{Ca}. When I_{Ca} was elicited by a step potential from -70 to +10 mV, 500 μM PERC decreased peak I_{Ca} to 56 ± 3% and end I_{Ca} to 39 ± 6% of control amplitude (n=7), suggesting that end current is more sensitive to PERC effects than is peak current. PERC (500 μM) also shifted the voltage of half-maximal activation ($V_{½}$) of I_{Ca} from -1.6 mV to -15.8 mV (n=5). As such, the current-voltage (I/V) relationship in the presence of PERC demonstrated increased I_{Ca} amplitude at hyperpolarized test potentials (-20 and -10 mV), but decreased I_{Ca} amplitude at test potentials greater than 0 mV (n=5). In addition, peak of the I/V relationship was shifted by approximately 10 mV to more hyperpolarized potentials. These results demonstrate that PERC blocks I_{Ca} at low micromolar concentrations, and suggest that effects on VGCC could contribute to the neurotoxicity of this solvent. (This is an abstract of a proposed presenatation and does not necessarily reflect EPA policy)

1295 INHIBITORY EFFECTS OF PERCHLOROETHYLENE ON HUMAN NEURONAL NICOTINIC ACETYLCHOLINE RECEPTORS.

A. S. Bale, P. J. Bushnell and T. J. Shafer. *Neurotoxicology Division, NHEERL, ORD, USEPA, Research Triangle Park, NC.*

Perchloroethylene (PERC) is a volatile organic solvent with a variety of industrial uses. PERC exposure has been shown to cause adverse neurological effects including deficits in vision and memory in exposed individuals. Despite knowledge of these effects, the mechanisms by which PERC may modulate central nervous system function are relatively unknown. Studies with other volatile organic compounds (VOCs) such as alkylbenzenes and 1, 1, 1-trichloroethane have correlated neurobehavioral changes to modifications in brain receptor function. Specifically, the nicotinic acetylcholine receptor (nAChR), which is can play a role in cognition and memory, has recently been shown to be sensitive to VOCs, including toluene, as well as volatile anesthetic gases. Therefore, we examined whether nAChRs were sensitive to PERC. Using two electrode voltage clamp techniques, acetylcholine-induced currents were measured in recombinant human α4β2 and α7 nAChRs expressed in Xenopus oocytes. PERC (100-500 μM) inhibited nAChR function in a concentration-dependent and reversible manner. PERC (500 μM) decreased α4β2-mediated acetylcholine responses by 50 percent (n=3) and α7 responses by 60 percent (n=5) compared to control current amplitudes. Toluene (1 mM), an alkylbenzene solvent, was used as a positive control and also inhibited receptor responses (α4β2, 24.2 percent, n=4; α7, 18.0 percent, n=2) as has been previously shown in rat nAChRs. These results show that nAChRs represent a potential target for solvents such as PERC in the central nervous system and suggest that nAChR inhibition could contribute to neurotoxic effects associated with this compound. Furthermore, the data implies that human nAChRs are more sensitive to inhibition by PERC than toluene. (This is an abstract of a proposed presentation and does not necessarily reflect USEPA policy.)

1296 BROMINATED FLAME RETARDANTS; OXIDATIVE STRESS AND CELL DEATH USING CEREBELLAR GRANULE CELLS AND GRANULOCYTES.

F. Fonnum[1], T. Reistad[1] and E. Mariussen[2]. *[1]Norwegian Defence Research Establishment, N 2027 Kjeller, Norway and [2]Norwegian Institute for Air Research, N 2027-Kjeller, Norway.*

Studies have shown that brominated flame retardants have an effect on behavior in laboratory animals. We have therefore studied the effect of these compounds on neurons in culture. We have found that pentabromodiphenylether (PBDE), tetrabromobisphenol-A (TBPPA) and hexabromocyclododecane (HBCD)in low micromolar concentration induce cell death to cerebellar granule cells in culture. The effect on cell death were all reduced by the NMDA receptor blocker MK-801 and by 50μ vitamin E.This indicated that calcium influx through the NMDA receptor and free radical formation could play a role in cell death. TBBPA was the only compound that lead to free radical production using the fluorescent probe DCF-DA.The results on free radical formation was confirmed with human granulocytes.The free radical formation in both cases was inhibited by U0126, a MAPK inhibitor. In granulocytes we have further shown by Western blotting that TBBPA will induce phosphorylation of ERK.

1297 ORTHO-SUBSTITUTED 2, 2', 3, 3', 4, 4', 5-HEPTACHLOROBIPHENYL (PCB170) ALTERS NEUROPLASTICITY IN ACUTE HIPPOCAMPAL SLICE.

K. Kim[1], T. E. Albertson[2] and I. N. Pessah[1]. *[1]Molecular Biosciences: VM, University.C. Davis, Davis, CA and [2]Pulmonary and Critical Care Medicine, University.C. Davis, Sacramento, CA.*

There is mounting evidence that exposure to non-coplanar PCB's is associated with significant changes in locomotor activity, spatial learning and memory in rodents. In the current study, PCB 170-induced changes in synaptic transmission of rat hippocampal slices were monitored by electrophysiological measurements. Field excitatory postsynaptic potential (fEPSP) was evoked by single pulse stimulation of Schaffer Collateral/commissural fibers at striatum radiatum of the CA1 region in the hippocampus. Following exposure to 100 nM PCB 170, time-dependent changes in the slope and amplitude of fEPSP were seen, with pases of enhancement and depression. To investigate the contribution of inhibitory neurons in the actions of PCB 170, hippocampal slices were pre-treated with the GABAa receptor antagonist, picrotoxin (PTX, 100 uM). Pre-treatment with PTX resulted in negligible change in EPSP slope elicited by single pulse stimuli. Importantly PCB170 (10 nM) introduced in the presence of GABAa blockade enhanced EPSP slope (200-300%) revealing a significant facilitation of synaptic transmission. Non-coplanar PCBs therefore influence both excitatory and inhibitory pathways in CA1 that can mask their potent effects. These results demonstrate that blockade of inhibitory inputs with PTX can unmask the potent actions of ortho-substituted PCB 170 toward facilitating excitatory transmission. Moreover the measured effect of PCB 170 on neuroplasticity is a summation of actions on inhibitory and excitatory pathways in hippocampus, possibly stemming from a common mechanism.

1298 ORGANOPHOSPHORUS COMPOUNDS SELECTIVELY INHIBIT ESTERASE ACTIVITY AND GROWTH FACTOR-INDUCED CELL GROWTH IN AN *IN VITRO* BLOOD BRAIN BARRIER MODEL.

D. K. Parran[1,2], W. Li[1], L. Correll[1], B. Jortner[1,2] and M. Ehrich[1,2]. *[1]Department of Biomedical Sciences and Pathobiology, Virginia Tech, Blacksburg, VA and [2]Laboratories for Neurotoxicity Studies, Virginia Tech, Blacksburg, VA.*

The blood brain barrier (BBB) is a structural and functional interface between the circulatory system and the brain. The BBB protects the free passage of substances into the brain as well as maintains homeostasis of the central nervous system. Organophosphorous (OP) compounds such as chlorpyrifos (CPF) are lipophillic and are able to pass through the BBB and may disrupt BBB integrity and function. To determine possible mechanisms of action for CPF toxicity, we used an *in vitro* BBB model where bovine microvascular endothelial cells (BMEC) and neonatal rat astrocytes are co-cultured. We examined the hypothesis that CPF and CPF-oxon have potential to disrupt the BBB by selectively altering esterase activity as well as affecting growth factor signaling. The co-culturing of BMEC and astrocytes re-

sulted in tight junction formation, which was evident by electron microscopy and western blot analysis of ZO-1, a marker of tight junctions. Vascular endothelial cell proliferation and migration are critical events for angiogenesis and are regulated by vascular endothelial growth factor (VEGF) and fibroblast growth factor (FGF). Following 24hr exposure to VEGF, FGF or VEGF/FGF, cell number increased by 113%, 121% and 141% respectively in serum-free conditions. Concurrent exposure of various concentrations of CPF (0.01, 0.1 and 1 mM) diminished VEGF-induced (15%, 52% and 50%), FGF-induced (4%, 56% and 56%) and VEGF/FGF-induced (18%, 59% and 63%) proliferation. It has been suggested that carboxylesterase (CaE) was important in detoxication of OP compounds and inhibition of this enzyme may potentiate OP neurotoxicity. At final concentrations of 0.1, 1 and 10 mM, CPF inhibited CaE activity (43%, 50%, and 100%). At all tested concentrations, CPF-oxon totally inhibited CaE activity. These data suggest the possibility that CPF and CPF-oxon may alter growth factor signaling as well as the inhibition of esterases leading to a disruption on BBB structure and function.

1299 *IN SITU* EFFECTS OF ORGANOPHOSPHATE (OP) COMPOUND EXPOSURE ON ATP PRODUCTION IN HUMAN NEUROBLASTOMA CELLS.

L. Correll[1], C. Massicotte[2], C. van der Schyf[3] and M. Ehrich[1]. *[1]Virginia-Maryland Regional College of Veterinary Medicine, Virginia Tech, Blacksburg, VA, [2]School of Veterinary Medicine, University of Pennsylvania, Philadelphia, PA and [3]School of Pharmacy, Texas Tech University, Amarillo, TX.*

In situ study of cell energetics has benefits in allowing for evaluation under conditions that require fewer cells and cause less organelle damage than studies using isolated mitochondria. We examined ATP production in digitonin permeabilized SH-SY5Y human neuroblastoma cells depleted of residual ATP by a 30 min, 37 degree preincubation of harvested cells in phosphate buffered saline (PBS). Reactions mixtures included 40 mcg/ml digitonin and 1 mM ADP with and without 10 mM each of glutamate and malate (mitochondrial respiratory chain complex I substrates). A complex I inhibitor (rotenone 20 mcg/ml) and the OP compound phenyl saligenin phosphate (PSP), 0.01 mM, were included in some incubates as well. After incubations of 5 to 25 min, ATP was extracted from neutralized trichloroacetic acid precipitates and quantified, based on mg protein, using a luciferase enzyme assay. Results demonstrated increased production of ATP with time and addition of complex I substrates. The inhibitory effects of rotenone were exaggerated 50% - 70% by the presence of 0.01 mM PSP at time points of 15 min or more. These results suggest that PSP may have an effect on cellular energetics of neuroblastoma cells when evaluations are done in situ.

1300 cAMP AND RETINOIC ACID INDUCED DIFFERENTIATION OF HUMAN SVG CELLS: MORPHOLOGIC AND TRANSCRIPTIONAL EFFECTS.

L. D. Burgoon[1,3,4], K. Y. Kwan[2,4], J. E. Trosko[3,4,5] and T. Zacharewski[2,3,4]. *[1]Pharmacology & Toxicology, Michigan State University, East Lansing, MI, [2]Biochemistry & Molecular Biology, Michigan State University, East Lansing, MI, [3]Institute for Environmental Toxicology, Michigan State University, East Lansing, MI, [4]National Food Safety & Toxicology Center, Michigan State University, East Lansing, MI and [5]Pediatrics & Human Development, Michigan State University, East Lansing, MI.*

Previous work has shown that treatment of human SVG cells with 5μM forskolin (F) and 200μM 3-isobutyl-1-methylxanthine (I) increases cAMP levels resulting in differentiation and dramatic morphologic changes. Gene expression profiles were analyzed over time (2, 4, 6, 12, 24hrs) during F/I induced differentiation, using a microarray spotted with approximately 3, 000 cDNAs. Data was normalized and clustered before and after filtering by General Linear Mixed Model with post hoc t-test (GLMM-T) or Shannon Entropy. Genes involved in the regulation of morphology, especially regulation of actin dynamics, were identified as having been affected by F/I treatment over time. GLMM-T filtering of the data identified a cluster of genes downregulated in vehicle treated cells at 6, 12, and 24hrs following exposure that may represent a vehicle or a response to the transfer of cells to serum free media. cAMP induction of retinoid X receptor α (RXRα) suggested that retinoic acid treatment may interact with cAMP-induced differentiation. Cotreatment of SVG cells with F/I and all-trans retinoic acid (ATRA; 0.05, 0.5, 5μM in ethanol) resulted in a significant increase in the percentage of differentiated cells over time ($p < 0.001$) compared to F/I and F/I + ethanol groups, but no dose-dependent response to ATRA was observed. These results indicate that ATRA may enhance F/I related gene expression effects regulating actin dynamics. This work is supported by EPA Grant ES 04911-12 and NIH grants ES 011777 and T32 ES07255.

1301 MODULATION OF THIOL STATUS BY MANEB IN NEURONAL CELLS.

D. W. Lee, D. A. Cory-Slechta and L. A. Opanashuk. *Department of Environmental Medicine, University of Rochester School of Medicine and Dentistry, Rochester, NY.*

Recent attention has focused on exposure to environmental chemicals as risk factors for Parkinson's disease (PD). The dithiocarbamates are a class of synthetic organic chemicals that have various agricultural, clinical, and industrial applications. They can act as chelating agents to alter the redox status of cells by generating a state of oxidative stress within exposed cells. Maneb (MB) is a manganese-complexed ethylene-bis-dithiocarbamate fungicide that is used to control early and late blights on potatoes and tomatoes. Case studies of agricultural workers exposed to MB have shown the development of an extrapyramidal syndrome reminiscent of PD. The goal of this study was to determine whether MB alters thiol status in neuronal cells. PC12 cells and primary ventral mesencephalic cultures treated with MB show elevated intracellular glutathione (GSH) and heme oxygenase-1 (HO-1) levels, which may serve as a first line of defense against oxidative stress. No changes were observed in glutatione peroxidase enzymatic activity and oxidized GSSG, suggesting that MB could directly act on γ-glutamyl-cysteine synthetase (γGCS) to increase intracellular GSH levels. To examine this possibility, PC12 cells were pretreated with 50μM BSO (an inhibitor of γGCS) for 6h, which induced a 60-80% depletion in intracellular GSH. Cells were subsequently treated with varying concentrations of MB (50-2500ng/mL) and harvested at 0, 6, 12, 24, or 48h after MB treatments to measure GSH recovery. While lower MB concentrations (<500ng/mL) resulted in a rapid recovery of GSH levels, higher concentrations (>500ng/mL) delayed recovery. The lack of GSH recovery was also accompanied by increased cell death, as indicated by decreased membrane integrity and a decline in metabolic function. These studies confirm that MB regulates thiol and ultimately redox status within neuronal or PC12 cells, thus, underlying the importance of GSH in the detoxification of reactive oxygen species that can be generated from pathways that lead to the progression of neurodegenerative diseases such as PD. (T32 ES07026)

1302 DOPAMINERGIC TOXICITY OF THE HERBICIDE ATRAZINE IN *EX VIVO* STRIATAL SLICES.

N. M. Filipov, M. Stewart, R. L. Carr and S. S. Sistrunk. *CEHS, Basic Sciences, Mississippi State University, Miss. State, MS.*

A link between Parkinson's Disease and pesticide exposure has been suggested and recently is was shown that the herbicide atrazine (ATR) modulates catecholamine metabolism in PC12 cells. Because ATR might affect basal ganglia function and, at present, there are no data addressing that, the objective of this study was to determine if ATR is capable of modulating dopamine (DA) metabolism in *ex vivo* striatal tissue slices. Striata from adult male Sprague-Dawley rats were incubated with up to 500 μM ATR in a metabolic shaker bath at 37 °C and an atmosphere of 95% O_2 and 5% CO_2 for 4 h. At the end of incubation, samples were collected for both tissue and media levels of DA and its metabolites (3, 4-dihydroxyphenylacetic acid, DOPAC and homovanillic acid, HVA), which were determined by high-performance liquid chromatography with electrochemical detection (HPLC-ECD). Lactate dehydrogenase (LDH) release into the medium was used as an index of non-specific cytotoxicity. To gain a mechanistic insight how ATR affects DA metabolism, several pharmacological manipulations were performed. Striata exposed to ATR, at concentrations of 100 μM and greater had a dose-dependent decrease of tissue levels of DA. At doses of ATR 50 μM and greater, the DOPAC+HVA/DA ratio was dose-dependently increased. Tyrosine hydroxylase (TH, the rate-limiting enzyme in DA synthesis) activity was not affected by ATR treatment. However, high potassium induced DA release into the medium was decreased, whereas the increase in media DA observed in the presence of the DA uptake inhibitor nomifensine was dose-dependently increased even further by ATR. All of these effects of ATR were observed at levels that were not toxic to the tissue. Taken together, results from this study suggest that ATR decreases tissue DA levels not by affecting TH activity, but by increasing DA turnover. The increased DA turnover may be due to ATR effects on (*i*) vesicular storage of DA, (*ii*) cellular uptake of DA, (*iii*) monoamine oxidase activity, or (*iv*) any combination of these mechanisms.

1303 THE DITHIOCARBAMATE PROPINEB DEPOLYMERIZES ACTIN AND INCREASES ACETYLCHOLINE RELEASE IN DIFFERENTIATED PC12 CELLS.

M. Marinovich, M. Binaglia, B. Viviani, S. Bartesaghi and C. L. Galli. *Department of Pharmacological Sciences, University of Milan, Milan, Italy.*

The dithiocarbamate Propineb is widely used in Europe as fungicide, and due to its large spectrum of action on fungi an expansion of the market is expected. Neurological complications as well as movement disorders characterized by plastic

rigidity, muscle twitch and paralysis are the prevailing symptoms in chronically exposed animals and humans. Recently we showed that propineb interferes with cholinergic transmission *in vivo* and this study was designed to investigate *in vitro* the molecular mechanisms involved. Propineb 0.001-100 nM released acetylcholine (ACh) from rat pheochromocytoma cells (PC12) differentiated with NGF. Ach release dose-dependently increased up to propineb 1 nM, to decrease for the highest concentrations (10-100 nM). *In vivo*, propineb induced-potentiation of cholinergic transmission seemed to be partly dependent on the activation of ganglionic nicotinic receptor. However, mecamilamine 1 or 50 μM, an antagonist of neuronal nicotinic receptor, did not reduce ACh release induced by propineb in PC12 cells suggesting the involvement of different mechanisms. The increase in ACh release was not associated with alterations of intracellular Ca^{2+} homeostasis and was not prevented in Ca^{2+} free conditions. Nevertheless, treatment of PC12 cells with propineb 1 nM induced a significant actin depolimerization within 30 sec from the exposure. Actin, as ACh release, was not affected by propineb 100 nM. These data suggest the involvement of cytoskeletal structure in the modulation of propineb effect independently by intracellular calcium.

1304 CHLORPYRIFOS INHIBITS AXON OUTGROWTH IN PRIMARY CULTURES OF PERIPHERAL NEURONS THROUGH INHIBITION OF THE MORPHOGENIC ACTIVITY OF ACHE.

A. S. Howard[1], R. Bucelli[2], D. A. Jett[1] and P. J. Lein[1]. [1]*Environmental Health Sciences, Johns Hopkins University Bloomberg School of Public Health, Baltimore, MD and* [2]*Biology, Canisius College, Buffalo, NY.*

While there is increasing evidence that perinatal exposure to organophosphorus containing pesticides (OPs) is linked to cognitive and behavioral problems, the mechanism(s) by which this can occur is not known. One possibility is that OPs disrupt neuronal morphogenesis through interaction with AChE *via* either inhibition of the catalytic activity of AChE or inhibition of the morphogenic activity of AChE. To investigate these possibilities, we have utilized two *in vitro* model systems: neurons from the superior cervical ganglia (SCG), which are cholinoceptive in culture and neurons from the dorsal root ganglia (DRG), which are neither cholinergic nor cholinoceptive in culture. Neurons were treated with either chlorpyrifos (0.01 – 10μM) or its oxon metabolite (0.01 – 10 nM) for 24 or 72 hr. In both culture systems, we see a decrease in axon outgrowth in neurons treated with concentrations of the OP chlorpyrifos that do not decrease the catalytic activity of AChE. Thus the effect does not appear to be dependent on acetylcholine signaling. Furthermore, the decrease in axon outgrowth can be seen following either short-term (24 hr) or long-term (72 hr) exposure in SCG cultures. In an effort to determine if chlorpyrifos mediates its effects through the morphogenic domain of AChE, we used neurons from the AChE knockout mouse. Specifically we chose dorsal root ganglia (DRG) neurons because these neurons are known to express AChE during the period of axon outgrowth *in vivo*. We have found that in culture, DRG from AChE -/- animals do not extend axons as rapidly as DRG from AChE +/+ animals and that the DRG from AChE +/+ animals put out shorter axons in the presence of chlorpyrifos as compared to vehicle control. In contrast, the DRG from AChE -/- animals appear to be unaffected by treatment with the pesticide. These data support the hypothesis that OPs disrupt axon outgrowth through inhibition of the morphogenic activity of AChE.

1304a 1, 3-DINITROBENZENE INTERACTION WITH nNOS, PEROXYNITRITE FORMATION AND APPARENT INCREASE IN CEREBELLAR TYROSINE NITRATION.

J. J. Tobias and T. Miller. *Graduate Center for Toxicology, University of Kentucky, Lexington, KY.*

1, 3-dinitrobenzene (DNB) is a cerebellar neurotoxicant. Co-localized in the cerebellum, the enzyme neuronal nitric oxide synthase (nNOS) produces nitric oxide ($NO^{\bullet}$) and L-citrulline. Recently, we initiated a series of studies aimed at determining the mechanism(s) of interaction of 1, 3-DNB with nNOS. Previous *in vitro* studies in our laboratory have shown that the DNB's redox-cycle in the presence of nNOS, resulting in an accelerated rate of NADPH oxidation. The increased NADPH oxidation results in superoxide radical ($O_2^{\bullet-}$) formation. The $O_2^{\bullet-}$ traps the enzymatically-produced $NO^{\bullet}$, thus resulting in increased nNOS activity due to the release of $NO^{\bullet}$-mediated auto-inhibition of nNOS. Most importantly, the 1, 3-DNB-mediated generation of $O_2^{\bullet-}$ by nNOS leads to peroxynitrite ($ONOO^-$) production, converting nNOS from a NOS to an enzyme that produces the powerful oxidant $ONOO^-$. Furthermore, $ONOO^-$ production is blocked by inclusion of either SOD or nitroarginine, demonstrating the requirement for both $O_2^{\bullet-}$ and $NO^{\bullet}$, respectively. $ONOO^-$ is known to nitrate tyrosine residues. In our studies, an increase in tyrosine nitration relative to the controls supports the hypothesis that a mechanism involving the interaction of 1, 3-DNB with nNOS, resulting in the generation of $ONOO^-$, may occur *in vivo* and play a role in 1, 3-DNB-mediated cerebellar neurotoxicity. (Supported by the Research Challenge Trust Fund of the University of Kentucky)

1304b EFFECTS OF ORGANOPHOSPHORUS TOXICANTS ON G-PROTEIN COUPLED RECEPTOR KINASE 2-MEDIATED PHOSPHORYLATION OF M2 RECEPTORS.

C. N. Pope[1] and L. Zou[2]. [1]*Department of Physiological Sciences, Oklahoma State University, Stillwater, OK and* [2]*Department of Biochemistry and Molecular biology, Shenyang Medical College, Shenyang, Liaoning, China.*

We studied the possible effects of chlorpyrifos, parathion and their oxons on the phosphorylation of muscarinic M2 receptors by G-protein coupled receptor kinase 2 (GRK2). Reconstituted purified recombinant human M2 receptor was incubated with varying concentrations of paraoxon, chlorpyrifos oxon or the parent insecticides along with GRK2, G protein beta-gamma subunits, and [32P]ATP in the presence of the agonist carbachol (1 mM). Paired tubes contained the muscarinic antagonist atropine (10 μM) or the GRK inhibitor heparin (10 μM). Proteins were separated by electrophoresis, gels were dried and autoradiograms developed. Bands containing M2 receptor were excised and counted by liquid scintillation. Both atropine and heparin completely blocked agonist induced M2 receptor phosphorylation. Chlorpyrifos oxon inhibited phosphorylation of muscarinic M2 receptors by GRK2 with an IC50 of approximately 70 μM. Chlorpyrifos also inhibited M2 receptor phosphorylation, but was less potent and efficacious than chlorpyrifos oxon. Interestingly, paraoxon and parathion had little effect on receptor phosphorylation under the same conditions. To evaluate further modulation of M2 receptor phosphorylation by chlorpyrifos oxon, we purified M2 receptors from porcine brain by using ABT-agarose affinity chromatography. Purified porcine brain M2 receptor was detected as one primary band with a molecular weight of 68, 000 by Coomassie Blue staining. CPO had relatively similar concentration-dependent effects on the GRK2-mediated phosphorylation of porcine M2 receptors. Chlorpyrifos oxon and chlorpyrifos may therefore alter GRK2-mediated regulatory pathways for M2 receptors, either by direct interaction with the M2 receptor or GRK2. These differential actions could contribute to selective differences in toxicity following exposure to chlorpyrifos compared to other OP toxicants.

1305 INCREASED UBIQUINATION OF THE KINASE TAK1 FOLLOWING As (III) EXPOSURE IN HEK293 CELLS.

D. S. Kirkpatrick[1,2], R. R. Vaillancourt[1,2], Z. E. Derbyshire[1,2] and A. J. Gandolfi[1,2]. [1]*Superfund Basic Research Program, University of Arizona, Tucson, AZ and* [2]*Center for Toxicology, University of Arizona, Tucson, AZ.*

Previous studies have shown that low-level As (III) treatment (0.1 μM- 10 μM) increases the level of ubiquitin (Ub)-protein conjugates in HEK293 cells. In the current study, the effect of As (III), a known activator of NF-kB and AP-1 complexes, on ubiquitination of the kinase TAK1 was examined. TAK1 is a member of the mitogen-activated kinase kinase kinase (MAPKKK) family that stimulates downstream activation of JNK and p38 MAP kinase. While ubiquitination of proteins often acts as a signal for proteolytic degradation, ubiquitination of TAK1 has been shown to activate this kinase, leading to phosphorylation of the downstream substrates MKK6 and IKK. The kinase activity of TAK1 can be activated by IL-1, TGF-b, ceramide, and lipopolysaccharide. The objective of this study is to determine if As (III) may be an additional activator of TAK1. For these studies, HEK293 cells were transfected with epitope-tagged HA-TAK1 or pcDNA3 vector as a control. Cells were treated with As (III) for 4 hr with concentrations ranging from 0.1 μM to 50 μM. Immunoprecipitations were performed with antibodies to the HA-epitope and proteins separated by SDS-PAGE. Western blots were performed to probe for the presence of high-molecular weight Ub-protein conjugates with antibodies to Ub, TAK1, and the HA-epitope. Results from these experiments show that high concentrations of As (III), 25-50 μM, initiated a robust increase in the ubiquitination of TAK1. Lower concentrations of As (III), 1-10 μM, cause subtle increases in the ubiquitination of TAK1. High-molecular weight Ub-conjugates were not seen in immunoprecipitations from pcDNA3-transfected cells. Ongoing studies seek to understand whether As (III) is capable of activating the kinase activity of TAK1. The current results demonstrate that As (III) has a specific effect on the Ub-modification status of TAK1 that may help explain some of the stress signaling associated with As (III) exposure. (NIH ES 04940, NIH ES 12007)

1306 ARSENIC IMPACTS NRF2 TRANSCRIPTION FACTOR AND RELATED GENE EXPRESSION IN CULTURED KERATINOCYTE CELLS.

J. Pi[1], Q. Wei[1], M. P. Waalkes[1] and Y. Kumagai[2]. [1]*Inorganic Carcinogenesis Section, LCC, NCI at NIEHS, Research Triangle Park, NC and* [2]*Department of Environmental Medicine, Inst. of Community Medicine, University of Tsukuba, Tsukuba, Japan.*

Arsenic is a known human skin carcinogen. Oxidative stress resulting from an imbalance between antioxidants and oxidants during arsenic metabolism has been implicated as a possible etiologic factor in arsenic toxicity and carcinogenesis. Nrf2, a

leucine zipper transcription factor, plays a central role in the regulation of expression of antioxidant enzymes through binding to antioxidant or electrophile response elements in the promoter regions of the target genes. Thus, the effects of acute inorganic arsenite (As^{3+}) exposure on Nrf2 expression and translocation, as well as expression of Nrf2 related genes, were studied in HaCaT cells, an immortalized human keratinocyte cell line. When HaCaT cells were exposed to As^{3+} (0, 2.5 or 10 μM) and fractionated, Nrf2 protein accumulated in the nuclear fraction in a time and dose-dependent fashion which reached a peak at 6 hr. Total cellular Nrf2 protein and cytosolic Nrf2 increased in a similar fashion with As^{3+} exposure but both reached peaks at 12 hr. These results suggest As^{3+} up-regulates Nrf2 expression and induces Nrf2 translocation from the cytosol to the nucleus. Additional study showed the expression of the manganese superoxide dismutase (MnSOD) gene, a possible target of Nrf2, increased after As^{3+} exposure. The levels of MnSOD RNA were correlated with Nrf2 protein levels in nuclear extract, suggesting Nrf2 mediated MnSOD up-regulation by As^{3+}. When HaCaT cells were pre-treated with Tiron, a scavenger of superoxide radical, As^{3+}-induced increases in Nrf2 levels in all cellular fractions were suppressed, indicating As^{3+}-induced superoxide formation is a possible regulator of Nrf2. These results suggest that As^{3+} alters Nrf2 expression and cellular localization, and activates expression of an Nrf2-related gene (MnSOD) in HaCaT cells. These actions appear related to oxygen radical formation.

1307 P53 SIGNALING PATHWAY INVOLVED IN ARSENITE-INDUCED HOS CELL TRANSFORMATION AND ITS PREVENTION BY CAFFEIC ACID PHENETHYL ESTER(CAPE).

J. Wu, J. Eckard, T. G. Rossman, C. Yang and K. Frenkel. *Department of Environmental Medicine, NYU School of Medicine, New York, NY.*

Chronic arsenic exposure is of concern mainly because of its carcinogenicity, but its mechanism is not well understood. Many studies have focused on the expression of the p53 gene in response to acute exposure to arsenite, but very little data concerning the role of p53 in response to chronic arsenic exposure are available. HOS (human osteoblast-like) cell transformation assay was used to mimic chronic exposure to arsenic and explore the mechanism of the p53 signaling pathway using genearrays. After HOS cells were continuously exposed to low concentrations of arsenite (NaAsO2, 0.3 uM) for 8 weeks, transformed HOS (As-HOS) cells were cloned on agar. mRNA expression related to p53 signal pathway in As-HOS cells was significantly down regulated as compared to parental HOS cells. The average fold decreases for p53, mdm2, gadd45, gadd45b, p21, pig8, bax, and TRPM2 were 5.4, 10.5, 32.2, 8.1, 5.9, 7.1, 6.2, and 16.3, respectively. When HOS cells were incubated together with arsenite and CAPE (0.5 uM) for 8 weeks, the cell transformation was suppressed and the expression of above genes increased 3.1, 3.1, 7.7, 3.1, 7.3, 2.5, 1.7 and 12.2 fold, respectively, compared to those expressed by As-HOS cells. Since we also found that CAPE induces As-HOS cell death by apoptosis but causes no damage to parental HOS cells, we conclude that the deficiency in p53 and its target genes, such as gadd45 (growth arrest gene), p21 (cyclin-dependent kinase inhibitor), bax (apoptosis gene), mdm2 (p53 binding protein), Pig8 (p53 interaction gene), and PRPM2 (apoptosis gene), caused by arsenite prevents the HOS cells from entering cell cycle arrest or apoptosis, and leads to cell transformation instead. Since the lower expression of p53 mRNA made As-HOS cells more vulnerable to an anticancer agent CAPE, enhancing the p53 signaling pathway might be helpful in preventing arsenite-induced cell transformation. [Supported in part by NIH grants, ES10344, ES 00260, and CA 37858]

1308 EFFECT OF CADMIUM ON P53 AND MITOGEN-ACTIVATED PROTEIN KINASES IN A MURINE MACROPHAGE CELL LINE: RELATION TO APOPTOSIS.

J. Kim[1], S. Kim[1], V. J. Johnson[2] and R. P. Sharma[1]. *[1]Physiology/Pharmacology, University of Georgia, Athens, GA and [2]Chronic Inflammatory & Immune Disease Team, NIOSH/CDC, Morgantown, WV.*

Cadmium (Cd) is a persistent metal pollutant prevalent in the environment. It is immunotoxic *in vivo* and induces apoptosis in many cultured cells. P53 and mitogen-activated protein kinases (MAPKs) are important regulators of apoptosis; however, the Cd-modulated p53 and MAPKs signaling mechanisms leading to cellular toxicity on macrophages have not been investigated. Present study was designed to determine the impact of cadmium on cell proliferation, cell cycle and apoptosis, and to investigate the possible involvement of p53 and MAPKs signaling pathways in J774A.1 murine macrophages. Cd inhibited cell proliferation *via* cell cycle arrest and induced apoptosis in a dose-dependent manner. Cd at 20 μM markedly increased cells in G2/M and hypodiploid sub-G1 phases of the cell cycle suggesting cycle arrest and cell death. Treatment with Cd at 20 and 50 μM induced phosphorylation of extracellular signal-regulated kinase (ERK), but did not alter p53 mRNA expression or the activation of p38 MAPK and c-Jun N-terminal MAPK. ERK inhibitor, PD98059, suppressed Cd-induced ERK activation. Inhibition of ERK suppressed DNA synthesis and had an additive effect with Cd-inhibited proliferation suggesting that Cd-induced ERK activity is not responsible for the G2/M arrest and subsequent inhibition of cell proliferation. Instead, the increase in ERK activation in cells treated with Cd may reflect a stress response. Pretreatment with PD98059 increased Cd-induced cytotoxicity suggesting that ERK activation may be a survival response in the present cell system. Cycloheximide, an inhibitor of protein synthesis, did not alter Cd-induced cytotoxicity indicating that J774A.1 cell death by Cd is independent of *de novo* protein synthesis including p53. Results suggested that p53 is not involved in Cd-induced cell cycle arrest and apoptosis in J774A.1 cells. ERK activation by Cd is not related to decreased proliferation of macrophages but may play a protective role against Cd-induced cytotoxicity.

1309 MITOGEN AND STRESS SIGNAL TRANSDUCTION PATHWAYS CONTRIBUTE TO SODIUM ARSENITE-INDUCED CYCLOOXYGENASE-2 EXPRESSION IN NORMAL HUMAN EPIDERMAL KERATINOCYTES.

K. J. Trouba, K. M. Geisenhoffer and D. R. Germolec. *NIEHS, Research Triangle Park, NC.*

Arsenic is an atypical human skin carcinogen whose mode of action is not defined. Based on evidence that arsenic influences inflammatory events that are involved in skin carcinogenesis and dermatotoxicity, this study addressed the ability of sodium arsenite to regulate the pro-inflammatory enzyme cyclooxygenase-2 (COX-2) in normal human epidermal keratinocytes (NHEK). It was hypothesized that arsenite regulates COX-2 expression in NHEK; an effect dependent on specific mitogen- and stress-related signal transduction pathways. NHEK were exposed to sodium arsenite in a dose- and time-dependent manner and COX-2 expression/activity, DNA synthesis, and mitogen activated protein kinase (MAPK) phosphorylation quantified. Specific inhibitors of p42/44 and p38 MAPK pathways were used to examine the contribution of mitogen and stress signaling to arsenite-induced COX-2 expression. Non-cytotoxic concentrations of arsenite ($\leq$ 5μM) elevated COX-2 expression in a dose-dependent manner at the gene and protein level, as well as increased prostaglandin E2 (PGE_2) secretion; a functional measure of COX-2 activity. Arsenite also initiated an acute and delayed increase in the phosphorylated/activated form of p42/44 MAPK, but did not stimulate p38 MAPK phosphorylation. Pharmacological inhibition of mitogen-activated protein kinase kinase (MEK) using the inhibitor PD98059 partially attenuated arsenite-induced *COX-2* mRNA expression whereas the p38 MAPK inhibitor SB202190 had minimal effect on the induction of *COX-2*. In contrast, elevation of COX-2 protein by arsenite is reduced by both PD98059 and SB202190 treatment. These results demonstrated that sodium arsenite modulates COX-2 in NHEK at the transcriptional, translational, and functional level; effects dependent in part on MAPK signaling. Because COX-2 plays a critical role in skin cancer, this enzyme and/or the pathways that regulate its expression could be key components involved in arsenic skin carcinogenesis.

1310 ACTIVATION OF ERK SIGNALING PATHWAY AND AP-1 IN UROTSA CELLS BY INORGANIC AND METHYLATED TRIVALENT ARSENICALS.

Z. Drobna, I. Jaspers and M. Styblo. *Department of Pediatrics and The Center for Environmental Medicine and Lung Biology, University of North Carolina, Chapel Hill, NC.*

Arsenic is classified as a human carcinogen. The molecular mechanism by which arsenic induces cancer is not well understood. In humans, inorganic arsenic (iAs) undergoes oxidative methylation, yielding trivalent and pentavalent mono- and dimethylated species. Recent studies have shown that trivalent methylated arsenicals are more cytotoxic, genotoxic and more potent enzyme inhibitors than trivalent iAs, arsenite (iAsIII). Mono- and dimethylated trivalent arsenicals were detected in the urine of individuals chronically exposed to iAs. It is generally accepted that transactivation of the transcription factor AP-1 is required for tumor promotion. In this study, we examined signaling pathways that are responsible for AP-1 activation in SV40-immortalized normal human urothelial (UROtsa) cells exposed to iAsIII, monomethylarsine oxide (MAsIII) or iododimethylarsine (DMAsIII). One-hour exposures to 0.1 to 5.0 μM iAsIII, MAsIII or DMAsIII significantly increased DNA-binding activity of AP-1. The EMSA/supershift and Western blot analyses showed that p-c-Jun and Fra-1 were the major AP-1 constituents. MAsIII was the most potent activator of AP-1 followed by DMAsIII and iAsIII. The activation of AP-1 by trivalent arsenicals was associated with an increased phosphorylation (activation) of ERK1, 2 and ERK5. Pretreatment of UROtsa cells with PD98059 or U0126 (specific inhibitors of the MEK/ERK signaling pathway) completely suppressed phosphorylation of ERK1 and 2, but only partially decreased the phosphorylation of ERK5 in cells exposed to MAsIII or DMAsIII. Similarly, treatment with either inhibitor decreased, but not abolished the phosphorylation of c-Jun in exposed cells. Neither arsenical induced activation of JNK1, 2 or p38 under these exposure conditions. These results indicate that trivalent arsenicals induce AP-1 DNA-binding activity in UROtsa cells through ERK-mediated phosphorylation of c-Jun and that ERK5 may be an essential component of this mechanism.

1311 ARSENIC TRIOXIDE-INDUCED APOPTOSIS REQUIRES JNK ACTIVITY.

K. K. Mann, K. Davison and W. H. Miller. *Lady Davis Institute for Medical Research, McGill University, Montreal, QC, Canada.*

Despite arsenic's reputation as an environmental contaminant, it is currently an effective chemotherapy used to treat acute promyelocytic leukemia (APL). In fact, APL cells are uniquely sensitive to arsenic and undergo apoptosis rapidly after treatment. This apoptosis has been linked to accumulation of free radicals and the resulting state of oxidative stress. Therefore, we've focused our investigations on the stress-activated protein kinase, c-jun N-terminal kinase (JNK) and it's role in arsenic signaling pathways. Using the arsenic-sensitive, APL cell line, NB4, we found that arsenic increased the expression of phospho-JNK1 and to a lesser degree, phospho-JNK2, although the total levels of JNK proteins did not change. JNK activity also increased after arsenic treatment. Previously, we and others have shown that buthionine sulfoximine (BSO), which depletes glutathione and alters the redox state of the cell, enhanced arsenic's cytotoxicity. In correlation with increased apoptosis, phospho-JNK protein expression and JNK activity could be further enhanced by co-treatment with BSO. In arsenic-resistant NB4 subclones established in our laboratory, which have normal levels of JNK1 protein, arsenic alone did not induce JNK activity, although BSO co-treatment restored JNK activation and cell death in response to arsenic. We used chemical and genetic approaches to determine whether JNK activation was required for apoptosis. Dicumarol, a pan-JNK inhibitor, blocked arsenic-induced apoptosis significantly in APL cells. To confirm and extend this result, we utilized SEK1-/- fibroblasts, which are deficient in the upstream regulator of JNK, SEK1. Although SEK1-/- cells express normal levels of JNK protein, arsenic-induced JNK activity and apoptosis are impaired significantly in SEK1-/- cells as compared to wild-type counterparts. In contrast, doxorubicin induced more apoptosis in SEK-/- cells than in wild-type controls. Therefore, we conclude that JNK activation is required for arsenic-induced cytotoxicity of APL cells and may be necessary for effects of environmental arsenic exposure as well.

1312 INHIBITION OF NUCLEAR FACTOR κB (NF-κB) PROMOTES APOPTOSIS OF KIDNEY EPITHELIAL CELLS VIA MITOCHONDRIAL CYTOCHROME C RELEASE AND CASPASE 3 ACTIVATION.

F. J. Dieguez-Acuna, J. S. Woods, M. E. Ellis, P. L. Simmonds and J. V. Kushleika. *Environmental Health, University of Washington, Seattle, WA.*

NF-κB is a pleiotropic transcriptional activator that promotes survival and prevents apoptosis in numerous cell types. We previously reported (TAAP 173:176, 2001;EHP 110S5, 2002) that mercuric ion (Hg^{2+})at < 10 μM impairs NF-κB activation in normal rat kidney epithelial (NRK52E) cells and increases their sensitivity to apoptosis by LPS, TNF-α and other agents to which these cells are otherwise resistant. To further demonstrate that increased sensitivity to apoptosis incurred by Hg^{2+} pretreatment is associated specifically with inhibition of NF-κB, we conducted studies to determine if comparable increased sensitivity could be elicited by treatment with sepcific NF-κB inhibitors. Pretreatment of cells with Bay 11-7082 (0-10 μM, a specific inhibitor of IκB kinase, attenuated NF-κB activation by TNF (3 ng/ml) in a dose-related manner, and this corresponded to a subsequent increase in sensitivity to TNF-induced apoptosis, as measured by TUNEL assay (7.5% of untreated or TNF alone versus 28% and 56% of cells pretreated with 2.5 or 5 μM, respectively, Bay 11 before TNF). Comparable results were obtained after pretreatment of cells with SN-50, a synthetic polypeptide that blocks nuclear translocation of NF-κB, before TNF. Increased sensitivity to TNF-induced apoptosis following attenuation of NF-κB activity was characterized by translocation of mitochondrial cytochrome c and activation of caspase 3. The latter was completely prevented by constitutive p65 expression. These findings support the hypothesis that sensitivity to apoptosis induced by Hg^{2+} (and other NF-κB inhibitors) is regulated at the level of NF-κB in kidney epithelial cells and that this effect is mediated *via* a mitochondrial and caspase 3 pathway. Supported by ES04696, ES07032 and ES07033.

1313 ARSENITE INDUCED ACTIN CYTOSKELETON AND VINCULIN DISRUPTIONS CAN BE BLOCKED BY PROTEIN SYNTHESIS INHIBITORS.

T. Suramana [1], J. M. Murray [2], N. Nuntharatanapong[1], K. Hu[2], T. Posayanonda [1], R. Sindhuphak [3], N. Dusitsin [3] and P. Sinhaseni [1,3]. [1]*Department of Pharmacology, Faculty of Pharmaceutical Sciences, Chulalongkorn University, Bangkok, Thailand,* [2]*Department of Cell and Developmental Biology, University of Pennsylvania School of Medicine, Philadelphia, PA and* [3]*The Institute of Health Research, Chulalongkorn University, Bangkok, Thailand.*

Arsenite produces a variety of stress responses including metabolic inhibition and eventually apoptosis in many cell types. Morphological alterations in arsenite- exposed cells suggest that disruption of cytoskeletal structure elements are responsible for cellular integrity, shape, and locomotion change seen in many disease processes. In this study, we found that protein synthesis inhibitor cycloheximide or RNA synthesis inhibitor actinomycin D can block the actin cytoskeleton and vinculin disruptions induced by sodium arsenite (25 micromolar) in Balb/c 3T3 cells. In immunoblot assays, cycloheximide and actinomycin D can not block PAK, JNK, phospho-JNK, p38, and phospho-p38 expressions induced by arsenite. Since protein synthesis are physiological processes related to the maintenance of homeostasis, down-stream effectors of EGFR-PI3K signaling pathway related to the protein synthesis, including transcription and translation processes, are proposed to play a major role for arsenite-induced toxicity. Our present studies demonstrated that the JNK and p38 activations are not affected. We have earlier reported that tyrosine kinase inhibitor genistein, EGFR inhibitor 4, 5-dianilinophthalimide or PI3K inhibitor wortmannin completely blocked these toxic responses induced by arsenite (Suramana et al., 2002). The role of specific anchoring protein which may be attached to enzymes requires actin cytoskeleton and focal adhesion protein are being investigated.

1314 DNA DAMAGE INDUCED BY METHYLATED TRIVALENT ARSENICALS IS MEDIATED BY REACTIVE OXYGEN SPECIES.

S. Nesnow[1], B. C. Roop[1], G. Lambert[1], M. Kadiiska[2], R. P. Mason[2], W. R. Cullen[3] and M. J. Mass[1]. Arsenic is a human carcinogen; however, the mechanisms of arsenic's induction of carcinogenic effects have not been identified clearly. We have shown previously that monomethylarsonous acid (MMA^{III}) and dimethylarsinous acid (DMA^{III}) are genotoxic and can damage supercoiled ϕX174 DNA and the DNA in peripheral human lymphocytes in culture. These trivalent arsenicals are biomethylated forms of inorganic arsenic and have been detected in the urine of subjects exposed to arsenite and arsenate. We show here by molecular, chemical, and physical methods that reactive oxygen species (ROS) are intermediates in the DNA-damaging activities of MMA^{III} and DMA^{III}. Using the ϕX174 DNA nicking assay we found that the ROS inhibitors Tiron, melatonin, and the vitamin E analog Trolox inhibited the DNA-nicking activities of both MMA^{III} and DMA^{III} at low micromolar concentrations. The spin trap agent 5, 5-dimethyl-1-pyrroline-N-oxide (DMPO) also was effective at preventing DNA nicking by MMA^{III} and DMA^{III}. ESR spectroscopy studies using DMPO identified a radical as a ROS intermediate in the DNA incubations with DMA^{III}. This radical adduct was assigned to the DMPO-hydroxyl free radical adduct on the basis of comparison of the observed hyperfine splitting constants and line widths with those reported in the literature. The formation of the DMPO-hydroxyl free radical adduct was dependent on time and the presence of DMA^{III} and was completely inhibited by Tiron and Trolox and partially inhibited by DMSO. Using electrospray MS, micromolar concentrations of DMA^{V} were detected in the DNA incubation mixtures with DMA^{III}. These data are consistent with the conclusions that the DNA-damaging activities of DMA^{III} are mediated by ROS formed concomitantly with the oxidation of DMA^{III} to DMA^{V}. The data suggest that ROS generated from DMA^{III} may play an important role in the carcinogenic activity of arsenic.

1315 DEFEROXAMINE SYNERGISTICALLY ENHANCING IRON-INDUCED STIMULATION OF ACTIVATOR PROTEIN-1 THROUGH INCREASED ERKS PHOSPHORYLATION.

J. Dai, C. Huang and X. Huang. *Environmental Medicine, New York University School of Medicine, New York, NY.*

Deferoxamine (DFO) is the only approved drug in the US for iron overload treatment. Studies have demonstrated the ability of DFO to remove iron bound to low molecular weight (LMW) chelators and those bound to proteins, such as ferritin. Because of its ability to sequester LMW iron, DFO is known as an antioxidant. Recently, the DFO-Fe complex ferroxamine and even DFO alone were shown to act as pro-oxidants. In the present study, we have shown in mouse epidermal JB6 cells that ferrous sulfate transactivated activator protein-1 (AP-1) and nuclear factor of activated T cells (NFAT), two transcription factors responsive to oxidative stress. Interestingly, pretreatment of cells with DFO, followed by iron treatment, synergistically increased AP-1 activity, a ten-fold increase over the control as compared to iron alone, a 3-fold increase. In contrast, DFO prevented iron-induced NFAT activation and significantly inhibited iron-induced ferritin and lipid peroxidation in human liver HepG2 cells. We have further shown that iron stimulated the phosphorylation of extracellular signal-related kinases (ERKs) and p38 mitogen-activated protein kinases (MAPK) but not c-jun NH2 terminal kinases (JNKs) after 15-90 min treatments. The increased phosphorylation was lessened by the pretreat-

ment of cells with N-acetyl-L-cysteine, an antioxidant. DFO inhibited iron-induced ERKs phosphorylation within 1 h of treatment, whereas it further enhanced ERKs phosphorylstion in longer periods of treatment (over 6 h). These results suggest that the phosphorylation of ERKs and p38 MAPK by iron is a stress response through oxidative pathways, and the increased phosphorylation of ERKs by DFO may be due to the imbalance between phosphatases and kinases. It was previously shown that DFO inhibited alkaline phosphatase. Whether DFO inhibits the tyrosine and serine/threonine phosphatases leading to the synergistic increase in AP-1 is being studied. The clinical implication of this observation may be important because many genes are regulated by AP-1.

1316 INVOLVEMENT OF OXIDATIVE STRESS IN THE METALLOTHIONEIN SYNTHESIS INDUCED BY MITOCHONDRIAL INHIBITORS.

M. Sato, N. Futakawa, M. Kondoh, M. Higashimoto and M. Takiguchi. *Faculty of Pharmacy, Tokushima Bunri University, Tokushima, Japan.*

Antimycin A and 2, 4-dinitrophenol (DNP) are potent inhibitors of respiration and radical generators in mitochondria. We previously reported that metallothionein (MT) was induced by antimycin A or DNP. However, the involvement of oxidative stress in the induction of MT by antimycin A or DNP remains obscure. Therefore, we examined the involvement of oxidative stress in MT synthesis by the inhibitors. Administration of mitochondrial inhibitors elevated the level of lipid peroxidation in not only the liver but also hepatic mitochondria, indicating the production of mitochondrial oxidative stress. Antimycin A treatment elevated the levels of lipid peroxidation and MT in the liver time dependently, and the increase in hepatic MT and lipid peroxidation levels occurred in parallel. In addition, under the condition of glutathione depletion, due to pre-administration of L-buthionine-SR-sulfoximine (BSO), MT synthesis by mitochondrial inhibitors was further elevated, although the BSO treatment did not alter the hepatic MT concentrations. The data suggest that inducement of MT synthesis in the liver of antimycin A- or DNP-treated mice is due to the enhancement of lipid peroxidation. The occurrence of oxidative stress was confirmed by the fact that antimycin A or DNP increased hydrogen peroxide formation in mouse fibroblast cells. Furthermore, intracellular accumulation of hydrogen peroxide caused by the actions of mitochondrial inhibitors was greater in MT-null than in wild-type fibroblast cells, suggesting that MT plays a role as a radical scavenger against intracellular reactive oxygen species (ROS) caused by mitochondrial stress. The results suggest that mitochondrial oxidative stress induces the synthesis of MT, which may contribute to regulation of mitochondrial ROS production.

1317 EFFECTS OF CADMIUM ON THIOREDOXIN AND THIOREDOXIN REDUCTASE IN HUMAN PULMONARY FIBROBLASTS.

R. Watkin and B. Hart. *Biochemistry, University of Vermont, Burlington, VT.*

The heavy metal Cadmium (Cd) is a known carcinogen that has been shown to induce oxidant stress. Glutathione (GSH) and thioredoxin (Trx) are major thiol-containing constituents implicated in a number of cellular functions including protection against oxidative stress and maintaining redox balance. Our previous research has shown that GSH and enzymes involved in GSH metabolism are up-regulated by Cd in acute and adapted pulmonary models. Trx expression is known to be induced by a variety of stress factors including UV radiation, hyperoxia, and hydrogen peroxide. The objective of the present study was to determine if exposure to Cd also up-regulated the activity and levels of expression of thioredoxin and cytosolic thioredoxin reductase (cTR), an enzyme that reduces oxidized thioredoxin. To test this hypothesis, sub-confluent normal human lung fibroblasts (IMR-90) were exposed to 10 µM CdCl2 for different durations up to 24 hrs, total RNA was extracted and purified, and mRNA levels of Trx and cTR were examined following RT-PCR. Basal gene expression of cTR was approximately double that of Trx. Following exposure to Cd, Trx transcript levels increased, peaking around 16 hrs at ~ 3-fold that of control levels, and remained high after 24 hrs. cTR mRNA levels also peaked around 16 hrs at ~ 2.15-fold that of control levels, but dropped to ~ 1.5-fold by 24 hrs. Similar elevations in the enzymatic activity of Trx and cTR were also observed in extracts from cells exposed to Cd. Studies are continuing to determine whether Trx and cTR levels are also altered in cells adapted to Cd and to further characterize the relationship between Cd and the thioredoxin system.

1318 CALCITE IS A LIKELY ANTAGONISTIC FACTOR AGAINST BIOAVAILABLE IRON-CONTAINING COAL-INDUCED TOXICOLOGICAL EFFECTS.

Q. Zhang and X. Huang. *Environmental Medicine, NYU School of Medicine, New York, NY.*

Coal mining causes chronic obstructive pulmonary diseases such as pneumoconiosis and emphysema. The disease is most common in the Pennsylvania (PA) coal miners and least common in miners from Utah (UT). We have previously shown that levels of bioavailable iron (BAI) in the coals correlated well with the prevalence of coal worker's pneumoconiosis (CWP) from that coalmine region. PA coals contained large amounts of BAI enhanced the coal dust-induced lipid peroxidation and cytokine formation in A549 cells, which were dimished by the pretreatment of cells with DFO, a specific iron chelator. UT coals had the least amount of BAI due to the presence of calcite (CaCO3) in the coals, which makes the iron less bioavailable. In the present study, pre-determined percentages of calcite (0, 2, 5, 10% w/w) were added to three PA coals. After suspending the mixtures in an aqueous solution (phosphate-buffered saline, 10 mM, pH 4.5), which mimics the phagolysosomal conditions of cells, the levels of pH as well as calcium ions (Ca2+) were increased as a function of time. In contrast, levels of BAI (both Fe2+ and Fe3+) were decreased at day one and had completely disappeared after one-week incubation. The attenuating effects were calcite dose-dependent. A549 cells as well as primary rat alveolar macrophages were then treated with the 10% calcite-PA coal mixture for 24 hours. We have found that the mixture significantly decreased the PA coal-induced ferritin formation, lipid peroxidation, as well as interleukin-6 release. Calcite alone had no significant toxicological effects on the cells. Our results suggest that calcite may play a protective role by inhibiting the bioavailability of iron in the coals, and thus limiting the toxicological effects of BAI. Our studies suggest that the addition of calcite into the water spray when mining BAI-containing coal may be an effective tool for preventing the occurrence of such diseases. Supported by OH03561.

1319 THE EFFECT OF TRACE ELEMENT MIXTURES ON THE INDUCTION OF δ-AMINOLEVULINIC ACID:A 90-DAY DRINKING WATER STUDY IN RATS.

M. H. Whittaker, M. Lipsky, G. Wang, X. Chen and B. A. Fowler. *Toxicology Program, Department of Epidemiology & Preventive Medicine, The University of Maryland, Baltimore, MD.*

δ-Aminolevulinic acid (ALA) is a heme precursor that can generate reactive oxygen species (ROS) upon iron-catalyzed aerobic oxidation. ROS such as the superoxide anion (O_2^-), hydrogen peroxide (H_2O_2), and the hydroxyl radical ($^{\cdot}OH$) can cause oxidative damage to proteins, subcellular structures, and DNA. This study investigated whether subchronic exposure to single trace elements (lead, cadmium, or arsenic) or trace element mixtures increased urinary ALA excretion. Male Sprague-Dawley rats were administered 25 ppm lead (Pb)(as lead acetate), 10 ppb cadmium (Cd)(as cadmium chloride), 5 ppm arsenic (As)(as sodium arsenite), or trace element mixtures (PbxCd, PbxAs, CdxAs, PbxCdxAs) in deionized drinking water for 90 days. Mean urinary ALA concentrations were significantly increased among 7 of the 8 groups compared to the control: 97.2 (control), 126 (Pb), 148 (Cd), 134 (As), 74.1 (PbxCd), 113 (PbxAs), 146 (CdxAs), and 141 (PbxCdxAs) µg ALA/24 hours. On a percentage basis, urinary ALA concentrations (µg/24 hours) were +29%, +53%, +38%, -18%, +16%, +50%, and +45% different than the control, respectively. The accumulation of ALA is due to inhibition of heme pathway enzymes, notably ALA dehydratase (ALAD). As expected, ALAD activities were inhibited in both the kidney and blood. Inhibition of kidney ALAD activity was observed among all groups compared to control (-51%, -22%, -5%, -24%, -54%, -5%, and -8%). Inhibition of blood ALAD activity was observed among all groups compared to control (-62%, -57%, -59%, -67%, -88%, -54%, and -54%). This experiment demonstrates that accumulation of ALA is occurring in response to subchronic administration of trace elements and trace element combinations, and is a first step towards elucidating the effect of oxidative stress upon trace element toxicity. Experiments are underway to characterize the heat shock protein-32 (heme oxygenase-1) response to subchronic administration of trace element mixtures [Supported by USEPA Star Grant R827161-01-0].

1320 DISTRIBUTION OF IRON IN TISSUES AND CELLS OF RATS EXPOSED TO SILICA.

J. Stonehuerner and A. Ghio. *USEPA, Chapel Hill, NC.* Sponsor: M. Madden.

The stable iron isotope 57Fe has been used to study the distribution of iron in tissues, bronchial alveolar lavage fluid (BALF), and alveolar macrophages (ma) of rats in- stilled with silica relative to saline. Sixty-day old male Sprague-Dawley rats were instilled intratracheally with 10 mg silica in 0.5 mL normal saline (NS). Controls were simi- larly instilled with 0.5 mL NS. Animals were immediately injected intraperitoneally with 1 mL 1.0 mM 57FeCl3 in PBS. Animals were sacrificed 1, 24, or 96 hrs. after silica installation. The distribution of iron was determined by ICP/MS analysis of acid digests of tissues, BALF, and ma for 57Fe. 57Fe distribution in lung and liver tissue was remar- kably similar for samples and controls. Plasma 57Fe levels were increased in both groups at the 1 hr. time point and remained elevated at 96 hr. although silica-treated rats exhibited a higher initial [57Fe] accompanied by a time- dependent decrease. The biggest differences between treated animals and controls were in BALF and ma where silica- treated animals exhibited increases in 57Fe at all time points with the highest level observed at 24 hr. These results demonstrate the utility of 57Fe analyses in elucidating the

metabolic fate of iron compounds known to cause a variety of negative health effects. This is an abstract of a proposed presentation and does not necessarily reflect EPA policy.

1321 FEASIBILITY OF SCROTAL ULTRASOUND EVALUATION IN THE CYNOMOLGUS MONKEY.

G. F. Weinbauer[1] and A. Kamischke[2]. *[1]Covance Laboratories GmbH, Muenster, Germany and [2]Institute of Reproductive Medicine of the University, Muenster, Germany.* Sponsor: P. Thomas.

The cynomolgus monkey (Macaca fascicularis) represents a suitable nonhuman primate model for human reproductive physiology and is frequently used in toxicity studies. The purpose of this investigation was to evaluate the feasibility of scrotal sonography in the cynomolgus monkey model. In man, testicular sonography allows repeated and safe imaging diagnostics of the scrotal contents and determination of testicular volume without side effects. Thus it has become an important diagnostic tool in andrology. As in humans, measurements of testis volume were performed in the cynomolgus monkey with a 7.5-megahertz sector scanner (Sonoline Versa Pro, Siemens, Erlangen, Germany). For all interventions, the monkeys were sedated with an intramuscular injection of ketamine hydrochloride. In the cynomolgus monkey, as in man, normal testis and epididymis displayed homogenous parenchymal echogenicity. Furthermore, similar to man, the rete testis could be easily identified in the monkey by ultrasound due to its higher echogenicity, and prepubertal animals testes were characterized by hypoechogenicity. Testicular volume determination by scrotal ultrasonography was compared to caliper measurements. The total coefficient of variation for all sonographic measurements was 10.3%. The corresponding coefficient of variation for caliper testicular volume was 15.9%. Both methods of volume determination were highly significantly ($p < 0.001$) correlated with each other. In conclusion, scrotal sonography in the cynomolgus monkey revealed a similar echogenicity to that of man and provides an appropriate method for determination of testicular volume.

1322 ANALYSIS OF ANDROGEN- AND EGF-RECEPTOR EXPRESSION IN THE FETAL RAT PHALLUS AFTER EXPOSURE TO VINCLOZOLIN.

C. J. Wolf[1,2], B. Abbott[1], G. A. LeBlanc[2] and L. E. Gray[1]. *[1]ORD, RTD, USEPA, Research Triangle Park, NC and [2]Environmental and Molecular Toxicology, NCSU, Raleigh, NC.*

Improper development of the male phallus during fetal sexual differentiation resulting in hypospadias is at least partially due to impaired androgen receptor (AR) function. Other mediators may be involved since hypospadias in humans is not usually associated with mutations of the AR. Epidermal growth factor (EGF) is suspected since it has been implicated in other developmental processes in the reproductive tract as an AR-dependent gene. The fungicide vinclozolin (V) is an AR inhibitor that induces cleft phallus and hypospadias in male rats exposed during fetal sexual differentiation. We investigated the ability of V to alter the expression of AR and EGF receptor (EGFR) in the fetal phallus at a dose that induces cleft phallus in the 100% of male offspring. Pregnant rats were dosed (po) with either corn oil (2.5 ml/kg) or V (400 mg/kg) on gestational days (GD) 14-18. On GD 18 phalluses were collected (3 phalluses/ 3 litters/ 3 treatment groups: control female, control male and V-treated male), fixed in 3% paraformaldehyde, dehydrated in ethanol and paraffin embedded. 6 µm sections were placed on slides in matrix fashion with 1 representative per litter per treatment group per slide. Immunohistochemistry for AR or EGFR was performed by the avidin-biotin-peroxidase technique. Densitometric analysis of sections was performed blind using ImagePro Plus software. Mean density and area of the epithelial layers of the epidermis and the urethral groove, and number and summed area of receptor-positive cells in the mesenchyme was measured. We found a slight reduction in both AR and EGFR expression in control females as compared to control males, but no change in AR or EGFR expression by V. These results imply that events other than AR number or EGFR number mediate V-induced hypospadias. Future studies will focus on differences in gene expression induced by V that contribute to hypospadias. This abstract does not necessarily reflect EPA policy.

1323 EFFECTS OF ENDOCRINE DISRUPTING CHEMICALS (EDCS) ON FETAL TESTES HORMONE PRODUCTION.

C. R. Lambright, V. S. Wilson, J. R. Furr, C. J. Wolf, N. Noriega and L. E. Gray. *ORD/NHEERL/RTD, USEPA, Research Triangle Park, NC.*

Exposure to EDCs during critical periods of fetal sexual development can have profound effects on the male reproductive system. We examined effects of gestational exposure to eight EDCs on testes testosterone (T) and progesterone (P4) production. Chemicals included fungicides (Procymidone (PD), Vinclozolin (V), Prochloraz (PZ)), phthalate esters (DEHP, DBP, BBP) and herbicides (Linuron (L), Neburon (N)). Doses of 200, 200, 250, 1000, 1000, 1000, 100, 100 mg/kg/day respectively were administered daily GD 14-18 to SD rats and chosen based on previous studies indicating that the majority of fetuses would be affected. PD and V are androgen receptor (AR) antagonists, while the phthalates alter fetal Leydig cell differentiation and reduce fetal T production. L and PZ have been reported to display multiple endocrine activities, including AR antagonism and inhibition of fetal T synthesis. N has been shown to bind AR *in vitro*, but it is unknown if it alters sexual differentiation. Dams were sacrificed on GD 18 and fetal testes were incubated in M199 medium supplemented with 10% DCC serum for 3 hours. Medium were collected for hormonal analysis. L, N, DEHP, DBP, and BBP all caused a significant reduction in fetal testes T and P4 release. As anticipated, V and PD treatment did not reduce the release of either hormone. PZ exposure resulted in a 10-20 fold increase in P4 and a slight decrease in T versus the control, suggesting a specific inhibition of CYP450 conversion of P4 to the androgens. Other studies are ongoing to examine the direct effects of these chemicals *in vitro*. Gene expression will also be examined in the testes using microarrays and PCR. These studies provide background from which we can further investigate the mechanisms by which these chemicals affect fetal testes hormone production after gestational exposure. Abstract of a proposed presentation and does not necessarily reflect EPA policy.

1324 PROGRESSIVE LOSS OF SPERMATOGENESIS IN LYSOPHOSPHATIDIC ACID RECEPTORS KNOCKOUT MICE.

X. Ye[1], J. J. Contos[1], M. Skinner[2], S. Kawamura[1], C. McGiffert[3], S. Miyamoto[1], J. H. Brown[1] and J. Chun[1]. *[1]Department of Pharmacology, University of California, San Diego, La Jolla, CA, [2]Center for Reproductive Biology, Washington State University, Pullman, WA and [3]Neuroscience Program, University of California, San Diego, La Jolla, CA.* Sponsor: D. Eastmond.

Lysophosphatidic acid (LPA; 1-acyl-2-sn-glycerol-3-phosphate) can evoke many cellular and biochemical responses in a variety of cell types. The LPA-induced responses are mediated through three G protein-coupled LPA receptors: LPA1, LPA2, and LPA3. To elucidate their *in vivo* function, each of the LPA receptor genes was targeted for deletion in mice. We demonstrate that LPA receptors are involved in mouse spermatogenesis. Mice lacking one, two and three LPA receptors show gene dose-response suppression of spermatogenesis. The suppression of spermatogenesis is progressive. Consequently, the male knockout mice have decreased sperm counts and a reduced rate of fertilization. Since there is no significant difference between knockout and wild type mice in serum testosterone levels, it is likely that the deficit in spermatogenesis in LPA receptor(s) null mice is not caused by endocrine but local defects. Indeed, increased apoptosis and decreased cell proliferation as well as impaired signaling are detected in the testes of LPA receptor(s) null mice. Our study has established a novel *in vivo* function of LPA receptors in spermatogenesis.

1325 IDENTIFICATION OF PROTEINS INVOLVED IN TESTICULAR TOXICITY INDUCED BY HALOACID BY-PRODUCTS OF DRINKING WATER DISINFECTION.

E. Kaydos[1], M. Holmes[2], J. Suarez[3], N. Roberts[3] and G. Klinefelter[3]. *[1]Department of Environmental and Molecular Toxicology, NC State University, Raleigh, NC, [2]Center for Biomedical Research, Population Council, NY, NY and [3]Reproductive Toxicology Division, USEPA, ORD, NHEERL, Research Triangle Park, NC.*

Dibromoacetic acid (DBA), a prevalent disinfection by- product in drinking water, perturbs spermiogenesis in adult rats suggesting that Sertoli-germ cell communication is compromised. When isolated seminiferous tubules from rats exposed to DBA *in vivo* were cultured, quantitative analysis of autoradiograms following two-dimensional gel electrophoresis (2D SDS-PAGE) revealed that the synthesis of multiple cytosolic proteins in tubules representing stages I-V was diminished; four of these cytosolic proteins were also diminished by *in vitro* DBA exposure. We sought to identify these four proteins to determine whether Sertoli cells and/or germ cells are target cells in haloacid-induced toxicity. Seminiferous tubules representing stages I-V of spermatogenesis were isolated from adult rats and cultured overnight. Tubule homogenate was centrifuged and supernatant was concentrated and assayed for protein. Proteins resolved by 2D SDS-PAGE gels were stained with SyproRuby and gel punches of each of the four proteins were frozen at -70 °C. After tryptic digestion and extraction, proteins were resolved and analyzed by electrospray ionization /ion trap mass spectrometry. Data were analyzed using the Sequest search algorithm. The major proteins represented were: 14-3-3 Epsilon, 14-3-3 Theta/ Zeta, cAMP-dependent Protein Kinase Regulatory Subunit, and 1-Cys Peroxiredoxin. While cAMP-dependent Protein Kinase Regulatory Subunit is in-

volved with FSH-mediated signaling in Sertoli cells, 14-3-3 Theta and 14-3-3 Epsilon modulate protein kinase C activity and are also found in Sertoli cells. 1-Cys Peroxiredoxin and 14-3-3 Zeta have phopholipase A2 activity. These data reveal disruption in Sertoli cells and imply that germ cell compromise may be secondary to Sertoli cell insult.

1326 DI(*n*-BUTYL) PHTHALATE INTERFERES WITH FETAL TESTICULAR STEROIDOGENESIS AT THE LEVEL OF CHOLESTEROL TRANSPORT AND CLEAVAGE.

C. Thompson, S. M. Ross and K. W. Gaido. *CIIT Centers for Health Research, Research Triangle Park, NC.*

The phthalate ester di(*n*-butyl) phthalate (DBP) produces antiandrogenic effects on male reproductive development in rats. In the fetus, these effects are mediated, not by interaction with the androgen receptor, but rather through diminution of testosterone (T) production by the testes. Previous studies have shown that several genes involved in cholesterol transport and steroidogenesis are downregulated at the mRNA level following *in utero* exposure to DBP. The purpose of this study was to make a functional determination of the points in the cholesterol transport and steroidogenesis pathways affected by DBP. We cultured fetal testis explants with T precursors and assessed cholesterol uptake and T production. Pregnant Sprague-Dawley rats were treated with 500 mg/kg DBP or corn oil control *via* oral gavage from gestational days 12 to 19. Following the final treatment, testes were removed from the fetuses and cultured for 3 h with ^{3}H-cholesterol, leuteinizing hormone (LH), Bt_2-cAMP, 22(R)-hydroxycholesterol, pregnenolone, progesterone, or 17-hydroxyprogesterone. T production in unsupplemented cultures of DBP-exposed testis was roughly 10% of that seen in corn oil controls (164.7 ± 32 pg/h vs. 1684.1 ± 347 pg/h). Both control and treated explants could be stimulated by LH or Bt_2-cAMP, but T production by DBP-treated testes remained less than 50% of control levels. Incorporation of ^{3}H-cholesterol by mitochondria of DBP-treated explants was 67% of that observed in controls, although this difference was not statistically significant ($p = 0.08$). Pregnenolone, progesterone, and 17-hydroxyprogesterone all significantly increased T production compared to unsupplemented DBP-treated explants. However, there was no significant difference between the unsupplemented explants and those treated with the membrane-permeable 22(R)-hydroxycholesterol. These data indicate that the toxic effects of DBP on the fetal testis are mediated at the level of cholesterol cleavage by $P450_{scc}$ and possibly at the level of cholesterol transport into the mitochondria.

1327 EFFECTS OF METHOXYCHLOR (M) OR ITS ACTIVE METABOLITE, 2, 2-BIS(*p*-HYDROXYPHENYL)-1, 1, 1-TRICHLOROETHANE (HPTE), ON TESTOSTERONE (T) FORMATION BY CULTURED NEONATAL (FETAL) LEYDIG CELLS (LC).

E. P. Murono and R. C. Derk. *Pathology and Physiology Research Branch, CDC/NIOSH, Morgantown, WV.* Sponsor: V. CASTRANOVA.

M is a pesticide developed as a replacement for dichlorodiphenyltrichloroethane (DDT). Its active metabolite is thought to be HPTE. Both M and HPTE have been reported to exhibit weak estrogenic or antiandrogenic activities, their proposed mechanism(s) of action. In the present studies, we examined the effects of M or HPTE on T biosynthesis by cultured LC from neonatal rats, which represent fetal LC. Increasing concentrations of M or HPTE (100-1000 nM) caused a progressive decline in both basal and 10 mIU/ml human chorionic gonadotropin (hCG)- or 1 mM 8 Br-cAMP-stimulated T following exposure for 4 or 24 h, although the declines with HPTE were greater. To localize the site(s) of action of HPTE, LC were exposed to HPTE (100-1000 nM) for 24 h (both alone or with hCG), then fresh media containing steroid precursors of T were added to assess their conversion to T over 4 h. The conversion of 0.01 mM pregnenolone, progesterone or androstenedione to T was unaffected by prior exposure to HPTE; however, the conversion of 22(R)hydroxycholesterol to T progressively decreased, suggesting that among the enzymes involved in converting cholesterol to T, P450 cholesterol side-chain cleavage activity is inhibited by HPTE. The concomitant inclusion of the "pure" estrogen antagonist, ICI 182, 780, did not alter the inhibitive effects of HPTE, suggesting that the effects of HPTE are not mediated through the estrogen receptor (ER) pathway. Furthermore, the antiandrogen 4-hydroxyflutamide (100-1000 nM) had no effect on hCG-stimulated T following 24 h exposure, suggesting that HPTE is not acting as an antiandrogen through the androgen receptor (AR). These results suggest that the two prevailing proposed modes of action of MC/HPTE in altering male reproductive function (weakly estrogenic through the ER or antiandrogenic through the AR) do not apply with respect to their inhibitive effect on T formation by fetal LC.

1328 EVIDENCE FOR THE PRESENCE AND ACTIVITY OF SOLUBLE EPOXIDE HYDROLASE IN THE RAT EPIDIDYMIS AND SPERM.

S. B. DuTeaux[1], J. W. Newman[2], C. Morisseau[2], E. A. Fairbairn[1], B. D. Hammock[2] and M. G. Miller[1]. *[1]Environmental Toxicology, University of California, Davis, CA and [2]Entomology, University of California, Davis, CA.*

Soluble epoxide hydrolase (sEH) is proposed to play a role in mediating ion balance in the kidney through the catalytic transformation of bioactive arachidonic acid metabolites. The epididymis and kidney are related embryonically. In addition, the epididymis regulates ion concentrations through diffusion, active transport, and leaky epithelium much like the kidney. Based on these similarities, the present study used immunohistochemistry, Western blotting, and enzyme assays to address the possibility that sEH is present in the epididymis. Tissue sections probed with an antibody to sEH showed immunoreactive proteins in the clear cells of the caput, corpus, and cauda epididymis. The sEH antibody also reacted with proteins on the ventral acrosome and the principal piece of sperm. In Western blots, immunoreactive proteins in kidney cytosol were consistent with a 65 kD recombinant sEH standard. The same antibody recognized a single 75 kD protein in epididymal segments and a single 71 kD protein in sperm. Epoxide hydrolase activity was measured in kidney, epididymal, and sperm samples using [^{3}H]-*trans*-diphenylpropene oxide (tDPPO) as a substrate. Results indicate that all portions of the epididymis as well as sperm are capable of generating diols from the tDPPO epoxide. The specific activity of the corpus epididymis (110 pmol/min/mg) was similar to the activity in the kidney cortex (113 pmol/min/mg). Evaluation of *in vitro* arachidonic acid metabolism showed that the epididymis can generate epoxides and diols. In addition, epididymal metabolism was chemically inhibited by cyclohexyldodecyl urea, a potent sEH inhibitor. The present study indicates the presence of epoxide hydrolase activity in the epididymis at levels similar to the kidney. Because the protein detected in the epididymis is larger than the known mass of sEH, immunoinhibition assays and protein sequencing studies are planned to further elucidate the nature and identity of epoxide hydrolase in the epididymis.

1329 IDENTIFICATION OF TRICHLOROETHYLENE AND ITS METABOLITES IN HUMAN SEMINAL FLUID OF WORKERS EXPOSED TO TRICHLOROETHYLENE.

P. Forkert[1], L. Lash[2], R. Tardif[3], N. Tanphaichitr[4], C. VanderVoort[5] and M. Moussa[6]. *[1]Anatomy & Cell Biology, Queen's University, Kingston, ON, Canada, [2]Department of Pharmacology, Wayne State University School of Medicine, Detroit, MI, [3]Department of Environmental and Occupational Health, University of Montreal, Montreal, QC, Canada, [4]Hormones/Growth/Development Research Group, Ottawa Health Research Institute, Ottawa, ON, Canada, [5]California National Primate Research Center, University of California, Davis, CA and [6]Department of Pathology, London Health Sciences Centre, London, ON, Canada.*

We have investigated the potential of the male reproductive tract to accumulate TCE and its metabolites including chloral, trichloroethanol (TCOH), trichloroacetic acid (TCA)and dichloroacetic acid (DCA). Human seminal fluid and urine samples from eight mechanics diagnosed with clinical infertility and exposed to TCE occupationally were analyzed. In *in vivo* studies, TCE and its metabolites were determined in epididymis of mice exposed to TCE (1000 ppm) by inhalation for 1 to 4 weeks. In other studies, incubations of monkey epididymal microsomes were performed in the presence of TCE and NADPH. Our results showed that seminal fluid from all 8 subjects contained TCE, chloral and TCOH. DCA was present in samples from 2 subjects, and only 1 contained TCA. TCA and TCOH were also identified in urine samples from 2 subjects. TCA, chloral and TCOH were detected in murine epididymis after exposure to TCE for 1 to 4 weeks. Levels of TCE and chloral were similar throughout the exposure period. TCOH levels were similar at 1 and 2 weeks, but increased significantly after 4 weeks. Chloral was identified in microsomal incubations with TCE in monkey epididymis. CYP2E1, a P450 enzyme with a major role in TCE metabolism, was localized in human and monkey epididymal epithelium and testicular Leydig cells. These results indicated that TCE is metabolized in the reproductive tract of the mouse and monkey. Furthermore, TCE and its metabolites were identified in seminal fluid, and suggested associations between TCE metabolites, reproductive toxicity and impaired fertility. Supported by Health Canada/Environment Canada.

1330 2, 3, 7, 8-TETRACHLORODIBENZO-*P*-DIOXIN (TCDD) INHIBITS PROSTATIC EPITHELIAL BUD FORMATION IN THE UROGENITAL SINUS (UGS) OF C57BL/6J MICE VIA MESENCHYMAL BUT NOT EPITHELIAL ARYL HYDROCARBON RECEPTOR (AHR).

R. W. Moore, K. Ko, N. T. Rasmussen and R. E. Peterson. *School of Pharmacy, University of Wisconsin at Madison, Madison, WI.*

We previously reported that *in utero* TCDD exposure prevents prostatic epithelial buds from forming in the ventral region of the UGS and reduces the number of buds formed in the dorsal and lateral regions of the UGS. These effects of TCDD

are AhR dependent. However, whether TCDD acts on UGS mesenchyme, UGS epithelium, or both was unknown. The objective of this study was to test the hypothesis that TCDD inhibits bud formation by acting through AhR in UGS mesenchyme. First, we established a tissue separation and recombination method and *in vitro* culture system in which 10^{-8} M 5α-dihydrotestosterone (DHT) induced bud formation in recombined gestation day 15 UGS, as shown by scanning electron microscopy. We then found that 10^{-9} M TCDD severely inhibited DHT-dependent bud formation when ventral mesenchyme was recombined with ventral plus dorsal epithelium (VDE), but not when dorsal mesenchyme was recombined with VDE. When ventral mesenchyme/VDE recombinants were implanted under the renal capsule of nude male mice, prostatic tissue developed, as determined histologically and by high expression of mRNA for MP25, a ventral prostate-specific gene. To further refine the site(s) at which TCDD acts to inhibit bud formation, ventral mesenchyme and VDE were prepared from wild-type and AhR null mutant (AhRKO) mice. All possible combinations of wild-type and AhRKO ventral mesenchyme and VDE were prepared and incubated with 10^{-8} M DHT and either 0.1% DMSO or 10^{-9} M TCDD. TCDD significantly reduced the number of buds in recombinants containing mesenchymal AhR, regardless of epithelial AhR status. But bud formation was not inhibited by TCDD in recombinants lacking mesenchymal AhR, even when epithelial AhR was present. We conclude that TCDD inhibits prostatic epithelial bud formation in the UGS by interacting with AhR in the mesenchyme. (Supported by NIH Grant ES 01332)

1331 EFFECTS OF METHYL MERCURY AND CADMIUM ON STRESS SIGNALING AND UBIQUITINATION PATHWAYS IN A PRIMARY SERTOLI CELL-GONOCYTE CO-CULTURE SYSTEM.

X. Yu, E. M. Faustman, S. Hong and J. S. Sidhu. *Environ Health, University of Washington, Seattle, WA.*

We have recently developed and optimized a primary Sertoli cell-gonocyte co-culture system from neonate rat using modified extracellular matrix culture techniques. In order to apply this system for improving our understanding of the mechanisms of reproductive toxicity, we exposed the Sertoli cell-gonocytes to two known toxicants: methyl mercury (MeHg) and cadmium (Cd). Specific or non-specific proteasomal inhibitors:Lactacystin (Lact) and MG 132 (MG)were also included, since the disruption of specific ubiquitin-proteasome degradation may be associated with resultant toxicity. The effects on the morphology, MAPK, AKT signaling and ubiquitination pathway were examined. To establish these cultures, a sequential enzymatic digestion of testicular tubules from 5-day-old rats was used to obtain a cell suspension. This was plated with an addition of ECM overlay (150 μg/ml medium). MeHg (2.5μM), Lact (2.5 μM), MG (2.5 μM) and Cd (40 μM) were added to the culture medium 72h after plating. Morphological changes were monitored and photographed. Cells were harvested at 4, 8, and 24h after treatments and western blotting was performed using polyclonal antibodies to Phospho-p38 MAPK, p38 MAPK, AKT, Phospho-AKT, Phospho-SAPK/JNK, c-kit, and PARP. Exposure to Cd markedly increased the ubiquitin-conjugated proteins and also caused time-dependent activations of P-p38, P-SAPK/JNK and P-AKT. MeHg also increased ubiquitin-conjugated proteins and induced the P-p38 MAPK in a time dependent manner and marginally induced the P-SAPK/JNK phosphrylation. MG and Lact induced differential stress and ubiquitin signaling responses. The above results suggested that although the four chemicals increased the accumulation of ubiquitin-conjugated proteins, the molecular mechanisms appeared to be different. This study further confirmed that this co-culture system is useful for studying the molecular mechanism of the effects of developmental toxicants on Sertoli cells and/or spermatogonia. 1332 RECOMMENDED APPROACHES FOR THE EVALUATION OF TESTICULAR AND EPIDIDYMAL TOXICITY.

L. Lanning[1], D. M. Creasy[2], R. E. Chapin[3], P. C. Mann[4], N. J. Barlow[5], K. S. Regan[6] and D. G. Goodman[7]. *[1]Otsuka Maryland Research Institute, Rockville, MD, [2]Huntingdon Life Sciences, Huntingdon, United Kingdom, [3]Pfizer Inc., Groton, CT, [4]Experimental Pathology Laboratory NorthEast, Galena, MD, [5]CIIT Centers for Health Research, Research Triangle Park, NC, [6]Regan Path/Tox Services, Ashland, OH and [7]Covance Laboratories Inc., Vienna, VA.*

Histopathology is acknowledged as the most sensitive endpoint for detecting testicular toxicity. The tissues must be appropriately and consistently collected, fixed, trimmed, sectioned, stained, and presented to the pathologist for evaluation. The pathologist must have an adequate understanding of the organization and dynamics of spermatogenesis in the species under investigation. Understanding and using consistent terminology for the changes observed and grading the severity of those changes are also important issues in the reporting and interpretation of testicular histopathology. As such, this poster is intended to provide practical recommendations made by the Society of Toxicologic Pathology on how to use routine histopathology to promote accurate and consistent evaluation of the testis for toxicological changes. Most of the information relates to the rodent as the most common species used for evaluating male reproductive toxicity. Information pertaining to other less commonly used species such as the dog and nonhuman primate is included where appropriate. Our key recommendations are as follows. (1) The use of modified Davidson's fixative is the preferred fixative for testes with Bouin's fixative as a second choice. (2) The counting of stages of the spermatogenic cycle is valuable only in very specific circumstances, while evaluation of the testis by a pathologist who knows how each stage should appear (i.e., "stage-aware") is much more valuable. (3) Hematoxylin and eosin stains are appropriate for studies longer than 28 days, and PAS-H is recommended for shorter studies. (4) The nomenclature and severity grading for disturbances in spermatogenesis may vary on a case-by-case basis depending on the specificity of the findings.

1333 MALE RATS EXPOSED TO LORATADINE FROM GESTATION DAY 12 TO POSTNATAL DAY 4 DO NOT EXHIBIT ALTERATIONS IN ANDROGEN-MEDIATED REPRODUCTIVE DEVELOPMENT.

B. McIntyre, P. Vancutsem, K. Treinen and R. Morrissey. *Schering-Plough Research Institute, Lafayette, NJ.*

Male rats exposed to antihistamines (H_1 antagonists) exhibit species-specific testicular atrophy that is characterized by hypospermatogenesis, suggesting a potential antiandrogenic action. Since normal pre- and postnatal male reproductive development and function is dependent upon testicular androgen production and is sensitive to antiandrogenic perturbations, it was of interest to determine if loratadine had the potential to alter androgen-mediated reproductive development. Loratadine was administered orally by gavage to pregnant Sprague-Dawley rats (n = 20/group) at doses of 4, 12 or 24 mg/kg from gestation day 7 to postnatal day 4, the period encompassing androgen-dependent male reproductive development. Vehicle control rats received 0.4% aqueous methylcellulose. Dams were allowed to deliver naturally and rear their offspring until postnatal day 21. On postnatal day 21 male offspring were retained for postweaning measurements and the female offspring were euthanized and their sex confirmed internally. Males were necropsied on postnatal day 72 to 85. Dams administered 24 mg/kg of loratadine exhibited a transient 45% decrement in maternal body weight gain at the initiation of dosing (gestation days 7 to 9). Mean pup body weight on postnatal days 1 and 4 were approximately 4% lower than controls. No other effects on offspring growth were observed. Anogenital distance on postnatal day 1 was unaffected by loratadine exposure. Loratadine exposure did not induce the retention of nipples in male rats. Exposure to loratadine did not affect preputial separation or induce hypospadias. Seminal vesicle and prostate weights were unaffected by loratadine exposure. These data clearly demonstrate that loratadine is not an antiandrogen as evidenced by the absence of alterations or malformations in androgen-dependent reproductive tissues in loratadine-exposed male rats.

1334 DECREASED ANOGENITAL DISTANCE (AGD) AND UNDESCENDED TESTES IN FETUSES OF RATS GIVEN MONOBENZYL PHTHALATE (MBEP) DURING PREGNANCY.

M. Ema and E. Miyawaki. *Division of Risk Assessment, National Insitute of Health Sciences, Tokyo, Tokyo, Japan.*

We previously reported that administration of butyl benzyl phthalate (BBP) to pregnant rats during late pregnancy caused decreased AGD and undescended testes in male offspring. The present study was conducted to determine the adverse effects of MBeP, a major metabolite of BBP, on development of the reproductive system in male offspring following maternal administration during late pregnancy. Pregnant rats were given MBeP by gastric intubation at 167, 250, or 375 mg/kg on days 15 to 17 of pregnancy and fetuses were examined on day 21 of pregnancy. Maternal body weight gain and food consumption during the administration period were significantly decreased at 167 mg/kg and higher. No increase in the postimplantation loss was found after administration of MBeP. The body weights of male and female fetuses were significantly lower at 375 mg/kg. A significant decrease in the AGD of male fetuses was observed after administration of MBeP at 250 mg/kg and higher. The AGD/cube root of body weight ratio in male fetuses was also significantly reduced at 250 mg/kg and higher. The AGD and AGD/cube root of body weight ratio of female fetuses in the MBeP-treated groups were comparable to those in the control group. A significant increase in the incidence of fetuses with undescended testes was found at 250 mg/kg and higher. These findings indicate that MBeP during late pregnancy produces adverse effects on development of the male reproductive system and suggest that MBeP participates, at least in part, in the induction of the adverse effects of BBP.

1335 MOLECULAR CHARACTERIZATION OF THE DEVELOPING RAT WOLFFIAN DUCTS FOLLOWING *IN UTERO* EXPOSURE TO DI(*n*-BUTYL) PHTHALATE.

P. M. Foster[1], K. J. Turner[2], M. Sar[2], N. J. Barlow[2], K. W. Gaido[2] and C. J. Bowman[2]. *[1]NIEHS, Research Triangle Park, NC and [2]CIIT, Centers for Health Research, Research Triangle Park, NC.*

Di(*n*-butyl) phthalate (DBP), a common plasticizer and solvent, disrupts androgen-dependent male reproductive development in rats. *In utero* exposure to 500 mg/kg/day DBP on gestation days (GD) 12 to 21 inhibits androgen biosynthesis, resulting in a decrease in fetal testicular testosterone (T) levels. One consequence of prenatal DBP exposure is malformed epididymides (~50%) in adult rats. Reduced fetal T levels may be responsible for the malformation since T is required for stabilization of the Wolffian ducts and development into epididymides. Currently, little is understood about the molecular mechanisms of Wolffian duct differentiation. The objective of this study was to investigate the molecular mechanisms of DBP-induced morphological disruption of the developing Wolffian ducts. Pregnant Crl:CD(SD)BR rats were gavaged with corn oil vehicle or 500 mg/kg/day DBP from GD 12 to termination on GD 19 or 21. There was no observable morphological difference between control and DBP-exposed Wolffian ducts on GD 19. On GD 21, 89% of male fetuses in the DBP dose group had underdeveloped Wolffian ducts with decreased coiling. RNA was isolated on GD 19 and 21 and analyzed using cDNA microarrays. These analyses identified several genes involved in tissue differentiation that may be associated with the morphological changes observed on GD 21. Significant changes in mRNA expression within the insulin-like growth factor (IGF) and fibroblast growth factor (FGF) pathways, matrix metalloproteinase (MMP) family, and components of the extracellular matrix were confirmed by real-time RT-PCR. Gene expression of IGF1, IGF2, and members of the MMP family was significantly increased with DBP exposure compared to controls on both GD 19 and 21. The mRNAs for FGF10, FGFR2, collagen, and fibronectin were increased only on GD 21. This study provides valuable insights into the molecular mechanisms of Wolffian duct differentiation and the effects of antiandrogens on duct development.

1336 EFFECTS OF *IN UTERO* EXPOSURE TO FINASTERIDE ON ANDROGEN-DEPENDENT REPRODUCTIVE DEVELOPMENT IN THE MALE RAT.

C. J. Bowman[1], N. J. Barlow[1], K. J. Turner[1], D. G. Wallace[1] and P. M. Foster[2]. *[1]CIIT, Centers for Health Research, Research Triangle Park, NC and [2]NIEHS, Research Triangle Park, NC.*

Finasteride is a specific inhibitor of type II 5α-reductase, the enzyme that converts testosterone to the more potent androgen receptor (AR) agonist dihydrotestosterone. Finasteride induces similar reproductive and developmental effects as those observed following *in utero* exposure to AR antagonists. Previous reports have concluded that decreased anogenital distance (AGD) and increased nipple retention observed in early postnatal life are not maintained in adulthood following *in utero* exposure to finasteride. In contrast, other antiandrogens have been shown to induce permanent effects on these androgen-sensitive end points. The objective of this study was to correlate changes in androgen-dependent end points in early postnatal life and at sexual maturity in the same animal over a range of doses. Pregnant Crl:CD(SD)BR rats (n = 5-6/group) were gavaged with either corn oil vehicle or finasteride at 0.01, 0.1, 1.0, 10, or 100 mg/kg/day on gestation days 12 to 21. All male offspring were monitored individually until necropsy on postnatal day (PND) 90. In early postnatal life, decreased AGD (on PND 1) and increased areolae-nipple retention (on PND 13) were significantly different from controls in all finasteride-exposed animals. Significant effects on decreased AGD and retained nipples were still seen on PND 90 in the animals exposed to finasteride at 0.1 mg/kg/day and above. Dorsolateral and ventral prostate weights were significantly decreased at and above 10 mg/kg/day on PND 90. Absence of prostates and bulbourethral glands was observed at the higher dose levels. In the highest dose group, the incidence of hypospadias and ectopic testes was 88 and 73%, respectively. The incidence of undescended testes was much higher than previously reported. The NOAEL for finasteride based on permanent effects in this study was 0.01 mg/kg/day. This is the first report to demonstrate that *in utero* exposure to finasteride results in a significant and permanent retention of nipples and reduction in AGD in sexually mature animals.

1337 EFFECTS OF *IN UTERO* EXPOSURE T0 LINURON ON RAT WOLFFIAN DUCT DEVELOPMENT.

K. J. Turner[1], B. S. McIntyre[1], S. L. Phillips[1], N. J. Barlow[1], C. J. Bowman[1] and P. M. Foster[2]. *[1]CIIT Centers for Health Research, Research Triangle Park, NC and [2]NIEHS, Rsearch Triangle Park, NC.*

Prenatal exposure to linuron, a weak competitive androgen receptor (AR) antagonist, perturbs androgen-dependent male rat reproductive development, resulting in epididymal malformations in combination with testicular atrophy in adulthood. Exposure to 50 mg/kg/day linuron on gestation days (GD) 12 to 21 results in epididymal malformations (~25% of rats) that can be observed on postnatal day (PND) 7. Studies were undertaken to identify potential molecular mechanisms associated with antiandrogen perturbation of Wolffian duct development into the epididymis. Pregnant Sprague-Dawley CD rats were gavaged with corn oil vehicle or linuron (50 mg/kg/day) from GD 12 to 21. Gene and protein expression was examined in testes on GD 21 and epididymides on GD 21 and PND 7. On GD 21, ~40% of epididymides from linuron-exposed rats showed decreased ductal coiling or were malformed. Linuron-mediated changes in testicular and epididymal mRNA expression were identified using cDNA microarrays and alterations in gene expression confirmed by real-time RT-PCR. Linuron exposure did not reduce mRNA expression of the AR or that of several steroidogenic enzymes in the fetal testis, which is in agreement with a previous study demonstrating that linuron exposure did not reduce fetal testosterone production. Significant changes in mRNA expression in GD 21 and PND 7 epididymides were identified in the bone morphogenetic protein, insulin-like growth factor, epidermal growth factor, fibroblast growth factor, and notch signaling pathways. These signaling pathways have been shown to be involved in tissue morphogenesis. Changes in the immunolocalization of AR and insulin-like growth factor receptor were observed in epididymides from linuron-exposed rats. This study has identified several highly conserved signaling pathways that are disrupted by linuron exposure, suggesting that they are involved in testosterone-mediated development of the Wolffian duct.

1338 EFFECTS FROM GESTATIONAL EXPOSURE TO A MIXTURE OF ATRAZINE AND ITS BIOLOGICAL METABOLITES IN MALE LONG-EVANS RATS.

R. Enoch[1], S. Greiner[2], G. Youngblood[2], C. Davis[2] and S. E. Fenton[2]. *[1]Biology, NCCU, Durham, NC and [2]RTD, NHEERL, ORD, USEPA, Research Triangle Park, NC.*

In order to characterize the potential developmental effects of atrazine (ATR) metabolites, we tested an environmentally-based mixture (EBM) of ATR (25%), and its metabolites hydroxyatrazine (20%), diaminochlorotriazine (35%), deethyl atrazine (15%) and deisopropyl atrazine (5%), based on published maximum ATR and metabolite concentrations in ground and surface water (estimated at 25 ppb, 1X). Pregnant Long Evans rats (N>8/dose) were gavaged with 0, 0.09, 0.9 or 8.729 mg/kg/d EBM on gestation days 15-19. These doses were based on estimated adult consumption and were 100, 1000, or 10000X, the 1X basis of total chlorotriazines. In male offspring, body weight (BW) did not differ by treatment on PND4, 21, or 120. Preputial separation (PPS) in controls occurred on PND 41.9±0.4, and EBM PPS was statistically delayed (means ranged from PND 43.0±0.5 to 43.6±0.7; P=0.05). BW at PPS of EBM-exposed males (range of means 238.6± 5 to 254.1± 6) was greater than control males (223.6±5.2g; P<0.01). At PND 120, EBM exposed males exhibited a dose-dependent increase in anterior pituitary gland weight when compared to controls (range of means 10.6±0.2 to 11.3±0.4 vs. 9.3±0.7mg; P<0.001). There was a dose-dependent decrease in ventral prostate weight due to EBM exposure (range of means 410±20 to 380±20 vs. 450±20mg; P=0.01), although the lateral prostate, testes, and seminal vesicle weights were unaffected when compared with controls. Also at PND 120, the EBM-exposed males (range of means 45.6±7.7 to 47.9±5.5 ng/ml) displayed a significant increase in serum estrone vs. control (28.9±2.5 ng/ml; P<0.01). Concentrations of serum and pituitary prolactin, serum estradiol, testosterone, and thyroid stimulating hormone were not different among dose groups. These data suggest that EBM delayed puberty without effect on body weight, and was capable of altering endocrine and reproductive tract endpoints. *(This is an abstract of a proposed presentation and does not necessarily reflect EPA policy. Supported by NHEERL Minority Training Agreement).*

1339 UVA EXPOSURE INCREASES XANTHOTOXIN-INDUCED GAMETE DNA DAMAGE IN MALE RATS.

M. M. Diawara, J. Carsella and D. Caprioglio. *Biology, University of Southern Colorado, Pueblo, CO.*

Previous research has shown that Wistar rats dosed with xanthotoxin (8-methoxypsoralen) have low birth rates when either the male or female in a mated pair is exposed. Reduced sperm counts, reduced litter size and birth defects were also exhibited when only the males were dosed and mated with undosed females, suggesting a direct adverse effect on the sperm. This was accompanied by teratogenic effects in offspring of naive females mated to dosed males. Therefore, the current study was initiated to see if xanthotoxin exposure would damage the DNA of rat spermatozoa. A comet assay protocol was developed to check the DNA of Spermatozoa for damage. Spermatozoa samples were collected from the testes of mature rats and reacted with varying concentrations of xanthotoxin (0, 2, 4, 6, 8, 10 mg/ml Acetone solution). Some of the treated samples were exposed to long-range UVA radiation and some were not. Samples were then digested with proteinase K in 1% SDS and TES buffer for 60 minutes. The cells were placed in a low melting point gel and then lysed. DNA damage in the samples was checked by Comet assay. The images

were gathered using a fluorescence microscope and analyzed by computer. The moments (ratio of nucleus to tail for each gamete) collected from groups of comets were statistically tested and means separated at the 5% level. The results indicate that the treated, irradiated sperm samples sustained significantly more damage than untreated samples. The assay also illustrates that the treated, non-irradiated sperm samples sustained significantly more damage than the untreated samples. The damage in these sperm samples occurred in a dose-dependant manner. The results suggest that the psoralens could compromise reproductive function in a naive female by indirect effect through the seminal fluid.

1340 FETAL TESTICULAR GENE EXPRESSION FOLLOWING *IN UTERO* EXPOSURE TO DI(*N*-BUTYL) PHTHALATE: ALTERATION OF KEY ANDROGEN-RELATED GENES.

N. J. Barlow[1], S. L. Phillips[1], D. G. Wallace[1], M. Sar[1], K. W. Gaido[1] and P. M. Foster[2]. *[1]CIIT Centers for Health Research, Research Triangle Park, NC and [2]NIEHS, Research Triangle Park, NC.*

Di(n-butyl) phthalate (DBP) has been shown to alter male reproductive development by decreasing fetal testicular testosterone (T) when fetuses are exposed on gestation days (GD) 12 to 21. Earlier findings indicated that there were changes in gene expression for several enzymes in the steroidogenic pathway and for a variety of other androgen-related genes. The objective of this study was to build on the previous data by using increased numbers of dams and fetuses to confirm these findings and to examine changes in gene expression for additional genes in the T biosynthetic pathway. Pregnant Crl:CD(SD)BR rats (n = 6-7 dams/group) were dosed by gavage with corn oil vehicle or DBP at 500 mg/kg/day on GD 12 to 19. Testicular mRNA isolated from three random individual GD 19 fetuses per litter was used for real-time quantitative PCR for the following genes: scavenger receptor (SRB1), steroidogenic acute regulatory protein (StAR), cholesterol side-chain cleavage enzyme (P450scc), 3β-hydroxysteroid dehydrogenase (3β-HSD), 17α-hydroxylase/17, 20-lyase (P450c17), 17β-hydroxysteroid dehydrogenase (17β-HSD), androgen receptor (AR), c-kit receptor (c-kit), proliferating cell nuclear antigen (PCNA), and testosterone-repressed prostate message-2 (TRPM-2). Following DBP exposure, there was downregulation of the following genes: SRB1, StAR, P450scc, 3β-HSD, P450c17, and c-kit; there was upregulation of TRPM-2. 17β-HSD, AR, and PCNA were not significantly changed. Downregulation of genes in the testosterone biosynthetic pathway confirms and extends previous findings and supports diminished T synthesis as the cause of reduced fetal testicular T observed following *in utero* exposure to DBP. A decrease in androgen levels was further supported by altered expression of other androgen-related genes such as TRPM-2. These data strongly support a generalized effect on steroidogenesis in fetal Leydig cells versus blockade of a single enzyme or protein in the steroidogenic pathway.

1341 TOXICOLOGY: ETHICAL, LEGAL, AND SOCIAL ISSUES.

S. G. Gilbert[1], W. Burke[3], E. Faustman[2], J. R. Botkin[4] and P. Gilman[5]. *[1]INND, Seattle, WA, [2]Department of Environmental Health, University of Washington, Seattle, WA, [3]Department of Medical History & Ethics, University of Washington, Seattle, WA, [4]Department of Pediatrics and Medical Ethics, University of Utah, Salt Lake City, UT and [5]USEPA, Washington, DC.*

Through an emphasis on exposure/response and mechanistic based research, the toxicological sciences exert an increasing influence on bioethical thinking and societal decision-making. Results from toxicology research have motivated many regulatory and legal actions, and public policy decisions, including the banning of some pesticides, reducing exposure in the workplace, and lowering of acceptable blood lead levels in children. Ongoing advances in the genomic and toxicological sciences continue to emphasis the importance of considering individual sensitivity and particularly the susceptibility of children. This session will explore the ethical, legal and social issues raised by the toxicological sciences by examining some of the difficult policy and research decisions that must be made as we address our need for additional information about the health effects of chemicals on adults and children and the impact of having this information. The objectives of this session are: 1) to explore the contributions and implications of toxicological research on bioethical thinking and public policy, and 2) to provide a forum for discussion of ethical issues raised by current and future toxicological and genomic based research. This session will be of interest to toxicologists concerned about the broader impact of our research on bioethical and societal decision-making.

1342 GENOMIC AND PROTEOMIC ANALYSIS OF SURROGATE TISSUES FOR ASSESSING TOXIC EXPOSURES AND DISEASE STATES.

D. J. Dix and J. Rockett. *Reproductive Toxicology, NHEERL, ORD, USEPA, Research Triangle Park, NC.*

Genomics and proteomics have made it possible to define molecular physiology in exquisite detail, when tissues are accessible for sampling. However, many tissues are not accessible for human diagnostic evaluations or experimental studies, creating the need for surrogates that afford insight into exposures and effects in such tissues. Surrogate tissue analysis (STA) incorporating contemporary genomic and proteomic technologies may be useful in determining toxicant exposure and effect, or disease state, in target tissues at the pre- or early clinical stage. In this symposium, speakers will discuss various applications of STA, including the use of peripheral blood lymphocytes (PBLs) as a source of biomarkers for radiation exposure; the use of PBLs and hair follicles to monitor the impact of toxicants on organs such as liver and testis; the use of mRNA in sperm to determine genetic and environmental effects on male fertility; and the use of serum protein profiles to monitor for ovarian cancer. The symposium will conclude with a discussion of the challenges of validating surrogate tissue fidelity and sensitivity. This is an abstract of a proposed symposium and does not necessarily reflect EPA policy.

1343 GENE EXPRESSION PROFILING OF ACCESSIBLE SURROGATE TISSUES TO MONITOR MOLECULAR CHANGES IN INACCESSIBLE TARGET TISSUES FOLLOWING TOXICANT EXPOSURE.

J. C. Rockett, C. Blystone, A. Goetz, R. Murrell and D. J. Dix. *Reproductive Toxicology Division, USEPA, Research Triangle Park, NC.*

Gene expression profiling (GEP) offers the potential to classify toxicant exposures, predict clinical outcome of such exposures, and provide mechanistic data useful for risk assessments. It could ultimately provide a vehicle for developing early diagnostic and preventative measures in at-risk populations or individuals. However, using GEP to monitor the impact of toxicant exposures on inaccessible tissues is a difficult prospect, since direct biopsy of such tissues is not feasible. A less invasive method must therefore be developed. We propose that gene expression changes in accessible (surrogate) tissues (e.g. blood) often reflect those in inaccessible (target) tissues, thus offering a convenient biomonitoring method to provide insight into the effects of environmental toxicants on target tissues. GEP of surrogate and target tissues have compared following exposure of animal models to model compounds and environmental toxicants. In an initial pilot study, gene expression changes in peripheral blood lymphocytes (PBLs) were compared to those in the uteri of adult rats to identify genes that were altered in both tissues following estradiol treatment. Ovariectomized rats were treated with either 17-b-estradiol or vehicle control for 3 days. PBL and uterine RNAs were hybridized to arrays containing 1185 genes. A number of genes (e.g. jun-D, phospholipase A2, thymidine kinase) were found to demonstrate a similar degree of expression change that was treatment-, but not tissue-specific. This indicates that accessible tissues such as PBLs can serve as surrogate tissues for observing gene expression changes in the uterus following chemical exposure, and provides supportive evidence for the surrogate tissue analysis concept. This presentation will also discuss data from a follow-up study, currently in progress, in which GEP of a variety of surrogate and target tissues is being conducted in rodent models exposed to conazoles. This is an abstract of a proposed presentation and does not necessarily reflect EPA policy.

1344 THE MALE GAMETE AS A PATERNAL MARKER OF GENETIC INSULT.

S. A. Krawetz[1,2,3], G. Ostermeier[1], K. E. Thompson[4], D. J. Dix[4], D. Miller[5], R. Goodrich[1,2,3] and M. P. Diamond[1,3]. *[1]Department of Ob/Gyn, Wayne State University, Detroit, MI, [2]Molecular Medicine and Genetics, Institute of Science and Computing, Wayne State University, Detroit, MI, [3]NICHD Reproductive Medicine Network, Wayne State University, Detroit, MI, [4]Reproductive Toxicology Division, NHEERL, ORD, USEPA, Research Triangle Park, NC and [5]Department of Ob/Gyn, University of Leeds, Leeds, Yorkshire, United Kingdom.*

The primary goal of systems biology is to understand the mechanisms of development in the normal and diseased states. This reflects the selective activation of the 40, 000-80, 000 genes that are encoded by our genome. The self renewing system of spermatogenesis provides an excellent model to address how this program is articulated. The recent demonstration that ejaculated spermatozoa contain sufficient mRNA for analysis uniquely positions us to begin to address the direct impact of the environment on the paternal genome. We know that environment, e.g. cigarettes, alcohol, caffeine and heavy metals, has a direct effect. This raises the question: what is the genetic load that the sperm will bring to a new being? Answering this question will fill a significant gap in our understanding of the healthy child. We will review the results of our methods and analyses showing that human sperm do indeed carry a wide spectrum of RNAs to the egg. This will include a microarray survey of 20, 002 expressed sequences. Analysis of this data using Onto-Express has revealed that some sperm mRNAs may impact post-fertilization. With this enabling foundation in place, we will also explore the use of sperm RNA as a biomarker of the "fitness and exposure of the male gamete." Data will be presented from our ongoing human studies and complementary toxicological studies profiling sperm mRNAs in rodents exposed to effective doses of reproductive toxicants.

This work was funded in part by NIH grant HD36512 and WSU grant 95200 to SAK; NIH grant HD39005 to MPD and by the US Environmental Protection Agency to D.D. GCO is supported in part by a WSU Deans PDF award and the NICHD CIR-LRP. This abstract of a proposed presentation does not necessarily reflect EPA policy.

1345 GENE EXPRESSION IN RESPONSE TO LOW DOSE IONIZING RADIATION: A FUNCTIONAL GENOMICS APPROACH.

A. J. Fornace, S. A. Amundson, C. Koch-Paiz and R. Lee. *Center for Cancer Research, National Cancer Institute, Bethesda, MD.* Sponsor: J. Rockett.

Gene expression changes occur in both human and murine cells in response to doses of radiation of 10 cGy and less. Using a quantitative single-probe hybridization method to accurately measure increases in mRNA levels relative to untreated cells, we have demonstrated a linear non-threshold response for multiple stress genes in the human p53-wt myeloid ML-1 line, and in human peripheral blood lymphocytes (PBL) irradiated *ex vivo*. Similar responses are also emerging in mice irradiated *in vivo*. cDNA microarray hybridization analysis was used to identify radiation-regulated genes that could potentially serve as biomarkers of radiation exposure. Initial studies identified several genes significantly up-regulated in human PBL between 24 & 72 hours after *ex vivo* irradiation. Three of these genes, DDB2, CDKN1A (CIP1/WAF1) and XPC, were induced in a linear fashion between 0.2 and 2 Gy at 24 & 48 hours after treatment, with less linearity at earlier or later times. These and other strongly radiation responsive genes are p53-regulated, indicating a major role for p53 in mediating radiation gene responses in PBL (and probably other primary cells). These results support the use of peripheral blood cells as an accessible and sensitive indicator of radiation exposure, and begin laying the foundation for expression profiles that may someday provide signatures for past radiation exposure. Reducing the dose-rate of exposure of ML-1 cells across 3 orders of magnitude shows a trend toward protection from apoptosis, and attenuated induction of GADD45A and CDKN1A. In contrast, there was no change in induction of MDM2. Clustering of cDNA microarray analysis results obtained from irradiations carried out at different dose-rates indicates 2 distinct groups of responding genes: a group of genes with attenuated induction at low dose-rates, and a group of genes with similar or possibly enhanced induction by low dose-rate exposure. Further analysis of these 2 classes of responding genes may provide key insights into the molecular mechanisms of radiation response and tolerance.

1346 SERUM PROTEOMIC PATTERN DIAGNOSTICS: USE OF ARTIFICIAL INTELLIGENCE BIOINFORMATICS TO DISCOVER SURROGATE MARKERS FOR EARLY DISEASE.

E. Petricoin. *Center for Biologics Evaluation and Research, Food and Drug Administration, Bethesda, MD.* Sponsor: J. Rockett.

The need for specific and sensitive surrogate markers for the presence of ovarian cancer is critical. Currently there is no effective screening options available for the patients with the ovarian cancer. CA125, the most widely used biomarker for ovarian cancer does not have a high positive predictive value and it is only effective when used in combination with other diagnostic tests. Unfortunately, ovarian cancer presents at a late clinical stage in over 80% of patients and is associated with an abysmal 5-year survival of 35%. In contrast, the 5-year survival for stage I ovarian cancer patients is in excess of 90%, with most patients cured of their disease by surgery alone. In contrast to past strategies where a single biomarker is used as a discriminator, we propose a new paradigm for biomarker discovery and profiling that is based on a multitude of proteomic patterns as the diagnostic endpoint in and of itself. We speculated that pathologic changes within an organ might be reflected in the serum as a surrogate proteomic patterns. Low-molecular weight proteins and peptides may provide the most target rich information archive since these molecules are most likely aberrantly secreted, clipped or shed as a cause or consequence of the disease and are deposited in the circulating serum. Serum analysis coupled with high-throughput robotic handling stations and rapid mass spectroscopy proteomic pattern generation allowed us to utilize artificial-intelligence based systems to uncover hidden diagnostic signatures. We have achieved a 99% sensitivity and 99% specificity in over 250 patient samples analyzed to date, including 100% of the 35 early stage I cancer patients, making this technique a clinical possibility.

1347 FUNDAMENTALS OF PROTEIN ALLERGENICITY: WHY ARE SOME PROTEINS ALLERGENIC?

K. Sarlo[1] and I. Kimber[2]. [1]*Procter & Gamble Co., Cincinnati, OH and* [2]*Syngenta Central Toxicology Laboratory, Macclesfield, United Kingdom.*

For a variety of reasons the toxicology of protein allergenicity has assumed greater significance. There is an increasing prevalence of atopic diseases in westernized populations, the use of protein and peptides in therapeutics and in consumer products is growing, and evaluation of potential allergenicity is a major issue in the safety assessment of novel foods, including foods derived from genetically modified crops. The questions that must be addressed are whether proteins and peptides have the inherent potential to cause sensitization and whether under the likely conditions of exposure this intrinsic hazard will translate into a risk of human allergic disease. With respect to the first of these questions a pivotal consideration is definition of the characteristics that confer on proteins the ability to cause allergic sensitization, or alternatively, what distinguishes protein allergens from other foreign proteins that despite being potentially immunogenic fail to induce sensitization. Among the features that are believed to influence sensitizing properties are: size, stability, glycosylation status and the way in which the protein is recognized, internalized and processed by the immune system. The purpose here is to examine the contribution of these variables to inherent sensitizing potential as a basis for future safety assessment strategies. With respect to the second question, one must consider how the allergenic potential and potency of the protein in combination with exposure translates into a risk for developing allergy.

1348 IMMUNOBIOLOGY OF SENSITIZATION BY PROTEIN ALLERGENS.

I. Kimber and R. J. Dearman. *Syngenta Central Toxicology Laboratory, Macclesfield, CHESHIRE, United Kingdom.*

Allergy induced by proteins may take a variety of forms. In many (but not all) instances allergic reactions are provoked by IgE antibody-dependent mechanisms and the acquisition of sensitization requires the stimulation of an IgE antibody response. The initiation and maintenance of IgE production are highly regulated by functional subpopulations of T lymphocytes and their cytokine products. Type 2 T helper (Th2) cells secrete cytokines such as interleukins 4, 5, 10 and 13 that support IgE antibody responses and facilitate the elicitation of IgE-mediated allergic hypersensitivity reactions. In contrast, products of Th1-type, and of T cytotoxic type 1 (Tc1) cells, and in particular interferon gamma, antagonize IgE responses. The initiation of specific IgE antibody production and the development of allergic sensitzation are dependent upon the characteristics of the protein itself (size, stability, glycosylation status and the way in which it is processed and presented to the immune system), the extent, duration and route of exposure and the age at which exposure occurs, and genetic and acquired predisposition (and particularly inheritance of an atopic phenotype). The immunobiology of sensitization will be considered in the context of both the inherent allergenic potential of proteins and the variables that determine individual susceptibility to allergic disease.

1349 STRUCTURAL BIOLOGY OF PROTEIN ALLERGENS.

R. C. Aalberse. *Immunopathology, Sanquin Research at CLB, Amsterdam, Noord Holland, Netherlands.* Sponsor: I. Kimber.

Size and solubility.The requirement for physical contact between protein and cell defines requirements for solubility and size, particularly allergens that enter the body by crossing a mucosal barrier (airways, gastro-intestinal tract). Typically, such allergens are soluble in aqueous buffers and have a molecular mass between 10 and 100 kD. Larger proteins may become allergenic upon limited proteolytic degradation. Smaller molecules may become allergenic upon linkage to a carrier protein. Stability is an issue primarily for food allergens (resistance to thermal denaturation and to gastric/intestinal juice). Glycosylation affects allergenicity in two ways. Glycans may influence stability. Moreover, glycans may be contact sites for IgE antibodies. Glycan allergenicity is mainly an issue in relation to non-mammalian glycoproteins, particularly plants and invertebrates. A common glycan structure is called the Crossreactive Carbohydrate Determinant (CCD). Since glycans are attached *via* post-translational mechanisms, their presence in recombinant glycoproteins depends on the expression system. Cross-reactivity may result in allergic symptoms without a prior contact. In some cases in-vitro tests indicate that a protein has IgE-binding activity, whereas in-vivo exposure does not result in symptoms. This discrepancy may be due to cross-reactivity that is apparent only *in vitro* (e.g. because of low affinity or because only a single cross-reactive epitope is present whereas biological activity requires multiple epitopes). Two proteins will be cross-reactive only if they (or their domains) belong to a similar protein fold family. However, a similar fold does not suffice: a substantial degree of amino acid identity is required, usually more than 60%. A crucial feature of IgE-mediated allergy is the involvement of TH2 cells. Since human IgG4 antibodies are also TH2-dependent, the induction of IgG4 antibodies can be used as surrogate marker for allergenic potential. An important feature of allergenic source materials is that they do not contain substances that stimulate TH1 responses (such as bacterial cell wall material), which down-regulate TH2 responses.

1350 FOOLING MOTHER NATURE: CAN PROTEIN ALLERGENS BE MADE HYPOALLERGENIC?

F. A. Harding. *Immunology, Genencor International, Palo Alto, CA.* Sponsor: K. Sarlo.

The critical role for CD4+ T cell activation in the induction of respiratory allergy has been clearly shown. T cell activation is dependent on a number of variables including the quality of the T cell receptor (TCR) signaling and the microenvironmental milieu. The component of antigen recognized by CD4+ TCRs is 10+/-2 amino acid fragments derived from the linear sequence. Peptides are bound by their receptor, HLA class II, and are displayed on the surface of antigen-presenting cells. A tri-molecular complex of HLA, peptide and TCR must form in order for antigen-specific signaling to occur. Interfering with this assembly by disabling any one of the components would obviate antigen-specific CD4+ T cell signaling, and by extension, any subsequent immune response including the induction of allergy. A number of mechanisms can be envisioned to interfere with the assembly of the tri-molecular complex. The derivation of peptide fragments from the antigen is a process that involves a number of well-characterized proteolytic enzymes. Modifying the protein sequence to inhibit or upregulate enzymatic processing is one technique currently under study. A second method is the modification of immunogenic peptide epitopes to interfere with either binding to HLA or to the TCR. In order to create hypo-immunogenic proteins, we are currently using the latter approach, while investigating the utility of the former. We have designed a functional assay that allows for the localization of immunodominant CD4+ T cell epitopes in any protein of interest. This information makes it possible to create protein variants with reduced capacity to induce immune responses. In our assay, CD4+ T cell epitopes are determined on a human population basis. Using this knowledge coupled with our ability to efficiently and rationally modify, express and screen protein variants, we have created active protein variants with reduced immunogenic potential that are specifically designed for the human population. Examples of this technique will be shown, using *in vivo* and *in vitro* methods to validate our approach. We think that yes, it is possible to fool Mother Nature!

1351 PROTEIN ALLERGENICITY: CHALLENGES FOR THE TOXICOLOGIST.

K. Sarlo. *Procter & Gamble Co., Cincinnati, OH.*

To assess the risk of developing allergy to protein, one must understand the inherent allergenic potential of the protein, how individuals will be exposed to this protein and the likelihood that this exposure can lead to allergy. *In vitro* tests to assess allergenic potential are in their infancy and *in vivo* animal models have not been fully developed and validated for a wide range of proteins. The questions of choice of species, which endpoints to measure, route of exposure and use of adjuvant all add complexity. For enzymes used by the detergent industry, animal models have provided data on inherent allergenic potency of enzymes and enzyme mixtures. These data were generated on relevant endpoints (allergic antibody) using a relevant route of exposure (respiratory tract) and have been used to set exposure guidelines to minimize sensitization among workers. Prospective surveillance of the worker population confirmed the assessments made in the animal models. By keeping exposure low, the rate of sensitization is low and this reduces the risk of disease among workers to near zero. This points to another area of complexity for protein allergy: how does one identify the thresholds for sensitization vs. disease and how does one use this information to manage protein allergens? We have some knowledge on the sensitizing and non-sensitizing exposure conditions for enzymes used in laundry products and personal cleansing applications. Via retrospective and prospective clinical evaluation of exposed populations, we are beginning to understand how intensity of exposure is related to sensitization and disease. Incorporating hazard information on an enzyme with the exposure assessment, we can compare to known exposures to predict the likelihood of sensitization. Prospective clinical testing is used when there is uncertainty in the comparisons. This risk assessment approach has supported the safe use of enzymes. Whether this approach can be applied to other proteins or to other modes of exposure (e.g., ingestion) remains to be seen.

1352 DOSE-DEPENDENT TRANSITIONS IN TOXIC MECHANISMS.

W. Slikker[1] and K. B. Wallace[2]. *[1]Division of Neurotoxicology, NCTR/USFDA, Jefferson, AR and [2]Department of Biochem & Mol Bio, University of Minnesota, Duluth, MN.*

As experience with dose-response and mechanism expands, it is evident that multiple mechanisms may exist for any given agent as the full dose-response curve is explored. It is highly likely that critical, limiting steps in any given mechanistic pathway may become overwhelmed with increasing exposures, signaling the emergence of new modalities of toxic tissue injury at these higher doses. Therefore, dose-dependent transitions in the principal mechanism of toxicity may occur and could have significant impact on the interpretation of data sets for risk assessment. The purpose of this Workshop is to serve as a reference around the principle that each saturable or inducible process that occurs as part of the overall chemical disposition and biological response represents a potential point of departure from linearity in the dose-response relationship. Major objectives are to document and establish methods for identifying that dose-dependent transitions in mechanism can occur and to discuss potential impacts of this phenomenon on the risk assessment process. Individual case studies that exemplify this phenomenon including butadiene, vinyl chloride, vinylidene chloride, vinyl acetate, formaldehyde and progesterone will be presented. The impact of these and other examples on risk assessment procedures will be presented. This timely topic should be of interest to basic researchers, modelers and risk assessors.

1353 DOSE, TISSUE AND SPECIES TRANSISTIONS IN BIOMARKERS.

J. A. Swenberg. *Environmental Sciences and Engineering, University of North Carolina, Chapel Hill, NC.*

DNA and hemoglobin adducts represent biomarkers of exposure that integrate bioactivation, detoxication and DNA repair. As such, they provide excellent data for understanding mechanisms that drive the carcinogenic process and for improving risk assessment. The two chemicals highlighted in this presentation, vinyl chloride (VC) and butadiene (BD), have been extensively studied. VC is metabolized by CYP2E1 in a saturable manner. It exhibits two transitions of interest. Its metabolism is linear at low concentrations and becomes saturated at concentrations >100 ppm. Since the ultimate carcinogen, 2-chloroethylene oxide, is highly reactive and unstable, it does not get transported to tissues distant to the site of metabolic activation. Thus, liver, but not brain DNA becomes alkylated. However, all tissues examined to date from non-exposed animal and human tissues contain identical DNA adducts that arise endogenously from lipid peroxidation. Interpolation of data from control and VC-exposed rat livers (10 ppm, 4 wks, 6 hr/day) demonstrated that low exposures typical of current occupational exposure would represent 5% and 50% increases over the identical endogenous DNA adducts for exposures to 0.1 and 1.0 ppm VC, respectively. BD is much more complex, with at least four different electrophiles being formed, which vary in mutagenic potency by at least 200-fold, and differ greatly by species. Both linear and nonlinear responses exist over a wide range of exposures. Furthermore, the epoxide metabolites are relatively stable and circulate to distant tissues. We have developed a battery of biomarkers for the metabolites of BD. These have been applied to tissues and globin from rats and mice. In addition, we have examined the same biomarkers in globin in humans. It is critical that a correct understanding of species differences be utilized in scientifically-based risk assessment.

1354 CASE STUDIES OF FORMALDEHYDE AND HYDROXYFLUTAMIDE: EVIDENCE FOR DOSE-DEPENDENT TRANSITIONS IN MECHANISMS DUE TO ALTERED HOMEOSTASIS AND RECEPTOR MEDIATED INTERACTIONS.

R. Conolly. *CIIT Centers for Health Research, Research Triangle Park, NC.*

Nonmonotonic dose-response curves, including thresholds and J-shapes, can arise when a chemical exerts different effects at different doses. With formaldehyde, a J-shaped curve for tumor formation in F344 rats may occur when cell division is depressed at low inhaled concentrations (≤ 2 ppm) but increased at higher, cytolethal concentrations. Depression of the division rate is associated with formation of DNA-protein cross-links (DPX) that may invoke cell cycle checkpoint controls or may physically block the replication complex. At higher concentrations, formaldehyde is cytolethal and regenerative proliferation drives the division rate above control levels. The summation of these low- and high-concentration effects provides an overall J-shaped dose response for cell division. When this dose-response is linked to tumor formation through a 2-stage clonal growth model, a J-shaped dose-response for tumor formation is predicted, even in the presence of a low dose linear, directly mutagenic effect whose magnitude is proportional to the DPX burden. J-shaped dose-response behaviors can also arise when two chemicals interact within a single mode of action. Dihydrotestosterone (DHT) and hydroxyflutamide (OHF) together produce a J-shaped curve for gene expression mediated by the androgen receptor (AR) in a HepG2 cell line using a luciferase reporter gene. DHT and OHF are both substrates for the AR. 10E-7 M DHT is used to generate a maximal rate of gene transcription, and the J-shaped dose-response for OHF arises in the presence of the DHT. The J-shape may be explained by a relative inefficiency of DHT-OHF heterodimers for promotion of gene transcription given efficient promotion by DHT and OHF homodimers. These two examples illustrate alternative mecha-

nisms whereby significant dose-dependent transitions can occur. The common theme in these examples is the need for at least two effectors of the dose-dependent transition, either two interacting modes of action or two chemicals interacting within a single mode of action.

1355 DOSE-DEPENDENT TRANSITIONS IN VINYL ACETATE AND VINYLIDENE CHLORIDE TOXICITY: TWO CASE EXAMPLES SUGGESTIVE OF IMPACTS ON BIOLOGICAL RESERVE CAPACITY.

M. S. Bogdanffy and R. A. Kemper. *Haskell Laboratory, DuPont, Newark, DE.*

Non-linear dose response curves in toxicology studies suggest modes of action in which a shift in the dominance of critical kinetic or dynamic determinants has occurred. Vinyl acetate and vinylidene chloride (VDC) are two examples where sharp changes in the shape of the dose response curve occur over a discrete dose range. Although the modes of action and target organs for toxicity are very different for these two compounds, together they illustrate the fundamental concept that alterations of cellular defenses beyond homeostatic bounds can yield the observed transition in dose response behavior. Vinyl acetate causes nasal olfactory degeneration, cellular proliferation and nasal tumors at high exposure levels. The mode of action is believed to be related to intracellular acidification, which results from metabolic formation of acetate, followed by cytotoxic or mitogenic cellular proliferation. Proliferation, in the presence of metabolically formed acetaldehyde, provides the driver for mutation and eventually cancer. All of these critical steps are present only at high exposure levels. Modeling and *in vitro* studies suggest that intracellular pH must be perturbed beyond homeostatic bounds to permit the subsequent mechanistic steps. Vinylidene chloride (VDC) is metabolized to an epoxide and 2-chloroacetylchloride both of which bind covalently to hepatic protein and deplete tissue glutathione (GSH). Dose-response curves for hepatotoxicity and lethality demonstrate abrupt changes despite a relatively linear dose response curve for GSH depletion and covalent binding. These two case studies suggest that perturbation of critical biochemical defenses (e.g. intracellular buffering mechanisms, glutathione stores, etc.) beyond homeostatic bounds can result in dose-dependent transitions in mechanism. These cases further suggest that research is needed to better define the limits of cellular defense mechanisms and functional reserve capacity and should raise regulatory awareness of changes in toxic mechanisms imparted by high dose (MTD) testing.

1356 DOSE-DEPENDENT TRANSITIONS IN TOXIC MECHANISMS: IMPLICATIONS FOR RISK ASSESSMENT.

D. W. Gaylor. *Gaylor and Associates, Little Rock, AR.* Sponsor: W. Slikker.

Reference doses associated with negligible health risks for non-cancer effects are established by dividing a point-of-departure (no or low observed adverse effect level or benchmark dose) by uncertainty factors to account for extrapolation from effects in animals to humans, duration of exposure, and allowance for inter-individual sensitivity. Cancer risk estimation generally has employed low-dose linear extrapolation to zero. If the shape of the dose response can be established, it may be possible to dispense with linear extrapolation and/or modify the point-of-departure relative to dose-dependent transitions for risk assessments of cancer and non-cancer effects. Comparisons of dose-dependent transitions across and within species may support the reduction of the size of one or more uncertainty factors. The statistical design and analysis of experiments to demonstrate dose-dependent transitions and determine the point-of-departure will be discussed.

1357 STRATEGIES TO IDENTIFY SATURABLE AND/OR INDUCIBLE KINETIC AND DYNAMIC STAGES OF DOSE-DEPENDENT TRANSITIONS IN TOXIC MECHANISM.

K. B. Wallace[1] and W. Slikker[2]. *[1]Biochemistry & Molecular Biology, University of Minnesota, Duluth, MN and [2]Division of Neurotoxicology, NCTR/FDA, Jefferson, AR.*

The ultimate expression of toxicity following exposure to foreign substances is dictated by a variety of saturable kinetic processes, both in the disposition of the chemical and biological expression of the pathogenic response. Examples of such processes include the absorption of the chemical in question, its transport and accumulation within specific tissues or cellular compartments, metabolic transformation to metabolites of differing activities, interaction on the biologically active form with specific tissue receptors, elicitation of defined intracellular signaling pathways to affect the ultimate biological response, various protective or reparative pathways that counteract the adverse biological effect, and altered molecular regulation to establish new homeostatic states in response to the biological stress imposed as a result of the chemical exposure. Saturation of any one of these steps redirects the disposition, metabolism or expression of biological activity for that compound. Consequently, as one explores the range of exposures it is not uncommon to encounter inflections in the dose-response relationships, which signify saturation of one or more essential steps in the pathogenic mechanism. This, then, brings into question assumptions associated with extrapolating mechanism-based risk assessments across the full range of exposures. Several examples will be presented in this workshop that illustrate transitions between mechanisms of toxicity that occur as a function of exposure dose. The goal will be to identify key determinants of dose-dependent transitions and to develop guiding principles for applying these phenomena to risk-assessment paradigms.

1358 QUESTIONS SURROUNDING DEPLETED URANIUM TOXICITY: ANSWERS FROM THE CLINIC AND THE LABORATORY.

K. S. Squibb[1] and D. Jacobson-Kram[2]. *[1]Program in Toxicology, University of Maryland School of Medicine, Baltimore, MD and [2]BioReliance, Rockville, MD.*

The use of depleted uranium (DU) by US military forces in the Gulf War created a unique exposure scenario by which soldiers were exposed to a metal well known for its chemical toxicity in workers in the nuclear industry. However, exposure during the Gulf War occurred either for a short period of time *via* inhalation of aerosolized uranium oxide, or as a chronic exposure in injured soldiers left with embedded uranium fragments. Questions regarding the long-term health effects of these two types of exposures have fueled considerable debate, raising questions regarding continued use of DU weapons by the military and liability of the government for health problems in the Gulf War veteran population. DU, used in munitions because of its high density and low cost, is a by-product of the uranium enrichment process. DU has a lower University^{235} content than natural uranium, with a University^{235}/U^{238} ratio of 0.245 *versus* 0.721 for natural uranium. Research to address questions of exposure and toxicity has moved forward on a number of fronts, including clinical surveillance of vets with DU shrapnel, ICP-MS exposure assessment techniques for differentiating between DU *versus* natural University excretion, *in vivo* animal toxicity and carcinogenicity studies using embedded DU metal, and genotoxicity studies of the chemical versus radiological hazards associated with DU. Results of these studies provide mechanistic and clinical toxicity information needed for assessing risk associated with exposure to DU during the Gulf War and emphasize the importance of the basic toxicological principles of dose, duration and route of exposure. Mechanistic studies begin to provide an understanding of the chemical versus radiological toxicity of this unique metal.

1359 HEALTH EFFECTS OF DEPLETED URANIUM ON EXPOSED GULF WAR VETERANS.

M. A. McDiarmid. *Department of Medicine, University of Maryland School of Medicine, Baltimore, MD.*

Medical surveillance of a group of US Gulf War veterans (N=63) who were victims of depleted uranium (DU) 'friendly fire' has been carried out since the early 1990s. Urine uranium concentration has been used as a measure of systemic exposure with health outcomes and organ system function evaluated as a dependent variable. DU possesses only 60% of the radioactivity of natural uranium, having been 'depleted' of much of its most highly radioactive University^{234} and University^{235} isotopes. Radiation dose estimates calculated from whole body radiation counting using the ICRP 30 Biokinetic model for University yielded upper limits of 0.1 rem/yr (the public dose limit) and 5.3 rem/50 yrs (with the annual occupational limit being 5 rem/yr as a comparison). Therefore, the focus has been on uranium's chemical, heavy metal character, rather than its radiologic toxicity. Findings to date reveal the persistent elevation of urine uranium, more than 10 years after exposure, in those veterans with retained shrapnel fragments, presumably from on-going mobilization of DU from fragments oxidizing *in situ*. Other clinical outcomes related to uranium measures have revealed few abnormalities. Renal function is normal despite the kidney's expected involvement as the 'critical' organ of uranium toxicity. Subtle perturbations in some proximal tubular measures may suggest early, albeit not statistically significant, effects of uranium. A mixed picture of genotoxic outcomes is also observed. Observations from this chronically exposed cohort inform health predictions of future effects in other potentially-DU exposed populations and provide helpful data for hazard communication of future deployed personnel. *Supported by the Office of Public Health and Environmental Hazards, Department of Veterans Affairs, and the VA Maryland Healthcare System/Baltimore Division*

1360 DETECTION OF DEPLETED URANIUM (DU) IN URINES OF GULF WAR VETERANS.

R. H. Gwiazda[1], K. Squibb[2], M. McDiarmid[2] and D. Smith[1]. *[1]Environmental Toxicology, University of California, Davis, CA and [2]School of Medicine, University of Maryland, Baltimore, MD.*

American soldiers involved in 'friendly fire' accidents during the Gulf War were injured with DU containing fragments or possibly exposed to DU *via* other routes such as inhalation or ingestion. To evaluate the presence of DU in these soldiers eight years later, the University concentration and DU content of urines were determined by an inductively coupled plasma mass spectrometry (ICP-MS) method in (a) DU exposed soldiers with shrapnel, (b) DU exposed soldiers with no shrapnel and (c) deployed soldiers who did not participate in combat. The minimum detectable fraction of DU in urine uranium by this method was 20% at a urine [U] of 21 ng/L, and the ability to detect DU in urine increased as urine uranium level increased. Many urines injected directly into the ICP-MS and measured at a mass resolution m/Δm of ~ 300 had University ratios enriched in ^{235}U. Analyses of the same urines at a mass resolution of 4000 showed that the apparent extra ^{235}U counts were due to an interference with a mass of 234.81 amu. Because no two-isotope combination could yield such light molecular weight, most likely the interference was a polyatomic molecule of more than two atoms. When analyses were done on uranium extracted from these urines the ^{235}U abundance was natural or depleted and the interference was eliminated. Urine uranium levels of soldiers with shrapnel were higher than those of the two other groups and DU was detected in 16 out of 17 subjects. In exposed soldiers with no shrapnel DU was detected in 10 out of 28 as opposed to 1 in 11 in the deployed but not in combat group, yet urine uranium levels of these two groups were not different. Using the criteria of presence or absence of DU in urine, uranium levels of DU bearing urines from groups (b) and (c) were significantly higher than uranium levels of urines with no DU. These results indicate that uranium uptake can occur *via* routes other than injury with DU bearing shrapnel and a one time event exposure can result in long term uranium excretion.

1361 *HPRT* MUTATIONS IN T-CELLS IN GULF WAR VETERANS EXPOSED TO DEPLETED URANIUM (DU).

R. J. Albertini[1], D. Jacobson-Kram[2], L. M. Sullivan[1], P. Gucer [3] and M. A. McDiarmid[3]. *[1]University of Vermont, Burlington, VT, [2]Bioreliance, Rockville, MD and [3]University of Maryland, Baltimore, MD.*

Gulf War veterans exposed to depleted uranium (DU) by "friendly fire" were studied for somatic cell genetic effects approximately ten years later. Urinary concentrations (urU) of uranium (U) were used to estimate current body burdens of DU. Some veterans harbor DU shrapnel visible on X-rays. Current mean age of the group is 35.1 ± 0.76 yr; all are male (56% Caucasian, 31% African American, 10% Hispanic and 3% "other"). The group was divided into high and low urU subgroups (> or < 10 mcg/gm creatinine). Mean frequencies of chromosome aberrations (CA) determined in peripheral blood T-lymphocytes by traditional methods were 0.01 ±0.005 and 0.02 ± 0.008 for the high and low urU groups, respectively, revealing no statistically significant difference and no DU effect (p=0.70). Mean frequencies of sister chromatid exchanges (SCE), however, were 6.35 ± 0.267 and 5.52 ± 0.182 for the high and low urU groups, respectively, showing a slight but statistically significant elevation in the high group (p = 0.03). *HPRT* mutant frequencies (MFs) in T-lymphocytes assessed by cloning assay ranged from 4.4 to 69.1 x 10-6 . There was a positive correlation between individual urU concentrations and MFs (r = 0.51) which remained statistically significant (p < 0.001) after adjusting for effects of age, cloning efficiency of the assay and smoking, thus revealing an unambiguous mutagenic effect of DU exposure. The lack of an increase in CA frequencies with an elevation of SCEs argues against ionizing radiation as the cause of the somatic cell genetic effects. It is reasonable to attribute the *HPRT* mutations, which could have either a radiation or chemical basis, to the latter. Chronic low-level high LET radiation could show this genotoxicity profile, however DU should provide only low intensity radiation. Characterization of molecular spectrum of the *HPRT* mutations will help assess these possibilities. Results suggest a need to more fully characterize DU genotoxicity and its public health implications.

1362 DEPLETED URANIUM METAL IMPLANTS ARE CARCINOGENIC IN RATS.

F. F. Hahn[1] and R. A. Guilmette[2]. *[1]Lovelace Respiratory Research Institute, Albuquerque, NM and [2]Los Alamos National Laboratory, Los Alamos, NM.*

The carcinogenicity of depleted uranium (DU) metal implants in muscle was determined in Wistar rats. Tissue reactions to DU implants were compared with implants of tantalum (Ta) metal and injections of Thorotrast® (Th®). Three sizes of DU fragments were surgically implanted, 5x5x1.5 mm, 2.5x2.5.1.5 mm or 2.0x1.0 mm diam. Four fragments were embedded in each rat, 2 in each thigh muscle. Other groups received Ta implants (5x5x1.5 mm) as controls for foreign-body materials, Th® injections *i.m.* as controls for radioactive materials, or sham surgery as negative controls. Fifty rats per group were observed for life span for the onset, incidence, and types of reactions at the site. At death, all major organ systems were microscopically examined for lesions. Radiographs of the DU implants showed marked corrosion on the surface as early as 3 mo. after surgery. Later, rarefactions in the radiographic profiles correlated with proliferative tissue reactions. Connective tissue capsules formed around the metal implants, but were much thicker around the DU. Soft tissue tumors arose from some capsules 16 to 20 mo. after implant. Over 90% were malignant. Tumor incidence was significantly increased around the larger squares of DU (18%) and the radioactive control, Th® (50%), when compared with the sham controls (0%). Incidence was slightly increased in rats with 2.5x2.5 mm DU squares (6%) and with 5x5 mm squares of Ta (4%). No tumors were seen in rats with the small DU pellets or in the sham controls. DU fragments of sufficient size cause localized proliferative reactions and soft tissue sarcomas in the muscles of rats that can be detected with radiography. Implanting materials *i.m.* in rats is a sensitive technique for detecting potentially carcinogenic materials in humans. These findings do not indicate, however, that DU fragments are necessarily carcinogenic in humans. Funding: US Army MRDC MIPR# KVFM5529 with US DOE, Coop. Agreement #DE-FC04-96AL76406. Research conducted using SOT criteria and in AAALAC-accredited facilities.

1363 RADIATION-INDUCED EFFECTS OF DEPLETED URANIUM *IN VITRO*: THE INVOLVEMENT OF BYSTANDERS AND INSTABILITY.

A. Miller[1], J. Kalinich[1], S. Hodge[1], B. Le Blanc[1], K. Brooks[1], M. Stewart[1], S. Marino[2], T. Hei[2] and D. McClain[1]. *[1]Applied Cellular Radiobiology, Armed Forces Radiobiology Research Institute, Bethesda, MD and [2]Center for Radiological Research, Columbia University, New York, NY.* Sponsor: K. Squibb.

Depleted uranium (DU) is a dense heavy metal used primarily in military applications. Published data from our laboratory have demonstrated that DU exposure *in vitro* to immortalized human osteoblast cells (HOS) is both neoplastically transforming and genotoxic. DU possesses both a radiological (alpha-particle) and chemical (metal) component. Since DU has a low-specific activity in comparison to natural uranium, it is not considered to be a significant radiological hazard. The potential contribution of radiation to DU-induced biological effects is unknown and the involvement of radiation in DU-induced biological effects could have significant implications for current risk estimates for internalized DU exposure. Several approaches were used to address this question. Using the same concentration of three uranyl nitrate compounds (isotopes) that have different uranium isotopic concentrations and therefore, different specific radioactivity, we examined their effect *in vitro* on neoplastic transformation, genotoxicity, mutagenicity, and induction of genomic instability. HOS cells were exposed to one of three-uranyl nitrate compounds (^{238}U-uranyl nitrate, specific activity 0.33 μCi/g; DU-uranyl nitrate, specific activity 0.44 μCi/g; and ^{235}U-uranyl nitrate, specific activity 2.2 μCi/g) delivered at a concentration of 50 μM for 24 hrs. Results showed, that at equal uranium concentration, there was a specific activity-dependent increase in neoplastic transformation frequency and other endpoints examined, suggesting that radiation plays a role in DU-induced biological effects *in vitro*. Lastly, using populations of DU-exposed, non DU-exposed cells, and a mixed population of DU-exposed and non DU-exposed cells, we provide the first evidence that cells that have taken up DU can induce a bystander transformation response in neighboring cells that neither took up DU nor were traversed by alpha particles (from DU).

1364 VANILLOID RECEPTORS: MEDIATORS OF RESPIRATORY INJURY.

G. S. Yost[1] and G. S. Yost[1]J. B. Morris[2]J. B. Morris[2]. *[1]Pharmacology and Toxicology, University of Utah, Salt Lake City, UT and [2]Toxicology Program, University of Connecticut, Storrs, CT.*

Vanilloid receptors (members of the superfamily of TRP non-voltage-gated cation channels) are the recently identified cation channels that are critical for sensory neuronal nociception to painful and tissue-damaging stimuli, including physicochemical (heat, cold, hypoosmolarity, and surface charge) and chemical (acids and capsaicinoids) insult. Cloning, expression, and characterization of a variety (at least six members) of related ion channel proteins, that are responsive to noxious environmental stimulants, have provided a cornucopia of molecular targets that mediate physiological responses. These receptors are highly expressed in dorsal root ganglia, and significant expression of several of the TRP proteins has also been demonstrated in respiratory tissues of animals and man. Activation of these respiratory receptors by a surprisingly diverse array of irritants, including particulate matter from ambient air, has been associated with toxic sequelae in the respiratory tract. However, the mechanisms responsible for receptor regulation, activation, and responsiveness in respiratory epithelial and neuronal cells have not been adequately elucidated. This workshop will present a highly focused, mechanistic evaluation of the chemical, biochemical, cellular, and toxicological factors that regulate vanilloid

receptor-mediated toxicities in the respiratory tract. Topics of the workshop will include structure/function characterization of TRPV receptors, human lung epithelial cell sensitization to capsaicinoids by over-expression of the recombinant human vanilloid receptor TRPV1, stimulation of respiratory sensory nerve reflex responses to inspired acidic aerosols in rodents, and TRPV1 receptor activation in human lung epithelial cells by particulate matter-mediated cytokine production that is correlated to surface charge. Mechanistic research into the activation and regulation of the vanilloid receptors may provide precise molecular descriptors of respiratory injury that can be used to achieve exciting new therapeutic modalities.

1365 TRPV ION CHANNEL PROTEINS: CANDIDATE MEDIATORS OF DIVERSE VISCERAL SENSORY PROCESSES.

M. J. CaterinaM. J. Caterina. *Biol. Chem. and Neurosc., Johns Hopkins University School of Medicine, Baltimore, MD.* Sponsor: G. Yost.

Among the molecules that detect irritant stimuli in cutaneous and visceral tissues is TRPV1 (VR1), a nonselective cation channel that can be activated by vanilloid compounds, protons, or heat, and is highly expressed in certain cutaneous and vagal sensory neurons. Recently, TRPV1 has also been found to be expressed in visceral epithelia, where it may mediate the indirect detection of irritants by afferent nerve fibers. At least six homologous TRPV genes have been identified. One, TRPV4, is highly expressed within tracheal epithelial cells and submucosal glands. This channel is unresponsive to vanilloid compounds or protons, but can be activated by certain other physico-chemical stimuli, such as hypoosmolarity. These findings suggest a number of possible roles for TRPV family members in physiological and pathophysiological respiratory function. 1366 ENHANCED CYTOTOXICITY OF CAPSAICINOIDS TO TRPV1-OVEREXPRESSING HUMAN LUNG CELLS.

G. S. Yost and C. A. Reilly. *Pharmacology and Toxicology, University of Utah, Salt Lake City, UT.*

Capsaicinoids are the active components of pepper sprays, and exposure to these sprays have been associated with respiratory failure and death in animals and people. Although inhalation of pepper spray extracts in rats causes acute inflammation and damage to respiratory cells, the mechanisms responsible for cellular damage have not been elucidated. Recent characterization of irritant receptors, including the human vanilloid receptor type-1 (VR1 or TRPV1) that is a capsaicin-responsive cation channel receptor, have provided molecular targets that could be responsible for respiratory cell death. *In vitro* cytotoxicity assays demonstrated that human lung cells (BEAS-2B and A549) were more susceptible to necrotic cell death than liver (HepG2) cells. Transcription of TRPV1 was demonstrated in all three of these cell lines, and the relative transcript levels were correlated to cellular susceptibility to capsaicin. Surprisingly, the prototypical antagonists of this receptor were cytotoxic to BEAS-2B cells, and the antagonists did not ameliorate capsaicinoid-induced damage. Conversely, TRPV1 antagonists or calcium chelation ablated IL-6 production after capsaicin exposure. Recombinant human TRPV1 was cloned and stably over-expressed in a new BEAS-2B cell line, and these cells exhibited dramatically increased (100-fold) cellular susceptibility to capsaicin, and an apoptotic mechanism of cell death. The cytotoxicity of capsaicin to TRPV1 over-expressing cells was not inhibited by the antagonists, or by treatments that modified extracellular calcium. Therefore, capsaicin activated the TRPV1 receptor in human bronchiolar epithelial cells to produce the calcium-dependent release of cytokines and, conversely, calcium-independent cell death. Thus, capsaicinoid-induced respiratory toxicities may be mediated by activation of vanilloid receptors that are expressed in epithelial cells, through a process that is independent from cytokine production. Supported by the Colgate-Palmolive Post-Doctoral Fellowship in *In Vitro* Toxicology and a Department of Commerce Contract (#60NANBOD0006)

1367 IMMEDIATE RESPIRATORY TRACT RESPONSES TO INSPIRED IRRITANTS: SENSORY NERVES AND VANILLOID RECEPTORS.

J. B. Morris and P. T. Symanowicz. *Toxicology Program and Pulmonary Research Consortium, University of Connecticut, Storrs, CT.*

Stimulation of respiratory tract sensory nerves produces a range of local and centrally mediated reflex responses. The local responses, mediated *via* local neuropeptide release and/or parasympathetic nerve activation, include mucus secretion, vasodilation, and neurogenic edema. Centrally mediated responses include changes in breathing pattern and cough. The receptors responsible for irritant detection and initiation of these responses are not known, nor is it known if irritants stimulate nerves directly or indirectly through paracrine mediators released by epithelial or other cells. Numerous *in vitro* studies have documented an important role for the vanilloid receptor in acid-induced stimulation of sensory nerves. *In vitro* studies in our laboratory have shown that the potent cigarette smoke irritant acrolein can also directly stimulate sensory nerves. *In vivo* studies are focused on examining the role of vanilloid receptors in initiating respiratory reflex responses to inspired irritants. Inhalation exposure to the known vanilloid receptor agonist capsaicin results in the same spectra of responses as that induced by the inspired irritants acrolein, acetic acid or sulfuric acid. More importantly, the reflex responses to inspired sulfuric acid aerosol in the rat are diminished by pretreatment with the vanilloid receptor antagonist ruthenium red. Similarly, pretreatment with this antagonist decreases the sensory nerve-mediated respiratory tract responses to inspired acetic acid in the mouse. These results suggest the vanilloid receptor plays a key role in detection and initiation of respiratory tract responses to inspired irritants. This work supported by the NIH NIEHS R01-08765 and the University of Connecticut Pulmonary Research Consortium.

1368 THE SURFACE CHARGE OF PARTICULATE MATTER (PM) ACTIVATES VANILLOID (VR1) RECEPTORS.

B. Veronesi[1], B. Veronesi[1], W. Bernt[2] and W. Bernt[2]G. Wei[4]G. Wei[4]M. Oortgiesen[3]M. Oortgiesen[3]. *[1]USEPA, Research Triangle Park, NC, [2]PCL, Novato, CA, [3]NRC, Washington, DC and [4]Cato Research Ltd, Research Triangle Park, NC.*

Exposure to PM produces a uniform degree of mortality in exposed populations, in spite of its diverse sources. This suggests a common mechanism of action. We have shown that PM initiates airway inflammation through activation of VR1 receptors carried on human respiratory epithelial cells (BEAS-2B). To determine what physicochemical feature of PM was culpable in this activation, the surface charges (i.e., zeta potentials) were measured on PM particles obtained from various sources. When measured in neutral pH vehicles, these PM particles carried zeta potentials of varying electronegativity. On exposure to BEAS-2B epithelial cells, each PM (60 mg/cm2) stimulated a differential release of IL-6. The zeta potential of individual PM samples significantly correlated (r2 = 0.98) with its respective level of IL-6 release, indicating that the surface charge carried on PM particles contributed to IL-6 release from target respiratory cells. To test whether surface charge itself could activate VR1 receptors, synthetic polystyrene micelles (SPM), charged with individual chemical groups (e.g., COOH-, SO2-, NH2+), were obtained and measured for their zeta potential. These SPM were next exposed to BEAS-2B cells and the resulting biological changes (e.g., membrane potential, intracellular calcium increases, IL-6 release) were measured. IL-6 release stimulated by the COOH- and SO2-charged SPM could be significantly depressed by capsazepine, an inhibitor of VR1 receptors. The rank order of the SPM's zeta potential and their respective IL-6 release also correlated. RT-PCR performed on SPM exposed BEAS-2B cell indicated that VR1-receptor transcript was only increased in BEAS-2B cells exposed to COOH- and SO2- charged SPM . Together, these data suggest that the negative surface charge carried on some colloidal particles is able to initiate airway inflammation through activation of the VR1 receptor and offers a common mechanism of action to explain PM toxicity.

1369 A DNA REPAIR ROLE FOR RECQ AND TOPOISOMERASES III AND IV IN *E. COLI*.

E. L. Zechiedrich[1,2], C. R. Lopez[1,2], S. Yang[1], R. W. Deibler[1,2], S. A. Ray[2], J. Pennington[2,3], R. J. DiGate[4], P. J. Hastings[3] and S. M. Rosenberg[1,2,3]. *[1]Molecular Virology & Microbiology, Baylor College of Medicine, Houston, TX, [2]Interdepartmental Program in Cell & Molecular Biology, Baylor College of Medicine, Houston, TX, [3]Molecular & Human Genetics, Baylor College of Medicine, Houston, TX and [4]Pharmaceutical Sciences, University of Maryland School of Pharmacy, Baltimore, MD.* Sponsor: J. Kramarik.

Across the domains of life, genetic data imply that topoisomerase III may have a fundamental function in maintaining genomic integrity. Cells lacking topoisomerase III display a number of DNA instabilities including a mutator phenotype, deletion of short repetitive elements, and a failure to segregate recombinant products of meiosis. Alterations in human RecQ-family DNA helicases, which interact with topoisomerase III, have been linked to the Bloom, Rothmund-Thomson, and Werner Syndromes. Patients with these inherited disorders have elevated rates of cancer incidence and cells from these individuals show genomic instability. Despite these findings, the role of topoisomerase III is unknown for any organism. Using genetic techniques, we found that the genes that encode topoisomerase III and temperature sensitive mutants of topoisomerase IV are synthetically lethal at the permissive temperature in E. coli. Fluorescence microscopy data revealed that the double mutant is defective in DNA segregation. The overproduction of topoisomerase III rescued both the lethality of temperature sensitive topoisomerase IV mutants at the non-permissive temperature and the DNA segregation defects. Either recQ or recA null mutations rescued the synthetic lethality of the double topoisomerase mutant. We suggest a model whereby RecA and RecQ initiate a recombinational repair of DNA that is resolved by the topoisomerases. Failure to resolve is lethal. Finally, we found that the deletion of the gene that encodes topoisomerase III and a ruvC null mutation are synthetically lethal, which suggests that topoisomerase III disentangles Holliday junctions to maintain genomic stability.

1370 MECHANISMS OF DNA DAMAGE-INDUCED MUTAGENESIS.

Z. Wang, D. Guo, Y. Zhang, X. Wu and Z. Xie. *University of Kentucky, Lexington, KY.*

Replication of damaged DNA (translesion synthesis) requires specialized proteins and frequently leads to mutations. In the yeast S. cerevisiae, the polymerase zeta (Pol zeta) mutagenesis pathway was originally identified as the major mechanism of UV-induced mutagenesis. The Pol zeta pathway requires at least Rad6, Rad18, Rev1, Rev3, and Rev7 proteins. Based on the yeast genes, we cloned the human RAD18, REV1, and REV3 genes. Human REV1 gene codes for a dCMP transferase, which is able to respond to several types of DNA lesions by inserting a C opposite the lesion. Human Rev1 protein may thus contribute to dCMP insertion opposite many types of DNA damage during translesion synthesis. The REV3 gene codes for the catalytic subunit of DNA Pol zeta. The role of Pol zeta in translesion synthesis was examined using the yeast model system. Purified yeast Pol zeta performed limited translesion synthesis opposite several lesions. Furthermore, yeast Pol zeta catalyzed extension DNA synthesis from primers annealed opposite these lesions. Our results led to a dual-function model for Pol zeta. One function of Pol zeta is to catalyze nucleotide insertion opposite the lesion and subsequently extend DNA synthesis past the lesion. The second function of Pol zeta is to catalyze the extension DNA synthesis following nucleotide insertion opposite the lesion by other polymerases. Recently, the Y family of DNA polymerases was discovered. The Y family DNA polymerases are capable of DNA synthesis opposite various base lesions with either error-free or error-prone consequences, depending on the specific lesion and the specific polymerase. Our biochemical studies suggest that the Y family polymerases may be functionally connected to the Pol zeta pathway through a two-step two-polymerase mechanism in translesion synthesis of many types of DNA lesions. As indicated by genetic experiments, many types of DNA damage would not be able to induced mutations without the Pol zeta pathway. Therefore, the Pol zeta pathway plays a critical role in DNA damaged-induced mutagenesis.

1371 A REQUIREMENT FOR REPLICATION IN ACTIVATION OF THE ATR-DEPENDENT DNA DAMAGE CHECKPOINT.

K. A. Cimprich, P. J. Lupardus, T. Byun, M. Yee and M. Hekmat-Nejad. *Molecular Pharmacology, Stanford University, Stanford, CA.* Sponsor: J. Kramarik.

To maintain genomic stability, cells depend on the DNA damage and replication checkpoints. ATR (ATM and Rad3-related) and the proteins in the Rad1 complex, Rad1, Hus1 and Rad9, are believed to be upstream components of these checkpoints. It is not understood how these proteins respond to a diverse range of DNA damaging agents, including ultraviolet radiation, ionizing radiation and alkylating agents. We have investigated the involvement of DNA replication in activation of the DNA damage checkpoint in Xenopus egg extracts. We find that DNA damage caused by ultraviolet radiation or methyl methanesulfonate slows replication in a checkpoint-independent manner and is accompanied by the accumulation on chromatin of ATR and components of the Rad1 complex. We also show that the replication proteins RPA and Pol α accumulate on chromatin following DNA damage, suggesting that single-stranded DNA may accumulate. Importantly, we find that the accumulation of ATR, Rad1, RPA and Pol α is blocked by geminin, suggesting that their binding is dependent on the initiation of DNA replication. In addition, several components of the Rad1 complex become phosphorylated after activation of this checkpoint. These phosphorylations are dependent on the kinase activity of ATR and on initiation of DNA replication, but they are not required for the association of the Rad1 complex with chromatin. Finally, we show that the damage-induced phosphorylation of Chk1 and checkpoint arrest are abrogated when replication is inhibited. Taken together, these data suggest that replication is required for activation of the DNA damage checkpoint and may provide a unifying model for ATR activation by diverse lesions during S phase.

1372 I) MECHANISMS OF NITRIC OXIDE-INDUCED HOMOLOGOUS RECOMBINATION IN *E. COLI* AND II) FLUORESCENCE DETECTION OF HOMOLOGOUS RECOMBINATION IN MICE.

B. P. Engelward[1], C. A. Hendricks[1], E. J. Spek[1], V. Jonnalagadda[1], K. H. Almeida[1] and M. G. Marinus[2]. *[1]Biological Engineering, MIT, Cambridge, MA and [2]Department of Pharmacology and Molecular Toxicology, UMASS Medical School, Worcester, MA.*

Homology-directed repair defends somatic cells against potentially toxic and mutagenic DNA lesions. Although homology directed repair is generally a conservative process, mitotic homologous recombination can lead to deletions and loss of heterozygosity. We have investigated the molecular basis of damage-induced homologous recombination and developed tools for studying homologous recombination in mammals. Nitric oxide (NO·) is involved in neurotransmission, inflammation and many other biological processes. Exposure of cells to NO· leads to a wide variety of DNA lesions. Using a genetic approach, we have determined the relative contribution of excision and recombination pathways in defending *E. coli* against NO· toxicity. We found that recombination-deficient cells (*recBCD*) are very sensitive to NO· toxicity. Although DNA glycosylases that initiate the base excision repair (BER) pathway do not influence survival in wild type cells, when certain DNA glycosylases (Fpg and Ung) are inactivated in *recBCD* cells, survival is significantly enhanced. We present a model in which accumulated BER intermediates induce homologous recombination. These studies shed light on the underlying mechanism of NO·-induced homologous recombination. For studies of homologous recombination in mammals, we have developed a mouse model in which mitotic homologous recombination events can be quantified *via* a fluorescent signal. The FYDR (fluorescent yellow direct repeat) mice carry two mutant copies of an expression cassette for the enhanced yellow fluorescent protein (EYFP). Recombination frequency can be measured by flow cytometry of primary cells isolated from FYDR mice. When challenged with mitomycin C, we observe a 15 fold increase in the frequency of recombinant cells. This new mouse model can be used for dissecting genetic and environmental factors that put mammals at risk of deleterious homologous recombination events.

1373 MUTAGENESIS AND DNA STRAND SCISSION AT 2-DEOXYRIBONOLACTONE OXIDATIVE DNA DAMAGE LESIONS.

T. L. Sheppard and Y. Zheng. *Department of Chemistry, Northwestern University, Evanston, IL.* Sponsor: J. Kramarik.

DNA damage by toxic agents, including ionizing radiation and oxidizing species, leads to chemical alteration of the genome. DNA damage reactions may give rise to genetic mutations and DNA strand breaks, which represent molecular mechanisms for aging and the induction of human diseases. In particular, DNA damage by reactive oxygen species (ROS) presents a major pathway for the introduction of premutagenic lesions in genomic DNA. One form of oxidative DNA damage is the 2-deoxyribonolactone (or oxidized abasic site) lesion, which results from oxidation of the C-1 position of the sugar unit of a DNA nucleotide. Although the mechanisms that lead to these oxidized sites have been established, the biochemical consequences of C-1 damage remain unclear. This study reports the measurement of the biological half-life of these lesions, the characterization of the products of DNA strand scission at the damage sites, and the assessment of the mutagenic effects of lactone modifications. This laboratory previously developed a method for the selective photochemical generation of lactone lesions within DNA oligonucleotides. Synthetic lactone-modified DNA was prepared and used to measure a half-life of 21-50 hours for DNA strand scission at the lesion under simulated physiological conditions. The products of DNA strand scission at the lesion site were unambiguously characterized by gel electrophoresis and MALDI-TOF mass spectrometry. The mutagenicity of the oxidized abasic site was assayed using DNA polymerase primer extension assays with DNA templates containing the lactone lesion. The lactone lesion stalls the polymerase at the damage site and displays A-rule mutagenesis behavior. In summary, the deoxyribonolactone lesion displays a biological half-life of approximately one day and acts as a non-instructive mutagenic site during DNA replication. The significant lifetime of this lesion suggests that DNA repair will be required to avoid mutagenesis at lactone sites during replication or transcription. Accordingly, the oxidized abasic site may represent a genotoxic lesion resulting from oxidative DNA damage.

1374 MODULATION OF AROMATASE ACTIVITY IN PRIMARY CULTURE OF HUMAN MAMMARY FIBROBLASTS.

M. Heneweer[1], M. van den Berg[1], P. C. de Jong[3], A. Bergman[2] and J. T. Sanderson[1]. *[1]Institute for Risk Assessment Sciences (IRAS), Utrecht University, Utrecht, Netherlands, [2]Department of Internal Medicine, St. Antonius Hospital, Nieuwegein, Netherlands and [3]Department of Environmental Chemistry, Stockholm University, Stockholm, Sweden.*

Aromatase activity in human mammary tissue is mainly located in fibroblasts and a positive feedback loop is thought to be responsible for accelerating estrogen-responsive breast tumor growth through stimulation of estrogen synthesis. Tumor cells secrete factors such as prostaglandin E2 (PGE2) and interleukin-6 (IL-6) that are able to upregulate aromatase gene expression in tumor-surrounding fibroblasts. Various *in vitro* studies have shown that pharmacological agents and xenobiotics are able to interfere with the aromatase enzyme. In this study we examined the possibility of using primary human mammary fibroblasts as an *in vitro* screening tool for

compounds that may be involved in the development of estrogen-dependent tumors. Primary human mammary fibroblasts were exposed for 24h to 100 μM 8-Br-cAMP, 1 μM PGE2 or 100 nM dexamethasone (DEX), which resulted in a 3-fold, 43-fold or 600-fold increase in aromatase activity, respectively. Since the synthetic glucocorticoid DEX upregulated aromatase activity in a highly effective manner, compounds with anti-glucocorticoid properties would be expected to decrease dexamethasone induced aromatase activity. A 24h-exposure of fibroblasts to 100 nM DEX, together with 0.1, 1 or 10 μM 3-$MeSO_2$-CB-101, resulted in a 22, 26 or 55% reduction of aromatase activity. Cytotoxicity (20%) occurred only at the highest tested concentration. We are in the process of testing several persistent methylsulfonated metabolites of PCBs and DDT that are known to have anti-glucocorticoid properties.

1375 PRENATAL EXPOSURE TO THE FUNGICIDE PROCHLORAZ ALTERS THE ONSET OF PARTURITION IN THE DAM AND SEXUAL DIFFERENTIATION IN MALE RAT OFFSPRING.

N. Noriega, E. Gray, J. Ostby, C. Lambright and V. Wilson. *RTD, NHEERL, ORD, USEPA, Research Triangle Park, NC.*

Prochloraz (PZ) is an imidazole fungicide reported to inhibit aromatase, as well as estrogen and androgen receptor mediated activities *in vitro*. Our laboratory demonstrated that PZ exposure from gestational day (GD) 14-18 decreased testosterone while increasing progesterone in fetal rat testes. Thus, PZ is interesting in that it may alter endocrine function through diverse mechanisms. We examined mechanisms of PZ action *in vitro* and conducted a preliminary study to investigate effects of gestational exposure on Sprague-Dawley dams and their offspring. *In vitro*, PZ displayed anti-androgenic activity in MDA-kb2 cells containing endogenous androgen receptor (AR) and stably transfected with a MMTV-luc reporter. Treatment above 1μM caused a dose-dependent inhibition of DHT-induced luc expression, and was cytotoxic at 100μM. Prochloraz inhibited R1881 binding to the rat AR (IC50 approx 60μM). Daily PZ administration (gavage) to pregnant dams from GD 14-18 at doses of 62.5, 125, 250 and 500 mg/kg bodyweight/day inhibited maternal weight gain in the 500 mg/kg group. Pup delivery was delayed by up to 30 hours in some high-dose treated dams and some pups were stillborn at 125 mg/kg/d and higher. No pups in the 500 mg/kg group survived to postnatal day 13. Prenatal PZ treatment reduced anogenital distance in 2 day old pups by about 8% in the highest dosage group (NS), and induced female-like areolas in male offspring at frequencies of 33%, 71% and 100% in 62.5, 125 and 250 mg/kg groups, respectively. Some males of the 250 mg/kg treatment group showed phallus abnormalities and delayed preputial separation. A larger scale follow-up is underway. Our results are consistent with published *in vitro* PZ effects, and indicate that PZ displays several forms of endocrine activity, resulting in delayed parturition and induction of male reproductive tract malformations. This is an abstract of a proposed presentation and does not necessarily reflect EPA policy.

1376 TRANSGENERATIONAL EFFECTS OF DI(2-ETHYLHEXYL) PHTHALATE IN THE MALE RAT.

L. E. Gray[1], N. J. Barlow[2], J. R. Furr[1], J. Brock[3], M. J. Silva[3], D. B. Barr[3] and J. S. Ostby[1]. [1]*ORD, NHEERL, RTD, EB, USEPA, Research Triangle Park, NC,* [2]*CIIT, Research Triangle Park, NC and* [3]*CDC, Atlanta, GA.*

Phthalate esters such as di(2-ethylhexyl)- (DEHP), di(n-butyl)-, and benzyl butyl phthalate are widely used plasticizers that have been implicated in adverse developmental reproductive effects. They alter sexual differentiation by altering fetal Leydig cell development and hormone synthesis which in turn, results in abnormalities of the testis, gubernacular ligaments, epididymis and other androgen-dependent tissues. In spite of these concerns, studies of DEHP including relatively low dosage levels with developmental exposure and examination of sensitive endpoints in an adequate number of adult offspring have not been published. The current study was designed to begin to address these data gaps. Pregnant SD rats were dosed by gavage with DEHP from gestational day (GD) 8 to day 17 of lactation with 0, 11, 33, 100 or 300 mg/kg/d. On GD 18, two dams per group were euthanized and amniotic fluid was collected for analysis of MEHP levels. In half of the males (PUB cohort), dosing was continued from 18 to 63-65 days of age while the rest (IUL cohort) were not dosed directly. The PUB cohort was necropsied at 63-65 days of age while the IUL cohort was necropsied at full maturity. The 300 mg/kg/d, IUL group displayed permanent reductions in anogenital distance and reproductive organ weights, and permanent nipples. In the high dose group, about 25% of the males displayed testicular and/or epididymal abnormalities. These abnormalities also were displayed at a low incidence in the 11, 33 and 100 mg/kg/d dose groups along with subtle reductions in reproductive organ weights. In the PUB group, puberty (100 and 300) and reproductive organ weights (300 mg) were affected. Liver and adrenal weights were affected in all dose groups including 11 mg/kg/d (by one-tailed t-test), the lowest dose tested. Amniotic fluid levels of MEHP are being analyzed and a second study is reexaming the low dose effects of IUL DEHP exposure. Abstract of a proposed presentation and does not necessarily reflect EPA, CDC or CIIT policies.

1377 ANDROGEN RECEPTOR MRNA IS UPREGULATED BY ESTROGEN IN MOUSE PROSTATE PRIMARY CELL CULTURE.

C. A. Richter[1], R. L. Ruhlen[1], W. V. Welshons[2] and F. S. vom Saal[1]. [1]*Biological Sciences, University of Missouri, Columbia, MO and* [2]*Veterinary Biomedical Sciences, University of Missouri, Columbia, MO.* Sponsor: M. Denison.

Prostate development is dependent upon androgen stimulation of mesenchymal tissue, which in turn directs the proliferation and differentiation of epithelial buds. The androgen-responsiveness of developing prostate tissue is influenced by estrogens. Low, physiological doses of estrogens and high, pharmacological doses of estrogens have opposite effects on prostate development. Small increases in estrogen exposure during development result in permanent increases in prostate size and androgen receptor (AR) mRNA and protein expression, while high doses of estrogens result in a decrease in prostate size. We have developed an *in vitro* model system capable of reproducing the low dose estrogen-induced upregulation of AR mRNA in a primary culture of mesenchyme cells collected from the male fetal mouse urogenital sinus during the initial formation of the prostate gland. Immunofluorescent staining for the mesenchymal cell marker vimentin has confirmed that these primary cultures contain a homogenous population of mesenchymal cells. Androgen receptor mRNA expression in the cells was quantified by real-time RT-PCR. Our results show a dose-dependent increase in AR mRNA expression with estrogen treatment. The estrogen-induced increase in AR mRNA expression is eliminated by concurrent treatment with an antiestrogen. In contrast to *in vivo* results, the dose-response curve for estradiol-induced AR mRNA expression is monotonic over six orders of magnitude. These results suggest that the low-dose effects of estradiol on prostate development are estrogen-receptor-dependent, are largely mediated through local effects on prostate cells, and can be modeled in a primary cell culture system. The high-dose effects of estradiol cannot be modeled in a primary cell culture system, and may be mediated through systemic effects of pharmacological doses of estrogens. Future work will focus on the interactions among nuclear receptors in prostate development and on the effects of environmental estrogens on prostate development.

1378 TRUNCATED ESTROGEN RECEPTOR PRODUCT (TERP-1) EXPRESSION IN THE RAT VAGINA.

G. Schoenfelder, K. Friedrich, B. Flick, M. Paul and I. Chahoud. *Department of Toxicology, Universitaetsklinikum Benjamin Franklin, Berlin, Berlin, Germany.* Sponsor: R. Stahlmann.

During the estrous cycle changing levels of circulating estrogens play a critical role in vaginal growth, epithelial morphogenesis, cytodifferentiation, and secretory activity. These estrogenic effects require the estrogen receptor alpha (ERalpha). The ERalpha-ligand complex subsequently interacts with estrogen response elements, resulting in enhancement or suppression of gene expression. A tissue-specific ERalpha variant, so called truncated ER product-1 (TERP-1) is functional active and able to modulate the trans-activating activity of ERalpha. TERP-1 expression is hormonally regulated and specifically modulated by estrogens during the estrous cycle. TERP-1 has been suggested not be translated to make significant levels of protein outside the male and female pituitary gland. We, therefore, examined TERP-1 expression in the rat vagina. In addition, we tested the hypothesis whether *in utero* exposure of a xenoestrogen can affect TERP-1 expression in the vagina of the offspring, because in previous studies (a) TERP-1 expression has been regulated by neonatal estrogen treatment and (b) striking morphological changes were observed in the vagina of post-pubertal offspring after exposure with different estrogens. For the first time, we can demonstrate on mRNA- and protein-level prepubertal- and cycle-dependent TERP-1 mRNA- and protein-expression in the rat vagina. We show that TERP-1 expression is increased in control animals from the neonatal to the prepubertal period and during diestrus stage when compared to the estrous. Furthermore, TERP-1 expression is increased during estrus in the vagina of female offspring *in utero* exposed to 0.1 mg bisphenol A (an estrogenic chemical) / kg bodyweight when compared to the control group. The ability of TERP-1 to both enhance and inhibit ERalpha-dependent activity leads to the suggestion that TERP-1 expression may play a physiological role in estrogens feedback of vaginal epithelium.

1379 PHYTOCHEMICALS CAN ALTER CATECHOL-O-METHYLTRANSFERASE (COMT) ACTIVITY IN CYTOSOLIC FRACTIONS FROM HUMAN MAMMARY TISSUES.

M. B. van Duursen[1], M. Kraaij[1], J. T. Sanderson[1], P. C. de Jong[2] and M. van den Berg[1]. *[1]Institute for Risk Assessment Sciences (IRAS), Utrecht University, Utrecht, Netherlands and [2]Department of Internal Medicine, St Antonius Hospital, Nieuwegein, Netherlands.*

Phytochemicals are natural dietary constituents from fruits and vegetables. Although phytochemicals can exert (weak) estrogenic actions, they are suggested to protect against breast cancer. Some of these phytochemicals are known to affect estrogen metabolizing enzymes. In breast tissue, estradiol is mainly metabolized to 2- and 4-hydroxyestradiol (2-OH-E2 and 4-OH-E2). In several studies, 4-OH-E2, but not 2-OH-E2, acted as a carcinogen. COMT converses the hydroxyestrogens to their inactive methoxy derivatives (2-MeO-E2 and 4-MeO-E2). In this study we investigated the effects of quercetin (Q), catechin (Ca), genistein (G) and chrysin (Ch) on COMT activity in cytosolic fractions of healthy human mammary tissues. The potency of these phytochemicals to affect estrogen metabolism was compared with that of Ro 41-0960, a known COMT inhibitor. Tissues from reduction mammaplasty were homogenized and cytosolic fractions were prepared through ultracentrifugation. Cytosolic protein was incubated with various concentrations of a phytochemical and equimolar concentrations (7.5 μM) of 2-OH-E2 and 4-OH-E2. Methoxyestrogens were extracted with dichloromethane and analysed by GC/MS. The catalytic efficiency of COMT was higher for 2-MeO-E2 formation (Vmax/Km; 3.0/5.0 = 0.6) than for 4-MeO-E2 formation (Vmax/Km; 1.3/9.5 = 0.1). At 7.5 μM 2- and 4-OH-E2, the constitutive activity was 4.2 ± 1.3 and 0.94 ± 0.16 pmol/min/mg protein for 2- and 4-MeO-E2 formation, respectively. Ro 41-0960, Q and Ca concentration-dependently inhibited COMT activity with EC50 values of 0.03, 0.4 and 1.2 μM, respectively, for both 2- and 4-MeO-E2 formation. G and Ch slightly reduced COMT activity at the highest concentration tested (30 μM). These data show that phytochemicals with a catechol structure have the potency to reduce COMT activity in mammary tissues which might reduce the clearance of potentially mutagenic estradiol metabolites.

1380 REGULATION OF METHOXYCHLOR-INDUCED OXIDANT PRODUCTION BY CHOLINERGIC SIGNALING.

D. E. Heck and F. Rezai. *Pharmacology & Toxicology, Rutgers University, Piscataway, NJ.*

The pesticide methoxychlor, an organochlorine derivative of DDT, has been widely used as a substitute for DTT due to its lower toxicity and diminished environmental persistence. Recently, reports of endocrine-modulating activities induced by methoxychlor have engendered public concern about this widely used agent. Although the association between human exposure to methoxychlor and hormone-disruptive activities mediating disorders of endocrine organs remains unclear, methoxychlor has been found to exert adverse effects on fertility, early pregnancy, and *in utero* development, in wildlife and laboratory animals. Findings indicating that exposure to methoxychlor can induce oxidative stress point to a role for reactive oxygen species (ROS) in the pathological effects of exposure to this agent. Therefore we tested the effects of methoxychlor on oxidant levels in mouse and human endothelial cells. Methoxychlor was found to be a potent inducer of ROS in these cells. ROS production was dependent on the dose of methoxychlor in a range of 0.01 -1 μM, and inhibited by pre-treatment of the cells with N-acetyl-L-cysteine, a stimulator of glutathione synthesis. In experiments designed to investigate the effects of methoxychlor on endothelial function, we found that methoxychlor induced ROS production was enhanced 8-9 fold by the acetylcholine receptor agonist carbachol. Furthermore, in the presence of α-bungarotoxin, a nicotinic acetylcholine receptor antagonist, methoxychlor-induced ROS production was dramatically inhibited. In addition, methoxychlor induced expression of the type II major histocompatability antigen (Ia), an effect that was also facilitated by carbachol and inhibited by α-bungarotoxin. These data indicate that exposure to methoxychlor results in the production of ROS and expression of Ia antigen, and that this effect can be modulated by cholinergic signals. We speculate that interactions between cholinergic signaling and methoxychlor-induced ROS production mediate, in part, the neurendocrine abnormalities induced by methoxychlor in developing animals. 1381 STEROID AND THYROID HORMONAL RECEPTOR GENE TRANSCRIPTION ASSAY AND ONE-GENERATION REPRODUCTION STUDY OF BUTYLATED HYDROXYANISOLE.

S. Jeong, B. Kim, S. Kim, J. Cho and O. Kim. *Toxicology Division, National Veterinary Research & Quarantine Service, Anyang, KyungGi, South Korea.*

Butylated hydroxyanisol (BHA) has been widely used as an antioxidant to preserve and stabilize the freshness of food and feed. It is generally recognized as safe however it is classified as suspect carcinogen and endocrine disrupter. We investigated endocrine disrupting effects of BHA in steroid and thyroid hormone receptor gene transcription assay and in rat one-generation reproduction study. BHA induced weak transcription activity by binding with androgen receptor as induction ratio (IR) compared to testosterone was 1.37 % at 10 mM while it induced high transcription activity by binding with thyroid receptor as IR compared to T3 was 85% at 10 mM. In addition, BHA showed agonistic reaction with T3. In one-generation study, BHA induced increase of relative organ weight of liver, kidney, adrenal gland and thyroid gland and decrease of mating rate, cohabitation period for conception and T4 in serum in parent generation when treated orally for 7 weeks in male rats and for around 10 weeks in female rats. BHA also aroused increase of the relative organ weights of liver, kidney, adrenal gland, brain but decrease of those of vagina, spleen, and prostate gland. In one-generation rats, sex ratio of male was decreased and the anogenital distances were shortened and vaginal patency and preputial seperation were observed later than control group. Also, BHA decreased sperm motility and number and the width and length of sperm head. T4 in serum was lower than control. Conclusively, BHA is disruptor of androgen and thyroid hormonal system *in vitro* and *in vivo* study. NOAEL and ADI of BHA according to the results from one-generation study were estimated as 10 mg/kg B.W. and 0.1 mg/kg B.W./day, respectively.

1382 MOLECULAR CHARACTERIZATION OF THYROID TOXICITY: ANCHORING GLOBAL GENE EXPRESSION PROFILES WITH BIOCHEMICAL AND PATHOLOGICAL ENDPOINTS.

D. Delker, N. Everds, J. O'Connor, S. Frame and C. M. Glatt. *Haskell Laboratory, DuPont, Newark, DE.*

Thyroid toxicity in rodents caused by a large and diverse set of xenobiotics is commonly observed as a potentially adverse effect. Hypersecretion of thyroid stimulating hormone following disruption of the hypothalamic-pituitary-thyroid axis has been recognized as a common mode of action for the incidence of proliferative lesions in thyroid follicular cells. Organic iodides have been shown to induce thyroid hypertrophy and increase alterations in colloid in rats, although the mechanism involved in this toxicity is unknown. Organic iodides increase hepatic enzymes and release free iodide into the circulating blood. It is unknown whether these and/or some other effect(s) on the thyroid cause toxicity. To evaluate the effect that free iodide has on the thyroid, rats were exposed for 2 weeks by daily gavage to sodium iodide (NaI), phenobarbitol (PB), or propylthiouracil (PTU). PB and PTU were used as positive control thyroid toxicants to compare the effects of compounds with alternative mechanisms (increased thyroid hormone metabolism and decreased thyroid hormone synthesis, respectively). Adult male rats, (~8 weeks of age), were dosed with 0.1, 1, 10, or 100 mg/kg/day NaI; 100 mg/kg/day PB; or 10 mg/kg/day PTU. Thyroid histopathology, liver biochemistry, serum hormones, serum iodide, and thyroid gene expression parameters were analyzed. Mean final body weights were significantly decreased (91% of control) in rats treated with PTU. Relative liver weights were significantly increased in rats treated with NaI at 10 and 100 mg/kg/day and in PB-treated rats (108, 113, and 144% of control, respectively), and were significantly decreased in PTU-treated rats (92% of control). Relative thyroid weights were significantly increased in PTU-treated rats (300% of control) only. Follicular cell hypertrophy and pale-staining colloid was present in PB-treated rats and more severe hypertrophy/colloid changes along with diffuse hyperplasia were present in PTU-treated rats. Differential transcript profiles were detected with rat Affymetrix gene chips.

1383 OCT-1: A KEY PLAYER IN VASCULAR BIOLOGY - IMPLICATIONS FOR CARDIOVASCULAR TOXICITY.

T. Thum and J. Borlak. *Drug Research, Fraunhofer Institute, Hannover, Lower Saxony, Germany.* Sponsor: H. Muhle.

High levels of oxidized LDL lead to vascular injury, but its mechanism of action is poorly understood. To become available oxLDL particles are internalized *via* the lectin-like oxLDL receptor and intracellular available oxLDL may trigger endothelial toxicity and vascular dysfunction by, as yet, unknown mechanisms. Previously, we demonstrated endothelial dysfunction to be linked to activation of the transcriptional repressor OCT-1 (Thum and Borlak, 2000). Here we test our hypothe-

sis of OCT-1 driven repression of genes upon oxLDL induced injury. We thus treated cultured human endothelial cells with ascending doses of oxidized LDL (10 microgram/ml - 100 microgram/ml) and demonstrate a dose dependent increase in intracellular radical oxygen production. This was accompanied by reduced levels of nitric oxide and repression of endothelial NO synthetase (eNOS) and other major cytochrome P450 monooxygenase activities. Importantly, OCT-1 gene expression was increased in a dose-dependent fashion (up to 5-fold) and OCT-1 binding to the regulatory elements of responsive genes may provide a mechanism of endothelial gene silencing. Electro-mobility shifts are now on the way to ascertain the proposed OCT-1 / DNA interaction. Reference: Thum T, Haverich A, Borlak J. Cellular dedifferentiation of endothelium is linked to activation and silencing of certain nuclear transcription factors: implications for endothelial dysfunction and vascular biology. 1384 ARTERIAL CARCINOGEN METABOLISM COULD INITIATE THE ACCELERATED ATHEROSCLEROSIS SEEN IN SMOKERS.

J. L. Holtzman[1,3], L. M. Dunning[1,3], W. Carter[2] and R. Edwards[4]. *[1]Pharmacology, University of Minnesota, Minneapolis, MN, [2]Imperial College, London, United Kingdom, [3]Therapeuttics Section, VA Medical Center, Minneapolis, MN and [4]Plastic Surgeons, Edina, MN.*

HYPOTHESIS: The accelerated atherosclerosis seen in smokers is initiated by the toxic products formed during the arterial metabolism of the 2 major carcinogens of tobacco smoke, the polycyclic aromatic hydrocarbons (PAH)s and N-nitrosoamines (NNA)s. BACKGROUND: A number of laboratories have reported that arteries from various animals metabolize the PAHs to form the ultimate carcinogens. These reactions are catalyzed by cytochrome P450s, CYP1A1 and 1B1. The 1A1 is present in the aortas of various animal after PAH induction. No studies have reported the presence of the P450s catalyzing NNAs activation, CYP2A6 and 2E1. OBJECTIVES: We sought to determine whether these P450s are present in human arterial walls. METHODS: We prepared microsomes by standard procedures from the arteries of patients undergoing abdominal plasties. The P450s were determined by immunoblotting after Enhanced Chemoluminescence detection. RESULTS: We obtained 125 ug of microsomal protein from each artery. All 4 CYPs were observed at concentrations comparable to those found in hepatic microsomes after PAH induction. SIGNIFICANCE: These data support the hypothesis that the accelerated atherosclerosis seen in smokers is due to the metabolism of the PAHs and NNAs in the arterial wall leading to toxic injury and initiation of the accelerated atherosclerosis seen in smokers. These observations may have broad implications for the prevention of this disease process.

1385 REGULATION OF ACTIVATOR PROTEIN-1 (AP-1) BY 8-ISO-PGE2 IN A THROMBOXANE A2 RECEPTOR-DEPENDENT AND -INDEPENDENT MANNER.

T. Weber. *Molecular Biosciences, Battelle, Richland, WA.*

The thromboxane A 2 (TXA2) receptor (TP) is represented by two alternatively spliced isoforms, termed the platelet/placental (TP-P) and endothelial (TP-E) type receptors. Experimental evidence suggests that TP isoforms may be regulated by novel ligands termed the isoprostanes, which paradoxically act as TP agonists in smooth muscle and TP antagonists in platelet preparations. Here we have investigated whether prototypical isoprostanes (8-iso-PGF2alpha and 8-iso-PGE2) regulate the activity of TP isoforms expressed in Chinese Hamster Ovary (CHO) cells using activator protein-1 (AP-1)-luciferase activity as a reporter. AP-1-luciferase activity was increased by a TP agonist (U46619) in CHO cells transfected with the human TP-P and TP-E receptors and this response was fully inhibited by TP antagonists (ISAP, SQ29, 548). AP-1-luciferase activity was potently (nM) increased by 8-iso-PGE2 in CHO TP-P and TP-E cells, and this response was partially inhibited by cotreatment of cells with TP antagonists, while 8-iso-PGF2alpha was without effect. Cyclooxygenase inhibitors did not abolish 8-iso-PGE2 mediated AP-1-luciferase activity, indicating that this response is not dependent on de novo TXA2 biosynthesis. Interestingly, 8-iso-PGE2-mediated AP-1-luciferase activity was near maximal in naive cells between 1-10 nM concentrations, and this response was not inhibited by TP antagonist or reproduced by agonists for TP or EP1/EP3 receptors. These observations (1) support a role for novel ligands in the regulation of TP-dependent signaling, (2) indicate that TP-P and TP-E couple to AP-1, (3) provide further evidence that isoprostanes function as TP agonists in a cell-type specific fashion, and (4) indicate that additional targets regulated by 8-iso-PGE2 couple to AP-1.

1386 HYPERTENSION IN ARYL HYDROCARBON RECEPTOR NULL MICE CORRELATES WITH PLASMA ENDOTHELIN-1, BUT NOT ANGIOTENSIN II.

A. K. Lund and M. K. Walker. *College of Pharmacy Toxicology Program, University of New Mexico, Albuquerque, NM.*

The aryl hydrocarbon receptor (AhR) is a ligand-activated transcription factor known to mediate the toxicity of environmental pollutants, such as 2, 3, 7, 8-tetrachlorodibenzo-p-dioxin. The role of the AhR in development and physiological homeostasis is uncertain; however, functional inactivation as in AhR null mice results in progressive cardiac hypertrophy. Cardiac hypertrophy is often preceded by hypertension and elevated levels of vasoconstrictive peptides, such as endothelin-1 (ET-1) and angiotensin II (Ang II). We have previously reported that congenic AhR null mice exhibit elevated mean arterial blood pressure (MAP) at 3 mo which increases further at 5 mo. In addition, AhR null mice exhibit elevated plasma ET-1 at 5 mo, compared to age-matched C57Bl6 AhR wildtypes. To determine the role of Ang II and ET-1 in AhR null hypertension, AhR null mice were treated orally with ACE-inhibitor, captopril, at 400 mg/kg from 3-to-5 mo. At 5 mo, indwelling catheters were surgically inserted into the femoral artery and MAP was measured 3 days post-surgery. Mice were then sacrificed, blood collected, and plasma ET-1 and Ang II measured by RIA. Captopril treatment of AhR null mice reduced 5 mo MAP to 3 mo levels, compared to untreated AhR null mice (5 mo Rx, 116 ± 2; 5 mo no Rx, 123 ± 2, $p<0.001$; 3 mo no Rx, 114 ± 0.9 mmHg, $p=0.15$), but failed to reduce MAP to wildtype levels (102 ± 2 mmHg, $p<0.001$). Captopril also reduced plasma ET-1 in 5 mo AhR null mice to 3 mo levels (5 mo Rx, 10.3 ± 1.3; 5 mo no Rx, 12.5 ± 1.0, $p<0.02$; 3 mo no Rx, 11.2 ± 0.5 fmol/ml, $p=0.18$), but failed to reduce ET-1 to wildtype levels (6.2 ± 0.7, $p<0.001$). Finally, captopril reduced Ang II by 72 and 80% in AhR null mice compared to 3 and 5 mo untreated AhR null mice, respectively (5 mo Rx, 89.4 ± 16; 5 mo no Rx, 456 ± 42, $p<0.001$; 3 mo no Rx, 356 ± 95 fmol/ml, $p<0.001$). These data show that hypertension in AhR null mice correlates with plasma ET-1, but not Ang II. Future studies will determine whether ET-1 mediates hypertension in AhR null mice. Supported by ES10433 and AHA 0151511Z.

1387 EMBRYONIC CARDIAC HYPERTROPHY AND NEONATAL MACROSOMIA IS DEPENDENT ON AHR MATERNAL GENOTYPE.

E. A. Thackaberry[1], M. Goens[2], D. Gabaldon[1], S. M. Smith[3] and M. K. Walker[1]. *[1]College of Pharmacy Toxicology Program, University of New Mexico, Albuquerque, NM, [2]Department of Pediatrics, University of New Mexico, Albuquerque, NM and [3]Molecular and Environmental Toxicology Center, University of Wisconsin, Madison, WI.*

The aryl hydrocarbon receptor (AhR) is a cytoplasmic protein, originally characterized because of its high affinity binding for 2, 3, 7, 8, -tetrachlorodibenzo-p-dioxin (TCDD). AhR is required for most, if not all, of the toxic effects of TCDD; however, studies using AhR null mice have identified new roles for the AhR in normal physiology and development, distinct from its role as an environmental sensor of toxicants. Previous work in our laboratory has shown that adult AhR null male mice develop significant cardiac hypertrophy by 5 mo. In the current study, we investigated the role of the AhR in fetal cardiac development and discovered that AhR null mice showed a significant increase in heart weight, body weight, and heart/body weight ratio at birth. Importantly, a series of mating experiments determined that this phenotype was dependent on the maternal genotype alone, as mice born to AhR null females had increased heart and body weights compared to mice born to wildtype and AhR heterozygous dams, regardless of neonatal genotype. This implicates a maternal effect as the cause of the embryonic phenotype, and led us to explore whether AhR null mice develop gestational diabetes, which is linked to fetal cardiac hypertrophy and neonatal macrosomia. We found that pregnant mice lacking the AhR exhibit altered insulin regulation and responsiveness as seen by decreased fasting plasma insulin ($p<0.05$) and a trend towards insulin resistance ($p=0.08$). However, hyperglycemia and altered glucose tolerance, characteristics of gestational diabetes, were not observed. These results suggest that gestational diabetes is not responsible for the fetal cardiac hypertrophy and neonatal macrosomia in mice born to AhR null females, but alterations in insulin regulation and tissue responsiveness to insulin cannot be eliminated as potential causative factors. Supported by ES10433 to MKW.

1388 QUANTITATIVE GENE EXPRESSION CHANGES IN PERIPHERAL BLOOD LEUKOCYTES (PBL) OF RATS WITH FENOLDOPAM-INDUCED VASCULAR INJURY.

F. M. Goodsaid[1], R. Smith[1], G. Mandakas[1], I. Y. Rosenblum[1], J. Zhang[2], R. Honchel[2], A. Knapton[2], B. A. Rosenzweig[2] and F. D. Sistare[2]. [1]*Genetic and Molecular Toxicology, Schering-Plough Research Institute, Lafayette, NJ and* [2]*Center for Drug Evaluation and Research, USFDA, Laurel, MD.*

The identification of changes in mRNAs or proteins in accessible tissues that are predictive of vascular damage by drugs would facilitate testing and prioritization of candidate compounds and may assist with assessments of clinical relevance. In agreement with previous reports on the effects of fenoldopam, the present study demonstrated the induction of mesenteric vascular lesions in rats within 24 hours of dosing. PBL were isolated from rats (6 per group) dosed s.c. with either 60 mpk of fenoldopam, or with saline vehicle. Using qRT-PCR we measured expression changes for cytokines (IL1-IL18) and 33 additional targets. IL-1 beta, IL-7 and IL-10 show 2.8, 2.4 and 2.5-fold induction, respectively. Of the additional targets, significant induction was measured for: diaphorase 4 (3.4-fold), ERBB-2 (2.8-fold), IGF2 (2.9-fold), iNOS (4.2-fold), LP1 (4.2-fold), MET-HGFR (12.8-fold), MIP-1 beta (2.9-fold), and TNF-alpha (3.6-fold). Changes in the expression of product from some of these genes (IL-1 beta, TNF-alpha, iNOS, MET-HGFR) have been previously implicated with the development of vascular lesions. These data imply that certain PBL gene expression alterations may serve to herald the onset of drug-induced vascular injury and further investigations are in progress to assess sensitivity, specificity, and interspecies utility.

1389 IDENTIFICATION OF GENES LINKED TO DOXORUBICIN CARDIOTOXICITY AND TO THE CARDIOPROTECTANT EFFECT OF DEXRAZOXANE IN RATS.

K. Thompson[1], B. A. Rosenzweig[1], P. Pine[1], J. Zhang[1], E. H. Herman[1], A. D. Knapton[1], R. Honchel[1], B. Shimada[2], S. Kassam[2], D. B. Finkelstein[2], J. Lescallet[2], J. D. Retief[2] and F. D. Sistare[1]. [1]*DAPR, CDER, USFDA, Laurel, MD and* [2]*Affymetrix Inc., Santa Clara, CA.*

Doxorubicin (DOX) is a cardiotoxic anti-neoplastic drug that induces diffuse cardiac pathology characterized by myofibrillar loss and cytoplasmic vacuolization. Administration of dexrazoxane (DZR) prior to DOX significantly but only partially protects the heart from injury. Spontaneously hypertensive rats (SHR), which have increased sensitivity to DOX cardiotoxicity, were used to investigate gene expression changes in heart on Affymetrix RGU34A arrays. Adult male SHR were given either 2 or 3 weekly injections of 3 mg/kg DOX with or without pretreatment with 50 mg/kg DZR, or 1 mg/kg/wk DOX for 9 weeks. After 9 weeks of DOX, significant cardiac pathology is observed, and genes involved in tissue injury and remodeling are upregulated. An increase in immune cell markers was also seen, which is consistent with the increases in number of cardiac dendritic cells observed in a previous study. Very few significant changes in gene expression, histopathology or clinical chemistry were observed after 2 injections of DOX. After 3 weekly injections of DOX, alterations in serum levels of cardiac troponin T, cholesterol, triglycerides, and total protein were detected along with minimal myocyte damage. DZR alone had little effect on gene expression, but a subset of genes was identified that had significantly different levels of expression in SHR that received DZR in addition to DOX compared to DOX alone. Some members of this gene set reflect DZR inhibition of hydroxyl radical production by DOX (e.g., lower induction levels of GST and NAD(P)H-diaphorase). DZR pretreatment also modulated DOX-induced decreases in some genes involved in heart function like GLUT4 and the type II ryanodine receptor. A larger set of genes was identified that were significantly changed by DOX treatment +/- DZR. These genes may provide mechanistic clues for the rational design of clinical strategies to further reduce DOX cardiotoxicity.

1390 THE ROLE OF GLUTATHIONE S-TRANSFERASE A4-4 IN ENDOTHELIAL CELL DEFENSE AGAINST CYTOTOXICITY DUE TO OXIDATIVE STRESS.

Y. Yang[1], Y. Yang[2], N. He[3], M. B. Trent[1], Y. C. Awasthi[2] and P. J. Boor[1]. [1]*Pathology, University of Texas Medical Branch, Galveston, TX,* [2]*Human Biological Chemistry and Genetics, University of Texas Medical Branch, Galveston, TX and* [3]*Sealy Center for Cancer Cell Biology, University of Texas Medical Branch, Galveston, TX.*

A group of immunologically related a-class mammalian glutathione S-tranferases (GSTs) which utilize 4-hydroxynonenal (4-HNE) as the preferred substrate has been proposed to be a major cellular defense system against oxidative injury by products of lipid peroxidation, including aldehydes such as 4-hydroxynonenal (4-HNE) and acrolein. Previous studies have demonstrated that GSTs play an important role in protection of vascular smooth muscle cells against oxidant damage, but the role of GSTs in the endothelial cell, which plays a critical role in atherosclerosis, is not well studied. We tested the hypothesis that overexpression of GST would increase resistance to the, toxic aldehydes such as acrolein, formaldehyde, 4-HNE, and direct oxidative stress from H2O2. Stable transfection of mouse islet endothelial cells (MS1) with mGST A4-4, an isozyme of GST with activity in vascular wall, was established; transfected cells demonstrated enzyme activity three times (toward 1-chloro-2, 4-dinitrobenzene) and four times(toward 4-HNE) higher than wild-type MS1 cells or cells transfected with vector alone. Transfected cells expressed significantly ($p<0.05$) increased resistance to the cytotoxicity of allylamine (which is metabolized to acrolein), acrolein, 4-HNE, and H2O2, but little difference in resistance to formaldehyde. Transfected MS1 cells also showed a significantly higher rate of proliferation compared to wild-type or vector transfected MS1 cells. Intracellular malondialdehyde and 4-HNE levels determined by mass spectrometry were lower in mGST A4-4-transfected cells than in cells transfected with vector alone or MS1 wild type. Our results indicate that expression of mGST A4-4 in endothelial cells plays a key role in protecting the blood vessel wall against oxidative stress and, thus, is likely to be a critical defense mechanism against atherogens.

1391 SYNERGISTIC TOXICITY INDUCED BY DOXORUBICIN AND ANTI-ERBB2 IN RAT NEONATAL CARDIOMYOCYTES.

K. L. Gabrielson[1], M. Servinsky[1], N. Peterson[1], W. Shi[1], M. Akao[2], E. Marban[2], S. Barber[1] and R. Becker[1]. [1]*Comparative Medicine, Johns Hopkins University, Baltimore, MD and* [2]*Medicine, Johns Hopkins University, Baltimore, MD.* Sponsor: J. Yager.

Anti-erbB2 (Herceptin -Trastuzumab) is an effective treatment for breast cancers that over-express the Her2/neu oncogene. Unfortunately, cardiomyopathy is an adverse synergistic effect of Herceptin treatment in 28% of patients also exposed to the anthracycline doxorubicin. The mechanism(s) of synergistic cardiac toxicity observed with doxorubicin and anti-erbB2 treatment is not well understood. We have developed an *in vitro* system to study this toxicity using rat neonatal cardiomyocytes and an anti-rat-erbB2 monoclonal antibody (Mab 7.16.4). This antibody has been shown to induce the same biological effects in rat cells expressing erbB2, as Herceptin does in human breast cancer cells, including similar epitope recognition, inhibition of cell growth, reversion of phenotype and reduction in cancer cell growth *in vivo*. The ability of Mab 7.16.4 to bind specifically to erbB2 in rat cardiomyocytes was verified by FACS analysis. When given together, doxorubicin (.05microM) and anti-erbB2 (1microg/ml) induces synergistic toxicity in rat neonatal cardiomyocytes (by 48 hours as determined by MTT assay) compared to doxorubicin, anti-erbB2, saline or isotype control IgG2a treatments alone. Interestingly, cytotoxicity was found to correlate with activation of caspase-3 as assessed by immunofluorescence analysis. Treatment with anti-erbB2 for 10 min induces tyrosine phosphorylation of the erbB2 receptor, known to lead to activation of Akt and ERK/MAPK in response to the natural ligand, Neuregulin. However, activation of these pathways should suppress activation of caspase-3, suggesting that Mab 7.16.4-induced erbB2 phosphorylation may activate distinct signaling pathways that will be explored in future studies. Once the mechanism of toxicity is understood, successful cardiac-specific strategies can be developed for humans to prevent cardiac injury without affecting the anti-neoplastic effect of these two important breast cancer treatment drugs.

1392 *IN VITRO* INVESTIGATION OF DRUG-INDUCED HEPATIC STEATOSIS: BIOCHEMICAL AND GENOMIC APPROACHES.

J. D. Tugwood[1], L. E. Hollins[2] and M. J. Cockerill[2]. [1]*Safety Assessment UK, AstraZeneca Pharmaceuticals, Macclesfield, Cheshire, United Kingdom and* [2]*School of Biological Sciences, University of Manchester, Manchester, United Kingdom.* Sponsor: T. Orton.

The novel pharmaceutical agents #021 and #974 unexpectedly caused lipid accumulation in the liver when administered to rats and dogs. In an attempt to elucidate the molecular mechanisms underlying the hepatosteatosis induced by these compounds, a rat primary hepatocyte culture was employed. Initially, cultures were exposed to both compounds at various concentrations over a 24-hour time course, and cytotoxicity measured. This established for both compounds that 2μM and 20μM were a sub-toxic and toxic concentration respectively over this time course, and these concentrations were used in subsequent studies. Lipid accumulation in response to compound treatment was measured using Nile Red staining. Both compounds induced significant staining over a 18 to 24 hour period when administered at 20μM, as did the known hepatosteatotic agent amiodarone. No staining was observed in control cultures, or in cultures treated with compounds at 2μM. Transcript profiling analysis was also carried out using the Affymetrix GeneChip™ system. Rat hepatocyte cultures were exposed to vehicle controls, #021 and #974

over a time course of 1, 2, 4, 8, and 24 hours. Experiments were performed on two separate hepatocyte preparations, and RNA isolated for the gene array analysis. Following bioinformatic analysis of the data, a number of putatively regulated genes were selected for confirmation by quantitative RT-PCR. Among those genes confirmed as being regulated by the test compounds were some "known" steatosis-associated genes, including CYP2E1 (down-regulated), aldolase B (down-regulated), and FATP (upregulated at early time points). Also, some novel genes changes not previously associated with this type of toxicity were identified, and the significance of these is currently being investigated. In conclusion, rat primary hepatocyte cultures appear useful for studying liver toxicity induced by #021 and #974, since there is good concordance between the cytotoxic, biochemical and genomic endpoints measured.

1393 COMPARATIVE *IN VITRO* TOXICITY STUDIES BETWEEN PRIMARY RAT HEPATOCYTES AND RAT HEPATIC CELL LINES USING GENE EXPRESSION ANALYSIS.

S. Hussain[1], V. Chan[1], D. Rudnicki[2] and J. M. Frazier[2]. *[1]Toxicology, ManTech Environmental Technology, Inc., Dayton, OH and [2]Wright-Patterson AFB, OH, USA, Dayton, OH.*

Cultured liver cells to study chemical hepatotoxicity have become a powerful alternative to *in vivo* toxicological models. Primary hepatocytes are especially useful in screening cytotoxic and genotoxic compounds due to their similarities to liver cells *in vivo*. However, the *in vitro* model that best correlates with liver cells *in vivo* has yet to be determined. In order to select a model cell line, the present study was conducted to compare gene expression profiles of primary rat hepatocytes and rat hepatic cell lines (BRL 3A and Clone 9). Gene expression analysis, using Affymetrix microarrays (Rat Genome U34A), indicated significant changes in gene expression profiles both up and down regulation in rat liver cell lines compared to rat primary hepatocytes. We have also investigated cadmium (Cd) toxicity in primary hepatocytes and hepatic cell lines using LDH leakage, MTT reduction and ATP as end points. The fluorescence probes YO-PRO-1 and propidium iodide were used to detect apoptotic, necrotic and viable cells in Cd exposed liver cell lines. Cd induced apoptosis in liver cell lines at 50 uM while a much lower concentration (1 uM) was required in primary rat hepatocytes. In summary, the results show that primary cells were more sensitive to Cd compared to liver cell lines. The differences in gene expression observed between primary and immortalized hepatoctyes appear to support the increased sensitivity of primary cells to this heavy metal. Further, a detailed analysis of differential gene expression in primary cells and cell lines will assist in selecting a cell line model for toxicity screening of new chemicals.

1394 EVALUATION OF HEPATOCYTE SPHEROIDS AS A MODEL FOR TOXICITY STUDIES.

R. T. Dunn and M. T. Leininger. *Investigative Toxicology, Pharmacia Corporation, Kalamazoo, MI.*

The present studies characterized the utility of primary hepatocyte spheroids for toxicological investigations. Current *in vitro* models of hepatotoxicity have been scrutinized for lack comparability to liver. Among the inherent deficits are: resistance to enzyme induction, lack of tertiary liver structure, and low correlation with *in vivo* heptatoxicity. Primary hepatocyte spheroids offer an alternative cell culture environment amenable to formation of a liver-like structure. Thus the present study examined parameters of hepatocyte function in order to assess the value of hepatocyte spheroids as models for toxicology. Hepatocytes were isolated from livers of male Sprague-Dawley rats by collagenase perfusion. Following isolation of hepatocytes, cells were cultured in spinner flasks to facilitate spheroid formation as described (Abu-Absi et al., 2002). The ability of hepatocyte spheroids to demonstrate drug metabolizing enzyme induction (DME) was assessed as an index of hepatocyte functionality. Measurement of individual DMEs was performed by transcript profile analysis (TxP). Spheroids were exposed to classical inducers of rat cytochromes P450 for 6 or 24 hr. Among the compounds tested were: PCN (CYP3A), phenobarbital (CYP2B1/2B2), benzo[a]pyrene (CYP1A1 and 1A2), DEHP, clofibrate, and WY-14643 (CYP4A). Measurement of gene induction was carried out using SYBR green sequence detection. Total RNA was isolated and reverse transcribed into cDNA. The cDNA was used as template for the SYBR green detection assay utilizing primers specific for each CYP450 gene. Expression of the cytochromes was compared to genes whose transcript levels were stable across experimental conditions. Initial histological characterization indicated that hepatocyte spheroids were present as compact aggregates of multiple individual hepatocytes with high viability. Treatment of spheroid culture with enzyme inducers demonstrated responsiveness similar to that reported for each inducer *in vivo*. In addition, treatment of spheroids resulted in differential dose/time response for measured transcripts.

1395 *IN VITRO* HEPATOTOXICITY STUDY OF BARAKOL USING HUMAN HEPATOMA CELL LINE HEP G2.

S. Lawanprasert[1], C. Chaichantipyuth[1], S. Unchern[1], Y. Lawanprasert[3] and D. St. Clair[2]. *[1]The Institute of Health Research, Chulalongkorn University, Bangkok, Thailand, [2]Drug Control Division, Office of Food and Drug Administration, Bangkok, Thailand and [3]Graduate Center for Toxicology, University of Kentucky, Lexington, KY.*

Human hepatoma cell line HepG2 was used to assess the hepatotoxic effects of barakol, isolated from young leaves of Cassia siamea. Barakol at concentrations of 0.25, 0.50, 0.75 and 1 mM were added to HepG2 cells for 24, 48, 72 and 96 hours. Cytotoxicity was assessed by a rapid MTT cell viability screening assay. Activities of lactate dehydrogenase enzyme in the culture medium were determined at 24 and 48 hours of barakol incubation. Acetaminophen, the well-known hepatotoxin, at concentrations of 1, 3, 5, 7 and 10 mM were also assessed in parallel in the same manner. Using MTT assay, barakol demonstrated a dose- and time-dependent cytotoxic effects in the same manner as acetaminophen. Barakol exhibited a significant ($p < 0.05$) cytotoxic effect at concentrations of 0.75 mM or greater at 24 hours of exposure. At 48, 72 and 96 hours of exposure, cytotoxicities of barakol were shown at concentrations of 0.50 mM or greater. Fifty percent cytotoxicities (IC50) of barakol on HepG2 cells at 24, 48, 72 and 96 hours of exposure were 5.70, 0.96, 0.77 and 0.68 mM, respectively whereas the corresponding IC50 of acetaminophen were 12.14, 11.13, 1.39 and 1.30 mM, respectively. At the same concentration of 1 mM, barakol was significantly ($p < 0.05$) more cytotoxic to HepG2 cells than acetaminophen at every time point of compound exposures. However, both barakol and acetaminophen caused lactate dehydrogenase leakage in the same extent at 1 mM concentration and 48 hours exposure. A depleted reduced glutathione as well as a decrease of GSH/GSSG ratio following barakol exposure might explain the mechanism by which barakol induced hepatotoxicity.

1396 IDENTIFYING EARLY APOPTOTIC EVENTS IN RAT HEPATOMA (H4IIE) AND KIDNEY EPITHELIAL (NRK-52E) CELLS USING CELLOMICS™ ARRAYSCAN® II.

P. C. Wilga, D. K. Petrella, J. F. Pregenzer, R. K. Patel, J. J. Keckeissen, D. D. Baker, G. L. Cockerell and J. M. McKim, Jr.. *Investigative Toxicology, Pharmacia, Kalamazoo, MI.*

The use of multiple endpoint analysis and detailed dose responses early in drug discovery can provide information on a compound's potential to produce apoptosis. Although many compounds induce apoptosis through activation of caspases, this alone may not account for all apoptotic mechanisms. In order to more accurately identify compounds that induce apoptosis, the Cellomics™ Arrayscan® II system has been added to rapidly monitor apoptotic markers other than caspase activation. Utilizing an optical imaging system and multiple fluorescent channels, the Arrayscan® II concurrently analyzes changes in three apoptotic endpoints: Nuclear Fragmentation/ Condensation (NFC), Mitochondrial Mass/ Potential (MMP), and F-Actin Content (FAC). This study compared caspase activity assays to the Arrayscan® II following exposure of H4IIE cells to known inducers of apoptosis. Paclitaxel (0-300 μM) did not reveal any significant increase in caspase activity after 3 and 6 hr exposures. However, the Arrayscan® II detected a substantial increase in MMP at all doses. Increases in caspase activity were observed at 12 and 24 hr, but the Arrayscan® II showed increases in all three apoptotic markers (MMP, NFC, FAC). Staurosporine treatment showed increases in MMP at very low doses (<0.001 μM) and increases in NFC and FAC at higher doses (>0.05 μM) after 3 hr. Caspase activity was only noted at the highest treatment (10 μM). Caspase activity was not observed in either H4IIE or NRK-52E cells exposed to gentamicin (0-10 mM) for 72 hr. However, Arrayscan® II clearly showed significant increases in the NFC and FAC markers in NRK-52E cells, but not in the H4IIE cells. These findings were supported by ELISA results that showed DNA fragmentation in only the NRK-52E cells. These data support *in vivo* studies that showed renal specific toxicity with gentamicin. In summary, the Arrayscan® II screen appears to be a valuable and highly sensitive method for identifying compounds that induce apoptosis.

1397 ASSESSMENT OF HIGH PRECISION RAT LIVER SLICES AS AN *IN VITRO* MODEL FOR UPTAKE AND ACTIVITY OF PHOSPHORODIAMIDATE MOPHOLINO OLIGOMERS.

D. A. Leibelt, M. L. Cate, P. L. Iversen and V. Arora. *Research & Development, AVI BioPharma, Inc., Corvallis, OR.*

The objective of this study was to evaluate the suitability of high precision rat liver slices as a model to predict the antisense activity of phosphorodiamidate Morpholino oligomers (PMOs) in rat liver *in vivo*. PMOs are third generation antisense agents that are efficient inhibitors of translation *via* a non-RNase H, sequence-specific steric-blockade process. Previous studies with PMOs have demonstrated high bioavailability in the liver, as well as sequence-specific and

dose-dependent target gene inhibition following systemic administration in rats. The high precision rat liver slice model offers an extremely efficient method to study gene inhibition by allowing a large sample size while minimizing the number of animals required. The present studies addressed PMO biodistribution in rat liver slices. Uptake of PMO was investigated with respect to both dose and time. Livers were resected from Sprague-Dawley rats and 200 µm thick slices prepared utilizing a Brendel/Vitron tissue slicer. Slices were cultured in glass scintillation vials containing Waymouth media using a dynamic organ culture system in a 95% O_2 and 5% CO_2 environment. Effect of PMO concentration on uptake was studied using incubation with fluorescein-labeled PMO at concentrations of 1, 10, 30, and 100 µM for 18 hrs. Effect of time on PMO uptake was studied by incubation of slices at a concentration of 10 µM for various time points ranging from 10 seconds through 18 hours. Effect of media serum content on PMO activity was studied for serum concentrations ranging from 0 through 25%. The results indicate that the uptake of PMO into cultured rat liver slices was dose-dependent and time-dependent after 1 minute. Fluorescence photomicrography was employed to confirm intracellular distribution of PMO. We conclude that PMOs demonstrate high biodistribution in precision rat liver slices. This technique can serve as an efficient model for predicting the *in vivo* antisense activity of PMOs in rat liver while reducing the number of animals required in the investigation.

1398 AN *IN VITRO* PREDICTIVE TOXICOGENOMICS SCREEN (PTS) FOR HEPATOTOXICITY.

R. W. Gerwien[1], J. F. Simons[1], O. R. Crasta[1], D. M. Dziuda[1], C. Hyde[1], H. E. Olsen[1], K. M. Hershman[1], J. S. Bader[1], H. Ellinger-Ziegelbauer[2], M. J. Czar[1], M. F. DeCristofaro[1], M. M. Lakkis[1], T. A. Lohret[1], D. A. McCabe[1], J. J. DeClement[1], T. A. Mansfield[1], H. J. Ahr[2], W. Kroll[3] and M. McKenna[1]. *[1]Pharmacogenomics, CuraGen Corporation, New Haven, CT, [2]Research Toxicology, Bayer AG, Elberfeld and [3]Bayer Corporation, West Haven, CT.*

The application of genomics to toxicology offers the promise of greater sensitivity at much lower cost than traditional diagnoses. We describe an *in vitro* toxicogenomic based high-throughput rat hepatotoxicity assay predictive of 11 different liver pathologies. In Phase I of this project, our research group employed GeneCalling® to identify multivariate markers, or gene expression patterns, associated with these specific toxicities. This database includes greater than 100 toxic and non-toxic compounds administered sub-acutely to male Wistar rats. Data for liver histopathology and gene dysregulation were analyzed using statistical learning techniques to identify toxicity markers and generate a series of 11 predictive models. Phase II created an *in vitro* PTS by assessing gene dysregulation in primary hepatocyte cultures after 24 hour exposure to the same compounds used in Phase I. *In vitro* samples were assigned the same toxicity annotation as observed *in vivo* on a per compound basis. Although the identity of toxicity marker genes differ between *in vitro* and *in vivo*, the two sets do overlap in terms of toxicologically relevant pathway dysregulation. The genes in this marker set have been transferred to customized microarrays that are part of our industrialized toxicogenomics assay. Preliminary results indicate we are able to rank compounds based on the likelihood they will produce toxicity. Furthermore we have an accuracy of greater than 90% for approximately 80-85% of all samples on average. We envision this assay being integrated into the drug development pipeline to assess rat liver toxicity at either an early point during hit identification or later during lead optimization.

1400 USE OF HIGH THROUGHPUT METHOD FOR SCREENING THE MEIC GROUP IN THE HUMAN LIVER C3A CELL LINE TO EVALUATE THE RELEVANCE AND RELIABILITY OF THE ACTIVTOX SYSTEM FOR PREDICTING ACUTE SYSTEMIC TOXICITY.

T. M. Fletcher[1], A. Rizvi[1], T. Guthrie[1], M. Walterschied[2] and J. Kelly[2]. *[1]Cancer Therapeutics and Immunology, Southern Research Institute, Birmingham, AL and [2]Amphioxus Cell Technologies, Houston, TX.* Sponsor: J. Page.

Rationale: A perennial question surrounding the use of *in vitro* ADMET systems is whether they, in fact, represent the *in vivo* situation. In an attempt to answer this question, the Scandinavian Society for Cell Toxicology organized the Multicenter Evaluation of *In Vitro* Cytotoxicity (MEIC) study. As part of the study, MEIC chose fifty chemicals where reliable acute toxicity information from humans was available from death records. We have analyzed a subset of these chemicals using the ACTIVTox system as a means of examining the same question: does *in vitro* reflect *in vivo*? **Methods:** All assays were performed using Amphioxus Cell Technologies' ACTIVTox human C3A hepatocyte cell line. Toxicity was evaluated by use of cellular proliferation or membrane integrity assays, both of which utilized the conversion of resazurin into a fluorescent resorufin product as an end-point. **Results:** The IC50 values determined in the two assays were compared to the MEIC database where the *in vivo* toxicity information was derived from a LD50 with human acute lethal doses. For many of the compounds, the IC50 determined in both assays was comparable. However, for several of the test compounds, there was a disparity in the results obtained between the two assays. In the latter cases, whenever there was a difference in the two assays, we chose the lowest IC50. In this way, no toxicity would be underestimated. **Conclusion:** There was a remarkable coincidence observed in the data. No compounds were dramatically underestimated thus eliminating the fear of missing toxic compounds, and three compounds were significantly overestimated. These compounds are copper sulfate, hexachlorophene and thioridazine, all three known hepatotoxins. This study lends support to the use of *in vitro* ADMET systems as reliable models for predictive *in vivo* toxicity.

1401 COMPARATIVE DOSE-RELATED EFFECTS OF INHALED CARBON BLACK PARTICLES IN THE LUNGS OF RATS, MICE, AND HAMSTERS.

A. Elder[1], N. Corson[1], R. Gelein[1], P. Mercer[1], J. Finkelstein[2], P. Keng[3], J. Harkema[4], K. Driscoll[5] and G. Oberdorster[1]. *[1]Environmental Medicine, University of Rochester, Rochester, NY, [2]Pediatrics, University of Rochester, Rochester, NY, [3]Radiation Oncology, University of Rochester, Rochester, NY, [4]Veterinary Pathology, Michigan State University, East Lansing, MI and [5]Procter & Gamble Co., Cincinnati, OH.*

After inhalation of high concentrations of carbon black (CB), rats, but not mice or hamsters, develop lung tumors that are associated with particle overload in the lungs. Since this response is not related to any direct genotoxicity of the particles, it is hypothesized that it is due to species-specific particle clearance kinetics and the processes of inflammation and cell proliferation. In this study, we compared particle-induced inflammation in response to inhaled CB (1, 7, 50 mg/m^3; 6 hr/day, 5 days/week for 13 weeks) in female F-344 rats, B6C3F1 mice, and F1B hamsters at several post-exposure time points (1 day; 3 and 11 months post-exposure). Aerosol particle sizes ranged from 1.2 to 1.6 µm (mass median aerodynamic diameter) with geometric standard deviations of 2.2-2.8. At the end of exposure, mice had retained the highest amount of CB in terms of particle surface area per gram of lung; hamsters had the lowest retained amount. However, rats demonstrated the slowest clearance such that the CB burden in the high dose group was higher than in mice or hamsters 11 months after exposure. For the low and mid dose groups, cellular and biochemical indices of inflammation, proinflammatory cytokines, and antioxidant levels were similar for all three species. At the highest dose, however, the responses in rats were greatest in magnitude and were more persistent. The results suggest that rats are the most susceptible of the three species to lung particle overload effects; hamsters are the least sensitive to the effects of inhaled CB. The results further suggest that an exposure dose of 1 mg/m^3 can be considered the NOAEL in this study for female rats, mice, and hamsters. This work was funded by the International Carbon Black Association.

1402 INFLAMMATORY RESPONSES IN THE MOUSE EXPOSED INTRATRACHEALLY TO CARBON BLACK, POLYSTYRENE PARTICULATE, AND DIFFERENT SIZE OF COAL FLY ASH.

I. Nishimura and T. Negishi. *Central Research Institute of Electric Power Industry, Abiko, Chiba, Japan.* Sponsor: Y. Aoki.

Inhaled particulate matter causes inflammation in the lung. Magnitude of the response differs with the size, exposure dose, and chemical constituent of the particulate. This study is conducted to compare changes in the lung inflammation due to different size and physicochemical nature of the particulates. We fractionated coal fly ash (CFA) to fine, mean diameter=1.26µm (F-CFA), and to coarse, 5.75µm (C-CFA), particulates. Carbon black (CB, 0.2-0.01µm) was chosen as a surrogate of diesel exhaust particulate and polystyrene particulate (PSP, 0.208µm) was used as a non-metal reference. Two doses, 0.1 (low) and 0.5 (high) mg/mouse, of CFAs and 0.5mg/mouse of CB and PSP, as well as solvent, were intratracheally instilled to groups (n=6 to 8) of 6 weeks old ICR male mice under halothane anesthetization. Mice were sacrificed to obtain bronchoalveolar lavage fluid (BALF) and lung free cells. Another set of identically treated mice was sacrificed for histopathological examination. The number of lung free cells in all exposed groups increased from day 1 to day 3, then it became comparable to control group at day 7. However, the difference between C-CFA and F-CFA group was not evident nor the difference between high and low dose group. Amounts of albumin and protein and lactate dehydrogenase activity in the BALF of all exposed groups showed statistically insignificant elevation throughout 7 days. Again, dose dependency in these endpoints was not pronounced. Histopathological inflammation scoring indicated that the score in high dose group of F-CFA, as well as CB and PSP, were augmented and remained higher for 7 days than that of control group and those of matched exposed groups in low dose. Results revealed that time course and magnitude of the lung responses were similar regardless of instilled particulates, CFA size difference between 1.26 and 5.75µm did not evoke apparent change, and dose-response between 0.1 and 0.5mg/mouse did not exist except for histopathological evaluation. (This study is sponsored by Dr. Yasunobu Aoki, NIES, Japan).

1403 RATS, BUT NOT HAMSTERS, HAVE PERSISTENT ALVEOLITIS AND TYPE II CELL PROLIFERATION AFTER CHRONIC INHALATION OF CARBON BLACK PARTICLES.

J. R. Harkema[1], J. G. Wagner[1], J. A. Simon[1], S. McBride[1], A. C. Elder[2], K. Driscoll[3] and G. Oberdorster[2]. *[1]Pathobiology, Michgian State University, East Lansing, MI, [2]Environmental Medicine, University of Rochester, Rochester, NY and [3]Procter & Gamble Co., Cincinnati, OH.*

Rats, but not hamsters, chronically exposed to high levels of airborne carbon black particles (Cb) or other low toxicity particles develop lung tumors in association with alveolar inflammation and epithelial proliferation. The purpose of the our study was to determine the postexposure (PE) persistence of alveolitis and type II cell proliferation in the lungs of rats and hamsters similarly exposed to Cb. Female F344 rats and 212 F1B Syrian golden hamsters were exposed by inhalation to 3 concentrations of Cb (1, 7, 50 mg/m3) for 6 h/day, 5 days/wk for 13 wk. Rodents were sacrificed one day or 13 wk PE. The left lung lobe of each animal was processed for light microscopy. Numeric cell densities of alveolar type II cells and neutrophils were determined using standard morphometric techniques. Compared to air-exposed controls (0 mg/m3 Cb), rats exposed to 7 and 50, but not 1, mg/m3 Cb had increased numeric cell densities of neutrophils (alveolitis) and alveolar type II cells (hyperplasia). At 1 day PE, rats exposed to 7 and 50 mg/m3 Cb had 75% and 128% more type II cells, respectively, than air-exposed controls. Type II cell proliferation persisted throughout 13 wk PE only in the lungs of rats that were exposed to 50 mg/m3 Cb (158% more than controls). In contrast, no alveolitis was evident in any of the Cb-exposed hamsters at one day or 13 wk postexposure. A mild and transient increase in the number of alveolar type II cells (37% more than controls) was evident only in hamsters exposed to 50 mg/m3 Cb and sacrificed one day PE. No type II cell hyperplasia was evident in the lungs of Cb-exposed hamsters sacrificed 13 wk PE. These results indicate that rats, but not hamsters, chronically exposed to high airborne concentrations of Cb develop severe and persistent pulmonary inflammation and alveolar epithelial proliferation. (Research sponsored by the International Carbon Black Association)

1404 AMBIENT AIR PARTICLES OF DIFFERENT SIZE FRACTIONS CAUSES RELEASE OF INFLAMMATORY CYTOKINES, CELL TOXICITY AND APOPTOSIS IN EPITHELIAL LUNG CELLS.

R. Hetland [2], F. Cassee[1], M. Refsnes[2], P. Schwarze[2], M. Låg[2], A. Boere[1] and E. Dybing[2]. *[1]National Institute for Public Health and the Environment, Bilthoven, Netherlands and [2]Department of Air Pollution and Noise, Norwegian Institute of Public Health, Oslo, Norway.*

A number of epidemiological studies have provided indications that smaller size may be more potent than larger to induce health effects. Nonetheless, the relative significance of various size fractions of ambient particulate matter (PM) to induce inflammatory and toxic effects in lung cells has not extensively been investigated. We explored the potency of different size fractions of urban ambient air particles to induce release of inflammatory cytokines in the human alveolar cell line A549 and primary rat type 2 cells. A mineral-rich PM10 fraction of mechanically-derived ambient air particles was also included. The coarse fraction of ambient air particles demonstrated a similar or higher potency to induce release of the proinflammatory cytokines IL-8/MIP-2 and IL-6 compared to the fine and ultrafine fractions. The coarse fraction was also the most toxic. In contrast to the A549 cells, no induction of cytokine release was induced by the ultrafine particles in the primary type 2 cells. The mineral-rich road PM10 was equally or more potent than the various size fractions of the ambient air particles to induce cytokines in both cell types. In conclusion, the induction of inflammatory and toxic effects in lung cells can be caused by both the coarse and fine fraction of ambient particulate matter.

1405 INDUCTION OF TUMOR NECROSIS FACTOR α (TNFα) SIGNALING GENES IN ALVEOLAR MACROPHAGES (Mϕ)AFTER EXPOSURE TO ULTRAFINE PARTICLES (UFP).

B. Chin and B. D. Thrall. *Molecular Biosciences, Pacific Northwest Laboratory/Battelle, Richland, WA.*

It is known that phagocytosis of UFP by Mϕ stimulates the release of proinflammatory cytokines such as TNFα. However, the subsequent effects of these cytokines on gene expression are less understood. TNFα is associated with the activation of Mϕ, production of cytokines and reactive oxygen species, proliferation and differentiation of monocytes, as well as recruiting other inflammatory cells to the site of injury. Using microarray analyses, we had previously identified genes induced by TNFα in Mϕ. Since exposure to UFP stimulates the expression and secretion of TNFα, we conducted experiments to determine whether genes directly stimulated by TNFα were also induced by UFP. Among the genes induced by direct exposure to TNFα were TNFα itself, as well as several genes involved in regulating TNFα signaling; TNFα receptor II (TNFRII), silencer of death domain (SODD), and zinc finger protein 36 (*zfp36*). The expression profile of these genes paralleled one another; they were induced after 1h, reached maximal expression after approximately 4h and then declined to near basal levels by 24h after TNFα challenge. Exposure to UFP also caused induction of TNFα, SODD, TNFRII, but the kinetics of induction differed from that observed with exogenous TNFα challenge. For these genes, the induction was gradual and sustained for up to 24h. Furthermore, unlike TNFα treatment, exposure to UFP did not induce *zfp36*, a gene whose product is reported to promote the degradation of TNFα mRNA. Thus, the differences in kinetics of TNFα regulated gene expression after TNFα or UFP challenge may, in part be due to differences in *zfp36* regulation. Taken together, our study demonstrates that direct challenge of Mϕ with either TNFα or UFP led to a different temporal expression profile of genes involved in regulating TNFα signaling

1406 EXPOSURE OF RAT LUNG MACROPHAGES TO JP-8 JET FUEL.

D. L. Courson[1], E. C. Kimmel[2], J. E. Reboulet[2], A. E. Jung[2] and P. G. Reinhart[3]. *[1]ManTech Environmental, Wright-Patterson AFB, OH, [2]Geo-Centers Inc., Wright-Patterson AFB, OH and [3]Naval Health Research Center (Toxicology Detachment), Wright-Patterson AFB, OH.*

A variety of adverse health effects have been reported in military and civilian fuel handlers which have been attributed to exposure to JP-8 vapors and aerosols. Many of the reported effects are similar to those produced by endotoxin (LPS). Both commercial and military fuel stores have been shown to be contaminated by LPS in addition to other microbial products. The purpose of this investigation was to determine the effect of LPS contamination in jet fuel on pulmonary macrophage cytokine expression. We exposed cultured rat lung macrophages to samples of JP-8, samples of JP-8 that had been filtered to remove LPS, and filtered samples of JP-8 spiked with a known quantity of LPS. We looked at the cytokine expression of IL-1β, IL-6 and TNF-α in the spent media. We observed increases in IL-6 and TNF-α in the jet fuel exposed groups, as compared to the controls. Filtering LPS attenuated these findings, however the change was not statistically significant. Our results suggest that LPS in jet fuel may be partly responsible for the elevation of cytokine expression associated with JP-8 jet fuel exposures.

1407 FINE DUST PARTICULATE MATTER INDUCES POTENT CYTOKINE RELEASE THROUGH TRPV1 ACTIVATION IN LUNG CELLS.

C. R. Langelier, J. M. Veranth, M. M. Veranth, D. L. Lanza and G. S. Yost. *Pharmacology & Toxicology, University of Utah, Salt Lake City, UT.*

Fine particulate air pollution exposure is associated with a significantly increased risk of lung cancer, cardiopulmonary disease and mortality. Despite the fact that epidemiological evidence linking particulate matter (PM) pollution and disease has existed for over half a century, a comprehensive mechanistic understanding of PM toxicology does not yet exist. It is known that inflammation is an important initial event in PM lung toxicity that may mediate the subsequent development of cardiovascular health problems. In this work, fine particulate samples <2.5 micromolar (PM 2.5) were examined for production of interleukin-6 (IL-6) in the human epithelial lung cell line BEAS-2B. Unexpectedly, a Utah desert dust sample induced significantly greater IL-6 production than a coal fly ash particulate sample of anthropogenic origin. Particulate matter may mediate lung cell toxicity through interactions with the vanilloid receptor TRPV1. To further test this supposition, cytokine production by PM 2.5 in a BEAS-2B cell line engineered to over-express TRPV1 was measured. This engineered cell line exhibited a significantly greater PM 2.5-induced IL-6 response, corroborating the importance of TRPV1 in particulate matter-lung cell interactions. In addition, PM 2.5-exposed BEAS-2B cells treated with capsazepine (CPZ), an antagonist of TRPV1, exhibited a marked decrease in IL-6 production. In order to examine potential cell-signaling pathways responsive to PM 2.5-induced TRPV1 activation, expression of the MAP kinase ERK was examined in cells treated with PM 2.5 and CPZ. ERK expression was found to increase in a dose-dependent manner with PM 2.5 concentration and was reduced in cells treated with CPZ. These data demonstrate that desert dust particles believed to be benign are in fact surprisingly pro-inflammatory, and that particulate matter likely elicits lung cell toxicity through interactions with TRPV1 and subsequent activation of an ERK-mediated cell-signaling pathway. This work was supported by NIST Contract #60NANBOD0006.

1408 OVERLAPPING MOLECULAR TACHYKININERGIC EFFECTS IN F344 RATS FOLLOWING SIDESTREAM CIGARETTE SMOKE EXPOSURE.

N. N. Sun[1], S. S. Wong[1], I. M. Keith[2] and M. L. Witten[1]. *[1]Center for Toxicology, University of Arizona, Tucson, AZ and [2]Schhool of Veterinary Medicine, University of Wisconsin, Madison, WI.*

Environmental tobacco smoke induces many adverse health effects in the lung directly involving bronchopulmonary C-fiber afferents, but the underlying molecular tachykininergic mechanisms are not completely clear. Young female Fischer 344 rats were randomly divided in two groups (24/group): capcaicin and its vehicle pretreatment, respectively. Half of rats/each group were exposed to air (control) or 0.4 mg/m3 total particulate matter of sidestream cigarette smoke (SSCS) for 4 hours/day, respectively, for 7 continuous days through a nose-only exposure chamber. SSCS resulted in typical neurogenic inflammation in the lung as indicated by elevation of plasma extravasation and proinflammatory cytokines, such as interleukin (IL)-1β and IL-12. SSCS depleted the tachykinin peptide substance P (SP), but induced an upregulation of the transcript level of β- preprotachykinin-I (PPT-I) encoding SP. SSCS also induced overexpression of neurokinin-1 receptor (NK-1R) or reduction of its mRNA level in the lungs. Moreover, neutral endopeptidase (NEP) was substantially inactivated by SSCS exposure. Taken together, our findings suggest that overlapping tachykinergic mechanisms may involve in the initiation of SSCS-associated neurogenic inflammation. All of these changes may be regarded as important factors that switch neurogenic pulmonary responses from their physiological and protective functions to a detrimental role.

1409 LACK OF ROLE OF VR1 IN RESPIRATORY RESPONSES TO IRRITANTS.

J. B. Morris[2,1], P. T. Symanowicz[2,1] and G. Gianutsos[1]. *[1]Toxicology Program, University of Connecticut, Storrs, CT and [2]Pulmonary Research Consirtium, University of Connecticut, Storrs, CT.*

The receptors through which irritants stimulate sensory nerves are not known. The vanilloid receptor (VR) is expressed in respiratory sensory nerves and *in vitro* studies suggest that it may be activated by electrophiles or by protons. The goal of the current study was to examine the respiratory responses to inspired irritants in spontaneously breathing wild type (C57Bl/6J) and VR1 knockout [B6.129S4-Vr1(tm1Jul)]mice. Three irritants were studied: capsaicin (a known VR agonist), acrolein (a prototypical electophilic irritant) and acetic acid (a prototypical acidic irritant). Capsaicin induced sensory irritation (slowed breathing rate due to a pause during expiration) and also airway obstruction (increased in SRaw) in wild type but not VR1 knockout mice. Acetic acid also induced sensory irritation and airway obstructive responses. Surprisingly these responses were identical in both wild type and knockout mice. Similar to acetic acid, the sensory irritation and airway obstructive responses to acrolein were also identical in both strains. Thus, although stimulation of the VR1 can result in airway obstruction and sensory irritation, this receptor does not appear to play a role in induction of these responses by the irritants acrolein or acetic acid. (Supported by the University of Connecticut Pulmonary Research Consortium and ES08765.)

1410 TACHYKININ SUBSTANCE P SIGNALING INVOLVES IN DIESEL EXHAUST (DE)-INDUCED BRONCHOPULMONARY NEUROGENIC INFLAMMATION IN RATS.

S. S. Wong[1], N. N. Sun[1], I. M. Keith[2], C. Kweon[3], D. E. Foster[3], J. J. Schauer[4] and M. L. Witten[1]. *[1]Center for Toxicology, University of Arizona, Tucson, AZ, [2]Department of Comparative Biosciences, The University of Wisconsin School of Veterinary Medicine, Madison, WI, [3]Engine Research Center, The University of Wisconsin, Madison, WI and [4]Wisconsin College of Engineering and State Laboratory of Hygiene, The University of Wisconsin, Madison, WI.*

This study characterized the molecular neurotoxicity of diesel exhaust (DE) on the tachykinin substance P (SP) signaling system in the lungs. A total of 96 female Fischer 344 (F344)/NH rats (~175g) were randomly assigned to 8 groups in a 2 X 3 factorial design [Capsaicin vs. non-capsaicin (vehicle) pretreatment and filtered room air vs. 2 exposure levels of DE] with diesel engine room control. The rats were nose-only exposed to air or low and high levels of DE, respectively, directly from the diesel engine for 4 h/day, 5 days/week, for 3 weeks. The findings demonstrated that exposure to DE induced dose-dependently bronchopulmonary neurogenic inflammation, especially in the capsaicin-pretreated groups, as measured by plasma extravasation, edema, and inflammatory cells. Inhalation of DE affected SP signaling processes, including stored SP depletion and the gene/protein overexpression for neurokinin-1 receptor (NK-1R). DE also significantly decreased the activities of neutral endopeptidase (NEP), which is a main degradation enzyme for SP. Consequently, these changes may be regarded as critical factors that switched neurogenic pulmonary responses from their protective functions to a detrimental role that perpetuates lung inflammation. It suggests that the tachykinergic mechanism may be involved in the initiation of DE-associated lung inflammation and these changes may possibly associated with the mass concentration of DE particles due to their physical-chemical characterizes.

1411 13-WEEK INHALATION TOXICITY STUDY OF BITUMEN FUMES IN WISTAR(WU) RATS.

R. Fuhst, W. Bartsch, H. Ernst, G. Pohlmann and A. Preiss. *Fraunhofer Institute of Toxicology and Aerosol Research, Drug Research and Clinical Inhalation, Hannover, Germany.* Sponsor: H. Muhle.

A 90-day toxicity inhalation study was conducted in Wistar WU rats (Crl:WU) with bitumen fumes generated from a sample of bitumen fume condensate collected from a storage tank. The composition of the fume was aimed to be similar to an exposure atmosphere during road paving. The objective of this study was to determine the concentration levels and maximally tolerated dose for a future carcinogenicity study. 16 male and 16 female rats per group, about 10 weeks old, were exposed to clean air, or to target concentrations of 4, 20, and 100 mg/m^3 THC (total hydrocarbon). The exposure atmosphere comprised a mixture of aerosol particles and hydrocarbon vapour. The duration of the exposure was 6 hrs/day, 5 days/week for 14 weeks. In males (100 mg/m^3) differences in body weight were observed, which increased during the course of the study resulting in a markedly lower mean body weight (- 10%) compared to the controls. Milder effects on body weight (-5%) were noted in all female groups exposed to bitumen fumes. A statistically significant lower food consumption was noted in the male high dose group. Statistically significant test substance-related histopathological changes were only observed in the nasal and paranasal cavities in the bitumen high dose group. Eosinophilic cytoplasmic inclusions (hyalinosis) were observed exclusively in nasal epithelial cells of the high dose group. Associated with degenerative hyalinosis was focal/multifocal basal cell hyperplasia which could be observed in the olfactory/respiratory transition areas of high-dosed males. Another significant treatment-related change was multifocal mucous (goblet) cell hyperplasia. Multifocal mucosal inflammatory cell infiltration was a further exposure-related effect which could be observed exclusively in the bitumen high dose group. The NOAEL of Bitumen fumes under the above described conditions in Wistar (WU) rats is 20 mg/m^3 THC. Concentration levels of 4, 20, and 100 mg/m^3 THC are proposed for the planned carcinogenicity study. The study was sponsored by ARBIT, Germany.

1412 FOUR-WEEK INHALATION TOXICITY OF N-VINYL CARBAZOLE IN RATS, FURTHER STUDIES.

D. P. Kelly, G. T. Makovec and G. S. Ladics. *Haskell Laboratory, DuPont Company, Newark, DE.*

A previous 4-week inhalation study with n-vinyl carbazole (nVC) showed nasal and laryngeal effects in rats exposed at 2, 10, or 44 mg/m^3. To determine a no adverse effect level, groups of 15 male Crl:CD®(SD)IGS BR rats were exposed nose-only to nVC at design concentrations of 0.02 (vapor), 0.2 (vapor) or 2 mg/ m^3 (combined aerosol vapor concentrations). Exposures were 6 hours/day, 5 days/week, over a 4-week period. Five rats/group were sacrificed for respiratory tract evaluation at the end of the 4-week exposure period and at the end of 1 month and 3 month recovery periods. No lung weight, body weight, or clinical signs of toxicity were seen at any concentration. At the end of the exposure period, minimal to mild histopathologic effects were observed in the upper respiratory tract at concentrations of 0.2 and 2 mg/ m^3. Rats exposed at 2 mg/ m^3 showed mucoid depletion of goblet cells in the anterior section of the nose along with hypertrophy of basilar epithelial cells in the respiratory mucosa lining the nasal septum. In addition, the 2 mg/ m^3 rats showed squamous metaplasia in the laryngeal epithelium. The incidences of the nasal lesions in the 2 mg/ m^3 rats had decreased but repair was not complete by the end of the 3 month recovery period. The laryngeal lesions in these rats were not present after 1 or 3 month recovery periods. The only effect observed in the 0.2 mg/ m^3 rats was mucoid depletion of goblet cells in the anterior section of the nose. This lesion was not observed in the recovery rats at this concentration. No histopathologic effects were observed in the rats exposed to nVC at 0.02 mg/m^3.

1413 VP 14637: TWO-WEEK INHALATION TOXICITY STUDY IN NEONATAL DOGS.

W. W. Lee[1], M. H. Davies[2], A. Viau[1], J. R. Hincks[2], G. Rhodes[2], A. Adjiri-Awere[3], J. A. Nash[4] and C. Gordon[1]. *[1]Inhalation Toxicology, CTBR, Senneville, QC, Canada, [2]ViroPharma, Inc., Exton, PA, [3]Pathology, CTBR, Senneville, QC, Canada and [4]DMPK, CTBR, Senneville, QC, Canada.*

VP 14637 (phenol, 2, 2-[(4-hydroxyphenyl) methylene]bis[4-[[(5-methyl-1H-tetrazol-1-yl)imino]methyl]]) is an inhibitor of respiratory syncytial virus (RSV) fusion protein. VP 14637 is under investigation for treatment of RSV infection in

humans. This study was conducted to characterize the potential toxicity, and the toxicokinetics of VP 14637 in male and female neonatal beagle dogs. Beginning at 10 days of age, three groups of neonatal dogs were given inhalation exposures (oronasal by nebulizer) to aerosolized VP 14637 (mean deposited dosages of 31, 99, or 262 mg/kg/day). Based upon exposure duration, and measured minute volumes and aerosol parameters, the dosage of 262 mg/kg/day was the highest possible dosage. Measured aerosol particle size data (MMAD = 2.6-2.8 mm) allowed for respiratory deposition fractions of 50-70%. As control, two other groups were exposed only to air, or to the vehicle (ethanol/propylene glycol/water) for VP 14637. After 2 weeks of dosing, main study animals were necropsied. A sub-group, exposed to vehicle or 262 mg/kg/day of VP 14637 for 2 weeks, continued in a 1-month treatment-free observation period and then necropsied. After the 14th daily exposure, mean concentrations of VP 14637 in plasma increased with increasing dosages, but were <4 ng/mL indicating that systemic exposure to inhaled VP 14637 was low. At the end of the dosing and observation periods, there were no findings (parameters assessed: clinical status, respiratory function, ophthalmology, electrocardiography, clinical and gross pathology, organ weights, and histology) related to treatment vehicle or VP 14637 at dosages up to 262 mg/kg/day. Specifically, there was no evidence of respiratory impairment, and no histologic changes in the respiratory tract attributed to treatment with vehicle or VP 14637. In conclusion, inhalation of the highest possible dosage of VP 14637 for 2 weeks, given the constraints of studying neonatal dogs, had no observed effects.

1414 *IN VIVO* AND *IN VITRO* RESPIRATORY TRACT INHIBITION OF RAT CYP450 FOLLOWING EXPOSURE TO *m*-XYLENE AND METABOLITES.

A. Vaidyanathan, J. D. Foy and R. A. Schatz. *Toxicology, Northeastern University, Boston, MA.*

Xylenes are used as a solvent in paints, cleaning agents and gasoline. Exposure occurs primarily by inhalation. The volatility and lipophilicity of the xylenes make the lung and nasal mucosa the primary target organs. m-Xylene (m-XYL) is metabolized *via* CYP450 isozymes to 3-methybenzyl alcohol (3-MBA) and subsequently to m-tolualdehyde (m-ALD). The purpose of this work was to determine if pulmonary and nasal mucosa CYP isozymes involved in the metabolism of the xylenes are inhibited in a dose dependent manner following inhalation of m-XYL: 100 and 300 ppm; 3-MBA: 50 and 100 ppm; or m-ALD: 50 and 100 ppm, and to investigate the type of inhibition caused by these compounds using *in vitro* kinetics. A single 6 hour inhalation exposure to m-XYL (100 ppm and 300 ppm) inhibited pulmonary CYPs 2B1, 2E1, and 4B1 in a dose dependent manner. Inhalation of 3-MBA (50 ppm and 100 ppm) inhibited pulmonary CYPs 2B1 and 4B1 in a dose dependent manner. m-ALD (50 ppm and 100 ppm) inhibited pulmonary CYPs 2B1 and 2E1 in a dose dependent manner, while 4B1 activity was increased dose dependently. Nasal mucosa CYP 2B1 and 2E1 activity was inhibited following exposure to m-XYL (100 ppm and 300 ppm) dose dependently. 3-MBA (50 ppm and 100 ppm) inhibited nasal mucosa CYPs 2E1 and 4B1 dose dependently. CYPs 2B1, 2E1 and 4B1 were inhibited in a dose dependent fashion following inhalation of m-ALD 50 ppm and 100 ppm. *In vitro*, IC50 values for m-XYL, 3-MBA and m-ALD for pulmonary CYP 2B1 were 0.1, 1, 0.5 mM and nasal mucosa were 0.1, 1, 0.1 mM; pulmonary CYP2E1 were 1, 8, 0.01 mM and nasal mucosa were 0.05, 10, 0.1 mM; pulmonary CYP 4B1 were 3, 6, 0.3 mM and nasal mucosa were 5, 1, 0.1 mM. IC50 values were used to investigate the type of inhibition caused by these compounds. Eadie-Hofstee plots for CYPs 2B1, 2E1 and 4B1 for lung and nasal mucosa show non-competitive inhibition by m-XYL, 3-MBA or m-ALD. Alterations of cytochrome P450 activity caused by m-XYL may result in changes of metabolic profiles of xenobiotics in coexposure scenarios in increased or decreased toxicity in an organ-specific manner.

1415 EVALUATION OF ACUTE RESPIRATORY EFFECTS IN HEALTHY ADULTS FOLLOWING CONTROLLED ENVIRONMENTAL EXPOSURES TO FRAGRANCED INCENSE STICKS.

R. Rogers[1], R. Ibach[1], C. Jeng[1], N. Prasad[2] and J. Burdick[3]. *[1]Toxcon Health Science Research Centre, Edmonton Alberta, AB, Canada, [2]University of Alberta, Edmonton Alberta, AB, Canada and [3]White Barn Candle Co., Reynoldsburg, OH.* Sponsor: J. Merrill.

Recently, attention to the potential for indoor air quality impact from burning incense has increased with focus on incense smoke as source of particulate exposure in indoor air. This study evaluated acute pulmonary responses and symptoms in healthy adults following burning of incense formulations, differing only in fragrance. Airborne particulates were monitored using a TSI aerodynamic particle sizer (APS) following a controlled burning paradigm. Mean aerodynamic diameters of airborne particles for all exposures were 0.55µm–0.63µm. Particle mass concentrations were similar across all treatments with an average range of 2.0 µg/m^3–6.6 µg/m^3. Twenty-seven (27) healthy adult subjects were exposed for 5 minutes to each of twelve separate incense burns, randomized over a 12–hour period. Ten different incenses were evaluated with one treatment repeated (3x) to evaluate reproducibility of response over time. Irritation was assessed by comparing pre vs. post exposure responses (20 total symptoms grouped as upper respiratory, lower respiratory and nonspecific) *via* questionnaire and pulmonary function *via* FEV_1 measurement. Sensory questionnaires allowed comparison of fragrance strength/aesthetics to reported subjective symptom responses and pulmonary function. No statistically significant differences (Wilcoxon Signed Rank Test; 5% level) were found between pre vs. post exposure for any treatments under any clinical symptom group. Analysis using paired student t-test of FEV_1 data revealed small but statistical differences ($p>0.001$) between pre vs. post exposures for all treatments, the greatest change in any exposure group was a decline in FEV_1 of 0.28 which is not considered clinically significant. No cumulative effect on FEV_1 for particulate exposure in this design was noted and no relationship was apparent between fragrance strength/perception to symptoms or pulmonary function.

1416 EXPOSURE CHARACTERIZATION FROM A FRAGRANCED PLUG-IN AIR FRESHENER.

D. Isola[1], L. W. Smith[1], R. Ansari[2] and M. S. Black[3]. *[1]Research Institute for Fragrance Materials, Inc., Hackensack, NJ, [2]Quest International Fragrances Company, Mount Olive, NJ and [3]Air Quality Sciences, Marietta, GA.*

Consumer exposure to inhaled fragrance materials is not well characterized, thus raising concerns about asthma, lung disease, and neurological effects. A plug-in air freshener was developed to simulate a product that gives a continuous low level of scent over time. The surrogate formulation contained 20% dipropylene glycol mono-methyl ether (DPM) as a solvent and 8.89% each of benzyl acetate (BA), eugenol, hexyl cinnamaldehyde (HCA), 1, 3, 4, 6, 7, 8-hexahydro-4, 6, 6, 7, 8, 8-hexamethylcyclopenta-γ-benzopyran (HHCB), hydroxycitronellal, β-ionone, d-limonene, linalool, and methyl dihydrojasmonate (MDJ). Representative fragrance materials were chosen based on volatility, chemical structure, toxicity, and volume of use. The product was plugged into a standard wall outlet (110 volts) and was heated to 60-70oC to control emissions for a minimal change in the hedonics of the formulation. Samples of the reservoir were taken at 1, 3, and 6 hours on the first day and twice weekly thereafter. Amount remaining was quantitated using gas chromatography and a nonpolar column, following calibration with neat materials to determine retention times. Current gravimetric analysis showed the greatest losses were seen from Days 1 to 7. The data are presented in the table below. Emission was calculated from absolute and percent weight loss of each material from the reservoir. Losses decreased thereafter and approached constancy. The concentration of total test formulation averaged 0.144 g/d. In a 41 m^3 room, the concentration converts to approximately 0.0035 ppm formulation/d. These data show relative constancy of emission at low levels of exposure and will be used in the design of future clinical studies.

day	0	1-7	8-14	15-20	21-25	26-28
g wt loss/day	0	0.22	0.15	0.13	0.11	0.11

1417 SIMULTANEOUS ANALYSIS OF ACETONE CONCENTRATION IN THE NASOPHARYNGEAL AND EXHALED BREATH OF HUMAN VOLUNTEERS.

R. E. Schwartz[1], G. L. Foureman[2], C. Timchalk[3], K. K. Weitz[3], J. J. Soelberg[3] and K. D. Thrall[3]. *[1]Otolaryngology, Richland, WA, [2]USEPA, NCEA, Research Triangle Park, NC and [3]Battelle, Pacific Northwest Laboratory, Richland, WA.*

A controlled human inhalation study was conducted to quantitate the nasal clearance of acetone using real-time ion-trap mass spectrometry (MS/MS). Previous investigations in human volunteers have been difficult due to methodological limitations. New methods were used to evaluate nasal wash-in and wash-out during cyclic-breathing to measure nasal clearance in two human volunteers exposed to uniformly labeled 13C-acetone (~1 ppm) for 30 minutes under different breathing maneuvers (inhale nose/exhale nose; inhale nose/exhale mouth; inhale mouth/exhale nose). An air-sampling probe inserted in the nasopharyngeal cavity of the volunteer was connected to an MS/MS system capable of sampling every 0.8 sec. A second MS/MS system simultaneously sampled from the exhaled breath stream *via* a breath-inlet interface. The breathing cycle was monitored throughout the exposure using a plethysmograph. Graphical overlays of the plethysmography and MS/MS results show clear differences in 13C-acetone levels in the nasopharyngeal

region as a function of breathing maneuver. In both volunteers steady-state 13C-acetone concentrations were rapidly obtained; 40 to 75% of the compound was absorbed, depending on the breathing maneuver. For one volunteer the overall nasopharyngeal clearance followed the order of mouth inhale/nose exhale > nose inhale/nose exhale >/= nose inhale/mouth exhale. Whereas, clearance profiles in the other volunteer were comparable regardless of breathing strategy. The simultaneous acquisition of both nasopharyngeal and exhaled breath indicated that exhaled 13C-acetone exceeded the nasopharyngeal concentration by as much as a factor of 2, which is consistent with a wash-in and wash-out of acetone during cyclic-breathing. These results demonstrate the utility of real-time MS/MS analysis to quantitate nasal clearance of vapors in humans and should prove useful for refining current default risk assessment assumptions. (Supported by EPA Contract 68-C-00-122).

1418 DEVELOPMENT OF A MODEL SYSTEM TO EVALUATE VINYL ACETATE-INDUCED INTRACELLULAR ACIDIFICATION IN NASAL EPITHELIUM.

J. M. Orozco[1], M. S. Bogdanffy[2] and R. Lantz[1,2]. *[1]Pharmacology and Toxicology, University of Arizona, Tucson, AZ, [2]Department of Cell Biology and Anatomy, University of Arizona, Tucson, AZ and [3]DuPont Haskell Laboratory, Newark, DE.*

Vinyl acetate is a synthetic organic ester that has been shown to be carcinogenic to rats after inhalation exposure. Vinyl acetate is metabolized by carboxylesterase to form acetic acid and acetaldeyde, which is a key step in the pathogenesis of non-neoplastic and neoplastic responses. A pharmacokinetic and pharmacodynamic model for the effects of vinyl acetate predicts that three protons should be produced per mole of vinyl acetate causing acidification of exposed tissues. Isolated rat hepatocytes have demonstrated an intracellular drop in pH upon exposure to vinyl acetate using ratiometric fluorescent imaging. The objective of this study is to develop a model system using ratiometric confocal microscopy to monitor intracellular pH changes and to test the hypothesis that vinyl acetate metabolism in nasal epithelium leads to a reduction in intracellular pH. Respiratory and olfactory turbinate explants were removed from male CrlCD:BR rats. Cells were isolated from the turbinates and plated onto culture dishes for imaging. Cells were loaded with the pH sensitive dye SNARF-1 for 30 min. Using standard confocal laser excitation (488nm), the ratio of SNARF-1 emission at 620-680nm to emission at 550-600nm was measured for various conditions. Exposing the cells to pH standard solutions of pH 7.5, 7.0, and 6.5 containing nigericin generated a pH calibration curve. Cells were exposed to up to 1mM vinyl acetate or 30mM NH_4Cl solution as a positive control. After exposure, cells were washed to show that the responses were reversible. Vinyl acetate exposures produced a decrease in intracellular pH. Conversely, exposure to 30mM NH_4Cl causes a significant increase in intracellular pH for isolated cells. Both effects were reversible. These results show that vinyl acetate can lower pH in nasal epithelium and the that intracellular pH can be measured using a confocal imaging system. (Supported by the Vinyl Acetate Toxicity Group).

1419 INHIBITION OF HEAT SHOCK PROTEIN INDUCTION IN MOUSE OLFACTORY EPITHELIUM BY *IN VIVO* ADMINISTRATION OF PURINERGIC RECEPTOR ANTAGONISTS.

C. C. Hegg, K. Davis and M. T. Lucero. *Physiology, University of Utah, Salt Lake City, UT.*

Heat shock proteins (HSPs) accumulate in cells exposed to a variety of physiological and environmental factors such as heat shock, oxidative stress, toxicants and odorants. Ischemic, stressed, and injured cells release ATP in large amounts; moreover, a recent toxicology study showed that intracellular ATP significantly decreased when the olfactory epithelium (OE) was damaged by noxious fumes, presumably through release by injured cells[1]. Our hypothesis is that noxious stimulation (in this case, strong odor) evokes the release of extracellular ATP in the OE. Extracellular ATP, a signal of cellular stress, induces the expression of HSPs *via* purinergic receptors. As previously shown in rats[2], *in vivo* odorant exposure (0.02% heptanal, 3 hours) led to transient selective induction of HSP25 and HSP72 in sustentacular support cells in Swiss Webster mouse OE. We investigated whether administration of purinergic receptor antagonists suramin and pyridoxalphosphate-6-azophenyl-2', 4'-disulfonic acid (PPADS) can block the induction of HSP expression. Mice were injected with 100 μmoles/kg suramin + PPADS and exposed to 0.02% heptanal for 3 hours. Purinergic receptor antagonists blocked the expression of HSP25 and HSP72 in sustentacular support cells. The olfactory neuroepithelium is constantly exposed to airborne pollutants and microbes, consequently, it continuously regenerates. ATP released by acutely injured cells could act as an early signal of cell and tissue damage, causing HSP expression and stimulating regeneration due to the mitogenic and growth-promoting effects of purinergic receptor activation. 1420 SENSORY IRRITATION AND ODOR FROM BRIEF EXPOSURES TO GLUTARALDEHYDE VAPOR.

W. S. Cain, R. Schmidt and A. A. Jalowayski. *Otolaryngology, University of California San Diego, La Jolla, CA.* Sponsor: J. Cometto-Muñiz.

Glutaraldehyde (GA) vapor occurs in various occupational settings, most notably in healthcare where glutaraldehyde-based products serve to disinfect instruments. The potency of GA to evoke odor, sensory irritation of the eyes, and nasal pungency in brief exposures (ca. 3 sec for the nose and 25 sec for the eyes), with analytical confirmation of concentration, merits attention. A psychophysical study of 53 females, aged 18 to 35 years and screened for normal health of the upper airways and eyes, led to psychometric functions for odor detection (n=43), detection of ocular irritation (n=41), and nasal pungency (n=40). The methodology entailed performance in forced-choice tasks and repetitive verification of delivered concentrations by the OSHA 64 method during testing. The subjects in each task yielded their own individual functions. Subjects began to detect odor above chance at concentrations below 0.1 ppb and reached 50% detection at 0.3 ppb. The subjects began to detect the chemesthetic properties of ocular irritation and nasal pungency above chance at concentrations of about 200 ppb and reached 50% detection in the zone 400-500 ppb. The functions for chemesthesis rose particularly sharply, from near-chance performance to near-perfect detection, over a span of concentration of 4:1. For subjects who achieved 50% chemesthetic detection by the highest test concentration of 800 ppb, the geometric coefficients of variation equaled 1.6 and 1.5 for ocular irritation (n=34) and nasal pungency (n=25), respectively. For these brief exposures, no subjects gave evidence a chemesthetic threshold as low as the STEL of 50 ppb. Supported by the Dow Chemical Company and BASF.

1421 MUCOUS CELL METAPLASIA IN RAT NASAL EPITHELIUM AFTER A 13-WEEK EXPOSURE TO CARBON BLACK PARTICLES.

P. Santhanam[1], J. R. Harkema[1], J. G. Wagner[1], L. A. Bramble[1], A. C. Elder[2] and G. Oberdorster[2]. *[1]Pathobiology, Michgian State University, East Lansing, MI and [2]Environmental Medicine, University of Rochester, Rochester, NY.*

Rats chronically exposed to high levels of carbon black particles (Cb) develop numerous and persistent lung lesions including chronic alveolitis, alveolar septal fibrosis, and type II cell hyperplasia. The purpose of the present study was to determine if long-term inhalation of Cb would also cause chronic lesions in the nasal airways of rats. Female F344 rats were exposed to three concentrations (1, 7, 50 mg/m3) of high surface area Cb (HSCb) or one concentration (50 mg/m3) of low surface area Cb (LSCb) for 6 h/day, 5 days/wk for 13 wk. Rats were sacrificed one day or 13 wk post-exposure (PE). The nasal airways of each rat were processed for light microscopic analysis. Chronic rhinitis and mucous cell metaplasia (MCM) with increased numbers of mucous goblet cells and increased amounts of intraepithelial mucosubstances (IM) in transitional and respiratory epithelium were present in rats exposed to HSCb. Persistant HSCb-induced nasal lesions were evident only in rats exposed to 7 or 50 mg/m3. Standard morphometric techniques were used to determine the amounts IM in the surface epithelium lining the nasal airways. The magnitude of these nasal lesions was both dose- and time-dependent. Rats exposed to 50 mg/m3 HSCb and sacrificed at one day and 13 weeks PE had approximately 750x and 8x more IM, respectively, in the maxilloturbinates than that of control rats exposed only to filtered air (0 mg/m3 Cb) and sacrificed at similar times PE. Interestingly, rats exposed to 50 mg/m3 LSCb had no nasal lesions. These results indicate that Cb-induced nasal lesions in rats were dependent on dose, particle surface area, and time PE. The persistent nature of the HSCb-induced MCM in rats suggests that Cb exposure may have the potential to induce similar long-lasting alterations in the nasal airways of humans (Research sponsored by the International Carbon Black Association).

1422 QUANTIFICATION OF A 3-METHYLINDOLE MERCAPTURATE ADDUCT IN THE URINE OF CIGARETTE SMOKERS.

D. Lanza[1], S. S. Hecht[2] and G. S. Yost[1]. *[1]Pharmacology & Toxicology, University of Utah, Salt Lake City, UT and [2]Laboratory Medicine & Pathology, University of Minnesota Cancer Center, Minneapolis, MN.*

3-Methylindole (3MI) is a degradation product of the amino acid tryptophan, and a pyrolysis product present in cigarette smoke. The pnuemotoxicity of 3MI is well established, and its toxicity is dependent on activation by cytochrome P450 en-

zymes. The most reactive of the intermediates formed *via* dehydrogenation of 3MI is 3-methyleneindolenine. This highly reactive electrophile is trapped endogenously with glutathione and the mercapturate adduct can be detected and quantified in urine by HPLC. Urine samples were obtained from cigarette smokers participating in a smoking cessation study. Samples were obtained before and after cessation. The quantity of mercapturate present in urine increased with the number of cigarettes to a maximal value of 558 nmols mg creatintine-1 ml-1 at 15 cigarettes smoked per day. Interestingly, at numbers higher than 20 cigarettes/day the detectable amount of adduct begins to decrease and ultimately is reduced to a low value of 20 nmols mg creatintine-1 ml-1 at 35 cigarettes per day. Adduct levels dropped by an average of 147% after 30 days without smoking. The non- linearity of adduct concentration vs. number of cigarettes consumed can be interpreted in at least two ways. Previous studies in our laboratory indicated that 3-methyleneindolenine inhibits the P450 enzyme (CYP2F1) required for its formation. Therefore, at higher substrate concentrations, the enzyme is inactivated and less detectable product is formed. Alternatively, cytochrome P450 expression in lung is highly cell-type specific, and another interpretation of these data is that the cells responsible for the majority of the metabolic activity are killed at higher cigarette consumption levels. (Supported by NIH Grant HL13645)

1423 INHALATION OF CADMIUM AT A CONCENTRATION ASSOCIATED WITH SIDESTREAM CIGARETTE SMOKE ALTERS ANTIMICROBIAL HOST DEFENSE.

J. T. Zelikoff, G. Chee, K. Schermerhorn, C. Prophete and M. D. Cohen.
Environmental Medicine, New York University School of Medicine, Tuxedo, NY.

Cadmium (Cd), a potent immunotoxicant and human carcinogen present in cigarettes, is released into indoor environments in sidestream smoke (SS). Depending on the cigarette type and tobacco source, smoking a pack of cigarettes introduces 8 - 13 ug Cd into the general indoor environment. Inasmuch as children in homes where members smoke have a greater frequency of lower respiratory tract infections (LRTI) than those in non-smoker homes, a laboratory study was undertaken to determine the role of a single smoke component as a concomitant stressor in suppressing lung immune defense mechanisms. Five- and 3-wk-old rats were exposed by nose-only inhalation to 80 ng CdO for 1 or 3 wk (5 hr/d), respectively. At different timepoints post-exposure, rats were either: intratracheally-instilled with *S. pneumoniae*and bacterial burdens subsequently assessed; sacrificed and their lungs fixed for histopathologic analyses or lavaged for cytokine and immune functional measurements; or, sacrificed and their spleens used to assess lymphoproliferation. Peripheral blood was used to evaluate blood cell profiles. Rats exposed for 1 wk to CdO and then challenged 1 or 2 d post-exposure with *S. pneumoniae* evidenced a 50% increase in bacterial lung burdens 4 hr post-infection compared to infected air-exposed controls; by 7 d, bacterial numbers reached control levels. Although inhalation of CdO for 1 or 3 wk had no effect on lung histology, lavage cell differentials, circulating blood cell profiles, or lymphoproliferation, macrophage oxyradical production was depressed for up to 7 d post-exposure in rats from both regimens. Results of this study not only provide information necessary for defining health risks of low-dose exposure to inhaled Cd particulates, but offer a possible mechanism underlying the relationship between SS and decreased resistance to LRTI in infants. Philip Morris Foundation.

1424 TOBACCO SMOKE EXPOSURE AND BONE STRENGTH IN MICE.

M. P. Akhter[1], D. J. Wells[1] and C. Gairola[2]. *[1]Creighton University, Omaha, NE and [2]University of Kentucky, Lexington, KY.*

Smoking has been implicated in early onset of menopause and the development of osteoporosis (bone fragility) in women smokers. In the present study, we have measured various biomechanical properties of femurs (cortical bone) obtained from control and smoke-exposed mice to determine if experimental exposure to cigarette smoke influences bone strength characteristics. Female C57BL mice were exposed to sidestream cigarette smoke in a whole-body exposure chamber, set at 30mg smoke particulates/m^3 for 4hrs/d and 5d/wk for 12 consecutive weeks. Femurs were collected and frozen (-20^{0}C) in saline for subsequent biomechanical testing. Mid-shaft femurs were mechanically tested in 3-point bending (Instron 5543, MA) at a rate of 3mm/minute and then analyzed for various structural (ultimate & yield load, and stiffness) and material (ultimate & yield stress and flexural modulus) strengh parameters. Elevated levels of blood carboxyhemoglobin and pulmonary CYP1A1 protein in smoke-exposed mice confirmed their effective exposure to gaseous and particulate constituents of smoke. The data (Table) showed that flexural modulus, a material strength parameter, was significantly decreased ($p<0.05$), and stiffness, a structural parameter, was marginally reduced ($p<0.1$) in femurs obtained from smoke-exposed mice when compared to control group. We conclude that exposure to tobacco smoke adversely affects some biomechanical strength properties of cortical bone in mice.

FEMORAL BONE STRENGTH (mean±sd)

	Control (n=16)	Smoke-exposed (n=16)
Ultimate load (N)	16.9±2.4	17.8±1.98

1425 PYRIDINES THAT INHIBIT DIVERSE BIOLOGICAL PROCESSES ARE MORE CONCENTRATED IN SIDESTREAM THAN MAINSTREAM SMOKE SOLUTIONS FROM COMMERCIAL BRAND CIGARETTES.

R. J. Roza[1], K. Riveles[1], D. Kwan[1], J. Arey[2] and P. Talbot[1]. *[1]Cell Biology & Neuroscience, UC Riverside, Riverside, CA and [2]Environmental Sciences, UC Riverside, Riverside, CA.*

Several pyridine derivatives that have an adverse effect on both oviductal functioning and chick chorioallantoic membrane growth at picomolar doses have been identified in cigarette smoke. The purpose of this study was to determine the concentrations of 2-methylpyridine, 2-ethylpyridine, and 3-ethylpyridine in mainstream and sidestream smoke solutions of various cigarettes. The cigarettes selected included regular and light US filtered cigarettes (Marlboro and Camel), several new US brands that claim to have reduced carcinogens (Omni and Advance), and University of Kentucky research 2R1 and 1R4F cigarettes. The relative absorbance of each smoke solution was first measured using a spectrophotometer (λ=300 nm). Sidestream smoke solutions showed a 6- to 10-fold higher absorbance than mainstream. The Omni sidestream smoke solution had the highest absorbance values compared to the other commercial brands. Next, the smoke solutions were extracted and 2-methylpyridine, 2-ethylpyridine, and 3-ethylpyridine were identified and quantified by gas chromatography-mass spectrometry. The concentrations of all three pyridine compounds were higher in sidestream than in mainstream smoke solutions. The sidestream smoke solutions from Advance cigarettes had the highest concentration of 3-ethylpyridine; from Omni cigarettes had the highest concentration of 2-methylpyridine; and from 1R4F cigarettes had the highest concentration of 2-ethylpyridine. This is the first time that this particular group of toxicants has been shown to be in higher concentrations in sidestream smoke solutions. These findings suggest that there may be additional risks associated with exposure to sidestream smoke.

1426 EFFECTS OF THE ADDITION OF BENZYL ALCOHOL TO TOBACCO ON THE CHEMICAL COMPOSITION AND BIOLOGICAL ACTIVITY OF CIGARETTE SMOKE.

L. Merriman[1], E. L. Carmines[1], C. L. Gaworski[1], B. Gerstenberg[2], T. Meisgen[2], H. Schramke[2] and E. Van Miert[3]. *[1]Philip Morris USA, Richmond, VA, [2]INBIFO, Cologne, Germany and [3]CRC, Zaventem.*

Benzyl alcohol is a commonly used tobacco flavoring material in cigarettes. An evaluation of the potential effects of benzyl alcohol on the chemical composition and biological activity of mainstream smoke was conducted. Purge and trap analysis showed benzyl alcohol as the major distillation product at 100°C, suggesting that it will volatilize prior to the burning tobacco and not be available for pyrolysis. Benzyl alcohol was incorporated into American-blend cigarette tobacco at a target level of 0.05% and at multiple target levels of 0.5% (10X) and 2.1% (42X). A cigarette without benzyl alcohol served as the control. Mainstream smoke constituents analyzed were selected from those proposed by the US CPSC or classified as human or animal carcinogens by the IARC. Results obtained from genotoxicity (Salmonella Reverse Mutation Assay of the particulate matter), cytotoxicity (Neutral Red Uptake Assay of particulate matter and gas vapor phase), and inhalation toxicity

(90-d, rat nose-only whole smoke inhalation) were comparable to those obtained with the control cigarette. Smoke constituent changes occurring in benzyl alcohol treated cigarettes were generally within 20% variation of controls and considered unrelated to benzyl alcohol addition. This assessment suggests that benzyl alcohol did not extensively alter the normal chemical balance nor biological activity of the cigarette smoke, even at the exaggerated levels tested.

1427 CHARACTERIZATION AND VALIDATION OF A RODENT NOSE-ONLY EXPOSURE SYSTEM FOR ACUTE TOXICITY EVALUATION OF POLYMER AND TOBACCO COMBUSTION PRODUCTS.

R. Lemus[1], K. M. Lee[2] and M. S. Werley[1,3]. *[1]Philip Morris USA, Richmond, VA, [2]Battelle Toxicology NW, Richland, WA and [3]Present address Chrysalis Technologies, Inc., Richmond, VA.*

An apparatus consisting of a Deutsches Institut für Normung (DIN) 53-436 moving furnace, connecting glasswares, and 24-port nose-only inhalation unit, was constructed and validated to evaluate irritant effects of tobacco/polymer combustion products (CPs). To approximate cigarette burning conditions a furnace temperature (FT) of 750°C and DIN wet total particulate matter (DWTPM) of 150 µg/L were selected. Male SW mice (12/run) were exposed once for 30 min to 100% tobacco blend (TB) or 70/30 (wt/wt%) TB-Nylon 12 (N12) CPs. CO/CO_2, NO/NOx, DWTPM, hydrogen cyanide (HCN), acetaldehyde, formaldehyde, acrolein, and nicotine were measured in the test atmosphere. Respiratory function (Buxco®) during exposure, postexposure blood cyanide (CN^-) levels, respiratory tract histopathology (1 & 7 days postexposure) and alveolar macrophages (AM), LDH and protein changes in BAL fluid (Day 1) were evaluated. Validation demonstrated steady DWTPM and spatial uniformity (<10%). Nose port temperature (22-26°C), RH (45-75%) and FT (750±20°C) were acceptable on runs conducted over 3 separate days. Variability for most analytes was within 10%. Replacement of tobacco mass with N12 resulted in nicotine, and NO/NOx decreases, and increases in DWTPM, HCN, aldehydes and CO relative to the TB run. Reductions in respiratory rate and minute volume were slightly greater in the N12-group than TB-group. Blood CN^- levels were below LOD for both groups. Day-1 postexposure lesions in nasoturbinate, lateral wall, and maxilloturbinate were minimal to moderate and limited to nose level 1. Vacuolization and necrosis were more severe in the N12-group compared to TB-group, but these lesions resolved by day 7. No changes in BAL parameters were noted, except a decrease on the ratio of resting/activated AM in the N12 and TB-groups compared to naïve control. This validation and pilot study have shown that the system may be useful in the acute toxicity assessment of CPs.

1428 COMPARATIVE ANALYSIS OF BRONCHOALVEOLAR LAVAGE (BAL) FLUID BIOMARKERS IN MICE FOLLOWING ACUTE CIGARETTE SMOKE EXPOSURE.

C. J. Obot[1], A. F. Fuciarelli[2], M. K. Lee[2], R. B. Westerberg[2] and W. J. Mckinney[1]. *[1]Philip Morris, Richmond, VA and [2]Battelle Toxicology . NW, Richland, WA.*

Although potential biomarkers of effect (e.g. inflammation) have been used clinically to evaluate cigarette smoke (CS), their link to chronic obstructive pulmonary disease is not clear. The use of animal models can help clarify the association between biomarkers and disease. Recent studies suggest that C57/BL/6 (C57) mice develop emphysema following chronic CS exposure, while ICR mice do not. Based on this information we investigated acute mainstream cigarette smoke-induced biomarker responses in these two mouse strains. Young male C57 and ICR mice received 2-hr nose-only inhalation exposures to CS from 1R4F reference cigarettes (600µgTPM/L) or filtered air for 1 or 7 consecutive days. BAL fluid samples (n=3-6) were collected at 0, 4, 12, and 24 hours post-exposure and analyzed for potential biomarkers of effect {LDH, protein, cell differentials, KC (IL-8), IL-13 TNFα, IFNγ, IL-5, IL-10, IL-6, IL-1β, GM-CSF, GSH/GSSG, 8-isoprostane, collagenase/elastase and desmosine}. At 0-hr blood samples were analyzed for biomarkers of exposure (HbCO, nicotine and cotinine). Exposure biomarkers were slightly greater in the C57 relative to the ICR. After 1-day exposure ICR KC levels were significantly increased 2.8-fold over C57 at 4 hrs post-exposure. Following 7-days exposure the peak response shifted from 4 to 12 hrs post-exposure and increased 19 and 28 fold in C57 and ICR respectively. Also at 12 hrs, ICR BAL fluid KC and GM-CSF levels were significantly increased 4.3 and 2.2 fold respectively over C57. Neutrophils (3.5 folds) were greater in exposed ICR relative to C57 at each time point. In summary, ICR mice had a greater acute CS-induced biomarker response when compared to C57 mice. This suggests that while rapid changes in certain biomarkers may provide relevant information about early CS-induced biological effects, more studies are needed to determine if they are predictive of disease.

1429 VALIDATION OF A NEW LUNG FUNCTION METHOD IN ORALLY INTUBATED MICE USING A MODEL FOR RESPIRATORY ALLERGENICITY.

A. Braun[1], M. Rott[2], M. Hecht[1], T. Glaab[2], J. M. Hohlfeld[1,2], N. Krug[1] and H. G. Hoymann[1]. *[1]Fraunhofer Institute of Toxicology and Aerosol Research, Hannover, Germany and [2]Department of Respiratory Medicine, Hannover Medical School, Hannover, Germany.* Sponsor: H. Muhle.

Rationale: The aim of the study was to compare a novel system for invasive lung function measurements in mice with standard lung function measurements in conscious mice. Therefore, airway response was measured in a model of fungal asthma. Methods: Female BALB/c mice were sensitized with Aspergillus fumigatus extract (AF) on day 0, boosted on day 14 and challenged intratracheally or inhalationally on day 21 (AF groups). Negative controls (NEG) received the vehicle alone. Lung function was measured during inhalational allergen challenge to assess early airway response (EAR) and 48 h after challenge to assess airway hyperresponsiveness (AHR) by provocation with increasing doses of methacholine (MCh) aerosol. Two groups (AF, NEG) were anesthetized, intubated orally and placed into a novel whole-body plethysmograph in supine position to measure lung resistance, dynamic compliance and midexpiratory flow (EF50). For comparison, two additional groups (AF, NEG) were placed consciously in a head-out plethysmograph to measure EF50 to assess AHR. Results: The conscious AF animals showed a marked hyperresponsiveness: the MCh dose needed to induce a 50% decrease in EF50 was 3.3 times lower compared to NEG. In comparison, the intubated AF animals showed also a marked hyperresponsiveness: the MCh dose needed to induce a 50% decrease of EF50 was 3.1 times lower, and to induce a 100% increase in resistance was 3.2 times lower than compared to NEG. In addition, a marked early airway response was found in this model of allergic asthma: lung resistance was increased 266 % above baseline value (NEG: 32 %). Conclusion: The new technique is a valid method to measure allergic airway responses precisely without injuring the animals in a model for respiratory allergenicity.

1430 ASSESSMENT OF A SINGLE CONTROLLED VENTILATION INHALATION EXPOSURE TO A THERAPEUTIC PEPTIDE IN CYNOMOLGUS MONKEYS.

B. Sparrow[1], L. Baird[2], A. Koester[1], R. Moutvic[1], R. Beihn[3], K. Gumbhir-Shah[4], M. Brooker[1] and I. Grossi[1]. *[1]Battelle Memorial Institute, Columbus, OH, [2]Dyax, Corp, Cambridge, MA, [3]Scintiprox, Inc., Indianapolis, IN and [4]PharmaConsult, Inc., Basking Ridge, NJ.*

Delivery of therapeutic peptide molecules to the circulatory system *via* pulmonary inhalation is of great interest to the pharmaceutical industry. Using a controlled ventilation inhalation procedure and a target tidal volume of 75% vital capacity, an aerosol of DX-88, a recombinant kallikrein inhibitor peptide, co-mixed with the radioactive tracer Technetium-99m was delivered into the lungs of six anesthetized female Cynomolgus monkeys. Immediately following dosing, whole-body gamma scintigraphy images were collected to assess the lung deposition pattern of the aerosol and quantitatively determine the mass of DX-88 deposited within the lungs. Blood was collected post-exposure at predetermined time points over 24 hours and serum was analyzed for DX-88 concentration. Pharmacokinetics of DX-88 was evaluated by non-compartmental methods. Toxicity, based on clinical observations, body weights, food consumption, electrocardiology, heart rate, blood pressure and clinical, macroscopic and microscopic pathology, was evaluated through 14 days post-exposure. Scintigraphy analysis of the lung deposition patterns indicated aerosol deposition occurred primarily in the central lung with some deposition also in the trachea. The mean estimated inhaled dose of DX-88 was approximately 3 mg/kg with a measured deposited dose of 2 mg/kg. Pharmacokinetic analysis indicated a peak DX-88 serum concentration (9.93 ug/mL) at approximately 30 minutes post-exposure with a systemic clearance of approximately 1.5 mL/min/kg and a terminal half-life of 130 minutes. There were no remarkable clinical findings related to DX-88 over the conduct of the study. This study demonstrated that a single inhaled dose of DX-88 could be effectively delivered to the circulatory system with no adverse toxicity.

1431 EXPOSING THE ISOLATED PERFUSED RAT LUNG TO RESPIRABLE AEROSOLS OF DRUGS AND POLLUTANTS.

P. Gerde, L. Låstbom, P. Ewing and Å. Ryrfeldt. *Institute of Environmental Medicine, Karolinska Institutet, Stockholm, Stockholm, Sweden.*

The isolated perfused lung (IPL) of rodents is a valuable model for studying absorption and local metabolism of pollutants and drugs in the lungs. However, there have been relatively few options for exposing the IPL to respirable aerosols of dry powders. We have connected a previously developed aerosol generator for bolus

type exposures to the IPL of the rat. The generator uses compressed air to create a short burst of a highly concentrated aerosol in a 300 mL holding chamber. The particle size typically ranges from 1-3 μm. We exposed the rat IPL to tritium-labelled diesel soot at an air concentration of ~3 mg/L and a flow rate of 300 mL/min in a minute-long exposure immediately after aerosol generation. The lungs were ventilated at 60 breaths/min and the tidal volume was 0.7 mL. At the end of exposure the lungs were removed for determination of soot deposition in major airways and lung lobes. Results show that at the present flow rate, ~3% of the soot in the air passed over the lungs was deposited. Based on the amount inhaled, the deposition was ~20%. More than 90% of the deposited soot was located from the level of the lobar bronchi and below, indicating a highly respirable aerosol. We will use the system for studying mechanisms of absorption and metabolism of toxicants and drugs in the lungs. (Research supported by the Swedish Agency for Innovation Systems, Vinnova, and the Swedish Council for Working Life and Social Research, FAS)

1432 THE ASSESSMENT OF PULMONARY INFLAMMATION IN RODENTS USING EXHALED BREATH.

E. Bermudez[1], J. Jackman[2] and O. R. Moss[1]. *[1]CIIT, Research Triangle Park, NC and [2]Johns Hopkins University Applied Physics Laboratory, Laurel, MD.*

Identification of individuals exposed to biological warfare (BW) agents, prior to the onset of clinical symptoms, is of extreme importance in the resolution of situations where a BW attack is suspected. The pulmonary system is a major portal for the introduction of BW agents and the early inflammatory response of the lung may be useful for the identification of the BW organism and the evaluation of exposed individuals. Exhaled breath has been used to assess the physiological state of humans by examining the levels of recoverable volatile compounds. More recently, there has been an effort to recover non-volatile compounds, such as proteins, with some success in humans and cattle. The work described here focuses on the capture, in the exhaled breath of laboratory rodents, of proteins elaborated due to pulmonary inflammation. Fifty mice were placed in a nose-only Canon exposure tower and the exhaled breath was condensed in dry ice-acetone-cooled collection vessels. The direction of airflow through the tower was reversed to minimize the loss of condensate on the stainless-steel surfaces. The recovery of water as condensate was approximately 80% of the maximum calculated volume of water in the exhaled breath. Bronchoalveolar lavage (BAL) was performed on ten animals to determine the inflammatory status of the lung. Protein concentrations in the exhaled breath condensate were at or near the limit of detection (1 μg/ml) of the assay and were approximately equivalent to 0.001% of the protein recovered by BAL. Pulmonary inflammation elicited by endotoxin treatment was readily detectable in BAL fluid as increased concentrations of protein, tumor necrosis factor, and interferon (IFNg). Very low concentrations of IFNg were detectable in concentrated exhaled breath condensate and corresponded to approximately 0.001% of the levels measured in the BAL fluid. The apparent capture of a protein indicative of inflammation was demonstrated. Optimization of system parameters will include the use of other species, such as the laboratory rat.

1433 ARGININE METABOLISM IN LUNG TISSUE: IMPLICATIONS FOR MEASUREMENT OF NOS ACTIVITY.

K. Fang, A. Gunnison and C. Nadziejko. *Envrionmental Medicine, NYU School of Medicine, Tuxedo, NY.*

Nitric oxide synthase(NOS), converts L-arginine to nitric oxide (NO) and citrulline. Synthesis of NO requires NADPH and other co-factors. Within the lung, NO plays a key role in regulation of pulmonary artery pressure, cytotoxicity, and inflammation. Thus, inactivation of NOS by inhaled toxicants can have serious health effects. We are investigating the effects of *in vivo* tobacco smoke exposure on NOS activity assayed by the conversion of 3H L-arginine to 3H L-citrulline. We examined whether this technique is subject to interference by other pathways of arginine metabolism when it is used on lung homogenates. Frozen mouse lungs were homogenized and centrifuged at 100, 000 g for 1 hr. The cell membrane (pellet) and cytosol (supernatant) fractions were added to buffer containing 3H labeled L-arginine, unlabeled arginine, NADPH, BH4, calmodulin, and calcium. The reaction solution was incubated for 40 min at 37 C. Ion exchange columns were used to retain 3H L-arginine and 3H L-citrulline was collected from the filtrate. Both pellet and supernatant fractions produced 3H L-citrulline but the rate of production was higher in the absence of NADPH, indicating the presence of a non-NADPH dependent pathway of arginine metabolism. When N-hydroxy-nor-L-arginine, an arginase inhibitor, was added to the reaction mixture, all of the citrulline production by the lung pellet and supernatant fractions was NADPH dependent (ie due to NOS). Arginase converts arginine to ornithine. Ornithine can be metabolized to citrulline in tissues with an intact urea cycle. Although the lung lacks the enzyme to convert ornithine to citrulline, addition of 3H ornithine to lung homogenates under conditions used to measure NOS activity resulted in radiolabeled material that passed through the ion exchange column. This result indicates that measurement of NOS activity in lung homogenates can give inaccurate results due to interference by arginase. Also competition between arginase and NOS for arginine is another mechanism that can potentially affect NO production in the lung. Supported by a grant from Phillip Morris

1434 IDENTIFYING POTENTIAL RESPIRATORY SENSITIZERS: PROTEINS.

J. A. Hotchkiss, S. M. Krieger, J. M. Rase, M. R. Woolhiser, T. D. Landry and M. P. Holsapple. *Toxicology, Environmental Research and Consulting, The Dow Chemical Company, Midland, MI.*

Exposure to respirable xenobiotic proteins has been linked to the development of type I respiratory allergy. Application of strict exposure guidelines can minimize occupational exposure, but testing guidelines to distinguish between allergenic and antigenic proteins are not available. In this study male BDF1 mice were intranasally instilled (50μl/instillation) with saline or saline containing 0.05, 0.5, or 5.0 μg of an allergenic bacterial protease (Subtilisin Carlsberg; SC), or 0.5, 5.0, or 25 μg of a potent protein antigen (Keyhole limpet hemocyanin; KLH) on days 1, 3, 10, 17, and 24. Exposure-related differences in airway hyperreactivity of mice exposed to 5.0 μg doses of SC or KLH were assessed, on day 25, by methacholine challenge in whole-body plethysmography chambers. Mice were sacrificed on days 11 and 15 (3 instillations) or days 25 and 29 (5 instillations). Serum levels of total IgE and protein-specific IgG1/IgG2a were determined by ELISA. Right lung lobes were lavaged to determine total and differential inflammatory cell counts. Left lung lobes were analyzed to determine the amount of stored mucosubstances in epithelium lining large (G5) and small (G11) diameter main (axial) pulmonary airways. Both SC and KLH induced similar dose and time-dependent increases in stored mucosubstances and influx of eosinophils into bronchoalveolar airspaces. Both proteins induced dose and time-dependent increases in total serum IgE levels and modest increases in IgG2a, but, only SC also induced elevated levels of IgG1. Only SC-exposed mice had increased airway hyperreactivity (increased sensitivity to methacholine challenge) compared to saline-instilled control mice. These data suggest that elevated antigen-specific IgG1, not total IgE, levels are most predictive of a neoantigen's potential to induce airway hyperreactivity. We are testing additional proteins and propose that both total IgE levels and antigen-specific IgG1/IgG2a ratios must be used to assess the potential of xenobiotic proteins to induce allergic respiratory sensitization.

1435 OBSERVATIONS AND RECOMMENDATIONS REGARDING THE BUXCO AEROSOL DELIVERY/UNRESTRAINED PLETHYSMOGRAPH SYSTEMS.

J. McDonald[1], L. Bowen[1], J. Mauderly[1] and M. Lomask[2]. *[1]Toxicology, Lovelace Respiratory Research Institute, Albuquerque, NM and [2]Buxco Electronics, Inc., Sharon, CT.*

The BUXCO rodent plethysmograph exposure system is an aerosol delivery device used primarily for conducting methacholine airway challenge tests in rodents. Operation and configuration of the exposure system will affect the aerosol characteristics and therefore the methacholine challenge response. For nebulizers, different volumes of the same concentration of solution placed in the nebulizer reservoir will yield significantly different aerosol output (~factor of 2 for 2 x volume of same solution concentration). However, different volumes of solution did not affect the size distribution of the aerosol, with observed methacholine aerosol size distributions consistently in the 2-micron size range (mass median diameter). The caliber and length of aerosol delivery lines may affect background environmental noise levels as measured within the animal chambers, and may also create moderate but observable distortion in the respiratory signals, which has potential impact on PenH computations. Tuving of various calibers (internal diameters) have been investigated to asses the degree of these effects. Airway challenges are typically conducted in sequence. When challenges are conducted sequentially, it was observed that both methacholine concentration and humidity have a lag time for clearance from the chamber. It is important that the system is thoroughly flushed during sequential use, or residual methacholine and humidity will build up in the chamber, potentially confounding concentration-response relationships potentially causing water condensation that could plug aerosol transit lines. Part of this work supported by the National Environmental Respiratory Center with support from multiple government and industry sponsors, including the USEPA. This abstract does not represent the views of any sponsor.

1436 EVALUATION OF THE EFFECTS OF INTERMITTENT EXPOSURE TO ELEVATED INHALED CO_2 CONCENTRATIONS UPON BLOOD GAS AND HEMATOLOGIC PARAMETERS IN THE CANINE.

M. Shaw, R. Moutvic, M. Brooker and I. Grossi. *Battelle Memorial Institute, Columbus, OH.*

Evaluation of inhaled therapeutics in repeat-dose non-clinical studies is a critical step in approval of inhaled therapeutics for use in man. Deep lung deposition is the preferred site of deposition for many inhaled therapeutics. Since tidal breathing animals use only a small portion of their total lung volume, improved penetration into and deposition of aerosols in the lung could be achieved through increased tidal volume. Increases in inspired CO_2 will produce increases in minute ventilation as the body attempts to maintain acid-base balance. The increase in minute ventilation will be produced primarily through increases in tidal volume. Six beagle dogs (3/sex) were exposed to an approximately 4% CO_2 atmosphere using a head-dome exposure system daily for 1 hour for 7 consecutive days. Respiratory parameters were monitored before and during exposure. Venous blood gases (pO_2 and pCO_2) and pH were monitored before and after each exposure. Blood samples were collected before and after the 7-day exposure period for hematological evaluations. Increased concentration of CO_2 in the test atmosphere resulted in increases (2.1 to 2.5 fold relative to pre-exposure values) in tidal volume, minute volume and peak inspiratory flow. Small (1.1 to 1.2 fold) increases in frequency and inspiratory time were observed. Generally, blood levels of pO_2 and pCO_2 increased and pH decreased post exposure relative to pre exposure values. Evaluations of erythroid parameters indicated a decrease in red blood cell count, hematocrit, hemoglobin and percent reticulocytes after seven days of exposure when compared to pre-study baseline. There were little or no changes in mean corpuscular hemoglobin, mean corpuscular hemoglobin concentration or mean corpuscular volume. While increased respiratory pattern control and increased inhaled volumes would be a useful tool in non-clinical repeat dose inhalation toxicity studies, the use of increased concentration of CO_2 in the test atmosphere in the non-anesthetized animal model would require further studies.

1437 GENERATION OF LIFE-LIKE RODENT NASAL MODELS.

E. A. Gross, J. T. Kelly, D. R. Joyner, C. S. Dunn, J. S. Kimbell and B. Asgharian. *CIIT Centers for Health Research, Research Triangle Park, NC.*

Transport of gases and particles in the upper respiratory tract can be simulated and have been used to predict airflow and gas uptake patterns in the three dimensionally reconstructed nasal passages of F344 rats (Kimbell et al., 1997, Toxicol. Appl. Pharmacology 145, 388-398; Kimbell et al., 2001, Toxicol. Sciences. 64, 100-110; Moulin et al., 2002, Toxicol. Sciences. 66, 7-15). The model used in the previous studies was made from step sections through a fixed plastic embedded specimen. One potential source of error with this type of specimen is decreased surface area to nasal airway volume ratio for a dead, fixed specimen compared with those visually evaluated from MRI scans of live rodent nasal airways (Wiethoff et al., 2001, Toxicol. Appl. Pharmacology 175, 68-75). To obtain more life-like specimens for modeling, rats were killed with CO2 and not exsanguinated. This helped to maintain the natural size and shape of the highly vascularized nasal turbinates and septum. The specimens were fixed very briefly in 10% neutral buffered formalin. The nasal airways of the specimens were filled with cryo-embedding medium, which had been saturated with Xerox copy toner to enhance the contrast of the airway with the tissue structures and provide support during sectioning. The specimens were frozen and step-sectioned. Photographs of the block surface were taken and airway perimeter, area and x, y coordinate files were generated using image analysis software. Evaluation of images indicated that the structures of the rat nasal turbinates are much larger in the frozen specimen than they appeared in previous paraffin or plastic embedded slide sets confirming what was seen by Wiethoff et al. in mouse MRI scans. These data show airway volume to be decreased with much of the airway space seen in fixed paraffin or plastic sections taken up by the enlarged turbinates. Computational meshes can be constructed from this data set and used for simulations of airflow, gas uptake and/or particle deposition. This study provides a next step in model refinement by providing more life-like dimensions for the rat nasal turbinates and airways.

1438 AN AUTOMATED AEROSOL SYSTEM THAT USES REAL-TIME DOSIMETRY FOR INHALATION EXPOSURES WITH PRIMATES.

C. J. Roy and J. M. Hartings. *Aerobiology and Product Evaluation, USAMRIID, Fort Detrick, MD.*

Well-characterized inhalation exposure systems are critical for preclinical testing and pathogenesis studies involving nonhuman primates (NHP). Estimation of dose in inhalation studies has been traditionally determined through the use of predictive measures such as whole-body plethysmography (WBP) or estimated from historical data. A dynamic aerosol system has been developed that integrates complete data acquisition and control for all exposure parameters during inhalation. Among the functions is real-time respiratory measurement, which allows the length of exposure to be based on respiration during exposure rather than reliance upon predictive measures. This function automatically compensates for fluctuations in respiration during exposure. Anesthetized rhesus macaques (n=15) were sham-exposed to test the dosimetry function of the newly-developed system. WBP was performed immediately before dosing with the automated system. A cumulative tidal volume (10 liters) was used to demonstrate the dosimetry function. Time to reach the requisite cumulative tidal volume ranged from approximately 1 to 7 minutes and was weakly associated with animal weight ($r^2 = 0.26$). Analysis of the variance between methods was significantly different ($p<0.01$); similarly, there were intra-animal differences in breath frequency, tidal volume, and minute volume measurements in 10/15 (67%; $p<0.01$) of the NHPs under study. A post hoc calibration of the WBP unit with a mechanical ventilator indicated a 5-10% reduction of tidal volume measurement as breath frequency or supplied tidal volume increased; the automated system showed minimal differences within the same range. Results indicate that the real-time dosimetry function returns accurate respiratory measurement and closed-loop computer controlled feedback improves real-time data collection for the entire inhalation procedure. These preliminary data demonstrate that real-time dosimetry can be successfully integrated as a control mechanism into a complete system for aerosol dosing of NHPs with superior accuracy and precision.

1439 1, 3-BUTADIENE SOOT (BDS) AS A STANDARD REFERENCE MATERIAL FOR INHALATION TOXICOLOGY STUDIES.

W. J. Catallo, S. Barker, W. Henk and A. Penn. *CBS, LSU School of Vet. Med., Baton Rouge, LA.*

Incomplete combustion of 1, 3-butadiene gives rise to BDS containing a broad spectrum of PAHs (128-2000 amu and beyond) in high amounts (1000-5000 cigarette equivalents of the benzopyrene isomer series). The BDS particles also contain other mutagenic PAHs, stable and transient free radicals and strong oxidants. Under simple constant burn conditions, 94 % (w/w) of the particles reproducibly are <4 um. Human lung epithelial cells (NHBE and BEAS-2B) treated with BDS extracts, or BDS alone, in serum-free culture exhibited genotoxicity, autofluorescence, morphological alterations and conspicuous cell blebbing after one treatment and incubation times of 4 - 72 h. Direct exposure of the cells to BDS a) in the plume and b) by addition of collected particles on the surface of the culture medium yielded the same effects more rapidly when the DMSO vehicle was absent, indicating that DMSO was unnecessary for BDS bioassays. Indeed, BDS may have interacted with the DMSO, thus attenuating the observed BDS toxicity. As indicated by SEM and dynamic light scattering experiments, microparticles (<0.5 um) moving through the medium to the cells were sufficient to elicit autoflourescence and other endpoints. Potentiometry and voltammetry data supported these observations: neat BDS added directly to the surface of the culture medium produced rapid changes in solution redox potential. These data and those from elemental and organic chemical analyses indicate that BDS particles have highly reproducible size frequency and compositional features that favor its use as a standard material for inhalation toxicology studies. As the mixture is almost completely PAH in nature, the effects of polar species, trace metals, and inorganic compounds on observed endpoints can be discounted. Further, BDS can be applied directly (no vehicles) to putative target cells in culture, mimicking *in vivo* exposures. This allows for alignment and intercomparison of dosimetry and observed effects in cell culture assays with those in inhalation studies *in vivo.*

1440 OXYGEN TENSION AFFECTS PHENOTYPE IN CULTURED BONE MARROW-DERIVED MACROPHAGES.

J. C. Pfau, A. Archer, J. Reeves, J. C. Schneider and A. Holian. *Center for Environmental Health Sciences, University of Montana, Missoula, MT.*

The unique role of alveolar macrophages (AM) in clearance without inflammation, while maintaining pro-inflammatory capabilities, requires complex regulation. A better understanding of normal lung immune homeostasis could lead to vast improvements in our ability to address chronic inflammation following environmental exposures. This study tested the hypothesis that AM are functionally adapted to the relatively high oxygen partial pressure (PO2) of the lung, and that this induces them to be predominantly immune suppressive through modification of redox sensitive transcription factor pathways. Balb/c mouse bone marrow derived macrophages (BMC) were differentiated under two different PO2, and then compared functionally to AM and peritoneal macrophages (PM) using flow cytometry, and microtiter assays for phagocytosis and antigen presentation. BMC differentiated in normoxia (PO2 140 mmHg, BMC140) are similar to AM in having low ex-

pression of surface markers of activation, and showing relatively poor phagocytic and antigen presenting cell (APC) activities. However, BMC grown in low oxygen tension like that found in other tissues (<40 mmHg, BMC40), express more activation markers and are better phagocytes and APCs, making them similar to peritoneal macrophages (PM). We have also shown that BMC140 are more oxidative intracellularly than BMC40, based on oxidation of the fluorescent dye, dichlorofluorescein (DCF), and produce more glutathione (GSH), possibly to compensate. Finally, NF-kB translocation in response to lipopolysaccharide (LPS), measured by laser scanning cytometry and immunofluorescence, was reduced in BMC140 as well as in AM, compared to BMC40 and PM, respectively. These data suggest that the regulation of the immune suppressive AM phenotype may occur, at least in part, *via* inhibition of the NF-kB pathway due to the unique redox environment. Alteration of that redox control following toxic exposures may lead to more active phenotypes that may be responsible for chronic inflammation. Supported by EPA Center Grant and NRSA fellowship, ES11249.

1441 ELIMINATION OF CARBON MONOXIDE IN AWAKE RATS.

Z. Gu and A. J. Januszkiewicz. *Respiratory Research, Walter Reed Army Institute of Research, Silver Spring, MD.* Sponsor: P. DelValle.

Rats are often used for studying carbon monoxide (CO) poisoning. However the characteristics of CO elimination in rats have not been fully defined. This study examined CO elimination and respiratory patterns in rats exposed briefly (5 min) to high concentration CO (1000, 3000, 6000, and 12000 ppm). Awake male Sprague-Dawley rats (250-380g) were placed into tube restrainers attached to a dynamic exposure chamber. Respiratory measurements were made using partial body flow plethysmographs. Rats were allowed to breathe USP air immediately before and after the CO exposures. All animals survived the exposures, through a 4-hr post-exposure sampling period. Prior to exposure mixed-blood COHb saturation in all rats was essentially zero. At the end of the 5-min exposure average COHb was found to increase to 17+/-4, 30+/-6, 46+/-10, and 59+/-12% in the 1000, 3000, 6000, and 12000 ppm CO groups, respectively. One hr after exposure, COHb decreased to 9+/-2, 14+/-4, 16+/-4 and 22+/-6% in the four CO groups. At 2 hrs COHb decreased to 7+/-2, 7+/-3, 8+/-3, and 10+/-3%, and at 4 hrs COHb further returned towards pre-exposure control (3+/-1, 3+/-2, 4+/-2, and 3+/-1%) in above groups, respectively. Elimination half time for COHb was approximately 147+/-12, 93+/-7, 57+/-4, and 49+/-3 min in above groups, respectively. During the first hr after exposure average minute ventilation volumes increased 20, 50, 100, and 160% above respective controls (pre-exposure) in the above groups, respectively. In the second hr these values decreased to 10, 20, 50, and 60% above controls, and further decreased to 10, 10, 20 and 20% above controls by the fourth hr post exposure. These results suggest that COHb elimination in rats appears to follow a first-order rate. Furthermore, COHb elimination in rats is extremely rapid (compared to reported results from large animal species and humans), and hyperventilation is an important mechanism for regulating the recovery from CO poisoning in this species.

1442 INHALATION NOSE-ONLY EXPOSURE OF NEONATAL AND JUVENILE RATS.

M. Stoute[1], A. Viau[1], K. Robinson[2] and C. Banks[1]. *[1]Inhalation Toxicology, CTBR, Senneville, QC, Canada and [2]Reproductive Toxicology, CTBR, Senneville, QC, Canada.* Sponsor: L. Dostal.

Due to the recent focus on non-clinical testing of pharmaceutical products used for pediatric populations, the feasibility of inhalation nose-only exposure of neonatal and juvenile rats was assessed. Five litters of 4 male and 4 female rat pups obtained from timed-mated CD females were used for the study. Exposed animals, 2 pups/sex/litter, were acclimated to the restraint tubes for increasing periods of time (1, 2 and 4 hours) from Day 7 to 9 post partum. Animals were exposed to an air atmosphere (generated by a PARI LC PLUS nebulizer) on a nose-only flow-through chamber for 4 hours daily from Day 10 up to Day 34 post partum. A cage-control group comprised of 2 pups/sex/litter was maintained under normal laboratory conditions from Day 7 up to Day 34 post partum for comparison to the animals exposed to inhalation procedures. Detailed examinations were performed at least once weekly and body weights were monitored at intervals throughout the study. On Day 21 post partum, all pups were weaned from their dams. One pup/sex/litter from the exposed and cage-control groups was euthanized on Days 21 and 35. All these pups underwent a complete macroscopic examination. There were no clinical signs considered related to the inhalation procedures. There were lower body weight gains in inhalation exposed animals when compared to the cage-controls. However, individual body weights remained within the expected range. There were no macroscopic observations considered related to the inhalation restraint procedure. Nose-only exposure of neonatal and juvenile rats was considered to be a feasible method. Therefore, neonatal and juvenile rats can be used for toxicity assessment of drugs intended for pediatric populations *via* the inhalation route.

1443 CYTOTOXICITY AND CYTOKINE PRODUCTION IN LUNG EPITHELIAL CELLS *IN VITRO* FOLLOWING CHROMIUM AND MANGANESE EXPOSURE.

D. M. Tessier and L. E. Pascal. *Environmental & Occupational Health Sciences, University of Illinois Chicago, Chicago, IL.*

Condensed vapors of heavy metals are a significant hazard of welding activities, associated with an increased risk for developing respiratory disease. Chromium, nickel and manganese are predominant metals in welding fumes, and were therefore the focus of the present study. Molecular and cellular effects of heavy metal exposure to lung epithelial cells *in vitro* were investigated using cytotoxicity assays, immunoblot analysis of protein phosphorylation and immunochemical detection of the inflammatory cytokines IL-6, IL-8 and TNF-alpha. We show that chromium(VI) and manganese, but not nickel, are cytotoxic to normal human lung epithelial cells *in vitro* (SAEC and BEAS-2B), at concentration ranges correlated to concentrations of these metals found in welding fumes. Chromium(VI) and manganese (0.2 - 200 uM) caused cytotoxic effects within one hour post-treatment, with a maximal effect of 64% and 60% loss of cell viability, respectively following 24 hrs exposure. The toxic effect was associated with increased levels of intracellular phosphoprotein, a measure of intracellular signalling responses, and subsequent release of inflammatory cytokines IL-6 and IL-8, while no release of TNF-alpha was observed. Changes in cellular phosphoprotein levels and cytokine release were apparent within 1 hour following heavy metal treatment. IL-6 and IL-8 are released from lung epithelium to recruit cells of the immune system to sites of tissue damage and to initiate tissue repair mechanisms. Therefore, the observed effects of chromium(VI) and manganese in lung epithelial cells demonstrate a mechanism through which cytotoxicity of these metals in the lung can result in inflammatory responses and tissue restructuring, both of which are hallmarks of various respiratory diseases.

1444 EFFECTS OF EXPOSURE TO DIESEL EXHAUST PARTICLES (DEP) ON PULMONARY ACTIVATION OF MUTAGENIC AGENTS.

J. Y. Ma[1], H. W. Zhao[1], M. W. Barger[1], J. K. Ma[2] and V. Castranova[1]. *[1]HELD, NIOSH, Morgantown, WV and [2]School of Pharmacy, WVU, Morgantown, WV.*

DEP have been shown to induce a transient increase in CYP1A1 that returns to basal level at 7 days post-exposure, but to cause a sustained decrease in CYP2B1 in rat lung, whereas carbon black (CB) results only in a sustained decrease of CYP2B1. The present study examined the effects of DEP-altered pulmonary cytochrome P450 on the metabolization of mutagenic agents. Sprague-Dawley rats were intratracheally instilled with saline or a single dose of DEP or CB at 35 mg/kg body weight. At 1, 3, or 7 days post-exposure, S9, microsomes, and cytosol were isolated from lung tissue. The mutagenicity of 2-aminoanthracene (2-AA) and 2-aminofluorene (2-AF) were monitored using the Ames test with *S. typhimurium* YG1024. The results show that S9 or microsomes, but not the cytosolic enzymes, activated the mutagenicity of 2-AA and 2-AF in a dose-dependent manner. The CB-exposed S9, with down-regulated CYP2B1, significantly reduced 2-AA mutagenicity compared to the control S9 at all time points. In contrast, the induction of 2-AA mutagenicity by DEP-exposed S9, with down-regulated CYP2B1 but induced CYP1A1 at 1 and 3 days post-exposure, decreased with increasing exposure time. At 1 day post-exposure, the DEP-S9 had a similar effect to that of control S9, but induced higher mutagenicity than the CB-S9. This DEP-derived S9 activated 2-AA mutagenicity decreased at 3 days post-exposure and further declined to the level of CB-S9 at 7 days post-exposure. Heat-inactivated S9 or addition of a CYP1A1 inhibitor, alpha-naphthoflavone, blocked 2-AA activation. These results suggest that both CYP1A1 and CYP2B1 activate 2-AA mutagenicity. At 3 days post exposure, DEP-S9 decreased, while CB-S9 increased 2-AF mutagenicity compared to control S9, suggesting that both CYP1A1 and CYP2B1 decrease 2-AF mutagenicity. These results show that mutagenic activation is substrate-specific, depending on competing metabolic pathways. DEP exposure, which alters the cytochrome P450 system, may have a profound effect on pulmonary handling of mutagenic agents.

1445 EXPOSURE OF CULTURED MYOCYTES TO ZINC RESULTS IN ALTERED BEAT RATE AND INTERCELLULAR COMMUNICATION.

D. W. Graff[1], R. B. Devlin[1], J. A. Brackhan[2], B. J. Muller-Borer[2], J. S. Bowman[2] and W. E. Cascio[2]. *[1]NHEERL, USEPA, Research Triangle Park, NC and [2]Division of Cardiology, University of North Carolina, Chapel Hill, NC.*

Exposure to ambient air pollution particulate matter (PM) is associated with increased morbidity and mortality. Recent toxicological studies have reported PM-induced changes in a number of cardiac parameters, including heart rate variability, arrhythmias, repolarization, and internal defibrillator discharges. The purpose of

this study is to identify cellular processes that may contribute to cardiac dysfunction following PM exposure. Isolated neonatal rat ventricular myocytes were cultured for 11 days and then exposed to different concentrations of Zinc (Zn), a soluble component found in many PM samples. Zn significantly decreased spontaneous myocyte beat rate by 15% 2 hrs following exposure and 17% at 4 hrs compared to baseline. Since beat rate is influenced by intercellular communications, fluorescent recovery after photobleaching (FRAP) was then measured. FRAP rate, a physiological measure of cell-to-cell communication and gap junction permeability, was significantly decreased by 76% 4 hrs after exposure but not at 2 hrs. Changes were measured in gene expression of gap junction proteins which mediate communication between myocytes. Exposure of myocytes to Zn for 24 hrs resulted in a 76% increase in mRNA coding for connexin 43. These data suggest that soluble metals found in air pollution particles can affect the ability of cardiac myocytes to spontaneously beat, possibly by disruption of cell-to-cell communication. These effects potentially reflect disturbances in repolarization and impulse propagation which could contribute to PM-associated cardiac morbidity and mortality. This abstract does not necessarily reflect EPA policy.

1446 IRON-MEDIATED AMIODARONE RADICAL FORMATION.

J. W. Card, L. L. Bedard, L. A. Bourne, S. L. Graham, W. J. Racz, J. F. Brien and T. E. Massey. *Pharmacology and Toxicology, Queen's University, Kingston, ON, Canada.*

Numerous adverse effects of amiodarone (AM) may be mediated by free radical species. The current study investigated AM radical formation in microsomal and microsome-free systems. Hamster liver microsomes were incubated with AM, NADPH, and the spin trap α-phenyl-N-t-butylnitrone (PBN). Analysis by electron spin resonance (ESR) spectroscopy revealed a PBN-trapped radical with a triplet of doublets pattern and splitting constant values consistent with those of a carbon-centred radical. Incubation in the absence of NADPH, with microsomes exposed to carbon monoxide, with boiled microsomes, or under anaerobic conditions, did not alter the signal intensity or splitting constant values of the PBN-trapped radical, indicating that cytochrome P450 activity was not required for its formation. However, signal intensity was decreased by addition of the reducing agent sodium dithionite, suggesting a role for iron redox reactions in radical signal generation. Microsome-free incubations with AM and Fe^{2+} sulphate generated a signal pattern with intensity and splitting constant values similar to those in the microsomal incubations, whereas Fe^{3+} sulphate did not generate a measurable signal. Furthermore, the magnitude of the Fe^{2+}-mediated signal was decreased by sodium dithionite or the iron chelator deferoxamine, indicating that Fe^{2+} oxidation to Fe^{3+} is involved in radical generation. Thus, AM radical formation occurs in microsomal and microsome-free systems, and Fe^{2+} appears to play an important role in its generation. (Supported by Canadian Institutes of Health Research grant number MT-13257).

1447 EFFECTS OF SOLUBLE AND INSOLUBLE FRACTIONS OF A STAINLESS STEEL MANUAL METAL ARC WELDING FUME ON FREE RADICAL PRODUCTION AND LUNG INJURY AND INFLAMMATION.

M. D. Taylor, J. R. Roberts, S. S. Leonard, X. Shi and J. M. Antonini. *HELD/PPRB, NIOSH, Morgantown, WV.*

The goals of this study were to examine the roles of the soluble (Sol) and insoluble (Insol) fractions of a stainless steel welding fume (Tot) collected during manual metal arc welding in the development of rat lung damage and inflammation and correlate those effects with free radical production and metal composition. Welding fume fractions were separated by incubation in saline followed by centrifugation and filtration. Metal composition analysis by energy dispersive spectroscopy revealed both Cr and Mn in the Sol fraction. Using electron spin resonance, the generation of radicals from Cr(VI) was observed, with the highest signal from Tot, an intermediate signal from Sol, and a low signal from Insol. To examine the effects of the fumes on lung damage and inflammation, male Sprague-Dawley rats were intratracheally instilled with Tot at 2 mg/rat, or the equivalent volume of Sol, Insol, or the vehicle (saline). On days 1, 3, and 6, the right lung was assayed for lipid peroxidation (LPO) products while the left lobes were subjected to bronchoalveolar lavage (BAL). LPO was elevated in the lungs following Tot treatment, with most of the effect attributed to the Insol fraction. All fractions caused increases in BAL cell number, including elevated macrophage recovery. However, the Tot and Insol fractions caused increased PMN numbers at days 1 and 3, while the Tot and Sol fractions led to increased eosinophils at day 1. The changes in left lung weight were additive (Sol + Insol = Tot) on day 6, while albumin, total protein, and LDH activity in the first BAL fraction were all additive at day 3. These findings indicate that the ability of the fume to produce free radicals and much of the damage observed in the lungs of rats after Tot treatment depends on both the Sol and Insol fractions of the fume. However, PMN recruitment and LPO were due mainly to the insoluble particulates while eosinophil recruitment was due to the soluble components, most likely soluble metals.

1448 PULMONARY TOXICITY STUDIES WITH TiO2 PARTICLES CONTAINING VARIOUS COMMERCIAL COATINGS.

D. B. Warheit, T. R. Webb and K. L. Reed. *Pulmonary Toxicology, DuPont Haskell Lab., Newark, DE.*

Most of the pigment-grade TiO2 samples that have been tested in inhalation toxicity tests have been of the generic variety -(i.e., generally uncoated TiO2 samples or 99% TiO2 and 1% Al2O3). However, questions have been raised over the past twenty years regarding the potential pulmonary toxic effects, if any, of the commercially coated TiO2 materials, generally which contain higher concentrations of aluminum oxide and/or amorphous silica on their surfaces. The aims of this study were to assess in rats, using a well-developed short-term pulmonary bioassay, 1) the acute pulmonary toxicity of several intratracheally instilled commercial coatings on pigment grade TiO2 particles relative to uncoated, TiO2 particle control samples and 2) to bridge the results of these instillation studies with data previously generated from inhalation studies with uncoated TiO2 particles, using the uncoated TiO2 particles as the inhalation/instillation bridge material. Groups of rats were intratracheally instilled with 2 or 10 mg/kg of TiO2 particles containing coatings ranging from 0-7% Al2O3 and/or 0 - 10.5% amorphous silica. Saline-instilled rats served as controls. The lungs of sham and exposed rats were evaluated by bronchoalveolar lavage at 24 hr, 1 week, 1 month and 3 months postexposure (pe). The results demonstrated that the high dose (10 mg/kg) pigment grade TiO2 particles with the greatest Al and amorphous silica coatings produced the most sustained and intense lung inflammatory response, as evidenced by lung cell differentials and BAL fluid levels of LDH and protein, but not alkaline phosphatase. This effect was measured through 1 month but not a 3-month postexposure period. Our bioassay results indicate that the coatings containing the largest concentrations of amorphous silica and aluminum oxide produced the most significant lung inflammatory response but it is important to note that these effects were transient and not sustained. Studies are ongoing to assess the lung tissue responses of rats exposed to the various commercial coatings on pigment grade TiO2 particles.

1449 DEVELOPMENT OF A RAT MODEL OF INHALATION FUME FEVER.

B. R. Laurence, K. L. Reed, R. Valentine, T. R. Webb and D. B. Warheit. *Pulmonary Toxicology, DuPont Haskell Lab., Newark, DE.*

Occupational fume fevers represent a transient flu-like syndrome in humans associated with the inhalation of freshly formed metal or polymer ultrafine UFP (<100 nm) or fine-sized particles (< 2 mm), notably zinc oxide or PTFE/FEP. Presently, the key physical/chemical features of particulates associated with fume fever are unknown. Some preliminary studies have demonstrated that rats exposed to fine aerosols of ZnO particles or aged, combusted FEP UFP develop a transient lung inflammatory response which seems to mimic fume fever in humans. The development of animal models of fume fever, may provide clues to the mechanism of inflammatory injury occurring in workers following exposures. In preliminary, range-finding studies, rats were exposed to aerosols of zinc oxide (ZnO) particles for a single period of 1 or 3 hours (either 25 or 50 mg/m3), and the lungs of ZnO and sham-exposed animals were evaluated at 24, 72, or 168 hrs (1 week) postexposure using bronchoalveolar lavage fluid (BALF) analyses. Three hour exposures to ZnO at 25 mg/m3 produced a moderate and transient pulmonary inflammatory response (~22% pmns) at 24 hours postexposure, which was reduced at 72 hrs (~10% pmns) and resolved by 1 week postexposure. BAL fluid parameters reflected this minor inflammatory response, as the BAL fluid LDH, protein, and alkaline phosphatase values from the 3 hr ZnO rats were approximately 2X relative to sham controls at 24 hrs pe. Rats exposed to ZnO for 1 hr demonstrated very little response at any time postexposure. Three hour exposures to ZnO at 50 mg/m3 produced a similar pattern, but of greater intensity - i.e., (~45% pmns) at 24 hours postexposure, which was reduced at 72 hrs (~15% pmns) and resolved by 1 week postexposure. BAL fluid LDH, protein, and alkaline phosphatase values in the 3 hr ZnO rats were > 3X relative to sham control values. Studies are ongoing to determine the mechanism of this transient pulmonary inflammatory response, as well as the effects of ultrafine ZnO and PTFE and other metals.

1450 RECOVERY OF MANUAL METAL ARC-STAINLESS STEEL WELDING FUME EXPOSURE INDUCED LUNG FIBROSIS IN SPRAGUE-DAWLEY RATS.

K. Song[1,2], I. Yu[1,2], H. Chang[3], J. Han[1], Y. Chung[1], K. Han[2], K. Chung[2] and H. Chung[1]. *[1]Center for Occupational Toxicology, OSRHI/Korean OSHA, Daejeon, South Korea, [2]College of Pharmacy, Sung Kyun Kwan University, Suwon, South Korea and [3]Department of Pathology, Kosin Universtiy, Busan, South Korea.*

Welders with radiographic abnormalities of pneumoconiosis have shown a gradual clearing of the x-ray identified effects following removal from exposure. In some cases, pulmonary fibrosis associated with welding fume would appear to a more se-

vere form of fibrosis in welders. To investigate the disease and recovery process of pneumoconiosis induced by welding-fume exposure, rats were exposed to welding fumes with concentrations of 63.6 ±4.1 mg/m^3 (low dose) and 107.1 ±6.3 mg/m^3 (high dose) total suspended particulates for 2 h per day in an inhalation chamber for 2 h, 15, 30, 60 and 90 days, thereafter the rats were removed from the exposure, and allowed to recover from the welding fume induced lung fibrosis for 90 days. When compared to the control group, the lung weights increased significantly both in the low and high-dose group from day 15 to day 90. The histopatholgical examination combined with fibrosis specific staining indicated that the lungs in the low-dose group did not exhibit any significant progressive fibrotic changes. Whereas, the lungs in the high dose group exhibited early delicate fibrosis from day 15, which progressed in to the preivascular and peribronchiolar regions by day 30. Interstitial fibrosis appeared at day 60 and became prominent by day 90, along with additional appearance of pleural fibrosis. The recovery, evaluated by body and lung weight, and histopathological examination, was noted from the rats both in the high and low dose group that had been exposed up to 30 days. Although the rats exposed for 60-90 days at the low dose recovered from the fibrosis, the rats exposed for 60-90 days at the high dose could not recover fully from the fibrosis. Taken together, the pneumoconiosis induced by welding-fume exposure could be recovered if the degree of exposure was short-term and moderate.

1451 MECHANISMS OF NICKEL INDUCED LUNG CANCER—NICKEL SUBSULFIDE *vs* NICKEL SULFATE.

J. Benson[1], T. H. March[1], K. K. Divine[1], J. Seagrave[1], S. A. Belinsky[1] and A. R. Oller[2]. *[1]Lovelace Respiratory Research Institute, Albuquerque, NM and [2]Nickel Producers Enninronmental Research Association, Inc., Durham, NC.*

Early epidemiological and rodent bioassay data indicate that the carcinogenic potential of nickel compounds depend on their chemical form. The purpose of this study was to determine why the nickel sulfate ($NiSO_4$) is not carcinogenic, while nickel subsulfide (Ni_3S_2) is. Male F344/N rats were exposed by inhalation to 0, 0.03, 0.11, or 0.22 mg Ni/m^3 as $NiSO_4$ or to 0, 0.04, 0.11 or 0.44 mg Ni/m^3 as Ni_3S_2, 6 hr/day, 5 days/wk for up to 13 wks. Groups of rats were sacrificed after 3 and 13 wks of exposure and after a 13 week hold period. Endpoints included evaluations of pulmonary inflammation, epithelial and nonepithelial cell proliferation, DNA strand breaks and global DNA methylation. Histologic findings were qualitatively similar for the two compounds and included pulmonary inflammation, (Ni_3S_2 > $NiSO_4$), bronchiolar epithelial degeneration ($NiSO_4$> Ni_3S_2), type II cell hyperplasia (Ni_3S_2 > $NiSO_4$), and bronchiolar epithelial apoptosis ($NiSO_4$ > Ni_3S_2). Small increases in labeling index were observed in Ni_3S_2 exposed rats at 3 and 13 wks. $NiSO_4$ inhalation did not result in significant changes in labeling index at 13 wks. DNA damage in isolated lung cells (epithelial cells and macrophages) was greater among Ni_3S_2 than $NiSO_4$ exposed rats at 3 wks. In contrast, the extent of DNA induced strand breaks was greater among $NiSO_4$-exposed than Ni_3S_2 exposed rats when assays were performed on DNA isolated directly from lung tissue. The extent of damage increased with time and dose. Both compounds increased the extent of global DNA methylation at 13 ws, but the effect of cytotoxicity on the ability to detect methylation is not clear. While histologic lesions persisted throughout the hold period, alterations in labeling index, DNA damage, and methylation did not. Results obtained show few differentiators between $NiSO_4$and Ni_3S_2 that explain the observed differences in their carcinogenic potential. (Research supported by Nickel Producers' Environmental Research Association, Inc.).

1452 EFFECTS OF ARSENITE ON INFLAMMATORY RESPONSES OF HUMAN BRONCHIAL EPITHELIAL CELLS.

A. R. Molinelli[1] and M. C. Madden[2]. *[1]Curriculum in Toxicology, University of North Carolina - Chapel Hill, Chapel Hill, NC and [2]NHEERL, USEPA, Research Triangle Park, NC.*

The majority of the health concerns related to arsenic stem from its potential presence in water, but it has been documented as a trace pollutant in airborne particulate matter (PM). Arsenic may play a role in lung carcinogenesis as well as in PM related morbidity and mortality increases. In the present study we examined the cytotoxicity of arsenic on human bronchial epithelial cells (BEAS-2B) and its potential to induce the inflammatory mediator interleukin-8 (IL-8). BEAS-2B cultures were exposed for 24 hours to sodium arsenite (0.05-500 μM) after which the median toxic dose was found to be ~100 ± 9.6 μM as determined by lactate dehydrogenase release and ~48 ± 0.4 μM by neutral red uptake. IL-8 release peaked at an arsenite concentration of 50 μM (836 pg/ml IL-8 vs. 31.2 pg/ml for the control) with no significant increases detected at other concentrations (n=4). This data suggests that arsenite can induce an inflammatory response in BEAS-2B cells similar to that observed with other air pollutants such as metal-laden PM. Because oxidative stress might play a role in arsenic toxicity we examined the cell media for the presence of aldehydes by HPLC/MS and intracellular oxidation of 2', 7'-dichlorofluorescin. We found no evidence of increased oxidant formation after up to 24 h. exposures. The fact that we did not find evidence of oxidative stress with our system does not imply that it is not a contributing factor for the observed effects. Further analyses into the possible reasons for the IL-8 increase as well as other evidence for arsenite induced oxidative stress are underway. [This is an abstract of a proposed presentation and does not necessarily reflect official EPA policy. Supported by NIEHS T32-ES07126-20 and EPA/UNC CT827206].

1453 VANADIUM CONCENTRATIONS IN LUNG, LIVER, KIDNEY, TESTES AND BRAIN AFTER THE INHALATION OF 0.02M OF V2O5. AN EXPERIMENTAL MODEL IN MICE.

I. Sanchez[1], I. Lopez[1], P. Mussali[1], P. Bizarro[1], G. Niño[1], L. Saldivar[3], G. Espejel[3], M. Avila[1], D. Morales[2], L. Colin[2], V. Delgado[1], S. Acevedo[1], A. Gonzalez[1], M. Avila-Costa[3] and T. I. Fortoul[1]. *[1]Biologia Celular y Tisular, UNAM, Mexico City, Mexico, [2]Neurociencias, UNAM, Mexico City, Mexico City, Mexico and [3]Facultad De Quimica, UNAM, Mexico City, Mexico City, Mexico.*

Our interest for Vanadium (V) is related with its increase in the atmosphere as a consequence of the combustion of Mexican Maya oil and fuel, which are rich in this element. With this antecedent we decided to structure an inhalation model in mice which inhaled 0.02M V2O5 2 hours /twice a week for 4 weeks. Animals were sacrificed at the end of each week and samples from: lung, liver, kidney, testes and brain were processed to determine V concentration by Atomic Absorption Spectrometry . Results showed that V concentrations highly increased after the first week of inhalation in all the organs evaluated, and remained almost the same during the 4 weeks. The highest concentrations were found in the liver followed by the kidney; the organ with the lowest concentration was the testes. In the kidney, however, at week four, a decrease in V concentration was observed. Conclusions: Although the lung is the first organ reached by vanadium, we found that the liver and the kidney had the highest V concentrations. The differences between organs may be due to the different mechanisms of handle the element in each organ or as a consequence of the organ susceptibility. So, it is important to evaluate a correlation with tissue morphologic variations and V concentration to establish the time course modifications that triggers those changes. Supported in part by DGAPA 210301 and P.O.S Institute.

1454 DIFFERENTIAL *IN VITRO* IMMUNOLOGICAL RESPONSES TO ZINC (ZN), AN ACTIVE COMPONENT OF URBAN PARTICULATE MATTER (PM).

R. J. Mitkus, J. Powell, M. Akkerman and K. Squibb. *Epidemiology and Preventive Medicine, University of Maryland School of Medicine, Baltimore, MD.*

Epidemiological evidence suggests that human morbidity and mortality are associated with exposure to ambient air particulate matter of size 10μm or less (PM10). Although urban PM is composed of a complex mixture of trace metals, elemental carbon, and organic compounds, results of numerous studies suggest that component metals, such as Zn, are important mediators of the pulmonary inflammatory response to PM exposure. To examine the mechanism by which this occurs, we hypothesized that Zn stimulates airway cells to release cytokines and chemokines that are important in the inflammatory response. In *in vitro* studies, two cell types (human alveolar type II, A549 cells and RAW 264.7 mouse macrophage-like cells) were exposed to NIST 1648 urban PM and $ZnCl_2$ for 24 hrs. In response to NIST 1648 exposure (200 μg/ml), RAW 264.7 cells released greater amounts of IL-6 and TNF-α compared to culture media controls, and A549 cells responded by increased MCP-1 response but no change in the release of IL-8. RAW 264.7 macrophage-like cells did not respond to Zn exposure; however Zn concentrations ranging from 25-400 μM did stimulate A549 cells to release IL-8 (a chemoattractant for neutrophils). Also, interestingly, increasing concentrations of $ZnCl_2$ led to decreasing MCP-1 (a chemoattractant for monocytes/macrophage) release by A549 cells without a significant decrease in cell viability. These data support the hypothesis that Zn, as a component of ambient air PM, plays a critical role in modulating the immune response to PM through its effects on alveolar epithelial cell chemokine release, which could lead to a preferential influx of neutrophils into the lung following exposure. *Supported by the Baltimore Supersite Program grant R82806301 and NIEHS Training Grant T32ES07263*

1455 A CASE OF DRUG-INDUCED PURE RED CELL APLASIA IN RATS.

F. Goldfain-Blanc[1], A. Beamonte[1], D. Bazot[1], H. Bertheux[1], N. Casadevall[2] and G. Descotes[1]. *[1]Drug Safety Assessment, Servier, Fleury les Aubrais Cédex, France and [2]Hopital de l'Hotel-Dieu, Paris, France.*

As part of the early preclinical development of a new antipsychotic compound, Wistar rats (6-week old; 3/sex/group) were dosed orally (15-150 mg/kg/d) for up to 7 days. There were expected changes in appearance and behavior, and dose-related

decrease in body weight gain and feed intake, but also a fluid and pale bone marrow in rats given high doses. Erythrocyte, leukocyte and platelet counts were normal as were clinical chemical values. Bone marrow sections showed a mild to severe bone marrow hypoplasia with reduced numbers of erythroid elements. Reticulocyte counts were decreased as was the proportion of the erythroid series on bone marrow smears (increased M:E ratio) leading to the hypothesis of a central and preferential effect of the compound on the erythroid lineage. In a mechanistic experiment, rats (9-week old; 6/sex/group) were given 0, 5, 15, 45 or 90 (close to MTD) mg/kg/d for 9 days and phlebotomized (13 ml/kg, ie 20% blood loss) on the 7th day of exposure to stimulate erythroid regeneration. Red blood cell mass, reticulocyte counts and erythropoietin (EPO) levels were monitored before and 4, 24 and 48 hr after bleeding. Plasma EPO measured by ELISA using mouse monoclonal antibodies against huEPO, known to cross-react with rEPO, was found elevated in all groups 24 and 48 hr after stimulation. Reticulocytes increased 24 hr after bleeding in controls with a peak at 48 hr, while compound-exposed rats had low reticulocyte counts suggesting an impairment of the proliferative response to EPO, confirmed by hypoplastic erythroid bone marrow and reduced splenic extramedullary erythropoiesis. Rat bone marrow cultured with the compound and EPO or GM-CSF indicated that the erythroid colony-forming unit (CFU-E) is the primary target for toxicity of this compound.

1456 TOXIC, ALLERGIC OR IDIOSYNCRATIC TOXICITY OF KAVA PYRONES - RELATION TO REGULATORY DECISIONS.

C. Siegers and J. Schulze. *Institute of Experimental and Clinical Pharmacology and Toxicology, University of Luebeck, Luebeck, Germany.*

Severe hepatotoxicity has been linked in recent years to intake of Kava pyrones. The assumed toxicity has led to withdraw these preparations from the German market; decisions in other countries are pending (September 2002). We reassess Kava extract toxicity with regard to known mechanisms of hepatic injury. Hepatotoxicity is known since 1990 but has attracted major attention only since 1999; spontaneous reports indicate the potential severity. The increase in spontaneous reports in Europe since 1999 may be due to raised awareness, mistaken association and/or aggravation of preexisting liver disease; multiple reporting at different agencies has also occured. Kava preparations do rarely cause serious liver toxicity. In one case, an idiosyncratic reaction has been supported by reexposure, in another case, peripheral lymphocyte proliferation was increased. In all other cases, including two lethal cases, no attempt has been made to elucidate possible mechanisms of toxicity. Known *in vitro* activities do not correlate to the observed clinical symptoms. The long delay between starting Kava intake and appearance of adverse effects, and the lack of a dose response curve suggest that direct toxicity is not relevant in therapeutic concentrations. The few data available from animal experiments suggest direct toxicity to appear only at much higher doses not relevant for anxiolysis. Current therapeutic alternatives are benzodiazepines and antidepressants also known to exert drug toxicity including hepatotoxicity. Despite the wave of reports Kava pyrones still appear to be a reasonable alternative for long term treatment of anxiety; suitable precaucions should be taken to minimize patient risks.

1457 CORRELATION OF PCB BURDEN MEASURED IN AIR OR BLOOD.

J. Schulze and C. Siegers. *Institute of Experimental and Clinical Pharmacology and Toxicology, University of Luebeck, Luebeck, Germany.*

Banned since the 1970th, PCB still persists in the environment and causes continuous exposure. Present exposure stems mainly from food contamination and airborne pollution. To estimate the body burden, the six typical congeners 28, 52, 101, 138, 153 and 180 (sentinel congeners) are determined. After correction for the relative amount of these congeners in a PCB mixture the total body burden from all 209 congeners is derived empirically. For PCB congeners present in food - i.e. mainly congeners 138, 153 and 180 - the amounts present in body fat and serum roughly coincide with food levels. For the more volatile congeners 28 and 52 mainly liberated from industrial products and found in inhalative exposure, even high air levels do not result in elevated serum levels. In most cases, no PCB 28 or 52 are detected in serum from exposed persons even with air concentrations exceeding 1 000 ng/m3. To understand the discrepancy between detectable exposure and undetectable body burden we calculate PCB expected serum concentrations from published pharmacokinetic parameters and exposure levels. Surprisingly, even at 1 000 ng/m3, no PCB 28 and 101 should be detectable assuming a limit of detection of 100 pg/ml serum. PCB 52 having a much larger serum half life, is calculated at twice the limit of detection. These calculations are in good agreement with the lack of detection in serum from long time exposed persons. The calculated serum concentrations for steady state conditions naturally are mainly determined by the excretion half times, which have been published for rats and humans. In children and young adults the total amount of fat is still increasing, and even lower serum concentrations are to be expected; in starving, dieting, old or sick individuals, when body fat is lost, stored PCB may be liberated in much greater amounts and serum concentrations greater than expected from steady state. The results from our model calculations can explain the lack of detectable serum PCB 28 and 52 even at rather high exposure concentrations.

1458 PRECLINICAL SAFETY OF BG00001, A REPLICATION DEFECTIVE ADENOVIRAL VECTOR EXPRESSING THE HUMAN INTERFERON-β (HIFNβ) GENE, FOLLOWING INTRAPROSTATIC DOSING IN RHESUS MONKEYS.

C. Sachs[1], M. Parr[1], C. T. Chutkowski[1], J. Barsoum[1], C. Chan[2], M. Walker[2], C. Farman[2], D. L. Hutto[1], P. L. Martin[1] and J. D. Green[1]. *[1]Biogen, Inc., Cambridge, MA and [2]Sierra Biomedical, Sparks, NV.*

In orthotopic models of human prostate cancer BG00001 treatment led to complete tumor regression of pre-established tumors. To support initiation of clinical trials, male rhesus monkeys (5/group) were administered BG00001 at doses of 0, 0.5, 5 and 500 x 10^9 viral particles (vp) *via* intraprostatic injection during laparotomy. Subsets of animals were necropsied at 6, 22, and 61 days postdose. There were no BG00001-related changes in clinical signs, or other postdose observations. Postmortem findings were related to surgery and/or injection procedures. Microscopic evidence of inflammatory changes in the prostate interstitium, seminal vesicles, and urinary bladder were present in all dose groups and resolved over time. Real time PCR detected BG00001 DNA in plasma of high-dose animals at Day 3 but vector was undetectable at subsequent timepoints. Changes in serum IFN-β activity followed a similar time course, indicating the therapeutic hIFN-β transgene was expressed resulting in systemic exposure. Vector DNA was also found in liver of both high-dose animals and one low-dose animal necropsied on Day 6 but not at later time points. BG00001 was detected in prostate tissue of all groups administered BG00001. Vector persistence in the prostate was noted thru Day 22 in the low-dose group and until Day 61 in the mid- and high-dose groups. BG00001 was also found in seminal vesicles and the ureter in most high-dose animals. No BG00001 was found in testes suggesting male germ cells were not inadvertently transduced by vector. There were no BG00001-related histopathology findings in testes. No effects on sperm motility, concentration and sperm morphology in semen were noted. Intraprostatic administration of BG00001 was well tolerated by male rhesus monkeys at all administered dose levels. The results of this study suggest that unlike current therapies for prostate cancer, BG00001 treatment may not cause sterility.

1459 MULTIPARAMETER HYPOTHESIS FOR IDIOSYNCRATIC DRUG TOXICITY.

A. P. LI. *Phase-1 Molecular Toxicology, Inc., Santa Fe, NM.*

Idiosyncratic drug toxicity is a serious problem in drug development. This often-fatal event occurs at low incidence (<1/5000) and therefore cannot be effectively detected in routine clinical trials. Its occurrence is usually discovered *via* postmarketing survey after the drug in question is exposed to a large number of individuals, leading to the necessity of withdrawal of the drug from the market or severely limiting its applications. I propose here that idiosyncratic drug toxicity requires the co-occurrence of multiple independent events. The final incidence is a result of the product of the incidence of each independent events. I further propose that the critical events are functions of several critical parameters which are: chemical properties (chem); dose of exposure (exp); drug metabolizing enzyme activities (met); and genetic predisposition to sensitivity of drug toxicity (gene). The equation of the probability for idiosyncratic drug toxicity (Pidt) is as follows: P(idt)=P(chem)xP(exp)xP(met)xP(gene). While different drug will be represented by different probability functions for each critical parameter, I propose that idiosyncratci drug toxicity can be eliminated by critically examining the chemical properties during drug discovery stage; exposure levels during drug development stage; metabolic properties, including drug, food, and evironmental interactions during drug development; and pharmacogenomics during clinical trials. The most practical approach is to reduce P(chem) *via* the discovery of chemical properties that would lead to idiosyncratic drug toxicity, and the elimination of drug candidates with these undesirable qualities. Toxicogenomics may be the most useful approach for the discovery of key chemical properties related to idiosyncratic drug toxicity.

1460 EVALUATION OF THE TOXICITY OF BROMOCHLOROACETIC ACID ADMINISTERED FOR 26 WEEKS IN DRINKING WATER TO B6C3F1 MICE AND F344 RATS .

M. George[1], A. Murr[1], J. Goldman[1], C. Herbert[2], R. Joe[3], R. Melnick[3], D. Geter[1] and A. B. DeAngelo[1]. *[1]NHEERL, USEPA, Research Triangle Park, NC, [2]Southern Research Institute, Birmingham, AL and [3]NTP, NIEHS, Research Triangle Park, NC.*

Bromochloroacetic acid (BCA), a chlorine disinfection by-product, is found at ppb levels in finished drinking water. Male and female B6C3F1 mice and F344/N rats were exposed to 250, 500, and 1000 mg/L BCA in the drinking water for 26 weeks.

At necropsy the colon, small intestine, kidney, liver, stomach and urinary bladder were excised and prepared for a histopathological examination. Mouse: Dose-dependent decreases in body weights were observed for both sexes (16-20% maximum). A dose-dependent increase in relative liver weights was observed for male (50% maximum) and female (70% maximum) mice. Kidney weights were not affected. BCA enhanced the incidence and severity of vacuolization in the cytoplasm of periportal hepatocytes which appeared more prominent in the livers of female mice compared to male mice. BCA treatment increased mean numbers of lymphoid nodules, subunits of Peyer's patches, in the middle and distal colon segments of male mice, but not female mice. No BCA-associated pathology was seen in any of the other organs examined in the control and high dosed groups. Rat: Alterations in the body, liver and kidney weights of male and female rats exposed to BCA in the drinking water were not observed (all <10%) when compared to the control values. Altered vacuolization in the cytoplasm of periportal hepatocytes was less severe than that observed for the mouse. BCA treatment increased the number of extended (3-4 days estrous or 4 days diestrous) and abnormal (> 4 days estrous or 4 days diestrous) cycles in the female rat. A normal cycle persists for 4 or 5 days with either 1 or 2 day estrous and 2 or 3 days diestrous. The extended and abnormal cycles were paralleled by increased serum estradiol concentrations. BCA treatments did not alter serum progesterone or corticosterone levels over the control values. (This is an abstract of a proposed presentation and does not necessarily reflect the views of the EPA).

1461 SAFETY, BIODISTRIBUTION AND PERSISTENCE EVALUATION OF EP HIV-1090 DNA VACCINE IN RABBITS.

H. H. He[1], C. E. Frantz[1], S. Lin[1], S. Phillips[1], E. Payson[1], M. Newman[2], B. Livingston[2], D. McKinney[2] and P. Y. Chang[1]. *[1]Biopharmaceutical, SRI International, Menlo Park, CA and [2]Epimmune Inc., San Diego, CA.*

Vaccinations using cloned DNA vectors containing antigen-specific gene fragment(s) have been shown to be useful in eliciting immune responses against the infectious agents, EP HIV-1090 plasmid DNA vaccine was constructed to encode multiple T-lymphocyte epitopes and designed to induce immune responses against the Human Immunodeficiency Virus Type 1. The objective of these studies was to determine the safety, biodistribution and persistence of this vaccine. For the safety study, male and female rabbits were immunized with either 0, 1, or 6 mg of the vaccine on Days 1, 11, 22, 33, and 44. While some slight transitory injection site irritation was observed, the severity and duration of effects were similar for both the control and high dose groups. There were no test article-related effects observed on the animals; therefore, the no-observed-adverse-effect level is considered to be at least 6 mg/immunization. In order to address the concern of potential integration of vaccine sequences into the host genome, kinetics of clearance of the vaccine from tissues was evaluated using a quantitative PCR-based technique. Positive plasmid signals were found in a number of tissues up to 7 days after treatment, but vaccine was cleared from most of these tissues by 56 days after treatment. Plasmid signals persisted at the injection sites (skin & muscle) for up to 16 weeks; however, no plasmid signals were seen in the muscle after the genomic DNA fraction was subjected to one round of gel purification. Small residual amounts of vaccine were present in the skin of 1 out of 10 animals after 3 gel purifications. When two additional sequence segments of plasmid were evaluated in skin DNA, no plasmid DNA was detected in any of the skin genomic DNA after 2 rounds of gel purification, indicating that DNA vaccine was only loosely associated with genomic DNA and not integrated into the genome of the animal. Work was conducted under NIAID contract N01-AI-95375.

1462 SUBCHRONIC, DEVELOPMENTAL, AND REPRODUCTIVE TOXICITY OF A FLUOROALKYLETHYL PHOSPHATE SURFACTANT.

J. C. Stadler, D. A. Delker, G. T. Makovec, J. E. Hansen, S. M. Munley and E. Mylchreest. *DuPont Haskell Laboratory for Health and Environmental Sciences, Newark, DE.*

A fluoroalkylethyl phosphate surfactant was evaluated in rats in 90-day, one-generation reproduction, and developmental toxicity studies. In the 90-day study, the test substance was suspended in isopropanol (IPA) at oral doses of 0, 10, 60 or 300 mg/kg/day (35% ai) and 60 mg/kg/day IPA. There were no compound effects on mortality, clinical signs or neurobehavior. Effects on body weights, food parameters, red cell mass, and hepatic enzymes were seen at the highest two doses, and increases in thyroid weight and cellular hypertrophy were observed at the high dose. Adverse microscopic changes in the liver (focal hepatocellular necrosis) occurred at all dose levels in males and at only the high dose in females. These effects were not seen with IPA dosed alone. Non-adverse physiological changes included increased liver and kidney weights, hepatocellular hypertrophy, and an increased rate of peroxisome proliferation. The NOEL for female rats in this study was 10 mg/kg/day. In the reproductive study, where surfactant doses were 0, 75, 500 and 3500 mg/kg/day (20% ai in water, no IPA), parental body weights, weight gains and food parameters were reduced at the high dose, with males more affected than females. There were no effects on reproduction parameters at any dose level, except for F1 pup weights, which were progressively reduced from birth to weaning (92% and 76% of control, respectively) at the high dose. In these rats dosed with the active in water, thyroid hypertrophy and liver necrosis were not observed. The NOEL for reproductive parameters was 500 mg/kg/day. In the developmental study, doses were 625, 1250 or 2500 mg/kg/day (20% ai in water). At 2500 mg/kg/day, effects on maternal weight, food consumption, and fetal weight occurred. At 1250 mg/kg/day, there were maternal body weight reductions. No effects were seen at 625 mg/kg/day. Overall, the most sensitive target of toxicity was the liver, but the test substance was not considered a reproductive or developmental toxin.

1463 A DERMAL SAFETY EVALUATION OF *p-(t*-BUTYL)-α-METHYLHYDROCINNAMIC ALDEHYDE (BMHCA).

J. Cocchiara and A. Api. *Research Institute for Fragrance Materials, Inc., Woodcliff Lake, NJ.*

The Research Institute for Fragrance Materials, Inc. (RIFM) has a long history of testing fragrance ingredients for sensitization potential as a means of primary prevention of sensitization in the normal general population. Over the last several years, primary prevention of sensitization has evolved from human maximization testing to sensitization safety assessments. An example of a recently completed sensitization safety assessment on BMHCA (CAS Number 80-54-6) will be presented. BMHCA is a colorless to pale yellow liquid with a powerful, floral-fresh odor. The Human Repeated Insult Patch Test (HRIPT) data generated by RIFM, showed that a 25% solution in an ethanol/DEP combination caused one reaction in a total of 225 subjects. The animal data are equivocal. Magnusson-Kligman Maximization studies show both sensitization and no effects at the same challenge concentrations. The clinical evidence is weak since only one study (Larsen et al., 1996) shows >1% reactivity (2/167 reactions or 1.2% reactivity). The Larsen study also showed that 3/167 (1.8%) exhibited irritant reactions. The weight of evidence shows that the no observed effect level (NOEL) for BMHCA is in the region of 25% (or 29, 527 μg/cm2). The NOEL of 25% would support a use level of 2.5% on the skin.

1464 EVALUATION OF POTENTIAL EXPOSURE TO VOLATILE ORGANIC COMPOUNDS EMITTED FROM A SPRAY GRADE CONTACT CEMENT.

C. W. Jarand, C. A. Robbins and B. J. Kelman. *GlobalTox, Redmond, WA.*

A commercially available contact cement, HHR Solvent Type Spray Grade Contact Cement, was analyzed for VOC emissions under differing application conditions and drying periods. A laboratory model was designed to evaluate VOC emissions for a typical application. Analysis was performed following the EPA compendium method TO-17 (Determination of Volatile Organic Compounds in Ambient Air Using Active Sampling Onto Sorbent Tubes). Two different types of samples were prepared which simulated an open or sandwiched sample. A PTFE impinger was used as sampling chamber with VOCs captured on thermal desorption tubes. Desorption tubes were exchanged every 3 hours of sampling over a 12 hour period with an air sampling flow rate of 20 ml/min. Desorption tubes were analyzed by GC-MS. The percentage of toluene emitted relative to the total mass of applied adhesive was determined over the time course of the experiment and was found to follow an exponential decay for both the open and sandwiched samples. A number of other components were identified at reduced concentrations relative to toluene. These components included 2-methyl-2, 3-pentanediol, methylcyclohexane, a cyclopentane or a mix of cyclopentanes at lower concentrations than toluene. Several other aliphatic hydrocarbons, including n-hexane, and aromatic hydrocarbons were identified at significantly reduced concentrations relative to toluene. The relative concentration of toluene to other components was also found to be substantially different between the open and sandwiched samples. The laboratory results were applied to a box model which allowed calculation of concentrations based on time of air exchange and total drying time. Under recommended application conditions and 3 hours of air exchange, the maximum potential toluene concentration was 42 ppm, well below the OSHA PEL Ceiling exposure limit of 300 ppm. All other volatile constituents were calculated to be at significantly decreased concentrations relative to toluene, with none exceeding the OSHA PEL.

1465 RODENT RESPIRATORY SAFETY PHARMACOLOGY STUDIES: A BREATH-SIMULATED MODEL AND ADDITIONAL *IN VIVO* VALIDATION.

S. Mason[1], H. Penton[1], A. Viau[2] and P. Dominic[2]. *[1]Safety Pharmacology, CTBR, Senneville, QC, Canada and [2]Inhalation Toxicology, CTBR, Senneville, QC, Canada.* Sponsor: D. Jones.

Respiratory safety pharmacology at this laboratory has historically been performed using the Buxco Electronics LS-20 system with Non-Invasive Airway Mechanics (NAM) for determination of respiratory parameters in multiple species. To increase

flexibility and scope for these studies, the Buxco BioSystem XA v.2.5 with flow-derived parameter (FDP) analysis software for assessment of respiratory physiology was validated using a purpose built reciprocating piston-type pump. A variable speed motor, gear and interchangeable pistons varied the volume of air (TV) delivered with each stroke to mimic breathing patterns of different animal species and altering motor speed controlled frequency (f). Reference methods allowed a direct comparison of pump volume output and frequency with the original BioSystem XA derived TV and f values. As this method was considered reliable for use when assessing TV, f and minute volume (MV), a further qualification was performed using Sprague-Dawley and Wistar rats, previously acclimated to head-out plethysmograph chambers. Animals were administered 20 mg/kg morphine or 10 mg/kg theophylline intravenously into the tail vein *via* a port in the chamber to access the dose site. Respiration was monitored for 15 minutes prior to dosing, continuously for 3 hours post dose and again for 15 minutes at 6 hours post dose. Decreases in MV elicited by reduced f were noted for morphine treated animals, with corresponding increases in these parameters for rats dosed with theophylline. Pre-dose values were compared with historical data at this laboratory and were within similar ranges. Respiratory data following dosing were similar to those in published literature. As such, qualification using an independent mechanical pump, with further validation using accepted animal models, is considered to have demonstrated the accuracy of the system to detect both normal and abnormal respiration. The Buxco BioSystem XA is therefore considered acceptable for use on rodent respiratory safety pharmacology studies at this laboratory.

1466 SAFETY PHARMACOLOGY STUDIES FOR THE ASSESSMENT OF COMPOUND-RELATED EFFECTS ON THE GASTROINTESTINAL SYSTEM.

A. Adamou[1] and S. Mason[2]. [1]*General Toxicology, CTBR, Senneville, QC, Canada and* [2]*Safety Pharmacology, CTBR, Senneville, QC, Canada.* Sponsor: D. Jones.

As stipulated in the ICH S7A guidelines, effects of a test substance on the gastrointestinal system should be assessed where the core battery of studies or the repeat-dose toxicity studies do not address potential adverse pharmacodynamic effects on the functions of this specific organ system. A GLP-compliant series of studies to assess effects on the gastrointestinal (GI) system was validated at CTBR using the Sprague-Dawley rat. These include GI injury potential following single or repeat dose administration, transit time in-vivo, and measurement of gastric secretion. Reference compounds with well-documented effects, were used to demonstrate the effectiveness and acceptability of the assays. Six or 7 week old male Sprague-Dawley rats were used for all tests. Dose levels were based on those in published literature and on experience with studies of a similar type in this laboratory. Gastric and intestinal ulceration indices reflected a dose-related increasing trend for gastrointestinal damage following single and repeat-dose administration. Phenol red (gastric motility indicator) concentration in the stomach, measured colorimetrically, was higher for animals administered atropine and significantly lower for animals administered metoclopramide when compared to control animals. Charcoal propulsion in the intestine was significantly decreased for animals administered atropine and apomorphine when compared to control animals. When administered metoclopramide twice the number of treated animals than control rats were observed to have distal movement equal to or in excess of 80% total small intestine length. Gastric secretion measurements (pH and free and total acid concentration) following administration of omeprazole and ranitidine reflected the expected increase in pH and decrease in free and total acid concentration when compared to control animals. All responses obtained were characteristic of those anticipated following administration of the reference compounds and, as such, these studies are considered validated in the rat CTBR.

1467 A DERMAL SAFETY EVALUATION OF CINNAMIC ALCOHOL.

A. Api and J. Cocchiara. *Research Institute for Fragrance Materials, Inc., Woodcliff Lake, NJ.*

The Research Institute for Fragrance Materials, Inc. (RIFM) has a long history of testing fragrance ingredients for sensitization potential as a means of primary prevention of sensitization in the normal general population. Over the last several years, primary prevention of sensitization has evolved from human maximization testing to sensitization safety assessments. An example of a recently completed sensitization safety assessment on cinnamic alcohol (CAS Number 104-54-1) will be presented. Cinnamic alcohol is a white to slightly yellow solid with a warm, balsamic, floral, sweet odor. The Human Repeated Insult Patch Test (HRIPT) data generated by RIFM showed that a 4% solution in an ethanol/DEP combination caused two reactions in a total of 109 subjects. Upon rechallenge using a 24-hour occluded patch, a 24-hour semi-occluded patch and 5-day repeated open application test, reactivity was observed only under occlusive patch conditions at readings. No skin reactivity was observed under semi-occlusive patch conditions or under open exaggerated rub-in conditions. Cinnamic alcohol was evaluated for sensitization in 23 studies in guinea pigs using various test methods such as the Magnusson-Kligman maximization test, Buehler Delayed Hypersensitivity test, Modified Draize Test, Freund's Complete Adjuvant Test, Closed Epicutaneous test, or the Open Epicutaneous Test, at concentrations ranging from 1% up to 100%. Sensitization was observed at all dose levels over 1%. Clinical data show that cinnamic alcohol elicits sensitization in dermatitic patients. The weight of evidence shows that the NOEL for cinnamic alcohol is in the region of 4% (or 4724 ug/cm2). The NOEL of 4% would support a use level of 0.4% on the skin.

1468 PATHWAYS OF TOXICITY:AN EARLY SCREENING APPROACH.

P. S. Rao, M. Wojke, J. Dwyer, M. Hower and Z. Jayyosi. *Drug Safety Evaluation, Aventis, Bridgewater, NJ.*

The objective of this study was to develop screens for early safety evaluation of developmental compounds. Acetaminophen, thioacetamide, tacrine, camptothecin, staurosporine, chloramphenicol, nitrofurantoin, ferric nitrilotriacetate and cyclosporine were selected as model compounds affecting key toxicity pathways which could be monitored at the cellular and gene expression levels. Rat primary hepatocytes were treated for up to 24 hours with the model compound. Apoptosis, oxidative stress, and cytotoxicity were assessed by measuring caspase 3/7 activity, cell-death, reactive oxygen species formation, lactate dehydrogenase level, ATP content and GSH/GSSG ratio. Alterations in the expression of genes involved in these pathways (Bcl-2, p21, Bax, SAG, CDK4, PCNA, Mn-superoxide dismutase, Grp78, heme monooxygenase-1, glutathione peroxidase, glutathione reductase, and gamma-glutamylcysteine synthetase) were measured using Q-RT-PCR. Staurosporine caused a significant dose-related increase in caspase 3/7 activity with a concomitant increase in cytotoxicity parameters. In parallel, Bcl-2, BAX, p21, SAG and MnSOD gene expression increased with time and dose, indicative of apoptosis. Treatment with nitrofurantoin caused an increase in reactive oxygen species formation and caspase activity. In parallel, nitrofurantoin caused an increase in Bax, HOX, glutathione reductase, and gamma glutamylcysteine synthetase gene expression. These results were indicative of oxidative stress as the primary effect of nitrofurantoin with apoptosis as a secondary effect. Similar correlation between functional assays and gene expression changes were observed for the other model compounds. Preliminary results from these studies indicate that these assays could be used for the assessment of key biochemical functions noted above. Gene expression changes corroborated the biochemical findings and allowed for early identification of the toxicity pathways. Thus, this study indicates that such assays can be used as a battery to screen chemical series in early development to rank compounds based on their mechanism-based toxicity potential.

1469 INHIBITION OF VITAMIN K1 2, 3-EPOXIDE REDUCTASE BY PHARMACEUTICALS AND XENOBIOTICS.

C. R. Wilson, L. J. Likens, M. P. Ward and S. B. Hooser. *Animal Disease Diagnostic Laboratory, Purdue University, West Lafayette, IN.*

Vitamin K-responsive coagulopathies have been recognized in patients taking phenytoin or sulfinpyrazone, and in mammals exposed to the xenobiotics aflatoxin B1 and the soy isoflavone biochanin A. Deficiencies in vitamin K-dependent proteins, which result in increased prothrombin and activated partial thromboplastin times, PIVKA, and undercarboxylated osteocalcin, have been associated with these compounds. These deficiencies are similar to those caused by anticoagulants such as warfarin (Coumadin), used therapeutically in humans, or in anticoagulant rodenticides. The pharmacological site of the anticoagulant action of warfarin is through inhibition vitamin K1 2, 3-epoxide reductase (VKOR). To help explain the vitamin K-dependent coagulopathies associated with aflatoxin B1, biochanin A, phenytoin, and sulfinpyrazone, inhibition of VKOR activity was investigated in murine hepatic microsomes *in vitro*. Microsomal incubations contained 1 ml of microsomes (2 mg protein/ml), the substrate VKO (12 mM), and varying concentrations of inhibitors (in DMSO). After a 1 minute preincubation, 2 mM dithiothreitol (reducing agent) was added. Using HPLC/PDA, concentrations of vitamin K1 formed by VKOR at each concentration of inhibitor were compared to the vitamin K1 formed by DMSO controls. Coumarin (negative control) at concentrations greater than 36.4 mM did not inhibit VKOR activity. Diphacinone and warfarin (positive controls) at concentrations of 0.006 uM and 0.27 uM, respectively, inhibited VKOR activity by 50%. Biochanin A, phenytoin, and sulfinpyrazone at concentrations of 0.19 mM, 0.49 mM, and 1.9 mM, respectively, inhibited VKOR activity by 50%. Aflatoxin B1 inhibited enzyme activity by 30% at 0.85 mM. These results suggest that inhibition of VKOR by aflatoxin B1, biochanin A, phenytoin, and sulfinpyrazone may help to explain the vitamin K-dependent coagulopathies observed with these compounds.

1470 ANTIMICROBIAL RESISTANCE AND TRICLOSAN.

G. Goodfellow[1], V. Lee-Brotherton[1], J. Daniels[1,2], A. Roberts[1] and E. Nestmann[1,2]. *[1]Cantox Health Sciences International, Mississauga, ON, Canada and [2]CanTox Inc., Bridgewater, NJ.*

Over the last 30 years, triclosan (2, 4, 4′-trichloro-2′-hydroxy-diphenylether) has been safely used in various personal care products, such as dentifrices, bar soaps, liquid hand and body soaps, and deodorants (personal care products constitute roughly 97% of triclosan use). Presently, triclosan is permitted for use in cosmetics and toiletries in Europe at a concentration of up to 0.3% as a preservative, and without specific concentration limits as an antimicrobial ingredient. As part of the safety evaluation process of such an antimicrobial agent, nonclinical and clinical investigations into the potential for resistance to develop or be transmitted were conducted. The *in vitro* studies for triclosan showed that bacterial resistance to triclosan was either intrinsic (*e.g.*, effective cell wall pumps, cell wall effects) or acquired (*e.g.*, decreased cell wall permeability, efflux pump mechanisms). However, despite these *in vitro* findings, clinical studies of 6-12 months duration in oral care and skin care applications have yielded no evidence of the development of resistance. As well, in a separate 5-year clinical trial using triclosan-containing toothpaste, no clinical or microbiological signs of bacterial overgrowth were observed. In addition, the potential for cross-resistance to antibiotics was also evaluated. Nonclinical and clinical data have demonstrated that: (1) although triclosan and isoniazid target the same protein, enoyl-acyl carrier protein reductase, it is at different sites; (2) clinically important antibiotic-resistant strains remain sensitive to triclosan; and, (3) bacterial strains with increased minimum inhibitory concentration (MIC) values to triclosan do not exhibit an increased resistance to antibiotics. The totality of these *in vivo* and *in vitro* studies, conducted from the molecular level up to the human use level, suggest that under the conditions of use, there is no evidence that triclosan poses any risk to humans by reducing or transmitting antibacterial resistance.

1471 A SINGLE-DOSAGE OCULAR AND CUTANEOUS PHOTOTOXICITY SCREEN FOR ORAL DRUGS.

C. P. Sambuco, D. B. Learn, P. D. Forbes, M. Arocena, M. L. Matticoli and A. M. Hoberman. *Argus Research, Horsham, PA.*

Many published studies involve safety studies in albino rodents. This report provides a model for evaluating test articles orally administered to rats that have melanin pigment in both cutaneous and ocular tissues. In four studies, male Crl:(LE)BR (Long-Evans) pigmented rats were randomly assigned to dosage groups (five rats per group), and administered (by gavage, 10 mL/kg) vehicle or a suspension of 8-methoxypsoralen (8-MOP, 50 mg/kg) in corn oil. Hair was removed from the backs of rats before formulation administration and one lightly and one darkly pigmented skin site and the eyes of each rat were exposed to UVR one hour after formulation administration. All rats were lightly anesthetized and restrained for UVR exposure. An instrumental exposure dose equivalent to a Standard Erythema Dose was delivered to each rat (SED; defined by Commission Internationale de L' Eclairage Committee, CIES 007/E-1998). Clinical observations were recorded daily; ophthalmologic examinations were performed by a veterinary ophthalmologist before and three days after UVR exposure. Ocular tissues harvested at necropsy and examined histopathologically were: cornea, lens, bulbar conjunctiva, vitreous and aqueous chambers, optic nerve, retina, sclera, iris, ciliary body and choroids. The UVR dose was below the skin and ocular response threshold in the rats administered the vehicle. Skin reactions indicative of phototoxicity occurred in lightly and darkly pigmented skin sites in rats orally administered 8-MOP and exposed to UVR (erythema grades 1 and 2, edema grades 1 and 2). Ocular responses included swelling of peri-orbital skin and diffuse corneal edema after UVR exposure in rats administered 8-MOP. Histopathological evaluation confirmed ocular phototoxicity in the examined tissues. Based on these findings, pigmented rats are useful in assessing the potential for cutaneous and ocular phototoxicity of test articles.

1472 TOXICITY COMPARISON OF LIPOSOMES COMPRISED OF DIOLEOYLTRIMETHYLAMMONIUM PROPANE:DIOLEOYLPHOSPHATIDYLETHANOLAMINE (DOTAP:DOPE) OR DIMETHYLDIOCTADECYLAMMONIUM BROMIDE:DIOLEOYLPHOSPHATIDYLETHANOLAMIN E (DDAB:DOPE) FOLLOWING MULTIPLE IV INJECTIONS IN FISCHER 344 RATS.

P. Tosca[1], I. Grossi[1], M. Brooker[1], N. Turner[1], E. Chang[2] and S. Donohue[3]. *[1]Battelle Memorial Institute, Columbus, OH, [2]Georgetown University, Washington, DC and [3]National Cancer Institute, Bethesda, MD.*

Liposomes serve as carriers for various pharmaceutical agents. Cationically charged liposomes interact with cell membranes and increase the cellular uptake of drugs *in vivo*. Although liposomes composed of varying lipid combinations have been utilized experimentally, only a few of these have been approved for clinical use. The safety testing, quality control and manufacturing requirements present a hurdle in getting new liposomes into the clinic. The toxicity of two different liposomes was compared to determine if one would be more suitable for development. DOTAP:DOPE (1:1 umoles) and DDAB:DOPE (1:1 umoles) were intravenously administered to male Fischer 344 rats every 3 days from day 1 through day 22, either as a single slow injection or 3 slow injections (3 hr intervals) per day. Liposomes were prepared at two concentrations, 1.25 and 2.08 umoles/mL in 5% dextrose, USP. Eight animals per group received doses of 10 or 27 umoles of liposome. Toxicity endpoints included clinical observation, body weight, clinical and gross pathology. Clinical signs included sporadic diarrhea, hunched posture and discolored, swollen tail at the site of injections. Frequency and severity of signs were similar for the two liposomes at the same dose, however, more frequent dosing produced more severe tail lesions such that the 3 injections/day could not be continued through the duration of the study. No treatment-related effects were seen in hematology, clinical chemistry or gross examination of tissues (except the tails). The results of this study indicate no measurable differences in toxicity between DOTAP:DOPE and DDAB:DOPE and consequently no advantage in using one liposome preparation over the other. Conducted under contract N01-CM-87028, Division of Cancer Treatment of the National Cancer Institute.

1473 COMPARISON OF HUMAN *VERSUS* CYNOMOLGUS MONKEY PLATELET AGGREGATION INDUCED BY FIVE DIFFERENT AGENTS.

Y. Mori, K. Okasaki, B. Lee, S. Meyer, K. Fukuzaki and R. Nagata. *SNBL USA, Ltd.,, Everett, WA.*

We investigated human and cynomolgus monkey platelet aggregation induced by 5 different aggregation agents: adenosine diphosphate (ADP), collagen (COL), arachidonic acid (AA), platelet activation factor (PAF) and epinephrine (EPI). Platelet aggregation in platelet-rich plasma was monitored after adding one of 5 agents using PAKS-4 platelet aggremometer (Helena). Several notable differences were found between human and monkey platelet aggregation after exposure to ADP, PAF or EPI. 1) At low ADP concentration (5 μM), secondary aggregation was observed in human platelets but not in monkey platelets. However, human and monkey platelets showed similar aggregation patterns (primary and secondary) at higher ADP concentrations (10 and 20 μM). 2) Monkey platelets showed no or significantly lower aggregation at up to 30 μg/mL of PAF, whereas even lower concentration (1.0 μg/mL) PAF induced strong aggregation in human platelets. 3) EPI did not induce aggregation of monkey platelets at up to 300 μM, whereas it did induce human platelet aggregation at down to 1 μM. We further investigated the effect of EPI on monkey platelet aggregation subsequently induced by the other aggregation agents. Monkey platelets were first stimulated with EPI (300 μM), and then the maximum no effect dose (MNED) of ADP, COL, AA or PAF was added. Although MNED of ADP, COL, AA or PAF did not induce monkey platelet aggregation alone, pre-treatment with EPI potentiated the induction of aggregation. Any combination of the other 4 agents had no aggregating effect at the MNED. The potentiating effect of EPI was observed even at 1000-fold lower concentration (0.3 μM) but completely inhibited by α2-adrenergic receptor antagonist, yohimbine. We conclude that EPI is able to stimulate monkey platelets and potentiate aggregation when trace amounts of other aggregation agents are added. Therefore, an α2-adrenergic receptor pathway appears to be involved in the enhanced susceptibility of monkey platelet aggregation by inducing agents.

1474 APPLICATION OF EXPERIMENTAL CARDIAC SENSITIZATION RESULTS IN PHYSIOLOGICALLY-BASED PHARMACOKINETIC MODELS.

W. J. Brock[1], H. J. Trochimowicz[2], M. Cisneros[3] and G. M. Rusch[4]. *[1]Environ, Princeton, NJ, [2]Delaware Toxicology Associates, Newark, DE, [3]Great Lakes Chemical Corp., West Lafayette, IN and [4]Honeywell Corp., Morristown, NJ.*

An increased sensitivity of the heart to intravenous administration of epinephrine has long been recognized as a risk during exposure to hydrocarbons, principally halogenated hydrocarbons. This increased sensitivity of the heart is known as cardiac sensitization, and requires a certain critical blood level of the sensitizing agent and epinephrine. The original research and methods to assess cardiac sensitization potential in animals occurred about 30 years ago, although in the last 15 years others methods have been developed in response to replacement of the chlorofluorocarbons. The cardiac sensitization methodology has been used for semi-quantitative risk evaluations for occupational exposures but is now being used more quantitatively for regulatory purposes. While the risks associated with cardiac sensitization are low based on endogenous adrenaline experiments conducted in the 1970s, the incidence of abusive inhalation of CFCs has led to deaths. However, with the advent of physiologically-based pharmacokinetic (PBPK) modeling, greater emphasis on quantitative risk assessment can be used. In this work, we have examined the various methodologies used for detection of cardiac sensitization to determine the

limitations and advantages. In addition, using the PBPK models developed by others, we examined the potential concerns/opportunities associated with the use of the models based on the variations associated with the cardiac sensitization methodology.

1475 ACUTE TOXICITY OF POLYACRYLAMIDE AND SOL-GEL NANOPARTICLES IN RATS.

R. J. Schneider[1], R. L. Lightle[1], R. G. Reddy[2], A. Rehemtulla[3,2,1], B. D. Ross[4,2], R. Kopelman[5] and M. A. Philbert[1]. *[1]Environmental Health Sciences, University of Michigan, Ann Arbor, MI, [2]Molecular Therapeutics, Inc., Ann Arbor, MI, [3]Radiation Oncology, University of Michigan, Ann Arbor, MI, [4]Radiology, University of Michigan, Ann Arbor, MI and [5]Chemistry, University of Michigan, Ann Arbor, MI.*

Dynamic NanoPlatforms (DNPs) are nanoparticles (20 - 200 nm) developed for real-time intracellular measurement, with applications for analysis of drug, toxin, and environmental effects on cell function. The flexibility of these nanoparticles has further led to the development of particles for imaging of tumors and the potential simultaneous *in situ* treatment of cancer through photodynamic therapy. DNP matrices are composed of cross-linked polyacrylamide (PAA) or sol-gel silica. This study establishes the biocompatibility of the particles *in vivo* after exposure to PAA or sol-gel nanoparticles. Polyacrylamide (5-500mg/kg) and sol-gel (10mg/kg) suspensions were administered as a single i.v. dose in the tail vein of a conscious rat. Toxicity was assessed at 1, 3, 7, and 28 days by determination of serum levels of enzymes indicating hepatic, renal, pulmonary/cardiovascular and musculoskeletal damage, and histopathology. No significant change in serum levels of enzymes or histopathology was noted with either particle matrix at doses up to 50mg/kg (PAA) or 10mg/kg (sol-gel) for 28 days. However, a single dose of 500mg/ kg PAA-DNPs resulted in mortality of 11/16 (69%) treated rats in less than 24hr. Increases in circulating enzyme indicators of damage suggest the potential for liver, kidney and/or cardiac toxicity. Histopathological evaluation supports these findings. In conclusion, rats exposed to concentrations up to 50mg/ kg (PAA) or 10mg/kg (sol-gel) were not consistently different from controls. The data suggest that the composition of the particle and total body particle loads influence the degree of toxicity observed. Supported by NIH-ES 08846 & NCI-NO1-CO-07013.

1476 A SIX-WEEK INHALATION NEUROTOXICITY STUDY OF METHYL BROMIDE IN DOGS.

G. J. Schaefer[1], D. T. Kirkpatrick[1], J. F. Holson[1], C. P. Chengelis[1], K. S. Regan[2] and V. J. Piccirillo[3]. *[1]WIL Research Laboratories, Inc., Ashland, OH, [2]Regan Pathology/Toxicology Services, Inc., Ashland, OH and [3]VJP Consulting, Inc., Ashburn, VA.*

Previous studies of inhaled methyl bromide have produced inconsistent results regarding functional deficits at low concentrations. A National Academy of Sciences report (Methyl Bromide Risk Characterization in California, 2000) recognized a deficiency in neurotoxic assessment in the dog. Therefore, this study was designed to provide well-defined behavioral and neurological endpoints, as well as a comprehensive histopathological evaluation. Exposures were selected to bracket possible human exposure scenarios, while avoiding unnecessary toxicity (for humanitarian reasons). Beagles (4/sex/ group) were exposed by whole-body inhalation to methyl bromide at concentrations of 0, 5, 10 and 20 ppm for 7 hours per day, 5 days per week for 6 consecutive weeks. Clinical examinations were performed daily and detailed physical examinations were conducted weekly. Individual body weights and food consumption were recorded weekly. A functional observational battery (FOB), as well as an automated measure of locomotor activity were conducted twice prior to the initiation of exposures and during study weeks 2, 4 and 6. The laboratory had previously validated both the FOB, which consists of a comprehensive checklist of behaviors in the home cage, on a platform and in an open-field, and the locomotor activity procedure, using a custom-built system for dogs. Following in-situ perfusion after the last inhalation exposure and a macroscopic examination, tissues from the brain, spinal cord and peripheral nerves were examined microscopically. Clinical observations, body weights, food consumption, body temperatures and FOB and locomotor activity parameters were unaffected by methyl bromide. Furthermore, no macroscopic or microscopic changes were observed. Based on the results of study, no evidence of neurotoxicity was observed in dogs following methyl bromide inhalation in concentrations up to 20 ppm.

1477 SEX DIFFERENCES IN EXPRESSION OF PERIPHERAL BENZODIAZEPINE RECEPTOR (PBR) BINDING SITES IN RAT BRAIN AFTER THE ADMINISTRATION OF HEPTACHLOR AND HEPTACHLOR EPOXIDE DURING DEVELOPMENT.

E. F. Garcia, B. J. Baliwas, T. T. Tran and D. E. Woolley. *Neurobiology, Physiology and Behavior, University of California at Davis, Davis, CA.*

The peripheral benzodiazepine receptor (PBR) has been found in steroid producing tissues where it functions to mediate the entry of cholesterol into mitochondria. The PBR has also been identified in brain where it is limited to glia. Others have shown that increases in PBRs occur after neuronal damage. In previous work we have shown that acute exposure to heptachlor, a GABA-A antagonist that does not cause neuronal damage, in adult rats results in a rapid increase in PBR binding sites in brain; this was similar to increases found 4 days after trimethyltin neuronal damage. In this study we evaluated the effects of acute exposure of heptachlor on PBR numbers in the developing rat brain. Rats ranging in age from birth to 45 days were exposed to a single dose *per os* (PO) of heptachlor (60 mg/kg in oil). A clear sex difference in PBR numbers after exposure to heptachlor is seen at all ages between 10 and 20 days. During this period, heptachlor increased PBR numbers 2-fold in females but did not affect PBR numbers in males. Increases in PBR numbers in males were not produced by heptachlor until 30 and 45 days of age. The effects of maximal electroshock (MES) were compared with the effects of heptachlor at day 12 and 20. Both males and females exhibited increases in PBR numbers following MES, demonstrating that males are capable of showing increases in PBR numbers during development. Heptachlor epoxide, a more persistent and toxic metabolite of heptachlor was also tested during developmental. In this experiment PBR numbers were significantly increased in males but not in females- just the opposite of the effect of heptachlor. Our findings indicate that there may be an interaction between PBRs and the action of heptachlor in brain. *Supported by: Hawaii Heptachlor Research and Education Foundation.*

1478 EFFECTS OF CHRONIC DERMAL EXPOSURE TO NONLETHAL DOSES OF METHYL PARATHION ON BRAIN REGIONAL ACETYLCHOLINESTERASE (ACHE) AND MUSCARINIC CHOLINERGIC RECEPTORS IN FEMALE RATS.

T. Ma, R. E. Kramer, R. C. Baker, L. Fan and I. K. Ho. *Pharmacology & Toxicology, University of Mississippi Medical Center, Jackson, MS.*

The *in vivo* and *in vitro* effects of methyl parathion, a phosphorothionate insecticide, on cholinergic neurotransmitter systems in the brain of rats were investigated. Three groups of adult female rats received 0, 0.1, or 1.0 mg/kg methyl parathion *via* dermal exposure for 95 days. Exposure to 0.1 mg/kg methyl parathion produced inhibition of AChE in the caudate-putamen and thalamic nuclei, whereas 1.0 mg/kg resulted in inhibition of AChE in most brain regions. The same doses of methyl parathion had no effect on [3H]QNB binding to muscarinic receptors in the brain regions examined. The *in vitro* study demonstrated that methyl parathion causes preferential inhibition of AChE and [3H]QNB binding in specific brain regions. As an inhibitor of AChE, methyl paraoxon was 1000-fold more potent than was methyl parathion. Similarly, methyl paraoxon showed brain region-specific inhibition of the enzyme. Generally, the brain stem was highly sensitive to organophosphate-induced inhibition of AChE activity and [3H]QNB binding. Because central respiratory neurons gather in the brain stem, preferential effects there and in other brain regions may underlie lethal toxicity of methyl parathion and other organophosphates. (Supported by CDC grant RO6/CCR419466)

1479 MODULATION OF MUSCARINIC RECEPTORS IN THE RAT BRAIN DURING THE DEVELOPMENT OF TOLERANCE TO METHYL PARATHION.

T. Sun, T. Ma and I. K. Ho. *Pharmacology and Toxicology, University of Mississippi Medical Center, Jackson, MS.*

Methyl parathion is a potent and irreversible acetylcholinesterase (AChE) inhibitor, which produces peripheral and central cholinergic over-stimulation. Tolerance can be induced by repeated exposure to sublethal doses of methyl parathion. Because extensive enzyme inhibition often induces compensatory changes in cholinergic receptor population, we compared the effect of methyl parathion on brain muscarinic receptors at different time points during the development of tolerance to methyl parathion. Adult male rats were treated with either vehicle or methyl parathion (3 mg/kg/day, s.c.) and observed for the signs of toxicity. Animals were sacrificed 7 or 21 days after the daily treatment for measurement of acetylcholinesterase activity and binding to muscarinic radioligands, [3H] QNB (nonselective), [3H] pirenzepine (M1-selective), and [3H] AFDX-384 (M2-selective). After 21 days of treatment, methyl parathion caused 80% AChE inhibition and substantial reductions in [3H] QNB binding (14.3 ~ 32.7%), [3H] pirenzepine binding (around 21%), [3H] AFDX-384 binding (21.7 ~ 37.7%) in the striatum, hippocampus formation, and cortex. After 7 days of treatment, the inhibition of AChE in brain regions was from 39% to 72%, whereas receptor densities were only marginally affected in a few regions. The timing of the changes in receptor population correlates well with our previous finding in changes of behaviors during the development of tolerance. Our results strongly suggest that down-regulation of muscarinic receptor plays a role in the development of tolerance to organophosphates. (R06/CCR419466)

1480 BRAIN ESTERASE ACTIVITIES IN RATS GIVEN MULTIPLE DOSES OF ORGANOPHOSPHORUS (OP) COMPOUNDS OVER 63 DAYS WITH 30 DAYS RECOVERY.

M. Ehrich, S. P. Hancock, L. Flory and B. S. Jortner. *Virginia-Maryland Regional College of Veterinary Medicine, Virginia Tech, Blacksburg, VA.*

Acetylcholinesterase (AChE) and neurotoxic esterase (NTE) activities in the hippocampus (H), cerebral cortex (CC), basal forebrain (BP) and caudate putamen (CP) were examined in adult male Long-Evans rats given OP compounds during a 63-day dosing period with 30 days recovery. Corticosterone 400 mcg/ml in drinking water was given throughout the 90-day test period. The insecticide chlorpyrifos (60 mg/kg sc) was given on Days 7 and 42. Tri-ortho-tolyl phosphate (TOTP), 300 mg/kg PO, was given 7 times between Days 14 & 28 and again between Days 49 & 63. At 63 days, AChE activities in H, CC, BP and CP of rats given only chlorpyrifos were 40%+/-7 (mean+/-SEM, n=6), 32%+/-4, 35%+/-6, and 30%+/-3 of control, respectively. AChE activities after chlorpyrifos + TOTP were <15% of control. Rats drinking corticosterone-treated water and given chlorpyrifos + TOTP also had AChE activities <15% of control. On Day 91, AChE activities were 62%+/-3, 74%+/-2, 61%+/-9 and 62%+/-9, respectively, in the H, CC, BF and CP of rats given only chlorpyrifos. The activities of AChE in rats given TOTP only or given chlorpyrifos + TOTP ranged from 41-75% of control. Corticosterone treatment did not appear to affect AChE activities alone or in OP-treated rats. NTE activities in the H, CC, BF and CP were only affected by TOTP, with activities at 43%+/-5, 40%+/-5, 33%+/-4, and 45%+/-8 of control in these brain regions, respectively, at 63 days. NTE activities in all brain regions were at control values on Day 91. These results demonstrate that the OP treatments had great effects on AChE activity in all brain regions examined, and that recovery was not complete even 30 days after cessation of treatment with TOTP or 47 days after treatment with chlorpyrifos. The 30-day time period was, however, sufficient for recovery of NTE activity in rats given TOTP in multiple doses. (Supported by DAMD 17-99-1-9489. This abstract does not necessarily reflect the position or policy of the US Government.)

1481 NEUROPATHOLOGICAL STUDY OF THE INTERACTIONS OF STRESS AND TWO NEUROTOXIC ORGANOPHOSPHATES IN RATS.

B. S. Jortner, S. Hancock, J. Hinckley, L. Florey and M. Ehrich. *Department of Biological Sciences and Pathobiology, Virginia Tech, Blacksburg, VA.*

Interest exists concerning toxic actions of chemical mixtures and the role of stress in modulating such events. We previously reported data from a study designed to assess effects of stress and the concurrent exposure to two organophosphorus compounds in rats (Society for Neuroscience Abstracts, 2002). The present work updates the neuropathologic findings. The toxicants used were the insecticide chlorpyrifos (as a single 60 mg/kg subcutaneous dose) and the classical delayed neurotoxicant tri-ortho-tolyl phosphate (TOTP, given seven times over a two-week period as 75, 150 or 300 mg/kg gavage doses). Stress was mimicked by administration of corticosterone in the drinking water (400 ug/ml) over a 63-day period. The toxicants were given in two courses between days 7-27 and days 42-62, with sacrifice on day 63 (experimental groups n=12). Neurochemical findings are reported in an abstract by M. Ehrich et al. at this meeting. Neuropathologic studies demonstrated an axonopathy in the distal (medullary and cervical) levels of the gracile fasciculus, which progressed to overt myelinated fiber degeneration. Lesions included swollen or collapsed axons and myelinated fiber breakdown. These were primarily related to the TOTP dosage, with the 300 mg/kg group having a higher incidence and more extensive changes (including enhanced proximal extent of the nerve fiber lesions) than those animals given 150 mg/kg. Stress did not appear to affect the expression of the neuropathic process. Preliminary studies suggest that chlorpyrifos enhanced the severity of the lesions. The nature and distribution of this nerve fiber degeneration are consistent with this being a rat model of organophosphorus ester-induced delayed neuropathy (OPIDN). (Supported by: US Army Medical Research and Materiel Command DAMD17-99-1-9489. This abstract does not necessarily reflect the position or policy of the US Government.)

1482 THE TOXICOKINETICS OF PERIPHERAL CHOLINESTERASE INHIBITION FROM ORALLY ADMINISTERED CARBOFURAN IN RATS.

J. D. McCarty[1], S. A. Anderson[2] and K. L. Li[1]. *[1]Toxicology, FMC Corporation, Princeton, NJ and [2]RTI, Research Triangle Park, NC.*

This study was performed with the carbamate pesticide carbofuran to determine the time course of inhibition and recovery of cholinesterase activity (CA) after oral administration. A single dose of carbofuran in corn oil vehicle was administered *via* oral gavage to cannulated adult male and female CD rats at one of three dose levels: 0, 0.5, or 1.0 mg/kg. Blood samples were collected at -15 (predose baseline), 15, 30, 45, 60, 75, 90, 120, 150, 180, 240, 360 and 480 minutes after dosing for determination of plasma and erythrocyte (RBC) CA. Carbofuran did not inhibit plasma CA at either dose level when compared to controls. Following a single oral administration of 0, 0.5, or 1.0 mg/kg, RBC CA was inhibited at the low and high dose levels in both the males and females. To account for inherent variability as seen in the control values, the percent of baseline RBC CA was calculated at each time point (for each animal in each dose group). For the 0.5 mg/kg dose group, the percent of baseline activity was not statistically different from controls from 150 through 480 minutes for males and from 75 through 480 minutes for females (with the exception of the 240 min time point in males and the 360 min time point in females). For the 1.0 mg/kg dose group, percent of baseline RBC CA was not significantly different from controls at the 180 and 360 minute time points for males and the 240 and 480 minute time points for females. When normal variability is taken into account by evaluating the data as percent of baseline value, a return to normal RBC CA occurred by 150 minutes (males) and 75 minutes (females) in the low dose group.

1483 DEVELOPMENT OF A NEONATAL RAT PHYSIOLOGICALLY BASED PHARMACOKINETIC/PHARMACODYNAMIC (PBPK/PD) MODEL FOR CHLORPYRIFOS.

C. Timchalk, A. Kousba and T. S. Poet. *Molecular Biosciences, Pacific Northwest National Laboratory, Richland, WA.*

Juvenile rats are more susceptible than adults to the high dose effects of organophosphate (OP) insecticides, like chlorpyrifos (CPF); therefore, it is assumed that infants and children are likewise more susceptible. Age-dependent differences are primarily a function of metabolic capacity for several important enzyme systems. This includes CYP450 activation to CPF-oxon, and detoxification to trichloropyridinol (TCP), as well as B-esterase (B-EST) and A-esterase (A-EST) detoxification of CPF-oxon to TCP. A PBPK/PD model describing the time-course of CPF, CPF-oxon, and the inhibition of acetylcholinesterase (AChE) in adult rats and humans was modified to allometrically scale (based on body weight) the age-dependent development of CYP450 and A-EST enzyme activity. The model provided a good simulation of brain and RBC AChE inhibition in post-natal day (PND) 17 rats orally administered 15 mg/kg CPF. The model was used to simulate concentrations of CPF-oxon in the brain of neonatal rats (PND4) following single acute oral exposure to a range of CPF doses (0.5-50 mg/kg). Doses greater than 5 mg/kg resulted in theoretical concentrations of CPF-oxon in the brain of PND4 rats that was greater than in adults, this difference increased with dose. Doses less than 1 mg/kg resulted in brain CPF-oxon concentrations in PND4 rats that were similar to theoretical adult AUCs. The model simulation suggests that neonatal rats are more sensitive than adults to the effects of acute high dose exposures. However, the model also indicates that even though neonatal rats have lower metabolic capacity, it is adequate to detoxify CPF at relevant environmental exposure levels. These simulations are consistent with differences in the acute toxicity response noted between neonatal and adult rats following exposure to CPF. This model represents an important starting point in the development of a PBPK/PD model to better define the potential of CPF to cause neurotoxicity in sensitive populations, such as infants and children. (Supported by EPA grant R828608)

1484 POTENTIAL UTILITY OF SALIVA BIOMONITORING FOR ORGANOPHOSPHATE INSECTICIDE DOSIMETRY AND ESTERASE INHIBITION.

A. Kousba, T. S. Poet and C. Timchalk. *Molecular Biosciences, Pacific Northwest National Laboratory, Richland, WA.*

Chlorpyrifos is a phosphothioate, which is a commonly used organophosphate (OP) insecticide. Its active metabolite CPF-oxon is a potential inhibitor of cholinesterase enzymes (ChE), such as acetylcholinesterase (AChE) and butyrylcholinesterase (BuChE). Whereas the inhibition of AChE is associated with neurotoxicity, BuChE inhibition represents a detoxification mechanism and a potential biomarker of exposure/response. In the current study CPF, dissolved in corn oil, was administered orally as a single dose (0, 1, 10, and 50 mg/kg) to male Sprague-Dawley rats followed by saliva and blood collection at 0, 3, 6, and 12 hour post-dosing. CPF and its major metabolite trichloropyridinol (TCP) were quantified in blood and saliva using gas chromatography (GC) and a modified Ellman method was used to monitor the resultant ChE inhibition. A preliminary *in vitro* study, using both AChE and BuChE specific inhibitors, indicated that the vast majority (>90%) of rat salivary ChE activity was due to BuChE. Utilizing saliva as a source of BuChE, the bimolecular inhibition rate constant (Ki) and the first-order reactivation rate (Kr) were ~8000 $\mu M^{-1}\ h^{-1}$ and 0.08 h^{-1}, respectively. Oral administration produced a dose-dependent inhibition of ChE in plasma and saliva. At all dose levels the maximum salivary ChE inhibition (3-6 hr post-exposure) was slightly less than that of the plasma, and saliva exhibited a faster ChE recovery. CPF and TCP

were quantified in blood, whereas TCP was detected in saliva and only at higher doses. Although the saliva TCP concentrations were significantly less than the plasma concentrations, the TCP pharmacokinetics were comparable (i.e. similar half-life). These results suggest that saliva may be a useful biological matrix for monitoring CPF exposure and response either through measuring the metabolite levels or the degree of ChE inhibition. These data will be used for further validation of an already constructed pharmacokinetic/pharmacodynamic model for CPF. (Sponsors EPA grant R828608 and CDC/NIOSH R01OH03629-01A2).

1485 DEVELOPMENT OF A PHYSIOLOGICALLY BASED PHARMACOKINETIC AND PHARMACODYNAMIC (PBPK/PD) MODEL FOR THE ORGANOPHOSPHATE PESTICIDE, DIAZINON.

T. S. Poet, A. Kousba, H. Wu, S. L. Dennison and C. Timchalk. *Molecular Biosciences, Pacific Northwest National Laboratory, Richland, WA.*

Organophosphate (OP) pesticides, like diazinon (DZN), constitute a large class of insecticides that are widely utilized, and the potential exists for significant exposures from multiple routes. The objective was to develop a PBPK/PD model capable of predicting the relationships between exposure, bioactivation, detoxification, and the inhibition of target esterases (EST). In this model, CYP450 metabolism of DZN to the oxon and detoxification to 2-isopropyl-4-methyl-6-hydroxypyrimidine (IMHP) are both mediated by CYP450s in the liver. Hydrolysis of the oxon *via* A-EST occurs in the liver and blood and interactions with target B-EST (acetyl-, butyryl- and carboxyl-) were modeled as second order processes occurring in the liver, blood, diaphragm and brain. Metabolic rate constants for the CYP450- and A-esterase-mediated metabolism were measured *in vitro*. B-EST inhibition and regeneration rates have been determined *in vitro* and model optimization against cholinesterase (ChE) inhibition data. To facilitate model development, single oral-dose pharmacokinetic studies were conducted in rats (1 - 100 mg/kg) and the kinetics of DZN and IMHP as well as the extent of plasma ChE and RBC and brain acetylcholinesterase (AChE) inhibition were determined. In blood, the concentration of IMHP was greater than DZN and the kinetic time-course was linear over the dose-range and reasonably simulated by the model. Peak ChE inhibition occurred at ~6 hr post-dosing and the model accurately simulated the dose-dependent inhibition of plasma ChE, RBC AChE and brain AChE. This DZN PBPK/PD model quantitatively estimates target tissue dosimetry and ChE inhibition and will be integral to risk assessments for DZN and OP mixture exposures under a variety of scenarios. (Sponsored by CDC/NIOSH Grant R01 OH03629-01A2).

1486 MASS SPECTRAL EVIDENCE THAT MIPAFOX-INHIBITED NEUROPATHY TARGET ESTERASE (NTE) DOES NOT UNDERGO DEALKYLATION.

T. J. Kropp[1], P. Glynn[2] and R. J. Richardson[1]. *[1]Environmental Health Sciences, University of Michigan, Ann Arbor, MI and [2]MRC Toxicology Unit, University of Leicester, Leicester, United Kingdom.*

Organophosphorus compound-induced delayed neurotoxicity (OPIDN) is thought to be initiated by inhibition and aging of neural NTE. Aging of phosphylated NTE and other serine esterases involves progressive resistance to reactivation, attributed to anion formation *via* time dependent dealkylation of the active site OP adduct. Because N, N? diisopropylphosphorodiamidofluoridate (mipafox, MIP) inhibits NTE and produces OPIDN, it has been assumed that MIP inhibited NTE undergoes aging *via* dealkylation. Recent work, however, showed that MIP-inhibited NTE could be reactivated at low pH after allowing time for aging. In contrast, diisopropylphosphorofluoridate (DFP) inhibited NTE and DFP- or MIP inhibited butyrylcholinesterase (BChE) could not be reactivated after allowing time for aging. These observations suggest the hypothesis that DFP- or MIP-inhibited BChE and DFP-inhibited NTE undergo aging *via* dealkylation, whereas MIP-inhibited NTE does not. This hypothesis was tested by inhibiting horse serum BChE or human recombinant NTE esterase domain (NEST) with MIP or DFP. Using peptide mass mapping with surface enhanced laser desorption/ionization mass spectrometry, *m/z* peaks corresponding to active site peptides and their intact or dealkylated adducts were examined in control and treated samples at 0, 1, 2, 12, 24, and 36 h after inhibition. Time-dependent mass shifts representing a change from intact to dealkylated active site adducts were found for MIP- and DFP-inhibited BChE. Moreover, a peak corresponding to dealkylated active site adduct was found at all times for DPF inhibited NEST. In contrast, a peak representing intact active site adduct was found at all times for MIP-inhibited NEST, showing that dealkylation did not occur. The results suggest that MIP produces OPIDN through a mechanism other than dealkylation of MIP-inhibited NTE. If an anionic active site adduct is required, it is possible that this arises from removal of the acidic phosphoramido proton. (Supported by DAAD19-02-1-0388).

1487 TENTATIVE MODELS FOR THE THREE-DIMENSIONAL STRUCTURE OF THE NTE ESTERASE DOMAIN (NEST): PREDICTIONS FROM THREADING AND DOCKING.

J. Wang and R. J. Richardson. *Environmental Health Sciences, University of Michigan, Ann Arbor, MI.*

Neuropathy target esterase (NTE), the primary target for initiation of organophosphorus compound-induced delayed neuropathy, is a 1327-amino acid integral membrane protein, whose three-dimensional structure is intractable to experimental determination. Moreover, sequence analysis shows that NTE is a member of a novel protein family, so that its theoretical model cannot currently be obtained by homology modeling. The NTE esterase domain (NEST) corresponds to NTE residues 727-1216 and is the minimum NTE construct with full esterase activity. The threading program PROSPECT was employed to conduct fold recognition and sequence structure alignments for NEST. Based on the alignments obtained from threading, atomic structures of NEST were generated using the program MODELLER. Resultant models were refined in the CHARMm module of InsightII 2000. Finally, candidate structures were evaluated by docking the neuropathic compounds diisopropylphosphorofluoridate and ethyl 4-nitrophenyl phenylphosphonate as ligands into the NEST model using the Affinity module of InsightII 2000. This strategy yielded three putative structures of NEST for further study. The models were consistent with experimental data from ligand binding and site-directed mutagenesis. Namely, they predicted Ser^{966} as the active-site serine, Asp^{1086} and Asp^{960} as possible critical residues for catalysis, and Asp^{1044} or Asp^{1004} as possible acceptor residues for the intramolecular transfer of an alkyl group during aging of phosphylated enzyme. These models for NEST provide a starting point for gaining atomic-level insight into interactions of NTE with small molecules and could be further refined and validated through interative modeling and experimental validation. (Supported in part by DAAD19-02-1-0388).

1488 DECREASE OF 5-HT LEVELS AFTER PYRETHROID TREATMENT.

A. Anadon, M. A. Martínez, M. Martínez, M. J. Díaz, M. T. Frejo, V. J. Castellano and M. R. Martínez-Larranaga. *Department of Toxicology and Pharmacology, Faculty of Veterinary Medicine, Complutense University, Madrid, Spain.*

Deltamethrin, cyfluthrin and cyhalothrin, Type II pyretroid insecticides, are used topically for the control of ectoparasites. Type II pyrethroids when injected peripherally to rat produced a severe syndrome characterized by salivation and choreoathetosis. Because of a variety of putative biochemical and physiological target sites may contribute to pyrethroid toxicity, the objective of the present study was to investigate neurochemical effects following the administration of deltamethrin (40 mg/kg, i.p. for 6 days), cyfluthrin (14 mg/kg i.p. for 6 days) and cyhalothrin (8 mg/kg, per os for 6 days) in male Wistar rats(n =6/group). Animals were sacrificed 24 hours following pyrethroid administration and their brains were rapidly removed. The frontal cortex, hippocampus, midbrain and striatum were dissected and analyzed for content of 5-hydroxytryptamine (5-HT) and its metabolite 5-hydroxy-3-indole acetic acid (5-HIAA) using a HPLC method with electrochemical detection. A serotonin depleting effect was produced by these pyrethroids. Deltamethrin decreased 5-HT and 5-HIAA levels in midbrain (38%; $P<0.05$; 17%, $P<0.05$) and striatum (46%, $P<0.001$; 21%, $P<0.05$) and decreased 5-HIAA levels in frontal cortex (62%, $P<0.001$) and hippocampus (48%, $P<0.001$) respect to corn oil controls. Cyfluthrin decreased 5-HT and 5-HIAA levels in frontal cortex (25%, $P<0.05$; 30%, $P<0.01$), hippocampus (20%, $P<0.05$; 19%, $P<0.05$) and striatum (31%, $P<0.01$; 36% $P<0.01$) respect to corn oil controls. Cyhalothrin decreased 5-HT levels in frontal cortex (35%, $P<0.001$), hipoccampus (26%, $P<0.05$), midbrain (28%, $P<0.05$) and striatum (24%, $P>0.001$) and decreased HIAA levels in frontal cortex (36%, $P<0.01$) and midbrain (27%, $P<0.05$). The data presented herein suggests that a lower activity of serotonergic system exists in the action of Type II pyrethroids. This work has been supported by projects No. PB9701236, (DIGICYT), No. 08.8/0002/98 (CAM) & No. 99/0936 (FIS), Spain.

1489 CONVERSION OF DELTA PH AND ELLMAN VALUES FOR CHOLINESTERASES.

B. W. Wilson[1], J. D. Henderson[1], D. E. Arrieta[1], S. A. McCurdy[2] and R. Reitstetter[3]. *[1]Environmental Toxicology, University of California, Santa Cruz, CA, [2]Epidemiology and Preventive Medicine, University of California, Davis, CA and [3]Clinical Investigation, Brooke Army Medical Center, San Antonio, TX.*

Intensive use of anticholinergic pesticides such as organophosphate esters and threat of chemical warfare establish the need for rapid, high throughput, reliable and standardizable determinations of blood cholinesterase levels to provide early warning of exposures to neuroactive chemicals. Many clinical and research labora-

tories use the colorimetric Ellman assay based on hydrolysis of acetylthiocholine. CHPPM (US Army Center for Health Promotion and Preventive Medicine) uses a slower method, the delta pH based on that of Michel to monitor approximately 25, 000 DOD personnel annually. One of the goals of this project is to establish a conversion factor between the pH and colorimetric assays applicable to monitoring studies and field tests. Blood drawn under the appropriate regulations by CHPPM was centrifuged and detergent-lysed before being subjected to the delta pH assay with acetylcholine as substrate. Duplicate RBC samples were sent to UC Davis to be assayed with acetylthiocholine by the Ellman method. Samples were lysed, diluted with buffer and run with and without quinidine to separate activities due to acetylcholinesterase and non-specific cholinesterases. For example, slopes of delta pH vs Ellman for three of five sets of samples yielded r^2 correlations of 0.74 to 0.8. Comparisons continue to establish critical assay conditions and Ellman equivalents of the delta pH assay. Supported by DOD (DAMD17-01-1-0772), NIOSH (#CDC U07/CCU906162-06) and NIEHS (#ES05707).

1490 DIFFERENTIAL PROFILES OF CHOLINESTERASE INHIBITION AND NEUROBEHAVIORAL EFFECTS IN RATS EXPOSED TO FENAMIPHOS AND PROFENOPHOS.

K. L. McDaniel, P. M. Phillips and V. C. Moser. *NHEERL, USEPA, Research Triangle Park, NC.*

The relationship between cholinesterase (ChE) inhibition and neurobehavioral changes was examined using two ChE-inhibiting organophosphorus pesticides, fenamiphos and profenophos. Both pesticides inhibit blood ChE, yet brain ChE is relatively spared (little to no inhibition up to lethal doses). Interestingly, pronounced neurobehavioral signs were observed following fenamiphos but not profenophos. A direct comparison was then undertaken to evaluate the influence of brain ChE on the behavioral signs observed. After a single oral dose, both pesticides greatly inhibited blood ChE (87-98% inhibition), yet whole brain ChE was only inhibited by 9-14% at the highest doses. Fenamiphos produced dose-dependent lacrimation, salivation, tremors, gait abnormalities, and decreased motor activity and tail pinch response. Despite the similar ChE inhibition profile, profenophos produced no changes in any of these measures. Thus, the neurobehavioral effects of fenamiphos could not be explained based on brain ChE inhibition alone. Pretreatment with anticholinergic drugs was used to evaluate the contribution of peripheral vs central ChE inhibition. Scopolamine (SCO) and methylscopolamine (MSC) were used as central/peripheral and peripheral-only cholinergic receptor blockers, respectively, in combination with fenamiphos. Neither drug altered fenamiphos effects on ChE. Some effects of fenamiphos were blocked or attenuated only by SCO, whereas other effects were blocked by both drugs. These data indicate that some of the pronounced neurobehavioral changes observed following fenamiphos may be centrally mediated (blocked by SCO only), despite the relative sparing of brain ChE. Regionally specific ChE inhibition or direct cholinergic receptor activation may be responsible for these effects. Other behavioral changes may be mediated more peripherally (blocked by both MSC and SCO), yet the contrast between profenophos and fenamiphos indicates that these neurobehavioral effects cannot be predicted on the basis of blood ChE. This abstract does not necessarily reflect EPA policy

1491 CHRONIC DIETARY EXPOSURE WITH INTERMITTENT SPIKE DOSES OF CHLORPYRIFOS FAILS TO ALTER BRAINSTEM AUDITORY EVOKED RESPONSES (BAERS) IN RATS.

J. E. Graff, D. W. Herr, R. S. Marshall and D. L. Hunter. *Neurotoxicology, USEPA, Durham, NC.*

Human exposure to pesticides is often characterized by chronic low level exposure with intermittent spiked higher exposures. Cholinergic transmission is involved in auditory structures in the periphery and the brainstem and is altered following chlorpyrifos exposure. This study examined the effects of chronic (1 year) dietary exposure (0, 1, or 5 mg/kg/day) to chlorpyrifos in male Long Evans rats (100-110 days old at study initiation) on BAERs. The chlorpyrifos doses were chosen to produce minimal and approximately 50% inhibition of brain cholinesterase activity, respectively. In addition to dietary exposure, half of the animals received an oral bolus of 45 mg/kg chlorpyrifos (in corn oil) every other month (n = 16-18 rats/treatment). Subjects were weight maintained at 350g throughout the study. After the final spiked exposure, the animals were allowed to recover for about 2.5 months, so only irreversible effects would be examined. Subjects were surgically implanted with screw electrodes over the cerebellum and allowed to recover for one week. Unanesthetized animals were placed in a restrainer and presented with the following auditory stimuli (presented at 5.6 hz): rarefaction click, 4 and 16 kHz pure tone pips presented at 50, 65, and 80 dB SPL, and 64 kHz pure tone pip presented at 65, 70 and 80 dB SPL. Dietary exposure to chlorpyrifos (alone or in combination with oral spike doses) did not produce changes in brainstem auditory evoked responses. The evoked responses showed the expected intensity and frequency-dependent changes, indicating that the animals responses were under stimulus control. Thus, chronic exposure to chlorpyrifos did not appear to alter auditory responses at the level of the brainstem in adult animals. *This is an abstract of a proposed presentation and does not necessarily reflect EPA policy.*

1492 COMPARATIVE EFFECTS OF METHYL PARATHION (MPS) AND ITS METABOLITE METHYL PARAOXON (MPO) ON ACETYLCHOLINE (ACH) RELEASE AND MUSCARINIC AUTORECEPTORS IN JUVENILE AND ADULT RATS.

G. Wang[1,2], J. Liu[1], H. Zhang[1,3] and C. N. Pope[1]. *[1]Oklahoma State University, Stillwater, OK, [2]Baylor College of Medicine, Houston, TX and [3]University of Rochester, Rochester, NY.*

Previous studies have demonstrated that young rats are more sensitive than adults to acute toxicity of high dosage of MPS. The present study investigated the relationship between the toxicity of MPS and ACh release and its muscarinic receptor mediated regulation in juvenile and adult rat brain. AChE activity and QNB binding from the same rats and effects of MPS and MPO *in vitro* on muscarinic receptors were also evaluated. The results showed that in absence of physostigmine (PHY) and atropine (ATR) in buffers, MPO *in vitro* reduced ACh release in a concentration dependent manner (20-40% in 21 day rats, 10-40% in adult rats); in presence of PHY and in absence of ATR in buffers, MPO had no effect on ACh release in both age groups; and PHY was always included in the perfusion buffers and ATR was added 10 min before the second stimulus, MPO also decreased release as before; but MPS *in vitro* did not show any effect on the ACh release. The ChE activity in juvenile rats showed a quicker recovery by 24h and 96h than that in adult rats. Different quantitative reductions in QNB binding were noted in both age groups 24h and 96h after exposures to both dosages of MPS, by 4 hours, however, a significant reduction of QNB binding was noted in juvenile rats only. DSAR or S1 was significantly reduced 24h after LD10 exposure in juvenile striatum, but was no remarkably affected at any other timepoint or with lower dosage. Different quantitative reductions in S2/S1 release ratios were noted in both age groups 96h after exposures to both dosages of MPS, but no significant reduction was noted at other timepoints. The results suggested that MPO may have potential direct effects on muscarinic receptor function and effects of MPS on ACh release and its muscarinic receptor-mediated regulation during maturation as a possible contributing factor to age-related differences in sensitivity.

1493 PYRIDOSTIGMINE BLOCKS PARAOXON-INDUCED BLOOD-BRAIN BARRIER LEAKAGE.

X. Song[1], C. N. Pope[1], R. Murthy[2], J. Shaikh[1] and J. Bressler[2]. *[1]Physiological Sciences, Oklahoma State University, Stillwater, OK and [2]Kennedy Krieger Institute, Johns Hopkins School of Public Health, Baltimore, MD.*

Increased entry of pyridostigmine (PYR) into the brain has been hypothesized as a contributing factor to unexplained Gulf War Illnesses. Some organophosphorus (OP) cholinesterase (ChE) inhibitors can compromise blood-brain barrier (BBB) integrity, generally through elicitation of convulsions. Preliminary results suggested, however, that low-level paraoxon exposure (0.1 mg/kg, im, causing roughly 50% ChE inhibition) could increase BBB leakage as evidenced by the enzymatic marker horseradish peroxidase (HRP) in 25-30 day old Long Evans rats. We evaluated the interaction between acute paraoxon and acute PYR on HRP accumulation and brain ChE activity. PYR (30 mg/kg, po, or saline) was administered 50 minutes prior to paraoxon (or vehicle, 0.4% DMSO in saline). Rats (n=3/trt) were anesthetized (diethyl ether) 7.5 minutes later and heart was exposed for intracardiac HRP injection (40 mg/ml in 2% Evans Blue, 200 ml/rat) through the left ventricle, beginning exactly 10 min after paraoxon. One minute after HRP injection, rats were sacrificed, whole brain was dissected and placed in 2.5 % glutaraldehyde for 48 hours. Cortical (temporal and frontal) regions were sectioned at 70 mm on a vibrotome and then histochemically processed and counted for number of BBB leaks per section as evaluated by HRP staining. Brain ChE activity was measured under the same treatments except rats were not injected with HRP. Paraoxon caused a significant >4.5 fold increase in number of BBB leaks in the temporal cortex. Rats treated with PYR alone or PYR prior to paraoxon exhibited minimal leaks, similar to controls. Little brain ChE inhibition was noted after PYR exposure while paraoxon alone caused 55-58% inhibition. Interestingly, brain ChE inhibition was somewhat lower (40-42% inhibition) in rats exposed to both PYR and paraoxon. The results suggest that paraoxon-induced BBB leakage does not facilitate PYR entry, but that PYR may inhibit BBB leakage by paraoxon. (Supported by grant DAMD17-00-1-0070 from US Army)

1494 INTERACTIVE TOXICITY OF CHLORPYRIFOS AND PARATHION IN NEONATAL RATS.

R. Kacham, S. Karanth and C. N. Pope. *Physiological Sciences, Oklahoma State University, Stillwater, OK.*

Organophosphorus insecticides (OPs) elicit their effects by inhibiting the enzyme, acetylcholinesterase. Young mammals are generally more sensitive to acute OP poisoning compared to adults. There is very little information on the combined action of multiple OP exposures, however. Recently, we reported interactive effects of OPs, chlorpyrifos (CPF) and parathion (PS) in adult rats (Karanth et al., 2001). In the present study, we evaluated the *in vivo* effects of sequential and concurrent exposures to CPF and PS in neonatal (7 days old) rats. LD1 values for CPF (8 mg/kg, po) and PS (0.5 mg/kg, po) were estimated by dose-response studies. Rats were exposed to OPs either simultaneously or sequentially (separated by 4 h) and functional signs of toxicity and lethality were recorded. Animals were sacrificed at 4, 8 and 24 hr (after first exposure) for biochemical measurements. The concurrent group showed more lethality (9/12) than either of the sequential dosing groups. Among the sequential groups, CPF-first showed higher lethality (3/8) than PS-first (1/8). After 4 hr of first dose, brain cholinesterase (ChE) inhibition was significantly higher in concurrent group (80%) compared to CPF-first (60%) and PS-first (30%) while at 8 hr, ChE inhibition was higher in CPF-first group (90%) than in PS-first group (79%) or concurrent group (78%). At 24 hr after exposure, recovery from inhibition was faster in concurrent group compared to sequential groups. ChE inhibition in plasma and diaphragm were also higher in concurrent group compared to sequential groups after 4 hr of exposure. Carboxylesterase inhibition was relatively similar among the groups in plasma (52-78%) and liver (77-84%) at different time-points. These results suggests that neonatal rats, in contrast to adult rats, are more sensitive to concurrent than sequential exposures. The mechanisms contributing to age-related sequence-dependent differences in interactive toxicity are unclear.

1495 AGE AND STRAIN COMPARISONS OF CARBACHOL-STIMULATED INOSITOLPHOSPHATE (IP) RELEASE IN RAT RETINA AND FRONTAL CORTEX.

J. Perez, L. D. Sutton and A. M. Geller. *Neurotoxicology, USEPA, Research Triangle Park, NC.*

PURPOSE: This study investigated age- and strain-related differences in retinal and brain IP second messenger pathways. This work is a prelude to further experiments on age-related effects of organophosphorous pesticides (OP) on retinal toxicity. Acute OP exposure in young adult rats produced a long-lasting down-regulation of the IP pathway in retina but not in brain; we hypothesize that this effect in aged rats may result in permanent retinal damage. Strain comparisons were necessary because of the limited availability of aged rats. This study compared IP release in retina and frontal cortex. METHODS: Tissue was taken from young and old rats of different strains: Fisher-344 (F-344, albino; 70-day, 1- or 2-year old), Long-Evans (LE, pigmented; 70-day old only), and Brown Norway (BN, pigmented; 70-day and 2-year old only). 3H-myo-inositol (3H-MI) was incorporated into whole retina and cortical slices. IP released during incubation with carbachol was separated by anion exchange column chromatography and is reported here as the fraction released of the total amount of 3H-MI incorporated. RESULTS: In the retina, F-344 and LE had higher levels of stimulated IP release compared to BN. No age-dependent differences in IP release were noted. In the frontal cortex, as in the retina, stimulated IP release was higher in F-344 than in BN. In the young LE tested, LE had even higher levels of IP release than F-344. No age-related differences were noted in within-strain comparisons. DISCUSSION: In summary, carbachol-stimulated IP release in retina and frontal cortex was higher in rats from the F-344 and LE strains compared to the BN strain. In addition, within-strain comparisons indicate that IP release in both tissues is similar in young and aged F-344 and BN rats. These results suggest that carbachol-stimulated IP release depends on strain, but not on age or pigmentation. This is an abstract of a proposed presentation and does not necessarily reflect EPA policy.

1496 DIFFERENTIAL SENSITIVITY TO ANTICHOLINESTERASE PESTICIDES IN THE JUVENILE RAT: EFFECTS ON THERMOREGULATION.

C. M. Mack and C. J. Gordon. *USEPA, Research Triangle Park, NC.* Sponsor: D. Herr.

Organophosphate (OP) and carbamate (CB) pesticides inhibit cholinesterase (ChE) activity and induce acute hypothermia in adult rats. Studies have shown that juveniles are generally more susceptible to neurotoxic insult than adults, however, the effects of OP and CB pesticides on thermoregulation in developing animals are relatively unknown. Thus, we investigated alterations in core body temperature (Tc) in juvenile animals exposed to an OP or CB. Male rats were implanted on postnatal day (PND) 15 with a radio transmitter to monitor Tc and motor activity. PND 17 pups received a single dose of the OP chlorpyrifos (CHP) (1, 5, 10 or 15 mg/kg) or the CB carbaryl (CAR) (10, 20, 80, 120, or 160 mg/kg) or corn oil, po. Pups were returned to their dams and littermates immediately after dosing. CHP doses of 10 and 15 mg/kg resulted in 1.0 °C and 2.5 °C reductions in Tc, respectively. Tc recovered 16 hr after dosing. MA was significantly reduced following 15 mg/kg CHP. Conversely, the highest dose of CAR (160 mg/kg) resulted in a 1.3 °C reduction in Tc that recovered in 9 hr. In contrast, adult rats dosed with 50 mg/kg CHP underwent a 2.2 °C hypothermia while 75 mg/kg CAR led to a 1.8 °C hypothermia. Therefore, compared to adults, 17 day old rats are 5-times more sensitive to CHP, an irreversible ChE inhibitor but approximately one-half as sensitive to CAR, a reversible inhibitor. Overall, it appears that during development in the rat from pre-weanling to adult, there is a progressive attenuation in sensitivity to CHP, but an exacerbation in sensitivity to CAR. This abstract does not necessarily reflect USEPA policy.

1497 INDUCTION AND PROMOTION OF DELAYED POLYNEUROPATHY BY PHOSPHOROAMIDATES. *IN VITRO* AND *IN VIVO* STUDIES.

G. Gardiman, A. Moretto and M. Lotti. *Environmental Medicine & Public Health, University of Padua, Padua, Italy.*

Certain esterase inhibitors, such as sulfonyl fluorides, carbamates and organophosphorus compounds (OP), exacerbate the clinical/morphological expression of axonopathies (promotion). The model for studying promotion is OP induced delayed polyneuropathy (OPIDP) in the hen. Promotion was associated with inhibition of a phenyl valerate esterase (PV) activity in whole nerve homogenate (M200) and of a PV activity associated with soluble nerve proteins (approx. MW 70 kDa) (S-PV). Inhibition and 'aging' (a molecular rearrangement after inhibition) of a PV called neuropathy target esterase (NTE) trigger OPIDP. Promoters inhibit NTE but do not cause OPIDP because they do not 'age' NTE. D(+) and L(-) methamidophos (O, S-dimethyl phosphorothioamidate) which caused promotion and, at higher doses, OPIDP were exceptions. In fact, NTE sensitivity to inhibition by methamidohos isomers was lower than that of S-PV. We assessed the ability of some methamidophos analogs to cause OPIDP, promotion or both. The O-ethyl and O-isopropyl analogs could not be tested *in vivo* because of high acute toxicity. In fact, they were more potent inhibitors of acetylcholinesterase (the target of the acute toxicity of OPs) than of NTE and S-PV. NTE, M200 and S-PV were inhibited by the O-n-hexyl analog (10 mg/kg sc) by 73, 62 and 87%, by the O-n-butyl analog (8 mg/kg sc) by 74, 63 and 89%, and by the O-n-propyl analog (15 mg/kg sc) by 40, 28 and 64%, respectively. The O-n-hexyl analog did not cause OPIDP (suggesting that NTE did not age) and promoted OPIDP caused by dibutyl dichlorvos (0.4 mg/kg sc): the median clinical score (range) increased from 1(0-3) to 7(4-8) (0-8 point scale). The O-n-butyl analog caused mild OPIDP (score 1) and, when given after dibutyl dichlorvos, it increased the score to 5(4-7). However, it was not clear whether this was promotion or cumulative effect. The O-n-propyl analog neither caused OPIPD nor promotion. These data indicate that phosphoroamidates are a particular class of compounds and support the association between promotion and substantial inhibition of S-PV activity.

1498 EXPLORING THE EXPLANATION OF AGE-RELATED SENSITIVITY TO A PYRETHROID INSECTICIDE, DELTAMETHRIN, IN RATS.

W. Haines[1,2], R. S. Marshall[2], D. L. Hunter[2] and S. Padilla[2]. *[1]UNC Toxicology, Research Triangle Park, NC and [2]Neurotoxicology Division, USEPA, Research Triangle Park, NC.*

This study was designed to assess the age-related sensitivity of a pyrethroid insecticide, deltamethrin [(S)- -cyano-3-phenoxybenzyl (1R, 3R)-3-(2, 2-dibromomovinyl)2, 2-dimethylcyclopropanecarboxylate], in Long Evans, hooded, male rats. Previously, in the literature, deltamethrin has been demonstrated to be more toxic to young rats (Sheets et al., Toxicol Appl. Pharmacology, 1994). These studies are designed to explore the reasons for this increased sensitivity. Our hypothesis is that weanling rats are more sensitive than adults to the toxic effects of deltamethrin due to pharmacokinetic differences. To test this hypothesis, we first validated a high performance liquid chromatography (HPLC) method to quantitate deltamethrin in tissues from both weanling and adult rats (modified from Anad n et al., Toxicol Appl. Pharmacology 1996). Advantageous mobile phase, extraction solvent, limit of detection, and recovery of deltamethrin was determined in plasma. To estimate the time of peak deltamethrin concentration in plasma, adult (90 days) and weanling (22 days) male rats were gavaged (n = 3-5) with a single dose of either 0 (corn oil vehicle) or 4 mg/kg of deltamethrin, and plasma collected between 1 and 24 hours after dosing. HPLC analysis of the plasma revealed that the time of peak deltamethrin concentration in both age groups approximately 2 hours after dosing, and there does not appear any difference between weanling and adult deltamethrin concentrations at this time. Thus, it seems that the plasma concentration of deltamethrin does not explain the age-related differences in sensitivity. This abstract does not reflect EPA policy.

1499 DOES CHRONIC CHLORPYRIFOS TOXICITY COMPROMISE DOPAMINERGIC FUNCTION IN THE RAT STRIATUM?

S. L. Oxendine[1,2], S. Southerland[2], R. Marshall[1], D. Hunter[1], R. Mailman[2] and S. Padilla[1,2]. *[1]Neurotox., USEPA, Research Triangle Park, NC and [2]Curr.in Toxicology., UNC-CH, Chapel Hill, NC.*

Although the specific etiology is not known, epidemiological studies implicate pesticide exposure as a major risk factor for Parkinson's disease. Acetylcholine's ability to reverse parkinsonian symptoms suggests that dopamine and acetylcholine exert opposing effects on extrapyramidal function. Recognition of this reciprocal balance has prompted speculation as to whether perturbations of cholinergic transmission might initiate dopaminergic dysfunction. Chlorpyrifos (CPF) is a commonly used anti-cholinesterase (anti-ChE) insecticide. We hypothesized that chronic, oral exposure to CPF would depress striatal dopaminergic function. Adult, male, Long Evans rats were given CPF for one year at three levels of dietary exposure (0, 1, or 5 mg/kg/day; n=10/group); half of the rats in each dietary exposure group received high dose bimonthly CPF challenges (spikes) by oral gavage and the other half received vehicle. Animals were sacrificed and tissues were taken for analysis at 6 or 12 months and also 3 months after dosing ceased. Cholinergic endpoints (i.e., ChE inhibition), as well as measures of dopaminergic function (i.e., [3H]mazindol binding; concentrations of dopamine and its metabolites) were assessed in the striatum. During dosing, there was substantial striatal ChE inhibition in all spiked groups and in the 5mg/kg CPF feed group, but three months after dosing ended, ChE had returned to control levels in all groups. There appear to be no changes in dopamine transporter binding or in concentrations of dopamine and its metabolites at any time or in any of the treatment groups. These data indicate that chronic exposure to CPF would not be expected to compromise dopaminergic function. This abstract does not reflect EPA policy. S. Oxendine is funded through a Minority Fellowship in Neuroscience.

1500 INHIBITION OF CHOLINESTERASE AND CARBOXYLESTERASE FOLLOWING *IN VIVO* EXPOSURE OF RATS TO MIXTURES OF PARATHION AND AZINPHOSMETHYL.

E. C. Meek, R. L. Carr, H. W. Chambers, M. Burnett, R. Coker and J. E. Chambers. *Center for Environmental Health Sciences, Mississippi State University, Mississippi State, MS.*

The patterns of inhibition of brain and serum cholinesterase (ChE) and serum carboxylesterases (CbxE) were determined after oral administration of two OP insecticides singly or in simultaneous or sequential mixtures. The effective dose levels that would inhibit 10% of brain ChE at the time of peak inhibition were determined to be 1.0 mg/kg parathion (P) and 1.5 mg/kg azinphosmethyl (A) at 10 and 2 hr, respectively. Sequential exposures were performed with the first insecticide administered followed by the second insecticide at the peak inhibition time for the first. Tissue samples were collected at 2, 4, 8, 10, and 24 hr. Brain and serum ChE levels were determined by continuous spectrophotometric assay, and serum CbxE inhibition was determined by discontinuous spectrophotometric methods. Inhibition of brain ChE for A was 9% at 2 hr, 4% at 4 hr, and 0% at 8, 10, and 24 hr; for P was 7% at 8 hr, 12% at 10 hr, and 0% by 24 hr. Simultaneous exposure prolonged inhibition (from 2% at 2 hr to 17% at 10 hr, with a peak of 23% at 8hr). Sequential exposure (A followed by P) indicated no significant greater-than-additive effects; inhibition ranged from 7% at 2 hours to 4% at 24 hr with peak inhibition at 8 hours (20%). P followed by A produced a similar trend; 0% at 2 hr, peak at 8 hr (23%), and 0% at 24 hr. Inhibition of serum ChE levels decreased at successive time points, and simultaneous and sequential exposures showed no greater-than-additive effects. CbxE was greatly inhibited by P (ranged from 81% at 2 hr to 28% at 24 hr). Peak inhibition of CbxE by A was only 13% at 8 hr. Simultaneous exposure resulted in prolonged inhibition compared to the single compounds. Sequential exposures showed no greater-than-additive effects. There was no evidence of interactions in the exposure to binary mixtures of these two insecticides administered at relatively low dosages. (Supported by American Chemistry Council CRAM 2a-99).

1501 INVESTIGATION OF THE COMBINED TOXICITY OF A MIXTURE OF CHLORPYRIFOS AND METHYL PARATHION.

J. A. Kamykowski[1], J. E. Chambers[1], H. W. Chambers[2] and R. L. Carr[1]. *[1]Center for Environmental Health Sciences, College of Veterinary Medicine, Mississippi State University, Mississippi State, MS and [2]Department of Entomology and Plant Pathology, Mississippi State University, Mississippi State, MS.*

The organophosphorus insecticides chlorpyrifos (CPS) and methyl parathion (MPS) exert their toxic effects through a common mechanism of toxicity, the inhibition of cholinesterase (ChE). This study compared the effects of low level exposure to CPS, MPS, and a mixture of the two compounds on brain and serum ChE and serum carboxylesterases (CbxE). The time to peak inhibition of brain ChE was determined for CPS and MPS and the effective dosages (ED) to inhibit 10-15% of brain ChE for each compound were determined. Adult male rats were orally exposed to either the ED for CPS (5 mg/kg), the ED for MPS (1.75 mg/kg), or a mixture of the two and brain and blood were collected at 30 min, and 2, 4, 8, 12, and 24 hours post exposure. With CPS alone, inhibition of brain ChE was not present at 30 min or 2 hours but increased to peak at 11% by 12 hours. Serum ChE inhibition was 33% at 30 min and increased to peak at 58% by 12 hours. Serum CbxE inhibition was over 90% at 30 min and remained so through 12 hours. With MPS alone, inhibition of brain ChE was 10% at 30 min and increased to 16% at 12 hours. Serum ChE and CbxE inhibition was 51-52% at 30 min but decreased thereafter. With simultaneous exposure to CPS and MPS, inhibition of brain ChE was 14-15% at 30 min to 2 hours with peak inhibition of 25% occurring at 12 hours. The pattern of serum ChE inhibition reflected the early inhibition similar to MPS and this inhibition increased with time similar to that of CPS. The pattern of serum CbxE inhibition was similar to that of CPS. The patterns of ChE and CbxE observed following simultaneous exposure were consistent with *in vitro* potencies as esterase inhibitors and did not give evidence of greater-than-additive effects. (Supported by American Chemistry Council CRAM 2a-99).

1502 THE EFFECT OF EARLY POSTNATAL EXPOSURE TO CHLORPYRIFOS AND CHLORPYRIFOS-OXON ON NEUROTROPHIN LEVELS IN THE RAT FOREBRAIN.

A. Betancourt and R. L. Carr. *Center for Environmental Health Sciences, College of Veterinary Medicine, Mississippi State University, Mississippi State, MS.*

Recent studies have demonstrated that young animals are more susceptible to the toxic effects of organophosphorus insecticides such as chlorpyrifos (CPS) than are adults. CPS exerts its toxicity through the inhibition of cholinesterase (ChE) but it has been suggested that CPS may exert its neurotoxicity in juveniles through non-cholinergic mechanisms. The development of the brain is a highly coordinated process in which neurotrophins play an essential role in neuronal proliferation and differentiation. It is possible that the neurotoxic effects of CPS in juveniles may be related to interference with the levels of the neurotrophins in the brain. This study investigated the effects of repeated exposure of neonatal rats to either CPS or its active metabolite chlorpyrifos-oxon (CPO) on the levels of two neurotrophins, nerve growth factor (NGF) and brain derived neurotrophic factor (BNDF). Two dosages of (1.5 and 3.0 mg/kg) and CPO (0.25 m/kg and 0.35 mg/kg) that produced similar degrees of brain ChE inhibition were administered daily from postnatal day (PND) 1-6. Rats were sacrificed on PND 4, 7, and 12 and forebrain ChE, NGF, and BDNF levels were determined. ChE activity was persistently inhibited with CPS but transiently inhibited with CPO. Forebrain NGF levels were decreased on PND 4 with the high dosage of CPS and on PND 7 with both dosages of CPS with recovery by PND 12. No effects on NGF were observed with CPO. No effects on BDNF levels were observed with either CPS or CPO. The basis for the decrease in NGF levels following neonatal exposure to CPS but not CPO appears to be related to the persistent inhibition of ChE induced by CPS. The compensatory down regulation of muscarinic receptors in response to the persistent inhibition may be involved.

1503 ROUTE OF EXPOSURE, NITROGEN SUBSTITUTION AND ACID STABILITY INFLUENCE THE HAZARDS AND COVALENT PROTEIN MODIFICATIONS PRODUCED BY DITHIOCARBAMATES.

W. M. Valentine, R. W. Thompson, E. G. Tonkin, K. Amarnath, V. Amarnath and H. L. Valentine. *Pathology, Vanderbilt University Medical Center, Nashville, TN, TN.*

Dithiocarbamates and their disulfides have a broad spectrum of applications in agriculture, industry and medicine and the reported biological effects of dithiocarbamates have also been quite varied. The nitrogen substituents and oxidation state of a dithiocarbamate influence its rate of decomposition, decomposition products and metabolic pathways. Similarly, due to differences in acid stability and the potential for acid hydrolysis to occur following oral exposure, the route of exposure may also influence the disposition and biological effects of a dithiocarbamate *in vivo*. In this study rats were exposed by oral and parenteral routes of administration to representative dithiocarbamate compounds with differing nitrogen substituents and oxidation states for acute and subchronic durations. Morphological assessments, clinical chemistry, covalent protein modifications and urinary metabolites were then used to characterize the target cells and disposition of the dithiocarbamates. Oral administration of acid labile N, N-diethyldithiocarbamate (DEDC) produced a neurofilamentous axonopathy and covalent protein cross-linking consistent with *in vivo* release of carbon disulfide. In contrast, parenteral administration of DEDC, oral administration of the bis disulfide of DEDC, disulfiram, or the

acid stable pyrrolidine dithiocarbamate produced a Schwannopathy accompanied by segmental demyelination and the formation of S-(dialkylaminocabonyl) cysteine adducts. Oral administration of the monoalkyldithiocarbamate N-methyldithiocarbamate resulted in acute hepatotoxicity characterized by centrilobular necrosis and the formation of S-(methylaminothiocarbonyl) cysteine adducts consistent with the generation of a methylisothiocyanate intermediate. These data provide relationships useful for predicting the potential hazards associated with a particular dithiocarbamate and route of exposure. Supported by ES06387, ES00267 and ES07028

1504 FIPRONIL BLOCK OF GLUTAMATE-ACTIVATED CHLORIDE CURRENTS IN COCKROACH NEURONS.

T. Ikeda[3,2], X. Zhao[3], V. Salgado[1], Y. Kono[2], J. Z. Yeh[3] and T. Narahashi[3]. *[1]Bayer CropScience, Monheim, Germany, [2]Institute of Agriculture and Forestry, Tsukuba, Japan and [3]Molecular Pharmacology and Biological Chemistry, Northwestern University Medical School, Chicago, IL.*

Fipronil is a highly effective broad-spectrum insecticide with many applications in agriculture, public health and animal health, and good efficacy against many resistant strains. While fipronil is known to be a highly effective and selective blocker of insect GABA-gated chloride channels, its activity against other ligand-gated chloride channels has been less well characterized. We studied the effects of fipronil on the inhibitory glutamate receptor-chloride channel complex, which is found only in invertebrate nerve and muscle. Glutamate-activated chloride currents were recorded from neurons isolated from cockroach thoracic ganglia, using the whole-cell patch clamp technique and symmetrical chloride concentration. The application of 1 mM glutamate to most neurons evoked rapidly-desensitizing inward currents with an EC50 of 36.8 ≥ 3.0 μM and a Hill coefficient of 1.56 ≥ 0.17. The time constant of desensitization was approximately 500 ms. The similarity between the reversal potential and the chloride equilibrium potential indicated that glutamate-induced currents were carried by chloride ions. Fipronil suppressed the glutamate-induced peak currents in a dose-dependent manner with an IC50 of 0.73 ≥ 0.27 μM and a Hill co-efficient of 0.68 ≥ 0.15, and greatly slowed the rate of desensitization. Picrotoxinin at 100 μM slightly suppressed glutamate-induced currents, to 87.8 ≥ 3.7 % of control, while dieldrin at 100 μM had no effect (96.7 ≥ 3.1%). AP5 and CNQX, mammalian excitatory glutamate receptor antagonists, were without effect on glutamate-activated Cl- currents. It was concluded that fipronil block of the glutamate receptor-chloride channel complex may play a role in the higher toxicity against insects compared to mammals. Supported by NIH Grant NS14143.

1505 STATE-DEPENDENT BLOCK OF MAMMALIAN AND INSECT SODIUM CHANNELS BY THE INSECTICIDES INDOXACARB AND DECARBOMETHOXY-INDOXACARB.

X. Zhao[1], T. Ikeda[1], V. Salgado[2], J. Z. Yeh[1] and T. Narahashi[1]. *[1]Molecular Pharmacology and Biological Chemistry, Northwestern University Medical School, Chicago, IL and [2]Bayer CropScience, Monheim, Germany.*

Indoxacarb, the only commercial pyrazoline-type insecticide, is effective against insects resistant to various insecticides. We compared the effects of indoxacarb and its decarbomethoxyllated metabolite DCJW on Na+ channels in rat dorsal root ganglion (DRG) neurons and cockroach thoracic ganglion neurons, using the whole-cell patch clamp technique. In DRG neurons, indoxacarb and DCJW at 1-10 mM slowly and irreversibly blocked both tetrodotoxin-sensitive (TTX-S) and tetrodotoxin-resistant (TTX-R) Na+ channels in a voltage-dependent manner. TTX-S Na+ channels were more sensitive than TTX-R Na+ channels to both compounds at the resting potential near −80 mV, but this difference was due largely to their different inactivation kinetics. Cockroach neurons had two types of TTX-S Na+ currents, also differing in inactivation kinetics and insecticide sensitivity. At −100 mV, type-I Na+ currents were inhibited reversibly by 100 nM indoxacarb and irreversibly by 100 nM DCJW. In contrast, type-II Na+ currents, which inactivate at more positive potentials compared to type I, were not affected by indoxacarb or DCJW at −100 mV, but were inhibited by both at more depolarized potentials, from −60 mV to −40 mV. In both mammalian and insect neurons, the slow inactivation curves of Na+ channels were shifted in the hyperpolarizing direction by indoxacarb and DCJW. For example, the shift amounted to 4.27 mV by 100 nM DCJW in cockroach type I Na+ channels and to 8.1 mV by 1 μM DCJW in rat TTX-S Na+ channels. It was concluded that indoxacarb insecticides bind specifically to inactivated states of sodium channels, and that their differential blocking actions on different Na+ currents result in large part from differences in the voltage dependence of inactivation. Cockroach Na+ channels appear to be more sensitive to the indoxacarb insecticides than rat Na+ channels. Supported by NIH Grant NS14143.

1506 THE INTERACTION OF PARAOXON WITH HUMAN RECOMBINANT ACETYLCHOLINESTERASE.

C. A. Rosenfeld and L. G. Sultatos. *Pharmacology and Physiology, New Jersey Medical School, Newark, NJ.*

Previous studies from this laboratory have reported that the inhibitory constant, k_i, for the inhibition of mouse or rat acetylcholinesterase by the organophosphate paraoxon (*O*, *O*-diethyl *p*-nitrophenyl phosphate) changes as a function of paraoxon concentration. The current study extends these observations by characterizing the kinetic interaction of paraoxon with human recombinant acetylcholinesterase over a wide range of oxon concentrations, including those that yielded pseudo-first order conditions with respect to enzyme, as well as second order conditions. The k_i was calculated by application of continuous systems modeling to experimentally determined residual acetylcholinesterase activity following addition of various paraoxon concentrations (Kardos and Sultatos, 2000, *Tox. Sciences.*, 58: 118-126). Incubation of 100 nM paraoxon with 0.4 nM human recombinant acetylcholinesterase at room temperature revealed a k_i of 0.066 $nM^{-1}h^{-1}$. In contrast, 0.156 nM paraoxon under the same incubation conditions gave a k_i of 0.550 $nM^{-1}h^{-1}$. These data suggest that individual paraoxon molecules at the lower concentration have a greater capacity to inhibit acetylcholinesterase than individual paraoxon molecules at the higher concentration. Furthermore, this observation supports the hypothesis that paraoxon binds to a site separate from the active site, and modifies the reactivity of the active site towards additional paraoxon molecules.

1507 TOXICOKINETIC-TOXICODYNAMIC RELATIONSHIPS IN CASES OF CYHALOTHRIN EXPOSURE.

M. R. Martínez-Larrañaga, M. A. Martínez, M. Martínez, M. J. Díaz, M. T. Frejo, V. J. Castellano, G. Isea and A. Anadon. *Department of Toxicology and Pharmacology, Faculty of Veterinary Medicine, Complutense University, Madrid, Spain.*

The primary site of action of the pyrethroid insecticides is the nervous system. Type II pyrethroids, such as cyhalothrin, are characterized by blocking nerve conduction and by causing convulsions and paralysis. The nerve-blocking action of Type II pyrethroids has been associated with the release of neurotransmitters. Because the value of Toxicokinetic-Toxicodynamic (TK-TD) relationships in medical toxicology is now recognized, the objective of the present study was to correlate the dopamine (DA) and 5-hydroxytryptamine (5-HT) levels and the corresponding cyhalotrin concentrations in nervous tissues of rats exposed to cyhalothrin. Two experiments were carried out: (1) male Wistar rats treated with cyhalothrin (single dose of 20 mg/kg, per os) were killed at different time period after treatment and nervous tissue samples isolated, homogenized and extracted in acetonitrile to determine cyhalothrin levels by HPLC-UV; (2) male Wistar rats treated with cyhalothrin (8 mg/kg, per os, for 6 days) and male Wistar rats treated with corn oil (control animals) were killed 24 h after dosing and nervous tissue samples isolated and contents of DA and 5-HT quantified by HPLC-ED. Our results suggest that TK-TD relationships should be considered for the risk assessment of pyrethroids. This work has been supported by projects No. PB9701236, (DIGICYT), No. 08.8/0002/98 (CAM) and No. 99/0936 (FIS), Spain.

Toxicokinetic-Toxicodynamic (TK-TD) relationships for cyhalothrin

	Kinetic parameters			DA and 5-HT decreasing effect	
Brain regions	C_{max} (μg/mL)	AUC (mg/mL·h)	$t_{1/2}$ (h)	DA (% of control)	5-HT (% of control)
Hippocampus Striatum Frontal cortex Hypothalamus	15.1 ± 18.1 17.4 ± 25.6	215.2 ± 258.2 276.6 ± 0.21	23.0 ± 2.3 18.7 ± 1.6	-32% ± 3% -36% ± 4% -53% ± 3% -54%	-20% ± 3% -45% ± 3% -35% ± 3%

Results are significantly different from the control value at $P<0.05$, $P<0.01$ or $P<0.001$.

1508 COMBINED EXPOSURE TO DIETHYLDITHIOCARBAMATE (DDC) AND IRON (FE): EFFECTS ON THE NIGROSTRIATAL DOPAMINERGIC SYSTEM.

M. Thiruchelvam , S. E. Mayson, E. K. Richfield and D. A. Cory-Slechta. *Department of Environmental Medicine, University of Rochester School of Medicine & Dentistry, Rochester, NY.*

Environmental neurotoxicants, in particular pesticides and heavy metals have been implicated in the etiology of Parkinson's disease (PD). The purpose of the present study was to investigate a possible mechanism for the accumulation of Fe in the substantia nigra pars compacta (SNpc) in PD, and to propose an animal model for the disease. It hypothesized that DDC, a common dithiocarbamate fungicide,

when administered in conjunction with Fe, would chelate this metal and selectively increase its deposition in SNpc. Fe accumulation can increase oxidative stress, and result in dopaminergic (DA) neuronal degeneration and associated decreases in DA and metabolite levels in the striatum. Male C57BL/6 mice of 8 weeks of age were treated i.p. twice weekly for 4 weeks with saline, 100 mg/kg DDC, 10mg/kg (low Fe), 25 mg/kg (high Fe) ferric citrate or with the combination of 100 mg/kg DDC and 10 mg/kg or 25 mg/kg ferric citrate. Combined DDC + Fe produced progressive decreases in locomotor activity over the course of exposure when measured either immediately or 24 hours after treatment. Decreases in locomotor activity were still evident 7 days after the final treatment only in the combined exposure groups, with the DDC + high Fe group showing the greatest decrease. DDC + Fe also significantly decreased levels of striatal DA, DOPAC and HVA. In frontal cortex, the levels of DA and its metabolites were generally decreased by Fe alone, but showed a trend towards higher levels in the combined DDC + high Fe group. These results could indicate a protective role for DDC in the frontal cortex, acting to remove Fe from this region, while having the opposite effect in the nigrostriatal DA system, possibly resulting in an accumulation of Fe in the SNpc. Alternatively, these results could suggest earlier stages of DA dysfunction occurring in frontal cortex. Combined exposure to DDC and Fe may serve as a useful model to study the mechanisms of pathogenesis associated with PD. Supported by ES01247 & ES10791.

1509 NEUROBEHAVIORAL EVALUATION OF HOUSEHOLD EXPOSURE TO DURSBAN.

R. M. Singer. *Independent, Santa Fe, NM.*

Exposure to Dursban has been associated with chronic neurobehavioral effects (headaches, fatigue, problems with memory and concentration, irritability etc.) EPA states that the application of termiticide post construction results in exposures to applicators and to residents that exceed acceptable toxicity limits. Subject: Male, 41 years, high school graduate, married, 3 children Exposure: Approximately 70 gallons of Dursban applied in a structure with foundation cracks. 14 pet fish immediately died. All family members had acute symptoms, including nausea, diarrhea, chest tightness, anxiety. Subject was involved with clean-up intermittently over a period of months. Dust samples one month after the application showed 810, 000 mcg/kg of chlorpyrifos. Air sampling another month later showed elevated VOC's consistent with Dursban exposure. ACHE testing was inconclusive. Later and persistent symptoms included fatigue, memory loss, personality changes, and impaired executive function. Assessment approach: Evaluation 4 years post-incident included an extensive interview, administration of tests which have established normative bases and which are known to be sensitive to neurotoxicity, tests for malingering and distortion, and record review. Findings: Prior IQ was at the 50th%tile, or in the average range. The Neurotoxicity Screening Survey showed results consistent with those of patients diagnosed with neurotoxicity. Deficits included Full-scale IQ 6th%tile, Working Memory at the 2nd%tile, verbal fluency (COWAT) (10th%tile); manual dexterity (Grooved Pegboard) (2nd%tile); auditory information processing and tracking (PASAT) (1st%tile); Stroop Color and Word Test (evaluates mental flexibility) 7th%tile; Visual Search and Attention Test (visual detection skills) 2ndtile. Malingering was ruled out by 5 separate tests. Personality testing using the NEO Personality Inventory found significant personality disorder, but there was no evidence of such disorder pre-incident. Record review found no competing explanations of his illness. Results were consistent with Dursban neurotoxicity.

1510 CHARACTERIZATION OF A MONKEY MODEL OF LASER-INDUCED CHOROIDAL NEOVASCULARIZATION (CNV).

B. J. Christian[1], T. Nork[2], R. A. Leedle[1], J. M. Miller[1] and C. A. O'Neill[3]. *[1]Covance Laboratories, Inc., Madison, WI, [2]Comparative Ophthalmic Research Laboratories, University of Wisconsin, Madison, WI and [3]Genentech Inc., South San Francisco, CA.*

Capillary growth into the subretinal space through breaks in Bruch's membrane occurs in the exudative form of age-related macular degeneration (AMD). The primate CNV model has been used to evaluate potential therapies for AMD. The objective of this study was to characterize the progression of the CNV sites with respect to vascular leakage and to compare these data with histopathologic observations. Seven cynomolgus monkeys underwent laser treatment. Nine laser sites were placed in the macula of each eye with a diode laser (532 nm). Fundus photography and fluorescein angiography were performed at weekly intervals for 6 weeks following laser treatment. Animals were then euthanized. The eyes, perfusion fixed in situ, were collected, embedded in epoxy resin, sectioned at 1 micron, stained with toluidine blue, and examined microscopically. Laser sites were scored according to the intensity of vascular leakage, with Grade IV representing the most severe and clinically relevant form. Grade IV vascular leakage occurred in 22% of individual laser sites involving 63% of eyes. Microscopically, focal neural retina injury and obliteration of Bruch's membrane and the choriocapillaris were observed for most laser sites. In many sites, choroidal capillaries extended into the subretinal space or in a space created by duplication of the retinal pigment epithelial basal lamina. The presence of capillaries in either circumstance generally correlated with Grade IV vascular leakage. Additionally, some sites with less severe vascular leakage also had capillary growth. Intravitreal treatment with a recombinant antigen binding fragment of a humanized monoclonal antibody to vascular endothelial growth factor prevented Grade IV vascular leakage and most capillary proliferation. This study corroborates the usefulness of the monkey CNV model in assessing the efficacy and safety of potential therapies for diseases with subretinal neovascularization such as AMD.

1511 LASER-INDUCED CHOROIDAL NEOVASCULARIZATION IN DRUG DEVELOPMENT — EXPERIENCES WITH THE PRIMATE MODEL.

M. C. Wills[1] and W. H. Bee[2]. *[1]Sierra Biomedical, a division of Charles River, Sparks, NV and [2]Scios, Inc., Sunnyvale, CA.*

Introduction Age-related macular degeneration (AMD) is the most common cause of vision loss in individuals over the age of sixty. Dry AMD accounts for about 90 percent of all cases, but results only in minimal visual symptoms. The wet form of AMD results in severe vision impairment and is characterized by choroidal neovascularization (CNV): vessels grow from the vascular choroid through Bruch's membrane and invade the outer retina, which subsequently leads to degeneration of the RPE- and photoreceptor cells. Among the models used for AMD, non-human primates are the only laboratory mammals having a macula. The experiences with laser induced CNV in primates are described and discussed. Material and Methods Twelve cynomolgus monkeys were used in three studies. Eight to ten lesions were placed around the macula. Lesions were placed in one or both eyes. A green laser operating at 532 nm and a red laser at 810 nm were utilized. The quality of the lesions is influenced by the lesion size (75-100 μm), the laser power (450-900 mW) and the exposure time (0.1-0.2 s). Eyes received either no treatment or an intravitreal injection of control article or Pigment Epithelium-Derived Factor (PEDF). Primary evaluation was achieved with fluorescein angiography. Lesions that developed a clear luminescent circle were counted as CNV. Results The laser-induced AMD model in cynomolgus monkeys has provided important information about CNV. Verteporfin administration prevents angiographic leakage for at least 4 weeks in this monkey model. Our studies confirmed inhibiton of CNV by Pigment Epithelium-Derived Factor (PEDF). The laser lesions are not permanent and start to regress between one and two months. CNV can be re-induced following regression of initial lesions. Discussion While the model differs from clinical AMD in that the CNV regresses, it provides a valid model of neovascularization originating from the choroid. Efficacy and safety of anti-angiogenic compounds can be tested with this model.

1512 ENHANCED EXPRESSION OF VASCULAR COAGULATION ADHESION MOLECULE (VCAM-1) IN 2-BUTOXYETHANOL-INDUCED HEMOLYSIS AND THROMBOSIS IN FEMALE RATS.

C. R. Moomaw, J. F. Foley and A. Nyska. *Laboratory of Experimental Pathology, NIEHS, Research Triangle Park, NC.* Sponsor: R. Maronpot.

In previous studies we found that exposure of rats to 2-butoxyethanol (BE) was associated with morphological changes in red blood cells; hemolytic anemia; and disseminated thrombosis and infarction in bone, heart, lung, brain, eye, liver, tooth, and nasal mucosa. Females are more susceptible to the toxic effects than males. Histopathological changes noted in the eyes included hemorrhages in the retina, photoreceptor degeneration, and thrombi in ciliary processes and limbal blood vessels. Several mechanisms for the thrombosis formation were proposed, such as hemolysis with potential release of protocoagulant factors from destroyed erythrocytes, direct endothelial damage induced by BE, and disturbed blood flow secondary to changes in erythrocytic rheological factors. Vascular cell adhesion molecule-1 (VCAM-1), a membrane glycoprotein belonging to the immunoglobulin supergene family, is functionally important for the adhesion of leukocytes to activated endothelium. P-selectin, a membrane glycoprotein contained within platelets and endothelial cells, is rapidly mobilized to the plasma membrane following cell activation and acts to regulate transient interactions of endothelial cells and leukocytes. In the present work we investigated VCAM-1 and P-selectin expression and distribution over time in our rat BE hemolysis and thrombosis model. Female Fischer F344 rats were exposed to two, three, or four daily doses of BE at 250 mg BE/kg body weight and studied histologically and immunohistochemically using specific monoclonal antibodies. Strong VCAM-1 expression was seen in the cytoplasm of epithelial and stromal ciliary processes and retinal pigment epithelium, only in eyes of rats exposed to 3 and 4 doses of BE, correlating with the appearance of thrombosis in the iris and retina. No change in P-selectin expression was seen. This immunolabeling distribution suggests that VCAM-1 plays a role in the pathogenesis of BE-related thrombosis by promoting adhesion of the circulating cell to endothelium.

1513 D2 AGONIST INDUCED RETINAL DEGENERATION CONFINED TO ALBINO RATS.

A. B. Mauz, S. J. Platz and S. Pollentier. *Boehringer Ingelheim Pharmacology KG, Biberach, Germany.* Sponsor: S. Platz.

The non-ergoline dopamine agonists pramipexole and ropinirole with *in vitro* selectivity and full intrinsic activity at the D2 and D3 dopamine receptor subtypes both induce retinal degeneration that is confined to albino rats in 2-year carcinogenicity studies. For pramipexole, we observed retinal degeneration with a dose-dependent increase of severity in albino Wistar rats under daily administration (2 and 8 mg/kg/day) over two years. No such effects were seen at 0.3 mg/kg/day. The retinal degeneration was morphologically characterized by a reduced thickness of the outer nuclear layer, in particular of the inferior hemisphere. While the observations can be attributed to an age related light-induced mechanism, a possible ocular toxicity could not conclusively be excluded. In a mechanistic study, the effects of continuous light exposure (24 h/day) and concomitant pramipexole administration were further investigated in albino and pigmented rats. Slightly increased retinal degeneration after 13 weeks of treatment was found in albino Wistar rats, but not in pigmented Brown Norway rats. Thus light does not exacerbate retinal degeneration in pigmented rats. In addition, pigmented Brown Norway rats were given pramipexole for 2 years. No retinal degeneration was detected by routine light microscopy after the end of treatment. By means of a highly sensitive image analysis, morphometry revealed only a slight reduction in thickness of the outer nuclear layer. Species-specificity was confirmed for both pramipexole and ropinirole, as no drug-induced retinal degeneration was found in 2-year albino mice carcinogenicity, in 52-week toxicity study in albino (Wistar) rats and 52-week study in non-human primates. The retinal degeneration found in long term studies in albino rats administered pramipexole and ropinirole was not observed in human patients. Based on available data, both compounds therefore produce no greater clinical risk of ocular toxicity than L-dopa or other dopamine agonists.

1514 THE CYNOMOLGUS MONKEY AS A MODEL FOR OCULAR TOXICITY TESTING: INCIDENCE AND CHARACTERIZATION OF SPONTANEOUS LESIONS IN THE OCULAR FUNDUS.

B. Niggemann, U. Korte, G. F. Weinbauer and F. Vogel. *Covance Laboratories GmbH, Muenster, Germany.* Sponsor: P. Thomas.

Man and nonhuman primates share many ocular similarities such as retinal cell anatomy, blood vessel system and presence of a fovea. Because of these similarities ocular function can be investigated satisfactorily in nonhuman primate models in toxicity studies. The cynomolgus monkey (Macaca fascicularis) has proven to be a highly suitable and well established animal model for examining the ocular toxicity of drugs in preclinical research. The spectrum of ophthalmoscopic techniques for evaluation of the posterior part of the eye is comparable to that of man and comprises indirect ophthalmoscopy, fluorescein angiography, fundus photography and electro-retinography. Since it is necessary to be aware of spontaneously occurring ocular diseases and abnormalities to assess the influence of test articles on the eye, the fundus of 1829 animals was examined in otherwise untreated animals. Altogether 134 (7.3%) spontaneous findings were seen, such as optic nerve variations or differences in the retinal pigmentation. Specifically, drusen, variable macula pigmentation, altered translucence, vascular variability, microaneurisms, punctiform hemorrhages and optic nerve disk variability were encountered. Systematic photographic documentation has been initiated using a digital fundus camera in order to establish a photo database to enable standardized diagnosis and description of findings. These spontaneous lesions must be clearly distinguished from traumatic injuries such as chorioretinal or vitroretinal scarring. In summary, extensive background data for the cynomolgus monkey in regard to spontaneous ocular lesions are available and allow the proper assessment of possible drug-related findings in toxicity studies In addition, photo documentation is important to objectively demonstrate the drug-related findings and also document changes over a certain time period.

1515 EVALUATING THE EYE IRRITANCY OF SOLVENTS IN A SIMPLE FRAGRANCE MIXTURE WITH THE BOVINE CORNEAL OPACITY AND PERMEABLITY (BCOP) ASSAY.

N. Cuellar[1], P. H. Lloyd[2], J. E. Swanson[1], J. C. Merrill[3], M. L. Clear[3], G. Mun[3], J. W. Harbell[3] and K. L. Bonnette[4]. *[1]S.C. Johnson & Son, Inc., Racine, WI, [2]SCJ EURAFNE Ltd.,, Egham, Surrey, United Kingdom, [3]Institute for In Vitro Sciences, Gaithersburg, MD and [4]Springborn Laboratories, Inc., Spencerville, OH.*

Fragrances are complex mixtures used in many consumer products. Organic solvents are major components of fragrance formulations functioning mainly as solubilizers and fragrance delivery mechanisms. Solvents appear to have an additive effect on the level of irritation of these formulations. In order to understand this solvent effect, we evaluated the use of the BCOP for predicting the irritancy potential of simple fragrance mixtures containing six commonly used solvents. Additionally, we wanted to correlate the *in vitro* corneal depth of injury with *in vivo* results using histological evaluation. Abattoir-derived corneas were exposed to test materials for 1 and 3 minutes and opacity and permeability end points measured to calculate an *in vitro* score at 20 hours. Negative (medium) and positive (100% ethanol) controls were tested concurrently with all formulations. For comparison to BCOP, potential irritant effects of the test articles were also evaluated in a primary eye irritation study (EPA-OPPTS 870.2400). Animals were scored at 1, 4, and 24 hours followed by a fluorescein exam. Both *in vivo* and *in vitro* tissues were taken for histology. Fragrance/solvent mixtures, except ethanol, showed an increase in irritation *in vivo* and in the BCOP in comparison to solvent alone and fragrance alone. Histological changes included epithelial damage/loss, stromal swelling, and inflammatory infiltration (in vivo) or keratocyte changes (in vitro). These data show the need for using formula specific benchmarks to accurately assess ocular irritation in the *in vitro* BCOP assay, thus eliminating the need for *in vivo* testing of product evaluations.

1516 CORNEAL PERMEABILITY IN AN IMPROVED HOLDER FOR THE BOVINE CORNEA OPACITY AND PERMEABILITY (BCOP)ASSAY.

P. L. Casterton[1], J. Ditlev[2] and J. L. Ubels[2]. *[1]Access Business Group, Alticor Corp., Ada, MI and [2]Biology, Calvin College, Grand Rapids, MI.*

In the BCOP assay corneas are mounted in a holder between two saline-filled chambers. After exposure to a test material, light absorbance and fluorescein permeability to are measured to assess damage to the cornea. Problems with this assay are, 1) the flat surfaces of the holder clamp directly onto the cornea, causing edge damage to the epithelium and the endothelium, and 2) since the bovine cornea is convex and non-spherical, clamping the cornea in the circular opening between the chambers of the holder wrinkles the cornea. We developed a new holder for the BCOP assay that does not damage the cornea because it contacts the sclera and maintains normal curvature. Opacity tests showed that the new holder is a significant improvement over the standard holder. The purpose of this study was to compare corneal permeability to fluorescein between the new holder and standard holders. The permeability (pg/cm^2/minute) of intact corneas, corneas without epithelium and corneas treated with isopropyl alcohol, 1% NaOH, acetone, 30% trichloroacetic acid or benzalkonium chloride (0.01% or 0.1%) for 10 min was determined by measuring fluorescence of samples from the endothelial chamber during a 90 min exposure of the epithelium to 0.0008% Na-fluorescein solution. Permeability in the new holders is lower than in the standard holders for all conditions tested except corneas without epithelium or after acetone treatment. Variability of permeability data from the new holders was markedly less than that from standard holders for all conditions tested. Lower corneal permeability and decreased data variability in the new holders may be due to improved structural integrity of the cornea. Corneal edge damage and wrinkling in the standard holder may increase permeability to a variable extent depending on the degree of trauma to the tissue during the mounting process. Data collected using the new holder appear to be more reliable because the assay begins with an intact cornea. A new BCOP assay protocol should be developed using the improved corneal holder.

1517 ISOLATION AND CHARACTERIZATION OF UDP-GLUCURONOSYLTRANSFERASES FROM FEMALE RHESUS MONKEY.

B. Dean[1], S. Chang[1], P. E. Thomas[2] and C. King[3]. *[1]Drug Metabolism, Merck & Co., Inc., Rahway, NJ, [2]Joint Graduate Program in Toxicology, Rutgers University, Piscataway, NJ and [3]Drug Metabolism, Merck & Co., Inc., San Diego, CA.*

Three isoforms of the UDP-glucuronosyltransferase (UGT) family have been cloned and sequenced from a female rhesus monkey liver cDNA library using primers designed for human and cynomolgus monkey UGTs. The clones were expressed in the HK-293 cell line and microsomes were prepared for activity assays. The first isoform, a UGT1A family member, has sequence homology and substrate specificity very similar to human UGT1A1 and has been named rhesus UGT1A01. The activity of UGT1A01 was assayed by a general UGT substrate [7-hydroxy-4-(trifluoromethyl)-coumarin], in addition to more specific substrates (β-estradiol, bilirubin, 1-naphthol and 17α-ethinylestradiol). UGT1A01 was also detected in a western blot utilizing a polyclonal antibody developed against the human UGT1A family. The two other isoforms are from the 2B family of UGTs, each a product from a single gene, and have been given the names UGT2B9*2 and UGT2B33. Microsomal preparations of the UGT cell lines catalyzed the glucuronidation of 7-hydroxy-4(trifluoromethyl)-coumarin in addition to selected estrogens (17α-ethinylestradiol, β-estradiol and estriol) and morphinan (morphine, naloxone, and naltrexone) substrates. Substrate specificity and kinetic parameters (Km and Vmax)

are similar in comparison to human UGT2B7 and cynomolgus monkey UGT2B9. Kinetic parameters for the estrogen substrates were also determined in microsomes isolated from rhesus liver and kidney. Comparison of Km values for the individual isoforms to that of female liver microsomes suggest the use of β-estradiol-3-glucuronidation, β-estradiol-17-glucuronidation, and estriol-17-glucuronidation to assay UGT1A01, UGT2B9*2 and UGT2B33 activity in rhesus liver microsomes, respectively.

1518 EFFECTS OF MICROSOMAL ENZYME INDUCERS ON THYROID HORMONE GLUCURONIDATION: CHARACTERIZATION OF THE ROLE OF UDP-GLUCURONOSYLTRANSFERASE 1A FAMILY OF ENZYMES.

T. A. Couch and C. D. Klaassen. *University of Kansas Medical Center, Kansas City, KS.*

Microsomal enzyme inducers (MEI) that upregulate UDP-glucuronosyltransferases (UGTs) may also increase the hepatic glucuronidation of thyroxine (T_4), resulting in a reduction of serum T_4 concentration, and a subsequent increase in thyroid stimulating hormone (TSH). Increased TSH can result in increased thyroid cell proliferation, and thus promote thyroid tumors in rodents. Enhanced T_4 glucuronidation, presumably catalyzed by UGT1A1 and 1A6, is suggested to increase TSH levels in rats. The aim of this study was to determine whether increased T_4 glucuronidation, decreased serum T_4, and increased TSH following MEI treatment are dependent on the UGT1A family of enzymes. Male Wistar and UGT1A-deficient Gunn rats were fed control diet or a diet containing pregnenolone-16α-carbonitrile (PCN; 800 ppm), 3-methylcholanthrene (3-MC; 200 ppm), or Aroclor 1254 (PCB; 100 ppm), chemicals known to increase UGTs and decrease serum T_4 levels, for 7 days. Serum free and total T_4 and triiodothyronine (T_3), serum TSH, and hepatic glucuronidation activities toward T_4 and T_3 were determined. T_4 glucuronidation was increased in Wistar rats after MEI treatment: PCN (298%), 3-MC (85%), and PCB (450%). In Gunn rats, T_4 glucuronidation was minimal, and remained unchanged after MEI treatments. T_3 glucuronidation was significantly increased after PCN (121%) or PCB (58%) treatment in Wistar rats, but only PCN increased T_3 glucuronidation in Gunn rats (43%). In both rat strains, PCN, 3-MC, and PCB treatments decreased both total and free serum T_4, whereas serum T_3 was relatively maintained. TSH was increased in Wistar and Gunn rats after PCN (130 and 277%) or PCB treatment (72 and 60%). From these data, it can be concluded that T_4 glucuronidation is catalyzed primarily by UGT1A enzymes. However, the decrease in serum T_4 concentration and increase in TSH are not dependent on increased T_4 glucuronidation, and therefore cannot be attributed to the UGT1A family of enzymes. (Supported by NIH grants ES-08156 and ES-07079)

1519 NUCLEAR RECEPTOR PXR IS REQUIRED FOR INDUCTION OF UDP-GLUCURONOSYLTRANSFERASES IN MOUSE LIVER BY PREGNENOLONE-16α-CARBONITRILE.

C. Chen[1], J. L. Staudinger[2] and C. D. Klaassen[1]. [1]*University of Kansas Medical Center, Kansas City, KS and* [2]*University of Kansas, Lawrence, KS.*

Treatment of mice with the prototypical microsomal enzyme inducer pregnenolone-16α-carbonitrile (PCN) alters the hepatic expression of many genes involved in biotransformation and transport of xenobiotics and endogenous compounds, such as cytochrome P450s 3a and 7a1, and organic anion transporting polypeptide 2 (Oatp2), *via* the nuclear receptor pregnane X receptor (PXR). PCN also induces the glucuronidation of a number of substrates in rat liver. However, the role of PXR in the induction of UDP-glucuronosyltransferases (UGTs) by PCN is not known. Therefore, the aim of this study was to determine the role of PXR in the induction of UGTs by PCN. Four to 6 month-old male PXR-null and wild-type mice received control or PCN-treated (1500 ppm) diet for 21 days. On day 22, livers were taken to prepare microsomes and total RNA to determine UGT activity and mRNA levels, respectively. In wild-type mice, PCN treatment significantly increased UGT activity toward bilirubin, 1-naphthol, chloramphenicol, thyroxine, and triiodothyronine. On control diet, the UGT activity towards the above substrates (except for 1-naphthol) in the PXR-null mice was significantly higher than that of wild-type mice. However, UGT activity in PXR-null mice was not increased by PCN. In agreement with the above findings, mRNA levels of mouse UGT 1A1 and 1A9, which are involved in the glucuronidation of bilirubin and phenolic compounds, were increased about 100% in wild-type mice following PCN treatment, whereas UGT 1A2, 1A6 and 2B5 were not affected. In contrast, PCN treatment had no effect on the mRNA levels of these UGTs in PXR-null mice. Taken together, these results indicate that PCN treatment induces glucuronidation in mouse liver, and that PXR is involved in the regulation of constitutive expression and induction of some UGTs. (Supported by NIH grant ES-08156)

1520 STABLE AND UNSTABLE GLUCURONIDES IN CURCUMIN METABOLISM.

E. Pfeiffer[1], S. Höhle[1], A. M. Solyom[2], B. N. Timmermann[2] and M. Metzler[1]. [1]*Institute of Food Chemistry and Toxicology, University of Karlsruhe, Karlsruhe, Germany and* [2]*Arizona Center for Phytomedicine Research, University of Arizona, Tucson, AZ.*

Curcuminoids are constituents of the rhizome of Curcuma longa, commonly called turmeric, and have recently gained much interest due to their putative anti-inflammatory and anti-carcinogenic activities. Since very little is known about the metabolism of curcuminoids in the mammalian organism, we have studied the biotransformation of the major curcuminoids, i.e. curcumin, monodemethoxy-curcumin and bisdemethoxy-curcumin in liver microsomes, liver cytosol and precision-cut liver slices from non-induced male Sprague-Dawley rats, as well as in microsomes and cytosol from human liver. Hydroxylated or demethylated products were not detected in any of these systems. The major phase I metabolites were identified as hexahydrocurcuminoids by capillary gas chromatography-mass spectrometry. These reductive metabolites were formed in slices and cytosol but not microsomes of rat and human liver. In slices, most of the hexahydrocurcuminoids were present as polar and stable glucuronides, which were also formed when hexahydrocurcuminoids were incubated with microsomes from rat and human liver in the presence of uridine diphosphoglucuronic acid. Rat hepatic microsomes and curcuminoids gave rise to the formation of lipophilic (i.e. ethylacetate-extractable) glucuronides, which were chemically unstable and decomposed rapidly to the curcuminoids in aqueous solution. In contrast, microsomes from human liver converted the curcuminoids to two glucuronides, one of which was lipophilic and the other hydrophilic. Based on the comparison with structurally related glucuronides and on chemical considerations, we postulate that the unstable and lipophilic glucuronides of the curcuminoids carry the glucuronic acid group at the enolic hydroxyl group of the aliphatic moiety, whereas the stable and hydrophilic glucuronides of the hexahydrocurcuminoids represent phenolic glucuronides. Supported in part by NIH Grant P50 AT00474 to the Arizona Center for Phytomedicine Research.

1521 EFFECT OF ESTRAGOLE, SAFROLE AND MYRISTICIN ON *IN VITRO* HUMAN CYP3A4, CYP2D6 AND CYP1A ACTIVITIES.

L. V. Iyer, S. E. LeValley, L. H. Sharp, W. M. Shinn, S. S. Nath, P. G. Catz, R. R. Swezey and C. E. Green. *Metabolism and Pharmacokinetics, SRI International, Menlo Park, CA.*

Some allylbenzene compounds found in essential oils and food flavorings (e.g. basil, anise, fennel, nutmeg) are known to be liver carcinogens in rodents after metabolic activation. The current study was performed to investigate the effect of three of these compounds, estragole, safrole, and myristicin on *in vitro* CYP3A4, CYP2D6 and CYP1A activities in human liver microsomes. Pooled microsomes were incubated with estragole, safrole or myristicin in concentration ranges of 10 nM to 150 μM. CYP3A4, CYP2D6 and CYP1A activities were measured using standard assays - testosterone 6-β-hydroxylation, bufuralol 1'-hydroxylation and 7-ethoxyresorufin *O*-deethylase (EROD), respectively. Appropriate controls were included, including ketaconazole (5 μM) and quinidine (2 μM) as inhibitors of CYP3A4 and CYP2D6 activities. None of the three compounds influenced CYP2D6 activity in the concentration ranges studied. Safrole was a strong inhibitor of CYP3A4 (IC_{50}=0.43 μM) and CYP1A (IC_{50}=2 μM). Estragole and myristicin were also capable of inhibiting CYP3A4 and CYP1A at relatively higher concentrations [estragole - IC_{50} of 5.9 μM (CYP3A4) and 20 μM (CYP1A); myristicin - IC_{50} of 11 μM (CYP3A4) and 5 μM (CYP1A)]. These results indicate that estragole, safrole and myristicin may interfere with the metabolism of concomitantly administered therapeutic drugs, nutritional supplements or other food components that are substrates for CYP3A4 and CYP1A. Supported by funds from NIEHS contract (N01-ES-95437).

1522 *IN VITRO* DETERMINATION OF KINETIC CONSTANTS FOR 1, 3-DICHLOROPROPANE, 2, 2-DICHLOROPROPANE, AND 1, 1-DICHLOROPROPENE IN RAT LIVER MICROSOMES AND CYTOSOL.

R. Tornero-Velez[1], J. Laskey[2] and M. Evans[3]. [1]*ESE, UNC, Chapel Hill, NC,* [2]*SEE, Research Triangle Park, NC and* [3]*NHEERL/ETD/PK, USEPA, Research Triangle Park, NC.*

In 1998, the USEPA placed 1, 3-Dichloropropane (1, 3-DCP), 2, 2-dichloropropane (2, 2-DCP), and 1, 1-dichloropropene (1, 1-DCP) on the Contaminant Candidate List (CCL) and prioritized these drinking water contaminants for health effects research. We determined the kinetic constants of these compounds for the mixed-function oxidase (MFO) and glutathione (GSH) *S*-transerase (GST) pathways because they play an important role in the toxicity of halogenated hydrocarbons. Hepatic microsomal (M) and cytosolic (C) fractions were prepared from male

Fischer 344 rats and an automated equilibrium headspace technique was employed to assess substrate loss. Headspace concentrations were determined by gas-chromatography and concentration time-courses were modeled with a two-compartmental gas-liquid model and analyzed with Matlab®. We observed no metabolism for 2, 2-DCP *via* the GST pathway and only a minor level of clearance *via* the MFO pathway ($7x10^{-4}$ L/h/mg M-protein). The clearance of 1, 3-DCP *via* the MFO pathway was substantially greater than that of 2, 2-DCP ($4.1x10^{-2}$ L/h/mg M-protein; V_{max}=641 pmol/min/mg M-protein, K_m=0.95μM). The clearance of 1, 3-DCP *via* the GST pathway was minor relative to the MFO pathway ($2.4x10^{-4}$ L/h/mg C-protein; 0.6% of microsomal rate), and was consistent with the results of other α, ω-dihaloalkanes that show increased rates of GSH conjugation with increasing chain length. The clearance of 1, 1-DCP *via* the MFO pathway ($2.26x10^{-2}$ L/h/mg M-protein; V_{max}=3430 pmol/min/mg M-protein, K_m=2.5 μM) was substantially greater than for the GST pathway ($3.9x10^{-4}$ L/h/mg C-protein; 1.72% of microsomal rate). In summary, this *in vitro* approach has proven useful in evaluating the metabolism of volatile halogenated hydrocarbons. These rate constants may be incorporated in pharmacokinetic models to predict *in vivo* kinetics. *(This is an abstract of a proposed presentation and does not necessarily reflect United States Environmental Protection Agency (EPA) policy.)*

1523 METABOLISM OF RUTAECARPINE BY RAT LIVER MICROSOMES: A PARTIAL CHARACTERIZATION OF METABOLITES.

S. Lee[1], J. Lee[2], T. Jeon[1], D. Kim[2], E. Lee[1], H. Chang[1], Y. Jahng[1] and T. Jeong[1]. *[1]Pharmacy, Yeungnam University, Kyungsan, Kyungbuk, South Korea and [2]BBRC, KIST, Seoul, South Korea.*

Rutaecarpine is an alkaloid originally isolated from the unripe fruit of *Evodia rutaecarpa*. In addition to its traditional use in treatment of gastrointestinal disorders, rutaecarpine has recently been characterized to have anti-inflammatory activity through cyclooxygenase-2 inhibition. More recently, to develop rutaecarpine as an anti-inflammatory agent, total synthesis of rutaecarpine has successfully been established in our group. In the present studies, metabolic fate and cytochrome P450s involved in the metabolism of rutaecarpine was partially investigated in rat liver microsomes. When rutaecarpine was incubated with rat liver microsomes, 5 major peaks were detected on an HPLC. Four peaks (M1, M2, M4, M5) were believed to be a metabolite hydroxylated on the C-ring and one (M3) to be a metabolite hydroxylated on the phenyl moiety of E-ring. Using enriched rat liver microsomes, the anticipated isoforms of cytochrome P450s in the metabolism of rutaecarpine were partially characterized. The phenobarbital-induced microsomes greatly increased in the formation of the metabolites M1 and M3. The 3-methylcholanthrene-induced microsomes increased in the formation of metabolites M2, M3 and M4. (Supported by a grant of the Korea Research Foundation for the Institute for Drug Research, Yeungnam University).

1524 BIOTRANSFORMATION OF *N*-ETHYL-*N*-(2-HYDROXYETHYL)PERFLUOROOCTANESULFONAMIDE (N-ETFOSE) BY RAT LIVER MICROSOMES, CYTOSOL, AND SLICES.

L. xu[1], A. M. Seacat[2], J. L. Butenhoff[2] and M. W. Anders[1]. *[1]Pharmacology & Physiology, University of Rochester, Rochester, NY and [2]3M Medical Department, 3M Corp., St. Paul, MN.*

Perfluorosulfonic acid derivatives have been used in a range of commercial applications. Perfluorooctanesulfonic acid (PFOS) is environmentally and biologically stable, which has prompted studies about its formation from a range of precursors. The objective of this study was to elucidate the pathways for the biotransformation of the PFOS precursor N-EtFOSE. N-EtFOSE and several putative metabolites were incubated with liver microsomes and cytosol and with liver slices from male, Sprague-Dawley rats. Metabolites were analyzed and quantified by LC/MS/MS. Microsomal fractions fortified with NADPH catalyzed the *N*-deethylation (5.70 ± 0.30 pmol/min/mg protein) of N-EtFOSE to give *N*-(2-hydroxyethyl)perfluorooctanesulfonamide (FOSE alcohol). The broad-spectrum cytochrome P450 inhibitor *N*-benzylimidazole and the NADPH-cytochrome P450 reductase inhibitor diphenyliodonium chloride blocked the biotransformation of N-EtFOSE to FOSE alcohol, indicating a role for cytochromes P450. Microsomal fractions also catalyzed the *N*-dealkylation (117 ± 6 pmol/min/mg protein) of FOSE alcohol to give perfluorooctanesulfonamide (FOSA). Cytosolic fractions fortified with NAD^+ catalyzed the oxidation of FOSE alcohol to perfluorooctanesulfonamidoacetate (FOSAA) (3.12 ± 0.20 pmol/min/mg protein). The oxidation of N-EtFOSE to *N*-ethylperfluorooctanesulfonamidoacetate (N-EtFOSAA) was observed in liver slices, but not in cytosolic fractions. FOSA was biotransformed in liver slices to perfluorooctanesulfonic acid (PFOS), albeit at a low rate. The *O*-glucuronides of N-EtFOSE and FOSE alcohol and the *N*-glucuronide of FOSA were identified by LC/MS/MS. These results show that the major pathway for the biotransformation of N-EtFOSE is *N*-dealkylation to give FOSA. The biotransformation of FOSA to PFOS explains the observation that PFOS is formed in animals given N-EtFOSE. (Supported by the 3M Co.)

1525 *IN VITRO* DETOXICATION OF ORGANOPHOSPHATES AND THEIR MIXTURES BY RAT LIVER AND SERUM ESTERASES.

H. W. Chambers[2] and J. E. Chambers[2]. *[1]Entomology and Plant Pathology, Mississippi State University, Mississippi State, MS and [2]Center for Environmental Health Sciences, Mississippi State University, Mississippi State, MS.*

Organophosphates (OPs), such as the oxon (bioactivated) metabolites of many common phosphorothionate insecticides, can be detoxified through the stoichiometric phosphorylation of B-esterases [carboxylesterases (CbxE) and cholinesterases (ChE)] or through the catalytic detoxication by calcium-dependent A-esterases. The detoxication of five OPs by liver and serum esterases was quantified using an exogenous source of cholinesterase (from bovine brain) to determine residual OP concentrations. The compounds studied were the oxons of three diethyl phosphorothionates, chlorpyrifos-oxon, diazoxon and paraoxon, and of two dimethyl phosphorothionates, methyl paraoxon and azinphosmethyl-oxon. Inhibition of CbxE (as monitored by the hydrolysis of the model substrate 4-nitrophenyl valerate) by the OPs was measured in parallel samples. With EDTA-treated samples to prevent A-esterase hydrolysis, in serum, OP detoxication correlated reasonably well with CbxE inhibition (194-310 pmol OP detoxified/unit CbxE inhibited), suggesting that stoichiometric detoxication by CbxE was responsible for the majority of the detoxication observed. In liver, however, detoxication of diethyl OPs (134-146 pmol/unit) was lower than that for dimethyl OPs (717-728 pmol/unit). It seems likely that, in liver, a second detoxication mechanism is operating on the dimethyl OPs. Detoxication of OP binary mixtures, whether added simultaneously or sequentially, was within the expected range, suggesting that no greater-than-additive interactions occurred *in vitro*. Only two compounds tested (chlorpyrifos-oxon and diazoxon) were substrates for calcium-activated A-esterase at the sub-micromolar concentrations assayed. Prior treatment with non-substrate OPs (i.e., paraoxon, methyl paraoxon and azinphosmethyl-oxon) had no measurable effect on hydrolysis of either of the substrate OPs. (Supported by American Chemistry Council CRAM 2a-99).

1526 COMPARISON OF HEPATIC *IN VITRO* METABOLISM OF THE PYRROLIZIDINE ALKALOID SENECIONINE IN SHEEP AND CATTLE.

J. M. Duringer[1], M. Craig[1] and D. Buhler[2]. *[1]Biomedical Sciences, Oregon State University, Corvallis, OR and [2]Environmental and Molecular Toxicology, Oregon State University, Corvallis, OR.*

Pyrrolizidine alkaloids (PAs) are found in approximately 3% of the world's flowering plants and represent a significant group of plant toxins that affect livestock, wildlife and human health. In particular, tansy ragwort (Senecio jacobaea) is a plant found throughout the rangelands of the Pacific Northwest that produces PAs, including senecionine, which are toxic to the livestock that consume them. Sheep and cattle have been found to differ significantly in their response to PAs with sheep being relatively resistant to toxicity, while cattle are more susceptible. Resistant species abate PA toxicity by: producing a larger proportion of the non-toxic N-oxide metabolite versus the toxic DHP (6, 7-dihydro-7-hydroxy-1-hydroxymethyl-5H-pyrrolizine) metabolite; conjugating the DHP product to glutathione; and eliminating the parent compound at a faster rate than susceptible species. In this study, we compared the *in vitro* hepatic metabolism of senecionine in sheep and cattle, two species commonly affected by PA-containing plants, using incubations of liver microsomes and cytosol and studied the production of the N-oxide and DHP metabolites as well as metabolism of the parent compound by HPLC. It was found that the two species differed in production of N-oxide ($p<0.0001$) and in the percent of parent compound metabolized ($p<0.0001$). Gender differences were found to be non-significant. The Km and Vmax for both N-oxide and DHP were studied and compared among the two species and between both genders. They differed on most comparisons. This data characterizes the metabolism of senecionine in two livestock species that are exposed to PA-containing plants and reaffirms the interspecies variability in metabolism of this group of toxins. Further, these results point to the importance of N-oxide production and the ability of the parent compound to be metabolized as important factors in sheep (a PA-resistant species) for abating PA toxicity.

1527 MECHANISM(S) OF DIFFERENTIAL INHIBITION OF HEPATIC AND PANCREATIC FATTY ACID ETHYL ESTER SYNTHASE ACTIVITY BY TRI-*o*-TOLYL PHOSPHATE METABOLITES.

B. S. Kaphalia, K. A. Mericle and G. Ansari. *Pathology, The University of Texas Medical Branch, Galveston, TX.*

Fatty acid ethyl ester synthase (FAEES) is a family of enzymes involved in conjugation of fatty acids with endogenous and exogenous substrates having hydroxyl and/or amino group(s). In previous studies, we have reported that FAEES activity is expressed by beta-esterases, carboxyl esterase (CE) in the liver and cholesterol es-

terase (ChE) in the pancreas. The hepatic FAEES is structurally and functionally different than that in the pancreas. We also found that hepatic FAEES activity is inhibited by tri-o-tolyl phosphate (TOTP, beta-esterase inhibitor), and that metabolism of TOTP is prerequisite for such inhibition. However, no inhibition of FAEES activity was found in the pancreas. Therefore, we synthesized two putative metabolites of TOTP [2-o-(cresyl)-4H-1:3:2-benzodioxaphosphoran-2-one (CBDP; cyclic saligenin phosphate) and di-o-tolyl-o-(alpha-hydroxy) tolyl phosphate (hydroxylated-TOTP)] and studied their effect on FAEES activity in HepG2 (hepatocellular carcinoma) and AR42J (rat pancreatic tumor) cells. Both metabolites inhibited FAEES activity significantly in HepG2 cells within 15 min of incubation. However, no inhibition was observed in AR42J cells, similar to our previous findings in cell culture/in vivo studies using TOTP as inhibitor. To further unfold the chemistry of FAEES inhibition, we incubated commercial grade CE and ChE with CBDP or hydroxylated-TOTP, and found that both metabolites irreversibly inhibit FAEES as well as esterase activity of both CE and ChE. In order to identify the binding site of CE and ChE for CBDP, commercial grade CE or ChE was incubated with CBDP and subjected to 2-D gel electrophoresis for proteomic analysis. These studies will be helpful in elucidating the mechanism of FAEES inhibition and understanding its biochemical significance.

1528 MODULATION OF FATTY ACID METHYL ESTER FORMATION IN RATS USING TRI-*o*-TOLYLPHOSPHATE.

K. A. Mericle, B. S. Kaphalia and G. Ansari. *Experimental Pathology, University of Texas Medical Branch, Galveston, TX.*

Fatty acid methyl esters (FAMEs) are formed *via* conjugation of fatty acids with methanol, catalyzed by Fatty Acid Ethyl Ester Synthase (FAEES). Toxicity of these esters has been reported *in vitro* and *in vivo*. Since the same protein expresses FAEES and esterase activity, we hypothesize that inhibitors of esterases (FAEES) such as tri-o-tolylphosphate (TOTP) can modulate the formation of FAMEs. To test this, four groups of rats were used, group 1 served as control (vehicle only). Group 2 was treated with methanol only (3 g/kg *via* gavage), group 3 was given TOTP only (100 mg/kg i.p. in corn oil) and group 4 was administered TOTP as in group 3, followed by methanol after 18 hours. Three hours after exposure, animals were sacrificed and FAEES activity and FAME levels were measured in blood, liver, pancreas and brown fat. About 95% of FAEES activity was inhibited in the liver and whole blood of TOTP-treated rats (group 3) but no inhibition was observed in the pancreas. Total hepatic FAMEs were found to be lowest for the TOTP-treated group and highest in the methanol-treated animals (group 2). Total pancreatic FAMEs in different groups were unchanged (not statistically different), while significant increases in brown fat were observed in both methanol- treated groups. Low levels of FAMEs detected in the whole blood were found to be inconclusive. To verify that the oxidative metabolism of methanol was unaffected by TOTP, alcohol dehydrogenase activity was also measured and found to be unchanged in any group as compared to control. These results demonstrate that TOTP inhibits the formation of FAMEs in the liver *via* inhibition of FAEES, but not in the pancreas. These results confirm that hepatic metabolism of methanol to FAMEs can be modulated by esterase (FAEES) inhibitors.

1529 BIOTRANSFORMATION OF 1, 1, 1, 3-TETRACHLOROPROPANE IN RATS AFTER INHALATION EXPOSURE.

W. Dekant and T. Bayer. *Department of toxicology, University of Wuerzburg, Wuerzburg, Germany.*

1, 1, 1, 3-Tetrachloropropane is used in the production of chlorinated silicone fluids. Inhalation exposure of rats to 1, 1, 1, 3-tetrachloropropane results in myocarditis. The heart is a target organ not yet observed with chlorinated hydrocarbons. Likely, the organ-specific toxicity is based on biotransformation. To elucidate a mechanism explaining the organ-specific toxicity of 1, 1, 1, 3-tetrachloropropane, the biotransformation was studied in male and female rats (n = 5) after inhalation exposure to 100 ppm and 200 ppm for 6h. Urine samples were collected for 72 h after the end of the exposure and chlorine-containing metabolites in the urine were identified by GC/MS. In urine, 1, 1, 1-trichloropropane-3-ol was present as a major metabolite (likely as glucuronide) and 3, 3, 3-trichloropropionic acid and 3, 3-dichloroacrylic acid were excreted as minor metabolites in addition to very small amounts of the parent compound. Only minor parts of the calculated received doses of 1, 1, 1, 3-tetrachloropropane were recovered in urine as chlorine-containing metabolites. Elimination of these metabolites with urine was rapid. Inhalation of 1, 1, 1, 3-tetrachloropropane also resulted in an increase in the urinary excretion of acetone and of free fatty acids, and in the urinary excretion of 2-butanone, 2-pentanone and 2-hexanone. These results suggest a cytochrome P450 mediated oxidation of 1, 1, 1, 3-tetrachloropropane to give 3, 3, 3-trichloropropanal, which is reduced to 1, 1, 1-trichloropropane-3-ol or oxidized to 3, 3, 3-trichloropropionic acid. 3, 3, 3-Trichloropropionic acid and 3, 3-dichloroacrylic acid may be the metabolites responsible for toxicity. The cardiac toxicity of 1, 1, 1, 3-tetrachloropropane may be due to biotransformation of the metabolite 3, 3, 3-trichloropropionic acid by mitochondrial b-oxidation to give 3, 3-dichloroacryloyl-CoA acid. This a, b-unsaturated carbonyl compound may react with nucleophilic sites in mitochondria and may thus induce mitochondrial dysfunction and myocarditis since the heart is highly dependent on mitochondrial fatty acid oxidation for energy production.

1530 ALIPHATIC NITRILES: EFFECT OF ALCOHOL ON TOXICITY AND METABOLISM IN MALE SPRAGUE-DAWLEY RATS.

M. Y. Farooqui. *Biology, University of Texas Pan American, Edinburg, TX.*

Effect of alcohol was studied on the toxicity and metabolism of one unsaturated aliphatic nitrile acrylonitrile and was compared with the effect on one saturated nitrile acetonitrile in male Sprague-Dawley rats. The experimental rats received an oral dose of alcohol 0, 2, 3 or 4.5 g / Kg as a 50% aqueous solution and control rats received an equal volume of glucose solution isocaloric to each of the alcohol solutions of 0. 3.5, 5.3 and 7.9 g / Kg glucose respectively. Twelve hours following alcohol or glucose administration, the rats received an oral sublethal dose of 0.5 LD50 of acrylonitrile or 0.25 LD50 of acetonitrile. Animals were then observed for the typical signs of nitrile toxicity including salivation, lacrimation, convulsions. Both rat groups exhibited typical signs of nitrile toxicity except that the alcohol group was faster in exhibiting the signs. Known effects of nitriles on cyanide and thiocyanate production and glutathione metabolism were studied in organs and biological fluids of rats from both groups. The effect of alcohol was found to be dose dependent. Blood cyanide concentration was significantly lowered by alcohol at 12 hours after acetonitrile administration at the alcohol dose of 2 and 3 g / Kg whereas this effect was noticed at the alcohol dose of 3 and 4.5 g / Kg at 12 hour after acrylonitrile administration. Analysis of organ homognates including those of liver, spleen, brain, and kidney showed that the effect of alcohol on the nitrile induced effect on glutathione metabolism was dose and time dependent without a specific pattern. (Supported by NIH South Texas Doctoral Bridge Program Grant # 2 R25GM50080).

1531 MUTAGENICITY STUDIES OF URINARY METABOLITES FROM RATS TREATED ORALLY WITH LOCAL ANESTHETICS.

J. M. Sanders[1,2], A. Abu-Shakra[3], L. T. Burka[1] and M. L. Cunningham[1]. *[1]NIEHS, Research Triangle Park, NC, [2]NCSU, Raleigh, NC and [3]NCCU, Durham, NC.*

Biotransformation in mammals of the local anesthetics, lidocaine (LD) and prilocaine (PL) may result in the formation of suspected carcinogens, 2, 6-xylidine (XD) and *o*-toluidine (TD), respectively. Metabolic activation of LD and PL could result in the excretion of mutagens in urine following administration of either compound. As part of an effort to characterize the carcinogenic potential of LD and PL, urine was collected for testing in the Ames mutagenicity assay from male F344 rats administered either LD, PL, XD, or TD at 100 mg/kg by gavage. Urine samples were filter-sterilized, incubated w/wo glucuronidase/sulfatase and Aroclor 1254-induced rat S9, and tested with *Salmonella typhimurium* strains TA98 and TA100 directly in the plate incorporation assay. Positive controls included testing for the presence of mutagens in urine of rats receiving 40 mg/kg of benzo[a]pyrene (B[a]P) by gavage. Initial experiments investigated the mutagenicity and toxicity of parent compounds LD and PL to Salmonella strains TA97, TA98, TA100, TA102, and TA104, w/wo S9 metabolic activation. No mutagenicity was observed for either compound in any of the strains at doses of 5 to 200 μmol/plate. Toxicity varied among treatment groups, but generally was not observed at doses lower than 100 μmol/plate. Urine samples (250 μl) collected 8 hours following oral administration of either LD or PL, incubated with glucuronidase/sulfatase, were not toxic or mutagenic to strains TA98 and TA100, w/wo S9 metabolic activation. In contrast, 2-5 fold increases in TA98 and TA100 revertants were observed for 0-8 hr urine from B[a]P-treated rats. Larger volumes (500 μl) of untreated urine from rats receiving either LD, PL, XD, or TD were neither toxic nor mutagenic to strain TA100. No potent mutagens have been detected in urine of LD- or PL-treated rats in this study. However, these results do not rule out the existence of either LD- or PL-derived mutagens in urine of these rats at levels below the limit of detection of the present experimental design.

1532 EFFECTS OF CALORIC INTAKE ON ETHANOL METABOLISM IN PREGNANT RATS: ROLE OF ALCOHOL DEHYDROGENASE AND ALDEHYDE DEHYDROGENASE.

M. J. Ronis[1,3], M. Zipperman[3], B. Gardner[3], T. Fletcher[3], T. M. Badger[2,3], M. Ferguson[3], K. Hale[3] and R. Haley[3]. *[1]Pediatrics, University of Arkansas for Medical Sciences, Little Rock, AR, [2]Physiology, University of Arkansas for Medical Sciences, Little Rock, AR and [3]Arkansas Children's Nutrition Center, Little Rock, AR.*

Urine ethanol concentration (UEC) dynamics were examined in animals infused ethanol intragastrically *via* total enteral nutrition at caloric levlels of 220, 187 or 154 $kcal^{3/4}$/kgd. When ethanol was infused into pregnant rats from gestational(GE)

d 6 as part of 220 kcal diets beginning at 10 g/kg/d and ending with constant infusion at 12 g/kg/d on GE d 12, little ethanol was found in the urine. When ethanol infusion began at 12.5 g/kg/d and ended at 15 g/kg/d, UECs peaked at 300-500 mg/dl on GE d 15-17 (d 9-10 of infusion). When pregnant rats were infused with 10-12 g/kg/d ethanol as part of 154 kcal diets, UECs peaked at 400-600 mg/dl on GE d 12-13 (d 6-7 of infusion). In a second study, when a similar protocol was utilized to compare infusion of 10-12 g/kg/d ethanol in non-pregnant rats fed 187 or 220 kcal diets with pregnant rats fed 220 kcal, UECs peaked at d 6-7 of infusion in the non-pregnant rats but only at d 9-10 of infusion in the pregnant animals and the area under the UEC-time curve was reduced in the pregnant rats ($p \leq 0.05$) compared to the other two groups. Although we have evidence that pulsatile UECs are associated with increased expression and activity of hepatic class I alcohol dehydrogenase (ADH), maternal hepatic ADH activity measured on GE d 20 was identical in non-pregnant and pregnant rats fed 220 kcal diets. However, maternal hepatic aldehyde dehydrogenase (ALDH) activity was significantly elevated on GE d 20. In contrast, under-nutrition using 154 kcal resulted in reduced hepatic maternal ADH activity on GE d 20 ($p \leq 0.05$). Thus ALDH may be responsible for increased ethanol metabolism in pregnancy and impaired ADH activity may account for increased UECs in undernourished pregnant animals. Supported in part by R01 AA12819 (MJJR).

1533 EFFECT OF POLYUNSATURATED FATTY ACIDS ON DNA ADDUCT FORMATION BY HETEROCYCLIC AROMATIC AMINES IN HCA-7 CELLS.

H. J. Moonen[1], M. van Zwam[2], M. van Herwijnen[1], J. Kleinjans[1] and T. de Kok[1]. *[1]Health Risk Analysis & Toxicology, Maastricht University, Maastricht, Netherlands and [2]Toxicology, Wageningen University, Wageningen, Netherlands.* Sponsor: M. van den Berg.

Background: The metabolic activation of the heterocyclic aromatic amines (HCA) 2-amino-3-methylimidazo[4, 5-*f*]quinoline (IQ) and 2-amino-1-methyl-6-phenylimidazo[4, 5-*b*]pyridine (PhIP) can proceed *via* both a hepatic and an extrahepatic pathway. In the extrahepatic pathway, the enzyme cyclooxygenase (COX) is believed to play a crucial role. Fatty acids, a class of compounds that is known to play a major role in carcinogenesis, are also subject to metabolic activation by COX. *Objective*: In this study, we investigated the effect of the polyunsaturated fatty acids (PUFA) arachidonic acid (AA, 20:4*n*-6) and eicosapentaneoic acid (EPA, 20:5*n*-3) on DNA adduct formation by IQ and PhIP in the human adenocarcinoma cell line HCA-7, which is known to express high levels of COX-2. Furthermore, the relative importance of both COX-2 and cytochrome P4501A2 (CYP1A2) was studied by using selective enzyme inhibitors. *Methods*: HCA-7 cells were exposed to either 25 µM IQ or 50 µM PhIP and different concentrations of AA and EPA. Indomethacin (IM), NS-398 and phenethyl isothiocyanate (PEITC) were used as inhibitors of COX, COX-2 in particular and CYP1A2, respectively. After 24 h exposure, the cells were harvested and DNA was isolated. Finally, DNA adduct levels were determined using ^{32}P-postlabeling. *Results*: Both AA and EPA exerted an increasing effect on DNA adduct formation in HCA-7 cells by both IQ and PhIP in a concentration dependent manner for concentrations up to 60 µM. All enzyme inhibitors showed a dose dependent decrease in adduct formation by both IQ and PhIP, indicating that HCA-7 cells also express CYP1A2 activity, and that both COX and CYP1A2 are involved in the metabolic activation of IQ and PhIP. *Conclusions*: These results indicate that COX, and more specifically COX-2, can play an important role in the metabolic activation of HCA. Furthermore, PUFA can stimulate the activation of HCA by COX, leading to higher amounts of HCA-DNA adducts in HCA-7 cells.

1534 SPECIES DIFFERENCES IN THE METABOLISM OF DI(2-ETHYLHEXYL)PHTHALATE (DEHP) IN SEVERAL ORGANS FROM MOUSE, RAT AND MARMOSET.

Y. Ito[1], H. Yokota[2], R. Wang[3], O. Yamanoshita[4], G. Ichihara[1], H. Wang[1], Y. Kurata[5] and T. Nakajima[1]. *[1]Occupational and Environmental Health, Nagoya University Graduate School of Medicine, Nagoya, Aichi, Japan, [2]Rakuno Gakuen University, Hokkaido, Japan, [3]National Institute of Industrial Health, Kanagawa, Japan, [4]Shinshu University School of Medicine, Matsumoto, Japan and [5]Mitsubishi Research Institute, Tokyo, Japan.*

In order to clarify species differences in kinetics of Di(2-ethylhexyl) phthalate (DEHP), we measured the activities or expression of five enzymes, lipase, UDP-glucuronyltransferase (UGT), cytochrome P450 4A (CYP4A), alcohol dehydrogenase (ADH) and aldehyde dehydrogenase (ALDH), in several organs (livers, lungs, kidneys, and small intestines) from mice, rats and marmosets. Lipase activity, measured by a formating rate of mono(2-ethylhexyl)phthalate (MEHP) from DEHP, was ranged from 22 to 148 times: the activity was the highest in the small intestine from mice and the lowest in the lung from marmosets. UGT activity for MEHP in liver microsomes was the highest in mice, followed by rats and marmosets. The differences, however, were only marginal when compared with those of lipase activity. CYP4A was constitutively expressed in livers from rats, but not in those from mice and marmosets at the same conditions. ADH activity showed the highest in the liver from any animals either used 2-ethylhexanol or 2-phenoxyethanol as a substrate. ADH activity also represented species differences; the activity in the livers from marmosets was 1.6 to 3.9 times as high as those from rats or mice, which was quite different from the results of lipase or UGT activity. ALDH activity was the highest in the liver from any animal, similar to ADH activity. In comparison among species, the activity was higher in rats or marmosets (2 to 14 times) than in mice. These results clearly show that species differences exist in the metabolism of DEHP, and lipase activity is the most prominent.

1535 REDOX-CYCLING OF 7H-DIBENZO[C, G]CARBAZOLE-3, 4-DIONE AND SUPEROXIDE FORMATION.

D. Warshawsky and W. Xue. *Environmental Health, University of Cincinnati, Cincinnati, OH.*

7H-dibenzo[c, g]carbazole (DBC) is a potent environmental carcinogen. We have previously reported a metabolic activation mechanism of DBC which involves the formation of reactive and redox active o-quinone of DBC (DBC-3, 4-dione, DBCQ) [Polycyclic Aromatic Compounds, 22, 295-300 (2002), Chem. Res. Toxicol. 15, 915-921 (2002)]. The DBCQ has been demonstrated to be a highly reactive Michael acceptor capable of adduction with nucleophiles and DNA/RNA constituents both *in vitro* and *in vivo*. The present study provides experimental evidence that the DBCQ is redox active. The non-enzymatic reduction rate of DBCQ by NAD(P)H was determined to be 0.22±0.05 nmol/min (n=8) for DBCQ and the oxidation of NAD(P)H was accompnied by the formation of superoxide anion radical. The superoxide formation rate was determined to be 0.13 ±0.05 nmol/min (n=4). These data indicate that in the redox-cycle for DBCQ, reactive oxygen species (ROS, i.e. hydrogen peroxide, hydroxyl radical and superoxide anion) are involved. Since ROS is related to oxidative DNA damage, DBC quinone is produced and may be responsible for the extreme cytotoxicity of DBC.

1536 METHAMPHETAMINE METHYLATION IN AQUEOUS SOLUTIONS OF FORMALDEHYDE.

P. Tirumalai, P. M. Gannett, P. S. Callery, T. M. Bland and T. S. Tracy. *Basic Pharmaceutical Sciences, WVU-HSC, Morgantown, WV.* Sponsor: M. Davis.

Methamphetamine is a widely abused drug in the US and is of forensic and toxicologic interest due to its potential involvement in deaths from intentional or accidental overdose. If drug involvement in a death is not suspected prior to embalming of the body, it may become necessary to measure drug levels in tissues that have been embalmed or preserved in formaldehyde-based embalming fluids. We hypothesized that formaldehyde would react with methamphetamine, producing new chemical entities, with the potential for complicating forensic and toxicologic analyses. To simulate the range of conditions tissues might be exposed following embalming or preservation, methamphetamine was reacted with 5, 10 or 20% formaldehyde solutions at pH 3.5, pH 7 and pH 9.5. Degradation profiles were obtained at day 0, 1, 7 and 30- post initiation of reaction, by HPLC with UV detection and the products characterized and identified by LC-MS. There was no significant degradation at pH 3.5. The percent methamphetamine remaining under other experimental conditions is presented in the table below.The decomposition of methamphetamine appears to be both pH and formaldehyde concentration dependent with the primary reaction product being N-methylmethamphetamine(1-phenyl-2-dimethylaminopropane). Supported under award number 2001-RC-CX-K013 from the Office of Justice Programs, National Institute of Justice, Department of Justice. Points of view in this document are those of the authors and do not necessarily represent the official position of the US Department of Justice.

%Formaldehyde	Day 1(%remaining)	Day 7(%remaining)	Day 30(%remaining)

1537 COMPARATIVE METABOLISM AND DRUG RESIDUES IN PHEASANTS, BOBWHITE QUAIL, PARTRIDGE AND CHICKENS.

K. A. Cortright, I. T. Taylor and A. L. Craigmill. *Environmental Toxicology, UC Davis, Davis, CA.*

Currently there is interest in grouping similar avian species with regard to their metabolism of drugs and toxicants. This interest stems from needs in avian production and clinical medicine. The present studies were conducted to compare the metabolic capabilities of four Galliform species that are raised commercially for food and also found in the wild. Residues of the anthelmintic fenbendazole were quantified in edible tissues of pheasants, partridge and bobwhite quail after 6 days exposure to 100 ppm fenbendazole in feed. Liver, breast muscle, leg muscle, and skin were harvested at intervals after the final dose for HPLC measurement of fenbendazole (FBZ), fenbendazole sulfoxide (FBZ-SO) and fenbendazole sulfone (FBZ-SO2). In partridge and pheasants, only FBZ-SO and FBZ-SO2 were recovered from all tissues; in bobwhite quail, parent FBZ was also found in all tissues at all times. In partridge and pheasant the concentration of total residues was below FDA tolerances established for the fenbendazole marker residue (FBZ-SO2) in turkeys for liver (6 ppm) and muscle (2 ppm). In bobwhite quail, liver residues exceeded these tolerances, but residues in muscle were below tolerance. To further explore differences in metabolism, hepatic microsomal substrate assays are being conducted with pheasants, bobwhite quail, and chickens. A variety of substrates representing different cytochrome P450 isozymes are being tested. Preliminary results measuring constitutive ethoxyresorufin-O-deethylase activity show pheasants averaging 485 pmole product/min x mg protein with 0.44 nmole total cytochrome P450 per milligram protein. Chickens show about one-tenth of this activity at 39 pmol product/min x mg protein and 0.16 nmole total P450 per milligram protein. These studies suggest that there may be significant differences in drug/toxicant metabolism among the four game bird species. The quantitative versus qualitative nature of these differences is the focus of future studies. Supported by the USDA National Research Support Program Number 7 Minor Use Animal Drug Program.

1538 SYNTHESIS OF RETINYL PALMITATE- AND RETINOL-DERIVED PHOTOCHEMICAL, OXIDATIVE, AND DEHYDRATION PRODUCTS.

V. M. Samokyszyn. *Pharmacology and Toxicology, University of Arkansas for Medical Sciences, Little Rock, AR.* Sponsor: J. Hinson.

Retinyl palmitate (RP) is a major component of numerous skin creams and lotions. In addition, significant skin surface areas are exposed to solar radiation following topical application of these products. However, the metabolic and photochemical fate of RP, particularly following chronic topical applications, has not been elucidated. We have synthesized several retinoids, using novel synthetic methods, to serve as HPLC standards; These compounds are hypothesized to be generated *in vivo*. 9Z-Retinol (9Z-ROL) was synthesized by reduction of 9Z-retinal with sodium borohydride. 9Z-ROL or 13Z-ROL were reacted with palmatoyl chloride in the presence of 1, 8-bis-(dimethylamino)naphthalene (Proton Sponge) and using 4-dimethylaminopyridine as a catalyst to yield the corresponding 9Z and 13Z geometric isomers of RP. These compounds are anticipated to be generated upon exposure to UV through excited singlet states. 5, 6-Epoxy-RP was synthesized by regiospecific oxidation of RP with monoperoxyphthalic acid or 3-chloroperoxybenzoic acid. The corresponding oxirane of ROL was synthesized by oxidation of retinyl acetate with peracid followed by saponification. These products are anticipated to be generated *in vivo* through peroxyl radical-dependent mechanisms. 4-Oxo-RP was synthesized from RP *via* regiospecific oxidation using manganese dioxide. 4-Hydroxy-RP was synthesized by reduction of the latter with sodium borohydride. 4-Hydroxy-ROL and 4-oxo-ROL were synthesized by oxidation of retinyl acetate with manganese dioxide followed by reduction with lithium aluminum hydride or by saponification, respectively. These oxidized retinoids are anticipated to be generated *in vivo* as a consequence of cytochromes P450- and alcohol dehydrogenase-dependent activities. Anhydroretinol was synthesized by reaction of retinyl acetate with Amberlyst 15 in ether. The structures of all products and intermediates were confirmed on the basis of NMR, IR, UV, and mass spectrometry. This work was supported by the National Toxicology Program.

1539 FURTHER STUDIES ON THE SELECTIVITY AND INHIBITORY MECHANISM OF AZAMULIN, A NEW CYP3A CHEMICAL INHIBITOR PROBE.

D. M. Stresser, M. I. Broudy, S. S. Dehal, C. J. Patten and C. L. Crespi. *BD Biosciences, Woburn, MA.*

Azamulin (14-O-(5-(2-amino-1, 3, 4-tiazolyl)thioacetyl)-dihydromutilin) is an azole derivative of the pleuromutilin class of anti-infectives. We have extended our studies on the cytochrome P450 (CYP) isoform inhibition specificity of azamulin. Previously, we have shown that inhibition specificity for CYP3A4, as determined by IC50 value, was more than three orders of magnitude greater than all enzymes examined from the CYP1 and CYP2 families. These families, along with CYP3, encompass the major CYP enzymes that metabolize xenobiotics. Selectivity was superior to another commonly used inhibitor of CYP3A, ketoconazole. We now extend our results to the CYP4 family, which may also metabolize xenobiotics. Both ketoconazole and azamulin were non-inhibitory to CYP4F3b and CYP4A11 activities at concentrations considered CYP3A-selective. However, same concentration of ketoconazole inhibited CYP4F2 activity approximately 62%, whereas inhibition by azamulin was negligible. The Ki of azamulin for CYP3A-catalyzed testosterone 6βhydroxylase activity in human liver microsomes was 0.076 μM as determined by Dixon plot. Inhibition is consistent with a mixed-type mechanism. Our data further demonstrate the suitability of azamulin as a highly potent and selective inhibitor for assessing the catalytic role of CYP3A in microsomes from liver or extrahepatic tissues.

1540 OXIDATIVE STRESS STIMULATES THE FORMATION OF CYTOCHROME P450 3A PROTEIN CONJUGATION IN A PROCESS THAT IS INHIBITED BY SUBSTRATE.

A. L. Kimzey, N. Bollinger, S. Shen and R. C. Zangar. *Pacific Northwest National Laboratory, Richland, WA.*

We recently demonstrated that hepatic microsomes from nicardipine-treated rats formed cytochrome P450 3A (CYP3A)-ubiquitin conjugates when incubated at 37°C. These protein complexes apparently were the result of CYP3A cross-linking with other proteins that were already polyubiquitinated rather than direct "classical" ubiquitination of CYP3A. CYP3A substrates inhibited this cross-linking and the associated protein degradation, suggesting that the process is important in substrate-mediated stabilization of CYP3A. We now demonstrate that oxidative stress appears to be a key factor in the formation of CYP3A-ubiquitin conjugates in incubated microsomes and primary cultured rat hepatocytes. Our data further suggest that the effects of oxidative stress are mediated by lipid hydroperoxides, which are utilized by CYP3A during catalysis in a "peroxide shunt" pathway. Hydroxynonenal (HNE) is an autolysis product of lipid hydroperoxides. HNE-protein adducts were concentrated in the same high mass range as the CYP3A-ubiquitin conjugates, suggesting that HNE may be directly responsible for the protein crosslinking. Therefore, these studies suggest a new model of the molecular processes involved in substrate-mediated stabilization of CYP3A. That is, in the presence of substrate, the lipid hydroperoxides are consumed as cofactors in the CYP3A catalytic cycle. In the absence of substrate, the lipid hydroperoxides still bind CYP3A but eventually degrade to reactive products that can crosslink proteins and stimulate protein degradation. This research was supported by NIH grant DK54812.

1541 CYTOCHROME P450 CYP2E1 AND CYP 3A4 ACTIVITIES IN HEPATITIS C PATIENTS.

S. I. Shedlofsky[1], R. Tosheva[1], K. Anderson[2] and R. Blouin[3]. *[1]GCRC, University of Kentucky, Lexington, KY, [2]GCRC, UTMB, Galveston, TX and [3]College of Pharmacy, University of Kentucky, Lexington, KY.*

Some cytochrome P450 enzymes, e.g., CYP2E1 and CYP3A4 can "leak" reactive oxygen species and contribute to hepatic oxidative stress. Because damage from hepatitis C virus (HCV) infection might involve oxidative stress, we studied CYP2E1 and CYP3A4 activities in HCV infected humans and controls. **METHODS:** Sixteen HCV subjects and 5 control subjects from this study and 5 subjects from a previous study were admitted for a day to the General Clinical Research Center. All were volunteers and informed consent was obtained. HCV infection was documented by standard clinical tests and subjects were otherwise healthy and treatment naïve. Each subject received a single 250 mg chlorzoxazone tablet (CZX) as a probe for CYP2E1 and 2 mg IV midazolam (MDZ) as a probe of CYP3A4. Blood & urine were collected at time points and clearances determined by standard methods. CZX, 6–OH–CZX were measured by HPLC and MDZ by GC with electron capture. **RESULTS:** Age, race, gender, smoking status, medications, liver biopsy results, genotype & quantity of HCV virus, ALT, ferritin, and parameters of the systemic oxidative stress (whole blood GSH & urine F2–isoprostanes) are presented. HCV subjects had evidence of increased oxidative stress. Results for MDZ systemic clearance were determined for 7 HCV patients and a group of 7 controls – MDZ systemic clearance was 6.4±2.1 ml/min/kg in the HCV group compared to 4.7±1.5 ml/min/kg in the controls. The 36% increase in the HCV subjects reached statistical significance (p=0.038). Oral CZX clearance in 16 HCV subjects and 5 controls was 5.08±1.99 and 6.8±3.51ml/min respectively. Formation clearance of 6–OH–CZX in 10 HCV subjects and 2 controls were 1.89±1.8 and 2.24±0.72 L/h respectively (Not significantly different). **CONCLUSION:** HCV patients with a relatively mild degree of liver injury and increased systemic oxidative stress show increased activities of cytochrome P450 CYP3A4, while no changes in the activities of CYP2E1 were found.

1542 CYP2E1 IS NOT SPECIFIC FOR FORMATION OF 6-HYDROXYCHLORZOXAZONE IN VIVO.

K. K. Wolf[1], S. Wood[3], J. Bement[3], W. Bement[3], S. Wrighton[4], E. Jeffery[5], F. Gonzalez[6], P. Sinclair[3,2,1] and J. Sinclair[3,2,1]. *[1]Pharmacology and Toxicology, Dartmouth Medical School, Hanover, NH, [2]Biochemistry, Dartmouth Medical School, Hanover, NH, [3]VA Medical Center, White River Junction, VT, [4]Lilly Research Laboratories, Indianapolis, IN, [5]Food Science/ Human Nutrition, University of Illinois, Urbana, IL and [6]NIH, Bethesda, MD.*

Clinically and experimentally, the 6-hydroxylation of chlorzoxazone (CHZ) is widely used to measure levels of CYP2E1. However, expressed human forms of CYPs 2E1, 3A4 and 2D6 exhibited comparable CHZ 6-hydroxylase activities. Antibodies to CYP3A4 cause up to 47 % inhibition of this activity in human liver microsomes (Gorski et al., 1997). Furthermore, in addition to CYP2E1, expressed forms of rat CYPs 1A2, 3A1 and 2C11 catalyze CHZ 6-hydroxylase activity (Kobayashi et al., 2002). We assessed the specificity of CYP2E1 for the 6-hydroxylation of CHZ, by comparing the formation of 6-OH-CHZ in vivo in wild-type and Cyp2e1(-/-) mice. 6-OH-CHZ was measured in sera of mice, because, in humans and in rats, levels of this metabolite are reported to be greater in serum compared to urine at early times after administration of CHZ. Mice of both genders were administered a dose of 15 mg CHZ/kg. CHZ and 6-OH-CHZ were measured by HPLC in sera at different times after administration of the parent drug. 6-OH-CHZ was formed by both Cyp2e1(-/-) mice and wild-type mice. Our results indicate that CYPs other than CYP2E1 contribute to formation of this metabolite *in vivo*. This work was supported by NIH (AA12898, JS) and the Department of Veteran Affairs.

1543 VALIDATION AND AUTOMATION OF AN ASSAY ENABLING RAPID SCREENING FOR POTENTIAL TOXICOLOGICAL IMPLICATIONS OF CYP2E1 INHIBITION.

A. V. Rizvi[1], O. V. Trubetskoy[2], T. L. Guthrie[1], J. O. Watson[2] and T. M. Fletcher[1]. *[1]Cancer Therapeutics and Immunology, Southern Research Institute, Birmingham, AL and [2]Panvera Corporation, Madison, WI.* Sponsor: J. Page.

Rationale: Human CYP2E1 is an alcohol-inducible enzyme that plays an important toxicological role due to the isozyme's involvement in metabolism of solvents, toxins and environmental pollutants with implications in cancer, liver and kidney toxicity. Identification of CYP2E1 inhibitors may allow prevention of the adverse drug reactions arising from toxic metabolites formed *via* the CYP2E1 metabolic pathway. The screening is currently limited due to the absence of the systematic high throughput screening (HTS) approach. Here we describe the development of an automated fluorescence-based HTS assay for the rapid detection of compounds interfering with CYP2E1 pathway. **Method:** The CYP2E1 Vivid® assay is based on a rapid conversion of initially non-fluorescent ("blocked") Vivid® CYP2E1 Blue substrate into a highly fluorescent dye as a result of oxidation by a CYP2E1 isozyme (fluorescent reporter reaction). Measuring the inhibition of the fluorescent reporter reaction in the presence of the specific drug or compound allows detection of CYP2E1 substrates and inhibitors. Vivid® CYP2E1 Substrate is a member of the panel of the Vivid® fluorogenic substrates created by a rational design approach to enable sensitive detection in HTS format. Here we employed Vivid® CYP2E1 Blue fluorogenic substrate for the development of HTS assay for screening CYP2E1 metabolism and inhibition in automated format using the Southern Research Institute's Core HTS Rail System. **Results:** As part of testing the reliability and quality of these screening assays in HTS automated format, we assessed the assay linearity range, kinetic parameters (apparent Vmax and Km), solvent sensitivity, inhibitory potential, Z'-factor and assay dynamic range. **Conclusions:** Our results demonstrate that the established parameters of the CYP2E1 Vivid® assay make it an excellent method for the sensitive detection of compound interactions with the CYP2E1 isozyme in a HTS format.

1544 IDENTIFICATION OF P450 ENZYMES INVOLVED IN THE METABOLISM AND TOXICITY OF CARBON DISULFIDE.

P. S. Dalvi, T. Wilder-Kofie, B. Mares, C. Lane, R. R. Dalvi and L. H. Billups. *Biomedical Sciences, Tuskegee University, Tuskegee, AL.*

Carbon disulfide (CS_2) is a widely used, highly volatile industrial solvent, and also a widespread environmental contaminant. The objective of this study was to test the hypothesis that CS_2 interacts with induced hepatic cytochrome P450 (CYP) isozymes 1A1, 2B1, 2E1 and 3A2, and metabolizes to reactive sulfur species that may be responsible for hepatic damage. Because 3-methylcholanthrene, phenobarbital, isoniazid, and pregnenolone-16 -carbonitrile are typical selective inducers of CYP1A1, 2B1, 2E1, and 3A2, respectively, they were chosen in this study to pretreat male Sprague-Dawley rats to induce the CYP isoforms. Twenty-four h following the final dose of the inducers, rats were treated ip with a low dose (0.1 mmol/kg) or a high dose (0.5 mmol/kg) of CS_2. Half of the rats from each group were sacrificed at 3 h after treatment to identify inhibited isozymes since CS_2 is a suicide inhibitor of CYPs, and the remaining half at 24 h to determine the hepatic damage using serum ALT activity and liver histopathology as toxicity indicators. At 3 h after treatment, CYP3A2 was inhibited only by the high dose while CYP1A1, 2B1 and 2E1 were inhibited by both doses of CS_2 significantly and differentially. However, within 24 h of treatment the inhibition of CYP1A1 and 3A2 was reversed with no serious liver damage while that of CYP2B1 and 2E1 was irreversible and accompanied by severe liver damage especially in phenobarbital-pretreated rats. These results suggest that induced CYP2B1 and 2E1 play an important role in the metabolism of CS_2 yielding reactive sulfur species which may be responsible for the observed liver damage.

1545 COMPARATIVE METABOLISM OF *cis* AND *trans* CROTONONITRILE (CRN) TO CYANIDE USING CYTOCHROME P405 2E1-NULL AND WILD TYPE MICE.

B. I. Ghanayem, L. El Hadri, B. Chanas, L. C. Ferguson and L. T. Burka. *Laboratory of Pharmacology and Chemistry, NIH/NIEHS, Research Triangle Park, NC.*

Crotononitrile (CrN), an unsaturated aliphatic nitrile, causes neurotoxicity in animals. It was reported that cis-CrN is a more potent neurotoxin than trans-CrN. CrN is metabolized to cyanide presumably *via* P450-mediated epoxidation. The metabolism of the two isomers and the enzymes involved are not well studied. Since CYP2E1 is involved in the metabolism of other nitriles, current studies were undertaken to compare the metabolism of the 2 isomers to cyanide using CYP2E1-null (KO) and wild-type (WT) mice. Male WT and KO mice received a single gavage dose of 12, 24, 48 or 96 mg/kg of cis or trans CrN. Mice were sacrificed after 1, 3, or 6 hr, and blood cyanide [CN] was measured. A dose-dependent increase in [CN] was detected in WT and KO mice, reaching a maximum 1 hr after dosing, and was significantly higher after cis vs. trans dosing. Significant decline in cyanide formation occurred in KO vs. WT treated with either isomer. The decrease in cis-CrN metabolism to [CN] in KO was more profound than that of the trans isomer. Treatment of WT or KO mice with 1-aminobenzotriazole before dosing with 48 mg/kg of either isomer resulted in a near complete inhibition of cyanide formation. Subsequent *in vitro* studies compared the reactivity of the 2 isomers and their epoxides (2, 3-epoxybutyronitriles, EBN) with 3H-glutathione (GSH). This study indicated that the reactivity of both cis and trans-CrN is negligible. In contrast, cis-EBN is significantly more reactive than cis-CrN and trans-EBN. Addition of GSH transferase to the incubation significantly enhanced the reactivity of cis- and trans-EBN. In conclusion, these data showed that 1) CYP2E1 plays an important role in the metabolism of CrN to [CN], however, other P450s are also involved 2) metabolism of cis-CrN results in greater CN- release than trans-CrN, and 3) cis-EBN is more reactive with GSH *in vitro* than the trans-EBN. Reaction of EBNs with GSH is a likely mechanism leading to cyanide formation and may explain the differences in cyanide release from cis and trans CrN *in vivo*.

1546 INHIBITION OF URETHANE METABOLISM AND BIOACCUMULATION IN CYTOCHROME P450 2E1-NULL MICE.

U. Hoffler[1,2] and B. I. Ghanayem[1,2]. *[1]Meharry Medical College, Nashville, TN and [2]NIEHS, Research Triangle Park, NC.*

Urethane is a well-established animal carcinogen and was classified as reasonably anticipated to be a human carcinogen. Urethane is formed as a fermentation by-product and therefore, the primary source of human exposure is through consumption of fermented foods and beverages. Past studies suggested that although CYP2E1 is involved, esterase plays a primary role in urethane metabolism. To define the role of CYP2E1, urethane metabolism was compared in wild-type (WT) and CYP2E1-null (KO) mice. 14C-Ethyl-labeled urethane was administered as a single 10 or 100 mg/kg gavage dose or at 100mg/kg/day for 5 consecutive days. Mice were placed in metabolism cages that allowed for the quantitation of expired 14CO2, organic volatiles, urine, and feces. In WT mice, 78-88% of dose was exhaled as 14CO2/day by animals given single or multiple doses. In contrast 30-38% of dose was eliminated as 14CO2 in 24 hr after a single dose in KO mice. After the 2nd day of dosing, 43% of dose was exhaled in 24 hr as 14CO2. 14CO2 exhalation reached a plateau at approximately 52% of dose/day after dose 3, 4, or 5. An average of 28 and 13% of the cumulative doses was eliminated as urethane-derived 14C in the urine and organic volatiles of KO mice, respectively. WT mice, however, eliminated approximately 10 and 3.5% of dose *via* these routes. Current work clearly shows that 14CO2 is the primary metabolite of CYP2E1-mediated oxidation of 14C-ethyl labeled-urethane. The concentrations of urethane-derived 14C in blood and tissues were dependent on dose and number of doses given, and significantly higher in the KO vs. WT mice. Using HPLC analysis, urethane constituted >90% of urethane-derived 14C in plasma of KO mice receiving single or multiple

doses of urethane. In conclusion, present work shows that KO mice experience a significant inhibition in urethane metabolism, leading to significant accumulation of urethane in the tissues of KO mice. Whether accumulation of urethane and/or metabolites formed *via* pathways other than CYP2E1 affect toxicity and carcinogenicity remains unclear.

1547 RELIABILITY OF CHLORZOXAZONE AS AN *IN VIVO* PROBE OF CYP2E1 ACTIVITY IN HUMANS.

L. Ernstgård, A. Rannug, M. Warholm and G. Johanson. *Institute of Environmental Medicine, Karolinska Institutet, Stockholm, Sweden.*

Chlorzoxazone (CZX) is metabolised by cytochrome P450 2E1 (CYP2E1) to a single oxidised metabolite, 6-hydroxychlorzoxazone (OH-CZX). The aim of the study was to test the reliability of CZX as an *in vivo* probe of CYP2E1 activity in humans. The OH-CZX/CX ratio was measured in plasma from 20 male volunteers (age 27 to 53) at 2 h following a single oral dose of 500 mg CZX. The experiment was repeated about 1.5 years later in 13 subjects. In 7 subjects the experiment was also repeated during three consecutive weeks and at three different doses of 250, 500, and 1000 mg. In addition, the effect of moderate ethanol intake (0.5 g ethanol/ kg body weight) the preceding evening was evaluated. The study was approved by the Regional Ethics Committee. The OH-CZX/CX ratio at 2 h ranged from 0.12 to 0.61 and the relative standard deviation was 42 % (n= 20). A positive correlation with body weight (r= 0.7, p= 0.0003) was seen in linear regression analysis, which might indicate that the dose was too high. In the test performed with 1.5 year interval, the inter-individual variability in metabolic ratio was 66 % and the intra-individual variability was 32 % (expressed as relative standard deviation, obtained from repeated measures ANOVA, n=13). The inter- and intra-individual variabilities in the test performed during three consecutive weeks were 60 % and 15 %, respectively (n= 7). The low intra-individual variability (15 %) indicates a relatively small method error. The OH-CZX/CX ratio decreased with increasing CZX dose (n = 7, p = 0.01, repeated measures ANOVA), suggesting metabolic saturation at the higher doses. There was no significant influence of ethanol intake on the ratio (n= 7, p= 0.8, paired t test). In conclusion, the OH-CZX/CX ratio in plasma at 2 h appears to be a reliable indicator of CYP2E1 activity. However, a lower dose than the commonly used 500 mg should be used to prevent metabolic saturation. Financial support was offered from the Swedish Council for Working Life and Social Research.

1548 COMPARATIVE METABOLISM OF ACRYLONITRILE AND METHACRYLONITRILE TO CYANIDE: STUDIES USING CYTOCHROME P4502E1 (CYP2E1)- AND MICROSOMAL EPOXIDE HYDROLASE (MEH)-NULL MICE.

L. El Hadri, B. Chanas and B. I. Ghanayem. *NIEHS, Research Triangle Park, NC.*

Acrylonitrile (AN) and methacrylonitrile (MAN) are structurally related aliphatic nitriles. Metabolism of these nitriles occurs *via* 2 competing pathways: glutathione conjugation, and epoxidation by cytochromes P450 (P450s). We have recently shown that CYP2E1 is essential for the metabolism of AN to cyanide and the ensuing acute toxicity. Current studies were designed to compare the metabolism of AN and MAN to cyanide and to assess the roles of CYP2E1 and EH using wild-type (WT), CYP2E1- and mEH-null male mice. Mice receiving a single gavage dose of 0.047, 0.095, 0.19, or 0.38 mmoles/kg of MAN or AN, were sacrificed 1 or 3 hr after dosing, blood was collected, and cyanide was measured. Expressions of CYP2E1, mEH, and soluble EH (sEH) in mice tissues were assessed using Western blot analyses. Current data showed that blood cyanide levels in WT mice increased in a dose-dependent manner, reached a maximum at 1 hr, and were significantly higher after MAN vs. AN administration. Further, while significant reduction in blood cyanide levels was detected in MAN-treated CYP2E1-null vs. WT mice, AN metabolism to cyanide was totally abolished in CYP2E1-null mice. Pretreatment of CYP2E1-null and WT mice with 1-aminobenzotriazole (P450s inhibitor) resulted in near complete inhibition of the metabolism of MAN to cyanide. Blood cyanide levels in AN-treated mEH-null mice were significantly lower relative to levels in WT mice. Similar reduction in blood cyanide was also observed in mEH-null mice treated with * 0.09 mmoles MAN/kg. However, no significant difference was observed at the highest MAN dose (0.18 mmoles/kg). Similar expressions of mEH and sEH in CYP2E1-null and WT mice were established. CYP2E1 and sEH levels were comparable in mEH-null and WT mice. In conclusion, these data showed that: 1) CYP2E1 is the only P450 responsible for AN metabolism to cyanide, 2) while CYP2E1 plays a major role in MAN metabolism to cyanide, other P450 enzymes are also involved, and 3) mEH plays a significant role in the *in vivo* formation of cyanide from aliphatic nitriles.

1549 THE EFFECT OF ETHYL-*TERT.*-BUTYL ETHER INHALATION ON CYTOCHROME P450 ISOZYMES AND *IN VITRO* MEASUREMENT OF ENZYME ACTIVITY IN RAT LIVER, LUNG, AND NASAL MUCOSA.

K. M. Broadwell and R. A. Schatz. *Toxicology, Northeastern University, Braintree, MA.*

The most widely used and studied fuel oxygenate is methyl-tert-butyl ether (MTBE), but there is strong support to replace MTBE with ethyl-tert-butyl ether (ETBE)due to reported health complaints suggestive of respiratory effects in areas where gasoline contains MTBE.The possible adverse effects of ETBE in humans is a public concern, and little is known regarding specific CYP 450 isozymes involved in its metabolism.The respiratory tract is the first tissue encountered with ETBE, and subsequently exposed to the highest concentrations relative to other organs.The purpose of this study was to investigate alterations in rat liver, lung, and nasal mucosa cytochrome P450s following ETBE inhalation exposure. ETBE(250ppm or 500ppm, 6 hours)resulted in dose dependent inhibition ofCYP1A1(47%and50%), CYP1A2(82%and61%), CYP2B1(66%and29%), CYP2E1(57%and36%), CYP2A3(75%and58%), CYP3A1(73%and37%)and CYP4B1(73%and 62%)activities in nasal mucosa microsomes. There were no changes in pulmonary CYP450 activity, however hepatic CYP2B1significantly increased (126%and363%) following exposure to ETBE. *In vitro* metabolism of ETBE was determined to investigate the nature of the inhibition of cytochrome P450 isozymes in the nasal mucosa.Nasal mucosa isozymes CYP1A1, CYP1A2, CYP2B1, CYP2E1, CYP2A3 were inhibited by ETBE(IC50 concentration). Eadie-Hofstee plots for the aforementioned isozymes show non-competitive inhibition by ETBE. Oxidative deethylation of ETBE yields a primary metabolite, tert-butyl alcohol(TBA), as well as acetaldehyde, a known respiratory irritant.Metabolic enzyme activity following *in vitro* incubations in pooled liver, lung, and nasal mucosa microsomes were determined based on the formation of the two metabolites.All three tissues were active in metabolizing ETBE to TBA and acetaldehyde, and followed Michaelis-Menten kinetics with the highest metabolic activity in the nasal mucosa.The cytochrome P540 changes in respiratory tissues as a result of ETBE exposure may lead to changes in metabolic profiles in coexposure scenarios to other xenobiotics.

1550 INACTIVATION OF CYP2F1 IMPARTS DOSE-DEPENDENT DECREASE IN SUSCEPTIBILITY OF LUNG CELLS TO 3-METHYLINDOLE.

W. K. Nichols, B. A. Carr, D. L. Lanza and G. S. Yost. *Pharmacology &Toxicology, University of Utah, Salt Lake City, UT.*

Cytochrome P450 (CYP) enzymes 2F1 and 3A4 have been shown to bioactivate 3-methylindole (3MI) to a reactive intermediate that can induce cellular necrosis in human bronchial epithelial cell lines that overexpress these proteins. The overexpression of CYP2F1 in BEAS-2B cells (B-CMV2F1) increased the susceptibility of these cells to 3MI-induced apoptosis and cytotoxicity. Inhibition of CYP by the suicide substrate, 1-aminobenzotriazole, protected cells from cytotoxic injury and apoptosis. Low doses of 3MI from 10-50 micromolar induced DNA fragmentation and increased Annexin-V binding in B-CMV2F1 cells compared to control BEAS-2B cells. Higher doses of 3MI from 500-1000 micromolar resulted in a decreased susceptibility of cells to 3MI in the B-CMV2F1 cells but not in control BEAS-2B cells. These observations are consistent with kinetic studies of the CYP2F1 enzyme that demonstrated an inhibition of the enzyme at higher substrate concentrations of 3MI. Several experiments using higher concentrations of 3MI in human lung cell lines suggest that a reactive intermediate(s) of this pulmonary toxicant may inactivate the CYP2F1 enzyme in target cells. Since the CYP2F1 enzyme is unique in its ability to selectively produce a reactive intermediate through the dehydrogenation pathway, compared to other pulmonary specific CYP enzymes, the susceptibility of lung cells to toxic injury may be dependent upon the relative ratio of active/inactivated CYP2F1 enzyme. (supported by NHLBI #HL13645)

1551 *IN VITRO* METABOLISM OF MYRISTICIN BY RAT AND HUMAN LIVER.

R. Swezey, S. E. LeValley, L. H. Sharp, M. N. Ho and C. E. Green. *Metabolism and Pharmacokinetics, SRI International, Menlo Park, CA.*

Myristicin biotransformation by cytochrome P450 (CYP) activity was assessed by incubating myristicin (100 μM) with microsomal preparations from livers of either rats or humans in the presence of an NADPH-generating system. For both species, microsomes pooled from several donors were compared with those from donors that had been exposed to phenobarbital (PB) to induce the synthesis of certain CYP isoenzymes. The products of the incubations were analyzed by HPLC with (a) UV absorption and (b) triple quadrupole tandem MS/MS detectors in series. Two predominant metabolites were found, one with a negative ion of molecular weight

179, and the other with a positive ion of molecular weight 209, which were identified as 5-allyl-1-methoxy-2, 3-dihydroxybenzene (the catechol metabolite) and 1'-hydroxymyristicin, respectively. Samples from the rat liver microsomal incubations were further analyzed by GC/MS to confirm the identity of the these two metabolites. UV absorption data were used to compare relative amounts of metabolites between samples. In all cases the catechol metabolite was the principal product of CYP activity, and in both species its formation was more rapid using microsomes from PB-induced livers. After 1 hour at 37° C with 1 mg/ml microsomal protein, the catechol metabolite accounted for 89.9 ± 4.5 % of the metabolites formed by PB-induced rat microsomes, and 84.1 ± 3.1 % of metabolites formed by pooled rat microsomes. Under these same conditions with human liver microsomes, the catechol metabolite was 73.8 ± 0.7 % of the total metabolites from PB-induced liver microsomes and 83.0 ± 2.5 % of the total from pooled human liver microsomes. PB induction of 1'-hydroxymyristicn formation was more pronounced in human microsomes than in rat microsomes. Preliminary studies incubating myristicin with rat and human primary hepatocytes attached to collagen-coated plates produced no evidence for formation of either of these two metabolites by intact cells. (*Supported by NIEHS Contract No. N01-ES-95437*).

1552 EXTRAHEPATIC METABOLISM OF BIOCHANIN A AND FORMONONETIN AND METABOLITE INHIBITION OF CYTOCHROME P450 1B1.

D. W. Roberts, W. H. Tolleson, M. I. Churchwell and D. R. Doerge. *Biochemical Toxicology, Nat Center Toxicology. Reseach, Jefferson, AR.*

Biochanin A (BA) and formononetin (FOR), are the 4′-O-methyl derivatives of the more potent phytoestrogens genistein (GEN) and daidzein (DA), respectively, and are the predominant isoflavones in red clover and chick peas. Previously, we demonstrated that human liver microsomes converted BA and FOR to GEN and DA. Since epidemiologic studies for breast cancer risk associate exposure to endogeneous estrogens with increased risk and soy diets high in DA and GEN with reduced risk, we investigated the extrahepatic metabolism of BA and FOR. Metabolic activation of estradiol (E2) to estrogen catechols is a prerequisite for its genotoxic activity with 4-hydroxylation leading to carcinogenicity and 2-hydroxylation associated with anticarcinogenicity. In humans, cytochrome P450 1B1 (1B1) is an extrahepatic E2 4-hydroxylase that activates procarcinogens, and elevated levels have been associated with estrogen carcinogenesis. We demonstrated 1B1-catalyzed O-demethylation of BA and FOR producing GEN and DA, which feedback to inhibit 1B1. Recombinant human 1B1 was incubated with BA or FOR in reactions containing NADPH regenerating systems and products were analyzed by HPLC with UV and coulometric detection. FOR was converted to DA and several hydroxylated metabolites and BA was converted to GEN and a different set of hydroxylated metabolites. DA and GEN were identified by their retention times and electrochemical oxidation profiles and confirmed by LC-MS. Inhibition of 1B1 7-ethoxyresorufin O-deethylase (EROD) activity by DA and GEN was determined using a 96-well plate assay. Inhibition of 1B1 EROD activity by GEN was primarily noncompetitive (Ki 1.9 μM). DA exhibited mixed, but predominantly noncompetitive inhibition of 1B1 EROD activity (Ki 3.7 μM). The data suggest that BA or FOR may exert anticarcinogenic effects directly by acting as competitive substrates for 1B1 or indirectly through their metabolites DA and GEN, which are both 1B1 inhibitors and more potent phytoestrogens than their methylated precusors.

1553 P450 INHIBITION BY METHYLENEDIOXYPHENYL COMPOUNDS PRESENT IN GOLDENSEAL.

P. Chatterjee, R. N. Havea and M. R. Franklin. *Pharmacology and Toxicology, University of Utah, Salt Lake City, UT.*

With the widespread use of nutritional supplements, pharmacokinetic interactions between botanicals and prescription or OTC drugs are of increasing concern. Goldenseal (Hydrastis canadensis) is a popular immunostimulant botanical that is widely available, either alone or in combination, with Echinacea. Earlier studies indicated that all three of the major methylenedioxyphenyl (MDP) compounds contained in goldenseal are able to inhibit *in vitro* cytochrome P450 catalyzed diclofenac-4'-hydroxylation (CYP2C9), bufuralol-1'-hydroxylation (CYP2D6), and testosterone-6β-hydroxylation (CYP3A4) activities, in human liver microsomes. MDP compounds are known for their ability to inhibit *via* the formation of metabolic-intermediate (MI) complexes with cytochrome P450. Therefore, a study was initiated to investigate the degree to which the inhibition of human cytochrome P450s by MDP compounds of goldenseal correlated with the formation of such complexes. Despite inhibiting CYP2C9, CYP2D6 and CYP3A4 activities, neither berberine nor hydrastinine were able to form MI complexes in human liver microsomes. Both the (+) and (-) isomers of hydrastine formed an MI complex. To delineate the CYP(s) responsible, MI complex formation was further investigated using supersomes (Gentest) containing a single CYP isoform. (+)-Hydrastine formed complexes with CYP1A2, CYP2C9, CYP2C19, CYP2D6, and CYP3A4 but not CYP2B6. (-)-Hydrastine formed complexes only with CYP1A2, CYP2C9, CYP2D6, and CYP3A4. Co-expression of cytochrome b5 with CYP3A4 and CYP2C9 in the supersomes significantly enhanced the rate of MI complex formation. Therefore, inhibition of multiple human P450s by MDP components present in goldenseal may arise from the quasi-irreversible inhibition by MI complex formation, but other mechanisms also contribute to the inhibition.

1554 HYDROXYL RADICAL FORMATION BY HETEROLOGOUSLY EXPRESSED MICROSOMAL ENZYMES.

P. E. Thomas and V. M. Mishin. *Laboratory for Cancer Research, Rutgers, The State University of New Jersey, Piscataway, NJ.* Sponsor: G. Witz.

It has been shown that the hydroxylation of terephthalate (TPT) to the highly fluorescent product 2-hydroxyterephthalate (2-OH TPT), is the result of reaction with hydroxyl radicals (●OH). Using a new method (Mishin and Thomas, 2002), we observed the formation of 2-OH TPT from TPT by cDNA-expressed: NADPH-cytochrome P450 oxidoreductase (OR) coexpressed with cytochrome b5 and rat cytochrome P450 enzymes (CYPs) coexpressed with OR and cytochrome b5. The formation of 2-OH TPT totally depended on the presence of NADPH and Fe/EDTA (or Fe/citrate) complexes. The 2-OH TPT generation was profoundly inhibited by DMSO a ●OH scavenger, catalase and glutathione peroxidase (+GSH), but superoxide dismutase did not have a significant effect. Several water-soluble substrates, specific for different CYP enzymes, (zoxazolamine, benzphetamine, chlorzoxazone, midazolam and buprenorphine) were without inhibitory effect on the formation of 2-OH TPT from TPT. A comparison of the relative rates of 2-OH TPT generation (nmoles 2-OH TPT/nmole P450/min) revealed CYP2A2 (23.4) and CYP2C6 (23.4) to have the highest rates and CYP2C12 (7.5) and CYP3A2 (8.1) to have the lowest rates. The other 12 CYPs-containing preparations, including CYP2E1, had similar rates that were intermediate. There was no correlation between OR levels in these expressed microsomal preparations and formation of 2-OH TPT even though OR alone (+NADPH) is sufficient for modest production of 2-OH TPT. We suggest that the generation of reactive hydroxyl radicals by microsomal enzymes proceeds *via* metal-catalysed Haber-Weiss reactions and is controlled by the rate of hydrogen peroxide formation by cytochrome P450 enzymes and redox cycling of iron ions.

1555 LUMINESCENT CYTOCHROME P450 ASSAYS THAT UTILIZE D-LUCIFERIN DERIVATIVES AS PROBE SUBSTRATES.

J. J. Cali[1], S. Ho[1], D. Ma[1], D. H. Klaubert[2], D. Simpson[1], W. Daily[2] and R. F. Bulleit[1]. *[1]Promega Corp., Madison, WI and [2]Promega Biosciences Inc., San Luis Obispo, CA.*

Cytochrome p450s (cyp450) are the main catalyst of the oxidative metabolism of drugs and other xenobiotics. Understanding how potential new drugs interact as substrates or inhibitors of cyp450s is an essential component of drug development. To facilitate the rapid screening of multiple compounds we tested derivatives of (4S)-4, 5-dihydro-2-(6-hydroxybenzothiazolyl)-4-thiazolecarboxylic acid (D-luciferin) as probe cyp450 substrates. The D-luciferin derivatives were not substrates for luciferase in light-generating reactions but were metabolized by cyp450s to D-luciferin, which in turn reacted with firefly luciferase to produce light. The reactions were formulated using a homogenous luciferase mixture that was added directly to a conventional cyp450 reaction with D-luciferin derivatives as substrates to produce a glow-style luminescent signal that was stable for several hours. The amount of D-luciferin produced by a cyp450 was proportional to the light output of the luciferase reaction. Light was therefore used as a measure of cyp450 activity. In accord with this scheme 6′-deoxyluciferin was hydroxylated by human cyp2C9 to form D-luciferin that was readily detected by bioluminescence. 6′-deoxyluciferin was highly selective for cyp2C9 over other cyp450s. Other reactions included the dealkylation of luciferin 6′ alkyl and substituted alkyl ethers to form D-luciferin by human cyp1A1, 1A2, 2C8, 2C9 and 3A4 with varying degrees of cyp450 isoform selectivity. The luminescent cyp450 assays detected known cyp450 inhibitors with IC50s similar to those reported using conventional substrates. The assays displayed exquisite sensitivity detecting the activity of as little as 0.01 pmoles recombinant cyp450 against a minimal or immeasurable background signal and were easily configured in multi-well plate formats. We conclude that certain D-luciferin derivatives can be used as probe cyp450 substrates in simple and robust luminescent assay formats for rapid screening of multiple compounds against cyp450 activities.

1555a RAT PULMONARY CYP1A1 INDUCTION IS INHIBITED BY RESPIRABLE COAL DUST EXPOSURE.

M. Ghanem[2,1], D. Porter[1], L. Battelli[1,2], M. Kashon[1], M. Barger[1], J. Y. Ma[1], V. Vallyathan[1], J. Nath[2] and A. Hubbs[1]. *[1]HELD, NIOSH, Morgantown, WV and [2]Genetics and Developmental Biology, West Virginia University, Morgantown, WV.*

Cytochrome P450 1A1 (CYP1A1) metabolizes polycyclic aromatic hydrocarbons in cigarette smoke to reactive intermediates that can initiate lung cancer. We hypothesized that coal dust (CD) exposure might modify pulmonary carcinogenesis

by altering pulmonary CYP1A1 induction. To test this hypothesis, we examined the ability of respirable CD particles (<5 microns) to inhibit pulmonary CYP1A1 induction. Male, Sprague-Dawley rats (220-270g) were intratracheally exposed to 0, 2.5, 10, 20, 40 mg coal dust/rat or vehicle (saline). After 11 days, rats were injected intraperitoneally (IP) with the CYP1A1 inducer β-naphthoflavone (BNF: 50mg/kg IP). Three days later, rats were sacrificed and CYP1A1 activity in the lungs was measured as 7-ethoxyresorufin-O-deethylase (EROD) activity. CYP1A1 protein was determined by Western blot using polyclonal rabbit anti-rat CYP1A1 antibodies. Pulmonary inflammation was assessed by determining bronchoalveolar lavage polymorphonuclear (PMN) cell counts, alveolar macrophage (AM) chemiluminescence (CL), and nitric oxide (NO)-dependent AM chemiluminescence. EROD activity was suppressed by CD exposure in a dose-dependent fashion (R2= 0.932, p=0.008). Western blot showed a significant reduction of CYP1A1 protein in rats treated with 40 mg CD and BNF when compared with rats treated with BNF alone ($p<0.05$). CD exposed rats had a dose-dependent increase of PMN (R2=0.974, p= 0.002). AM count was significantly higher in all rats exposed to CD and BNF compared with rats treated with BNF alone. NO-dependent CL was also significantly increased in rats treated with 40 mg CD and BNF compared to rats treated with BNF alone (p= 0.004). These results suggest that coal dust exposure inhibits induction of CYP1A1 activity by BNF and enhances pulmonary inflammation, in a dose-dependent manner.

1556 METABOLITE OF PNU-142721 FORMS SELECTIVE ADDUCT WITH CYS125 OF RAT BETA-GLOBIN.

R. Voorman[1], E. B. Smith[1], W. J. Adams[1], R. L. Heinrikson[2], G. S. Cavey[3], J. W. Leone[2] and P. E. Sanders[1]. *[1]Global Drug Metabolism, Pharmacia Corp, Kalamazoo, MI, [2]Biochemistry, Pharmacia Corp, Kalamazoo, MI and [3]Analytical Chemistry, Pharmacia Corp, Kalamazoo, MI.* Sponsor: G. Cosma.

PNU-142721E ((-)-6-chloro-2-[(1-furo[2, 3-c]pyridin-5-ylethyl)-thio]-4- pyrimidinamine) is a potent inhibitor of HIV-1 reverse transcriptase. Single dose excretion studies of [14C]PNU-142721 in the Sprague-Dawley rat revealed unusually long lived radioactivity associated with whole blood. Seven days post-dose, whole blood radioactivity was approximately 3 uM eq., more than 70-fold greater than corresponding plasma levels. In order to investigate the nature of the observed binding, rats were treated with increasing doses (10 to 100 mg/kg) or multiple doses (5 days) of [14C]PNU-142721 and blood samples were analyzed for radioactivity distribution. Results showed drug residues strongly associated with red blood cells; >90% of circulating radioactivity at 72 h post-dose was associated with red blood cells. Moreover, erythrocyte associated radioactivity increased additively with increasing dose or multiple doses. Fractionation and chromatographic analysis of protein from lysed erythrocytes showed distinct association of radioactivity with beta-globin. ESI-MS analysis of beta-globin isolated from a rat that had been treated with [14C]PNU-142721 showed the presence of a protein with a mass of 15976.1 Da, roughly 128 Da larger than the major form of rat beta-globin, suggesting addition of the chloropyrimidinamine functionality of PNU-142721. Amino acid sequence analysis of peptides generated from a tryptic digestion of the modified protein suggested that Cys125 of rat beta-globin was the site of modification. Further analysis of the radiolabeled peptides by MALDI-MS confirmed the sequence analysis and showed the chloropyrimidinamine adduct on cysteine. Comparison of rat and human hemoglobin sequences suggests that this reaction will not occur in humans because human beta-globin lacks a Cys residue at this position. However, it is unknown whether reactivity with protein thiols is a general feature of PNU-142721 metabolism.

1557 EQUINE CATECHOL ESTROGEN 4-HYDROXYEQUILENIN IS A SUBSTRATE AND AN INHIBITOR OF CATECHOL-O-METHYLTRANSFERASE.

J. Yao[1], Y. Li[1], M. Chang[1], H. Wu[1], J. E. Goodman[2,3], X. Liu[1], H. Liu[1], A. D. Mesecar[1], R. B. van Breemen[1], J. D. Yager[2] and J. L. Bolton[1]. *[1]University of Illinois at Chicago, Chicago, IL, [2]Johns Hopkins University, Baltimore, MD and [3]NIH, Bethesda, MD.*

Redox and/or electrophilic metabolites formed from estrogen metabolism may play a role in estrogen carcinogenesis. 4-Hydroxyequilenin (4-OHEN) is the major phase I catechol metabolite of the equine estrogens equilenin and equilin, which are components of the most widely prescribed estrogen replacement formulation, Premarin®. Previously, we have found that 4-OHEN rapidly autoxidizes to an *o*-quinone *in vitro* and causes toxic effects including inactivation of human detoxification enzymes. 4-OHEN has also been shown to be a substrate for catechol-*O*-methyltransferase (COMT) in human breast cancer cells. In the present study, we demonstrated that 4-OHEN was not only a substrate of recombinant human soluble COMT *in vitro* with a K_m of 2.2 μM and k_{cat} of 4.7 min^{-1}, but it also inhibited its own methylation by COMT at higher concentrations. In addition, 4-OHEN was found to be an irreversible inhibitor of COMT-catalyzed methylation of the endogenous catechol estrogen 4-hydroxyestradiol (4-OHE2). 4-OHEN *in vitro* not only caused the formation of intra- and inter-molecular disulfide bonds as demonstrated by gel electrophoresis, but matrix assisted laser desorption ionization time-of-flight mass spectrometry (MALDI-TOF-MS) also showed that 4-OHEN alkylated multiple residues of COMT. Peptide mapping experiments further indicated that Cys32 in recombinant human soluble COMT was the residue most likely modified by 4-OHEN *in vitro*. These data may suggest that inhibition of COMT methylation by 4-OHEN might reduce endogenous catechol estrogen clearance *in vivo* and further enhance toxicity.

1558 INHIBITION OF BAX TRANSLOCATION AND NECROSIS WITH BCL-XL OVEREXPRESSION IN A WELL CHARACTERIZED CELL CULTURE MODEL FOR TETRAFLUOROETHYLCYSTEINE-INDUCED NEPHROTOXICITY.

H. K. Ho[1], Z. Hu[3], S. Tzung[4], D. M. Hockenbery[4], N. Fausto[2], S. D. Nelson[1] and S. A. Bruschi[1]. *[1]Medicinal Chemistry, University of Washington, Seattle, WA, [2]Pathology, University of Washington, Seattle, WA, [3]Molecular Biology, Immunex Corp, Seattle, WA and [4]Fred Hutchinson Cancer Research Center, Seattle, WA.*

Tetrafluoroethylcysteine (TFEC)-induced nephrotoxicity is initiated by the covalent modification of a relatively small number of defined mitochondrial proteins (1). The murine TAMH cell line has been characterized and faithfully reproduces TFEC-mediated renal injury and necrotic cytotoxicity with dose- and time-dependent inhibitions of both mitochondrial aconitase and α-ketoglutarate dehydrogenase target proteins (2). An early cytosolic to mitochondrial translocation of BAX (a proapoptotic BCL-2 family member) was also observed in TAMH cultures dosed with toxicologically relevant concentrations of TFEC (e.g. 250 μM). BAX translocations were confirmed immunocytochemically using confocal microscopy and with complementary immunoblot techniques. Effective and significant cytoprotection to supra-toxicological concentrations of TFEC (≤600 μM) were evident using TAMH stable transfectants overexpressing the BAX heterodimerization partner BCL-xL (c.f. vector control transfectants or parental cell line). Furthermore, BCL-xL overexpression limited the extent of BAX translocation to mitochondria in agreement with the cytoprotection observed in BCL-xL transfectants. In conclusion, effective cytoprotection to TFEC-induced necrosis is evident with BCL-xL overexpression and this appears to correlate well with the prevention of BAX subcellular relocation to mitochondria. Further data will also be presented which confirm our previous and related microarray studies (3) regarding the genomic responses of TAMH cells to TFEC-mediated intramitochondrial damage. 1. Supported by NIH grants GM51916 (SAB), GM25418 (SDN), CA74131 (NF), American Cancer Society RPG-00-222-01-CDD (DMH) and NIEHS Center Grant P30ES07033.

1559 THE PROTECTIVE EFFECT OF FLAVONOIDS AGAINST OXIDATIVE DAMAGE INDUCED BY OCHRATOXIN A IN PROXIMAL TUBULAR CELLS.

Y. Simarro Doorten, S. M. Nijmeijer and J. Fink-Gremmels. *Vet. Pharmacy, Pharmacology and Toxicology, Utrecht University, Fac. of Veterinary Medicine, Utrecht, Utrecht, Netherlands.* Sponsor: M. Vandenberg.

Flavonoids are present in many food commodities and have gained increasing interest in relation to disease prevention because of their antioxidant activity. Hence, oxidative stress leads to a variety of patho-physiological events. Worldwide, the mycotoxin ochratoxin A is a frequently found contaminant in human food and animal feeds and has been detected among others in cereals, beans and coffee. In humans, long-term exposure to ochratoxin A has been linked to a chronic kidney disease, denoted as Balkan Endemic Nephropathy (BEN). Induction of oxidative damage is one of the mechanisms involved in the renal toxicity of ochratoxin A. In the present study, GERP and LLC-PK1 cells were used as a model for proximal tubule cells, the target cells of ochratoxin A, to study the antioxidant properties of selected flavonoids. Following exposure to ochratoxin A (100 μM for 24 hours), the reactive oxygen species (ROS) production was measured using the fluorescent probe 2′, 7′-dichlorodihydrofluorescein diacetate (H2DCF-DA). The ROS scavenging ability of the tested compounds (in a concentration range of 0.1-100 μM) could be ranked in the following order: eriodictyol> quercetin > esculetin >> ebselen / naringin. The results showed that eriodictyol, quercetin and esculetin have antioxidant properties, efficient in the protection against the oxidative stress induced by the mycotoxin ochratoxin A. Therefore, the protective antioxidant properties of these compounds should be investigated further with respect to their ability to reduce ochratoxin A pathologies *in vivo*.

1560 ELUCIDATION OF REACTIVE METABOLITES OF 4-IPOMEANOL BY LIQUID CHROMATOGRAPHY-TANDEM MASS SPECTROMETRY (LC-MS/MS).

J. Zheng and T. M. Alvarez-Diez. *Pharmaceutical Sciences, Northeastern University, Boston, MA.*

4-Ipomeanol, [1-(3-furyl)-4-hydroxypentanone], is a natural cytotoxin and a promising chemotherapeutic agent bioactivated in target organs by P450 enzymes into electrophilic metabolites that conjugate with glutathione (GSH). However, the structures of its reactive metabolites and the pathway of bioactivation are unknown. We propose them here. Methods: a) *In vivo*: bile of rats dosed with a mixture of d_0-4-ipomeanol/$d_6$4-ipomeanol was collected and analyzed by LC-MS/MS in order to investigate the structure of its reactive metabolites. b) *In vitro*: LC-MS/MS analysis of hepatic microsomal samples of rats incubated with 4-ipomeanol and GSH. Results: we detected 4 metabolites of 4-ipomeanol conjugated with GSH in rat bile samples. Multiple reaction monitoring scans showed that these four conjugates lose neutral fragments of 129 Da, which is characteristic of glutathione conjugates, and have a mass of 492 Da $(MH)^+$. The tracer d_6-4-ipomeanol confirmed that these conjugates derived from 4-ipomeanol. The mass of the deuterated glutathione conjugates was 498 Da (M+7)+. Since deuterium was incorporated in the alkyl chain of 4-ipomeanol, and the glutathione conjugates retain all deuterium atoms, it indicates that metabolism takes place on the furan moiety. One glutathione conjugate derived from 4-ipomeanol was also observed in hepatic microsomal samples of rats. No conjugates were detected in control samples. Conclusions: supported by the LC-MS/MS data, we propose a pathway of 4-ipomeanol bioactivation. Three reactive intermediates of 4-ipomeanol are proposed, two epoxides and an α, β-unsaturated dialdehyde, which conjugate with GSH forming 6 possible conjugates, two of which re-arrange into more stable structures. The masses of these proposed glutathione conjugates of 4-ipomeanol match well with observed masses. These data facilitate a further understanding of the mechanism of 4-ipomeanol induced cytotoxycity.

1561 HYDROQUINONE AND CATECHOL METABOLITES OF BENZENE INCREASE ENDOTHELIAL IL8 PRODUCTION BY HUMAN BONE MARROW ENDOTHELIAL CELLS.

D. Ross, J. A. Moran and K. B. Leader. *Pharmaceutical Sciences, UCHSC School of Pharmacy, Denver, CO.*

Benzene and the antipsychotic agent remoxipride have each been associated with induction of aplastic anemia. Both compounds also generate catechol and hydroquinone metabolites, which induce pro-apoptotic effects in bone marrow cells. Gene array analysis of remoxipride-derived catechol in HL60 cells revealed a consistent and time-dependent increase in IL8 expression and several IL8-related genes. An increase in the levels of IL8 protein in media as indicated by ELISA was also observed in HL60 cells exposed to remoxipride-derived catechol. HL60 cells secrete the endothelial form of IL8 (eIL8), which differs from the monocytic form by 5 amino acids at the amino terminus and has been reported to have proapoptotic activity. We have used human bone marrow endothelial cells as a model system to determine whether eIL8 production by bone marrow endothelial cells is affected by exposure to catechol (CAT) and hydroquinone (HQ) metabolites of benzene. The human bone marrow endothelial cell line, HBMEC60, was treated with increasing concentrations of CAT (1-100 μM) or HQ (0.1-100 μM). IL8 in media was quantified 24, 48, and 72 h after initial treatments. Treatment with either HQ or CAT resulted in a dose-dependent increase in IL8 at 48 and 72h. Phenol (100 μM), a benzene metabolite which does not induce apoptosis in human bone marrow progenitor cells, failed to increase IL8 levels in media at any time point. Because the ELISA assay used to quantify IL8 did not distinguish between the two forms of IL8, gel electrophoresis was conducted to determine which form was produced by HBMEC60s. Endothelial IL8 was the only form of IL8 detected in HBMEC60 media. In conclusion, the benzene metabolites, HQ and CAT, but not phenol, increased production of eIL8 by HBMEC60s in a dose-dependent manner. This increase in eIL8 may have relevance for benzene-induced disruption of hematopoiesis (Supported by ES09554 and Astra Zeneca).

1562 HEMATOPOIETIC STEM CELLS AS TARGETS FOR TRANSPLACENTAL TOXICANTS.

E. P. Gallagher[1], J. L. Gardner[1], C. M. Huisden[1], A. M. Doi[2] and C. G. Moneypenny[1]. [1]*Physiological Sciences, University of Florida, Gainesville, FL and* [2]*National Toxicology Program, NIEHS, Research Triangle Park, NC.*

Human fetal liver hematopoietic stem cells (HSC) comprise a significant percentage of human fetal hepatic cell populations and are capable of initiating long term hematopoiesis. Because of their hematopoietic function, injury to these cells may have potential ramifications with regards to the etiology of hematopoietic malignancy. In the current study, we examined the sensitivity of HSC to 4-hydroxynonenal (4HNE) an extremely mutagenic aldehyde and a primary toxic metabolite of alcohol. 4HNE can be formed *in utero* as a result of maternal alcohol consumption or *via* transplacental transfer of pro-oxidant drugs and chemicals. Soluble fractions prepared from HSC rapidly metabolized 4HNE through glutathione *S*-transferases and aldehyde dehydrogenases, but did not exhibit significant reductive capacity for 4HNE through aldehyde reductase or alcohol dehydrogenase pathways. Culture of HSC in the presence of 5 and 50 uM 4HNE resulted in a significant loss of cell viability and the formation of one or more high molecular weight 4HNE-protein adduct(s). In contrast, incubation of HSC with aflatoxin B_1 (AFB_1), a transplacental pro-carcinogen that requires cytochrome P450-mediated activation to form the reactive AFB_1-8, 9-*exo*-epoxide (AFBO), did not affect HSC viability or AFBO-DNA binding. Western blotting studies further demonstrated that HSC expressed comparatively low levels of CYP3A4/5-reactive protein(s) and did not express CYP1A2-reactive protein, isozymes important in AFB_1 bioactivation. Collectively, our results suggest that inefficient enzymatic reduction of 4HNE may underlie a susceptibility of HSC to cell injury. However, HSC may not be a target of the procarcinogen AFB_1 at physiologcally relevent doses. Supported by NIH ES09427 and USEPA STAR R827441.

1563 EFFECTS OF DIALLYL SULFIDE ON THIOACETAMIDE-INDUCED HEPATOTOXICITY: A POSSIBLE ROLE OF CYTOCHROME P450 2E1.

J. Kim, N. Kim, S. Lee, C. Kim, S. Hyun, T. Jeon and T. Jeong. *Pharmacy, Yeungnam University, Kyungsan, Kyungbuk, South Korea.*

Effects of diallyl sulfide (DAS) on thioacetamide-induced hepatotoxicity were investigated in male ICR mice. When mice were treated subcutaneously with 100, 200 and 400 mg/kg of DAS in corn oil for three consecutive days, the activity of cytochrome P450 (P450) 2E1-selective p-nitrophenol hydroxylase was dose-dependently suppressed. In addition, the activities of P450 2B-selective benzyloxyresorufin O-debenzylase and pentoxyresorufin O-dependentylase were dose-dependently induced by the treatment with DAS. To investigate a possible role of metabolic activation by P450 enzymes in thioacetamide-induced hepatotoxicity, mice were pretreated with 400 mg/kg of DAS for 3 days, followed by a single intraperitoneal treatment with 100 and 200 mg/kg of thioacetamide in saline for 24 hr. The activities of serum alanine aminotransferase and aspartate aminotransferase greatly increased by thioacetamide were recovered in DAS-pretreaed animals. Taken together, our present results indicated that thioacetamide might be activated to its hepatotoxic metabolite(s) by P450 2E1, not by P450 2B, in male ICR mice. (Supported by a grant of the Korea Health 21 R&D Project, 01-PJ2-PG3-21605-0002, Ministry of Health & Welfare, Republic of Korea.)

1564 DICHLOROACETYLATED PROTEIN ADDUCTS IN LUNG AND LIVER OF MICE TREATED WITH TRICHLOROETHYLENE.

B. Millen[1], J. Parker[2] and P. Forkert[1]. [1]*Anatomy & Cell Biology, Queen's University, Kingston, ON, Canada and* [2]*National Center for Environmental Assessment, USEPA, Washington, DC.*

Trichloroethylene (TCE) exposure elicits lung and liver toxicities. We have used an immunochemical approach to investigate formation of protein adducts in mice treated with TCE. We have used a polyclonal antibody that recognizes the dichloroacetylated proteins (DCA). In immunohistochemical studies, mice were treated with TCE (1000 mg/kg, i.p.) and sacrificed 4 h later. Lung and liver tissues were fixed with 4% paraformaldehyde. Tissues were stained using the anti-DCA antibody and the avidin-biotin complex procedure. Protein immunoblotting was performed with lung and liver microsomal proteins from mice treated with TCE (250, 500, 750 and 1000 mg/kg, i.p.). Proteins were separated and transferred to a nitrocellulose membrane. In time-course studies, mice were treated with TCE (1000 mg/kg, i.p.), and were sacrificed at 2 to 6 h after treatment. The immunohistochemical studies revealed staining for dichloroacetylated proteins that was highly localized in the bronchiolar epithelium of TCE-treated mice. Staining in the liver was localized in centrilobular hepatocytes. Protein blots prepared with the anti-DCA antibody showed a major protein band with a molecular weight of 51 kDa. Immunoreactivity of this band was dose-dependent in both lung and liver. Time-course studies showed that immunoreactivity was maximal at 4 to 6 h for lung and liver microsomal proteins. When the nitrocellulose membrane reacted previously with the anti-DCA antibody was stripped and re-probed with a CYP2E1 antibody, the same 51 kDa band immunoreactive for dichloroacetylated proteins was also immunoreactive for CYP2E1. However, CYP2E1 immunoreactivity in lung microsomal proteins from TCE-treated mice was decreased, compared with that in untreated mice. This TCE-induced effect was not as marked in blots prepared with liver microsomal proteins. These findings supported the proposal that TCE metabolism results in the formation of reactive metabolites that bind to proteins of which the CYP2E1 enzyme may be a major target. Supported by EPA.

1565 BIOTRANSFORMATION OF ZAFIRLUKAST BY CYTOCHROME P450 3A4.

K. W. Skordos and G. S. Yost. *Pharmacology and Toxicology, University of Utah, Salt Lake City, UT.*

Zafirlukast, (4, 5-cyclopentoxycarbonylamino-3-[(2-methoxy-4, 2-methylphenylsolfonylaminocarbonyl)phenylmethyl]-1-methylindole), is a leukotriene D4 receptor antagonist that is utilized clinically for the management of mild to moderate asthma. The drug is primarily metabolized by cytochrome P450 2C9, and was recently demonstrated to inhibit the cytochromes P450 2C9, 2C19, 3A4, and 1A2. Therefore, its clinical use requires drug monitoring due to potential interaction, particularly with the 3A4 substrate theophylline. Zafirlukast has a structural nucleus that is similar to the pneumotoxin 3-methylindole, which is bioactivated by P450 enzymes to a reactive, electrophilic methylene imine intermediate, by dehydrogenation. Kassahun et al proposed that zafirlukast is susceptible to bioactivation *via* a similar P450-mediated dehydrogenation pathway, forming an electrophilic iminium intermediate. The biotransformation of zafirlukast by recombinant cytochrome P450 3A4 has been evaluated in our laboratory. As confirmed by LC/MS, 3A4 catalyzed the formation of an electrophilic intermediate that was trapped with glutathione. The adduct was detected as partially separable diastereomers, which is consistent with glutathione addition at the methylene position of the indole nucleus, generating a chiral center at this position. Three additional hydroxylated metabolites were also formed. One of these metabolites may be a carbinol that forms at the methylene position of the indole, by hydroxyl rebound following initial hydrogen atom abstraction by the P450 enzyme. This hydroxylation reaction could compete with the dehydrogenation pathway. Participation of the proposed electrophilic iminium species as the ultimate inhibitor of cytochrome P450 3A4 is currently under investigation. Zafirlukast may therefore be a novel mechanism-based inhibitor of certain cytochrome P450 enzymes. (Supported by HL16345, Nation Heart, Lung and Blood Institute, NIH.)

1566 DETERMINATION OF TRACE LEVELS OF DICHLOROACETIC ACID (DCA) IN RAT LIVER BY LIQUID CHROMATOGRAPHY AND MASS SPECTROMETRY (LC/MS).

A. M. Dixon, D. C. Delinsky, S. Muralidhara, J. V. Bruckner, J. W. Fisher and M. G. Bartlett. *Pharmaceutical and Biomedical Sciences, University of Georgia, Athens, GA.*

DCA is a chlorination disinfection byproduct commonly found in drinking water. In addition, DCA is a metabolite of trichloroethylene (TCE), a metal degreaser that is also present in many drinking water sources. Results of studies of DCA in rodents suggest that exposure to even small quantities of the chemical in drinking water may be associated with increased cancer risks to humans. Methods currently utilized for the analysis of DCA require a derivitizing reagent that results in an artificially high level of DCA in samples, due to conversion of trichloroacetic acid (TCA) to DCA. The method developed in this study involves no derivitizing reagents, yet still achieves trace-level determination of DCA. Liver samples for this study were obtained from male Sprague-Dawley rats. Homogenized liver samples were spiked with appropriate amounts of DCA to yield 200-uL samples with concentrations of 0, 1, 5, 10, 50, 100, 500, 1000, 5000, and 10000 ng/mL DCA. Protein precipitation was accomplished by adding 400 uL of ice-cold acetonitrile to each sample. The supernatant was removed and diluted to a total volume of 1 mL with 60:40 acetonitrile:water. Solid phase extraction was then performed on each sample. The sample eluate was dried under nitrogen and reconstituted in 100 uL of 60:40 acetonitrile:water prior to LC/MS analysis. Good linearity was observed for samples across the entire concentration range, as a R^2 of .99 was achieved. The limit of detection was found to be 1 ng/mL (ppb). With this new method, it should be possible to better define TCE metabolic pathways leading to DCA and to quantify yields of DCA from TCE in different species. (Supported by SERDP Grant CU1073DOE and DOE Cooperative Agreement DE-FC02-02CH11109.)

1567 CHLOROETHANE METABOLISM COMPARED WITH TOXIC THRESHOLD ACTIVITIES.

J. W. Holder. *USEPA, Washington, DC.*

High chloroethane (15, 000 ppm CE) causes the highest incidence (86%) of any carcinogen in the NTP database producing an uncommon B6C3F1 mouse tumor type, endometrial carcinomas, which aggressively metastasize to 15 organs killing the ♀. F344 rats do not respond with carcinogenesis. The lowest CE noncancer effect is a low incidence of foramina in BF-1 mouse skulls at 5, 000 ppm, but none below. Other tox studies show no significant pathology < 5, 000 ppm. This analysis examines the metabolic bases for this apparent threshold of CE toxic activity. CE is oxidized by microsomal CyIIE1 and is conjugated by cytosolic GSH/GST (glutathione transferase). Oxidation proceeds *via* CypIIE1 by Michaelis-Menton elimination becoming saturated at 469 ppm CE. GSH (liver ≈5mM) effectively conjugates CE linearly up to about 5, 000 ppm CE. Above this, all rodent GSH organ levels significantly decrease, a metabolic state that likely does not maintain adequate electrophile xenobiotic protection. (1) B6C3F1 mice possess only about 1/3–1/2 of F344 rat GST levels, and (2) CE-caused GSH decreases are typically greater in the mouse than the rat. One exposure cycle shows GSH decreasing during 6 hrs CE exposure, recovery within 4 hrs, and over-compensation in some organs providing higher-than-normal levels at the end of the 18 hr resting portion just prior to the next exposure. (3) These low-to-high oscillations of GSH pools seem to occur most in murine liver, lung, and uterus—the cancer target organ. These 3 observations suggest the mouse is more at risk than the rat: this is consistent with observed toxicity. GSH oscillations week-after-week would place chronic metabolic stress on those organ systems most affected and could relate to the bioassay exposures causing foramina at 5, 000 ppm and overt uterine cancer at a persistent 15, 000 ppm CE. Notably CE toxic occurrences only take place at, or above, the CE exposures where oxidation and conjugation are both saturated. Persistent CE exposures < 469 ppm seem to produce steady-state metabolism. ∴ Low environmental CE exposures may not cause significant toxicity including chemical carcinogenesis especially since CE has low genotoxicity.

1568 HEXACHLOROBENZENE INCREASES UROPORPHYRIA IN MICE WITHOUT INCREASING CYP1A2.

N. Gorman[1,2], H. Trask[1,2], W. Bement[1], J. Sinclair[1,2,3], G. Gerhard[1,4], A. Smith[5], F. Gonzalez[6] and P. Sinclair[1,2,3]. *[1]VA Medical Center, White River Junction, VT, [2]Biochemistry, Dartmouth Medical School, Hanover, NH, [3]Pharmacology/Toxicology, Dartmouth Medical School, Hanover, NH, [4]Pathology, Dartmouth Medical School, Hanover, NH, [5]MRC Toxicology Unit, University of Leicester, Leicester, United Kingdom and [6]NIH, Bethesda, MD.*

Previous work has demonstrated that hepatic uroporphyrin (URO) accumulation caused by halogenated aromatic compounds such as TCDD is prevented in CYP1A2 knockout mice of the C57BL/6 strain. This includes the uroporphyria caused by hexachlorobenzene (HCB) which, unlike TCDD, causes only a small increase in CYP1A2. Constantin et al. have reported that treatment of iron-loaded SWR mice with HCB and 5-aminolevulinate (the porphyrin precursor) produces a rapid and large accumulation of hepatic URO [Biochem Pharmacology 52, 1407-13, 1996]. SWR mice express a low affinity receptor for halogenated aromatic compounds (Ahrd) compared to the high affinity receptor (Ahrb1) in C57BL/6 mice. We have reproduced this unexpected uroporphyria in SWR mice with the additional finding that no increases in hepatic CYP1A2 were found in HCB-treated mice. Similar results were obtained with identical treatment of mice of 129 [both (S1 and S6 sublines)] background which also carry the low affinity Ahrd receptor. In the 129S6 subline, the effect of administered iron could be replaced by using mice carrying the Hfe knockout. CYP1A2 was not increased by HCB in these 129 mice. As reported previously for CYP1A2 knockout C57BL/6 mice, uroporphyria was not produced in 129 S1 mice with the CYP1A2 knockout treated with HCB, iron and ALA. These results indicate that although some level of CYP1A2 expression is required for the induction of uroporphyria, the role of HCB in producing uroporphyria includes effects other than increasing CYP1A2. This work was supported by funds from the Department of Veterans Affairs and by grants from the National Institutes of Health ES06263 (PRS) and AG14731 (GG).

1569 INTERACTION BETWEEN A BROMINATED FLAME-RETARDANT (PBBE 99) AND AN *ORTHO*-SUBSTITUTED PCB (PCB 52) ENHANCES DEVELOPMENTAL NEUROTOXIC EFFECTS.

P. Eriksson, C. Fischer, H. Karlsson and A. Fredriksson. *Environmental Toxicology, Uppsala University, Uppsala, Sweden.*

Polybrominated diphenyl ethers (PBDEs) are used in large quantities as flame-retardant additives in polymers, especially in the manufacture of a great variety of electrical appliances, and textiles. PBDEs are persistent compounds that appear to have an environmental dispersion similar to that of PCBs and DDT. While there is a decrease for PCBs and DDT the PBDEs have been found to increase in the environment and in human mother's milk. In several reports we have shown that low-dose exposure of environmental toxic agents such as PCB, DDT, during the brain growth spurt (BGS), when the maturational processes of the developing brain are at a stage of critical vulnerability in neonatal mice, can lead to disruption of the adult brain function. Recently we have reported that different PBDEs, such as PBDE 47, PBDE 99, PBDE 153 and PBDE 209 can cause developmental neurotoxic effects when given to mice during this BGS. The neurobehavioural defects were also seen to worsen with age. In the present study a combined exposure to both PBDE 99 and PCB 52 was investigated. Ten-day-old NMRI male mice were given one single

oral dose of either PCB 52 1.4 μmol/kg bw + PBDE 99 1.4 μmol/kg bw, PCB 52 1.4 μmol/kg bw, PCB 52 14 μmol/kg bw, PBDE 99 1.4 μmol/kg bw, or PBDE 99 14 μmol/kg bw. Controls received a vehicle (20% fat emulsion). Spontaneous behaviour was studied in 4-month-old and 6-month-old mice. Animals exposed to the combined dose of PCB 52 (1.4 μmol/kg bw) + PBDE 99 (1.4 μmol/kg bw), PCB 52 (14 μmol/kg bw) and PBDE 99 (14 μmol/kg bw), showed significantly impaired spontaneous motor behaviour at the age of 4- and 6-months. In animals exposed to the combined dose of PCB 52 + PBDE 99, and the high dose of PCB 52, the defects worsen with age as the habituation capability was significantly worse in 6-month-old compared to 4-month-old. The present study shows that PBDEs and PCBs can interact and enhance developmental neurotoxic effects when the exposure occurs during a critical stage of neonatal brain development.

1570 COMPARISON OF PCB SPECIFIC CONGENER PROFILES IN SKIN AND EAR OF MICE EXPOSED TO AN ENVIRONMENTAL PCB/PCDF MIXTURE.

K. IMSILP, L. G. Hansen and R. B. Cope. *Veterinary Biosciences, University of Illinois, Urbana, IL.*

PCBs are ubiquitous environmental contaminants and bioaccumulate in a congener- specific manner in several tissues. Composition of PCBs is important for assessing exposure source and possible health effects. Our objective was to determine and compare the PCB specific congener profiles in surface-cleaned skin and ears of mice exposed to an environmental PCB/PCDF mixture. Ear notches (for identification) had been previously saved and analyzed as a possible biopsy medium. Two groups of hairless mice were placed on either PCB/PCDF contaminated soil collected from an old electric landfill in Illinois or on control soil for 4 weeks. Mice were weighed weekly. Skin and ear were washed with alcohol and collected immediately after the termination of exposure. PCB specific congener profiles were determined using a 6890N gas chromatography system equipped with DB-5 60M capillary column and a μ-electron capture detector (μ-ECD). Mice exposed to the chlorinated aromatic contaminated soil were significantly ($p<0.05$) heavier and contained significantly ($p<0.001$) higher total PCB residues than those exposed to control soil. PCB congener profiles of the skin and ear samples were similar, reflecting the profile of the soil and enhanced accumulation of the more persistent congeners. However, total PCBs in the skin and ear samples differed in that the ear showed significantly higher total PCBs ($p<0.05$) than in the skin. Skin, including the ear, is an important reservoir for PCBs and may serve as a useful biopsy medium.

1571 EXPRESSION OF CYCLOOXYGENASE-2 IN HL-60 CELLS EXPOSED TO POLYCHLORINATED BIPHENYLS.

S. A. Bezdecny[1,2,3], R. A. Roth[1,2,3] and P. E. Ganey[1,2,3]. [1]*Department of Pharmacology and Toxicology, Michigan State University, East Lansing, MI,* [2]*Institute for Environmental Toxicology, Michigan State University, East Lansing, MI and* [3]*National Food Safety and Toxicology Center, Michigan State University, East Lansing, MI.*

Polychlorinated biphenyls (PCBs) are persistent environmental contaminants that affect a number of cellular systems including neutrophils. PCBs can be divided into two classes based on the chemical structure. Non-ortho-substituted, coplanar congeners act through the aryl hydrocarbon (Ah) receptor, whereas ortho-substituted, noncoplanar congeners act through different and poorly understood mechanisms. It is these latter, noncoplanar PCBs that alter neutrophil function. The objective of these experiments was to explore further the mechanisms by which PCBs affect neutrophil function. The human promyelocytic leukemia (HL-60) cell line was differentiated with DMSO to a neutrophil-like phenotype. Treatment of differentiated HL-60 cells with 2, 2′, 4, 4′-tetrachlorobiphenyl, a noncoplanar, ortho-substituted PCB congener, caused an increase in f-Met-Leu-Phe-induced degranulation, as measured by release of myeloperoxidase (MPO). Treatment with the coplanar, non-ortho-substituted congener 3, 3′, 4, 4′, 5-pentachlorobiphenyl, had no effect on MPO release. The effect of PCBs on mRNA levels of cyclooxygenase-2 (COX-2) was examined using semiquantitative RT-PCR. COX-2 mRNA was significantly elevated in response to 2, 2′, 4, 4′-tetrachlorobiphenyl in a dose-dependent manner. COX-2 expression was maximized by 30 minutes of exposure to 2, 2′, 4, 4′-tetrachlorobiphenyl. 3, 3′, 4, 4′, 5-pentachlorobiphenyl did not increase COX-2 mRNA levels. These results demonstrate that noncoplanar, ortho-substituted PCBs alter the functional status of granulocytic HL-60 cells, causing enhanced degranulation and upregulation of COX-2, whereas coplanar, non-ortho-substituted PCBs lack this activity. These data suggest that ortho-substituted, noncoplanar PCBs alter HL-60 cell function and COX-2 expression *via* an Ah-receptor-independent mechanism. (Supported by ESO4911.)

1572 CO-ELEVATION OF HEPATIC GLUTATHIONE S-TRANSFERASE ACTIVITY WITH UROPORPHYRIN CONCENTRATION IN PORPHYRIC MICE.

M. R. Franklin[1], L. A. Johnson[1], J. D. Phillips[2] and J. P. Kushner[2]. [1]*Pharmacology and Toxicology, University of Utah, Salt Lake City, UT and* [2]*Medicine, University of Utah, Salt Lake City, UT.*

Mice heterozygous for a null mutation at the uroporphyrinogen decarboxylase locus (Uro-D+/-) fed a normal diet develop modest uroporphyria with polychlorinated biphenyl (PCB) exposure. Wild type (Uro-D+/+) mice treated with PCBs did not develop uroporphyria. The glutathione S-transferase (GST) activity in PCB-treated Uro-D+/- animals is double that of similarly treated Uro-D+/+ animals. The uroporphyria elicited with PCBs in Uro-D+/- animals is exacerbated by a single injection of iron-dextran and attenuated by maintenance since weaning on an iron deficient diet. With either iron-modifying treatment, the change in GST activity paralleled the change in uroporphyrin concentration. Uroporphyria can also be produced in Uro-D+/- but not Uro-D+/+ animals by continuous delta-aminolevulinic acid supplementation of their drinking water. This treatment elevated GST activity only in Uro-D+/- animals. High GST activity accompanying the uroporphyria elicited by delta-aminolevulinic acid treatment indicates that the association is independent of GST-inducing effects of PCBs. Thus over multiple treatment regimens producing uroporphyria, there is a tight association between the hepatic GST activity and uroporphyrin concentration, suggesting that uroporphyrin might be an endogenous inducer of GSTs.

1573 PCB-INDUCED INHIBITION OF MONOAMINE TRANSPORTERS PREDICTS RAT SYNAPTOSOMAL TISSUE AND MEDIA DOPAMINE AND DOPAC CONCENTRATIONS.

J. Bemis[1] and R. F. Seegal[1,2]. [1]*School of Public Health, University at Albany, Albany, NY and* [2]*Wadsworth Center, NY State Department of Health, Albany, NY.*

Polychlorinated biphenyls (PCBs) may alter behavior *via* changes in central dopamine (DA) function. The DA transporter (DAT) and vesicular monoamine transporter (VMAT), responsible for the uptake of extracellular DA or packaging of cytosolic DA into synaptic vesicles, respectively, aid in regulation of neurotransmitter trafficking. Although PCBs inhibit DA uptake *via* the DAT and VMAT, the consequences on DA function are not known. To address this question, we exposed purified adult rat striatal synaptosomes to PCB congeners, measured tissue and media DA and dihydroxyphenylacetic acid (DOPAC, the main intracellular metabolite of DA) concentrations and determined the relationship between these changes and DAT or VMAT inhibition. The ability of specific congeners to inhibit DAT activity correlated positively with PCB-induced reductions in tissue DA content and elevations in media DA concentrations. Structurally, the most active congeners were ortho-chlorine substituted, while coplanar congeners showed no activity. Congeners with the lowest EC50 values for VMAT inhibition elicited the greatest elevations in tissue plus media DOPAC, a recognized measure of non-vesicularly stored DA. Thus, VMAT inhibition was positively correlated with DOPAC formation, and by inference, elevations in free cytosolic DA. These data demonstrate that PCB-mediated monoamine transporter inhibition influences both media and tissue DA and DOPAC concentrations. Such alterations in media and tissue DA could potentially lead to impairment of signal transmission and/or terminal damage *via* the neurotoxic effects of free DA. Together these observations enhance the importance of DA transporters in the effects of exposure to PCBs. Supported by NIH Grant 1034004 to RFS.

1574 A DIORTHOCHLORINATED PCB CONGENER 2, 2', 4, 4'-TETRACHLOROBIPHENYL (TCB) ACTIVATES EXTRACELLULAR SIGNAL REGULATED KINASES (ERKS) INDEPENDENT OF PROTEIN KINASE C (PKC) IN JB6 MOUSE EPIDERMAL CELLS.

B. V. Madhukar and O. Hernandez-Maldonado. *Pediatrics/Human Development, Michigan State University, East Lansing, MI.*

Non-coplanar orhto cholorine substituted polychlorinated biphenyl (PCB) congeners may contribute significantly to the toxic effects of environmental PCB mixtures. The mechanisms of the toxic effects of the non-coplanar PCB congeners remain unclear. In this study we examined the cellular interactions of 2, 2'4, 4'-TCB on the ERKs, a sub-family of the mitogen activated protein kinases that play a central role in cell signaling, in a tumor promoter sensitive mouse epidermal cell line JB6 (JB6P+). Treatment of JB6P+ cultures for one hour with 2, 2', 4, 4'-TCB (0.1 - 20.0 μM) caused a dose dependent activation of ERK 1 and ERK 2 as assessed by changes in the phsophorylation state of these proteins. At 20.0 uM concentration the TCB caused a 10-fold increase in the phoshporylation state of these proteins. The onset of ERK activation by the TCB was seen only at 15 min post treatment

relative to the rapid (2 min) effect of the mitogenic growth factor TGF-αalpha. TCB induced ERK activation sustained for at least 24 hrs. Pre-treatment of the the cultures with University-0126 (10.0 μM) an inhibitor of the upstream kinase MEK completely inhibited ERK activation by the TCB. University-0126 also inhibited ER activation induced by TPA a potent activator of PKC. However, pre-treatment of JB6P+ cultures with bisindoloylmaleimide (5-0 μM) abrogated ERK activation by TPA but failed to inhibit that induced by the TCB. Gel-shift analysis showed that TCB induced the activation of the AP-1 transcription factor that independent of PKC but was dependent on ERK. These data suggest that diortho chlorine-substuted PCBs activate ERK associated cell signaling cascade independent of PKC. Such an activation of the ERKs may lead to the activation of transcription factors such as AP-1 to alter gene expression (supported by NIH grant ES-04911 and a Philip Morris Research grant).

1575 EFFECTS OF COMPLEX PAH MIXTURES AND 7H-BENZO(c)FLUORENE ON DNA ADDUCT FORMATION IN MICE.

L. Cizmas, G. Zhou, T. McDonald, S. Safe and K. C. Donnelly. *Texas A&M University, College Station, TX.*

Previous research has identified *7H*-benzo[*c*]fluorene (BCF) as a potent adductor of lung DNA (Carcinogenesis 21:1601-9). The goal of the present study was to determine the contribution of BCF to the formation of lung and skin DNA adducts following acute dermal exposure to analytical grade BCF and coal tar fractions. Coal tar was separated into 7 fractions (F1-F7). Polycyclic aromatic hydrocarbons (PAHs) including BCF were quantified using gas chromatography/mass spectrometry (GC/MS). An aliquot of the F2 fraction was further separated into a "BCF fraction" and an "F2-BCF fraction". The F2 fraction contained 7, 395 ppm BCF and 40, 122 ppm carcinogenic PAHs (cPAHs, or the sum of all class B2 carcinogens based on the USEPA classification). The BCF fraction contained 35, 000 ppm BCF and 215, 609 ppm cPAHs, while the F2-BCF fraction contained 3, 900 and 45, 216 ppm respectively. The three fractions and analytical grade BCF were applied dermally to female CD-1 mice. After 24 hr the mice were sacrificed and tissues harvested. DNA adduct levels were analyzed by nuclease P1-enhanced ^{32}P-postlabeling, and following subtraction of solvent control values, were quantified as RAL x 10^9 values. In skin DNA of mice dosed with 0.48 or 3.0 mg/mouse, F2 induced total adduct levels of 266.62 and 823.04 respectively, F2-BCF induced 126.41 and 331.37, and the BCF fraction yielded 424.26 and 1062.12 respectively. The lung DNA of mice dosed with 0.48 or 3.0 mg/mouse yielded the following total adduct levels: F2, 26.47 and 79.76 respectively; F2-BCF, 17.77 and 137.55 respectively; and the BCF fraction, 22.78 and 97.48. Mice that were dosed with 100 ug/mouse of analytical grade BCF, equivalent to the dose of BCF present in 3.0 mg of the BCF fraction, showed total adduct levels of 4.22 in skin DNA and 8.95 in lung DNA. At the site of application, DNA adduct levels were appreciably greater than were observed in the lungs. In addition, the removal of the BCF isolates did not reduce the level of adducts induced by F2 in the lungs. The results indicate that pharmacokinetics play an important role in DNA adduct formation.

1576 PAH REGUALTION OF CYP1 GENE IN ZR-75-1 HUMAN BREAST CANCER CELLS.

K. N. Min, Y. Y. Sheen, J. Y. Kim and M. J. Cho. *Pharmacy, Ewha Womans University, Seoul, Seoul, South Korea.* Sponsor: Y. Cha.

Recent industrial society has human widely exposed to PAHs that are comming from the incomplete combustion of organic material as widerspread environmetal contaminants. Biological activities of PAHs are not known although PAHs are considered as carcinogens. The mechanism of action of PAHs has been studied extensively, however it is not clear how PAHs turn on CYP1A1 in human breast cancer. Our labolatory have been studied the effect of PAHs in the human breast cancer cell MCF-7. In this study, we examined the ZR-75-1 human breast cancer cells as a new system to evaluate bioactivity of PAHs and to compare the PAH action with that of MCF-7 cells. ZR-75-1 human breast cancer cell line is response to estrogen and progesteron. We have been able to estabilish long term culture system of this cells then used for the study to the effect of 13 different PAHs and environmental samples. We demonstrate that PAHs induced the CYP1A1 promoter and 7-ethoxyresolufin O-deethylase(EROD) activity in a concentration-dependant manner. RT-PCR analysis indicated that PAHs significantly up-regulate the level of CYP1A1 mRNA. Some of PAHs showed stronger stimulatory effect on CYP1 gene expression than TCDD. Apparently, ZR-75-1 cells have Aryl hydrocarbon receptors, therefore it would be good experimental tool to study the cross-talk between PAHs and steroid actions. [Supported by grant from the Ministry of Environment of Korea]

1577 BINDING OF PAHS AND THEIR METABOLITES TO THE ESTROGEN RECEPTOR: A COMPARISON OF THREE.

J. M. Gozgit[1], K. M. Nestor[1], B. T. Pentecost[2] and K. F. Arcaro[1]. *[1]Environmental Sciences and Veterinary and Animal Sciences, University of Massachusetts, Amherst, MA and [2]Division of Genetic Disorders, Wadsworth Center, NYSDOH, Albany, NY.*

The goal of this study was to determine the extent to which 14 polycyclic aromatic hydrocarbons (PAHs) or their metabolites bind the estrogen receptor (ER). We examined 14 PAHs frequently detected in environmental samples. The ability of PAHs and/or their metabolites to bind the ER was tested in three assays: 1) a competitive binding assay using human recombinant ER (hrER) and [^{3}H]17β-estradiol ([^{3}H]E_2), 2) a whole-cell estrogen receptor binding assay using the ER-positive breast cancer cell line, MCF-7, and [^{3}H]E_2, and 3) a dual luciferase reporter assay using transiently transfected MCF-7 cell cultures. None of the PAHs significantly displaced [^{3}H]E_2 in the hrER competitive binding assay. In contrast, 8 of the 14 PAHs displaced [^{3}H]E_2 in the whole-cell ER binding assay when the assay was conducted at temperatures permissive of metabolism. These results suggested that PAHs were metabolized in MCF-7 cell cultures to compounds that bound the ER. To further test this hypothesis, PAHs were incubated in microsomes prepared from either 1) human livers, (Xenotech Ltd.,) or MCF-7 cell cultures. However, none of the PAH-microsomal reaction mixtures significantly displaced [^{3}H]E_2 in the hrER competitive binding assay, suggesting that the hrER competitive binding assay was not sensitive enough to detect the binding of the low concentrations of metabolites in the microsomal reaction mixtures. The dual luciferase reporter assay is similar to the whole-cell ER binding assay in that metabolism of PAHs may occur during the incubation period, and the PAHs did result in a significant induction of luciferase in this assay. The data from this study support the conclusion that some PAHs are metabolized in breast cancer cell cultures to compounds that bind the ER. (Supported by grants K02 ES11726 and R01 ES09795 from NIEHS)

1578 ARYL HYDROCARBON HYDROXYLASE (AHH) ACTIVITY AND BENZO(a)PYRENE (BaP) METABOLITE CONCENTRATIONS IN F-344 RATS SUBCHRONICALLY EXPOSED TO INHALED BaP.

A. Ramesh, M. Greenwood, F. Inyang, M. Niaz, P. Kopsombut, D. B. Hood, A. E. Archibong and A. M. Nyanda. *OB/GYN, Meharry Medical College, Nashville, TN.*

This study was conducted to measure the AHH activity and metabolism of BaP subsequent to subchronic exposure by inhalation. Fisher-344 male rats were exposed 4 hours a day, for 60 days (via nose-only inhalation) to aerosol exposure concentrations of 75 μg/m^3 of BaP adsorbed onto carbon black particles using a state-of-the-art model aerosol generation system. Control animals were either exposed to carbon black or unexposed controls. After exposure, rats were sacrificed, liver, lung, kidney, and testis were removed, and microsomes were isolated. Aryl hydrocarbon hydroxylase activities were determined by reverse-phase HPLC coupled with fluorescence detection using 3-hydroxy BaP as the standard. Tissue samples from the above mentioned organs were also analyzed for BaP and metabolites by HPLC. Our results demonstrate that liver possess a higher AHH activity than lung, testis, and kidney tissues. While lung ranked next to liver, there is no significant difference between testis, and kidney with regard to AHH activity measured. Among the metabolites detected, BaP 4, 5-7, 8-, 9, 10-dihydrodiols, 3(OH) BaP, and 9(OH) BaP were predominant. Interestingly, the most reactive metabolite of BaP, the 7, 8-diol-9, 10-epoxide (BPDE) concentrations were high in testis, compared to liver, lung, and kidney. The presence of AHH activity in testis, coupled with the detection of high concentrations of BPDE suggests the likelihood that long-term exposure to inhaled BaP results in a) elevated levels of AHH activity in target organs, b) contribute to the formation of toxic, reactive metabolites in these organs, and c) impairment of reproductive potential as exemplified by a decrease in progressive motility of stored sperm, and plasma testosterone concentrations of rats in studies conducted earlier in our laboratories (supported by MHPF/ATSDR grant #U50/ATU398948, NIGMS-SCORE grant #2SO6GMO8037-28, and NCRR-RCMI grant #G12RRO3032).

1579 CHARACTERIZATION OF GENETIC CHANGES ASSOCIATED WITH BENZO(a)PYRENE IN NORMAL HUMAN EPIDERMAL KERATINOCYTES: APPLICATION OF MICROARRAY TECHNOLOGY.

D. S. Perez, R. S. Yang and J. A. Campain. *Department of Environmental & Radiological Health Sciences, Colorado State University, Fort Collins, CO.*

We are interested in developing risk assessment strategies for environmentally relevant chemical mixtures. To this end, normal human epidermal keratinocytes (NHEK) were chosen as an *in vitro* model for measuring potentially carcinogenic

effects of petroleum-based hydrocarbons. Our initial studies demonstrated that benzo[a]pyrene (BaP) induces substantial alterations in NHEK in culture. Similar to the known skin carcinogen arsenic, BaP acts to inhibit differentiation, as measured by cornified envelope formation. BaP also increased the rate of proliferation in a dose-dependent manner in treated cells. Current studies utilizing microarray analysis are focused on identifying molecular markers altered during BaP treatment that may be involved in these effects. Preliminary results using the Clontech Human 3.8 II array are as follows: 1) in total, 34 genes were induced and 2 genes were suppressed by >2-fold in NHEK treated with 2μM BaP, as compared to control; 2) among genes overexpressed in BaP-exposed cells were carbonyl reductase 3 and flavin containing monooxygenase 1 (metabolizing enzymes), α integrin binding protein 63 (involved in suppressed differentiation), and IL-1α and Ras (both involved in proliferation), and; 3) the genes for cytochrome P450 XXIA and SEC14 were down regulated. These results will be confirmed using Real Time-PCR. Mechanistic studies with a subset of genes may allow us to correlate alterations in these molecular markers with the transformation process in NHEK, and to develop predictive capabilities for risk assessment of petroleum-based mixtures. Also, comparison of gene expression patterns induced by BaP with those seen in arsenic-treated keratinocytes may give clues as to the mechanisms whereby these two chemicals suppress differentiation. This research was supported by NIEHS Grant # RO1 ES09655 & Minority Supplement # RO1 ES09655-01S1.

1580 ESTIMATION OF CANCER POTENCY FOR TAMOXIFEN BASED ON STUDIES IN ADULT RATS AND NEONATAL RATS AND MICE.

R. S. Tomar, T. A. McDonald and M. S. Sandy. *OEHHA, Cal/EPA, Oakland, CA.*

Tamoxifen is the drug of choice to delay the recurrence of breast cancer and is used as a prophylactic in high-risk women to prevent the development of this disease. Epidemiology studies have demonstrated a two- to seven-fold increased risk of developing endometrial cancer in women treated with tamoxifen. In long-term (104 weeks) studies in mature male and female rats, tamoxifen induced hepatocellular carcinoma. In short-term exposure studies in rats (2-5 days) and mice (1-5 days) observed for 152 and 67 weeks, respectively, tamoxifen induced uterine adenocarcinoma. Tumor response was essentially similar (20 percent) in neonatal rats and mice on an equivalent mg/kg-day basis. The mouse dataset is comprised of multiple tamoxifen treatment groups, while the rat dataset consists of only one treatment group. Cancer potency (slope of the dose response curve) for neonatal exposure was compared to that for adult exposure. To calculate neonatal potency, dose administered to neonatal mice on days 1-5 of life was averaged over the first 21 days of life, a sensitive period for estrogenic effects in these animals. The potency derivations take into account the less-than-lifetime study duration of the neonatal studies and body size differences between humans and experimental animals. The human cancer potency estimate based on uterine adenocarcinoma in the neonatal female mouse was 28 (mg/kg-day)-1, whereas the potency estimates based on liver tumors in adult male and female rats were 0.24 (mg/kg-day)-1 and 0.23 (mg/kg-day)-1, respectively. The greater than 100-fold difference in the cancer potency derived from neonatal exposure in mice as compared to adult exposure in rats indicates that the neonatal period is a critical window of susceptibility to the carcinogenic effects of tamoxifen. Given concern over increasing incidence of endocrine related cancer, research is needed to determine if other estrogenic compounds are more potent early in life.

1581 CROSS FOSTERING OF MINIPIGS FOR JUVENILE TOXICOLOGY STUDIES: RESULTS OF A VALIDATION STUDY.

A. Makin, Z. El-Salanti, A. Christensen and R. J. Harling. *Toxicology and Pharmacology, Scantox A/S, Lille Skensved, Denmark.*

Most pre-clinical safety evaluation of human pharmaceuticals is performed in adult or young adult animals and therefore many drugs are not licenced for use in human paediatric populations. In order to gain regulatory approval for the use of products in pre-adult humans, it is required that appropriate toxicity studies are undertaken in juvenile animals. For non-rodent species, this presents a number of practical and logistical challenges. Examples include smaller litter sizes in comparison with rodents, long gestation periods, long pre-weaning periods, space requirements and cost. There are in effect, three possible basic approaches to study design. One is to use the whole litter as the basic group or experimental unit. Another is to all treatments represented within each litter. Thirdly, one can randomise the allocation of offspring to mothers at birth (cross-fostering) and to treat all animals allocated to one mother as a group. All three approaches have advantages and disadvantages, but the cross-fostering approach has the most potential benefits. We have performed an experiment to evaluate the possibilities of cross-fostering minipigs within our laboratory with a view to offering this study design as a service to our customers. Randomised cross-fostering of piglets was performed on Day 1 after birth, and various standard evaluations were performed during the first 4 weeks. During Week 2, the piglets were subjected to electrocardiographic and ophthalmological examination. In Weeks 1 and 4, blood and urine were collected for routine haematology, clinical chemistry and urinalysis examinations. After Day 29, the piglets were killed. Full autopsy and histopathology were performed. Experimental data obtained were compared with background data from older minipigs. It is concluded that cross fostering of minipigs for performance of juvenile toxicology studies is possible. For the researcher, there needs to be an understanding that there will be differences in expected values for some standard parameters in young animals compared to older ones.

1582 FLOW CYTOMETRY IN REPRODUCTIVE TOXICOLOGICAL STUDIES : IMMUNE SYSTEM ASSESSMENT.

W. C. Congdon, K. Fukuzaki, S. Meyer, R. Nagata, J. Jabbour, R. Klein and B. Melton. *SNBL USA Ltd, Everett, WA.*

The Cynomolgus monkey (Macaca fascicularis) has been increasingly utilized in pre-clinical safety evaluation of investigational new drugs (INDs). Recently the FDA has recommended immune system testing to evaluate possible immunotoxicity. Many new therapeutic strategies utilize proteins (Biologics), which either as part of a designed approach or as a side effect result in changes to immunologic capabilities. These changes may be described utilizing flow cytometry to examine lymphocyte populations. As a tool during reproduction studies, flow cytometry allows the determination of changes evoked in the fetus as determined in cord blood (segment II studies) or from neonatal samples (segment III studies). The neonate can also be followed through early development to determine any effects on immunocompetence. Current background studies conducted at SNBLUSA, utilizing cynomolgus monkeys, demonstrate differences among blood mononuclear subsets in normal mothers as compared to the fetus at 100 days and full term healthy neonates. Cord blood as well as peripheral blood samples from mothers and infants were immunostained with antibodies against T cells (CD3), T helper lymphocytes (CD4), T cytotoxic lymphocytes (CD8), Leucocytes (CD45) and nucleated red blood cells (CD71). The data Includes comparisons of: N=5, mother and fetal comparison, N= 5, mother neonate comparison and N=5, juveniles at the ages of 3 and 6 months. The data to date demonstrates that the level of all markers except CD71 were lower in the fetus than in the neonate. In the neonate CD3 and CD4 were higher than in their mothers by 30% and 80% respectively. CD71 binding is 6 fold higher than the mothers at 100 days gestation. CD45 leucocytes tend to remain constant at day 100 of gestation through birth. Lymphocyte profiles, on the juveniles (N=5), are being collected and will be compared to the 100 day and neonate profiles. Further characterization of immune cells at various stages of development will improve the assessment of immunotoxicity and the effect during reproduction on the immunocompetence of offspring.

1583 AN ASSESSMENT OF THE WEANLING BEAGLE DOG AS A MODEL FOR SCREENING PHARMACEUTICALS INTENDED FOR INTRAVENOUS INFUSION TO PEDIATRIC POPULATIONS.

S. Groom[1], C. Copeman[1], I. Tourigny[1] and K. Robinson[2]. [1]*Infusion, Pharmacology and Neurotoxicology, CTBR, Senneville, QC, Canada and* [2]*Reproductive Toxicology, CTBR, Senneville, QC, Canada.* Sponsor: L. Dostal.

Six weanling dogs were anesthetized and using aseptic techniques, surgically implanted *via* the femoral vein with a medical-grade silicone-based catheter at 63 days of age. These animals were then infused with physiological saline at rates of 1.5 and 5.0 mL/kg/h (i.e. rates considered well tolerated in adult beagle dogs) *via* an in-line 0.2 mm filter, for 24 hours/day for up to 13 weeks. Animals remained in good clinical condition, exhibited normal neurological behavior and electrocardiograms and demonstrated normal growth (including bone growth as measured by DXA and pQCT techniques) throughout the experiment. Dosimetry data confirmed animals received within 10% of the nominal dose volume at each infusion rate over the course of the investigation. The general lack of, or minimal, local tissue damage or inflammatory reaction at the infusion site suggests that the infusion interval could be extended beyond 13 weeks, if required. A marginal reduction in numbers of erythrocytes, slightly lower levels of hemoglobin concentration and hematocrit and markedly higher urinary volumes were noted at the higher infusion rate. The markedly higher urinary volumes produced by the 5.0 mL/kg/h animals might affect metabolism of those compounds eliminated primarily *via* the kidneys whilst the marginal alterations in red cell parameters might affect susceptibility to compounds that suppress erythrocyte production although based on the magnitude of these reductions it is considered unlikely. There were no significant alterations in any end-point measured at the lower infusion rate (1.5 mL/kg/h). Therefore, infusion rate selection requires careful consideration when using weanling dogs as the non-rodent infusion model. Selection of rates around 1.5 mL/kg/h would appear to be appropriate to assess the safety and pharmacokinetics of infused pharmaceutical products intended for use in human pediatric populations.

1584 AN ASSESSMENT OF THE EFFECTS OF HUMAN SOLUBLE IL-4 RECEPTOR ON REPRODUCTION AND NEONATAL DEVELOPMENT WHEN ADMINISTERED INTRAVENOUSLY TO PREGNANT CYNOMOLGUS MONKEYS.

L. L. Carlock[1], S. Oneda[2] and J. L. Bussiere[1]. *[1]Toxicology, Amgen Inc., Seattle, WA and [2]SNBL USA, Everett, WA.*

Fetal development, delivery, lactation, and functional and morphological development of offspring were evaluated in pregnant cynomolgus monkeys administered human soluble IL-4 receptor (sIL-4) intravenously twice a week during the organogenesis period (Gestation Days 20 to 50). Pregnant monkeys were divided into three groups: Vehicle control, low dose (0.2 mg/kg) and high dose (2.0 mg/kg). Each group was further divided into a Natural Delivery Group (dams delivered naturally, neonates examined up to 30 days after birth) and a Cesarean-Sectioning Group (cesareans on Day 100 of gestation, fetuses evaluated). Blood was collected from all dams, fetuses, and neonates for hematology, clinical chemistry, immunology (lymphocyte subset analysis), pharmacokinetics and antibody response to the drug. Dams were evaluated for clinical signs, body weight, food consumption, embryonic/fetal viability, and placental weight. Each fetus was examined for external development, visceral, skeletal, and histopathological changes. Neonates were evaluated for clinical signs, body weight, functional and morphological development. There were no test-article-related abnormalities in maternal clinical signs, body weight, food consumption, hematological, serum biochemistry or immunological examinations. There was an increase in abortion/embryo-fetal death in the 0.2 (9/21 or 42.9%) and 2.0 (5/19 or 26.3%) mg/kg groups compared to controls (3/17 or 17.6%). All fetuses removed at cesarean-sectioning were alive and no test article-related abnormalities were noted. There were three stillborn neonates (2.0 mg/kg group) which were determined to have died before birth - no air in the lungs (anectasis). No neonates died after birth and no test-article-related abnormalities were noted. In conclusion, the No-Observed-Adverse-Effect-Level for IV administration of sIL-4R to pregnant cynomolgus monkeys is less than 0.2 mg/kg based on increased abortion/embryonic death.

1585 CLOSER RESIDENTIAL PROXIMITY TO TRICHLOROETHYLENE-EMITTING SITES INCREASES RISK OF OFFSPRING CONGENITAL HEART DEFECTS AMONG OLDER WOMEN.

J. Yauck[1], M. Malloy[1], K. Blair[2], P. Simpson[3] and D. McCarver[1]. *[1]Pediatrics, Medical College of Wisconsin, Milwaukee, WI, [2]City of Milwaukee Health Department, Milwaukee, WI and [3]Pediatrics, University of Arkansas for Medical Sciences, Little Rock, AR.*

Animal & limited human data suggest that trichloroethylene (TRI) is a selective cardiac teratogen. To assess whether maternal residential proximity to TRI-emitting sites increases the risk of congenital heart defects (CHDs), records of 245 case & 3780 control infants born from 1997-1999 to Milwaukee mothers were reviewed. Case data were obtained by actively reviewing cardiac ECHO, surgical & autopsy reports from the Children's Hospital of Wisconsin. Control & additional case information, including maternal demographics, cigarette smoking & alcohol use in pregnancy & maternal diseases during pregnancy, were obtained from birth certificate data. Cases & controls were matched for birth year; infants with Down's Syndrome were excluded. TRI-emitting sites were identified from 6 environmental databases. Using GIS software, x/y coordinates were assigned to maternal residences & TRI sites & the resulting distances calculated. Classification trees were used to determine appropriate separation of mothers into groups based on older age (≥38 y) & presence of TRI "exposure" (residence within 1.32 mi of ≥1 TRI-emitting site). The proportion of offspring with CHD was greater among older, exposed mothers (29%) compared to older, non-exposed mothers (11%), or young women, irrespective of exposure (~5%, both groups). When other CHD risk factors were considered simultaneously, CHD risk was ~3-fold greater among infants of older mothers living within 1.32 mi of a TRI-emitting site [LR: OR(95% CI)=3.2(1.2-8.7)]. Older maternal age, alcohol use, pre-existing diabetes & chronic hypertension were all associated with increased risk [OR (95% CI)=2.0 (1.1-3.5), 2.1 (1.1-4.2), 4.1 (1.5-11.2), 2.8 (1.2-6.7), respectively]. Residence close to TRI-emitting sites alone was not associated with CHDs. The mechanism by which older age & TRI exposure interact to increase CHD risk is unknown.

1586 CONTINUOUS INFUSION AS A ROUTE OF ADMINISTRATION IN EMBRYO/FETAL DEVELOPMENT STUDIES IN THE RABBIT.

M. J. Beck, T. R. Gleason, C. A. Wally, C. P. Chengelis, D. G. Stump and M. D. Nemec. *WIL Research Laboratories, Inc., Ashland, OH.*

This study determined whether restraint alone or in combination with surgical catheter implantation would have a significant impact on reproductive outcome and what rate of infusion could be safely used not to confound pregnancy. The rabbit is a standard model in embryo/fetal development studies, and the infusion systems are compatible with standard caging. Groups consisted of 10 naive control rabbits, 10 rabbits fitted with tethers and jackets (but not surgically modified) and 20 tethered rabbits continuously infused with 0.9% saline *via* surgically-implanted indwelling femoral catheters. The femoral vein was isolated, an incision was made and a sterile DaVinci catheter with vascular access port was inserted. The vessel was ligated distally and the vascular access port was secured between the dorsal shoulder blades. The catheter was flushed with saline and locked with heparin. Following surgery, animals were allowed to recover for seven days, when the catheter was flushed with heparinized saline. Ten days after surgery, animals were maintained on 0.9% saline delivered at 0.3 ml/hour by calibrated infusion pumps through insemination until gestation day (GD) 7. The infusion rate was increased to 0.5 ml/kg/hour from GD 7-29. Rabbits were artificially inseminated 14 days after surgeries, observed for clinical signs of toxicity, and body weights and food consumption were recorded periodically during gestation. Laparohysterectomies and uterine and fetal examinations were performed on GD 29. One gravid female in the 0.9% saline group died on GD 26; the cause of death was not determined. No infusion- or tether-related clinical observations, internal findings, effects on intrauterine parameters, malformations or developmental variations were observed. Effects on body weights and food consumption were considered related to tethering. Based on the results of this study, catheter implantation and continuous infusion are considered appropriate for embryo/fetal development studies in rabbits.

1587 SODIUM METHYLDITHIOCARBAMATE MODULATES CYTOKINES *IN VIVO* IN B6C3F1 MICE WITH VARIOUS STIMULI.

L. P. Myers, R. Fan, Q. Zheng and S. B. Pruett. *Department of Cellular Biology and Anatomy, Louisiana State University Health Sciences Center, Shreveport, LA.*

Sodium methyldithiocarbamate (SMD) is a fumigant-type pesticide that is used as a general biocide in agriculture. Current EPA estimates rank SMD as the third most commonly used conventional pesticide. SMD use could increase due to EPA pressures to replace methyl bromide with SMD. In previous studies we have demonstrated that SMD suppresses cytokine upregulation *in vivo* after stimulation with anti-CD3. In the current study, we changed stimuli to examine the broadness of suppression by SMD and also included a study with an antigen, KLH (keyhole limpet hemocyanin). Similar to the studies with anti-CD3 as a stimulant, SMD suppresses upregulation of IL-12 when used in combination with poly I:C or LPS. However, unlike the anti-CD3 stimulation, SMD combined with LPS or poly I:C increased IL-10 production *in vivo*. Since IL-10 production might play a role in the cytokine suppression seen with SMD, we dosed IL-10 knockout mice with SMD and poly I:C. Similar to studies in B6C3F1 mice, IL-12 was suppressed in the IL-10 KO mice dosed with SMD and poly I:C. Therefore, it is unlikely that IL-10 plays a role in cytokine suppression by SMD. To examine the effects of SMD with antigen, we dosed mice with KLH (72 hr stimulation) and a single dose of SMD either 12 hours before sampling or 1.5 hrs before sampling. Real time PCR analysis of splenic mRNA indicated that IL-2 was enhanced with SMD at 1.5 hrs but not significantly different at 12 hrs, IL-4 expression was not altered with SMD, and IL-12 was suppressed by SMD 12 hrs but not significantly different at 1.5 hrs. Lastly, we examined mRNA expression by gene chip analysis on SMD, EtOH, and corticosterone treated mice. Analysis of the splenic mRNA indicated 74 genes altered by SMD, 114 genes altered by corticosterone, and 328 genes altered by EtOH. A comparison analysis between the three stressors suggested at least 5 gene products modified in a similar pattern, possibly indicating common stress-related genes. This work was supported by NIH grant #ES09158 and #AA09505.

1588 SUPPRESSION OF INTERLEUKIN-2 GENE EXPRESSION IN EL4.IL-2 CELLS BY ALKENYLBENZENES IS PARALLELED BY AN INHIBITION OF NF-AT.

S. Yea[1,2], H. Jeong[1], W. Jang[1,2], Y. Yang[1,3], K. Paik[1] and C. Yun[4]. *[1]The Paik-Inje Memorial Institute for Biomedical Science, Inje University, Pusan, South Korea, [2]Department of Biochemistry, College of Medicine, Inje University, Pusan, South Korea, [3]Department of Pathology, College of Medicine, Inje University, Pusan, South Korea and [4]Department of Genetic Engineering, Pai-Chai University, Taejon, South Korea.* Sponsor: H. Kim.

As natural components of certain spices, essential oils or vegetables, alkenylbenzene compounds may be consumed by human. However, the potential of alkenylbenzenes for immune modulation and their mechanism have not known. Based on that T-cells play an important role in immune response through the action of cytokines they elaborate, here we investigate the effect of seven naturally occurring alkenylbenzenes on interleukin-2 (IL-2) gene expression in EL4.IL-2 murine T-cells. EL4.IL-2 cells produced IL-2 in response to phorbol-12-myristate-13-acetate

(PMA) plus ionomycin, which were inhibited by myristicin, anethole, eugenol, and isoeugenol in dose-dependent manners. No effect was observed on the treatment of safrole, 4-allylanisole, and allylbenzene. The decrease in IL-2 production was found to correlate well with a decrease in its steady state mRNA expression as demonstrated by quantitative competitive RT-PCR. Electrophoretic mobility shift assay was performed to elucidate the effect of alkenylbenzenes on the activity of NF-AT. PMA plus ionomycin treatment induced NF-AT binding activity, which was inhibited by myristicin, anethole, eugenol, and isoeugenol. These results suggest that myristicin, anethole, eugenol and isoeugenol suppress IL-2 production through the decrease of IL-2 mRNA expression and the inhibition is mediated, at least in part, through the down-regulation of NF-AT, which may explain their potentials for immune modulation. (This work was supported by grant No. R01-2001-00209-0 from the Korea Science & Engineering Foundation.)

1589 Δ^9-TETRAHYDROCANNABINOL (THC) INCREASES INTRACELLULAR CALCIUM IN A CANNABINOID RECEPTOR-DEPENDENT MANNER IN T CELLS.

G. K. Rao and N. E. Kaminski. *Pharmacology & Toxicology, Michigan State University, East Lansing, MI.*

Cannabinoid compounds are widely known to alter leukocyte function. Previous studies from this laboratory have shown T cells to be a sensitive target to cannabinoid treatment. Particularly, cannabinoids inhibit the production of interleukin (IL)-2 by T cells. The regulation of IL-2 gene transcription is critically dependent on intracellular calcium ($[Ca^{2+}]_i$) and the downstream calcium-dependent transcription factor, NFAT. Therefore, the objective of the present studies was to examine the effect of THC, the primary psychoactive cannabinoid in *Cannabis sativa*, on $[Ca^{2+}]_i$ homeostasis in T cells. Both murine splenic T cells and HPB-ALL human T cell line were used to investigate the effect of THC on $[Ca^{2+}]_i$. THC (10μM) induced a rapid and robust rise in $[Ca^{2+}]_i$ in both splenic T cells (1500-2000 nM) as well as HPB-ALL cells (600-800 nM). Pretreatment of splenic T cells, which express transcripts for both CB1 and CB2 receptors, with a combination of cannabinoid receptor antagonists, SR141716A and SR144528 for CB1 and CB2 receptors respectively, antagonized the THC-mediated elevation in $[Ca^{2+}]_i$. Similarly, pretreatment of HPB-ALL cells, which only express CB2 receptor transcripts, with SR144528 also antagonized the rise in $[Ca^{2+}]_i$. Finally, studies done in the absence of extracellular calcium ($[Ca^{2+}]_e$), revealed a severe abrogation in the THC-mediated elevation in $[Ca^{2+}]_i$ in both splenic T cells as well as HPB-ALL cells. These data suggest that THC causes a rise in $[Ca^{2+}]_i$ in resting T cells in a cannabinoid receptor-dependent manner involving both release of calcium from intracellular pools as well as influx from extracellular sources. (Supported by NIH grant DA07908).

1590 INHIBITION OF INTERLEUKIN-2 (IL-2) BY THE ENDOGENOUS CANNABINOID, 2-ARACHIDONYL GLYCEROL, IS PARTLY MEDIATED THROUGH PEROXISOME PROLIFERATOR-ACTIVATED RECEPTOR-γ (PPAR-γ).

C. E. Rockwell and N. E. Kaminski. *Pharmacology & Toxicology, Michigan State University, East Lansing, MI.*

The putative endogenous cannabinoid, 2-arachidonyl glycerol (2-AG), is an arachidonic acid derivative that has been shown through radioligand binding studies to bind to the cannabinoid receptors, CB1 and CB2. 2-AG mimics many of the physiological effects of the plant-derived cannabinoids, such as Δ^9-THC, including hypothermia, antinociception, hypomotility, and immunosuppression. Specific to the present studies, 2-AG inhibits activation of T cells causing suppression of cytokines such as, IL-2, IL-4, and IFN-γ. We now show evidence that 2-AG is also a ligand for PPAR-γ, through which 2-AG may mediate its immunosuppressive activity. The first objective of the present studies was to determine whether 2-AG could drive 3T3-L1 preadipocytes to differentiate into adipocytes. 3T3-L1 is a murine fibroblast line that differentiates into adipocytes upon activation of PPAR-γ_2. 2-AG induced differentiation of 3T3-L1 cells at a concentration of 50 μM. The second objective was to determine whether 2-AG was able to upregulate expression of aP2. aP2 is a fatty acid carrier protein which is upregulated when activated PPAR-γ binds to the PPAR response element (PPRE). 2-AG increased expression of aP2 2-6 fold over control as measured by real-time PCR. The third objective of the present studies was to determine whether the PPAR-γ antagonist, GW9662, could antagonize the inhibition of IL-2 by 2-AG. GW9662 partially antagonized inhibition of IL-2 by 2-AG at a concentration of 1 μM, but not at higher concentrations. These data suggest that 2-AG is an endogenous ligand for PPAR-γ, which appears to contribute to the inhibitory effect of 2-AG upon IL-2 secretion by T cells. (Supported in part by NIH grant DA 12740)

1591 THE EFFECTS OF SPHINGOMYELIN, CONJUGATED LINOLEIC ACID AND BUTYRATE ALONE OR IN COMBINATIONS ON IMMUNE FUNCTION AND COLON CANCER IN RATS.

J. H. Exon, E. H. South and S. N. Nichenametla. *Food Science and Toxicology, University of Idaho, Moscow, ID.*

Sphingomyelin (SPG), conjugated linoleic acid (CLA) and butyrate BYT) are naturally occurring bioactive chemicals found in higher concentration in dairy products. Studied separately, each of these compounds has been shown to have chemopreventive properties to certain cancers in animal models. This study was designed to examine the effects of each compound alone and in combinations with the other compounds to observe potential additive or synergistic effects. Parameters examined were the development of preneoplastic colon lesions and major types of terminal immune responses in male Sprague-Dawley rats. Immune responses assessed were humoral immunity (antibody production), cell-mediated immunity (delayed-type hypersensitivity) and innate immunity (natural killer cell cytotoxicity-NK) The rats were treated with either 35 mg/kg SPG, 100 mg/kg CLA or 100 mg/kg of BYT or the same concentrations of all chemicals (ALL). Aberrant crypt foci (ACF) were induced in the colon by two ip injections (10 mg/kg) of the carcinogen azoxymethane (AOM) during the first two weeks of the study.). The animals were sacrificed after 10 weeks exposure and ACF were quantified in the colon and immune responses assessed. Treatment with CLA significantly enhanced natural killer cell activity compared to controls or the ALL group. Treatment with BYT enhanced NK cytotoxic responses compared to the ALL group but not the control. There was no effect of any treatments on DTH or antibody formation. It appears that the combination of bioactive compounds used in this study were less effective than the individual chemicals in alteration of immune functions. The effects on ACF formation are in progress.

1592 *IN VITRO* AND *IN VIVO* IMMUNOLOGICAL EFFECTS OF DOK DIN DAENG (*AEGINETIA INDICA* ROXB.) AN HERBAL DRUG OF THAILAND.

W. Auttachoat[1], B. Chitsomboon[1], M. Matsumura[2], V. Peachee[3] and K. White[3]. *[1]Suranaree University of Technology, Nakhon Ratchasima, Thailand, [2]University of Tsukuba, Ibaraki, Japan and [3]Virginia Commonwealth University, Richmond, VA.*

Several studies have reported *Aeginetia indica* Linn. (AIL), has potential of being a medicinal herb with antitumor activity. Seed extract of AIL has been shown by others to induce antitumor immunity in tumor-bearing mice. In Thailand, Dok Din Daeng, (DDD), a parasitic plant which grows on bamboo, has been used in Thai traditional medicine for treatment of diabetes and dermal swelling. In this study, difference parts of the plants: seed and whole plant were investigated *in vitro* and *in vivo*. DDD was obtained from seed using butanol extraction and from the plant by ethanol extraction. In *in vitro* studies DDD was observed to have immunostimulatory effects. Enhanced T cell proliferation was observed following Con A stimulation and treatment with plant DDD at concentrations from 1.25 - 500 ug/ml, no significant effect was observed from seed extracts. Enhanced B cell proliferation occurred following LPS stimulation and treatment with plant DDD at concentrations from 1.25 - 100 ug/ml, higher concentrations suppressed the B cell response. In contrast, seed extracts produced enhanced B cell responses at all concentrations evaluated (1.25-2000 ug/ml). When spleen cells were stimulated with anti-CD3 antibody, cultures treated with plant DDD at concentration of or less than 10 ug/ml did not differ from controls. A slight increase was observed at 100 ug/ml with significant decreases occurring at 500 and 1000 ug/ml concentrations. Overall, seed extracts produced slight increases (21%) in anti-CD3 proliferation. To confirm DDD potential as an immunostimulant, *in vivo* studies evaluating the effects of whole plant and seed extracts on antibody responses to T-dependent antigens, mixed lymphocytes response, natural killer cell activity and splenic populations are currently on going in female B6C3F1 mice following 28 days of daily exposure. The results of these studies should provide insight into the mechanism of action of this traditional Thai medicine.

1593 SILYMARIN INHIBITS INTERLEUKIN-1β AND PROSTAGLANDIN E2 SYNTHESIS AND PROTECTS AGAINST LIPOPOLYSACCHARIDE-INDUCED SEPSIS.

J. Kang[1], Y. Jeon[2], Y. Na[1], S. Park[3], K. Yang[3,1] and H. Kim[3]. *[1]Department of Biological Sciences, Korea Advanced Institute of Sicence and Technology, Taejon, South Korea, [2]Department of Pharmacology, Chosun University, Kwangju, South Korea and [3]Korea Research Institute of Biosicence and Biotechnology, Taejon, South Korea.*

Silymarin is a flavonoid antioxidant isolated from milk thistle and has anti-inflammatory, anticarcinogenic, and hepatoprotective effects. Here we report the inhibitory effect of silymarin on interleukin-1β (IL-1β) and prostaglandin E2 (PGE2) production in macrophages. Silymarin dose dependently suppressed the

lipopolysaccharide (LPS)-induced production of IL-1β and PGE2 in isolated mouse peritoneal macrophages. Silymarin treatment also resulted in a dose-related inhibition of IL-1β and PGE2 production in LPS-stimulated RAW264.7 cells. To further investigate whether the inhibitory effect of silymarin on IL-1β and PGE2 exerts at the transcriptional level, we assessed the effect of silymarin on mRNA expression of IL-1β and PGE2 by RT-PCR. Consistent with the previous results, the LPS-induced mRNA expression of IL-1β and cyclooxygenase-2 (COX-2) was completely blocked by silymarin in RAW 264.7 cells. Moreover, the LPS-induced DNA binding activity of NF-κB/Rel was also inhibited by silymarin in RAW 264.7 cells. Further study showed that silymarin protected mice against LPS-induced sepsis. In this model of sepsis, silymarin improved the rate of survival of LPS-treated mice from 6 % to 38 %. Taken together, these results demonstrated that silymarin has a protective effect against endotoxin-induced sepsis, and suggest that this is mediated, at least in part, by the inhibitory effect of silymarin on the production of IL-1β and PGE2.

1594 ACUTE EFFECTS OF 2-BROMOPROPANE AND 1, 2-DIBROMOPROPANE ON THE ANTIBODY RESPONSE IN FEMALE BALB/C MICE.

T. Jeong[1], N. Kim[1], C. Kim[1], J. Kim[1], T. Jeon[1], D. Kim[3], E. Lee[1] and W. Chae[2]. *[1]Pharmacy, Yeungnam University, Kyungsan, Kyungbuk, South Korea, [2]Medicine, Catholic University of Daegu, Daegu, South Korea and [3]BBRC, KIST, Seoul, South Korea.*

2-Bromopropane (2BP) is a major component of the mixture of SPG-6AR and Solvent 5200 that is a substitute of chlorofluorocarbon. Many female workers in a Korean electronic company were found to have amenorrhea and male workers were diagnosed with oligospermia. In the present studies, immunotoxic effects of 2-BP and an analog, 1, 2-dibromopropane (1, 2-DBP), were investigated in female BALB/c mice. The mice were treated po with either 2-BP at 2000 and 4000 mg/kg or 1, 2-DBP at 300 and 600 mg/kg once. Four days before necropsy, the mice were immunized ip with sheep red blood cells (SRBCs). The spleen and thymus weights were reduced by 1, 2-DBP. In addition, the antibody response to SRBCs was suppressed by the treatment with 1, 2-DBP. Meanwhile, these parameters were not significantly changed by the treatment with 2-BP. In a subsequent study, the time course effects of 2-BP and 1, 2-DBP on the hepatotoxic parameters were compared in mice. When mice were treated po with either one of these chemicals once for 6, 12, 24 and 48 hr, the activities of serum alanine aminotransferase and aspartate aminotransferase were significantly elevated only by 1, 2-DBP 24 hr after the treatment. In addition, the hepatic content of glutathione was reduced by 1, 2-DBP. The present results suggest that 1, 2-DBP contained in the Solvent 5200 may contribute to the immunotoxicity, although 2-BP is a major component. (Supported by grant No. RO1-2000-00182 from KOSEF, Korea).

1595 ALTERATIONS IN THE IMMUNE SYSTEM AFTER EXPOSURE TO THE TRIAZINE HERBICIDE ATRAZINE.

R. Cain, R. Schafer, J. B. Barnett and K. M. Brundage. *Microbiology, Immunology and Cell Biology, West Virginia University, Morgantown, WV.*

Atrazine (2-chloro-4-ethylamino-6-isopropylamino-s-triazine), a triazine class herbicide, is one of the most heavily applied herbicides in the United States. A recent USGS NAWQA (United States Geological Service National Water Quality Assessment) report (1999) determined that atrazine was detectable in 44% of the wells tested making it one of the most common herbicide contaminants found in ground water in agricultural areas. However, little is known about the immunotoxicity of atrazine. Although an earlier mouse study (Fournier et al. 1992) indicated that atrazine had limited immunotoxicity, a more recent study (Vos et al. 2001) examining cellular changes in rats suggested an immunotoxic effect. Using different and perhaps more sensitive techniques, we examined the effect of atrazine on the murine immune system. C57Bl/6 mice were exposed to a single oral dose (0.0875, 8.75 and 875 milligram/kilogram of body weight (mg/kg)) of atrazine mixed in peanut oil. Seven days after exposure, significant decreases in the number of $CD4^+$ T cells and $B220^+$ B cells in the spleen were observed at the 875 mg/kg dose. In the thymus, significant decreases occurred in thymus to body weight ratios and in the $CD4^+CD8^+$, $CD4^+CD8^-$ and $CD8^+CD4^-$ thymocyte subpopulations at this dose. Preliminary data suggest that both the 875 and 8.75 mg/kg atrazine doses decrease IFNg secretion and increase IL-2 and IL-6 secretion from splenocytes stimulated with conA or LPS for 24 and 48 hr respectively. Functional changes in the immune response to heat killed Streptococcus pneumoniae after exposure to either the 875 or 8.75 mg/kg atrazine dose demonstrated an increased frequency in B cells secreting antibody to the T-independent antigen phosphorylcholine. In addition, a decrease in the frequency of B cells secreting IgG antibodies to the T-dependent antigen pneumococcal surface protein A was observed. Together these data suggest that oral exposure to atrazine has the potential to alter the immune response. Supported by a WVU School of Medicine Research Grant

1596 PHENOTYPIC DIFFERENCES IN THE HEMATOPOIETIC BONE MARROW COMPARTMENT BETWEEN ARYL HYDROCARBON RECEPTOR DEFICIENT AND CONTROL C57BL/6 MICE AS REVEALED BY FLOW CYTOMETRY.

R. Garrett and T. A. Gasiewicz. *Environmental Medicine, University of Rochester School of Medicine & Dentistry, Rochester, NY.*

The aryl hydrocarbon receptor (AhR), most notably known as the mediator of TCDD toxicity, is a ubiquitous bHLH transcription factor responsible for a growing list of genes. Immune alteration, including effects on both cellular and humoral immunity, is one of the most consistently observed AhR-mediated endpoints across species. Recently, hematopoietic precursors of the bone marrow were identified as targets of TCDD. Further, *in vitro* studies with c-Kit+ Sca-1+ Lin- (KSL) bone marrow cells, a population that includes all hematopoietic progenitors, from wild-type (WT) and AhR-knockout (KO) animals revealed differential abilities to proliferate in culture. In order to ascertain whether there are basal differences in the numbers of primitive stem and progenitor cells, we isolated bone marrow from WT and KO C57Bl/6 mice and stained with appropriate combinations of fluorochrome-conjugated antibodies specific for the following hematopoietic populations: long-term hematopoietic stem cells (LT-HSC), short-term hematopoietic stem cells (ST-HSC), common lymphoid progenitors (CLP), and common myeloid progenitors (CMP). Cells were analyzed on a FACS Calibur flow cytometer. The percent of KSL cells was nearly 2-fold higher in KO animals than their WT counterparts. Within this broad population, there were a near 4-fold greater number of cells with a ST-HSC phenotype (KSL CD34+) in KO animals, but no such difference in cells with a LT-HSC phenotype (KSL CD38+). Although there was no difference in the amount of CMP present, KO animals have a nearly 2-fold greater number of CLP. Heterozygotes were identical to WT animals. These data suggest that the AhR is required to maintain normal numbers of primitive hematopoietic stem cells as well as lymphoid progenitors. Funded in part by NIH Grant ES04862, Center Grant ES01247, and Training Grant ES07026.

1597 CHARACTERIZATION OF IMMUNE CELL INFILTRATES IN LIVER AND SPLEEN BY FLOW CYTOMETRY FOLLOWING TREATMENT WITH AN ANTISENSE OLIGODEOXYNUCLEOTIDE.

H. S. Younis, A. A. Levin, T. Condon and S. P. Henry. *Toxicology/PKM, Isis Pharmaceuticals, Carlsbad, CA.*

The capacity for oligodeoxynucleotides (ODN) to induce an immune stimulation in rodents is species and sequence dependent. The features of immune stimulation include cytokine production, splenomegaly, lymphoid hyperplasia and infiltration of mononuclear cells into tissues. The objective of this research was to identify and characterize the cell types that comprise the immune cell infiltrate in the liver and spleen following treatment with ISIS 2302, an inhibitor of human ICAM-1. Female CD-1 mice were administered 50 mg/kg ISIS 2302 (sc, tiw) for 3 months. Non-parenchymal liver cells and splenocytes were harvested at necropsy. ISIS 2302 treatment increased liver and spleen weight by 1.7- and 5.3-fold, respectively. Flow cytometry analysis using cell specific surface markers for monocytes/macrophages (F4/80, CD11b), B-cells (CD19), T-cells (CD3) and dendritic cells (CD11c, Dec205) were used to determine the composition of infiltrating cells. In the liver, the infiltrates were comprised primarily of monocytes/macrophages, while a smaller fraction being dendritic cells. There was a 5-20-fold increase in the percentage of cells expressing F4/80, CD11b and CD11c, while no change was observed in the population of cells expressing CD3, CD19 and Dec205. The absolute number of cells in the spleen increased following ISIS 2302 treatment, but the percentage of splenocytes expressing CD3, CD19 and CD11b was reduced 20-30%. The percentage of cells expressing F4/80, CD11c and Dec205 in the spleen only increased 2-7%. Therefore, a large percentage of cells in the spleen are unaccounted for by the surface markers analyzed. Collectively, this work suggests that histiocytes make up the majority of the immune cell infiltrates in the liver following treatment with immunostimulatory ODN, and that these cells may be the initial target cells that become activated during ODN mediated immune stimulation.

1598 UPREGULATION OF TREM-1 BY ENDOTOXIN IN MOUSE LIVER MACROPHAGES.

L. Chen[1], M. Gordon[1], J. D. Laskin[2] and D. L. Laskin[1]. *[1]Pharmacology & Toxicology, Rutgers University, Piscataway, NJ and [2]Environ Comm. Med., UMDNJ-Robert W Johnson Med. Sch, Piscataway, NJ.*

Many xenobiotics induce hepatotoxicity by sensitizing liver macrophages to release excessive quantities of proinflammatory and cytotoxic mediators. In the present studies we determined if TREM-1, a newly identified receptor on macrophages of

the immunoglobulin superfamily that amplifies the inflammatory response by triggering secretion of proinflammatory mediators, was upregulated in hepatic macrophages following administration of endotoxin to C3H/HeOuJ and C3H/HeJ mice. C3H/HeJ mice have point mutations in the toll-like-4 receptor, a critical component of endotoxin-mediated cell signaling, and are resistant to endotoxin-induced toxicity when compared to C3H/HeOuJ mice. Hepatic macrophages were isolated from livers following perfusion with collagenase, centrifugal elutriation and density gradient centrifugation. Macrophages from the livers of either C3H/HeOuJ or C3H/HeJ control mice expressed very low levels of TREM-1 mRNA as determined by semi-quantitative RT-PCR. Treatment of mice with endotoxin (3 mg/kg, ip) caused a time-dependent induction of hepatic macrophage TREM-1 mRNA expression which was maximal after 20 hr. Significantly less TREM-1 mRNA was induced in C3H/HeJ mice when compared to C3H/HeOuJ mice. In macrophages from both strains of endotoxin-treated animals, tumor necrosis factor-α (20 ng/ml) or interleukin-1β treatment (50 ng/ml, 24 hr) *in vitro* caused a further 2-10 fold increase in TREM-1 mRNA expression. Lipopolysaccharide (LPS) decreased TREM-1 mRNA expression 2-3-fold in macrophages from C3H/HeOuJ mice but did not alter its expression in cells from C3H/HeJ mice. Taken together, these data demonstrate that endotoxin is a potent inducer of TREM-1 mRNA in hepatic macrophages and that expression of the protein may be an important mechanism for amplifying the inflammatory response to hepatotoxicants. Endotoxin-resistance in C3H/HeJ mice may be due to limited expression of the TREM-1 protein. Support: NIH GM34310 and ES06897.

1599 IMMUNOMODULATION BY DIETHYLSTILBESTEROL IS DOSE AND GENDER LINKED: INFLUENCE ON THYMIC APOPTOSIS AND MITOGEN-INDUCED PROLIFERATION IN CD-1 MICE.

J. B. Calamine[2], R. M. Gogal[1,2], A. J. Lengi[2], P. Sponenberg[2] and S. Ahmed[2]. *[1]Biomedical Sciences, EVVCOM, Va Tech, Blacksburg, VA and [2]Biomedical Sciences and Pathobiology, VMRCVM, Va Tech, Blacksburg, VA.*

It is perceived, but not shown, that the immunomodulatory influences of diethylstilbesterol (DES) may vary based on dose or gender. To address this, DES was subcutaneously administered to female and male CD-1 mice as four injections over 1 week at 0, 5, 15 and 30 μg/kg bw dose with immunological and reproductive parameters evaluated 24hr post last injection. Although female thymuses were significantly larger than male thymuses, short-term DES administration neither induced thymic atrophy nor altered relative percentages of thymic subsets. However, DES treatment did induce dose-related apoptosis in the CD4+8+, CD4+8- and CD4-8+ subsets using 7-amino-actinomycin D (7-AAD). The CD4-8- showed significant apoptosis only at the highest dose (30 μg/kg bw). Mitogen-induced proliferation of splenic lymphocytes also varied with hormonal doses and gender. In the females, splenic lymphocytes from low dose DES (5 μg/kg bw)-treated mice showed an increase in proliferative response to Con A, LPS or PMA/ionomycin compared to controls. Conversely, cultures from mice treated with the higher DES doses (15 or 30 μg/kg bw) showed suppressed proliferation, especially with Con A. In the males, DES appeared to produce minimal effects with the exception of increased proliferation to Con A in the 15μg/kg bw. Interestingly, the changes in mitogen-induced proliferation were not paralleled by similar changes in relative expression of CD90+ or CD45+ cells or ratios of anti-apoptotic Bcl-2 to apoptotic Bax proteins. Con A-activated splenocytes from DES-treated mice, specifically in the females, secreted less interferon-γ compared to controls. Collectively, these findings suggest that short-term exposure to DES generates a disparity in the immunological effects depending upon the dose of hormone and sex.

1600 THE GENERATION OF REACTIVE OXYGEN SPECIES DURING EXPOSURE OF PESTICIDE MIXTURES TO IMMUNE CELLS, *IN VITRO.*

V. Vemireddi[1] and H. P. Misra[1,2]. *[1]Biomedical Sciences and Pathobiology, Virginia Maryland Regional College of Veterinary Medicine, Virginia Tech, Blacksburg, VA and [2]Edward Via Virginia College of Osteopathic Medicine, Blacksburg, VA.*

Recent reports suggest that pesticides pose potential health risks to the humans and animals by affecting their immune system. We have observed earlier that endosulfan and permethrin cause immune cell cytotoxicity mainly *via* apoptosis. We hypothesized that these chemicals induce immunotoxicity through Reactive Oxygen Species (ROS) formation. In an attempt to test this hypothesis, we have studied the production of ROS in splenocytes of C57Bl/6 adult male mice exposed to endosulfan and permethrin, *in vitro*. The generation of intracellular hydrogen peroxide (H_2O_2) and superoxide anion was monitored using a flow cytometer in combination with dichlorofluorescin diacetate (DCFH-DA) and hydroethidine (HE) dyes, respectively. Results of these analysis revealed that individual pesticides increased the production of both H_2O_2 and superoxide anion in a dose- and time- dependent manner. The mixtures of pesticides elicited a synergistic effect on the generation of H_2O_2. However, exposure to mixtures of pesticides had little effect on the generation of superoxide anion radicals as compared to individual pesticides. These findings suggest that the pesticide-induced immunotoxicity observed earlier may, at least in part, be associated with the generation of ROS.

1601 DEOXYNIVALENOL-INDUCED APOPTOSIS MEDIATED BY P38 MAPK-DEPENDENT P53 GENE INDUCTION IN RAW 264.7 MACROPHAGES.

H. Zhou[1] and J. J. Pestka[1,2,3]. *[1]Food Science and Human Nutrition, Michigan State University, East Lansing, MI, [2]Department of Microbiology and Molecular Genetics, Michigan State University, East Lansing, MI and [3]Institute for Environmental Toxicology, Michigan State University, East Lansing, MI.*

Deoxynivalenol (DON, vomitoxin) and other trichothecene mycotoxins cause immunosuppression by inducing leukocyte apoptosis. Upstream signaling transduction mechanisms contributing to DON-mediated apoptosis were investigated in RAW 264.7 cells, a murine macrophage model. PP1, a Src-family-tyrosine kinase inhibitor selective for Hck, and 2-AP (2-aminopurine), the chemical inhibitor of dsRNA-dependent protein kinase (PKR), additively inhibited DON-induced caspase-3 activity and apoptosis as well as phosphorylation of the mitogen activated protein kinases p38, ERK and JNK. PP1 and 2-AP also inhibited DON-induced p53 binding activity and subsequent phosphorylation of its substrate p21. Pretreatment with PFTα, an inhibitor of p53, abrogated DON-induced caspase-3 and apoptosis. The p38 inhibitor, SB 203580, abrogated DON-induced p21 phosphorylation as well as reduced DON-induced p53 binding activity, whereas ERK and JNK inhibitors were partially inhibitory. Finally, p38 inhibition blocked DON-induced apoptosis, ERK inhibition promoted DON-induced apoptosis, and JNK inhibition had no effect. The results suggest that the principal pathway for DON-induced apoptosis in the macrophage involves the sequential activation of Hck/PKR, p38, p53, caspase-3. (Supported by NIEH Grants ES-09521 and ES-03358).

1602 JP-8 JET FUEL DOES NOT ALTER SERUM CYTOKINE LEVELS IN B6C3F1 MICE FOLLOWING 7-DAY ORAL OR DERMAL EXPOSURE.

D. E. Keil[1], C. Adams[2], L. Butterworth[1], J. EuDaly[2] and M. M. Peden-Adams[2]. *[1]NIOSH, Morgantown, WV and [2]Department of Health Professions, Medical University of South Carolina, Charleston, SC.*

The US Air Force uses approximately 2.5 billion gallons of jet propellant-8 fuel per year. As a result, a considerable number of military personnel are exposed to JP-8 fuel during refueling and servicing of aircrafts, and maintenance of fuel storage tanks. Those exposed have increased incidence of headaches, blocked nasal passages, ear infections, skin irritation, or fatigue. In rodent studies, we have previously reported that 7-day dermal or oral exposure to JP-8 suppresses humoral immunity and decreases thymus weight and cellularity. Additionally, other published studies have demonstrated that a single, dermal exposure to JP-8 modulated serum cytokine levels in mice, thereby accounting for a possible mechanism of immunosuppression. To determine if alterations in serum cytokines occurred after 7 days of exposure to JP-8, the following study was performed. B6C3F1 female mice aged 7-10 weeks of age were exposed to JP-8 dermally (50 uL applied to the clipped dorsal thorax of mice with an average weight of 20 g) or orally (2000 mg/kg/day) for a duration of 7 days. Serum was collected 24 hours after the last exposure to JP-8. Using ELISA and Cytometric Bead Array methods, it was determined that levels of IL-2, IL-4, IL-5, IL-6, IL-10, and TNF-alpha were not significantly altered after exposure to JP-8 *via* the oral or dermal route. It was also learned that, when used as a negative control in the dermal study, acetone as compared to olive oil induced a suppressive effect on IL-4 and IL-6 serum cytokine levels. Consequently, interpretation of immunological dermal studies utilizing acetone should be made with caution. Overall, these findings indicate that serum cytokine levels were not elevated after a 7-day exposure to JP-8, regardless of the route of administration. These observations indicate that serum cytokine levels are not sustained above normal levels following repeat exposure to JP-8.

1603 HEPATIC PHASE I AND II ENZYME PROFILES AFTER 7-DAY DERMAL OR ORAL EXPOSURE TO JP-8 JET FUEL.

C. Mikell[1], M. M. Peden-Adams[2], S. Dabra[2], J. EuDaly[2] and D. E. Keil[1]. *[1]NIOSH, Morgantown, WV and [2]Department of Health Professions, Medical University of South Carolina, Charleston, SC.*

Many military and industrial personnel are exposed to JP-8 jet fuel during service and refueling of aircrafts, and maintenance of storage tanks. In toxicological studies using mice, it has been demonstrated that JP-8 can induce immunosuppression fol-

lowing dermal, oral, or inhalation exposures. After dermal or oral exposure to JP-8, we have previously demonstrated that thymus weight and cellularity are significantly diminished and specific IgM antibody production is suppressed by 50% or more as compared to controls. To further evaluate the effects of JP-8, this study presents comparative metabolic enzyme profiles obtained after oral or dermal exposure to JP-8. Western blotting was performed to determine the protein expression of Phase I and Phase II hepatic enzymes at 24 hours or 7 days after a 7-day exposure to JP-8. Female B6C3F1 mice were exposed to JP-8 either orally (2000 mg/kg/day) or dermally (50uL neat application). Twenty-four hours post-exposure, protein expression of CYP2E1, 2B1, GSTmu, and GSTpi, but not CYP1A1, were significantly increased in mice exposed orally to JP-8. Following a week recovery period, these enzymes returned to constitutive levels. In dermal studies, despite the presence of immunosuppression comparable to orally exposed mice, there was minimal to no induction of CYP2B1, GSTmu, and GSTpi. Current studies are underway to confirm the dermal exposure profile for CYP2E1 and CYP1A1. Additionally, histological examination of the livers from these same mice exposed orally or dermally, indicated that there was no increase in the amount of fat, hydropic degeneration or necrosis in the liver. These data suggest that the metabolism of JP-8 may not be required for immunotoxicity.

1604 EFFECT OF CYCLOOXYGENASE (COX) INHIBITORS ON HUMAN LEUKOCYTE MIGRATION THROUGH ENDOTHELIAL CELL MONOLAYERS.

L. Fan, K. N. Khan, W. J. Komocsar and S. M. Furst. *Global Toxicology, Pharmacia, Skokie, IL.*

Previous studies have shown that traditional NSAIDs such as ibuprofen inhibit human leukocyte migration through endothelial cell monolayers. Leukocyte-endothelial cell interactions play a central role in various inflammatory processes. Upon signaling from chemokines, cytokines and adhesion molecules during inflammation, leukocytes first attach, roll and migrate through the vascular endothelium to the inflammation site. The current study using an *in vitro* double chamber cell culture system, compared the effect of an *in vitro* non-selective COX inhibitor (ibuprofen) and *in vitro* selective COX-2 inhibitors (SC-236, -791, -872 and -236) on human leukocyte migration through endothelial cell monolayers. Human umbilical vein endothelial cells were cultured on fibronectin coated 3m microporous membranes until an endothelial cell monolayer formed. Monolayers were treated with 10ng/ml recombinant human TNF for 4 hours before the migration assay began. 1x106 freshly isolated human leukocytes and/or cultured endothelial cell monolayers were preincubated with test agents at 1x, 10x and 50x multiples of their therapeutically relevant concentrations. Migration assays were carried out for 3 hours in a 37oC 5% CO2 incubator. Leukocytes that migrated through the endothelial cell monolayer to the lower chamber were quantitated. Each set of experiments was performed with peripheral blood from ten different normal human subjects. Our results confirmed inhibitory effects of ibuprofen on human leukocyte migration starting at the therapeutically relevant concentration. No effect on leukocyte migration was seen with the *in vitro* selective COX-2 inhibitors at 1X and 10X concentrations indicating that COX-2 inhibition does not affect leukocyte migration. At extremely high concentrations (50x), leukocyte migration was decreased with *in vitro* selective COX-2 inhibitors. This may be related to loss of COX selectivity and inhibition of COX-1 at these concentrations. In conclusion, *in vitro* selective COX-2 inhibitors do not affect leukocyte-endothelial cell interactions during the inflammatory process.

1605 ROLE OF IL-1BETA IN LPS POTENTIATION OF DEOXYNIVALENOL-INDUCED LEUKOCYTE APOPTOSIS IN MICE.

Z. Islam[1] and J. J. Pestka[1,2,3]. *[1]Michigan State University, East Lansing, MI, [2]Department of Microbiology and Molecular Genetics, Michigan State University, East Lansing, MI and [3]Institute of Envoronmental Toxicology, Michigan State University, East Lansing, MI.*

LPS and Deoxynivalenol (DON) co-exposure induces corticosterone-dependent apoptosis in thymus, Peyers patches, and bone marrow in mice after 12 hr. We investigated the role of endogenous and exogenous IL-1beta in stimulating corticosterone and in inducing leukocyte apoptosis in this model. LPS (0.1 mg/kg, ip) and DON (12.5 mg/kg, po) co-exposure induced splenic IL-1beta mRNA significantly compared to vehicle or each of the toxins alone. Mice deficient in IL-1 receptor did not exhibit LPS + DON-induced leukocyte apoptosis whereas toxin co-treatment induced apoptosis in corresponding wild-type mice. Plasma corticosterone levels in LPS + DON-treated IL-1 receptor deficient mice were significantly lower at 12 hr than wild-type mice. In B6C3F1 mice, intraperitoneal injection of IL-1 receptor antagonist (100 microg/mouse, twice at 3 hr intervals) also significantly inhibited LPS + DON-induced apoptosis in thymus, Peyers patches and bone marrow compared to LPS + DON-treated mice. Three injections of IL-1beta protein (500 ng/mouse, ip at 2 hr intervals) induced apoptosis in thymus (4.7%) and Peyers patches (16.0) whereas single injection of equivalent amount of IL-1beta (500 or1500 ng/mouse) did not induce apoptosis in any of the organs in B6C3F1 mice. In parallel to apoptosis, corticosterone levels in multiple IL-1beta injected mice were significantly higher (404.0 ng/ml) at 12 hr than control or single injected mice (90.4 ng/ml). ACTH levels in LPS + DON-treated mice were not correlated with the induction of plasma corticosterone or leukocyte apoptosis. Taken together, the results indicate that IL-1beta is a critical mediator of LPS + DON-induced leukocyte apoptosis and that it possibly acts through ACTH-independent corticosterone upregulation (supported by NIH Grants DK 58833 and ES 03358).

1606 ALTERATIONS OF MATERNAL/FETAL CYTOKINE CONCENTRATIONS IN SMOKERS AND NON SMOKERS AT CHILDBIRTH.

C. R. Cunningham, T. L. Wright, P. Lederer and S. R. Myers. *Pharmacology and Toxicology, Center for Environmental and Occupational Health Sciences, University of Louisville, Louisville, KY.*

Plasma cotinine concentrations are the benchmark for smoking status assessment. Smoking has been shown to elicit an inflammatory response associated with respiratory dysfunctions such as asthma and emphysema. As expected, maternal smoking during pregnancy has a deleterious effect on the fetus. Using commercially available ELISA kits, we measured cytokine concentrations in the plasma of mothers and matched cord blood samples collected at birth. Maternal/fetal pairs were placed in smoking and nonsmoking categories based on plasma cotinine concentration. Tumor Necrosis Factor-α, and the Interleukins 1β, 6, 8 and 10 were measured as markers of elevated inflammatory status. Preliminary studies show that with the exception of Il-1β, fetal cytokine concentrations were lower in the plasma of the babies whose mothers smoked. We attribute this difference to the suppression of the immune response caused by cigarette smoke exposure. These alterations may also be attributed to the stress of and the events leading up to delivery. We hypothesize that this altered immune response may account for the predisposition of children whose mothers smoked throughout pregnancy to respiratory ailments such as asthma as well as childhood allergy problems. Future studies will clarify the role of these individual cytokines in the spectrum of immune system maturity.

1607 TARGETED DELETION OF CD44V7 EXON LEADS TO DECREASED IL-2-INDUCED ENDOTHELIAL CELL TOXICITY AND VASCULAR LEAK SYNDROME.

R. McKallip[1], M. Fisher[2], A. K. Szakal[3], U. Gunthert[4], P. S. Nagarkatti[2] and M. Nagarkatti[1]. *[1]Microbiology and Immunology, Virginia Commonwealth University, Richmond, VA, [2]Pharmacology and Toxicology, Virginia Commonwealth University, Richmond, VA, [3]Anatomy, Virginia Commonwealth University, Richmond, VA and [4]Institute for Medical Microbiology, University of Basel,, Basel, Switzerland.*

Endothelial cell (EC) toxicity is widely reported in a number of clinical settings including autoimmunity, transplantation, graft versus host disease and cytokine therapy. Administration of IL-2 activates cytolytic lymphocytes to mediate EC injury and trigger vascular leak syndrome (VLS). In the current study, we investigated the nature of CD44 variant isoforms involved in EC injury and the mechanism of VLS induction. Administration of IL-2 into CD44 wild-type (WT) mice led to increased gene expression of CD44 variant isoforms containing the v6 and v7 exons and to significant induction of VLS in the lungs. In contrast, CD44v6/v7 KO and CD44v7 KO mice showed markedly reduced levels of VLS. The decreased IL-2-induced VLS in CD44v7 KO mice did not result from differential activation and expansion of CD8+ T cells, NK and NK-T cells or altered degree of perivascular lymphocytic infiltration in the lungs. Interestingly, IL-2 activated cytolytic lymphocytes from CD44v7 KO mice showed a significant decrease in their ability to mediate lysis of EC *in vitro*. Furthermore, adherence and conjugate formation of cytolytic lymphocytes from CD44v7 KO mice to EC isolated from the lungs of TIE2-GFP transgenic mice was markedly reduced when compared to LAK cells from CD44 WT mice. Finally, culturing of LAK cells with Abs against CD44v7 led to a significant reduction in the adherence to and killing of TME endothelial cells. The current study demonstrates that CD44 isoforms containing v7 play a key role in the adhesion of cytolytic lymphocytes to EC leading to injury of EC. This work was supported in part by grants from National Institutes of Health (HL 10455, HL 058641, DA 0114885, and ES 09098).

1608 DIFFERENTIAL REGULATION OF IL-2 GENE TRANSCRIPTION BY TGF-β1 IN NAIVE AND EFFECTOR/MEMORY CD4$^+$ T CELLS.

S. C. Mckarns and R. H. Schwartz. *Laboratory of Cellular and Molecular Immunology, NIAID/NIH, Bethesda, MD.*

TGF-β1 signaling in T cells plays a role in the maintenance of T-cell homeostasis and self-tolerance as illustrated by autoimmune disease in CD4-promoter dnTGF-βRII transgenic mice. The cellular and molecular mechanisms underlying homeostatic control of CD4$^+$ T cell populations remain elusive, but may be mediated, in

part, by the capacity of TGF-β1 to differentially regulate cytokine production. IL-2 is of particular interest since the autoimmune phenotype of IL-$2^{-/-}$ mice is similar to that observed in mice deficient in T cell-specific TGF-β signaling. Here we demonstrate that TGF-β1 is a potent inhibitor of IL-2 promoter activity in α-CD3 + α-CD28-stimulated naive 5CC7 TCR Tg $Rag2^{-/-}$ $CD4^+$ T cells transiently transfected with a luciferase reporter construct driven by a 2.2kb fragment of the IL-2 promoter. We further examine the effect of TGFβ-1 on IL-2 gene expression at the single cell level using $CD4^+$ T cells from homozygous or heterozygous mice in which green fluorescent protein (Gfp) cDNA was "knocked-into" the first exon of the IL-2 locus (GFP^{Ki}). Our results demonstrate a >90% inhibition of GFP-positive $CD4^+$ T cells by TGF-β1 following α-CD3 + α-CD28-stimulation of naive GFP^{Ki} T cells. Strikingly, upon re-stimulation with α-CD3 + α-CD28, resting previously-activated (Ag + APC) 5CC7 TCR Tg $Rag2^{-/-}$ $CD4^+$ T cells were unresponsive to inhibition of luciferase activity or GFP expression by TGF-β1. These results suggest that TGF-β1 may differentially regulate T cell homeostasis in a manner dependent upon the whether the target population of T cells has previously encountered an activation signal.

1609 A NOVEL RIBOFLAVIN-BASED PATHOGEN REDUCTION SYSTEM DOES NOT INTRODUCE NEOANTIGENS IN HUMAN PLATELETS.

J. T. Piper[1], M. D. Woolum[1], F. G. Burleson[2], G. R. Burleson[2] and R. P. Goodrich[1]. *[1]Gambro BCT, Inc., Lakewood, CO and [2]BRT - Burleson Research Technologies, Raleigh, NC.*

Gambro BCT is currently developing a pathogen reduction technology that utilizes riboflavin as a photosensitizer to mediate damage to pathogen nucleic acids. Because the pathogen reduction process uses a UV light source, the risk for the formation of process related neoantigens must be evaluated. This risk was evaluated by immunizing New Zealand White rabbits with control and pathogen reduced platelets, and comparing anti-sera raised against both to determine if antibodies against neoantigens were present. Control platelets were normal apheresis platelets. Pathogen reduced platelets were apheresis platelets containing 50 μM riboflavin, which were exposed to a total energy of 7 J/cm^2 UV light. Three animals received control platelets, and three animals received PR processed platelets. Antibody titers were checked, and boosts were given on days 21 and 42. After day 42, antiserum was collected from all animals, and the possible formation of antibodies against neoantigens was evaluated using the Ouchterlony double immunodiffusion assay. By comparing the immunoreactivity of antisera from animals given PR processed platelets against PR processed antigen and control antigen, complete identity was established. Therefore, it can be concluded that the riboflavin based pathogen reduction process does not introduce potentially harmful new antigenic determinants into human platelets.

1610 BIOMARKERS OF EFFICACY OF CHEMOPREVENTIVE AGENTS IN ANIMAL MODELS AND IN HUMANS.

G. D. Stoner[2], S. S. Hecht[1], M. A. Pereira[3], J. DiGiovanni[4] and T. W. Kensler[5]. *[1]University of Minnesota Cancer Center, Minneapolis, MN, [2]School of Public Health, The Ohio State University, Columbus, OH, [3]Department of Pathology, Medical College of Ohio, Toledo, OH, [4]Department of Carcinogenesis Science Park Research Division, UT MD Anderson Cancer Center, Smithville, TX and [5]Department of Environmental Health Sciences, Johns Hopkins School of Hygiene, Baltimore, MD.*

This symposium will summarize recent developments in the use of biochemical, molecular and morphometric biomarkers to assess the efficacy of chemopreventive agents in animal models and in humans. The discussion will include efficacy biomarkers for agents that inhibit both the initiation and promotion/progression stages of carcinogenesis. This topic is significant in that the field of cancer chemoprevention is rapidly emerging as a major area of research activity in the cancer field, and significant efforts are currently being made to identify appropriate biomarkers to assess the efficacy of chemopreventive agents. This symposium will be of interest to members of the SOT who have an interest in chemoprevention, as well as members of the carcinogenesis and molecular biology specialty sections.

1611 APPLICATION OF CARCINOGEN BIOMARKERS IN STUDIES OF LUNG CANCER CHEMOPREVENTION.

S. S. Hecht. *Cancer Center, University of Minnesota, Minneapolis, MN.* Sponsor: G. Stoner.

Lung cancer is the most common cancer in the world, with the number of cases estimated at 1.2 million annually. Cigarette smoking causes 90% of lung cancer. In people who cannot stop smoking and in ex-smokers, chemoprevention is an approach to decrease lung cancer mortality. Our targets for lung cancer chemoprevention are cigarette smoke carcinogens. Among these, benzo[a]pyrene (BaP) and 4-(methylnitrosamino)-1-(3-pyridyl)-1-butanone (NNK), may cause lung cancer in smokers. Isothiocyanates are effective chemopreventives against lung tumor induction in rodents treated with NNK, BaP, and other carcinogens. 2-Phenethyl isothiocyanate (PEITC) inhibits lung tumor induction by NNK in rats and mice while benzyl isothiocyanate (BITC) inhibits lung tumor induction by BaP and other polycyclic hydrocarbons in mice. A mixture of dietary PEITC and BITC inhibits lung tumor induction by a mixture of BaP and NNK in mice. Mechanisms of inhibition by isothiocyanates were examined by determining their effects on DNA and hemoglobin adducts of BaP and NNK, and on urinary metabolites of NNK. In mice, a mixture of dietary PEITC and BITC had little effect on levels of BaP-DNA adducts or O^6-methylguanine formed from NNK, while decreasing 4-hydroxy-1-(3-pyridyl)-1-butanone (HPB)-releasing DNA adducts of NNK. In rats, a mixture of dietary PEITC and BITC had no effect on BaP-DNA or BaP-hemoglobin adducts, while significantly decreasing levels of HPB-releasing DNA adducts of NNK in lung but not in liver. In tandem with these effects, levels of HPB-releasing hemoglobin adducts of NNK decreased and amounts of the NNK metabolites, NNAL and its glucuronides in urine increased. These results, along with the results of lung tumor inhibition experiments, demonstrate that the major inhibitory effect of dietary PEITC and BITC on lung tumor induction by a mixture of BaP and NNK results from the effects of PEITC on lung DNA adducts of NNK. Urinary metabolites of NNK are influenced by the metabolic activation of NNK in the lung, suggesting that these metabolites, measurable in humans, can be used as biomarkers of chemopreventive efficacy in smokers.

1612 BIOMARKERS OF CHEMOPREVENTION IN THE RAT ESOPHAGUS.

G. D. Stoner, R. M. Aziz, P. S. Carlton and L. A. Kresty. *Environmental Health Sciences, Ohio State University, Columbus, OH.*

Squamous cell carcinoma of the esophagus is one of the most common cancers worldwide. It has a complex etiology involving both lifestyle and dietary factors. Research in China suggests that nitrosamines such as N-nitrosomethylbenzylamine (NMBA) in the diet and N-nitrosonornicotine (NNN) in tobacco smoke are causative agents of the disease. NMBA and NNN induce esophageal tumors in rats, and we employ the rat model to identify chemopreventives for the esophagus. Isothiocyanates and polyphenols were found to be potent inhibitors of tumor initiation in rat esophagus, mainly through inhibiting the metabolic activation of NMBA or NNN. Recently, lyophilized strawberries and black raspberries were found to inhibit esophageal tumor initiation through similar mechanisms. In contrast, the chemopreventive agent, N-(4-hydroxyphenyl)retinamide (4-HPR), enhanced tumor development in the rat esophagus, by both increasing NMBA-induced DNA damage and the growth of preneoplastic cells. The detection of inhibitors of esophageal tumor development in rats pre-initiated with NMBA has been difficult. We have demonstrated the importance of H-ras activation in tumor development in rat esophagus. However, perillyl alcohol, an inhibitor of farnesylation of ras p21, enhanced tumor development in the esophagus when provided in the diet of preinitiated rats. Piroxicam, an inhibitor of cyclooxygenase 1 (COX-1), had no effect on tumor development in spite of its reduction in the levels of prostaglandin E_2 in the esophagus. Studies are underway to evaluate an inhibitor of cyclooxygenase 2 (COX-2) on esophageal tumorigenesis, since COX-2 is elevated in both preneoplastic and neoplastic lesions of the esophagus. In contrast, strawberries and black raspberries are effective inhibitors of tumor progression in the esophagus. Berries reduce the rate of cell growth in NMBA-treated esophagi. Organic extracts of berries downregulate the transcription activators, AP-1 and NF-κB, and their associated kinases, *in vitro*. Studies are underway to identify compounds in berries that exhibit chemopreventive efficacy in the esophagus.

1613 MODULATION OF THE METHYLATION OF DNA AND GENES AS SURROGATE END-POINT BIOMARKERS FOR CHEMOPREVENTION OF COLON AND LUNG CANCER.

M. A. Pereira and L. Tao. *Pathololgy, Medical College of Ohio, Toledo, OH.*

Alteration in DNA methylation is an extremely common molecular change found in cancer and includes the general hypomethylation of DNA and the hypermethylation of specific genes. Chemicals can alter DNA methylation so that some might induce cancer by changing a tissue DNA methylation pattern to that found in tumors, while others are likely to prevent cancer by reversing the methylation pattern in tumors back to the normal state. The development of drugs for the prevention of colon and lung cancer could be improved by the use of surrogate end-point biomarkers and by a better understanding of the mechanism of chemoprevention. To identify surrogate end-point biomarkers, tumors were induced in mouse lung by

vinyl carbamate and in rat colon by azoxymethane (AOM). The ability of short-term treatment of chemopreventive drugs to modulate DNA methylation in these tumors was determined. Mouse lung tumors relative to normal lung tissue had decreased methylation of DNA and of the c-myc and insulin-like growth factor II (IGF-II) genes. Seven days of treatment with Budesonide, a drug that has been shown to prevent lung tumors in mice, increased the methylation of DNA and of the two genes in the tumors. AOM-induced colon tumors relative to normal colon tissue in rats were demonstrated to have increased methylation of the estrogen receptor- gene. Five days of treatment with drugs that have been shown to prevent AOM-induced colon tumors, i.e. calcium chloride, α-difluromethylornithine, piroxicam or sulindac decreased the methylation of this gene. Interestingly, these drugs also appeared to cause a limited amount of methylation at CpG and other sites that were unmethylated in both normal colonic tissue and tumors. The ability of drugs to modulate DNA methylation was associated with their ability to decrease cell proliferation. In summary, seven days of treatment with chemopreventives led to modulation of DNA methylation in lung and colon tumors, supporting modulation of gene methylation as a surrogate end-point biomarker for assessing drug efficacy.

1614 USE OF AFLATOXIN BIOMARKERS TO EVALUATE STRATEGIES FOR PREVENTION OF LIVER CANCER.

T. W. Kensler. *Environmental Health Sciences, Johns Hopkins University, Baltimore, MD.*

Hepatocellular carcinoma (HCC) is one of the most common cancers worldwide and is the leading cause of cancer death in Qidong, People's Republic of China. Several nested case-control studies in nearby Shanghai have demonstrated a synergistic interaction between hepatitis B virus (HBV) and aflatoxins for risk of HCC. Thus, HBV vaccination programs and efforts to reduce aflatoxin exposures could have major impact on this disease. The extent of aflatoxin contamination in foods is a function of the ecology of molds and is not completely preventable. As such, chemoprevention may be useful. Experimentally, aflatoxin-induced HCC is inhibited by many chemopreventive agents. One agent, oltipraz, is a potent inducer of phase 2 enzymes involved in the detoxication of carcinogens including aflatoxin. To test whether enzyme induction is a useful strategy for chemoprevention in humans, a randomized, placebo-controlled, double-blind clinical trial was conducted in Qidong. Administration of oltipraz by mouth daily significantly enhanced excretion of a phase 2 product, aflatoxin-mercapturic acid, in the urine of study participants. While this trial highlighted the feasibility of inducing phase 2 enzymes in humans, additional strategies for preventing the toxicologic consequences of unavoidable exposures to aflatoxins are needed. Chlorophyllin (CHL), a mixture of water-soluble derivatives of chlorophyll used as food colorant and over-the-counter medicine, is an effective inhibitor of aflatoxin hepatocarcinogenesis in animals, apparently by impeding bioavailability of aflatoxin. In another clinical trial conducted in Qidong, we tested whether CHL could alter the disposition of aflatoxin by monitoring for levels of aflatoxin-N7-guanine excreted in urine using sequential immunoaffinity chromatography and mass spectrometry. This aflatoxin-DNA adduct excretion product serves as a biomarker of the biologically effective dose of aflatoxin and elevated levels are associated with increased risk of HCC. CHL proved to be a safe and effective agent for reducing biomarker excretion in individuals consuming dietary aflatoxins.

1615 TARGETS FOR CHEMOPREVENTION OF EPITHELIAL CANCERS IN TRANSGENIC MICE.

J. DiGiovanni, K. Kiguchi, R. Klein and S. M. Fischer. *The University of Texas M. D. Anderson Cancer Center, Science Park - Research Division, Smithville, TX.*

Both the TRAMP and the BK5.IGF-1 transgenic mouse models are being used for studies of prostate cancer chemoprevention. In TRAMP mice, the SV40 large T antigen is expressed in prostate under control of the probasin promoter. In BK5.IGF-1 mice, human IGF-1 is expressed in prostate under control of the bovine keratin (BK) 5 promoter. Recent work has shown that IGF-1R signaling pathways as well as COX-2 are up-regulated in prostate tissues of BK5.IGF-1 mice. In this regard, both PI3K and Akt are activated and COX-2 protein levels elevated in the dorsolateral (DLP) and in prostate tumors of the DLP of BK5.IGF-1 mice. A number of Akt downstream targets are also constitutively modulated (phosphorylated) in DLP tissues from these mice. COX-2 protein is up-regulated and PGE2 levels are elevated in DLP and tumors of 17-25 week old TRAMP mice. COX-2 protein levels were also elevated in cell lines established from TRAMP tumors. In these cell lines the COX-2 inhibitor celecoxib inhibited growth and PGE2 synthesis. These results suggest that both the PI3K/Akt and COX-2 pathways may be excellent targets for the prevention of prostate cancer in these model systems. Current studies are examining chemopreventive agents that target PI3K/Akt and cyclooxygenases pathways. In other studies, another novel transgenic mouse model is being used to examine the importance of COX-2 and its upstream regulation by EGFR/erbB2 signaling in cancers of the biliary tract. In these mice, rat erbB2 is overexpressed under control of the BK5 promoter. COX-2 protein is significantly upregulated in biliary tract epithelium and gallbladder adenocarcinomas that develop in these mice. In addition, the EGFR is activated constitutively in these same tissues. Thus, COX-2 and the EGFR appear to be excellent targets for chemoprevention strategies in these mice. Ongoing studies are examining the efficacy of COX-2 and EGFR inhibitors for prevention of biliary tract carcinogenesis in this model.

1616 ENVIRONMENTAL MODULATION OF PUBERTY.

B. J. Davis[1] and S. Fenton[2]. *[1]Laboratory of Women, NIEHS, Research Triangle Park, NC and [2]USEPA, Research Triangle Park, NC.*

The onset of puberty represents the orchestration of significant physiological events conducted by both genetic and environmental factors. Emerging data suggest that chemicals in the environment may be among the factors that influence pubertal characteristics and/or age of onset. This may be a particular concern for chemicals that advance the age of puberty in girls because of the emotional and physical complications associated with early puberty and because early age of menarche is a consistent risk factor for development of breast and uterine cancers later in life. This complex issue will be addressed by reviewing current knowledge of pubertal characteristics in humans and by analyzing evidence linking chemical exposures and puberty modulation. The current knowledge of neuroendocrine controls of puberty will be detailed using transgenic animal models, and we will explore recent developments in pubertal and *in utero*/lactational protocols for initial screening and testing of environmental contaminants.

1617 THE NEUROENDOCRINE CONTROL OF FEMALE PUBERTY AS REVEALED BY TRANSGENIC AND GENOMIC APPROACHES.

S. R. Ojeda, S. Heger, V. Prevot, A. Mungenas, A. Lomniczi, H. Jung and G. Smiley. *Oregon National Primate Research Center-, Oregon Health Sciences University, Beaverton, OR.* Sponsor: B. Davis.

The initiation of mammalian puberty requires increased LHRH secretion from the hypothalamus. This increase is determined by changes in the activity of neuronal and astroglial networks connected to LHRH neurons. The main inhibitory neurotransmitter controlling LHRH release is GABA, which delays the onset of puberty *via* activation of GABA-A receptors. GABA is also produced by a subset of LHRH neurons during developmental migration, but this capacity is lost when the neurons enter the brain towards their final destination. Transgenic expression of GAD-67 in LHRH neurons increased the number of neurons mistargeted during migration, suggesting that GABA production within the LHRH neuronal network may serve to enhance positional diversity. The mutant female mice also showed disrupted estrous cyclicity, decreased fertility, and a shortened reproductive span indicating that the normalcy of these major reproductive events requires silencing of GABA production within LHRH neurons. Astrocytes regulate LHRH secretion through growth factor-mediated cell-cell signaling pathways. Genetic disruption of erbB-1 or astrocytic erbB-4 in mice delays female sexual development due to impaired erbB ligand-induced LHRH release. The combined defect exacerbates the delay, indicating that both receptors act in concert. Global analysis of the changes in gene expression that occur in the primate hypothalamus during the onset of puberty revealed a broad range of expression changes in genes encoding transcriptional regulators, as well as neuron-neuron and neuron-glia communication. Thus, the initiation of puberty may require reciprocal neuron-glia communication involving excitatory amino acids and growth factors, and changes in synaptic make-up and glia-neuron adhesiveness. (NIH grants HD-25123, RR00163 and NICHD-U54-18185).

1618 A LONGER PUBERTY IN HUMANS: WHAT IN THE WORLD WILL BECOME OF IT?

M. R. Forman. *Cancer Prevention Studies Branch, NCI, Bethesda, MD.* Sponsor: B. Davis.

Age at onset of puberty is occurring earlier in boys and girls today than in the past 30 years in the United States based on nationally representative data. It occurs earlier in members of the African American ethnic group than other ethnic groups. Obesity and being taller at younger ages are proximal factors contributing to earlier age at onset of puberty, while the potential contributions of birth weight and early life environmental factors such as diet will be reviewed. Because puberty typically occurs three years before menarche in girls, is occurring earlier than in the past but

age at menarche has not significantly changed over time, puberty is occurring for a longer time interval. While pubertal stage in boys does not include an easily measured milestone such as menarche, earlier age of onset and comparable ages at reaching later pubertal stages over time leads to a similar pattern of a longer pubertal period. Pubertal stage differences in circulating levels of insulin-like growth factor 1 (IGF-1), leptin and other hormones and their co-variation with measures of body composition by gender and ethnic group will be described. Potential long-term effects from an extended pubertal period of the life cycle will be reviewed in relation to risk of chronic disease. Finally methodologic issues in pubertal staging have been described clinically and statistically; potential new molecular markers may be on the horizon.

1619 PUBERTAL DEVELOPMENT AND EXPOSURE TO POLYBROMINATED BIPHENYLS (PBBs).

M. Marcus. *Emory University, Atlanta , GA.* Sponsor: B. Davis.

In the early 1970s the Michigan Chemical Company made two products. One was a nutritional supplement for cattle feed (Nutrimaster) and the other was a flame retardant (Firemaster). A paper shortage and other obscure circumstances led to the delivery of Firemaster to the grain mill and contamination of cattle feed with PBBs. Farmers reported reduced milk production in their dairy herds, stillborn calves and calves born with hoof deformities. It took about 10 months for the contamination to be discovered and, in the meantime, thousands of farm families and local residents consumed contaminated meat and dairy products. PBBs are lipophilic and are eliminated slowly from the body. We found that breastfed girls born to the most highly exposed women had their first menstrual period a full year earlier than unexposed girls from the same community (11.6 years vs. 12.6 years).

1620 MAMMARY GLAND DEVELOPMENT: EARLY LIFE EFFECTS FROM THE ENVIRONMENT.

S. Fenton. *Reproductive Toxicology Division, USEPA, Research Triangle Park, NC.*

As signs of precocious puberty in girls reach the earliest mean age in history, many scientists are exploring the environment as a contributing factor. Accidental exposure to environmental toxicants and precocious use of estrogen or placental-protein containing hair care and beauty aid products have been suggested to alter the mean age at which groups of girls begin to show signs of puberty. An early sign of puberty includes breast development during those years preceding the completion of puberty. Development of the breast and the rodent mammary gland follow a similar timing in relationship to puberty. EPA scientists are developing and validating pubertal and *in utero*/lactational protocols using rodent models, for initial screening and testing of environmental contaminants. Our laboratory focuses on development of mammary tissue prior to and during puberty in rat offspring exposed to EDCs during late gestation, a critical time in the outgrowth of mammary epithelia. Rapid mammary epithelial development begins prior to the emergence of regular estrous cycles in rodents and is completed shortly after that time, a progression similar to that found in humans. Preliminary evidence indicates that the timing of mammary epithelial development can be altered by various EDCs, with compounds such as nonylphenol accelerating the pace and others (i.e., dioxin) delaying differentiation of the tissue. We have also begun to examine the mode of action(s) by which mammary gland development and other pubertal indicators are modulated by individual EDCs. (This is an abstract of a proposed presentation and does not necessarily reflect EPA policy)

1621 METHODS FOR THE IDENTIFICATION AND CHARACTERIZATION OF CHEMICAL RESPIRATORY ALLERGENS.

S. E. Loveless[2] and M. I. Gilmour[1]. [1]*DuPont Haskell Laboratory for Health and Environmental Sciences, Newark, DE and* [2]*USEPA, Research Triangle Park, NC.*

Chemical respiratory allergy (CRA) is an important occupational health problem because exposure to certain chemicals in the workplace can cause long-lasting effects, the symptoms of which can range from shortness of breath to life threatening anaphylactic shock. Currently, however, the prospective identification of chemicals likely to cause CRA is hampered by a lack of validated test methods. Accompanying the better understanding of the cellular interactions in allergic responses has come the realization that an essential molecule or pattern of molecules in this process may be identified that could serve as a predictor of potential respiratory allergens. The relevancy of route of exposure has been debated, with some scientists arguing that exposure of test animals to chemicals must occur *via* the respiratory tract by intranasal, intratracheal or inhalation exposure, while others claim that contact and respiratory allergens can induce differential immune responses following dermal exposure only. In January 1999, the chemical industry, through the American Chemistry Council (ACC) and the European Chemical Industry Council (CEFIC), committed more than $100 million over five years to health and environmental research related to chemical use. Respiratory allergy was identified in a global industry-wide survey as an important concern. Therefore, Immunotoxicology and Allergy research teams in both the US and Europe committed to sponsor a 3-year research program designed to develop methods to identify and characterize potential chemical respiratory allergens. Investigators at four laboratories were selected using a peer reviewed competitive process: Michigan State, Harvard, TNO Nutrition and Food Research Institute, and Syngenta (Central Toxicology Laboratory). This workshop will bring together investigators from all four laboratories to discuss the progress of their research. In addition, the current regulatory status and issues around predicting CRA will be discussed.

1622 AIRWAY CYTOKINE GENE EXPRESSION AS A BIOMARKER OF CHEMICAL-INDUCED AIRWAY ALLERGENICITY.

N. E. Kaminski[1], A. K. Farraj[2] and J. R. Harkema[2]. [1]*Pharmacology & Toxicology, Michigan State University, East Lansing, MI and* [2]*Department of Pathobiology & Diagnostic Investigation, Michigan State University, East lansing, MI.*

The overall objective of this workshop presentation will be to critically discuss the utility of employing cytokine gene expression in airways as a biomarker of whether an agent has the potential for inducing respiratory hypersensitivity and to contrast that to changes in serum IgE. A/J mice were employed in these studies due to the fact that they exhibit an enhanced T helper 2 phenotype and low background serum IgE. The principal source of mRNA used for the assessment of cytokine gene expression was the right lung lobes, although some measurements were also made using tracheobroncial lymph node-derived RNA. The experimental approach was to expose A/J mice *via* repeated intranasal administration to one of several model low molecular weight chemicals that are either well-established respiratory allergens (toluene diisocyanate or trimellitic anhydride) or contact allergens (2, 4 dinitrochlorobenzene or oxazolone). In order to assess the type and magnitude of airway response induced by each of the test agents evaluated, a broad range of endpoints were measured including histopathology of upper and lower airways, cellularity of bronchoalveolar lavage, changes in total serum IgE, and cytokine gene expression for IL-4, IL-5, IL-10, IL-13 and IFNgamma. Responses to each of the low molecular weight chemicals was compared to the protein allergen, ovalbumin. (Supported in part by the American Chemistry Council Grant 0051 and NIEHS Training Grant ES 07255).

1623 CAN NON-INVASIVE PLETHYSMOGRAPHY PREDICT RESPIRATORY ALLERGY TO CHEMICALS?

L. Kobzik. *Environmental Health, Harvard University, Boston, MA.* Sponsor: S. Loveless.

Non-invasive plethysmography in mice is being evaluated for use in predicting the potential of chemicals to cause respiratory allergy. This technique measures enhanced pause (Penh), an index of airway hyperresponsiveness (AHR), which is a characteristic pathophysiologic outcome in asthma. To determine the utility of noninvasive plethysmography as a predictor of respiratory allergy, toluene diisocyanate (TDI) and trimellitic anhydride (TMA) were used as prototypical respiratory sensitizers, while the well-known skin sensitizer, DNCB, was employed as a negative control. Results indicate that: 1) the vehicles used to deliver sensitizers into the lungs of mice by intranasal insufflation are without effect on AHR or pulmonary inflammation; 2) intranasal delivery of sensitizers into normal (unsensitized) mice is also without effect. These control observations are important in that they validate the specificity of any positive results observed. Also, after skin sensitization with DNCB, respiratory challenge has no effect on AHR or lung inflammation, confirming one-half of our hypothesis. Finally, TDI does cause increased airway responsiveness (AHR) when administered to skin-sensitized mice. The potential benefits and limitations of this technique for identification of respiratory sensitizers will be discussed.

1624 IDENTIFICATION AND CHARACTERIZATION OF CHEMICAL RESPIRATORY ALLERGENS IN RODENTS.

R. J. Dearman and I. Kimber. *Syngenta CTL, Macclesfield, Cheshire, United Kingdom.*

Chemical respiratory allergy is an important occupational health problem but there are currently available no validated methods for the prospective identification of such materials. This is due in part to the fact that the relevant cellular and molecu-

lar mechanisms are unclear, although there is evidence for the development of T helper (Th) 2 type responses and, in some cases, IgE production. Respiratory sensitizing potential has been explored as a function of induced increases in the total serum concentration of IgE in the Brown Norway (BN) rat and cytokine secretion profiles in BN rats and BALB/c strain mice. Animals have been exposed topically to the reference contact allergen 2, 4-dinitrochlorobenzene (DNCB), which lacks respiratory sensitizing potential, or to the reference respiratory allergen trimellitic anhydride (TMA). BN rats can be bled serially allowing longitudinal analyses and discrimination between transient and sustained changes in serum IgE. At concentrations of TMA and DNCB of comparable immunogenicity, only TMA treatment was associated with significant and persistent increases in serum IgE. However, there was considerable inter-experimental variation in the responsiveness of the BN rat to TMA exposure, with no response to TMA in some experiments. Furthermore, other respiratory allergens failed to provoke significant changes in serum IgE. Exposure of BALB/c strain mice or BN rats resulted in Th1- and Th2-type cytokine secretion patterns being induced by DNCB and TMA, respectively. Cytokine expression patterns by BN lymph node cells (LNC) were considerably more variable than those observed for LNC derived from BALB/c strain mice. To date, 7 contact allergens and 14 respiratory allergens from different chemical classes have been shown to stimulate type 1 and type 2 cytokine profiles, respectively, in the BALB/c strain mouse. These data suggest that the measurement of induced cytokine secretion profiles in the BALB/c strain mouse provides a robust method for hazard identification and characterization of chemical respiratory allergens.

1625 APPROACHES TO INDUCE RESPIRATORY ALLERGY IN THE RAT: IMPACT OF ROUTE, INTENSITY OF EXPOSURE, AND THE ROLE OF IRRITANCY AND IRRITANT-INDUCED INFLAMMATION.

J. H. Arts[1], N. Bloksma[3,2] and C. F. Kuper[1]. *[1]TNO Nutrition and Food Research Institute, Zeist, Netherlands, [2]Utrecht Institute for Pharmaceutical Sciences, Utrecht University, Netherlands and [3]Faculty of Biology, Utrecht University, Netherlands.* Sponsor: V. Feron.

Given the serious health problems caused by occupational respiratory allergy and the ever- increasing stream of new chemicals into workplaces, the early identification of chemical respiratory allergens is vital. Although a number of test protocols have been developed to predict respiratory allergenic potential, none of these are fully accepted. Using our test protocol, a two times topical application of trimellitic anhydride (TMA) followed by airway challenge of Brown Norway (BN) rats induced several changes when compared to non-sensitized rats. While there are good indications in laboratory animals and humans that skin exposure can act as a route for respiratory tract sensitization, less is known about the effect of the route on the type of immune reaction evoked and on dose-response relationships. Intranasal, inhalation and dermal routes were therefore compared to examine whether TMA-induced effects were dose-related or route-of-induction related. Preliminary results indicated that topically sensitized rats showed the largest effects. As to the intensity of exposure, using toluene diisocyanate (TDI), it was observed that a two-times topical application was not sufficient to increase total IgE, but the same total amount of TDI given in more applications within the same time frame did result in increased total IgE levels. Finally, as to the role of irritation and irritant-induced inflammation, allergic and irritant responses to TMA resulted in quite distinct breathing patterns; pre-exposure to irritating concentrations of SO2, however, offered some protection to TMA challenge in TMA-sensitized BN rats. In conclusion, the results of the present studies suggest that the BN rat is a promising model to predict chemical respiratory allergenic potential. This research is funded by the Dutch Ministry of SZW and CEFIC-LRI (Brussels, Belgium).

1626 CURRENT STATE OF PREDICTING THE RESPIRATORY ALLERGY POTENTIAL OF CHEMICALS: WHAT ARE THE ISSUES?

I. Gilmour[1] and S. E. Loveless[2]. *[1]NHEERL, USEPA, Research Triangle Park, NC and [2]Dupont Haskell Laboratory, Newark, DE.*

Many chemicals are clearly capable of eliciting immune responses in sensitized individuals, which, following re-exposure, can result in adverse allergic reactions. It is also generally agreed that contact sensitivity is the most common occupational health problem, and that respiratory sensitization occurs less frequently, and in a more restricted range of chemical classes. Various *in vivo* contact hypersensitivity tests, including the Buehler patch test, the mouse ear swelling test, and the local lymph node assay, have successfully identified contact sensitizers, although respiratory sensitizers also test positive in these assays. Guinea pig inhalation studies have been utilized to identify respiratory sensitizers, but these studies are expensive and labor-intensive and typically require protein conjugation of the chemical of interest in order to elicit a response. This workshop has highlighted pulmonary function testing, cytokine profiling and measurement of IgE as new, potential approaches for identifying respiratory sensitizers. While these techniques offer many advantages over the guinea pig models, further work is needed to validate these methodologies and to consider practical issues such as: which species and strain of animal to use; whether total IgE can be used as a surrogate for antigen specific reaginic antibody; and if measurement of IL4 after *in vitro* stimulation with mitogen is a reliable technique for identifying only respiratory sensitizers. Furthermore, timing and dose response curves for both the sensitization and challenge phases of the protocol need to be established to determine threshold and irritating concentrations of chemical, and to compare cytokine and antibody responses at doses which elicit the same level of immune-mediated hypersensitivity reactions. This abstract does not reflect EPA policy.

1627 NMR EVIDENCE FOR SIMULTANEOUS BINDING OF MIDAZOLAM WITH ALPHA-NAPHTHOFLAVONE OR TESTOSTERONE WITHIN THE ACTIVE SITE OF CYP3A4.

M. D. Cameron, K. E. Allen, B. Wen, A. P. Campbell and S. D. Nelson. *Medicinal Chemistry, University of Washington, Seattle, WA.*

Recent studies have indicated that CYP3A4 exhibits non-Michaelis-Menten kinetics for numerous substrates. Both homotropic and heterotropic activation have been reported and kinetic models have been used to suggest multiple substrates within the active site. We provide the first physio-chemical data supporting the hypothesis of allosteric binding within the CYP3A4 active site. Midazolam, a commonly used surgical anesthetic, is metabolized by CYP3A4 to two hydroxylated metabolites, 1'-OH- and 4-OH-midazolam. Incubations using purified CYP3A4 and midazolam showed that both α-naphthoflavone (α-NF) and testosterone affect the ratio of 1'-OH and 4-OH-midazolam. Similar to previous reports, α-NF was found to stimulate the formation of 1'-OH-midazolam while testosterone stimulated formation of 4-OH-midazolam. NMR was used to measure the closest approach of individual midazolam protons to the paramegnetic heme iron of CYP3A4 using paramagnetic T_1 relaxation times. Midazolam was ideally suited for these studies because the proton signals corresponding to both sites of oxidation were easily monitored along with two other protons, 2-H and one of the flourophenyl group protons. Incubations of 0.25 μM CYP3A4 and 500 μM midazolam resulted in calculated distances between 6.9 and 7.1 Å for all four monitored midazolam protons, consistent with free rotation within the active site or sliding parallel to the heme plane. Inclusion of 50 μM α-NF resulted in shortened proton-heme iron distances ranging from 5.6 to 6.7 Å. Consistent with kinetics of activation, the 1'-position was situated closest to the heme while the flourophenyl proton was the furthest. Proton-heme iron distances for midazolam with CYP3A4 and 50 μM testosterone ranged from 6.7 to 7.5 Å with the fluorophenyl proton furthest from the heme iron. Additionally, testosterone and α-NF experience paramagnetic relaxation when incubated with midazolam and CYP3A4, demonstrating their proximity to the heme iron in the active site. (Supported by NIH grant No. GM-32165, to SDN)

1628 THE EFFECT OF CHRONIC ETHANOL FEEDING ON THE PROTEIN LEVEL AND ACTIVITIES OF CYP3A ENZYMES IN THE LIVER OF MALE AND FEMALE SPRAGUE-DAWLEY RATS.

V. M. Mishin, C. M. Busch, Y. Jan and P. E. Thomas. *Laboratory for Cancer Research, Rutgers, The State University of New Jersey, Piscataway, NJ.* Sponsor: M. Iba.

Recent studies indicate that rat CYP3A subfamily is represented by at least four structural genes CYP3A1, CYP3A2, CYP3A9 and CYP3A18. In this study we investigated the protein levels and activities of CYP3A subfamily members in liver of control and ethanol-fed male and female rats. Chronic ethanol feeding (Lieber-DeCarli diet) of rats for 14 days results in the appearance of CYP3A1 protein in hepatic microsomes of female rats but not in male rats. Chronic ethanol feeding of rats of both sexes did not induce CYP3A2, an enzyme present in normal males but not females. Ethanol feeding did not effect the content of hepatic microsomal CYP3A9 and CYP3A18 in rats of either sex. We found that the enzymatic activities specific for CYP3A enzymes follow the change in immunodetecable CYP3A1. Thus, in hepatic microsomes from ethanol-treated female rats, there is an increase in quinine 3OH hydroxylation, a reaction that is more actively catalyzed by recombinant CYP3A1 compared to recombinant CYP3A2. Alprazolam hydroxylation changed little in hepatic microsomes of both untreated and treated rats. Thus, we found that ethanol has selective effect on the induction of catalytically competent CYP3A1 in the liver of female rats but not in males. Therefore, the induction of some CYP3A isozymes when large amounts of ethanol are consumed might have toxicological and pharmacological importance. (Supported by ES 05022)

1629 4-IPOMEANOL: MECHANISM-BASED INACTIVATOR OF CYP3A4.

T. M. Alvarez-Diez and J. Zheng. *Pharmaceutical Sciences, Northeastern University, Boston, MA.*

4-Ipomeanol, [1-(3-furyl)-4-hydroxypentanone], is a natural lung cytotoxin in animals bioactivated by cytochrome P450 enzymes into reactive metabolites. It has been investigated as a potential chemotherapeutic pro-drug. However, clinical studies reported unexpected dose-limiting liver toxicity, with no other side effects. The biochemical mechanism of its selective liver toxicity in humans is unknown. We tested 4-ipomeanol as a possible mechanism-based inactivator (MBI) of cytochrome P450 3A4 (CYP3A4). Methods: Incubations mixtures containing human recombinant CYP3A4, P450 oxido-reductase and increasing concentrations of 4-ipomeanol were prepared in microplates. The reactions were initiated by the addition of the cofactor nicotinamide adenine dinucleotide phosphate (NADPH). At 0, 4, 8 and 12 minutes, aliquots were withdrawn and assayed for CYP3A4 activity using the dibenzylfluorescein (DFB) / fluorescein assay. Some reaction mixtures included glutathione, catalase / superoxide dismutase (SOD), or DBF. Results: 4-ipomeanol accomplished all the criteria used to classify a compound as an MBI; **1.** 4-Ipomeanol produced a time- and concentration-dependent loss of the activity of CYP3A4. More than 80 % of the CYP3A4 activity was lost after its incubation with 4-ipomeanol for 12 minutes. Saturation kinetic was observed for concentrations of 4-ipomeanol higher than 75 μM. **2.** The inactivation of CYP3A4 was irreversible and NADPH- dependent. **3.** Glutathione and scavengers of reactive oxygen species, catalase/SOD, failed to protect CYP3A4 from inactivation by 4-ipomeanol. **4.** DBF substrate protected CYP3A4 for a limited time. In contrast, 4-ipomeanol metabolism had no effect in the activity of human CYP1A2, CYP2D6 or CYP2C9. Conclusion: 4-ipomeanol was found to be a potent and selective MBI of human CYP3A4 (K_{inact} = 0.07 min^{-1}, and K_I.of 20 μM). The association of CYP3A4 inactivation with hepatotoxicity is under investigation.

1630 QUANTIFICATION OF ROS PRODUCTION AND ENZYME INACTIVATION OF CYP1A BY CHLORINATED BIPHENYLS AND DIBENZO-*p*-DIOXINS.

J. Goldstone[1], N. V. Blough[2] and J. J. Stegeman[1]. *[1]Biology, Woods Hole Oceanographic Institution, Woods Hole, MA and [2]Chemistry and Biochemistry, University of Maryland, College Park, MD.*

The mechanisms by which planar (non-*ortho*-substituted) polychlorinated biphenyls (pPCBs) and polychlorinated dibenzo-*p*-dioxins exert toxicity are not well known. These compounds elicit oxidative stress, and prior work has shown microsomal cytochrome P450 1As (CYP 1A1) to be irreversibly inactivated by pPCBs and tetrachlorodibenzo-*p*-dioxin in an O_2-, NADPH-, and time-dependent process. This process is accompanied by the release of reactive oxygen species (ROS) but the quantitative relationship between inactivation and ROS release and the identity of the inactivating species are unknown. We have fluorometrically quantified the production of superoxide (O_2^-) by liver microsomal CYP 1A using dihydroethidium and an external standard consisting of the xanthine/xanthine oxidase system. NADPH oxidation was followed spectrophotometrically to examine the kinetic rates of pPCB-dependent enzyme inactivation and associated kinetic parameters of the pPCB-NADPH-cytochrome P450 reductase-CYP 1A system. With 3, 3′, 4, 4′-tetrachlorobiphenyl (PCB-77), O_2^- production rates were found to be as much as 90% of NADPH oxidation rates, suggesting that uncoupling by PCB-77 leads to ROS release after the addition of the first electron. The rate of inactivation of CYP1A (k_i) was decreased by the addition of increasing concentrations of DMSO. As DMSO is a small-molecule radical scavenger, these results, in addition to the increase in k_i observed when HOOH is added to CYP 1A, suggest that hydroxyl radicals generated in the active site could be responsible for the pPCB-dependent enzyme inactivation. A novel fluorescamine-derivatized nitroxide spin trap has been employed to characterize the radical production. The release of ROS resulting from the uncoupling of CYP 1As by pPCBs represent a possible mechanism of toxicity of these aryl hydrocarbon receptor agonists. (EPA R 827102-01-0 and NIH P42-ES07381)

1631 FUNCTIONAL ANALYSIS OF POLYMORPHISMS IN THE PROMOTER OF HUMAN CYTOCHROMES P450 1A1 AND 1B1.

W. Han[1] and S. D. Spivack[1]. *[1]Human Toxicology, Wadsworth Center, NYS Department of Health, Albany, NY and [2]Human Toxicology, Wadsworth Center, NYS Department of Health, Albany, NY.* Sponsor: L. Kaminsky.

Cytochromes P450 1A1 (CYP1A1) and 1B1 (CYP1B1) are major phase I PAH and estrogen metabolizing enzymes expressed in human lung. Inter-individual variation in the expression of both enzyme transcripts and activity has been observed in human. We have evaluated the functional consequences of SNPs, singly and in combination, in the constitutive and inducible expression of these genes. METHOD: Genomic DNA from peripheral blood mononuclear cells of twenty individuals was PCRed in a multiple overlapping fragment strategy for 1.5kb of high GC content promoter region of CYP1A1 and CYP1B1, and then direct cycle sequenced in duplicate. We found 12 CYP1A1 and 7 CYP1B1 polymorphisms, existing singly or in combination, that occur commonly in our subjects. We then cloned 1.5 kb insert sequence of each gene into a PGL3-basic luciferase reporter construct, and used iterative site-directed mutagenesis (Stratagene) to replicate the 12 CYP1A1 variants and 7 CYP1B1 variants. The constructs with wild-type and mono- or polycistronic variant insert were then subcloned into virgin PGL3 vector, to affirm that regulatory features were indeed a result of the 1.5kb insert sequence, and not due to the site-directed mutagenesis procedure itself. The subclones were then transfected into normal human bronchial epithelial cells (NHBE, Clonetics), and exposed to cigarette smoke extract (CSE), B[a]P and estradiol, each in three different doses. Additional cotransfections with estrogen receptor alpha were performed. RESULTS: To date, we have found no major expression differences between the wild-type and variant constructs for any haplotype, for reporter gene expression in response to CSE, B[a]P, nor on the repression effects of the chemopreventive agent resveretrol. Co-transfection of the NHBE cells with ER-alpha does appear to have additive effects with the inducing agents, but this appears independent of estradiol exposure. We are in the process of further evaluating carcinogen-hormonal interaction in estrogen receptor expressing lung cells.

1632 LACK OF A ROLE FOR CYP1A2 IN THE ACTIVATION OF 4-AMINOBIPHENYL INTO DNA-REACTIVE METABOLITES IN MICE.

C. D. Clay, Y. Tsuneoka, T. P. Dalton, H. G. Shertzer, M. L. Miller and D. W. Nebert. *Center for Environmental Genetics and Department of Environmental Health, University of Cincinnati Medical Center, Cincinnati, OH.*

4-Aminobiphenyl (ABP) is a prototypic aromatic amine that causes liver cancer in mice and bladder cancer in mice and humans. Metabolic activation of ABP is believed to involve N-hydroxylation, and CYP1A2 is the most active human or rodent CYP to catalyze this reaction. To assess the role of CYP1A2 in ABP activation to DNA-binding metabolites *in vivo*, we treated wild-type [Cyp1a2(+/+)] and Cyp1a2 knockout [Cyp1a2(-/-)] mice with ABP (50 umol/kg topically). Some mice had prior induction of CYP1 by 2, 3, 7, 8-tetrachlorodibenzo-p-dioxin (TCDD; 5 ug/kg, i.p.). Histopathology of liver and urinary bladder after this acute dose (24 h) showed an insignificant ABP effect, but untreated Cyp1a2(-/-) showed more fat deposits in the liver than untreated Cyp1a2(+/+), and TCDD increased fat deposits >2-fold in both genotypes. After 24 h, both male and female Cyp1a2(-/-) mice had similar levels of ABP-DNA adducts in liver and bladder as wild-type, with the exception that female Cyp1a2(-/-) actually had 3 to 4-fold higher levels of hepatic adducts than wild-type. In both genders and genotypes, TCDD pretreatment lowered both liver and bladder adducts. Interestingly, female mice of both genotypes displayed higher levels of liver DNA adducts compared to males, whereas males had higher levels of bladder DNA adducts compared to females. These results show clear sex differences in the pattern of liver and bladder DNA adducts produced by ABP. Furthermore, the results suggest that CYP1A2 does not appear to be a major contributor to the pathway responsible for ABP activation to DNA binding metabolites in mice. (Supported by NIH grants P30 ES06096, RO1 ES10133, RO1 ES06321, R01 ES08147)

1633 P450-MEDIATED METABOLISM OF CAPSAICIN DECREASES CYTOTOXICITY TO LUNG AND LIVER CELLS.

C. A. Reilly and G. S. Yost. *Pharmacology and Toxicology, University of Utah, Salt Lake City, UT.*

Capsaicin, a common dietary constituent, homeopathic remedy, and component of pepper spray self-defense weaponry, has been shown to be a potent respiratory irritant and toxicant. Capsaicin can cause acute respiratory dysfunction and failure with an LD50 of 1.6 and 190 mg/kg for intratracheal and oral doses in mice. We investigated the metabolism of capsaicin by liver and lung microsomes and recombinant P450 enzymes to ascertain the role of metabolism in the apparent lung-selective toxicity of capsaicin. LC/MS/MS and 1H-NMR were used to identify several metabolites of capsaicin produced by aromatic and alkyl hydroxylation, O-demethylation, N- and alkyl dehydrogenation, and macrocycle formation. The rates of metabolism were 11.0 and 0.6 nmol/min/mg for human liver and lung microsomes, respectively. Metabolism was limited to CYP1A1, 1A2, 3A4, 2B6, 2C8, 2C9, 2C19, 2D6, and 2E1. Microsomal metabolism of capsaicin was inhibited by 1-aminobenzotriazole (1-ABT) and stimulated by glutathione. Studies with recombinant CYP2E1 demonstrated that capsaicin was a potent inhibitor of this enzyme. Addition of 1-ABT to human lung bronchiolar epithelial and hepatoma cell cultures treated with capsaicin showed that inhibition of metabolism increased cytotoxicity. These data suggest that P450-mediated metabolism of capsaicin represents

a detoxification mechanism for capsaicin rather than bioactivation, despite evidence that potentially cytotoxic reactive metabolites are produced. Additional studies have identified the capsaicin receptor (TRPV1 or VR1) as a key mediator for the cell type- and tissue-selective cytotoxicity of capsaicin. Supported by NIST (Contract# 60NANBOD0006) and the Colgate-Palmolive Post Doctoral Fellowship in *In Vitro* Toxicology.

1634 EFFECTS OF NATURAL AND SYNTHETIC FLAVONOIDS ON AROMATASE (CYP19) ACTIVITY IN H295R HUMAN ADRENOCORTICAL CARCINOMA CELLS.

T. Sanderson[1], M. S. Denison[2], M. Kurth[3], M. H. Nantz[3], M. Springsteel[3] and M. van den Berg[1]. *[1]Institute for Risk Assessment Sciences, University of Utrecht, Utrecht, NL, Netherlands, [2]Department of Environmental Toxicology, University of California, Davis, CA and [3]Department of Chemistry, University of California, Davis, CA.*

Flavonoids and related structures (flavones, isoflavones, flavanones, catechins) have various biological properties, including anticarcinogenic, estrogenic and anti-estrogenic effects; they also modulate sex hormone homeostasis. A key enzyme in the synthesis of estrogens from androgens is aromatase (CYP19). We investigated the effects of various naturally occurring and synthetically derived flavonoids on the synthesis of estrogens by the enzyme aromatase in H295R human adrenocortical carcinoma cells. Among the natural flavonoids (in order of descending potency) chrysin, apigenin and narengenin were relatively weak inhibitors of aromatase activity (IC_{50}≥10 μM). Flavone (base structure) appeared to be an inducer, increasing aromatase activity just under 2-fold at 30 μM. Rotenone, a synthetic flavone-derivative and fish poison, was a relatively potent inhibitor of aromatase with an IC_{50} of 0.5 μM; cytotoxicity occurred at concentrations of 3 μM and above. The steroidal aromatase inhibitor 4-hydroxyandrostenedione, used as positive control, had an IC_{50} of about 20 nM. Several other synthetic flavonoid and structurally related quinolone analogs were screened and found to have various effects on aromatase activity, including both inhibition or induction of the enzyme activity at concentrations in the high nanomolar to lower micromolar range. Currently, studies are underway to determine structure-activity relationships for induction or inhibition of aromatase activity and mRNA expression by flavonoid structures in H295R cells.

1635 A MOUSE MODEL WITH LIVER-SPECIFIC DELETION OF THE NADPH-CYTOCHROME P450 REDUCTASE GENE.

X. Ding[1,2], J. Gu[1], L. Wu[1], Y. Weng[2,1], K. Kluetzman[1], H. Cui[1], Q. Zhang[1] and W. Yang[1]. *[1]Wadsworth Center, New York State Department of Health, Albany, NY and [2]School of Public Health, State University of New York at Albany, Albany, NY.*

To determine the relative roles of liver and extrahepatic tissues in the metabolic activation and tissue-selective toxicity of xenobiotic compounds, we have generated a mouse model for tissue-selective deletion of the NADPH-cytochrome P450 reductase (CPR) gene. The consequent loss of CPR expression will lead to a suppression of the activities of all microsomal P450s. The recombinant Cpr allele (named CPR^{lox}) contains loxP sequences in introns 2 and 15, respectively, which did not cause any changes in CPR expression. In the presence of Cre recombinase (Cre), the intervening exons would be deleted, leading to a null mutation. This is demonstrated by crossing $CPR^{lox+/+}$ mice with transgenic mice having liver-specific Cre expression (named Alb-Cre). Liver microsomal CPR level was about 50% lower in $CPR^{lox+/-}$/Alb-$Cre^{+/-}$ mice than in $CPR^{lox+/-}$/Alb-$Cre^{-/-}$ littermates at three weeks of age, and CPR levels in other tissues were not affected. Thus, the modified CPR gene can be efficiently and specifically deleted from the liver. The decreased level of CPR protein was accompanied by significant decreases in liver microsomal activities in the metabolic activation of two known P450 substrates, acetaminophen and 4-(methylnitrosamino)-1-(3-pyridyl)-1-butanone. Homozygous $CPR^{lox+/+}$/Alb-Cre^{+} mice, which are viable, have also been obtained and are being characterized. (Supported in part by NIH grant ES07462)

1636 GENE EXPRESSION PROFILING OF SKIN CARCINOGENESIS IN MICE USING CDNA MICROARRAYS.

K. Ridd[1], S. Dhir[1], R. Davies[1], J. Riley[1], D. J. Judah[1], A. Wolfreys[2], V. Baker[2], T. W. Gant[1] and A. G. Smith[1]. *[1]MRC Toxicology Unit, Leicester, Leicestershire, United Kingdom and [2]Unilever Research Colworth, Bedford, Bedfordshire, United Kingdom.*

The purpose of this study was to use cDNA microarrays to investigate the complex alterations in gene expression that occur during the promotion phase of the classic two-stage DMBA/TPA skin carcinogenesis model. The shaved dorsal skin of FVB/N female mice (3-5 weeks old) was topically painted with a single dose of DMBA. TPA promotion commenced one week later and continued twice weekly. Histology and microarray analysis were performed using skin excised after promotion for 2, 4, 6 and 15 weeks. cDNA microarrays were made in-house and consisted of 4147 mouse ESTs, including genes involved in apoptosis, oxidative stress, cell signalling and skin homeostasis. Mild diffuse epidermal hyperplasia was evident after 2 weeks of promotion with TPA and persisted for 15 weeks of TPA promotion. This hyperplasia was also evident in mice that had received TPA alone. Squamous papillomas were evident in 100% of the mice following 9 weeks of TPA promotion. No papillomas were seen in mice treated with DMBA or TPA alone. The maximum tumour burden was seen following 12 weeks of TPA promotion (16 ± 7.6), between 12 and 15 weeks some tumours coalesced reducing the number of individual papillomas. All papillomas were keratinised well-differentiated squamous neoplasms without evidence of invasive growth. Genomic analysis of the 15-week skin samples containing papillomas revealed an increase in the expression of the keratin gene family members. This was supported by histological data showing abundant keratin within the papillomas. Additionally members of the cornified envelope, indicative of epidermal cell differentiation (*loricrin, desmoglein 2* and *filaggrin*) were also increased in expression. Gene expression data will be presented in full for all time points analysed and will show how it has been possible to relate changes in gene expression to the pathology of skin carcinogenesis. The data provides further insight into the molecular events underlying the pathological changes in the promotion stage of this model.

1637 DMBA INDUCED DISRUPTION OF BONE MARROW HYPOCELLULARITY IS TNF-α DEPENDENT.

T. J. Page[1,3], C. R. Jefcoate[2,3], P. S. MacWilliams[1], M. Suresh[1] and C. J. Czuprynski[1,3]. *[1]Department of Pathobiological Sciences, University of Wisconsin, Madison, WI, [2]Department of Pharmacology, University of Wisconsin, Madison, WI and [3]Environmental Health Science Center, University of Wisconsin, Madison, WI.*

Polycyclic aromatic hydrocarbons (PAHs) are potent carcinogens and immunotoxicants. Using the prototypical PAH, 7, 12-dimethlybenz[a]anthracene (DMBA), we have shown previously that DMBA administration depletes the bone marrow of progenitor B cells and granulocytes *in vivo* and DMBA metabolites cause apoptosis of progenitor B cells *in vitro*. The goal of this study was to determine a mechanism of action for the effects of DMBA on the B cell population in the bone marrow. Our hypothesis was that DMBA exerts its adverse effects on the bone marrow, at least in part, by stimulating TNF-α production by bone marrow stromal cells. TNF-α can then up-regulate PKR (dsRNA dependent protein kinase), which in turn can activate p53, leading to apoptosis in the susceptible bone marrow cell populations. In support of this hypothesis, we have demonstrated that bone marrow cells produce TNF-α in response to DMBA *ex vivo*, and that TNF receptor gene deleted mice (null for both p55 and p75) are resistant to DMBA induced bone marrow cell depletion. We have observed PKR up-regulation in 70Z/3 cells (a murine preB cell line) after DMBA treatment, and in whole bone marrow cell lysates after i.p. injection of DMBA in C57BL/6 mice. Furthermore, p53 gene deleted mice are resistant to DMBA mediated bone marrow cell depletion, thus indicating that the process is p53 dependent. These studies demonstrate that TNF-α and its down-stream signaling pathways may play an important role in the mechanism of DMBA mediated bone marrow cell depletion.

1638 NATURALLY OCCURRING COUMARINS INHIBIT HUMAN CYTOCHROMES P450 AND BLOCK BENZO(a)PYRENE AND 7, 12-DIMETHYLBENZ[A]ANTHRACENE DNA ADDUCT FORMATION IN MCF-7 CELLS.

H. E. Kleiner, M. J. Reed and J. DiGiovanni. *Carcinogenesis, UT MD Anderson Cancer Center, Smithville, TX.*

Naturally-occurring coumarins (NOCs) inhibit skin tumor initiation in mice by blocking cytochrome P450 (CYP)-mediated bioactivation of benzo[a]pyrene (B[a]P) and 7, 12-dimethylbenz[a]anthracene (DMBA). Bergamottin selectively inhibits tumor initiation by B[a]P, whereas imperatorin and isopimpinellin inhibit tumor initiation with both carcinogens. The goals of the current study were to examine the whether NOCs, which are anticarcinogenic in mice, can block carcinogen bioactivation in cultured human cells. In these experiments we examined the effects of bergamottin, imperatorin, and isopimpinellin on DMBA and B[a]P DNA adduct formation in the human breast adenocarcinoma cell line, MCF-7. Co-incubation of cells with the three different NOCs significantly inhibited DMBA DNA adduct formation by 29% to 82% at doses ranging from 2 to 10 microM; and significantly inhibited B[a]P DNA adduct formation by 37% to 80% at doses ranging from 20 to 80 microM. HPLC analysis of the DNA hydrolysates demonstrated that inhibition of DNA adducts corresponded to inhibition of the major B[a]P and DMBA diol-epoxide derived adducts. Furthermore, these NOCs

significantly inhibited CYP mediated ethoxyresorufin O-dealkylase activities in MCF-7 cells treated with acetone, B[a]P, and DMBA. Bergamottin, which was not effective at blocking DMBA bioactivation in the mouse skin model, had effects similar to imperatorin and isopimpinellin in MCF-7 cells. These results demonstrate that NOCs, which are present in citrus fruits and other components of the human diet, are capable of inhibiting carcinogen metabolizing enzymes and blocking bioactivation of both B[a]P and DMBA in MCF-7 cells. (CA 79442, CA 16672, ES07783).

1639 SUPPRESSION OF FERTILITY AND ITS REGULATORY HORMONES BY INHALED BENZO(a)PYRENE (BaP).

A. E. Archibong[1], M. Niaz[2], M. Greenwood[2], F. Inyang[2], A. Ramesh[2], P. Kopsombut[2], D. B. Hood[2] and A. M. Nyanda[2]. *[1]OB/GYN, Meharry Medical College, Nashville, TN and [2]Pharmacology, Meharry Medical College, Nashville, TN.*

Two experiments were conducted where F-344 rats were assigned randomly to a treatment and a control group, to evaluate the effect of BaP on fertility and the hormones that regulate this process. In experiment 1, treatment consisted of sub-acute exposure of rats *via* inhalation to 100 $\mu g/m^3$, 4 hr/day for 10 days. From the 4th day of exposure, animals in the control (unexposed) and treatment group were synchronized with subcutaneous progesterone (P_4) injections (1 mg P_4/animal /day for 4 days). Two days were allowed for unstimulated folliculogenesis to occur, which corresponded with the last day of BaP exposure. Blood samples were collected daily for plasma, beginning from 24 hr post P_4 administrations until the cessation of exposures, by sinus retro-orbital puncture. Plasma samples were assayed for ovarian steroids. In experiment 2, pregnant rats were similarly exposed from day 8 of gestation through day 21. Blood samples were similarly collected on day 17 only for the determination of ovarian steroid and placental lactogen (PL) concentrations in plasma. Postpartum litter size was determined for exposed rats and compared to those of controls with unpaired T-test. Hormone levels for animals in experiment 1 were analyzed by ANOVA with repeated measures while those for animals in experiment 2 were analyzed with a one-way ANOVA. The differences among means for hormone data in the 2 experiments were tested for significance by orthogonal contrasts. Exposure to BaP resulted in a reduction of circulating ovarian steroid concentrations in non-pregnant and pregnant rats. Similarly, litter size as well as pups characteristics were affected by BaP exposure. A concomitant decrease in PL was observed among BaP-exposed rats. These data suggest that inhaled BaP compromised fertility and the hormones necessary for the regulation of this process. (Supported by MHPF/ATSDR grant #U50/ATU398948, NCRR-RCMI grant #G12RR03032, NIGMS-SCORE grant # 2S06GM08037-28.

1640 BENZO(a)PYRENE DIONES PREVENT EGF WITHDRAWAL-INDUCED APOPTOSIS IN HUMAN MAMMARY EPITHELIAL CELLS THROUGH THE REACTIVE OXYGEN SPECIES (ROS)-DEPENDENT ACTIVATION OF AKT.

A. D. Burdick[1], K. Liu[1], J. W. Davis[2] and S. W. Burchiel[1]. *[1]College of Pharmacy Toxicology Program, University of New Mexico, Albuquerque, NM and [2]Department of Genetic and Molecular Toxicology, Schering Plough Research Institute, Lafayette, NJ.*

Polycyclic aromatic hydrocarbons (PAHs), such as benzo[a]pyrene (BaP), are known mammary carcinogens in rodents and may be involved in the development of human breast cancer. Previous work in this lab has shown that BaP can mimic growth factor-like signaling in human mammary epithelial cells (HMECs). We have hypothesized that the mitogenic response to BaP may be due to the metabolic conversion of BaP into BaP-diones (i.e. BaP-quinones, BPQs) which redox-cycle to produce reactive oxygen species (ROS) and activate growth factor receptor pathways. Here, we demonstrate by electron paramagnetic spectroscopy (EPR) and gene expression analysis that 1, 6- and 3, 6-BPQ produce ROS in a growth factor dependent, spontaneously immortalized HMEC cell line, MCF-10A. Similar to BaP, treatment of MCF-10A cells with 1, 6- and 3, 6-BPQ increased cell number despite the absence of EGF in the media. This effect is likely due to a BPQ-induced protection from EGF withdrawal-induced apoptosis, since BPQs reduced Annexin-V staining as determined by FACS analysis. BPQs also produced a concentration-dependent increase in Akt phosphorylation occurring between 12 and 24 h of BPQ treatment. Co-treatment of MCF-10A cells with PI3-K inhibitors and N-acetylcysteine attenuated Akt phosphorylation and appeared to re-establish EGF withdrawal-induced apoptosis. Therefore, the ROS-dependent activation of PI 3-K/Akt by BPQs may represent one mechanism by which BaP increases HMEC cell proliferation in the absence of exogenously added growth factors. This work was supported by NIEHS R01-ES-07259 and ADB by the US Army Medical Research Grant BC-010026.

1641 BROMODICHLOROMETHANE TOXICOKINETICS: LINKING METABOLISM TO EFFECT.

R. A. Pegram[1], M. K. Ross[2], A. B. DeAngelo[1], J. W. Allis[1] and G. Zhao[2]. *[1]NHEERL, USEPA, Research Triangle Park, NC and [2]Curriculum in Toxicology, UNC, Chapel Hill, NC.*

Bromodichloromethane (BDCM), a trihalomethane (THM), is among the most prevalent disinfection byproducts found in chlorinated drinking water. Weak associations between THM exposure and cancers of the bladder and lower GI tract have been suggested by positive epidemiological studies of chlorinated drinking water exposures in humans. Chronic high-dose administration of BDCM to rodents induced kidney and colon carcinomas. A series of *in vivo* and *in vitro* studies have been undertaken to evaluate the toxicokinetics and effects of BDCM. BDCM is metabolized by cytochrome P450 isozymes and by cytosolic glutathione *S*-transferase theta 1-1 (GST T1-1). CYP2E1 is the principal metabolizing enzyme in both humans and rats, and the *in vitro* metabolic parameters for recombinant preparations of human and rat CYP2E1 were almost identical. We have found that CYP1A2 metabolizes BDCM, and can now report a lower Km for the human enzyme compared to its rat counterpart. BDCM is also metabolized to a mutagenic intermediate(s) *via* GST T1-1. The relative mutagenic potency of the four THMs correlates well with their relative potency as inducers of preneoplastic aberrant crypt foci in the rat large intestine. GST T1-1 is the primary catalyst for BDCM-glutathione conjugation, leading to product(s) that covalently modify DNA and form deoxyguanosine adducts *in vitro*, consistent with previous observations of GST T1-1-dependent mutagenicity of BDCM. Additional metabolites of this pathway were identified, including S-formyl-GSH and formate. Comparison of the catalytic efficiencies of CYP2E1- and GST T1-1-mediated BDCM metabolism indicate that GST-dependent metabolism is a quantitatively minor pathway, but glutathione conjugation may give rise to extremely reactive intermediates that induce disproportionately toxic responses. Tissues (kidney and colon) that have higher ratios of GST T1-1:CYP2E1 activities are targets for BDCM-induced carcinoma in rats. 1642 UPTAKE AND DISPOSITION OF 1, 1, 1-TRIFLUOROETHANE IN MAN.

S. Gunnare, L. Ernstgård, B. Sjögren and G. Johanson. *Institute of Environmental Medicine, Karolinska Institutet, Stockholm, Stockholm, Sweden.*

Hydrofluorocarbons (HFC) are used as substitutes for the ozone depleting chlorofluorocarbons, e.g. in refrigeration. There are scarce human data on the toxicokinetics and toxicology of HFCs. The aim of the study was to determine the toxicokinetics of 1, 1, 1-trifluoroethane (HFC-143a) in humans. Nine occupationally exposed male volunteers were exposed to 500 ppm trifluoroethane for 2 hours during light physical exercise (50W) in an exposure chamber. Blood, urine and exhaled air were collected before, during and up to 2 days after exposure and analysed for trifluoroethane by headspace gas chromatography. Trifluoroacetic acid and fluoride in urine were analysed using high performance liquid chromatography and a selective ion electrode, respectively. The electrocardiogram was monitored during and until 20 hours after exposure. Irritative and central nervous system symptoms (e.g. discomfort in the eyes, headache and dizziness) were rated in a questionnaire prior to, during, and after exposure. The study was approved by the Regional Ethical Committee. Preliminary analyses suggest no increases in symptom ratings during or after exposure. The uptake of trifluoroethane in the human body was only a few per cent. As expected, trifluoroethane in blood increased rapidly during exposure and decreased rapidly after exposure. A plateau of about 1.4 ppm trifluoroethane was reached. Two elimination phases were observed with half times of about 4 and 300 minutes, respectively. The toxicokinetic behaviour is explained by the low metabolic rate and low solubility in blood. Increased fluoride concentration in urine was seen in two of nine volunteers. To our knowledge, this is the first human toxicokinetic study of trifluoroethane.

1643 STANDARDIZATION OF THE TAPE-STRIP SAMPLE BY DETERMINATION OF KERATIN IN THE SAMPLE AFTER EXPOSURE TO JET FUEL.

Y. Chao and L. A. Nylander-French. *Environmental Sciences & Engineering, University of North Carolina at Chapel Hill, Chapel Hill, NC.*

Chemicals may bind to and react with keratin proteins in the skin. We have evaluated a non-invasive tape-stripping method for the extraction and quantification of napthalene and keratin from the skin for normalization and exposure assessment. Samples from 20 human volunteers were examined before and after exposure to 25 µl of jet fuel (JP-8). Due to variable amounts of squame recovered with each tape-stripped sample, we investigated the need to normalize extracted chemical to the amount of tissue stripped using keratin as a biomarker. Keratin proteins were ex-

tracted in a buffer and quantified using a modified Bradford Method (AmrescoTM). Confirmation of the extraction of keratin was verified by western blotting using a monoclonal mouse anti-human cytokeratin antibody (DakoTM Corporation). Tape stripping removed a consistent amount of keratin from the skin, which decreased with sequential tape strippings, and naphthalene was effectively quantified during the 25-min exposure from individuals with normal skin. The mean mass of keratin proteins for sequential tape strips varied from 154 ± 75.3 μg for the first tape strip to 52.8 ± 17.3 μg for the fifth tape strip for the unexposed sites and from 128 ± 63.8 μg for the first tape strip to 58.4 ± 21.6 μg for the fifth tape strip for the exposed sites. Jet fuel exposure did not affect the amount of keratin recovered from the tape strips. There was no significant difference in the removal of keratin per tape strip from unexposed and exposed sites between sex, age, ethnicity, or skin pigmentation. We conclude that the actual concentration of naphthalene, as a marker for jet fuel exposure, per unit of keratin can be determined using this method, which may prove to be required when measuring occupational exposures under occupational field settings. The technique developed may be a powerful tool to measure concentration of a compound in the skin and to determine dermal exposure. Supported by NIEHS P42 ES05948, USAF *via* Texas Tech University 1331/0489-01, & NIOSH 5-52678.

1644 IDENTIFICATION OF BIOMARKERS AND MECHANISMS OF THE ACUTE PHASE RESPONSE IN LIVER USING A CANINE MICROARRAY.

M. A. Higgins, B. R. Berridge, B. J. Mills, A. E. Schultze, H. Gao, G. H. Searfoss, T. K. Baker and T. P. Ryan. *Lilly Research Labs, Greenfield, IN.* Sponsor: C. Thomas.

A greater understanding of mechanisms of toxicity and better markers to measure adverse effects in the dog would improve our ability to extrapolate risk to humans. However, the tools to find these markers and mechanisms are lacking in the dog compared to other commonly used pre-clinical species, such as the rat and mouse. For this reason, we developed an Affymetrix-based oligonucleotide microarray capable of monitoring the expression of thousands of canine genes simultaneously. The array is composed of 22, 774 probe sets, with 13, 675 canine sequences, 115 normalization controls, and standard non-eukaryotic Affymetrix hybridization controls. An additional 8, 945 probe sets, designed to the terminal 600 bases of the coding region of full length human cDNAs to improve cross-species hybridization, were tiled on the array. To assess the ability of this genomic tool to detect differential gene expression, the array was used to profile the acute phase response in male beagle dogs after a single dose (0.2mg/kg) of lipopolysaccharide (LPS). Hepatic gene expression 4 and 24 hours post-LPS administration was compared to vehicle-treated animals (3 per treatment group). Further validating the array, a strong correlation was shown between gene expression data and alterations in clinical chemistry parameters such as serum amyloid A (SAA), alkaline phosphatase, and aspartate aminotransferase. Microarray data illustrated early aspects of an acute inflammatory response, with multiple cytokines and acute phase proteins induced 4 hours post treatment. The most robust transcriptional change was observed with SAA; transcript levels were induced 30-fold by 4 hours and steadily increased thereafter. In contrast, the most profound changes observed only at 24 hours involved genes associated with glucose and cholesterol metabolism, and biotransformation. In addition to these mechanistic findings, this new genomic tool identified several potential biomarkers that could serve as indicators of inflammation in human patients.

1645 SEPARATING GENES BETWEEN CHEMICAL SPECIFIC RESPONSES AND GENERAL STRESS RESPONSES BASED ON EXPRESSION PROFILES IN RAT HEPATOCYTES EXPOSED TO CADMIUM AND HYDRAZINE.

V. Chan[1], N. Kelley-Loughnane[2], B. Harker[1], D. Rudnicki[3], S. Hussain[1], C. Wang[1] and J. Frazier[3]. *[1]ManTech Environmental Inc., Wright-Patterson AFB, OH, [2]Geo-Center Inc., Wright-Patterson AFB, OH and [3]Operational Toxicology Branch, AFB, Wright-Patterson AFB, OH.*

DNA microarray analysis is a useful technique for studying the molecular basis for chemical toxicity from a global prospective. However, chemical exposure results in changed expression of a large number of genes. Some changes may be related to metabolic activity reflecting adaptive response, while others may be related to toxicity with adverse outcome. Besides affecting genes involved in general stress response, toxicants also have effects on genes responsive to specific stress/damage imposed by the toxic insults. We have identified that the expression levels of 91 and 133 genes were changed in primary cultures of rat hepatocytes exposed to cadmium and hydrazine, respectively. Unexpectedly, changes in expression levels of 209 genes were observed in untreated controls during a 24-hour period, which are probably resulted from dedifferentiation and adaptation to the *in vitro* culture environment of rat hepatocytes. Analysis of these gene lists revealed that 65 of 91 cadmium-related genes and 84 of 133 hydrazine-related genes are likely related to general stress response. Consistent with this notion, there is a significant overlap between the stress-related genes affected by these chemicals (i.e., 52 genes were identical). In contrast, 26 of 91 cadmium-related genes and 49 of 133 hydrazine-related genes appeared to be chemical specific. Between these two groups, only 11 genes were identical. The general stress genes were further characterized using Self Organization Map (SOM) Clustering. By comparing the clustering patterns of cadmium and hydrazine treatments with that of the controls, we were able to further divide genes into subgroups that are likely co-regulated under these experimental conditions. This result provides some insight into the molecular events associated with cadmium and hydrazine exposure.

1646 ALTERED PROTEIN / DNA INTERACTIONS OF LIVER ENRICHED TRANSCRIPTION FACTORS AS PREDICTORS FOR TOXICITY - IMPLICATIONS FOR TOXICOGENOMIC RESEARCH.

J. Borlak, A. Sowa and M. Niehof. *Drug Research and Medical Biotechnology, Fraunhofer Institute ITA, Hannover, Lower Saxony, Germany.* Sponsor: H. Muhle.

New platform technologies offer unique opportunities to explore simultaneously an expression of thousands of genes and proteins and in conjunction with other molecular endpoints, reliable predictions of drug safety may now be feasible, at early stages of drug development. Drug induced alterations in gene and protein expression are also considered to be of critical importance in the onset and progression of organ toxicity and major efforts are on the way to determine the relevance of individual expression profiles in response to drug exposure. The observed changes in target gene/protein expression may be traced back to modulation of transcription factor protein/DNA interactions. Examples will therefore be presented that demonstrate, on the one hand, the severe limitations in the use of tumor cell lines and other badly validated cell culture models for the prediction of tissue specific toxicity and, on the other hand, how properly designed and validated *in vitro* models hold promise for reliable predictions of hepatotoxicity. Results from studies with hepatotoxins, such as Aroclor1254, are given to provide the experimental evidence for the principality of this approach. (1) Schrem, H., Klempnauer, J. and Borlak, J. 1647 TOXICOGENOMICS OF BROMOBENZENE-INDUCED HEPATOTOXICITY.

W. H. Heijne[1], R. H. Stierum[1], B. Van Ommen[1], R. Lamers[2] and P. J. Van Bladeren[3]. *[1]Biomolecular Sciences, TNO Nutrition and Food Research, ZEIST, Utrecht, Netherlands, [2]Food and Food Supplement Analysis, TNO Nutrition and Food Research, ZEIST, Utrecht, Netherlands and [3]Toxicology, Wageningen University and Research Centre, Wageningen, Utrecht, Netherlands.*

Toxicogenomics combines the expression analysis of thousands of genes (transcriptomics) or proteins (proteomics) with classical methods in toxicology, enabling detailed comparison of mechanisms and early detection and prediction of toxicity. The bromobenzene-induced hepatotoxicity in rats was studied at the gene expression level using cDNA microarrays 6, 24 and 48 hours after an oral dosing (3 levels). Moreover, liver samples were subjected to proteomics analyses to identify proteins with a (putative) role in bromobenzene hepatotoxicity. Urine and plasma metabolite patterns were recorded by NMR and subjected to pattern recognition analysis. Profiles of gene and protein expression and metabolite levels from treated rats were clearly distinct from controls as was shown by principal component analysis, while the greatest difference from controls was observed in high dosed groups 24 hours after dosage. Apparent signs of hepatotoxicity were found only in high dosed rats after 24 and 48 hours as determined with clinical chemistry and histopathology. The physiological symptoms coincided with many changes of the hepatic mRNA and protein content. Transcriptomics analysis confirmed involvement of glutathione-S-transferase isozymes and epoxide hydrolase in bromobenzene metabolism. Observed glutathione depletion coincided with induction of key enzymes in glutathione biosynthesis. Oxidative stress was apparent from strong up-regulation of heme oxygenase, peroxiredoxin 1 and other genes. An acute phase response was characterized by both up- and downregulation of specific genes. Clusters of genes commonly regulated by a specific transcription factor were found to be expressed in a similar manner.

1648 GENE EXPRESSION CHANGES IN F344 RATS FOLLOWING A PHARMACOLOGICAL DOSE OF ACETAMINOPHEN.

R. Irwin, G. A. Boorman, R. Paules, A. Heinloth, R. W. Tennant, M. L. Snell and M. L. Cunningham. *NIH/NIEHS, Research Triangle Park, NC.*

Acetaminophen (APAP) is a commonly used over-the-counter analgesic and antipyretic that is hepatotoxic in high doses. Centrilobular necrosis occurs in the liver following APAP exposure after glutathione stores are depleted, allowing its toxic metabolite N-acetyl-p-benoquinone imine to react with cellular macromolecules causing mitochondrial dysfunction and hepatotoxicity. We treated ad libitum fed male Fisher 344 rats orally with APAP at doses that may be experienced during normal therapeutic regimes, 50 and 150 mg/Kg and examined gene expression changes in the liver after 6 hours. Although no clinical signs of toxicity were observed by histopathologic examination or clinical chemistry measurements, gene expression changes were observed consistent with energy metabolism disruption. The adaptive response by the liver included down regulation of fatty acid synthesis and cholesterol metabolism, pathways that are energy intensive. Upregulation of stress related genes such as heme oxygenase and metallothionein 1 were also observed. Several of the changes were consistent with previous reports but additional novel gene changes were observed. By 48 hours after dosing only a small number of genes are differentially expressed and these appear to be associated with a return to energy homeostasis. These early changes in gene expression indicate a disruption of energy metabolism and of normal metabolic processes at pharmacologic doses of APAP. These data suggest that differential gene expression analysis may provide a more sensitive indicator of toxicity than routine histology and clinical chemistry evaluations.

1649 IDENTIFICATION OF LIVER TOXICITY USING CLINICAL CHEMISTRY *VERSUS* GENE EXPRESSION MICROARRAY FACTORS.

M. Elashoff, W. Zeng, A. L. Castle, K. R. Johnson, B. W. Higgs, M. W. Porter, C. G. Chang and D. Mendrick. *Toxicology, Gene Logic, Gaithersburg, MD.*

Clinical chemistry parameters assay, at most, a few dozen factors in even the most comprehensive of safety studies, and usually only a subset of these measures can be assayed due to cost and workload concerns. Toxicogenomic studies are capable of assaying tens of thousands of genes in a single experiment. However, the advantages of transcriptome-wide observations over those of classical measures have only recently begun to be estimated. In this study, we characterize the ability of a modeling approach to define liver toxicity by using the Affymetrix RGU34 series of microarrays and, alternatively, by using 20 clinical chemistry measures, including serum concentrations of alanine aminotransferase, aspartate aminotransferase and alkaline phosphatase. The training set for each model consisted of > 1000 liver samples extracted from rats treated with known hepatotoxicants, non-hepatotoxicants, or various vehicles from a large reference database. The gene expression data-based model exhibited > 80% true positive rate along with < 5% false positive rate on a sample-by-sample basis. The clinical chemistry-based model produced a large decrease in true positive rate with a comparable rate of false positives. In addition, the gene expression data-based model identified human-specific toxicity in the absence of clinical chemistry indications. This study indicates there is a significant advantage in the use of gene expression data to characterize the toxic response for not only mechanistic pursuits, but also to predict and classify toxicity.

1650 PPAR ALPHA-DEPENDENT ALTERATIONS IN CHEMICAL-INDUCED STRESS AND LONGEVITY CORRELATES WITH INCREASED EXPRESSION OF HEAT SHOCK PROTEINS.

J. C. Corton[1], S. P. Anderson[2], A. J. Stauber[4], A. Laughter[3], C. Swanson[3], S. Xiao[3], J. Everitt[2,3] and K. Voss[5]. *[1]ToxicoGenomics, Chapel Hill, NC, [2]GlaxoSmithKline, Research Triangle Park, NC, [3]CIIT, Research Triangle Park, NC, [4]Lilly, Greenfield, IN and [5]USDA, Athens, GA.*

A number of mouse mutants that exhibit decreased levels of reactive oxygen species (ROS) and increases in longevity carry mutations in growth hormone signaling genes. In gene expression profiling experiments we observed in the livers of Snell dwarf mice an increase in the expression of genes under control of the nuclear receptor peroxisome proliferator (PP)-activated receptor alpha (PPAR) as well as PPAR itself. PPAR mediates the carcinogenic effects of PP and is a known or experimental therapeutic target for PP drugs in diseases associated with aging in which oxidative stress plays a major role. Transcript profiling experiments in wild-type mice treated with a PPAR agonist, revealed coordinated increases in the expression of members of heat shock protein (HSP) and anti-oxidant gene families. HSPs are required for the correct folding of nacent polypeptides and repair of misfolded proteins after damage from chemicals that induce ROS. We examined the extent of the overlap in regulated genes between a PP and a classical heat stress by exposing wild-type or PPAR-null mice to a 25 or 42 degree C heat stress for 40 min. Transcript profile experiments using Affymetrix chips containing ~9, 000 mouse genes were used to assess gene expression in the livers of the mice. We found that PPAR-null mice 1) exhibit defects in HSP gene product induction after heat shock or PP treatment, 2) are more sensitive to hepatocellular damage from treatments that increase oxidative stress, and 3) show decreased longevity. Our results are consistent with the hypothesis that PPAR alpha controls stress resistance and longevity through coordinated regulation of genes that mediate responses to ROS including members of the HSP gene family.

1651 IDENTIFICATION OF GENE EXPRESSION PROFILES PREDICTIVE OF SPECIFIC MODES OF HEPATOTOXICITY *IN VIVO*.

T. A. Mansfield[1], M. M. Lakkis[1], R. W. Gerwien[1], H. Ellinger-Ziegelbauer[2], M. J. Czar[1], M. F. DeCristofaro[1], K. M. Hershman[1], T. A. Lohret[1], H. E. Olsen[1], D. A. McCabe[1], J. J. DeClement[1], O. R. Crasta[1], D. M. Dziuda[1], C. Hyde[1], J. S. Bader[1], B. Stuart[3], B. Wahle[3], W. Bomann[3], H. J. Ahr[2], W. Kroll[4] and M. McKenna[1]. *[1]Pharmacogenomics, CuraGen Corporation, New Haven, CT, [2]Research Toxicology, Bayer AG, Elberfeld, Germany, [3]Toxicology, Bayer Corporation, Stilwell, KS and [4]Bayer Corporation, West Haven, CT.*

Liver toxicity is a major cause of drug failure during preclinical safety evaluation as well as in post-marketing. Recently, gene expression technologies have been integrated into toxicology studies. These technologies provide a new tool that can potentially be more efficient and sensitive than the current methods of evaluating drug-induced toxicity by providing an insight into the mechanisms of action that underlie specific toxicities at the molecular and cellular levels. The goal of this study was to establish a marker set of expressed genes that are associated and predictive of eleven specific subtypes of rat hepatopathologies: hypertrophy, cholestasis, apoptosis, zone 3 necrosis, multifocal necrosis, general necrosis, genotoxic and nongenotoxic carcinogenesis, steatosis, reactive inflammation and Kupffer cell aggregation. To achieve this, male Wistar rats were dosed with over 100 hepatotoxic and non-toxic compounds belonging to different chemical classes but with previously known toxic effects on rat liver. Rats were dosed daily with either a toxic dose or a low dose of each compound and euthanized at 4 specific time points. Transcriptional profiling of these liver samples was completed, and statistical analysis was implemented to select the final marker set using Kruskal-Wallis filtering and various statistical models including Logistic Regression, Classification Trees and Multivariate Analysis. A marker gene set has been selected that is predictive of all eleven histopathology modes *in vivo*, with an average cross-validated true positive rate of 89.2% and an average cross-validated true negative rate of 99.3%.

1652 PPAR ALPHA PLAYS A MAJOR ROLE IN DETERMINING THE GENE EXPRESSION PROFILE ALTERED BY CALORIC RESTRICTION.

S. P. Anderson[2], C. Swanson[2], J. Everitt[2,3] and J. C. Corton[1]. *[1]ToxicoGenomics, Chapel Hill, NC, [2]GlaxoSmithKline, Research Triangle Park, NC and [3]CIIT, Research Triangle Park, NC.*

Caloric restriction (CR) in diverse species results in increased resistance to chemical-induced stress and extension of lifespan. CR has been shown to have a major impact on the results of 2 year chemical bioassays. This is likely due to alteration in genes that increase resistance to damage from reactive oxygen species (ROS) and/or allow increased repair of cellular components. CR mimics some aspects of exposure to peroxisome proliferators (PP) including hypolipidemic effects and protection of the liver from cytotoxicants. As the nuclear receptor for PP (PP-activated receptor alpha (PPAR)) mediates some of the adaptive responses to fasting, we hypothesized that PPAR also plays an important role in mediating the effects of CR in the mouse liver. Male wild-type and PPAR-null mice were given an ad libitum diet or a diet consisting of 65% of ad libitum for 5 weeks. Both wild-type and PPAR-null mice fed the CR diet had significantly lower body weights than ad libitum controls. Transcript profile experiments using Affymetrix chips containing ~9, 000 mouse genes were used to assess gene expression in the livers of the mice. Almost 1000 genes were identified that were significantly different between two of the four groups. In both mouse strains CR down-regulated genes involved in cholesterol synthesis, bile acid synthesis, and male-specific responses and both up- and down-regulated Phase I and II metabolism genes. A large percentage of the altered genes (~35%) depended on PPAR for expression changes. These included the up-regulation of fatty acid catabolism genes and surprisingly, genes involved in nucleotide excision repair (NER). Preliminary western blotting experiments confirmed alterations in the lipid metabolism proteins. These results indicate that PPAR alpha plays an important role in regulating large numbers of genes that mediate the effects of CR in the liver and allows us to predict the abrogation of CR-mediated resistance to chemical carcinogens in the livers of PPAR-null mice.

1653 DIMETHYLSULFOXIDE ANTAGONIZES THE CLEFT PALATE-INDUCING EFFECT OF SECALONIC ACID D IN MICE BY NEGATING ITS EFFECTS ON THE EMBRYONIC PALATAL CYCLIC AMP PATHWAY.

V. C. Dhulipala[1], U. M. Hanumegowda[2], G. Balasubramanian[3] and C. S. Reddy[1]. *[1] Vet.Biomedical sciences, Uni of Missouri, Columbia, MO, [2]National Food Safety and Toxicology Center, Michigan State University, E.Lansing, MI and [3]Merck Research Laboratories, West Pointe, PA.*

Secalonic Acid-D (SAD) is a teratogenic mycotoxin causing cleft palate (CP) in the offspring of the exposed mice by reducing the proliferation of the palatal mesenchymal (PM) cells leading to smaller palatal shelf size. Coadministration of dimethylsulfoxide (DMSO) reversed the CP-inducing effect of SAD. Although SAD has been shown to affect both protein kinases A (PKA) and C (PKC) pathways, the effect on which of these pathways is relevant to its CP induction is unknown. The present studies were designed to further investigate the effect of SAD on the events of the PKC and cAMP pathways and to assess whether the protective effect of DMSO is mediated by its specific reversal of the effect(s) of SAD on one of the two pathways. Secalonic acid D was shown to inhibit the activity of PKC and the catalytic subunit of PKA (PKAc) but not the holoenzymes of PKA. Dimethyl sulfoxide specifically reversed the effect of SAD only on PKAc. Within the PKA pathway, SAD reduced the amount of PKAc migration into the nuclei of the PM cells; elevated phosphorylated cAMP response element (CRE) binding protein (pCREB) levels on GD 12 and reduced them on GD 14; reduced binding of CREB to the CRE but not of AP1 to 12-O-tetradecanoate-13 phorbol acetate-response element (TRE); downregulated the expression of the CRE-containing gene, proliferating cell nuclear antigen (PCNA); and reduced PM cell growth. Dimethyl sulfoxide reversed all of these effects with the exception of the elevation in pCREB levels on GD 12. These results suggest a greater significance of the PKA pathway in normal palate development than the PKC pathway and the relevance of its perturbation in the pathogenesis of CP by SAD.

1654 DEVELOPMENTAL TOXICITY OF THIODIGLYCOL IN RATS.

J. T. Houpt[2], G. Reddy[1] and L. C. Crouse[2]. *[1]Health Effects Research Program, US Army Center for Health Promotion and Preventive Medicine, Aberdeen Proving Ground, MD and [2]Toxicity Evaluation Program, US Army Center for Health Promotion and Preventative Medicine, Aberdeen Proving Ground, MD.*

Thiodiglycol (TG), a hydrolysis product of sulfur mustard (HD), is a potential contaminant of soil and water at certain military sites. In order to establish developmental criteria for TG to facilitate remediation, an oral developmental toxicity study was conducted in pregnant Sprague-Dawley rats. Neat thiodiglycol (99.9 %) was administered to mated female rats from day five through day nineteen of gestation. Three groups of rats (25/group) received TG by gavage at a rate of either 430, 1290 or 3870 mg/kg/day. A fourth group served as a sham control. On day twenty of gestation, all females were euthanized and a Caesarian section performed. Litters were examined for soft tissue and skeletal alterations. Maternal toxicity was limited to dams receiving TG at 3870 mg/kg/day. At this dose, body weights and food consumption were reduced during certain periods of gestation. Fetuses derived from those dams exhibited an increased incidence of variations when compared to controls, but were not statistically significant. Fetal body weights in the 3870 mg/kg/day group were significantly lower than controls. There was no increased incidence of anomalies when thiodiglycol-treated fetuses were compared to controls. It was concluded that TG is not teratogenic, but is a developmental toxicant at high dose levels that produced maternal toxicity. The No Observed Adverse Effect Level (NOAEL) of 1290 mg/kg/day was determined for oral developmental toxicity during the major period of organogenesis. (Abstract does not reflect US Army policy).

1655 DEVELOPMENTAL TOXICITY EVALUATION OF EMODIN IN RATS AND MICE.

J. D. George[1], C. J. Price[1], M. C. Marr[1], C. B. Myers[1] and G. D. Jahnke[2]. *[1]Life Sciences and Toxicology, RTI International, Research Triangle Park, NC and [2]Sciences International Inc., Alexandria, VA.*

Emodin (EMOD), a widely available over-the-counter herbal remedy, was evaluated for potential effects on pregnancy outcome. EMOD was administered in feed to timed-mated Sprague-Dawley (CD®) rats (0, 425, 850, and 1700 ppm; gestational day [gd] 6 to 20), and Swiss albino (CD-1®) mice (0, 600, 2500 or 6000 ppm; gd 6 to 17). Ingested dose was 0, 31, 57, and 80-144 mg EMOD/kg/day (rats) and 0, 94, 391, and 1005 mg EMOD/kg/day (mice). Timed-mated animals (25/group) were monitored periodically throughout gestation for body weight (wt), feed/water consumption and clinical signs. At termination (rats: gd 20; mice: gd 17), confirmed pregnant dams (21-25/group) were evaluated for clinical signs; body, liver, kidney and gravid uterine wts (GUW); pregnancy status; uterine contents; and number of corpora lutea. Live fetuses were weighed, sexed, and examined for external, visceral, and skeletal malformations/variations. There were no maternal deaths; discolored, soft or loose feces were observed at the high dose in mice. In rats, maternal body wt decreased at the high dose (gd 9, 12); wt gain was reduced at the mid (gd 6-9) and high dose (gd 6-9; 6-20). Maternal body wt (gestation) and wt gain (corrected for GUW) exhibited a decreasing trend. In mice, maternal body wt and wt gain decreased at the high dose. Prenatal mortality, live litter size, fetal sex ratio, and morphological development were unaffected in both rats and mice. At the high dose, rat average fetal body wt/litter was unaffected, but was significantly reduced in mice. The rat maternal LOAEL was 1700 ppm based on maternal body weight and weight gain; the NOAEL was 850 ppm. The rat developmental toxicity NOAEL was >1700 ppm; a LOAEL for rat developmental toxicity was not established. In mice, the maternal toxicity LOAEL was 6000 ppm based on reduction of maternal body wt and wt gain; the NOAEL was 2500 ppm. The developmental toxicity LOAEL was 6000 ppm, based on reduction of fetal body wt; the NOAEL was 2500 ppm. Supported by NIEHS/NTP Contract N01-ES-65405.

1656 DEVELOPMENTAL TOXICITY EVALUATION OF GOLDENSEAL ROOT POWDER (GRP) IN MICE.

C. J. Price[1], J. D. George[1], M. C. Marr[1], C. B. Myers[1] and G. D. Jahnke[2]. *[1]RTI, Research Triangle Park, NC and [2]Sciences International Inc., Alexandria, VA.*

Goldenseal (Hydrastis Canadensis) ranks among the top herbal supplements in the world market. Thus, potential effects during pregnancy warranted investigation. In this study, GRP was administered to timed-mated Swiss albino (CD-1®) mice in ground NIH-07 diet (0, 3125, 12, 500 or 50, 000 ppm) from gestational day (gd) 6 to 17. Average ingested doses were 0, 514, 2048 and 7738 mg GRP/kg/day. Alkaloid content included 5% berberine, 4.5% hydrastine and 0.1% canadine. Timed mated mice (25/group) were monitored throughout gestation for body weight (wt), feed/water intake and clinical signs. At termination (gd 17), confirmed pregnant dams (23-25/group) were evaluated for clinical signs; body, liver and gravid uterine wts (GUW); uterine contents; and number of corpora lutea. Maternal livers (10/group) were fixed, sectioned, stained (hematoxylin/eosin), and examined for histopathology. Live fetuses were weighed, sexed, and examined for external (100%), visceral (50%), or skeletal (50%) malformations/variations. No maternal deaths or remarkable clinical signs were noted, except yellow discoloration of fur due to contact with high-dose feed. At 50, 000 ppm, maternal feed intake decreased (gd 6 to 9 and 15 to 17), possibly due to altered palatability. Water intake increased at 3125 ppm (gd 6 to 9 and 9 to 12) and 50, 000 ppm (gd 6 to 9, 9 to 12 and 12 to 15). Maternal body wt, wt gain (treatment and gestation), GUW, and corrected wt gain were not affected. Maternal liver wt (absolute and relative) was increased at >12, 500 ppm in the absence of treatment-related histopathology. Prenatal mortality, live litter size, and fetal sex ratio were unaffected. At 50, 000 ppm, cleft palate, to which this species/strain is predisposed under stress, was slightly increased, and exencephaly was slightly above historical range (1% vs. 0.7%). Fetal body wt was significantly reduced (~8%) at 50, 000 ppm. The developmental toxicity NOAEL was 12, 500 ppm and the LOAEL was 50, 000 ppm (~300 times higher than estimated human intake). Support: NIEHS/NTP Contract N01-ES-65405.

1657 EFFECTS OF CALORIC INTAKE AND ETHANOL METABOLISM ON FETAL ETHANOL TOXICITY IN RATS.

M. Zipperman[3], B. Gardner[3], T. Fletcher[3], M. Ferguson[3], K. Hale[3], T. M. Badger[2,3] and M. J. Ronis[1,3]. *[1]Pediatrics, University of Arkansas for Medical Sciences, Little Rock, AR, [2]Physiology, University of Arkansas for Medical Sciences, Little Rock, AR and [3]Arkansas Children's Nutrition Center, Little Rock, AR.*

Urine ethanol concentrations (UEC) are significantly lower in pregnant than non-pregnant Sprague-Dawley rats infused with the same ethanol dose *via* total enteral nutrition. Under-nutrition appears to abolish this effect. Increased ethanol metabolism in pregnancy may be a protective mechanism that could account for the low penetrance of fetal alcohol syndrome (FAS) among the children of alcoholic mothers. In contrast, under-nutrition may be a risk factor for FAS. Groups of 3-15 time-impregnated female Sprague-Dawley rats were intragastrically infused TEN diets containing an optimal 220 kcal/kg$^{3/4}$/d for nutritional support during pregnancy from gestational (GE) d 6 until GE d 20. Ethanol was substituted isocalorically for carbohydrate calories at levels of 8-14 g/kg/d. UECs were measured and averaged from 69 ± 6 to 327 ± 22 mg/dl. No full litter resorptions occurred at ethanol doses below 11.8 g/kg/d and no significant reductions in birth weight were observed at ethanol doses lower than 13 g/kg/d. At 14 g/kg/d ethanol, 33% of litters were resorbed and those that survived had significant fetal wastage ($p \leq 0.05$) and reduced birth weight (3.7 ± 0.3 g, control vs. 1.4 g ± 0.2 g, ethanol). When groups of N = 7-8 dams were infused with 13 g/kg ethanol and fed TEN diets containing either

optimal 220 kcal/kg$^{3/4}$/d or restricted to 154 kcal/kg$^{3/4}$/d, full litter resorptions were noted in 63% of the 154 kcal rats and none of the 220 kcal rats. Decreased birth weights ($p \leq 0.05$) were observed in pups from the 154 kcal animals accompanied by significantly increased blood and urine ethanol levels (average UEC, 233 ± 34 vs. 157 ± 20 mg/dl) . Therefore, increased ethanol metabolism in pregnancy protects the fetus against ethanol toxicity and this toxicity is increased by underfeeding as a result of impaired ethanol clearance and increased fetal exposure. Supported in part by R01 AA12819 (MJJR).

1658 MATERNAL AND DEVELOPMENTAL TOXICITY OF PERFLUOROOCTANE SULFONATE (PFOS) IN THE MOUSE.

J. Thibodeaux[2], R. G. Hanson[2], B. E. Grey[2], B. D. Barbee[2], J. H. Richards[3], J. L. Butenhoff[1], J. M. Rogers[2] and C. Lau[2]. *[1]RTD, USEPA, Research Triangle Park, NC, [2]ETD, NHEERL, ORD, USEPA, Research Triangle Park, NC and [3]Med. Department, 3M, St. Paul, MN.*

The maternal and developmental toxicity of PFOS, an environmentally persistent compound that has been used in the manufacture of surfactants and insecticides, were evaluated. Timed-pregnant CD1 mice were gavaged with 1, 5, 10, 15, or 20 mg/kg/day PFOS/K+ from GD 2 to term. Controls received an equivalent volume of 0.5% Tween-20 vehicle (10 ml/kg). Some dams were killed on GD 18 for teratological examination, while those remaining were allowed to deliver to monitor the postnatal growth and development of their offspring. PFOS levels in maternal serum and liver were determined at term. Maternal weight gain was suppressed by 20 mg/kg PFOS, indicating the general maternal toxicity of the chemical. Serum triglycerides and thyroxine in dams treated with greater than 5 mg/kg PFOS were significantly lower than controls. Dose-dependent maternal liver weight increases were observed at term. PFOS did not alter the number of implantations, live fetuses, or fetal weight at term. Cleft palate, sternal defects, cardiac ventricular septal defect, and enlargement of the right atrium were detected, primarily in the 20 mg/kg group. Live birth was observed in all groups; however, neonates in the 20 mg/kg group were moribund and died within 4-6 h. While newborns in the 15 mg/kg group appeared viable, all were found dead within 24 h. Postnatal viability was greater in the lower dose groups and surviving neonates appeared to thrive, but significant delays in eye opening were observed. These dose-dependent adverse effects will be compared to the body burdens of PFOS. These results are similar to the maternal and developmental toxicity of PFOS previously described in the rat, although the mouse appears to be a less sensitive species. This abstract does not necessarily reflect EPA policy.

1659 EMBRYO-FETAL DEVELOPMENT STUDY OF HYDROXYPROPYL METHYLCELLULOSE ACETATE SUCCINATE (HPMCAS) IN RATS.

G. D. Cappon[1], T. L. Fleeman[1], M. S. Rocca[2], J. C. Cook[1] and M. E. Hurtt[1]. *[1]Drug Safety Evaluation, Pfizer Global Research and Development, Groton, CT and [2]TherImmune Research Corporation, Gaithersburg, MD.*

The potential for HPMCAS to produce developmental and reproductive toxicity was evaluated in a series of studies that included, rat and rabbit teratology studies, a rat fertility study, and a rat peri- and postnatal study (Hoshi and coworkers 1985). The authors concluded that there were no compound-related findings. However, in the cesarean-section phase of the rat teratology study, clubfoot was reported for 3, 8, 19 and 16 fetuses in the control, 625, 1250 and 2500 mg/kg groups, respectively. There were no significant increases in external anomalies, but the apparent dose-related increase in clubfoot was not specifically addressed. The increase in clubfoot did not appear to be related to treatment with HPMCAS based on the following: 1) the external diagnosis of clubfoot did not have an underlying skeletal finding; 2) the incidence of clubfoot in control animals was substantially outside of historical norms; and 3) clubfoot was not noted in offspring of HPMCAS treated animals allowed to deliver. To definitively address the uncertainty regarding the potential for HPMCAS to induce developmental anomalies, a repeat of the rat teratology study was performed. Groups of 20 pregnant Sprague-Dawley rats were dosed with 0, 50, 150, 625 or 2500 mg/kg HPMCAS from GD 7-18. Fetuses were examined on GD 22 for external, visceral and skeletal development. No developmental toxicity was observed as a result of HPMCAS exposure demonstrating that maternal HPMCAS exposure during gestation does not induce developmental anomalies. There were no findings of clubfoot or other limb anomalies in this study at dose levels equivalent to those that previously demonstrated an apparent increase in clubfoot. Therefore, the conclusion of Hoshi and coworkers that the apparent dose-dependent increase in clubfoot is not related to treatment with HPMCAS was confirmed by this repeat study.

1660 EMBRYO-FETAL DEVELOPMENT STUDY OF HYDROXYPROPYL METHYLCELLULOSE ACETATE SUCCINATE (HPMCAS) IN RABBITS.

T. L. Fleeman[1], G. D. Cappon[1], M. S. Rocca[2], J. C. Cook[1] and M. E. Hurtt[1]. *[1]Drug Safety Evaluation, Pfizer Global Research and Development, Groton, CT and [2]TherImmune Research Corporation, Gaithersburg, MD.*

The potential for HPMCAS to produce general and reproductive toxicity was evaluated in a series of studies that included acute toxicity studies in rats and rabbits, a 6-month rat study, rat and rabbit teratology studies, a rat fertility study, and a rat peri- and postnatal study (Hoshi and coworkers, 1985). There were no compound-related developmental findings in the rabbit. However, in the rabbit teratology study, the number of litters evaluated (12-13 per group) did not meet current regulatory guidelines. Therefore, the teratology evaluation of HPMCAS in rabbits was repeated with an increased number of does to meet regulatory guidelines. Groups of 20 pregnant New Zealand White rabbits were dosed with HPMCAS twice daily by oral gavage for a total dose of 0, 50, 150, 625 or 2500 mg/kg from GD 8-20. The does were euthanized on GD 30 and all fetuses were examined externally. Following external examination, the fetuses were examined viscerally by fresh tissue dissection. The fetuses were then stained with Alizarin Red and examined for skeletal development. There was no developmental toxicity demonstrated as a result of HPMCAS exposure. Therefore, the conclusion of the earlier study indicating that treatment with HPMCAS at doses up to and including 2500 mg/kg/day did not produce developmental toxicity was confirmed with this study.

1661 METHAMPHETAMINE ENHANCES OXIDATIVE DNA DAMAGE IN MURINE EMBRYONIC AND FETAL BRAIN AND LIVER.

A. Wong[1], W. Jeng[1], R. Ting-A-Kee[2] and P. G. Wells[1,2]. *[1]Faculty of Pharmacy, University of Toronto, Toronto, ON, Canada and [2]Department of Pharmacology, University of Toronto, Toronto, ON, Canada.*

Methamphetamine (METH) decreases dopamine levels, structurally alters dopaminergic neurons and causes functional deficits in adult animal models, but its developmental effects are unclear. We investigated METH-initiated reactive oxygen species (ROS) generation and oxidative DNA damage in the embryonic and fetal periods. Pregnant CD-1 mice were treated with METH (20 or 40 mg/kg ip) or its saline vehicle at 1000 hr on gestational day (GD) 14 or 17. Dams were sacrificed 1 or 4 hr later, and conceptal brains and livers were isolated and analyzed for oxidized DNA, determined by 8-oxoguanine formation. On GDs 14 and 17 at 1 hr, METH enhanced conceptal DNA oxidation in brain and liver by at least 2-fold ($p<0.05$). Maximal DNA damage generally was not significantly increased by the higher dose. At 4 hr, DNA damage was decreased, unchanged or greater in brain, and variably decreased in liver, suggesting more active repair in the latter. Both baseline and METH-enhanced DNA damage in brain and liver were 2- to 3-fold higher on GD 14 than GD 17 ($p<0.05$), likely due in part to the lower activity of antioxidative enzymes, and possibly DNA repair enzymes, on GD 14. The sustained or increased METH-enhanced DNA oxidation in brain over 4 hr, unlike liver, at both GDs suggests that the brain may be particularly susceptible to METH-initiated structural and functional anomalies. This is the first evidence of conceptal oxidative DNA damage caused by amphetamines, and suggests potential problems with amphetamine use by women of child-bearing age. (Support: CIHR)

1662 EFFECTS OF *I.P.* MATERNAL VITAMIN E ADMINISTRATION ON FETAL DEVELOPMENT AND PHENYTOIN EMBRYOPATHIES.

M. Sit[2], C. S. Chen[1] and P. G. Wells[1,2]. *[1]Faculty of Pharmacy, University of Toronto, Toronto, ON, Canada and [2]Pharmacology, University of Toronto, Toronto, ON, Canada.*

The anticonvulsant drug phenytoin (PHT) initiates the formation of reactive oxygen species (ROS), which may contribute to its embryopathic effects. Here, we examined the effect of *i.p.* maternal pretreatment with the antioxidant vitamin E (VE) on normal embryonic development and PHT teratogenicity. Pregnant CD-1 dams were treated at 0800 hr on gestational days (GD) 12 and13 with ±-α-tocopherol-acetate (125 or 250 mg/kg *i.p.*), or its corn oil vehicle, followed 3 hr later by PHT (65 mg/kg *i.p.*) or its 0.9% saline vehicle. On GD 19, dams were sacrificed and fetuses examined for anomalies. VE at either dose did not alter the spontaneous incidences of fetal resorptions, postpartum lethality or cleft palate, nor fetal birth weight. As expected, PHT increased the incidences of fetal resorptions, postpartum lethality, and cleft palate by 2.0-, 1.9-, and 2.3-fold respectively ($p<0.05$), while decreasing fetal body weight by 12% ($p<0.001$). Compared to its corn oil vehicle, VE 250mg/kg reduced PHT-initiated cleft palates by 54% ($p<0.004$). Trends were ob-

served for protection by VE compared to its corn oil vehicle against fetal resorptions and postpartum lethality, but the differences were not statistically significant ($p<0.08$, $p<0.1$). VE had no effect on PHT-initiated fetal weight loss. Compared to VE 125 mg/kg, VE at 250 mg/kg lowered spontaneous levels of fetal resorption by 58% ($p<0.05$), and appeared to lower the incidence of PHT-initiated cleft palates ($p<0.07$). Conversely, compared to higher dose of VE, VE 125 mg/kg reduced PHT-initiated postpartum lethality by 42% ($p<0.04$). These results indicate that maternal VE given *i.p.* provides dose-dependent protection against phenytoin teratogenicity, while suggesting that the optimal dose may vary for different embryopathies. Taken with other studies using dietary VE, the embryoprotective efficacy of VE against endogenous and xenobiotic-enhanced ROS depends upon the dose, route and duration of VE administration, and suggests an embryopathic role for ROS. (Support: CIHR)

1663 PROTECTION BY OXOGUANINE GLYCOSYLASE 1 (OGG1) AGAINST METHAMPHETAMINE-INITIATED DNA OXIDATION IN FETAL BRAIN IN OGG1 KNOCKOUT MICE.

P. G. Wells[1,2], W. Jeng[1] and A. W. Wong[1]. *[1]Faculty of Pharmacy, University of Toronto, Toronto, ON, Canada and [2]Department of Pharmacology, University of Toronto, Toronto, ON, Canada.*

Oxidative DNA damage, in particular the lesion 8-oxoguanine (8-oxoG), has been implicated in the initiation of teratogenesis. 8-OxoG is removed by oxoguanine glycosylase 1 (ogg1) in the initiating step of the base excision repair pathway. We have previously shown that *in utero* exposure to the neurotoxic drug methamphetamine (METH) on gestational day (GD) 17 results in increased DNA damage to fetal brain and liver in CD-1 mice. Here we used OGG1 knockout mice to investigate the developmental role of ogg1 in repairing METH-initiated fetal DNA oxidation following *in utero* exposure. METH (20 mg/kg) or its saline vehicle was administered on GD 17 to pregnant heterozygous (+/-) OGG1-deficient females (mated to OGG1 +/- males). Dams were sacrificed 4 hr later, and fetal brains and livers were isolated and analyzed for oxidized DNA, determined by 8-oxoG formation. In fetal liver, loss of functional ogg1 did not affect 8-oxoG levels in either saline or METH-exposed fetuses. In fetal brain, no significant differences were observed in DNA oxidation among saline-exposed wild type (+/+) OGG1-normal, +/- or homozygous null (-/-) OGG1-deficient fetuses. However, with METH exposure, there was an 80% increase in 8-oxoG levels in +/- OGG1-deficient fetuses compared to +/+ OGG1-normal littermates, and a doubling in DNA oxidation in -/- versus +/+ fetuses ($p<0.05$). DNA damage also was elevated in fetal brain from METH-exposed -/- fetuses compared to saline-exposed controls of the same genotype ($p<0.05$). This is the first evidence of increased DNA oxidation in drug-exposed fetuses lacking ogg1, and suggests that functional DNA repair may be important in protecting against METH-initiated developmental neurotoxicity. (Support: CIHR)

1664 SINGLE INTRAMUSCULAR INJECTIONS OF BOTOX® ARE NOT DEVELOPMENTALLY TOXIC IN RATS.

E. Chow[1], J. A. Wisler[1], A. M. Hoberman[2], M. S. Christian[2] and B. G. Short[1]. *[1]Toxicology, Allergan, Inc., Irvine, CA and [2]Argus Res. Lab., Charles River Research Lab., Horsham, PA.*

The expanding clinical use of BOTOX® for the treatment of neuromuscular disorders increases the likelihood that pregnant women may be exposed to the drug. No adverse effects on human reproductive endpoints have been reported and no direct embryo/fetal developmental effects have been observed in animal studies previously conducted to evaluate multiple gestational intramuscular injections of the drug. The objective of this study was to evaluate the effects of a single treatment of BOTOX® administered at specific points of gestation. Twenty groups of pregnant rats (18/treatment day/dosage) were treated on days 3, 6, 9, 12, or 15 of gestation with a single intramuscular injection (0.2 mL/kg) of BOTOX® at 0 (Control), 1, 4, or 16 University/kg in the left hindlimb. Dams were monitored for pharmacological effects of the toxin and clinical signs of toxicity. C-section was performed on day 21 of gestation to evaluate effects on implantation and embryo/fetal development. Pharmacological effects in the injected hindlimb (curling of the toes, lameness, and reduced grip strength) were observed in all drug-treated groups, and increased in degree and/or incidence with dosage. Decreased body weight and feed consumption occurred in dams treated with 16 University/kg, while no adverse effects were observed in dams given ≦4 University/kg. No drug-related effects on implantation or embryo/fetal development were observed. In summary, single intramuscular injections of BOTOX® given on days 3, 6, 9, 12, or 15 of gestation were not developmentally toxic in rats.

1665 LACK OF EMBRYO-FETAL TOXICITY WITH THE ANTI-INFECTIVE DB289 AND ITS ACTIVE METABOLITE DB75, A DIAMIDINE WITH DNA MINOR GROOVE BINDING ACTIVITY.

J. L. Allen[1], A. A. Bottomley[3], S. M. Fulcher[3], S. A. Ruckman[3], D. W. Boykin[4] and R. R. Tidwell[2]. *[1]Immtech International, Inc., Vernon Hills, IL, [2]Huntingdon Life Sciences Ltd, Huntingdon, Cambridgeshire, United Kingdom, [3]Georgia State University, Atlanta, GA and [4]University of North Carolina, Chapel Hill, NC.*

DB289 (2, 5-Bis[4-(N-methoxyamidino)phenyl]furan monomaleate) is a dimethoxime prodrug designed for oral delivery of the active diamidine, DB75 (2, 5-Bis[4-amidinophenyl]furan). DB75 has antiprotozoal, antifungal and antimalarial activities. DB289 is currently in Phase II clinical trials for the treatment of African sleeping sickness and Pneumocystis pneumonia. The mechanism of anti-infective activity is unknown, but probably involves binding of the diamidine molecule (DB75) to the minor groove of pathogen DNA. *In vitro* and *in vivo* genotoxicity assays indicate that DB289 and DB75 are not mutagenic or clastogenic. Nonetheless, the potential interaction of DB75 with DNA warrants evaluation of the potential effects on the developing embryo and fetus. DB289 was evaluated for potential effects on embryo-fetal development when administered orally to pregnant CD rats and New Zealand White rabbits during the period of organogenesis. Dosages of DB289 free base were 5, 10 and 20 mg/kg/day in rats, and 3, 10 and 15 mg/kg/day in rabbits. These dosages were based on the results of dose range-finding studies. In rats the only effects were grossly pale livers in occasional animals at 10 and 20 mg/kg. In rabbits maternal toxicity was evident at the two highest doses. Detailed fetal examinations indicated no adverse effect of DB289 treatment on the type, incidence or distribution of visceral or skeletal abnormalities in either species. DB289 and DB75 were detected in plasma at all dose levels confirming continuous systemic exposure in both rats and rabbits. Thus, DB289 and DB75 exposure and potential binding to the minor groove of DNA are not associated with adverse effects on embryo-fetal development in rats or rabbits.

1666 CHEMICAL CHARACTERIZATION OF PINE BARK AND GRAPE SEED EXTRACTS.

H. A. Weber[1], A. E. Hodges[1], L. A. Moody[1], B. M. O'Brien[1], J. R. Guthrie[1], R. K. Harris[1], A. P. Clark[1], D. Overstreet[2] and C. S. Smith[2]. *[1]Midwest Research Institute, Kansas City, MO and [2]NIEHS, Research Triangle Park, NC.* Sponsor: M. Cunningham.

Pine bark extract (PBE) and grape seed extract (GSE) are herbal supplements that have been selected for toxicological evaluation by the NIEHS. PBE and GSE are known to contain proanthocyanidins, or condensed tannins, which are polymeric compounds consisting of chains of flaval-3-ol units, (+)-catechin and (-)-epicatechin, linked through C4-C6 and C4-C8 interflavan bonds. PBE also contains taxifolin, a flavon-3-ol. These polyphenolic compounds are known to possess potent antioxidant activities and are used in the treatment of a wide variety of medical conditions, including circulatory disorders. A strategy, which included extraction, HPLC, GC/MS, LC/MS, MALDI-TOF/MS, and GPC, was developed for overall characterization and comparison of two lots of PBE and four lots of GSE. A gradient RP-HPLC method was developed to separate catechin and epicatechin monomers, dimers, and several corresponding gallic acid esters. Catechin and epicatechin solvent standards ($\backsim$ 30 to $\backsim$ 1000 µg/mL) were linear ($r \geq 0.9999$). Extraction of six PBE and GSE components proved to be linear ($r \geq 0.999$) over an analytical concentration of $\backsim$ 0.05 to $\backsim$ 25 mg/mL. The HPLC method was transferred directly to APCI LC/MS, which was used to identify the various monomers, dimers, and their gallates. GC/MS analyses of PBE and GSE led to the identification of the ethyl esters of hexadecanoic acid, linoleic acid, and oleic acid, as well as smaller phenolic and terpene components. GPC molecular weight distribution profiles indicated the presence of PBE and GSE components ranging from $\backsim$ 162 to $\backsim$ 5500 MW. The majority of PBE components were less than 1180 MW, while the majority of GSE components ranged from $\backsim$ 1180 to $\backsim$ 5000 MW. MALDI-TOF/MS analyses, used to characterize larger MW proanthocyanidins, confirmed the presence of hexamers and heptamers as well as pentamers with multiple gallic acid esters.

1667 ANALYTICAL METHOD VALIDATION OF *GINKGO BILOBA* L. POWDER EXTRACT DOSED IN 0.5% (W/V) AQUEOUS METHYLCELLULOSE.

B. M. O'Brien[1], D. Messer[1], A. Porter[1], K. Brackman[1], R. K. Harris[1], A. P. Clark[1], J. W. Algaier[1], D. Overstreet[2] and C. S. Smith[2]. *[1]Midwest Research Institute, Kansas City, MO and [2]NIEHS, Research Triangle Park, NC.* Sponsor: M. Cunningham.

Ginkgo biloba L. powder extract (GBPE) is an herbal supplement that has been selected for toxicological evaluation by the National Institute of Environmental Health Sciences (NIEHS). A method was validated for the analysis of GBPE in

0.5% (w/v) aqueous methylcellulose to cover a dose formulation range of ∽ 25 to ∽ 1000 mg/mL. The recently developed analytical method simultaneously monitors aglycones and terpenelactones using high-performance liquid chromatography (HPLC) with ultraviolet (UV) and evaporative light scattering (ELS) detection. Quercetin and bilobalide, two of the major components in GBPE, were used to prepare quantitation standards (∽ 30 to ∽ 75 µg/mL) to determine the weight percentages of quercetin glycosides and bilobalide present in GBPE solvent and spiked vehicle standards. In addition, quercetin was used as a marker compound to qualitatively monitor kaempferol and isorhamnetin (aglycones) and bilobalide was used as a marker compound to qualitatively monitor ginkgolides A, B, and C (terpenelactones). In order to simultaneously monitor aglycones and terpenelactones, standards containing GBPE were hydrolyzed at 90°C for 1 hr. The responses of quercetin and bilobalide from the quantitation standards were linear ($r \geq 0.99$) and accurate (%RE ≤ 3.3). The responses of quercetin and bilobalide from hydrolyzed GBPE solvent and spiked vehicle standards were linear ($r \geq 0.999$) and precise (%RSD ≤ 2.2). The average percent of quercetin glycosides and bilobalide in the solvent standards containing GBPE was 16.1 ± 0.4(s) and 7.0 ± 0.1(s) (n = 10), respectively. The average percent of quercetin glycosides and bilobalide in the spiked vehicle standards containing GBPE was 15.4 ± 0.7(s) and 6.8 ± 0.3(s) (n = 10), respectively. The average response recovery of marker compounds in GBPE from the spiked vehicle standards, relative to the solvent standards, was 95.4 ± 3.7(s)% for quercetin and 96.9 ± 3.9(s)% for bilobalide.

1668 A RAPID EXTRACTION AND ISOLATION METHOD FOR THE DETERMINATION OF PYRROLIZIDINE ALKALOIDS IN COMFREY.

D. Gray[1], G. Rottinghaus[2], A. Porter[1], N. Oberlies[3], N. Kim [3], R. McGivney[3], R. Harris[1], A. Clark[1], D. Overstreet[4] and C. Smith[4]. *[1]Midwest Research Institute, Kansas City, MO, [2]University of Missouri, Columbia, MO, [3]Research Triangle Institute, Research Triangle Park, NC and [4]NIEHS, Research Triangle Park, NC.*
Sponsor: M. Cunningham.

Preparations from comfrey (*Symphytum officinale* and *S.* x *uplandicum*) root and leaf contain varying levels of the hepatotoxic pyrrolizidine alkaloids (PAs). Reference compounds for comfrey are not commercially available, and there is currently no rapid extraction or analytical method to determine low levels in raw materials or commercially available extracts. A solid phase extraction (SPE) method was developed using an Ergosil cleanup column that specifically binds the PAs. Two comfrey root extraction methods were evaluated, and recoveries following SPE were determined for identified and proposed PAs. The simplified 1 hr extraction with basic chloroform using sonication resulted in PA yields ranging from 20 to 80 fold greater than the traditional 2 day alkaloid extraction/partition method with N-oxide reduction. With this improved method, 10 g of powdered comfrey root is extracted with 100 mL of basic chloroform. The extract is applied to the cleanup column under vacuum, washed with 2 mL of acetone:chloroform (8:2), followed by 2 mL petroleum ether to remove excess chloroform. The column is dried and the PAs are eluted to a final volume of 2 mL with methanol. Percent recoveries of the PAs following SPE had an overall average of 92.2%. The unique properties of the cleanup column allow a rapid sample cleanup and concentration of PAs from comfrey extract, and allows the eluant to be analyzed directly by HPLC, HPTLC, or GC methods.

1669 CHARACTERIZATION OF GINSENG FOR USE IN TOXICITY STUDIES.

S. Graves[1], B. Burback[1] and C. Smith[2]. *[1]Toxicology Columbus, Battelle, Columbus, OH and [2]NIEHS, Research Triangle Park, NC.* Sponsor: M. Hejtmancik.

Ginseng, a nutritional supplement, has been selected for toxicological evaluations in 14-day, 90-day and 2-year chronic rodent studies by the NTP. This material was characterized using a variety of techniques to determine its composition for comparison to literature information prior to it use. The objectives of the work were to determine the water/volatile content; the concentrations of organophosphate pesticides, nitrosamines, total and individual amino acids, metals, selected anions, and total and ethanol soluble carbohydrate concentration; the identity and concentrations of the major simple sugars and disaccharides; the molecular weight distribution of the glycans; the identity of all possible UV detectable components using HPLC/MS; the reverse phase HPLC/UV profile of the sample including the quantitation on any detected ginsenosides; a GC/FID profile of volatile organic soluble components and the identity of all possible components by GC/MS. These analyses indicated a water/volatile content of ~5%; no detectable levels of organophosphate pesticides or nitrosamines; a fatty acid concentration of <0.014%; amino acid contents ranging from 0.02 (cystine) to 3.1 (glutamic acid)% with a total amino acid concentration of 7.0%; potassium (0.9%)and silicon (0.2%) were the major metallic components; acetate (1.3%), chloride (0.6%), nitrate (0.14% and sulfate (0.01%) were the major inorganic anionic components; a total carbohydrate content of ~70%, all of which was ethanol soluble, the major simple sugars/disaccharides were sucrose (46.8%), glucose (2.9%), fructose (1.5%), and maltose (8.3%); the molecular weights of the glycans were ~6000 and ~10-12, 000; the ginsenosides represented ~10% of the total peak areas detected by reverse-phase HPLC at 205 nm; the ten largest ginsenosides were Rg1 (2.2%), Re (0.7%), Rf (0.3%), Rb1 (1.7%), Rc (1.0%), Rb2 (0.8%), Rd2(0.7%), Rh1 (<0.1%), Rg2 (<0.1%) and Rb3 (<0.1%); and the identified volatile impurities were furfural, furfuryl alcohol, 5-methyl-2-furfural, and 5-hydroxymethyl-2-furfural.

1670 CYTOTOXICITY OF SELECTED PTERINS IN MCF-7 CELLS.

J. L. Lord[1], R. P. Metzger[2] and A. de Peyster[1]. *[1]Graduate School of Public Health, San Diego State University, San Diego, CA and [2]Department of Chemistry, San Diego State University, San Diego, CA.*

Pterins are naturally occurring compounds, some (e.g., biopterin, folic acid) with important roles in metabolism. Xanthopterin (X, 2-amino-4, 6(3H, 5H)-pteridinedione) and isoxantopterin (IX, 2-amino-4, 7(3H, 8H)-pteridinedione) may also regulate cell replication in mammals and other species by mechanisms which are not well undersood. In clinical studies, levels of X and IX in urine from cancer patients differ significantly when compared with levels in from healthy subjects. Other studies report differing rates of pterin metabolism by tumor cells relative to controls, and variable effects and cytotoxic potencies of X in tumor cells, ranging from inhibition to proliferation. Unpublished studies suggest that oral X+IX alters growth of mammary tumors occuring spontaneously in female C3H/HeN-MTV+ mice. This in particular prompted us to examine for the first time the responsiveness of human mammary carcinoma MCF-7 cells to X and IX. Measuring cell viability using the MTS assay, X and IX were tested alone and in combinations at total pterin concentrations of 12.5-200 uM. When tested singly, the IC50s of X and IX were similar: 112±3.4 uM and 102±4.2 uM, respectively. MCF-7 cells seemed to be as sensitive as some renal cell lines (RPTC and LLC-PK1) that had been tested with X after the kidney was identified as a primary organ of toxicity. X and IX were less potent than tamoxifen, a known inhibitor of estrogen-sensitive MCF-7 cell growth. When IX:X were tested repeatedly in combination to explore interactions, IC50s showed the following order: 3:1<4:1<1:3≅1:2<2:1≅10:1<5:1<1:1≅1:4<1:5<1:10, although an ANOVA revealed no statistical differences. Up to 100 uM total pterins, the 3:1 ratio was always the most cytotoxic of the ratios tested, and the 4:1 ratio consistently ranked second. Over 100 uM, again the 3:1 ratio was the most cytotoxic, but the 1:3 ratio ranked second. Information from these experiments will be particularly useful when designing future mechanistic and efficacy studies to increase understanding of the potential for using pterins in cancer chemotherapy.

1671 EPIGALLOCATHECHIN 3-GALLATE ATTENUATES BRAIN DAMAGE INDUCED BY 3-HYDROXYKYNURENINE.

E. S. Park[1], J. H. Jeong[1] and J. D. Park[2]. *[1]Pathology, Chung-Ang University, Seoul, South Korea and [2]Preventive Medicine, Chung-Ang University, Seoul, South Korea.*

3-hydroxykynurenine (3-HK), an endogeneous metabolite of tryptophan in the kynurenine pathway, has been known to play roles of potential neurotoxin in several neurodegenerative disorders. Epigallocathechin 3-gallate (EGCG), extracts of tea leaves, is recognized as a promising natural substance in protecting neuronal diseases. In the present study, we investigated the possible protective roles of EGCG against 3-HK induced cell injury. We found that 3-HK induced the decrease in cell viability in SH-SY5Y cell lines. The reduced cell viability produced apoptotic characteristic features in cell culture. The cells cultured in 3-HK added medium showed the increase in reactive oxygen species (ROS) as well as in caspase activity. Both of them are involved in the apoptosis. EGCG attenuated the reduced cell viability by 3-HK in a dose and time dependent manner. In microscopy, EGCG inhibited the cell morphological disorders featured in 3-HK treated cells. Furthermore, the rise of ROS and caspase activity by 3-HK was also blocked by EGCG. These results showed that EGCG had a protective effect on the 3-HK induced cell death and also abolished ROS and caspase actions leading to apoptosis. These findings suggested that EGCG may be a promising substance against the neuronal degenerative diseases.

1672 BREVETOXIN AUGMENTS NMDA RECEPTOR SIGNALING IN MURINE CEREBROCORTICAL NEURONS.

S. Dravid[1], D. G. Baden[2] and T. F. Murray[1]. *[1]Physiology and Pharmacology, University of Georgia, Athens, GA and [2]Center for Marine Research, University of North Carolina, Wilmington, Wilmington, NC.*

Brevetoxins are potent allosteric enhancers of voltage-gated sodium channel function and are associated with the periodic Red Tide blooms. These neurotoxins produce acute neuronal injury and death in cerebellar granule cells following

acute exposure. In cerebrocortical neurons brevetoxin (PbTx-2) exposure enhances the amplitude of spontaneous Ca2+ oscillations. PbTx-2 produces this modulatory effect by influencing glutamatergic signaling. Activation of glutamate receptors is associated with an increase in Ca2+ influx, which triggers ERK1/2 activation. PbTx-2 exposure was similarly found to induce a concentration-dependent increase in ERK1/2 and Akt activation in cerebrocortical neurons. We have therefore explored the modulatory effect of PbTx-2 on NMDA receptor signaling using western blotting and calcium monitoring with a fluorescent plate reader (FLIPR). We found that PbTx-2 augments NMDA-induced ERK1/2 activation. Due to the involvement of Ca2+ in ERK1/2 activation, the effects of PbTx-2 on NMDA-induced Ca2+ influx were explored. PbTx-2 was found to potentiate NMDA-induced Ca2+ influx in cerebrocortical neurons. These results are consistent with studies demonstrating that a rise in intracellular sodium ion augments excitatory transmission through NMDA receptors. These findings may have important functional consequences for various physiological events in the central nervous system such as development, learning and memory.

1673 HEPATOPROTECTIVE EFFECTS OF THE RADIX OF *PLATYCODON GRANDIFLORUM* ON CARBON TETRACHLORIDE-INDUCED LIVER INJURY IN MICE.

H. Jeong[1,2]. [1]*Pharmacy, Chosun University, Kwangju, Kwangju, South Korea and* [2]*Pharmacy and Research Center for Proteineous, Chosun University, Kwangju, South Korea.*

The protective effects of a Platycodi Radix (Changkil: CK), the root of Platycodon grandiflorum A. DC (Campanulaceae), on carbon tetrachloride-induced hepatotoxicity and the possible mechanisms involved in this protection were investigated in mice. Pretreatment with CK prior to the administration of carbon tetrachloride significantly prevented the increased serum enzymatic activities of alanine and aspartate aminotransferase in a dose-dependent manner. In addition, pretreatment with CK also significantly prevented the elevation of hepatic malondialdehyde formation and the depletion of reduced glutathione content in the liver of carbon tetrachloride-intoxicated mice. However, hepatic reduced glutathione levels and glutathione-S-transferase activities were not affected by treatment with CK alone. Carbon tetrachloride-induced hepatotoxicity was also essentially prevented, as indicated by a liver histopathologic study. Histopathological evaluation of the rat livers revealed that CK reduced the incidence of liver lesions induced by carbon tetrachloride, including hepatocyte swelling, leukocyte infiltration, and necrosis. The effects of CK on the cytochrome P450 (P450) 2E1, the major isozyme involved in carbon tetrachloride bioactivation were also investigated. Treatment of mice with CK resulted in a significant decrease of P450 2E1-dependent p-nitrophenol and aniline hydroxylation in a dose-dependent manner. Our results suggest that the protective effects of CK against carbon tetrachloride-induced hepatotoxicity possibly involve mechanisms related to its ability to block P450-mediated carbon tetrachloride bioactivation.

1674 THE RADIX OF PLATYCODON GRANDIFLORUM REDUCES HEPATIC FIBROSIS IN RATS INDUCED BY DIMETHYLNITROSAMINE OR CARBON TETRACHLORIDE.

K. Lee [2] and H. Jeong[1,2]. [1]*Pharmacy, Chosun University, Kwangju, Kwangju, South Korea and* [2]*Research Center for Proteineous Materials, Chosun University, Kwangju, South Korea.*

Herbal medicines are increasingly being utilized to treat a wide variety of disease processes. We previously reported that aqueous extract from the roots of Platycodon grandiflorum A. DC (Campanulaceae), Changkil (CK), had hepatoprotective effects against acetaminophen induced liver injury. In the present study, we assayed the preventive and therapeutic effects of CK on experimental hepatic fibrosis induced by dimethylnitrosamine or carbon tetrachloride in rats. Rats were given a single intraperitoneal injection of 20 mg/kg dimethylnitrosamine or 0.5 ml/kg carbon tetrachloride twice weekly for 4 weeks. In each model, CK was given orally at 10-200 mg/kg daily for 4 weeks. CK reduced the hepatic levels of malondialdehyde, a production of lipid peroxidation and partially prevented the marked decrease in body weight and reduced the mortality rate. The degree of fibrosis was evaluated by image analysis and also by measurements of collagen and hydroxyproline content in the liver. CK treatment significantly decreased the dimethylnitrosamine- or carbon tetrachloride-induced collagen and hydroxyproline contents. Immunohistochemical examination showed that CK reduced the deposition of type I and III collagen and the expression of a-smooth muscle actin in the liver in a dose-dependent manner. These findings indicate that CK suppress the induction of hepatic fibrosis and suggest that CK might be useful therapeutically in hepatic fibrosis/cirrhosis.

1675 EVALUATION OF THE HEPATOPROTECTIVE AND ANTIOXIDANT ACTIVITY OF 18B-GLYCYRRHETINIC ACID.

S. Park[2] and H. Jeong[1,2]. [1]*Pharmacy, Chosun University, Kwangju, Kwangju, South Korea and* [2]*Research Center for Proteineous Materials, Chosun University, Kwangju, South Korea.*

The protective effects of 18 b-glycyrrhetinic acid (GA), the aglycone of glycyrrhizin derived from licorice, on carbon tetrachloride-induced hepatotoxicity and the possible mechanisms involved in this protection were investigated in mice. Pretreatment with GA prior to the administration of carbon tetrachloride significantly prevented an increase in serum alanine, aspartate aminotransferase activity and hepatic lipid peroxidation in a dose-dependent manner. In addition, pretreatment with GA also significantly prevented the depletion of glutathione content in the livers of carbon tetrachloride-intoxicated mice. However, reduced hepatic glutathione levels and glutathione-S-transferase activities were unaffected by treatment with GA alone. Carbon tetrachloride-induced hepatotoxicity was also prevented, as indicated by a liver histopathologic study. The effects of GA on the cytochrome P450 (P450) 2E1, the major isozyme involved in carbon tetrachloride bioactivation, were also investigated. Treatment of mice with GA resulted in a significant decrease of the P450 2E1-dependent hydroxylation of p-nitrophenol and aniline in a dose-dependent manner. Consistent with these observations, the P450 2E1 expressions were also decreased, as determined by immunoblot analysis. GA also showed anti-oxidant effects upon FeCl2-ascorbate induced lipid peroxidation in mice liver homogenate and upon superoxide radical scavenging activity. These results show that protective effects of GA against the carbon tetrachloride-induced hepatotoxicity may be due to its ability to block the bioactivation of carbon tetrachloride, primarily by inhibiting the expression and activity of P450 2E1, and its free radical scavenging effects.

1676 INHIBITORY EFFECT OF THE ROOTS OF *PLATYCODON GRANDIFLORUM* ON OXIDATIVE DAMAGE INDUCED BY BUTYL HYDROPEROXIDE IN RAT LIVER.

C. Choi [1] and H. Jeong[1,2]. [1]*Pharmacy, Chosun University, Kwangju, Kwangju, South Korea and* [2]*Research Center for Proteineous Materials, Chosun University, Kwangju, South Korea.*

Increasing evidence regarding free radical generating agents and inflammatory processes suggests that accumulation of reactive oxygen species can cause hepatotoxicity. In this study, we used t-butyl hydroperoxide (t-BHP) to induce hepatotoxicity *in vitro* and *in vivo* and determined the antioxidative bioactivity of aqueous extract from the roots of Platycodon grandiflorum A. DC (Campanulaceae), Changkil (CK). CK-treated cells showed an increased resistance to oxidative challenge, as revealed by a higher percent of survival capacity in respect to control cells. Treatment with CK significantly decreased the leakage of lactate dehydrogenase and also decreased lipid peroxidation in a dose-dependent manner in primary cultured rat hepatocytes. Furthermore, CK protected from the t-BHP-induced intracellular generation of reactive oxygen species assessed by monitoring dichlorodihydrofluorescein fluorescence. An *in vivo* study in rats showed that pretreatment with CK prior to the administration of t-BHP significantly prevented the increase in serum alanine aminotransferase and aspartate aminotransferase activity and hepatic lipid peroxidation in a dose-dependent manner. CK also protected the t-BHP-induced depletion of hepatic glutathione levels. Histopathological evaluation of the rat livers revealed that CK reduced the incidence of liver lesions induced by t-BHP, including hepatocyte swelling, leukocyte infiltration, and necrosis. Based on the results described above, we speculate that CK may play a hepatoprotective effects *via* reducing oxidative stress in living systems.

1677 RUBRATOXIN B INDUCED THE SECRETIONS OF M-CSF AND GM-CSF IN HEPATOCYTE-DERIVED CELL LINE HEPG2.

H. Nagashima, K. Nakamura and T. Goto. *National Food Research Institute, Tsukuba, Ibaraki, Japan.* Sponsor: M. Fukayama.

Rubratoxin B is a potent hepatotoxic and teratogenic mycotoxin produced by certain Penicillium fungi. To date, biochemical, cytological and serological changes have been reported, however, the mechanism of its toxicity remains unclear. In this study, the induction of cytokine secretion by rubratoxin B was investigated using hepatocyte-derived hepatoma cell line HepG2. IL-8, M-CSF and GM-CSF were detected in the media of rubratoxin B-treated cells, and their levels peaked at about 40 mg/ml. The secretions of cytokines were enhanced by TNF-alpha; however, no synergism between the effects of rubratoxin B and TNF-alpha were observed.

While tyrosine kinase inhibitor emodin increased GM-CSF secretion, the secretions of two other cytokines were decreased, indicating that they are regulated differently in rubratoxin B-treated cells. Calcium channel blockers reduced the secretions of these three cytokines, suggesting that calcium channels play important roles in signal transduction of rubratoxin B. To our knowledge, this is the first report that exogenous stimulus induced the secretions of M- and GM-CSF in hepatocyte-derived hepatoma cells, suggesting that rubratoxin B is a superb model compound to study the mechanisms of M- and GM-CSF secretions. Furthermore, our results indicate that not only hepatocytes are the target cells for cytokines but they stimulate other types of cells by cytokines.

1678 ACTIVATION OF *PERITONEAL MACROPHAGE* FUNCTIONS AND NUCLEAR FACTOR-KB-DEPENDENT GENE EXPRESSION BY AQUEOUS EXTRACT OF PLATYCODON GRANDIFLORUM.

J. Seo[2], J. Kim[1] and H. Jeong[1]. *[1]Pharmacy, Chosun University, Kwangju, Kwangju, South Korea and [2]R&D, Jangsaeng Doraji Co., Ltd.,, Chinju, South Korea.*

Aqueous extract from the root of Platycodon grandiflorum A. DC (Campanulaceae), Changkil (CK), is reported to have antitumor and immunomodulatory activities; however, the mechanism underlying its therapeutic effect is not known. The associated biological mechanisms are unclear, however, of the wide diversity of effects, it is believed that their activities may be exerted through several potent effector cells such as macrophages. Therefore, the effects of an aqueous extract from the root of Platycodon grandiflorum (Changkil: CK) on mouse peritoneal macrophage function were investigated. It was found that the CK stimulated macrophage proliferation, spreading ability, phagocytosis, cytostatic activity, and nitric oxide (NO) production in a dose-dependent manner, and that the production of cytokines such as TNF-a, IL-1b and IL-6 were similarly increased. Reverse-transcription polymerase chain reaction showed that CK increased the appropriate cytokine mRNAs. Transient expression assays with NF-kB binding sites linked to the luciferase gene revealed that CK-induced increase of inducible NO synthase mRNA and TNF-a mRNA were mediated by the NF-kB transcription factor complex. These results demonstrate that CK is a potent enhancer of macrophage function and CK stimulates NO and TNF-a release and is able to up-regulate iNOS and TNF-a expression through NF-kB transactivation.

1679 *IN VIVO* EFFECTS OF MYRIOCIN ON SPHINGOLIPID METABOLISM AND C-*MYC* EXPRESSION IN MOUSE LIVER.

Q. He, V. J. Johnson, M. F. Osuchowski and R. P. Sharma. *Department Physiol. Pharmacology, The University of Georgia, Athens, GA.*

Myriocin, a fungal metabolite isolated from *Isaria sinclairii*, is a potent inhibitor of serine palmitoyltransferase (SPT), a key enzyme in *de novo* synthesis of sphingolipids. Exposure of cells in culture to myriocin decreases biosynthesis of sphinganine leading to a depletion of free sphingoid bases, and therefore myriocin has been widely used to study the biological role of sphingolipid metabolism. To evaluate the toxic effects of myriocin *in vivo*, we investigated the levels of free sphingoid bases and expression of selected genes regulating cell growth in mouse liver. Male Balb/c mice weighing 22 g were injected intraperitoneally with myriocin at 0, 0.1 0.3, and 1.0 mg/kg body weight daily for 5 consecutive days. Animals were euthanized 24 hours after the last treatment. Levels of plasma alanine aminotransferase and aspartate aminotransferase, indicators of liver injury, were not significantly altered by the treatment, suggesting no overt liver toxicity at the doses of myriocin employed. A dose-dependent decrease in free sphinganine but not sphingosine was detected by high performance liquid chromatography in both liver and kidney. The activity of SPT in liver was decreased by 80% at the highest dose of myriocin. The decrease of free sphinganine paralleled the observed decrease in SPT activity. Reverse transcriptase polymerase chain reaction analysis on liver mRNA indicated a dose-dependent increase in the expression of liver c-*myc*, but no changes in tumor necrosis factor α, transforming growth factor β, and hepatocyte growth factor. Results showed that myriocin inhibited *de novo* synthesis of sphingolipids *in vivo* by SPT inhibition and altered c-*myc* expression in liver. Long-term exposure to myriocin or the organism producing it may have adverse effects on health by interfering sphingolipid metabolism and modulating the expression of c-*myc* oncogene. (Supported in part by NIH ES09403 and TW01009).

1680 ACTIVATION OF NF-KB/REL AND P38 IN CHITOSAN-STIMULATED MACROPHAGES.

Y. J. Jeon. *Pharmacology, Chosun University College of Medicine, Kwangju, South Korea.* Sponsor: H. Kim.

Water-soluble chitosan stimulates murine macrophage to produce cytokines including iNOS. In the present study we investigated the molecular mechanism by which chitosan stimulate macrophages to produce iNOS. Treatment of RAW 264.7 cells with chitosan activated NF-kB/Rel in a dose-dependent manner. The involvement of NF-kB/Rel activation in chitosan-induced iNOS expression was confirmed by the experiment with the specific NF-kB/Rel inhibitors. Treatment of RAW 264.7 cells with chitosan resulted in significant activation of p38. The specific p38 kinase inhibitor SB203580 abrogated the chitosan-induced iNOS synthesis. In conclusion, we demonstrate that NF-kB/Rel and p38 kinase activation are required to transduce signals leading to iNOS expression in chitosan-stimulated murine macrophages.

1681 CDNA MICROARRAY ANALYSIS OF MATRIX METALLOPROTEINASE GENE EXPRESSION IN RAT MICROGLIA EXPOSED TO THE MARINE TOXIN DOMOIC ACID.

A. M. Mayer[1], M. J. Fay[1], M. Hall[1] and A. M. Romanic[2]. *[1]Pharmacology, Midwestern University, Downers Grove, IL and [2]Cardiovascular Pharmacology, Glaxo SmithKline, King of Prussia, PA.* Sponsor: W. Prozialeck.

Amnesic Shellfish Poisoning(ASP), one of the shellfish poisoning syndromes in the United States, is caused by the marine diatom toxin domoic acid (DOM), a glutamate analog. Our working hypothesis is that exposure to DOM may activate BMΦ and cause generation of potentially neurotoxic matrix metalloproteinases (MMP). We have recently reported that after a short-term (1-6 hours) *in vitro* treatment of rat BMΦ with DOM there was an increase in MMP-9 protein levels (Mayer et al. *BioMedCentral Pharmacology* 1:7-19, 2001). To further evaluate the role of other MMPs we investigated MMP gene expression in 4 hour-DOM [1mM]-treated BMΦ using a MMP-specific rat cDNA array, consisting of 22 MMP genes, including MMP-9 (SuperArray Inc., Bethesda, MD). Total RNA was extracted from BMΦ using TRI REAGENT®. Through side-by-side hybridization with cDNA probes prepared from RNAs of control or 4 hour DOM-treated rat BMΦ, the expression profiles of the 22 MMP genes was determined. Only 6 out of the total of 22 MMP genes investigated appeared to be constitutively expressed in untreated (Control) rat BMΦ *in vitro*. Furthermore, DOM-treated rat BMΦ showed altered transcription of 6 MMP genes as follows; **enhanced expression**: collagenase-like A, MMP-19, MMP-2, and tissue inhibitor of metalloproteinase-4 or TIMP-4; **reduced expression**: MMP-9 and TIMP-2. Our results constitute the first experimental evidence that DOM appears to alter the expression of rat BMΦ MMP genes *in vitro*. Thus cDNA microarray analysis provides potentially useful information to investigate candidate MMP genes that are most likely involved in DOM toxicity to rat BMΦand perhaps *in vivo* in ASP. Supported by NIEHS grant ES10138-01(AMM).

1682 ST. JOHN'S WORT REDUCES TRIBROMOETHANOL-INDUCED SLEEP TIMES IN MICE.

A. C. Protain, H. J. Protain, M. R. Palic, C. S. Gardiner and G. K. DeKrey. *Biology, University of Northern Colorado, Greeley, CO.*

The effects of St. John's wort (SJW) on tribromoethanol (TBE)-induced anesthesia were examined in mice. SJW is a popular herbal supplement for humans, which appears to induce cytochrome P450 3A (CYP3A) and can cause serious drug interactions. The utility of a mouse model to study this interaction was tested. TBE is a mouse anesthetic metabolized by CYP3A. It was hypothesized that SJW induces CYP3A causing increased clearance of other drugs (e.g. TBE). Mice were treated daily with SJW extract *via* gavage (1.0, 0.1, or 0.01 mg/g bodyweight/day) or water for 21 days. As a positive control for CYP3A induction, mice were treated with dexamethasone (DEX, 0.05mg/g of bodyweight, I.P.) at 48 and 24 hours prior to treatment with TBE. TBE was given at 0.4mg/g body weight, (S.C.) on days 1, 7, 14, or 21. SJW exposure (1 mg/g bodyweight) significantly decreased in sleep time compared to control mice on days 7, 14, and 21: day 7: C 45.4±2, SJW 24.18±3; day 14: C 43.77±2.87, SJW 30.92±0.44; day 21: C 41.75±5.24, SJW 30.19±1.88 ($p<0.05$; means±SE (min)). These results offer a preliminary demonstration of the utility of the mouse to study SJW-drug interactions.

1683 ALTERATIONS IN HUMAN AND PORCINE RENAL CELLS AFTER REPEATED EXPOSURE TO OTA AND OTB.

A. H. Heussner[1], E. O'Brien[1], M. E. Stack[2] and D. R. Dietrich[1]. *[1]Environmental Toxicology, University of Konstanz, Konstanz, Germany and [2]Center for Food Safety and Applied Nutrition, USFDA, College Park, MD.*

Chronic dietary exposure to Ochratoxins induces porcine nephropathy (PMN) and has been strongly associated with the development of a similar human disease, namely Balkan Endemic Nephropathy (BEN). Both diseases are characterized by progressive fibrosis of the tubular interstitium and glomeruli. The mechanism(s)

underlying OTA's toxicity in the kidney is still unknown. Previous *in vitro* observations, have shown, that even after exposure to extremely high Ochratoxin concentrations (>10 μM), a certain percentage of renal epithelial cells always survive with an altered morphology and that fibroblastic cell types are more resistant to OTA-mediated toxicity. Thus, it is proposed that repeated exposure to ochratoxins transforms normal renal epithelial cells to a fibroblast-like phenotype. The aim of the study was to generate a pool of such altered cells and thereafter, to characterize the differences between these cells and their corresponding control cells. Thus, primary human and porcine renal epithelial cells were repeatedly exposed to acutely toxic concentrations of ochratoxin A (OTA) and its structural analogue ochratoxin B (OTB). For comparison with previous results, the human (IHKE) and porcine (LLC-PK1) continuous cell lines were tested in parallel. As shown before [Heussner et al., Toxicology. Sciences. 66 (1-S): 82 (2002)], repeated (x3) exposures of about 96 hours ensured selection and survival of the altered cell type. The morphology (microscopy), growth behavior (growth curves) and protein constitution (2D-PAGE, immunodetection of marker proteins) of these cells were subsequently characterized and compared with their respective untreated control cells. Preliminary results support the aforementioned hypothesis that renal epithelial cells attain a fibroblastic morphology and protein expression pattern.

1684 STRUCTURE-NEPHROTOXICITY RELATIONSHIPS AMONG THE CHLOROANILINES IN ISOLATED RENAL CORTICAL CELLS FROM FISCHER 344 RATS.

G. O. Rankin, D. K. Anestis, T. W. Crislip, A. S. Casto and H. Sun.
Pharmacology, Marshall University, Huntington, WV.

Chloroanilines are widely used as chemical intermediates in the manufacture of pesticides and other compounds. Chloroanilines can appear in the environment following accidental spillage into waterways, as wastewater contaminants and through the degradation of pesticides. Mammals exposed to chloroanilines *in vivo* can develop nephrotoxicity characterized as oliguric acute renal failure. The purpose of this study was to examine the nephrotoxic potential of several mono-, di- and trichloroanilines *in vitro* using freshly isolated renal cortical cells (IRCC) from untreated male Fischer 344 rats as the kidney model. IRCC were obtained following collagenase perfusion of the kidneys in anesthetized rats. Cells (~ 3 - 4 million cells/ml) were incubated at 37o C under a 95% oxygen/5% carbon dioxide atmosphere with up to 4.0 mM of a chloroaniline for 60 or 120 min. The compounds tested were 2-; 3-; and 4-chloroaniline; 2, 3-; 2, 4-; 2, 5-; 2, 6-; 3, 4-; and 3, 5-dichloroaniline; 2, 3, 4-; 2, 4, 5-; 2, 4, 6-; and 3, 4, 5-trichloroaniline. Cytotoxicity was determined at the end of the incubation period by measuring the release of the cytosolic enzyme lactate dehydrogenase (LDH) into the medium. None of the monochloroanilines were toxic at 60 or 120 min at the concentrations tested. Among the dichloroanilines, 3, 4- and 3, 5-dichloroaniline were the most toxic. These isomers increased LDH release at bath concentrations of 1.0 mM or higher at 60 min and at bath concentrations of 0.5 mM at 120 min. Trichloroanilnes were generally intermediate in toxic potential between 3, 4- or 3, 5-dichloroaniline and the remaining mono- and dichloroanilines. These results indicate that the number of chloro groups and their position on the aromatic ring are important determinants for nephrotoxic potential among the chloroaniline compounds.

1685 PYRUVATE REDUCES MYOGLOBIN *IN VITRO* TOXICITY IN RENAL CORTICAL SLICES.

M. Valentovic. *Pharmacology, Marshall University School of Medicine, Huntington, WV.*

Crush injury and drug overdose are associated with renal dysfunction due to myoglobin release. The purpose of the present study was to investigate pyruvate attenuation of myoglobin cytotoxicity using an *in vitro* renal slice model. Renal cortical slices from male Fischer 344 rats (200-250 g) were isolated, rinsed and allowed to equilibrate at 37oC for 5 min. Pyruvate treated slices (n=4/group) were co-incubated with 0 or 10 mM pyruvate along with 0, 4, 10 or 12 mg/ml myoglobin for 30-120 min. Cytotoxicity was assessed by comparison of lactate dehydrogenase (LDH) release, pyruvate stimulated gluconeogenesis and adenine nucleotide levels. Co-incubation with pyruvate prevented a rise in LDH leakage and maintained ATP levels comparable to control levels in the 4 and 12 mg/ml myoglobin treated group. Co-incubation with 1.67 mM glucose as an energy substrate did not attenuate myoglobin toxicity. A 60 and 120 min exposure to 4 and 12 mg/ml myoglobin decreased total glutathione levels. Glutathione levels following myoglobin exposure in the pyruvate treated tissue remained above control values indicating diminished oxidative stress. Glutathione disulfide levels were comparable in all pyruvate treated tissue exposed for 120 min to 4 and 12 mg/ml myoglobin while in the absence of pyruvate glutathione disulfide levels were increased 2 fold by 12 mg/ml myoglobin. These studies determined that pyruvate reduced myoglobin toxicity through a reduction in radical generation and *via* supply of an energy substrate.

1686 ADRENERGIC MODULATION OF ETHYLENE DIBROMIDE-INDUCED TOXICITY.

D. I. Mosquera[1], T. Stedeford[2,1,3], M. Banasik[2,3], C. Muro-Cacho[4] and R. D. Harbison[2]. *[1]Department of Neurology, University of South Florida, Tampa, FL, [2]Department of Environmental and Occupational Health, University of South Florida, Tampa, FL, [3]ICC, Polish Academy of Sciences, Gliwice, Poland and [4]Department of Interdisciplinary Oncology, H. Lee Moffitt Cancer Center and Research Institute, Tampa, FL.*

Ethylene dibromide (EDB) has been used as a model compound for eliciting hepato- and nephrotoxicity. Conjugation with glutathione (GSH) or direct oxidation by the cytochrome P450 system has been shown to play a role in the bioactivation of EDB. The aim of this study was to determine whether activation of α-adrenergic receptors, which causes a decrease in cellular GSH levels, could modulate the nephrotoxicity of EDB. For this purpose, male ICR mice were administered (i.p.) EDB and/or the α-adrenergic agonist, phenylephrine (Pe), or the α-adrenergic antagonist, phentolamine (Phe). Animals treated with EDB (40 mg/kg) had a 9.3-fold increase in urinary γ-glutamyl transpeptidase (GGTP) activity and a 38% decrease in renal GSH levels; however, animals co-treated with EDB and Pe (50 mg/kg) exhibited a 27.8-fold increase in urinary GGTP activity and a 60% decrease in GSH levels. The enhanced presence of urinary GGTP and decrease in cellular levels of GSH was nearly blocked by treating animals concomitantly with EDB and Phe (10 mg/kg) or EDB, Pe, and Phe. Histopathological examination revealed the enhanced degree of tissue damage and necrosis following treatment with EDB and Pe, and the protective effect of Phe at ameliorating EDB toxicity. These results indicate that factors that can influence α-adrenergic receptors may be critical in assessing dose-response data used in the risk assessment process. (Supported in part by the Department of Defense)

1687 HEAT SHOCK PROTEINS AND URANIUM NEPHROTOXICITY.

J. W. Munson[1], J. K. Tolson[1], B. S. Jortner[2], S. M. Roberts[1] and D. S. Barber[1]. *[1]Center for Environmental and Human Toxicology, University of Florida, Gainesville, FL and [2]Laboratory for Neurotoxicity Studies, Virginia-Maryland Regional College of Veterinary Medicine, Blacksburg, VA.*

Military use of depleted uranium has renewed interest in uranium toxicity. Experimental evidence suggests that prior exposure to uranyl compounds can reduce nephrotoxicity of subsequent uranium exposures. The mechanism of this protection is not clear but has been attributed to heat shock protein (Hsp) induced cytoprotection. This study examined the relationship between stress proteins and acquired resistance to uranyl compounds. Male Sprague-Dawley rats were conditioned with 5 mg/kg uranyl acetate i.p. (UA) or saline (control) 10 days prior to challenge with 10 mg/kg i.p. UA. Five days after the second administration of UA, renal function, pathology and Hsp expression were evaluated. Based on histology and serum markers, a single acute dose of UA (10 mg/kg) produced acute proximal tubular necrosis. However, rats preconditioned with UA (5 mg/kg) exhibited improved kidney function and pathology. Kidney samples taken at the time of the second UA administration revealed strong induction of Hsp25, Hsp32 and Hsp70i, but not Hsc70, in preconditioned animals. Immunohistochemical staining demonstrated that UA preconditioning upregulated Hsp70i throughout the kidney while Hsp25 was highly localized in regenerating tubular epithelium. These observations demonstrate that several stress proteins are induced by UA administration and suggest that stress proteins confer resistance to UA-mediated nephrotoxicity by sparing proximal tubular epithelial cells, especially those undergoing active regeneration.

1688 CELLULAR PROFILES OF BENZO(a)PYRENE-INDUCED NEPHROPATHY.

A. Nanez, N. F. Alejandro, M. H. Falahatpisheh, M. G. Tadesse and K. S. Ramos. *Center for Environmental and Rural Health, Texas A&M University, College Station, TX.*

The nephrotoxic effects of polycyclic aromatic hydrocarbons, such as benzo(a)pyrene (BaP), are not well understood. In agreement with data from rodent and human models of IgA nephropathy and glomerulonephritis, this laboratory has shown that repeated, weekly exposure of adult Sprague-Dawley rats to BaP (10 mg/kg *i.p.*) for up to 16 weeks is associated with glomerular hypercellularity. This response involves loss of renal function, as evidenced by increases in total urinary protein, protein/creatinine ratios, and urinary albumin, and structural deficits associated with activation of mesangial cells and disruption of visceral epithelial (i.e. podocyte) foot processes. Based on these observations we hypothesized that glomerular hypercellularity is mediated by proliferation of resident glomerular cells in response to hydrocarbon injury. To test this hypothesis, the present studies focused on the identification and quantification of glomerular cell types present in glomeruli of BaP-treated rats. Immunohistochemical markers of cellular identity

examined included Wilms' tumor suppressor protein (WT1) for podocytes, Thy1 for mesangial cells and CD68 for macrophages. Sprague-Dawley rats treated with BaP (10 mg/kg *i.p.*) for 8 weeks exhibited a significant increase in total cell number when adjusted for glomerular area [8.32 ± 0.11 ($p \leq 0.05$) compared to controls 7.86 ± 0.09]. Immunohistochemical analysis of WT-1 expression, a podocyte-specific antigen, showed modest, but significant increases in podocyte number normalized to glomerular area after 8 weeks of BaP treatment [2.4 ± 0.08 compared to controls 2.21 ± 0.06]. In contrast, CD68 and Thy1 expression was not altered following BaP exposure. These data indicate that BaP induced glomerular hypercellularity is partly mediated by podocyte proliferation. A role for other glomerular cell types in the nephropathic response remains to be established. (Supported by NIH grants ES04917, ES09106 and CA 90301).

1689 NEPHROPROTECTION FROM *S*-1, 2-DICHLOROVINYL-$_L$-CYSTEINE IN DIABETIC MICE.

A. V. Dnyanmote[2], S. P. Sawant[2], E. A. Lock[3], J. R. Latandresse[1] and H. M. Mehendale[2]. *[1]Toxicology, University of Louisiana at Monroe, Monroe, LA, [2]CTL, Syngenta, Macclesfield, Cheshire, United Kingdom and [3]Pathology Associates International, NCTR, Jefferson, AR.*

Streptozotocin (STZ)-induced diabetes has been reported to protect rats against renal injury produced by gentamycin, cisplatin and HgCl2. The aim of this work was to determine if STZ-induced diabetes protected Swiss Webster mice against a lethal dose (75 mg/kg ip) of *S*-1, 2-Dichlorovinyl-$_L$-cysteine (DCVC). Diabetes (plasma glucose > 200 mg/dL) was induced in male mice with STZ (200 mg/kg ip in 0.1 M citrate buffer) while the controls received only the citrate buffer. On day 10 the mice were then administered either DCVC (75 mg/kg ip) or vehicle alone. Ninety percent of the diabetic mice given DCVC survived in contrast to a 10% survival observed in non-diabetic mice given DCVC. Time-course measurements of plasma blood urea nitrogen (BUN) and creatinine as markers of renal injury and ^{3}H-thymidine (^{3}H-T) incorporation into renal DNA as an index of tissue repair were performed. Renal injury was also assessed by histopathology (H & E). Renal cytosolic and mitochondrial cysteine conjugate β-lyase activity, the enzyme that bioactivates DCVC, was also measured. In non-diabetic mice, DCVC produced a temporal increase in BUN and creatinine, which was associated with marked renal tubular necrosis and resulted in 90% mortality within 48 h. In contrast, in the diabetic mice, BUN and creatinine increased until 36 h after which time the renal injury declined to normal and the mice survived. An early and steady onset in nephrogenic repair in the diabetic mice, as evidenced by ^{3}H-T incorporation, may explain the recovery from ARF and survival. Renal β-lyase activity was not altered in the kidney of diabetic mice, indicating that lack of metabolic activation of DCVC could not explain the protection. These findings suggest that protection of diabetic mice from DCVC-induced mortality may be due to upregulation of tissue repair resulting in recovery from the renal injury and survival. (Supported by Kitty DeGree Endowment and the LBRS)

1690 CELLULAR AND MOLECULAR MECHANISMS UNDERLYING OCHRATOXIN A-INDUCED *IN VITRO* NEPHROTOXICITY.

A. Gennari, M. Boveri, P. Pazos, R. Callaghan, J. Casado and P. Prieto. *European Commission, JRC, IHCP, ECVAM, Ispra (VA), Italy.* Sponsor: E. Sabbioni.

Ochratoxin A (OTA) is a mycotoxin produced by storage moulds (primarily by Aspergillus and Penicillum species) that contaminates cereals and animal feed, causing nephropathy and renal tumors to a variety of animal species. *In vitro*, OTA may induce apoptosis, inhibit protein synthesis, and form DNA adducts. With the aim to study the cellular and molecular mechanisms underlying OTA-induced toxicity, the porcine renal proximal tubule epithelial cell line LLC-PK1 was exposed for 24 h to 0-50 μM OTA. Cytotoxicity assays, such as lactate dehydrogenase (LDH), revealed significant toxic effects after exposure of the cells to 50 μM OTA. At the same concentration, we observed alterations in the cytoskeleton organization with the classical formation of stress fibers, besides mitochondrial membrane potential modifications. In addition, confocal microscopy showed DNA fragmentation, clearly indicating induction of apoptotic cell death. Interestingly, by using a cDNA macroarray, the expression of genes involved in OTA-induced nephrotoxicity has been analyzed, revealing an up-regulation of the early growth response gene EGR 1. Our data confirm that the LLC-PK1 cell line may be considered a good *in vitro* model for studying toxicity in the renal epithelium.

1691 MODULATION OF RENAL CYCLOOXYGENASE-2 (COX-2) BY DIET AND STAGE OF ESTROUS IN CD SPRAGUE-DAWLEY RATS.

B. Blaydes[1], L. Muskhelishvili[2], J. R. Latendresse[2] and K. B. Delclos[1]. *[1]NCTR, Jefferson, AR and [2]Pathology Associates International, Jefferson, AR.*

Both cox-1 and cox-2 are constituitively expressed in rodent kidney with distinct regional localizations. Gene knockout and cox inhibitor studies have indicated that cox-2 plays a significant role in development of the kidney as well as in adult kidney function. Soy-containing diets have been shown to protect the rodent kidney in strains prone to polycystic kidney disease and after treatment with renal toxins. We hypothesize that modulation of renal cyclooxygenase activity by soy may play a role in this protection. In an initial experiment to examine this question, female NCTR CD rats were maintained on soy- and alfalfa-containing NIH31 diet until weaning when half were shifted to a soy- and alfalfa-free diet (5K96). Estrous cycles were monitored by daily vaginal cytology and animals were sacrificed on postnatal day 50 ±5 in either proestrus or diestrus. Stage of cycle at necropsy was confirmed by histological examination of the vagina, and serum was collected and analyzed for estradiol and progesterone. One kidney was snap frozen and the second processed for the preparation of frozen sections for immunohistochemical analysis. Measurements of cox-2 mRNA levels (relative to glucose 6-phosphate dehydrogenase mRNA) and protein levels were made by RT-PCR and Western blots, respectively. Analysis of mRNA levels indicated a significant effect of cycle stage, with levels in proestrus significantly greater than those in diestrus in both diets. Analysis of protein levels indicated significant effects of diet (NIH31 higher) and cycle and a significant interaction of cycle with diet. Consistent with the mRNA data, cox-2 protein was found in higher amounts in proestrus than in diestrus, but this was only the case with the 5K96 diet. This may indicate the involvement of both transcriptional and post-transcriptional controls of cox-2 expression. These data provide preliminary evidence that renal cox-2 is modulated by the hormonal fluctuations of the estrous cycle and that this modulation is affected by diet.

1692 DECREASED N- AND KSP-CADHERIN EXPRESSION ASSOCIATED WITH HGCL2-INDUCED ACUTE RENAL FAILURE IS RELATED TO THE SPATIAL EXPRESSION PATTERN OF CADHERINS ALONG THE NEPHRON.

J. Jiang[1], D. Dean[2], R. C. Burghardt[2] and A. R. Parrish[1]. *[1]Medical Pharmacology and Toxicology, Texas A&M University System HSC, College Station, TX and [2]Veterinary Anatomy and Public Health, Texas A&M University, College Station, TX.*

Cadherins are cell surface molecules which play an important role in cell-cell adhesion and signal transduction in conjunction with their cytoplasmic binding partners, catenins. In the kidney, these adhesion molecules are essential for the maintenance of epithelial barriers and are critical for establishing polarity in proximal tubule epithelial cells. Multiple cadherins and catenins are expressed in the kidney and although much is known about patterns of expression during development and in renal carcinomas, the spatial pattern of cadherin and catenin co-expression has not been defined. Cadherin and catenin expression was analyzed by western blot analysis, immunohistochemistry and immunofluorescence in mouse kidney. Four cadherins were detected by Western blot analysis in the adult mouse kidney including E-, K-, Ksp- and N-cadherin. In addition, four catenins were also detected, i.e., alpha-, beta-, gamma and p120. Using immunohistochemistry and immunofluorescence, N- and Ksp-cadherin were primarily localized to the proximal tubules, while E-cadherin expression was confined to the distal tubules. K-cadherin expression was not detected by either technique using several different antibodies. Alpha- and beta-catenin were expressed in both proximal and distal tubules, while p120 was limited to the proximal tubules and gamma-catenin to the distal tubules. This pattern of expression may explain, in part, the selective decrease in Ksp- and N-cadherin, as well as alpha- and p120-catenin, expression observed during the later stages of mercuric chloride-induced ARF as injury to the proximal tubules is a hallmark of acute renal failure.

1693 INFLUENCE OF EDTA AND CITRATE ON HEMOLYSIS INDUCED BY OXALATE.

C. Guo and K. McMartin. *Pharmacology, LSU Health Sciences Center, Shreveport, LA.*

Background: Ethylene glycol (EG) poisoning produces multiple system organ injury, including acute renal failure and CNS depression. A common observation in EG-poisoned patients is the precipitation of oxalate crystals (COM) in blood vessels and various tissues, including the renal tubular lumens. Oxalate crystals have been proposed as the etiologic agent for organ injury in EG poisoning. The hemolysis assay is a good model to screen for acute cell membrane damage induced by chemicals. In the present studies, we compared the inhibition of EDTA and citrate on the hemolytic rate induced by COM. Methods: 0.5% rat erythrocytes were exposed to COM, EDTA-treated COM and citrate-treated COM for 1 hour at 37oC. The hemolytic rate was measured at 540 nm. Results: EDTA and citrate significantly inhibited the hemolytic rate induced by COM. The effect of citrate was significantly greater than EDTA at the same dose levels, but EDTA and citrate produced different effects on the solubility of COM. COM remained in the precipitate in the presence of citrate, while EDTA produced significant amounts of soluble oxalate. Conclusion: The results indicate that EDTA and citrate have different mechanisms in prevention of the cell damage induced by COM.

1694 DEGRADATION OF AC2993 (SYNTHETIC EXENDIN-4) IN MICE, RAT, RABBIT AND MONKEY KIDNEY MEMBRANE PREPARATIONS.

K. McCowen, K. Copley and R. Hiles. *Amylin Pharmaceuticals, San Diego, CA.*

AC2993 is synthetically manufactured exendin-4, a 39-amino acid peptide. Nonclinical studies have shown that AC2993 has several potentially beneficial antidiabetic (glucose-lowering) actions. These include amplification of insulin secretion (insulinotropic effect), suppression of postprandial glucagon secretion (glucagonostatic effect), reduction in food intake, and modulation of nutrient delivery. It has been shown that the kidneys are the major route of elimination of systemic AC29931. The purpose of this study was to determine the relative rates of degradation and the major degradation products of AC2993 *in vitro* using membrane preparations of mice, rat, rabbit and monkey kidneys. Membranes were prepared from the kidneys by homogenization followed by differential centrifugation. The total protein content of each membrane preparation was determined by BCA assay; the final protein concentration was adjusted to approximately 10 mcg/mL in the assay. The rate of AC2993 degradation was determined by HPLC analysis of samples collected over a 120 min period following initiation of the reaction by the addition of 10 mcg AC2993. Relative rates of degradation were found to be rat > mouse > rabbit @ monkey. The major breakdown products are being identified using a combination of HPLC, LC/MS/MS, and protein sequencing. The first degradation product, in the mouse kidney membrane preparation, appears within one minute and has been identified as exendin?4 (1-22) using LC/MS/MS techniques. 1. Parkes D, Jodka C, Smith P, et al. Pharmacokinetic actions of exendin-4 in the rat: comparison with glucagons-like peptide-1. Drug Dev Res 2001; 53: 260-267.

1695 CADMIUM NEPHROTOXICITY IS ASSOCIATED WITH ALTERATIONS IN THE PATTERN OF CADHERIN LOCALIZATION IN THE PROXIMAL TUBULE EPITHELIUM.

W. C. Prozialeck, P. C. Lamar and S. M. Lynch. *Midwestern University, Downers Grove, IL.*

Exposure to cadmium (Cd) results in a generalized dysfunction of the proximal tubule that is characterized by an increase in the urinary excretion of glucose, amino acids and low molecular weight proteins. While these effects of Cd have been well-documented, relatively little is known regarding the mechanisms by which Cd alters proximal tubule function. Recent studies utilizing renal epithelial cell lines in culture have shown that Cd has specific damaging effects on the cadherin dependent junctions between the cells. The objective of the present study was to determine if Cd can disrupt cadherin-dependent junctions in the proximal tubule *in vivo*. Male Sprague-Dawley rats received subcutaneous injections of Cd (0.6 mg/kg in isotonic saline, 5 days per week for up to 6 weeks), while control animals received the saline vehicle alone. One day each week, 24-hour urine samples were collected and analyzed for protein and creatinine. The results showed that after 5-6 weeks, the Cd-treated animals developed significant proteinuria, with no change in creatinine excretion. Histopathologic analysis of the kidneys from Cd-treated animals showed widespread evidence of vacuolization and separation of the epithelial cells in the proximal tubule. Visualization of pan-cadherin immunoreactive materials by immunoperoxidase labeling showed that Cd caused a marked reduction in the intensity of cadherin labeling associated with the basolateral surface of the epithelial cells of the proximal tubule, but no change in the pattern of cadherin labeling in other segments of the nephron. Additional studies utilizing specific antibodies against E- and N-cadherin showed changes in the localization of both cadherins in the proximal tubule epithelium. These results indicate that Cd can disrupt cadherin dependent cell-cell junctions in the proximal tubule, and they raise the possibility that a loss of cadherin-mediated adhesion may contribute to the nephrotoxic effects of Cd. (Supported by Grant R01-ES06478).

1696 SERIALLY-AGITATED DILUTE SOLUTIONS OF CDCL2 FAIL TO PROTECT AGAINST THE ACUTE CYTOTOXIC EFFECTS OF CD2+ IN LLC-PK1 CELLS.

P. C. Lamar and W. C. Prozialeck. *Midwestern University, Downers Grove, IL.*

Homeopathic pharmacotherapy is based on the so called "law of similars" and the premise that drug efficacy can be enhanced by the repetitive agitation and dilution of drug solutions. Recently, it has been reported that homeopathically-prepared, dilute solutions of Cd salts can protect against the acute toxic effects resulting from exposure to high doses of Cd^{2+}. The objective of the present study was to determine if serially-agitated dilute solutions (SADS) of $CdCl_2$ can protect against the toxic effects of Cd^{2+} in LLC-PK_1 cells, an immortal cell line that has been widely used as a model for Cd^{2+} toxicity studies. SADS of $CdCl_2$ in endotoxin-free distilled water were prepared by starting with a 1 mM stock solution and using a homeopathic centesimal dilution technique; the final concentrations of the SADS ranged from 10^{-2} - 10^{-60} of the original stock solution. Confluent cells on Falcon cell culture inserts were pretreated with the SADS by adding the solutions directly to the tissue culture medium (10λ SADS/ml of medium) and incubating the samples for 24 hours. The cells were then challenged with a toxic dose of $CdCl_2$ (10 μM) and monitored for evidence of cytotoxicity using 3 end points (ie. morphologic changes, a decrease in the transepithelial electrical resistance (TER) and the leakage of lactate dehydrogenase (LDH) into the medium). The results showed that in all samples, exposure to 10 μM Cd for 1-6 hours caused the cells to separate from each other without detaching from their growing surface, an effect that coincided with a marked drop in the TER. Longer periods of exposure (8-24 hours) resulted in the death of the cells as evidenced by the detachment of the cells from the growing surface and the leakage of LDH into the medium. Most significantly, there were no differences in the intensity of these responses between the control samples and the samples that had been treated with the SADS. These results do not support the previous claims that SADS of Cd salts can protect the acute toxic effects of Cd^{2+}. Supported by Grant R01-ES06478 from the NIEHS.

1697 CADMIUM ADVERSELY AFFECTS CHOLINE UPTAKE AND THE CYTOSKELETON IN OPOSSUM KIDNEY CELLS.

J. R. Pennell and A. R. Villalobos. *Department of Environmental Medicine, University of Rochester, Rochester, NY.*

Long-term cadmium exposure has been shown to be nephrotoxic. The proximal tubule is a specific target, and damage to this segment results in elevated excretion of vital nutrients such as glucose and serum proteins. However, the effects of cadmium on renal reabsorption of choline, an essential nutrient for membrane and neurotransmitter synthesis, have not been well characterized. The effects of long-term cadmium exposures on apical choline uptake were characterized in immortalized opossum kidney cells, a model for renal proximal tubule. The effects of cadmium on the cytoskeleton were also studied, as they may contribute to changes in choline uptake. Cells were grown to confluence on solid supports and then treated for 24 h with 500 nM-25 μM $CdCl_2$ without FBS. Carrier-mediated uptake of 10 μM ^{3}H-choline±750 μM hemicholinium-3 was assayed (37C, 30 min). F-actin and microtubules were examined by epi-fluorescence microscopy. Cytotoxicity and cell viability were assessed based on LDH release and WST-1 formation, respectively. At Cd concentrations ≤ 1 μM, choline uptake was similar to control. However, treatment with 5-100 μM Cd progressively decreased uptake. LDH release from cells treated with ≤ 1 μM Cd was comparable to controls; however, release increased in a dose-dependent manner with 10 μM-25 μM Cd. WST-1 data suggest a biphasic dose-response to cadmium treatment, with increased viability at concentrations ≤ 10 μM and decreased viability at concentrations > 25 μM. Epi-fluorescence images indicated that ≤ 1 μM Cd induced little change in actin filaments, whereas ≥ 5 μM Cd decreased actin filaments. Microtubules remained intact at Cd concentrations ≤ 5 μM but were disrupted at concentrations ≥ 10 μM. These data show that extended exposure to 5-10 μM Cd may decrease choline uptake and disrupt the cytoskeleton with minimal adverse affects on cytotoxicity and cell viability. Decrease in uptake may be mediated in part by cytoskeletal disruption; this remains to be established. Modulation of signaling cascades or intracellular calcium may also be involved. ES10439; NS39452; T32ES07026

1698 INITIAL CHARACTERIZATION OF THE GLUTAMATE-CYSTEINE LIGASE MODIFIER SUBUNIT *Gclm(-/-)* KNOCKOUT MOUSE: NOVEL MODEL SYSTEM FOR A SEVERELY COMPROMISED OXIDATIVE STRESS RESPONSE.

Y. Yang[1], Y. Chen[1], M. Z. Dieter[2], H. G. Shertzer[1], D. W. Nebert[1] and T. P. Dalton[1]. [1]*Department of Environmental Health, University of Cincinnati Medical Center, Cincinnati, OH and* [2]*Department of Pharmacology, Toxicology, and Therapeutics, University of Kansas Medical Center, Kansas City, KS.*

Reduced glutathione (GSH) is the most abundant antioxidant in the cell and exists in both prokaryotes and eukaryotes. The rate-limiting enzyme in GSH biosynthesis is glutamate-cysteine ligase (GCL). In higher eukaryotes, this enzyme is a heterodimer comprised of a 72.8-kDa subunit with catalytic activity (GCLC) and a 30.8-kDa modifier subunit (GCLM), which changes the catalytic characteristics of the holoenzyme. To define the cellular function of GCLM, we disrupted the mouse *Gclm* gene to create a null allele. *Gclm(-/-)* mice are viable, fertile and have no overt phenotype. In liver, lung, pancreas, red cells and plasma, however, GSH levels in *Gclm(-/-)* homozygous knockout mice were 9-16% of that in *Gclm(+/+)* wild-type littermates. Cysteine levels in *Gclm(-/-)* mice were 9%, 35% and 40% of that in *Gclm(+/+)* mice in kidney, pancreas and plasma, respectively, but remained unchanged in the liver and red cell. Comparing the hepatic GCL holoenzyme with GCLC in the genetic absence of GCLM, we found the latter had a ~2-fold increase in Km for glutamate and a dramatically enhanced sensitivity to GSH inhibition. The major decrease in GSH, combined with diminished GCL activity, rendered

Gclm(-/-) fetal fibroblasts strikingly more sensitive to chemical oxidants such as H_2O_2. We conclude that the *Gclm(-/-)* mouse represents a model of chronic GSH depletion that will be very useful in evaluating the role of the GCLM subunit and GSH in numerous pathophysiological conditions, as well as in environmental toxicity associated with oxidant insult (supported in part by NIH P30 ES06096).

1699 HEPATOCYTE-SPECIFIC KNOCKOUT OF GLUTAMATE-CYSTEINE LIGASE CATALYTIC SUBUNIT IN MOUSE: EARLY DEATH WITH PROGRESSIVE LIVER DEGENERATION AND RESCUE BY N-ACETYLCYSTEINE.

T. P. Dalton, M. L. Miller, H. G. Shertzer, D. W. Nebert and Y. Yang. *Department of Environmental Health, University of Cincinnati Medical Center, Cincinnati, OH.*

GSH depletion has been associated with numerous liver diseases, but the cause-and-effect relationship has not been established. To define a role for hepatic GSH *in vivo*, we generated an hepatocyte-specific Cre recombinase-mediated disruption of the *Gclc* gene encoding the catalytic subunit of glutamate-cysteine ligase, an essential enzyme in GSH biosynthesis. By selective breeding, we recovered offspring that expressed Cre recombinase driven by the hepatocyte-specific albumin promoter and in which both *Gclc* alleles were flanked by *loxP* sites (floxed, *f*). In these mice, deletion of the *Gclc(f)* allele led to detection of the hepatocyte-specific *Gclc(h)* knockout allele as early as gestational day 16; however, *Gclc(h/h)* were born at the expected Mendelian frequencies. By day 14 after birth (d14), Southern blot analysis showed that deletion of *Gclc(f)* was complete, and hepatic GSH levels were 1-2% of normal. Surprisingly, *Gclc(h/h)* mice appeared normal until weaning, at which time they failed to gain weight and died of hepatic failure around d30. Plasma GSH levels dropped to 19%, 16%, and 2% of that in *Gclc(+/+)* wild-type at days 14, 21 and 30, respectively, but GSH depletion (20-50%) in nonhepatic tissues was not obvious until d21. Livers from d30 *Gclc(h/h)* mice showed focal necrosis, inflammation and apoptosis. Remarkably, N-acetylcysteine supplementation in the drinking water, starting at d21, rescued *Gclc(h/h)* mice. Our data suggest that GCLC is essential for hepatocyte function, but that other thiols may be able to replace some essential functions of GSH (supported in part by NIH P30 ES06096).

1700 ACETAMINOPHEN HEPATOTOXICITY IS NOT ENHANCED IN GENETICALLY ALTERED MICE (GR1A1NEU) WITH DIMINISHED GLUTATHIONE REDUCTASE ACTIVITIES.

L. K. Rogers, M. Park, S. E. Welty, T. N. Hansen and C. V. Smith. *Pediatrics, Columbus Children's Research Institute, Columbus, OH.*

Glutathione reductase (GR) is a component of the glutathione-dependent antioxidant system and functions to reduce glutathione disulfide (GSSG) to the thiol form (GSH). In previous studies *in vitro*, we have demonstrated that transgene-driven enhancement of GR activities increased resistance to oxidant injuries and that antisense expression of a transgene could diminish GR activities and resistance to oxidants. To test the hypothesis that decreased GR activities would increase susceptibilities to oxidant injuries *in vivo*, we studied a genetically altered strain of mice (Gr1a1Neu) [Pretsch, Genet Res Camb, 1999] that express <10% of the hepatic GR activities of the C3H wild type animals (Neu, 247+47, C3H, 3841+207 mU/g tissue). Despite the low GR activities in the Neu mice, no marked physiological effects have been observed or reported. Hepatic GSH (Neu, 7.59+0.9, C3H, 7.18+0.3 mM) and GSSG levels (Neu, 64+9; C3H, 45+18 uM) were not different between Neu and C3H mice, and basal glutathione peroxidase activities were (Neu, 106+22; C3H, 166+6 University/g tissue). As assessed by real time PCR, the relative hepatic GR mRNA expressions in the Neu mice were 1/1000 the levels observed in the C3H wild type mice. Male and female Neu and C3H mice that had been fasted 18 h were given doses of 0, 50, 100, 200, or 300 mg/kg of acetaminophen, 6 h later the animals were sacrificed, and plasma ALT activities were measured for assessment of liver injury. Plasma ALT activities were increased modestly in the Neu animals at 200 mg/kg (Neu, 85+32; C3H, 35+20 IU/L) and increased comparably in both strains at 300 mg/kg (Neu, 8346+2134; C3H, 9197+5116 IU/L). The data indicate that Neu mice are not markedly more susceptible to acetaminophen hepatotoxicity than are the control C3H mice, despite the profound differences in GR activities. Supported by GM44263 from NIH.

1701 CHLORDANE EFFECTS ON HEPATIC GLUTATHIONE LEVELS IN DAMS, PUPS AND VIRGIN RATS.

M. M. Mansour[1], M. Mahboob[2], V. V. St. Omer[1] and B. C. Datiri[1]. [1]*Biomedical Sciences, Tuskegee University, Tuskegee, AL and* [2]*Toxicology Unit, Biology Division, Indian Institute of Chemical Technology, Hyderadad-500 007, India.* Sponsor: R. Dalvi.

Technical chlordane (TC), a complex cyclodiene pesticidal mixture banned in the US in 1988, is still in the food chain, all environmental media & biota and in humans. It poses a risk to humans. Human liver may be a major target organ for chronic oral exposures at environmental levels. Our rat studies identified the liver as a target of chronic exposure since induction of hepatic cytochrome P450 (CYP1A1, 2B1, 2E1) occurred without hepatotoxicity. TC can induce its own metabolism and superoxides, potentially hepatotoxic. Glutathione(GSH) dependent enzyme system can provide major protection against toxic agents produced by xenobiotics. GSH is playing an important function in conjugating xenobiotics with its thiol(-SH) group. Thus, alterations in levels of GSH can also alter the detoxification potential of this enzyme system. We used Sprague-Dawley rats from our TC multigeneration study, to investigate the long-term oral effects of TC on hepatic GSH in dams their preweaned pups and virgin adults. Virgin F3 rats, pregnant F3 dams and their pups were daily exposed to TC at 0.00, 0.125, 0.25 and 1 mg/kg b.w./day. Pups were exposed *in utero* and *via* dam's milk and adults by gavage. Hepatic GSH content was determined using 5, 5'-dithio-bis (2-nitrobenzoic acid) as fluorescent reagent according to the method of Ellman, 1959. TC treatment increased, ($p<0.0001$), hepatic GSH levels in virgin rats at the high dose & in dams at the mid and high doses when compared to controls. In female pups, the GSH level increased ($p<0.0001$) at the low, mid and high dose levels. In male pups, increase ($p< 0.05$) in GSH level occurred only at high TC dose level. Results demonstrate that TC caused sex dependent effects (female>males)and increased GSH level may decrease the potential effects of the toxicant by GSH dependent detoxification.(Supported by MHPF/ATSDR U50/ATU398948)

1702 PROTECTION OF MICE FROM ACETAMINOPHEN-INDUCED HEPATOTOXICITY BY A SULFHYDRYL-PROTECTED PRODRUG OF GLUTATHIONE.

D. L. Crankshaw[3,1], L. I. Berkeley[1], J. F. Cohen[2] and H. T. Nagasawa[1,2]. [1]*Medical Research Service, VA Medical Center, Minneapolis, MN,* [2]*Medicinal Chemistry, University of Minnesota, Minneapolis, MN and* [3]*Food Science and Nutrition, University of Minnesota, Minneapolis, MN.*

Acetaminophen (ACP), in high doses, is known to elicit liver toxicity in mice manifested by profound elevation of transferase enzymes in serum with histological evidence of hepatic necrosis. We have previously observed that a number of cysteine prodrugs and double prodrugs can protect against this ACP-induced hepatotoxicity (Crankshaw, et al., J Biochem Mol Toxicol, in press). In developing a ^{14}C-glycine/HPLC method for assessing the incorporation of the cysteinyl moiety (from the prodrug) into GSH in rat lens (AM Holleschau, et al., 1996, Curr Eye Res 15:501-510), we discovered a radioactive peak near GSH which appeared to be produced metabolically. This substance was tentatively identified as the mixed disulfide, L-cysteine-glutathione disulfide (L-CySSG). In the present study, L-CySSG was found to be a highly effective protective agent against ACP-induced hepatotoxicity in mice. Thus, pre- (1.23 mmol/kg) and post- (2.45 mmol/kg) administration of L-CySSG to mice given 2.45 mmol/kg of ACP at 1 hr pre- and 30 min post-ACP (or the reverse protocol, dose-wise) fully protected mice from toxicity, as evidenced by minimal elevation in serum alanine transaminase (ALT) levels. The mixed disulfide prepared from D-cysteine and GSH, *viz.*, D-CySSG, was totally ineffective in protecting mice from ACP-induced hepatotoxicity. This suggests that L-CySSG must be metabolically activated to release GSH, presumably by enzymatic reduction of the disulfide bond. L-CySSG is, therefore, a sulfhydryl-protected prodrug of GSH. GSH monoethyl ester, a known prodrug of GSH, was only moderately hepatoprotective in this system. (Supported by the Department of Veterans Affairs)

1703 TOXICITY OF PHENOLIC COMPOUNDS: DIRECT DETECTION OF GLUTATHIONYL RADICALS PRODUCED BY MYELOPEROXIDASE-CATALYZED METABOLISM IN CELLS.

G. G. Borisenko[1], I. Martin[2], Q. Zhao[1], J. Jiang[1] and V. E. Kagan[1]. [1]*Department of Environmental and Occupational Health, University of Pittsburgh, Pittsburgh, PA and* [2]*King's College London, London, United Kingdom.*

Peroxidases (including myeloperoxidase and cyclooxygenase-2) catalyze one-electron oxidation of phenolic compounds to yield potentially cytotoxic phenoxyl radicals which can trigger/enhance oxidative stress. In particular, phenoxyl radicals can react with glutathione, the major regulator of redox-status in cells, to form intermediate glutathionyl radicals ($GS^{\bullet}$). We developed a new sensitive method for the detection of glutathionyl radicals based on a specific interaction of $GS^{\bullet}$ with Ac-Tempo (a conjugate of fluorogenic acridine with paramagnetic nitroxide Tempo). $GS^{\bullet}$ generated by peroxidase-catalyzed reaction through phenoxyl radical recycling or by photolysis of nitrosoglutathione, reacted with Ac-Tempo resulting in the decay of Tempo EPR signal and in the production of acridine fluorescence. Spin trapping of $GS^{\bullet}$ by DMPO and PBN inhibited interaction of $GS^{\bullet}$ with Ac-Tempo. Other radicals resulting from secondary $GS^{\bullet}$ reactions, i.e., the glutathione disulfide and superoxide anion radicals had no significant impact on the fluores-

cence production. The major product of $GS^{\bullet}$ and Ac-Tempo reaction was fluorescent acridine-piperidine as determined by combined HPLC and Mass spectrometry techniques. This method was applied for the fluorescence microscopic imaging of glutathionyl radicals known to be produced by myeloperoxidase-catalyzed metabolism of phenol in HL-60 cells. Indeed, Ac-Tempo fluorescence was observed upon addition of H_2O_2 and phenol, and it was inhibited by pre-incubation of cells with the thiol-blocking reagent, N-ethylmaleimide, or with the inhibitor of heme synthesis, succinyl acetone. Intracellular generation of $GS^{\bullet}$ was also detected in cyclooxygenase-2-transfected PC12 cells upon stimulation with phenol and H_2O_2. Thus, Ac-Tempo can be applied to detect, quantify and to image glutathionyl radical generation in cells. (Supported by NIH/NINDS/WHO #1 F05 NS43922-01)

1704 A ROLE FOR ASCORBATE AND PROTEIN-GLUTATHIONE MIXED DISULFIDES IN CELLULAR PROTECTION AND GSSG/GSH REDOX REGULATION.

J. Ehrhart[1,2] and G. D. Zeevalk[2]. [1]*White Eagle Toxicology, Doylestown, PA and* [2]*Neurology, UMDNJ-Robert Wood Johnson Medical School, Piscataway, NJ.* Sponsor: K. Reuhl.

Defects in mitochondrial metabolism and decreases in glutathione are present in idiopathic Parkinson's disease and are thought to contribute to the loss of dopamine (DA) neurons. Malonate, an inhibitor of SDH/complex II, has been used to model the effects of mitochondrial impairment in neurons and results in a greater loss of DA than GABA neurons *in vivo* and *in vitro*. Our past studies have shown that ascorbate, while providing protection to cultured mesencephalic DA and GABA neurons from malonate, significantly increased the formation of protein-glutathione mixed disulfides (PrSSG). To better understand the role of ascorbate and PrSSG in protection, time course studies were conducted with malonate ± ascorbate for 4-8 hr and intra- and extracellular GSH and GSSG, and PrSSG were determined. Ascorbate significantly decreased the efflux of GSH and GSSG, increased PrSSG levels and maintained a more reduced GSSG/GSH ratio compared to control and malonate alone. When glutathione was decreased in cells with buthionine sulfoxamine (BSO), malonate toxicity and reactive oxygen species (ROS) generation were greatly potentiated. Under these conditions ascorbate fully prevented the rise in ROS and provided complete protection. With 12 h exposure to malonate plus ascorbate in BSO treated cultures, the absolute amount of PrSSG formed was lower than in non-BSO treated controls, however, the proportion (‰) of PrSSG to intracellular GSH was significantly elevated. These findings suggest that ascorbate may be protective by acting as a free radical scavenger and by sequestration of GSH in the cell through PrSSG formation. This work was supported by PHS grant NS 36157

1705 ROLE OF GLUTATHIONE DEPLETION IN TOXICANT INDUCED INJURY TO CLARA CELLS.

A. Phimister and C. G. Plopper. *VM:APC, University California, Davis, Davis, CA.*

The early patterns of toxicity that occur in Clara cells (i.e. non-ciliated airway epithelium) exposed to the metabolically activated pulmonary toxicant naphthalene are closely associated with glutathione (GSH) depletion, and include: swelling, membrane bleb formation, cytoskeletal disruption, mitochondrial injury, and increased membrane permeability, which leads to necrosis. The purpose of this study was to define the cellular events that occur in response to acute GSH depletion alone. Mice were given a single injection of the selective GSH depletor diethylmaleate (DEM; 1g/kg ip). GSH levels in airways were measured directly by HPLC with electrochemical detection, 1-24 hours post-treatment. Changes in cell morphology, ultrastructure, and membrane permeability were examined by light and electron microscopy, and laser-scanning confocal microscopy. Airway GSH levels dropped rapidly following DEM treatment (70% loss within 2 hours) but returned to normal levels within 24 hours. Swelling was apparent in the Clara cells lining the distal (50% volume increase) but not proximal airways. Cell volume increased maximally by 3 hours post-treatment but returned to control levels within 24 hours. Most of the volume increase appeared to be from swollen endoplasmic reticulum. Membrane blebbing was apparent in some distally located Clara cells, where it appeared that the mitochondria were partitioned away from the blebs. Irregularly shaped, membrane bound structures were observed protruding from the apical surfaces of some cells 1 day after treatment, but their nature is uncertain. Airway cells did not appear necrotic nor did their membranes become permeable at any time point. In Clara cells GSH depletion in the absence of reactive metabolite formation, produces some changes associated with bioactivated toxicants (swelling and bleb formation), but does not increase membrane permeability or markedly alter mitochondria, and is not a lethal event.

1706 FORMATION OF A GLUTATHIONE ADDUCT WITH A COCAINE PYROLYSIS PRODUCT, ANHYDROECGONINE METHYL ESTER.

A. L. Myers, S. S. Wolfe, P. M. Gannett, T. S. Tracy and P. S. Callery. *Basic Pharmaceutical Sciences, West Virginia University, Morgantown, WV.* Sponsor: M. Davis.

Introduction: Anhydroecgonine methyl ester (AEME, methylecgonidine) is a pyrolysis product of smoked crack cocaine that appears to play a role in cocaine associated toxicity. AEME and its metabolic product, anhydroecgonine (AE, ecgonidine), have been detected in the urine of crack smokers. Because AEME can undergo a Michael addition reaction with toxicologically relevant nucleophiles, the chemical reactivity of AEME toward glutathione and *N*-acetyl-L-cysteine was studied. A better understanding of the chemical reactivity of AEME with glutathione may assist in the identification of toxic pathways associated with smoked cocaine. **Experimental:** AEME in acetonitrile was combined with reduced glutathione in water and ammonium acetate buffer (pH 7.4) and the mixture was stirred in a sealed tube under N_2. The resulting solution was evaporated to dryness and the residue dissolved in methanol for analysis by electrospray ionization ion trap mass spectrometry. This synthetic method was modified for the reaction of AEME with *N*-acetyl-L-cysteine in water and AE in methanol with glutathione. **Results:** A mass spectral ion at *m/z* 489 was consistent with assignment as a glutathione-AEME adduct. Multiple stage mass spectral analyses (MS^2 and MS^3) of the parent ion confirmed the structure of the product. The reaction of AEME with *N*-acetyl-L-cysteine yielded a base ion at *m/z* 345 for the adduct and daughter ions consistent with an AEME-*N*-acetyl-L-cysteine structure. Similarly, AE formed an adduct with glutathione, shown on mass spectral analysis (*m/z* 475) and further fragmentation by MS-MS. **Conclusions:** Adducts between AEME-glutathione, AEME-*N*-acetyl-L-cysteine and AE-glutathione were detected and their structures elucidated by mass spectrometry. Identification of these adducts *in vitro* suggests that AEME and AE can covalently link with glutathione and possibly with other sulfhydryl-containing cellular constituents, such as proteins.

1707 EXPRESSION AND STABLE TRANSFECTION IN NRK-52E CELLS OF THE MITOCHONDRIAL 2-OXOGLUTARATE CARRIER (OGC), A GLUTATHIONE TRANSPORTER.

F. Xu[1], L. H. Lash[1], D. A. Putt[1], B. Sun[1] and L. H. Matherly[2,1]. [1]*Pharmacology, Wayne State University, Detroit, MI and* [2]*Karmanos Cancer Institute, Wayne State University, Detroit, MI.*

Previous studies of ours showed that the OGC is one of two carrier proteins involved in the transport of glutathione (GSH) from cytoplasm into mitochondrial matrix in rat kidney proximal tubule. The cDNA for rat mitochondrial OGC was amplified from total rat kidney RNA by RT-PCR, expressed as a polyhistidine (His_6)-tagged fusion protein in *E. coli*, purified from inclusion bodies and by nickel-affinity chromatography, and reconstituted into proteoliposomes. Reconstituted rOGC-His_6 transported both 2-oxoglutarate (OG) and GSH, and transport of 1 mM of each of the substrates was inhibited by more than 80% by either 10 mM pyridoxal 5'-phosphate or phenylsuccinate. Further, GSH transport by the reconstituted carrier was inhibited by *S*-alkyl GSH analogues (-methyl to -hexyl), with the extent of inhibition generally increasing with increasing alkyl chain length. OG was transported in proteoliposomes with a K_m of 184 μM and a V_{max} of 475 nmol/min per mg protein. NRK-52E cells, a stable cell line derived from normal rat kidney proximal tubules, was stably transfected with the cDNA for rOGC-His_6. Expression of the carrier in mitochondria from the transfected NRK-52E cells was confirmed by Western blot analysis using an antibody directed to the His_6-tag, and transport activity with OG and GSH as substrates was increased by > 5-fold as compared to that in mitochondria isolated from wild-type NRK-52E cells. These results demonstrate that the expressed and reconstituted OGC exhibits similar properties to the native protein in rat kidney mitochondria. Overexpression in the NRK-52E cells provides a tool to investigate the function of this carrier in regulation of GSH status and function in renal mitochondria. (Supported by NIH Grant DK40725.)

1708 ROTENONE AND/OR CHLORPYRIFOS EXPOSURE OF HUMAN DOPAMINERGIC NEUROBLASTOMA CELLS (SH-SY5Y) AND CORTICAL NEURONS INDUCES ACTIVATION OF c-JUN N-TERMINAL KINASE (JNK) AND p38 MAPK, MITOCHONDRIAL TRANSLOCATION OF BAX, CYTOCHROME C RELEASE, AND APOPTOSIS.

K. M. Newhouse, A. Caughlan, R. Persinger, S. Chang and Z. Xia. *Environmental Health Box # 357234, University of Washington, Seattle, WA.*

Recent studies suggest that environmental toxicants including pesticides may contribute to the development of various neurodegenerative disorders including Parkinsons Disease. For example, the insecticide rotenone has been found to reproduce the behavioral and biochemical features of Parkinsons Disease in rats.

Additionally, organophosphate pesticides that target the CNS, like chlorpyrifos, are associated with impaired learning and memory in children. One mechanism implicated in neurodegenerative diseases is neuronal apoptosis. We hypothesize that exposure to pesticides may contribute to cell loss of sensitive neuronal populations through apoptosis. Our studies suggest that both chlorpyrifos and rotenone induce apoptosis in primary cultured cortical neurons and dopaminergic SH-SY5Y cells. Moreover, the combination of rotenone and chlorpyrifos exposure enhances apoptosis compared to either pesticide alone. Exposure to rotenone or chlorpyrifos activates the stress-activated protein kinases, c-Jun NH2-terminal protein kinase (JNK) and the p38 mitogen-activated protein (MAP) kinase. In addition, inhibition of these pathways attenuates the toxicity of these pesticides. We have also found that rotenone treatment results in Bax translocation to mitochondria, release of cytochrome C and caspase activation. Taken together, exposure of neuronal cells to either rotenone or chlorpyrifos alone or in combination triggers differential activation of the JNK and p38 MAPK pathways and induction of mitochondrial-pathway mediated apoptosis. These studies provide novel information concerning the molecular mechanisms of pesticide-induced apoptosis in neuronal cells and new insights concerning the role of environmental toxicants in neurodegeneration.

1709 MITOCHONDRIAL TRANSLOCATION OF PROTEIN KINASE C-DELTA PROMOTES PROTEOLYTIC DEGRADATION OF BCL-2 DURING ENVIRONMENTAL NEUROTOXIC INSULTS IN DOPAMINERGIC CELLS.

M. Kitazawa and A. G. Kanthasamy. *Biomedical Sciences, Iowa State University, Ames, IA.*

Previously, we demonstrated that exposure to environmental neurotoxins such as 1-methyl-4-phenylpyridinium (MPP+), dieldrin, and methylcyclopentadienyl manganese tricarbonyl (MMT) induces proteolytic activation of protein kinase Cδ (PKCδ) in a caspase-3 dependent manner in dopaminergic cells. Upon further characterization, we found that PKCδ activation not only mediates apoptosis but also regulates the upstream caspase cascade through positive feedback activation. In this study, we investigated the pro-apoptotic role of PKCδ in the upstream caspase cascade following dieldrin or MMT treatment in dopaminergic PC12 cells. Following acute exposure to dieldrin (100 μM) or MMT (200 μM), native PKCδ rapidly translocated to the mitochondria within 1 hr. This was followed by the release of key mitochondrial pro-apoptotic molecules, including cytochrome c and Smac, into the cytosol. The PKCδ specific inhibitor rottlerin blocked the dieldrin- and MMT-induced cytochrome c release but not the translocation of PKCδ. To further understand the role of PKCδ in mitochondrial function, we intracellularly delivered recombinant, catalytically active PKCδ into dopaminergic cells. The catalytically active PKCδ induced depolarization of the mitochondrial membrane potential, cytochrome c release, and caspase-9 activation, further confirming that PKCδ is an important signaling molecule in the caspase cascade. Immunoprecipitation analysis revealed that PKCδ associates with Bcl-2 and caspase-3 during dieldrin or MMT exposure. Furthermore, Bcl-2 was proteolytically cleaved after a 3-hr dieldrin or MMT treatment; both PKCδ and caspase-3 inhibitors blocked the cleavage. Together, our results suggest that the mitochondrial translocation of PKCδ is an initial pro-apoptotic event that subsequently promotes caspase-3 dependent proteolytic inactivation of Bcl-2 during environmental chemical-induced dopaminergic degeneration (supported by NIH ES 10586).

1710 RNAI-MEDIATED KNOCK-DOWN (GENE SILENCING) OF PRO-APOPTOTIC PKCδ *IN VITRO* MODELS OF PARKINSON'S DISEASE.

Y. Yang, V. Anantharam and A. Kanthasamy. *Biomedical Science, Iowa State University, Ames, IA.*

Double strand RNA (dsRNA)-mediated RNA interference (RNAi) is an emerging genetic technique used to ablate specific gene functions in eukaryotes. Recently, this novel approach is extended to mammalian cells to specifically ablate the function of a given gene with small interference RNA (siRNA). The application of siRNA technology in neuronal models to advance the understanding of the degenerative process has not yet been explored. Recently, we demonstrated that caspase-3 dependent proteolytic activation of protein kinase C delta (PKCδ) is critical for the induction of apoptotic cell death in mesencephalic dopaminergic neuronal (N27) cells during exposure to various environmental neurotoxic agents including 1-methyl-4-phenylpyridinium (MPP^+), dieldrin, and methylcyclopentadienyl manganese tricarbonyl (MMT). Herein, we demonstrate that siRNA mediated knockdown of PKCδ effectively protects dopaminergic neurons from environmental neurotoxic insult. Using stringent criteria, we designed four siRNAs for the rat PKCδ gene. *In vitro* transcription was used to synthesize duplex siRNAs. Each duplex siRNA was then transfected into N27 cells and the siRNA cellular localization was confirmed by siRNA-cy3 labeling. Determination of the gene silencing efficiency by both Western blot and immunohistochemical analyses revealed that two of the four siRNAs significantly suppressed PKCδ expression as compared to the control or nonspecific siRNA. PKCε expression was unaltered, demonstrating the isoenzyme specificity of these siRNAs. Furthermore, siRNA-4, the most effective siRNA, almost completely suppressed MPP^+- and dieldrin-induced DNA fragmentation, confirming the pro-apoptotic function of the PKCδ gene. Together, our results indicate that siRNA is a powerful genetic tool for the understanding of the cellular mechanisms underlying dopaminergic degeneration in Parkinson's disease. Perhaps even siRNA-based neuroprotective treatments for various neurodegenerative disorders, including Parkinson's disease, can be developed in the future (supported by NIH grants ES 10586 and NS 38644)

1711 CASPASE INHIBITION SWITCHES THE MODE OF DEATH PRODUCED BY CYANIDE IN CORTICAL NEURONS.

K. Prabhakaran, L. Li, J. L. Borowitz and G. E. Isom. *Medicinal Chemistry and Molecular Pharmacology, Purdue University, West Lafayette, IN.*

Execution of apoptosis involves mainly activation of the caspase family of proteases. However recent studies indicate that caspase inhibition occasionally turns the morphology of cell death from apoptotic into necrotic without inhibiting death itself. In the present study the effect of caspase inhibition on cortical cell death induced by cyanide was investigated. In cortical cells exposed to cyanide (400 μM) death was primarily apoptotic as characterized by positive TUNEL staining of apoptotic cells and DNA laddering on gel electrophoresis. Reactive oxygen species generation and subsequent increased caspase activity mediated cyanide-induced cortical apoptosis. Pretreatment of cortical cells with a broad-spectrum caspase inhibitor, Z-VAD-fmk, blocked cyanide-induced apoptosis (TUNEL staining and DNA degradation). Inhibition of caspases resulted in a parallel increase in necrotic-like cell death as measured by increased cellular efflux of LDH and propidium iodide uptake by the cells. The change in the mode of cell death was accompanied by a further increase in ROS generation and reduction in mitochondrial membrane potential. These data suggest that apoptosis and necrosis share common initiation pathways and the level or the extent of caspase activation plays an important role in the cell death pathway decision. (Supported by NIH grant ES 04140)

1712 INVOLVEMENT OF CASPASE-3 PROTEASE IN DOPAMINERGIC DEGENERATION FOLLOWING EXPOSURE TO METHYLCYCLOPENTADIENYL MANGANESE TRICARBONYL (MMT).

P. G. Gunasekar[1], G. T. Ramesh[2], K. Prabhakaran[3] and J. E. Klaunig[1].
[1]Pharmacology and Toxicology, Indiana University School of Medicine (IUPUI), Indianapolis, IN, [2]Biology, Texas Southern University, Houston, TX and [3]Medicinal Chemistry and Molecular Pharmacology, Purdue University, West Lafayette, IN.

Exposure to methylcyclopentadienyl manganese tricarbonyl (MMT), (used as an antiknock agent in gasoline) poses a significant health concern. Occupational workers who are exposed MMT manifest neural degeneration resembling Parkinson disease (PD). Identifying molecular mediators and their regulation in dopaminergic neuronal cells would allow us to determine the underlying mechanisms involved in MMT-induced dopaminergic degeneration. Here, we measured molecular responses of dopaminergic cells to different concentrations of MMT (0.1-1.0 mM)-induced cell death. Using substantia nigra cells, we showed that cells exposed to MMT (0.1-1.0 mM) for 24 hrs increased cell death over the control in a concentration dependent manner. This was determined by lactate dehydrogenease (LDH) release and apoptotic TUNEL staining. The increased cell death at various concentrations of MMT was blocked when cells were pretreated with caspase 3 inhibitor, Ac-DEVD suggesting the involvement of caspase 3 activation in MMT-induced dopaminergic cell death. In order to confirm this, we further, measured caspase-3 activity level in cells treated with MMT at the same concentration at different time periods. Like apoptosis and cell death, caspase-3 activity increased peak at 4 hrs after beginning of the exposure, while caspase-3 specific blocker z-VAD significantly reduced the same. There was a significant protection against MMT-induced cell death, when cells were pre-treated with Poly-ADP-Ribose Polymerase (PARP) inhibitor (Benzamide), which reflect the involvement of PARP following caspase-3 activation. These results suggest that the change in the levels of caspase-3 and PARP response to MMT exposure explained the involvement of caspase-3 and associated PARP activation during MMT-induced dopaminergic degeneration.

1713 METHYLCYCLOPENTADIENYL MANGANESE TRICARBONYL (MMT) INDUCES APOPTOSIS BY PKCδ DEPENDENT ACTIVATION OF NF-κB IN MESENCEPHALIC DOPAMINERGIC NEURONAL CELLS.

A. Kanthasamy, M. Kitazawa, S. Kaul, V. Anantharam and A. G. Kanthasamy. *Biomedical Sciences, Iowa State University, Ames, IA.*

Methylcyclopentadienyl manganese (MMT) is an organic manganese compound that has been legalized for use as a gasoline additive in the United States. Recently, we demonstrated that MMT exposure induces oxidative stress dependent apoptosis *via* capase-3 dependent proteolytic activation of protein kinase-delta (PKC-δ) in dopaminergic cells. The current study was designed to evaluate the effect of MMT on a redox transcription factor, NF-κB and it association with PKCδ in rat mesencephalic dopaminergic neuronal cells (N27 cells). Following a 3 hr exposure to MMT (30, 100, 200 μM) a pronounced increase in NF-κB activation and IκB-a degradation was evidenced. Pretreatment with a PKCδ inhibitor rottlerin or a caspase-3 inhibitor Z-DEVD-fmk, however, produced a near complete blockade of MMT-induced NF-κB activation, indicating the involvement of PKCδ and caspase-3 in the NF-κB activation process. Similarly, MMT-induced NF-kappa B activation was also dramatically reduced following pretreatment of dopaminergic cells with the specific NF-κB inhibitor SN-50. To further determine the importance of NF-κB activation in MMT-induced apoptosis, we tested the efficacy of NF-κB inhibitor and caspase-3 inhibitor on MMT-induced DNA fragmentation. Both SN-50 and Z-DEVD fmk significantly reduced the MMT-induced DNA fragmentation, indicating that the NF-κB pathway is critical for MMT-induced dopaminergic cell death. Together, we conclude that caspase-3 dependent proteolytic activation PKCδ may exert important regulatory effects on NF-κB activation to further facilitate the execution of MMT induced apoptotic cell death in dopaminergic neurons (supported by NIH ES 10586).

1714 LACK OF PHOSPHATIDYLSERINE EXTERNALIZATION IN ETOPOSIDE-INDUCED APOPTOTIC CELLS IS RELATED TO ITS ANTIOXIDANT PROTECTION OF PHOSPHATIDYLSERINE OXIDATION.

Y. Y. Tyurina[1], B. F. Serinkan[1], V. A. Tyurin[1], J. C. Yalowich[2], B. Fadeel[4] and V. E. Kagan[1,2,3]. *[1]EOH, University of Pittsburgh, Pittsburgh, PA, [2]Pharmacology, University of Pittsburgh, Pittsburgh, PA, [3]Cancer Research Institute, University of Pittsburgh, Pittsburgh, PA and [4]Division of Toxicology, Institute of Environmental Medicine, Karolinska Institutet, Stockholm, Sweden.*

Our previous work showed that clearance and phagocytosis of apoptotic cells is associated with selective oxidation and externalization of phosphatidylserine (PS) in plasma membrane, which could act as preferred ligand for certain macrophage receptors. Etoposide is an effective anticancer agent, which induces apoptosis in different cell lines. We demonstrated that etoposide (10-50 μM), induced apoptosis in HL-60 cells as evidenced by nuclear fragmentation and caspase-3 activation. Under these conditions, J774A.1 macrophages were not able to phagocytize etoposide-stimulated cells. Using Annexin V binding assay, we found that HL-60 cells failed to externalize PS in response to etoposide treatment (50 μM, 2h at 37°C). However a thiol specific reagent, N-ethylmaleimide (10 μM, 10 min at 37°C), inhibited aminophospholipid translocase and triggered externalization of PS in etoposide treated HL-60 cells and stimulated phagocytosis of these cells by macrophages. In addition, etoposide did not cause peroxidation of any phospholipids including PS. Next we utilized an oxidant-induced model of apoptosis, using H_2O_2. We found that H_2O_2-induced apoptosis in HL-60 cells was accompanied by nuclear fragmentation, caspase-3 activation, PS externalization and oxidation of different phospholipids including PS. Etoposide enhanced apoptosis induced by H_2O_2. Etoposide was able to completely block PS H_2O_2-induced oxidation in HL-60 cells and significantly but not completely inhibit PS externalization in HL-60 cells as well as their phagocytosis by macrophages. These results support our hypothesis that oxidation of PS is essential for its exposure on outer leaflet of plasma membrane and hence for recognition and phagocytosis of apoptotic cells. Supported by NIH HL70755 and CA 90787.

1715 FAS-TRIGGERED OXIDATION OF PHOSPHATIDYLSERINE IS ESSENTIAL FOR ITS EXTERNALIZATION DURING APOPTOSIS IN LUNG EPITHELIAL CARCINOMA A-549 CELLS UNDERGOING FAS-MEDIATED APOPTOSIS.

J. Jiang, B. F. Serinkan and V. E. Kagan. *Environmental and Occupational Health, University of Pittsburgh, Pittsburgh, PA.*

We have put forward a hypothesis that oxidation of phosphatidylserine (PS) catalyzed by cytochrome c is essential for PS externalization during apoptosis and for recognition of apoptotic cells. In this report, we used a model of Fas-triggered apoptosis in lung epithelial carcinoma A-549 cells rather than oxidant-induced apoptosis to maximize the apoptosis-associated oxidative stress and eliminate non-specific effects of oxidants on phospholipids. A549 cells were pretreated with interferon gamma (IFN-r, for 24 h) and exposed to anti-Fas antibody (CH-11) underwent apoptosis as evidenced by increased caspase-3 activity and externalized PS. Notably, PS was preferentially oxidized 3 h after anti-Fas triggering while two more abundant phospholipids phosphatidylcholine, phosphatidylethanolamine and the major intracellular antioxidant, glutathione, remained unoxidized. Fas-induced PS oxidation could be prevented by antioxidant enzymes catalase/superoxide dismutase (SOD). PS oxidation was preceded by release of cytochrome c from mitochondria into cytosol (2-h after anti-Fas stimulation. A pan-caspase inhibitor, z-VAD-fmk, blocked Fas-triggered caspase-3 activation, cyt c release, and PS externalization. In contrast, Z-DQMD-fmk, a caspase-3 inhibitor, blocked caspase-3 activity and PS externalization, but did not affect release of cyt c from mitochondria into cytosol. Most importantly, z-VAD-fmk, but not z-DQMD-fmk, inhibited oxidation of PS in Fas-triggered A549 cells. This suggests that cytochrome c-catalyzed PS oxidation participates in execution of apoptotic program and plays an important role in PS-dependent externalization and signaling during non-oxidant induced apoptosis in A549 cells. Supported by NIH grant HL70755-01.

1716 DIRECT INHIBITION OF I KAPPA KINASE ACTIVITY BY BENZENE METABOLITES SENSITIZES BONE MARROW CELLS TO CYTOKINE-INDUCED APOPTOSIS.

P. J. Kerzic[1], D. W. Pyatt[1], T. Zheng[1], A. T. Le[1], S. A. Gross[1] and R. D. Irons[1,2]. *[1]Toxicology, University of Colorado Health Sciences Center, Denver, CO and [2]Sino-U.S. Joint Clinical Molecular Laboratory, Fudan University-Fenglin Campus, Shanghai, China.*

The transcription factor NF-κB plays a critical role in hematopoietic progenitor cell (HPC) function and survival. NF-κB is activated *via* the I kappa kinase complex (IKK) by a variety of cytokines, including tumor necrosis factor-alpha (TNF-α), which also induces apoptosis in cells deficient in NF-κB. We have demonstrated that inhibition of NF-κB by the benzene metabolite hydroquinone (HQ) alters cytokine production in HPC and predisposes them to apoptosis. However, the mechanism by which HQ inhibits NF-κB activation, as well as the possible effects of other benzene metabolites on this important transcription factor, are unknown. We examined the effects of exposure to benzene metabolites on NF-κB in the erythroleukemic cell line TF-1 following activation with TNF-α. The effects of chemical treatment on NF-κB signaling, activation, and function were examined utilizing a combination of kinase assays on isolated IKK complexes and whole cells, electrophoretic mobility shift assays (EMSA), and DNA nick-end labeling to measure apoptosis. HQ, catechol, and p-benzoquinone, which directly inhibited IKK and activation of NF-κB, sensitized the cells to TNF-α induced apoptosis, whereas other benzene metabolites had no effect on IKK, NF-κB, or apoptosis. These findings indicate that benzene metabolites inhibit NF-κB *via* inhibition of IKK and collaborate with TNF-α in inducing apoptosis in HPC, raising the possibility that variations in TNF-α may play a role in mediating individual variation in susceptibility to hematotoxic agents.

1717 CASPASE ACTIVATION AND APOPTOSIS IN SILICA-INDUCED LUNG INJURY.

M. Thibodeau, S. Mowbray, C. Giardina and A. Hubbard. *University of Connecticut, Storrs, CT.*

Past studies have suggested a pro-inflammatory role for apoptosis and caspase activity in a mouse model of silica exposure (Am J Resp Cell Mol Biol 27: 78-84, 2002). However, caspase activation by silica in lung tissue has not been demonstrated *in vivo*. The goal of the current work is to investigate the contribution of caspase activation in the pathogenesis of silica-induced lung injury both *in vitro* and *in vivo*. To evaluate the *in vivo* activation of lung tissue caspases, C57Bl/5J mice were exposed to silica (α-quartz) particles by intratracheal (IT) instillation. Three days after IT instillation of 2 mg/mouse, a 2-fold increase in the activity of caspase-3, but not caspase-1 was observed. Fourteen days after silica exposure there was an increase in the activity of both caspase-1 and caspase-3. Caspase-3 activity was detected immunohistochemically in both lung macrophages and epithelium at 2 and 14 days post-instillation using an antibody against the large cleaved fragment of activated caspase-3. To further characterize the activation of caspases, the mouse macrophage cell lines RAW 264.7 and MH-S were exposed to α-quartz at 12.5 ug/cm2 or 50 ug/cm2 for either 6 or 24 hours. At both 6 and 24 hours post-exposure to α-quartz, flow cytometric analysis demonstrated pancaspase activation and the externalization of membrane phosphatidylserine, a marker of apoptosis. At 6 hours 18% of macrophages had an apoptotic subdiploid phenotype determined by flow cytometric cell cycle analysis. Apoptosis was attenuated by the pancaspase inhibitor ZVAD-FMK. To differentiate which caspases were activated, α-quartz treated macrophages

were incubated with fluoresceinated substrates to measure the activities of caspase-1, 3, 8, and 9. At 6 hours post-exposure to α-quartz 8-15% of the cell population had increased activity of the pro-apoptotic caspase-3, 8, and 9 whereas the pro-inflammatory caspase-1 had increased activity in 60% of the cells. In summary, our work demonstrates that silica activates lung caspases during both acute and chronic inflammation. (Supported by HL 10360 and ES 09433).

1718 CROSS-TALK BETWEEN DEATH RECEPTOR-MEDIATED AND MITOCHONDRIAL PATHWAYS OF APOPTOSIS INDUCED BY DES IN JURKAT CELLS.

N. C. Brown[1], M. Nagarkatti[1] and P. Nagarkatti[2]. *[1]Microbiology/Immunology, Virginia Commonwealth University, Richmond, VA and [2]Pharmacology/Toxicology, Virginia Commonwealth University, Richmond, VA.*

Exposure to diethylstilbestrol (DES), a synthetic estrogen has been associated with thymic atrophy and previous studies from our lab demonstrated that this occurs through the induction of apoptosis. In the current study, we investigated the mechanism of induction of apoptosis using Jurkat, a human T cell lymphoma line. Culture of Jurkat cells with DES caused a dose-dependent decrease in cellularity and induction of apoptosis. Furthermore, it was observed that DES treatment of FADD-/- and Caspase 8-/- Jurkat, led to decreased apoptosis when compared to wild-type (wt) Jurkat thereby demonstrating the involvement of the death-receptor pathway of induction of apoptosis. The wt, FADD-/-and Caspase8-/- Jurkat following treatment with DES also showed a decrease in mitochondrial membrane potential as determined by DiOC6 staining. Caspase 9-dominant negative (DN) and Bcl-2 over-expressing Jurkat were more resistant to DES induced apoptosis when compared to wt Jurkat cells. These studies therefore demonstrate that both death receptor mediated pathway and the mitochondrial pathway are involved in DES induced apoptosis of Jurkat cells. Further studies confirmed the cleavage of both caspase 8 and caspase 9 following DES treatment by immunoblotting. Caspase 8 may not directly activate the effector caspases but may recruit bid, a member of the bcl-2 family, to activate caspase 9 that could lead to cleavage of downstream effector caspases. It was observed that Bid was cleaved following DES treatment thereby suggesting cross-talk between the death receptor and mitochondrial pathways. In addition, the induction of apoptosis was diminished by treatment with caspase inhibitors Z-VDVAD-FMK, Z-IETD-FMK, Z-LEHD-FMK, Z-AEVD-FMK. Taken together, these studies demonstrate that DES-induced apoptosis in Jurkat is mediated through both death receptor and mitochondrial pathways. (Supported by NIH grants ES09098, DA014885 and HL058641).

1719 DES MEDIATES APOPTOSIS IN HEMATOPOIETIC STEM CELLS AND DEVELOPING THYMOCYTES LEADING TO IMMUNE DYSFUNCTION.

Y. Do[1], M. Nagarkatti[1] and P. S. Nagarkatti[2]. *[1]Microbiology and Immunology, Virginia Commonwealth University Campus, Medical College of Virginia, Richmond, VA and [2]Pharmacology and Toxicology, Virginia Commonwealth University Campus, Medical College of Virginia, Richmond, VA.*

Exposure to diethylstilbestrol (DES), a synthetic estrogen has been associated with an increased risk for breast cancer in "DES mothers" and a lifetime risk of cervicovaginal cancers and immunological abnormailities in "DES daughters". In the current study we investigated the immunological consequences following prenatal exposure to DES. To this end, pregnant C57BL/6 mice were treated with 10 or 50ug/kg body weight of DES or the vehicle at gestation day 15 and 16. After the end of pregnancy, mothers and pups were analyzed. The data showed severe thymic atrophy as well as increased induction of apoptosis in DES–treated mothers as well as in pups. Moreover, the thymocytes from DES–treated pregnant mice showed increased expression of CD3, αβTCR and CD44 indicative of apoptosis. Furthermore, there was no change in the expression of CD25 and CD69 markers. There was also no change in the percentage of CD4–CD8– (DN), CD4+CD8+ (DP), CD4+ and CD8+ (SP) T cells in these mice. In order to address whether DES affects only developing thymocytes or could also affect pluripotent hematopoietic stem cells, human cord blood CD34+ progenitor cells were examined for their susceptibility to induction of apoptosis. CD34+ cells were cultured in the presence of growth factors such as stem cell factor (SCF) and Flt3L for 2 weeks. Next, the cells were incubated *in vitro* with various concentrations of DES for 24hrs. Such an incubation resulted in a significant reduction in cellularity and induction of apoptosis as detected by using TUNEL and Annexin/PI staining. The DES–exposed cells also showed loss of mitochondrial membrane potential as studied by $DiOC_6$ staining. Together, this study demonstrates that DES induces apoptosis in developing thymocytes as well as in the hematopoietic stem cells. This may account for the immunological abnormalities as seen in DES daughters (Supported by NIH grants ES09098, DA014885 and HL058641).

1720 COMPETING CELL SURVIVAL AND CELL DEATH SIGNALS IN TGHQ TREATED HL-60 CELLS.

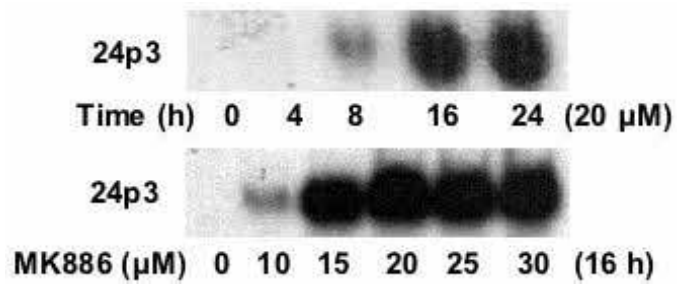
M. Yang, S. S. Lau and T. J. Monks. *Center for Molecular and Cellular Toxicology, The University of Texas at Austin, Austin, TX.*

Quinol-thioether metabolites are present in the bone marrow of rats and mice co-treated with hydroquinone and phenol. Several of these metabolites, including 2, 3, 5-*tris*-(glutathion-S-yl)hydroquinone (TGHQ) are hematotoxic in rats and induce DNA damage, growth arrest, and apoptosis in human promyelocytic leukemia (HL-60) cells. The mechanisms by which TGHQ-induces apoptosis in HL-60 cells is unclear and was the focus of the present studies. TGHQ catalyzed the rapid formation of reactive oxygen species (ROS), which reached maximal levels 1 h after treatment. Consistent with previous work, catalase inhibited TGHQ-induced apoptosis, with a concomitant reduction in ROS. Western analysis revealed the presence of cleaved caspase 9, 30 min after exposure of cells to TGHQ. By 2 h, procaspase 9 completely disappeared, with the concomitant appearance of two cleaved forms of caspase 3 (19, 12 kDa). Evidence for caspase 8 cleavage was apparent by 4 h. TGHQ also induced NF-κB-DNA binding activity, which was preceded by the rapid (15 min) phosphorylation and subsequent degradation of IκB-α. IκB-β phosphorylation and degradation occurred only after the initial phosphorylation of IκB-α. Consistent with these findings, the sesquiterpene lactone, parthenolide, which prevents IKKα activation, inhibited NF-κB activation and potentiated TGHQ-induced apoptosis. We investigated the effects of SN50, a cell permeable peptide corresponding to the nuclear localization sequence (VQRKRQKLM) of NF-κB, on TGHQ-induced apoptosis. SN50 potentiated TGHQ-induced apoptosis (PS externalization) consistent with the anti-apoptotic function of NF-κB in most cell types. The data suggest that in HL-60 cells TGHQ treatment activates the caspase-mediated apoptotic signaling pathway, and the NF-κB-mediated cell survival pathway. Factors that determine the functional outcome of these two competing pathways are under investigation. (ES07784, ES09224).

1721 MODULATION OF LIPOCALIN 24P3 EXPRESSION AS AN APOPTOTIC MECHANISM FOR MK886.

Z. Tong, X. Wu and J. P. Kehrer. *Center for Molecular and Cellular Toxicology, University of Texas at Austin, Austin, TX.*

MK886, a strong proapoptotic agent, is an inhibitor of 5-lipoxygenase (LOX) through binding to the 5-LOX-activating protein (FLAP). However, MK886-induced apoptosis is through a FLAP-independent pathway (Biochem. J. 340: 371 [1999]). A possible role of 24p3, a murine lipocalin implicated in apoptosis, in MK886-induced apoptosis was investigated. Exposure of murine prolymphoid progenitor cells (FL5.12) to MK886 dramatically increased 24p3 expression in a dose- and time-dependent manner (Figure). Induction could also be achieved with a structurally distinct FLAP inhibitor, MK591, but not with the structurally analogous compound indomethacin. MK886 is a peroxisome proliferator activated receptor (PPAR) inhibitor (Biochem. J. 356: 899 [2001]).The up-regulated 24p3 expression by MK886 was enhanced a further 2-fold by WY14643, an activator of PPARα, whereas ciglitazone, an activator of PPARγ attenuated expression by 50%. Neither WY14643 nor ciglitazone alone had any effect on the expression of 24p3. The induction of 24p3 by MK886 was inhibited by cycloheximide, suggesting it is dependent on the synthesis of new protein(s). Changes in 24p3 expression closely paralleled the induction of apoptosis. The overexpression of bcl_2 or bcl-x_L in FL5.12 cells prevented apoptosis induced by MK886 as well as the enhancement of apoptosis by WY14643. Thus, 24p3 is an MK886-inducible gene and may play an important role in MK886-induced apoptosis. (Supported by CA83701 and Center Grant ES07784.)



1722 CHANGES IN CELLULAR OXIDANT PRODUCTION IN RESPONSE TO PEROXISOME PROLIFERATOR ACTIVATED RECEPTOR (PPAR)α AND γ AGONISTS AND THE PPAR ANTAGONIST MK886.

E. B. Atarod and J. P. Kehrer. *Center for Molecular and Cellular Toxicology, University of Texas at Austin, Austin, TX.*

MK886, an inhibitor of 5-lipoxygenase activating protein (FLAP), induces apoptosis by mechanisms independent of both lipoxygenase and FLAP (Biochem. J. 340: 371 [1999]). MK886 has also been found to inhibit PPARs (Biochem. J. 356: 899 [2001]). PPARs have been implicated in apoptosis, but the mechanistic basis for this observation remains unclear. To assess the role of oxidative stress in MK886-induced apoptosis and its possible relationship with PPARs, we have studied Jurkat cells which express all PPAR isoforms. The PPARα (Wy14643) and PPARγ agonist (ciglitazone) do not cause apoptosis by themselves up to 50 and 25 μM, respectively. However, both agonists substantially increase the production of oxidants as shown by flow cytometry with dichlorofluorescin diacetate. MK886 (20 μM)-induced apoptosis is preceded by only a small increase in oxidants. In combination with 20 μM MK886, Wy14643 further increased the production of oxidants and apoptosis beginning at 4 h. Surprisingly, initial experiments showed that the antioxidants N-acetylcysteine and vitamin E did not prevent the generation of oxidants and appeared to further increase cell death. These data suggest that the production of oxidants is not directly related to the apoptosis induced by MK886 nor the enhancement seen with Wy14643. (This work was supported by CA83701 and Center Grant ES07784.)

1723 GLUTATHIONE AND THIOREDOXIN REDOX STATES ARE INDEPENDENTLY REGULATED DURING DIFFERENTIATION, APOPTOSIS, AND OXIDATIVE STRESS.

W. H. Watson, Y. S. Nkabyo and D. P. Jones. *Biochemistry, Emory University, Atlanta, GA.*

The glutathione (GSH) and thioredoxin (Trx1) systems protect cells from oxidative modification of protein thiols. GSH and its oxidized form (GSSG) constitute the predominant redox buffering system in the cell. The redox state of the GSH/GSSG couple is maintained at −260 mV in proliferating cells, but becomes more oxidizing as cells differentiate, and more positive still in cells undergoing apoptosis. It is unknown whether similar changes occur in Trx1. The purpose of the present study was to compare changes in GSH and Trx1 redox states in cell models of differentiation, apoptosis, and oxidative stress. GSH redox was determined by measuring intracellular GSH and GSSG concentrations by HPLC, and Trx1 redox was determined by the Redox Western blot technique. In spontaneously differentiating Caco2 cells, GSH/GSSG was oxidized and total GSH was decreased, whereas Trx1 was not oxidized and there was an increase in the total amount of Trx1 in these cells. Similarly, in staurosporine-induced apoptosis of HeLa cells, GSH/GSSG redox was dramatically oxidized with a concomitant loss of GSH, yet Trx1 redox and levels were only modestly affected. In contrast, in THP1 cells exposed to the oxidant tert-butylhydroperoxide, both GSH and Trx1 were oxidized to similar extents and over similar time courses. Thus, the redox states of GSH/GSSG and Trx1 are not in equilibrium, suggesting that these two redox-regulating systems have different roles in differentiation and apoptosis.

1724 ELEVATED LEVELS OF PHOSPHORYLATED CA2+/CAMP RESPONSE ELEMENT BINDING PROTEIN (PCREB) IN ISOLATED BRAIN MITOCHONDRIA FOLLOWING FOREBRAIN ISCHEMIA.

R. A. Schuh, T. Kristian and G. Fiskum. *Anesthesiology, University of Maryland, Baltimore, MD.*

Studies have implicated the Ca2+/cAMP response element binding protein (CREB) in cell survival and brain development as well as in learning and memory. Moreover, CREB has been shown to play a role in neuroprotection against various insults including acute cerebral ischemia. The cellular location of CREB has been identified as residing in the cytosol and the nucleus and recently has been reported to be present in brain mitochondria (J. Neurochem. 72:2272-7, 1999). In the current study, antibodies to CREB and phosphorylated CREB (pCREB) were used to probe for the presence of immunoreactivity in mitochondria isolated from different tissues and cells. Moreover, antibodies to Cytochrome c (Cyt c) and the pro-apoptotic Bax protein were used to probe for immunoreactivity in mitochondria isolated from adult rat brains following a 10 minute forebrain ischemia. At different reperfusion times the vulnerable CA1 subregion of the hippocampus was dissected and fractionated into cytosolic and mitochondrial fractions. Western immunoblots demonstrated the presence of CREB and pCREB in mitochondria isolated from rat and dog brain, rat liver and heart, and from GT1-7 and PC-12 cultured neural cells. Moreover, a transient decrease followed by increased pCREB immunoreactivity was detected in mitochondria isolated from the CA1 region of rat hippocampus during the first hour of reperfusion without any changes in CREB immunoreactivity. Further, decreased pCREB levels occurred concomitantly with Cyt c release from the mitochondria that is probably triggered by an accumulation of Ca2+. These results suggest the ubiquitous presence of CREB in mammalian mitochondria and that the phosphorylation state of mitochondrial CREB following reperfusion is altered. We hypothesize that CREB responds to physiological and pathological signals at the mitochondrial level and that altered posttranslational modifications of CREB may be important for neuronal survival following cerebral ischemia. Supported by: NS34152

1725 GLUCOSE TRANSPORT IN JURKAT CELL: CONCENTRATION-DEPENDENT REGULATION.

W. S. Koh, K. D. Shin, J. W. Lee and S. S. Han. *Korea Institute of Toxicology, Daejeon, South Korea.*

In this study, a mechanism by which glucose level modulates glucose transport in Jurkat cells was investigated. Glucose uptake was more efficient in the cells cultivated in low glucose (2.5 mM) medium than that grown in high glucose (20 mM) medium. Vmax (0.74 nmol·10^6cells^{-1}·min^{-1}) of glucose uptake measured with the cells grown in the low glucose medium was higher than the one (1.06 nmol·10^6cells^{-1}·min^{-1}) in the high glucose medium while Km was almost consistent through the change of glucose levels, indicating the increase of glucose transporter number. However, the RT-PCR showed that Jurkat cells express GLUT1 and 3 but not GLUT2, 4, or 5 and that the levels of the mRNA transcripts did not change with either glucose concentrations or the length of incubation time. This result was consistent with next result that the enhancement of glucose uptake could occur as early as 4 hours after the incubation in low glucose medium. To investigate if the enhance of glucose uptake was mediated by the activation of preexisting transporter, two different kinase inhibitors, SB202190 and wortmannin, were tested. SB202190 was efficient to block the hypoglycemia-induced enhancement of glucose uptake while wartmannin was not successful. This result implies that the signalling pathway from the hypoglycemia to the increase of glucose uptake includes p38MAPK and its upstream kinase, AMPK. The incubation of cells in low glucose medium increases the intracellular AMP and active form of p38MAPK, showing a maximum level at 1 hour. Taken together, these data suggest a signalling pathway for the hypoglycemia; a low glucose condition induces an enhancement in intracellular AMP level with the activation of AMPK, and then this in turn activates p38MAPK and finally glucose transporters.

1726 PHOSPHATIDYLSERINE IS REQUIRED ALONG WITH OXIDIZED PHOSPHOLIPIDS ON CELL SURFACE FOR SYNERGISTIC ENHANCEMENT OF PHAGOCYTOSIS BY MACROPHAGES.

V. A. Kini, Y. Y. Tyurina, G. G. Borisenko and V. E. Kagan. *EOH, University of Pittsburgh, Pittsburgh, PA.*

Externalization of phosphatidylserine (PS) from the inner to the outer leaflet of plasma membrane is a signaling event, which occurs during apoptosis. This signal triggers phagocytosis of apoptotic cells by macrophages. In our previous studies, we have demonstrated that execution of apoptotic program is accompanied by PS oxidation, which precedes externalization of PS and/or oxidized PS (PSox) indicating that PS oxidation stimulates its externalization. In this study, we showed that oxidized phospholipids such as oxidized phosphatidylcholine (PCox) and PSox can synergistically enhance phagocytosis of cells by the macrophage J774.A1 cell line. Liposomes containing PS and phosphatidylcholine (PC) in concentrations ranging from 1 nM to 150 nM were integrated into plasma membranes of HL-60 cells pretreated with N-ethyl maleimide an inhibitor of aminophospholipid translocase. Quantification of amounts of externalized PS/PSox was carried out using a sensitive EPR method based on the specific binding of paramagnetic annexin V-microbeads conjugates with PS on cell surface. We found that phagocytosis of PS-containing cells increased in a dose-dependant manner after a threshold. When PSox was integrated together with PS an almost 2-fold increase in the phagocytosis by macrophages was observed. Incubation of cells with liposomes containing PC or PC+PCox in the absence of PS did not cause any phagocytosis. When PCox was used in combination with PS, an increased phagocytosis was detected. Oxidized phospholipids appeared to decrease the threshold for recognition of target PS-containing cells by macrophages. Overall, these results suggest that PS is crucial for synergistically enhanced recognition of target cells in the presence of oxidized phospholipids. Supported by NIH HL 70755.

1727 P53 PHOSPHORYLATION REGULATES HYPOXIA-MEDIATED APOPTOTIC DEATH IN TUMOR CELLS.

A. Nieminen, E. Schneider and F. Agani. *Anatomy, Case Western Reserve University, Cleveland, OH.*

Tumor hypoxia develops in most solid tumors because of inadequate vasculature and abnormal vascular architecture. Frequently, these hypoxic cancer cells resist radiation and chemotherapy. The current study was undertaken to determine the regulation of p53 in hypoxic tumor cells. p53+/+ and p53-/- mouse embryonic fibroblasts (MEF) transformed with proto-oncogenes Ras and E1A were exposed to hypoxia for 0 to 7 h. Hypoxia increased total p53 protein levels after 2 h of hypoxia compared to normoxia. After hypoxia, 30 to 40% of total p53 protein was phosphorylated at Ser15 as assessed by Western blotting using a phospho-p53 (Ser15) specific antibody. No p53 phosphorylation was detected in normoxic cells. Hypoxia also activated the p53 responsive genes p21 and Bax and increased their protein levels. In addition, hypoxia up-regulated Mdm2 gene expression, a negative regulator of p53 as assessed by gene reporter assay. However, Mdm2 protein levels were only slightly increased during hypoxia compared to normoxia. Inhibition of the MAPK pathway by a specific inhibitor of MEK1, PD98059, increased caspase-3 activation and cell killing but decreased Mdm2 protein levels. This accelerated cell killing is likely due to decreased binding between p53 and Mdm2 proteins resulting in decreased degradation of p53 *via* proteasomes. Collectively, our results indicate that hypoxia induces p53 phosphorylation, increased p53 dependent Bax protein expression, caspase-3 activation, and apoptotic death. Supported by NS39469.

1728 MECHANISM-BASED COMPARISON OF *IN VITRO* AND *IN VIVO* CELL DEATH PATHWAYS IN RETINAL PHOTORECEPTOR CELLS EXPOSED TO THE 2-NITROIMIDAZOLE RADIOSENSITIZER, CI-1010.

T. J. Miller[1], L. A. Dethloff[2] and M. A. Philbert[1]. *[1]Environmental Health Sciences, University of Michigan, Ann Arbor, MI and [2]Pfizer, Inc., Ann Arbor, MI.*

CI-1010 ((R)-a([(2-bromoethyl)-amino]methyl)-2-nitro-1H-imidazole-1-ethanol monohydrobromide), a bifunctional nitroimidazole, produces selective, caspase-3 independent apoptosis in retinal photoreceptors, *in vivo*. The present study attempts to investigate mechanism(s) of CI-1010-induced photoreceptor cell death in the 661W photoreceptor cell line and *in vivo* retina. Cultured 661W cells treated with CI-1010 showed a dose-dependent decrease in viability determined using the MTT assay. Flow cytometry and western blot analysis revealed DNA fragmentation and PARP cleavage characteristic of apoptosis in 661W photoreceptor cells 48 h after exposure to 1 mM CI-1010. Caspase-3 activation, independent of caspase-8 and caspase-9 cleavage, was detected at 18 h, concomitant with decreased Bcl-xL and increased Bax expression. No change in protein expression of Fas and Fas ligand (FasL) was detected at any timepoint. Real-time confocal analysis and immunofluorescence of 661W cells showed retention of mitochondrial membrane potential and mitochondrial staining of cytochrome c up to 24 h following exposure. For comparison, retinas from adult C57BL/6 mice treated with a single intraperitoneal injection (1000 umol/kg) of CI-1010 were removed 6, 12, 18, and 24 h following treatment. Immunoblot analysis of CI-1010-treated retinas revealed activation of caspase-8 at 18 h in the absence of cleaved caspase-3, caspase-9, and PARP. No change in protein expression of Fas, FasL, Bcl-xL, Bax, and Bad, were detected by western blot at any timepoint. The pathway(s) leading to photoreceptor apoptosis *in vivo* after CI-1010 exposure requires further investigation. However, these results confirm activation of a caspase-3-independent pathway(s) of CI-1010-induced photoreceptor apoptosis *in vivo* and suggest that unidentified extrinsic signals may influence the activation of specific cell death pathway(s) in photoreceptors following exposure to CI-1010.

1729 BENZO(a)PYRENE 7, 8-DIHYDRODIOL-INDUCED APOPTOSIS IS AH RECEPTOR DEPENDENT AND REQUIRES MITOGEN ACTIVATED PROTEIN KINASES.

S. Chen[1], N. Nguyen[1], J. Park[1], M. Karin[1] and R. H. Tukey[1,2]. *[1]Department of Pharmacology, University of California, San Diego, La Jolla, CA and [2]Department of Chemistry & Biochemistry, Univerisity of California, San Diego, La Jolla, CA.*

Benzo[a]pyrene (BP) is a polycyclic aromatic hydrocarbon that is subject to metabolism and formation of BP-7, 8-dihydrodiol (BP-7, 8-diol) and BP-7, 8-dihydrodiol-9, 10-epoxide (BPDE). The formation of BPDE leads to apoptosis and cell death. To study the cellular events underling BP induced cell death, experiments were carried out with the two metabolic intermediates, BP-7, 8-diol and BPDE. BP-7, 8-diol, a non toxic metabolite in mutagenic assays, was found to initiate apoptosis in HepG2 cells, in part through activation of the dioxin or Ah receptor. The treatment of HepG2 cells with BP-7, 8-diol leads to cleavage of the cytosolic Bid protein, an increase in the pro-apoptotic Bak protein and a decrease in the anti-apoptotic Bcl-xl. BP-7, 8-diol initiated changes in the Bcl-2 family of proteins results in the release of cytochrome *c* from mitochondria. This triggers caspases activation and cleavage of caspases specific substrates, such as poly (ADP-ribose) polymerase (PARP-1). These changes in apoptotic markers may occur through CYP1A1 dependent metabolism of BP-7, 8-diol, since BP-7, 8-diol activates *CYP1A1* resulting in the accumulation microsomal CYP1A1. In HepG2 cells, BP-7, 8-diol and BPDE activate mitogen activated protein kinases (MAPKs) p38 and ERK1/2. MAPKs have been implicated in controlling cellular proliferation, apoptosis and death. Specific p38 and ERK1/2 inhibitors block apoptosis in HepG2 cells as monitored by caspases dependent cleavage of PARP-1. To investigate the specific role of MAPKs, mouse embryo fibroblasts deficient in p38 (p38-/-) were treated with BPDE and apoptosis monitored by Annexin V analysis and PARP-1 cleavage. Compared to wild type mouse embryo fibroblasts, p38-/- cells showed a greatly reduced apoptotic index. In addition, markers of apoptosis such as cytochrome *c* release from mitochondria confirmed that p38 plays an important role in BPDE initiated apoptosis. (Supported by ES10337).

1730 RESCUE OF CORTICAL NEURONS FROM CYANIDE-INDUCED APOPTOSIS: DEMANSTRATES BAX TRANSLOCATION IN THE APOPTOTIC PROCESS.

L. Li, K. Prabhakaran, J. L. Borowitz and G. E. Isom. *Medicinal Chemistry and Molecular Pharmacology, Purdue University, West Lafayette, IN.*

Cyanide produces an apoptotic death of cortical cells *in vivo*. To determine the time required to initiate apoptotic neuronal death, rat cortical cells were exposed to 300 μM cyanide for varying time (10 min to 8 h) followed by cyanide washout. Cells were then incubated for a total of 24 h and the level of apoptosis estimated by noting oligonucleosomal degradation of DNA on electrophoresis. Ten and 20 min exposures were insufficient to produce apoptosis, but a robust level of apoptosis was detected among the cell population after 30 min or longer. Similarly, translocation of Bax (determined by western blot analysis) from cytoplasm to mitochondria was seen after 30 min but not 10 or 20 min cyanide treatment. Cells exposed for 30 min to cyanide showed cytochrome c release from mitochondria 2 h later and caspase-3 activation after 8 h. Pretreatment of the cells with cyclosporin A blocked cytochrome c release and caspase activation, but not Bax translocation. Cyclohexemide, a protein synthesis inhibitor, blocked cyanide-induced Bax upregulation (cytoplasmic protein levels) but blocked neither Bax translocation to mitochondria nor cyanide-induced apoptosis. PBN, an antioxidant, inhibited Bax translocation, cytochrome c release and caspase-3 activation, as well as cyanide-induced apoptosis. It was concluded that treatment which inhibit Bax translocation (antioxidants) or inhibit the effects of Bax on mitochondria (cyclosporin A) also block apoptosis. Thus translocation of Bax from the cytoplasm to mitochondria occurs during a 30 min exposure of cortical cells cyanide and is a critical regulatory event in initiating subsequent apoptosis. (Supported by NIH grant ES04140).

1731 INHIBITION OF THE MITOCHONDRIAL PERMEABILITY TRANSITION IN THE MECHANISM OF HEAT SHOCK PROTECTION.

L. He and J. J. Lemasters. *Cell and Developmental Biology, Univeristy of North Carolina at Chapel Hill, Chapel Hill, NC.*

Heat shock proteins have been shown to inhibit apoptotic and necrotic cell death in various cell types after a variety of stresses. However, the specific mechanism underlying the protection by heat shock proteins remains unclear. To test the hypothesis that heat shock proteins inhibit cell death by suppressing the opening of mitochondrial permeability transition (MPT) pores, mitochondria from the livers of control and heat-preconditioned rats were isolated by differential centrifugation. Mitochondrial swelling was measured by absorbance change at 540 nm. Oxygen consumption was determined using a Clark type electrode. Membrane potential, Ca^{2+} uptake and reactive oxygen species formation was monitored using fluorescent dyes, TMRM, Fluo-5N and H_2DCFDA, respectively. Mitochondrial and cytosolic glutathione was measured using Bioxytech GSH-420 kit. Heat shock protein expressions were assessed using Western blot. Heat shock inhibited opening of regulated MPT pores induced by 200 μM $CaCl_2$ and by 50 μM $CaCl_2$ plus 5 μM $HgCl_2$ or 1 μM mastoparan. Half maximal swelling was delayed 15 min or more after heat shock comparison to the control. Heat shock also increased the threshold of unregulated (Ca^{2+}-independent and cyclosporin A-insensitive) MPT pore opening induced by $HgCl_2$ from 20 μM to 40 μM. Heat shock did not alter mitochondrial state 3 and state 4 respiration, respiratory control ratios, membrane potential, Ca^{2+}-uptake, or glutathione levels in mitochondria and the cytosol. However, mitochondrial formation of reactive oxygen species decreased 27% after heat shock. Western blot analysis showed that mitochondrial Hsp25 increased, whereas Hsp10, Hsp60, Grp75 and cyclophilin D did not change after heat shock. These results indicate that heat shock induces resistance to opening of MPT pores, which may con-

tribute to heat shock protection against cellular injury possibly through increased expression of mitochondrial Hsp25 and decreased formation of mitochondrial reactive oxygen species. Supported by NIH 1 P01 DK59340 and 5-R01 AG07218.

1732 EVALUATION OF DR5 MEMBRANE LOCALIZATION IN THE RODENT TESTIS USING FLOW CYTOMETRIC ANALYSIS.

Y. Chandrasekaran, C. J. Giammona and J. H. Richburg. *College of Pharmacy, The University of Texas at Austin, Austin, TX.*

Previous work by our laboratory has indicated that exposure of rodents to mono-(2-ethylhexyl) phthalate (MEHP) results in the up-regulation of the Fas receptor in testicular germ cells of rats and mice followed by an increase in the apoptotic cell death of these same cells. It has also been demonstrated that the initiation of germ cell apoptosis in MEHP-exposed rodents occurs, in part, due to the activation of the germ cell expressed Fas by Sertoli cell expressed Fas ligand (FasL). More recent research of our laboratory has revealed the presence of additional death receptors, DR4 and DR5, in the testis of C57 mice and in Sprague-Dawley rats. In the present study, we examined the membrane expression of DR5 on germ cells using both western blot analysis and flow cytometry as a first step in characterizing cell specific expression and responsiveness to toxicant exposure. Flow cytometric analyses indicates that multiple subpopulations (4n, 2n and 1n ploidy) of testicular cells stain positive for DR5. Flow cytometry and associated cell sorting along with immunohistochemistry further revealed that 1) approximately 20% of the 1n population (representing the haploid round and elongated spermatids) possessed DR5 on the membrane; 2) between 10-30% of the 4n cell population stained positive with the vast majority of these being spermatocytes; and 3) the 2n population appears to be a mixture of germ and somatic cells. In addition, gld mice, which express a dysfunctional form of FasL, display higher levels of DR5 on germ cell membranes of 4n cells than do C57 mice, as well as greater total receptor levels. Western blot analysis of C57 mice testes revealed an increased DR5 expression on the germ cell membrane after MEHP exposure. In summary, our findings suggest that DR5 is expressed by germ cells, DR5 levels are higher in animals lacking a fully functional Fas system, and that DR5 is responsive to MEHP-induced testicular injury. (This work was supported, in part, by NIH/NIEHS grants ES09145 and ES07784).

1733 THE EXPRESSION OF TNF-RELATED APOPTOSIS INDUCING LIGAND (TRAIL) IN RODENT SERTOLI CELLS.

Y. Ye, C. J. Giammona, P. Sawhney and J. H. Richburg. *College of Pharmacy, The University of Texas at Austin, Austin, TX.*

TRAIL is a member of the TNF family of ligands. TRAIL binds to the death receptors TRAIL-R1 (DR4) and TRAIL-R2 (DR5). The expression of TRAIL has been observed in many normal tissues. TRAIL has also been found to induce apoptosis in many tumor cell lines. However, only a limited number of non-transformed cell lines have been reported to undergo apoptosis after TRAIL addition. Recent reports have described the presence of TRAIL mRNA in testis. Investigations have also suggested that TRAIL protein is exclusively localized to select subpopulations of germ cells in the rat testis. In the present study we evaluated the expression of TRAIL in primary cultures of enriched rat and mouse Sertoli cells as well as in the mouse-derived TM4 Sertoli cell line. Western blot analyses demonstrate that TRAIL protein is expressed in TM4 cells as well as in enriched cultures of mouse and rat primary Sertoli cells. Immunohistochemical analysis of rat testis reveals that TRAIL protein was localized to both Sertoli cells and germ cells. These results were further confirmed in primary cultures of rat or mouse Sertoli cells and germ cells. In addition, TRAIL mRNA was measured in TM4 cells by RT-PCR. These observations indicate, for the first time, that Sertoli cells of the testis express both TRAIL mRNA as well as TRAIL protein in relatively abundant levels. (Supported, in part, by grants from NIH/NIEHS ES09145 & ES07784).

1734 ORGANIC ANION TRANSPORT INHIBITORS ATTENUATE GLUTATHIONE RELEASE DURING FAS-MEDIATED APOPTOSIS IN HEPG2 CELLS.

C. L. Hammond, M. S. Madejczyk and N. Ballatori. *Environmental Medicine, University of Rochester, Rochester, NY.*

In experimental models of apoptosis, reduced glutathione (GSH) appears to be selectively released from cells leading to cellular GSH depletion. Because GSH has many protective functions in the cell, GSH depletion may contribute to cellular demise. However, neither the mechanism of GSH release during apoptosis, nor its physiological significance has been elucidated. In the present study, the mechanism of GSH release was characterized in HepG2 cells induced to undergo apoptosis by 0.5 μg/mL Fas Ab and 20 μg/mL cyclohexamide (CHX). Approximately 50% of total GSH was released from cells treated with Fas and CHX, whereas untreated cells released 20% GSH over 5 hours. Fas and CHX-treated HepG2 cells showed increased caspase 3-like activity and apoptotic nuclear morphology, but minimal propidium iodide incorporation, suggesting that the cells are apoptotic and that plasma membrane damage is minimal. These results support the hypothesis that GSH is released through a specific transport mechanism. HepG2 cells were also treated with the organic anion transport inhibitors sulfinpyrazone, MK571, probenecid, and dibromosulfophthalein (DBSP) to examine the effects on GSH release and apoptosis. All four compounds inhibited basal GSH release, however only probenecid and DBSP inhibited the Fas and CHX-stimulated GSH release. Inhibiting GSH release with probenecid and DBSP also attenuated lactate dehydrogenase release. These results indicate that GSH release during apoptosis occurs through a different mechanism than basal GSH release. Because sulfinpyrazone and MK571 are known to inhibit the MRP proteins, the GSH release is probably occurring by a mechanism distinct from MRP proteins. In summary, Fas ligand-stimulated GSH efflux is inhibited by the organic anion transport inhibitors probenecid and DBSP, indicating a carrier-mediated GSH export pathway. Inhibition of GSH efflux was protective, suggesting that GSH extrusion may contribute to the cell death process. (Supported by NIH grants ES06484, DK48823, ES01247 and ES07026)

1735 VITAMIN E INDUCED CASPASE-8 MEDIATED APOPTOSIS OCCURS INDEPENDENTLY OF DEATH RECEPTOR ACTIVATION IN NEOPLASTIC MAMMARY EPITHELIAL CELLS.

S. Shah and P. W. Sylvester. *Pharmaceutical Sciences, University of Louisiana at Monroe (ULM), Monroe, LA.*

Tocotrienols, a subclass of vitamin E compounds, have been shown to suppress mammary tumorigenesis in animal models and inhibit growth of human breast cancer cells in culture. Tocotrienols have also been shown to induce apoptosis in neoplastic mouse mammary epithelial cells, by mechanisms not yet determined. Studies were conducted to determine the intracellular pathways mediating tocotrienol-induced apoptosis in neoplastic +SA mouse mammary epithelial cells. Following 24 hr treatment with γ-tocotrienol, there was a dose-dependent decrease in +SA cell viability resulting from induction of apoptosis. Cell viability studies were performed by MTT assay, and apoptosis induction was detected by TUNEL assay. Additional studies showed that treatment with a cytotoxic dose of 20 μM γ-tocotrienol increased caspase-8 and caspase-3 activity, as measured by colorimetric assay kits. Furthermore, treatment with specific caspase-8 or -3 inhibitor completely blocked the tocotrienol-induced apoptosis in +SA cells. Since activation of death receptors (Fas or TRAIL receptors) is required for the induction of caspase-8 activity and apoptosis, further studies were conducted to determine the exact death receptor(s) and ligand(s) involved in tocotrienol-induced apoptosis. Treatment for 24 hrs with Fas-ligand, Fas-activating antibody, or TRAIL had no effect on +SA cell viability. Moreover, treatment with 20 μM γ-tocotrienol for 0-24 hrs did not alter the total cellular or membrane levels of Fas-receptor or Fas-ligand. Western blot analysis also showed that γ-tocotrienol did not induce translocation of Fas-ligand from the cytosol to the membrane. Finally, 24 hr treatment with Fas-blocking antibody did not reverse the tocotrienol-induced apoptosis in +SA cells, indicating that tocotrienols do not activate these death receptors. In summary, these findings suggest that tocotrienol-induced activation of caspase-8 mediated apoptotic pathways in neoplastic +SA mouse mammary epithelial cells occurs independently of death receptor activation.

1736 1, 2, 3, 4-DIEPOXYBUTANE INDUCES P53 DEPENDENT APOPTOSIS IN HUMAN LYMPHOBLASTS.

S. Seemanapalli and P. M. Muganda. *Environmental Toxicology Ph.D Program, Southern University, Baton Rouge, LA.* Sponsor: F. Spencer.

1, 3-Butadiene (BD) is used in the manufacture of styrene-butadiene rubber, and is prevalent in petrochemical industrial areas. This compound is a known mutagen and human carcinogen, and possesses multi-organ systems toxicity that includes bone marrow depletion, spleen and thymus atrophy. Toxic effects of BD are mediated by its epoxy metabolites, 1, 2-epoxybutene (EB), 1, 2, 3, 4-diepoxybutane (DEB), and 1, 2-epoxy-3, 4-butanediol (EBD). The molecular mechanism(s) of BD toxicity however, are not fully understood. In working towards elucidating the cellular and molecular mechanisms of BD toxicity, we investigated the ability of the most potent BD metabolite, DEB, in inducing apoptosis in human TK6 lymphoblasts, as well as the role of the cellular p53 protein in that process. The tumor suppressor p53 protein is known to mediate cellular responses to environmental stress and DNA damage in a variety of systems. Using variety of assays (nuclear fragmentation, DNA ladder and Poly[ADP-ribose]polymerase cleavage), our results demonstrated concentration-dependent and time-dependent apoptosis in DEB exposed human TK6 lymphoblasts. DEB concentrations of 5μM induced apoptosis

in 28% of the cells at 48h post-exposure; under these conditions, control cells exposed to vehicle only did not show any features of apoptosis. The induction of apoptosis by DEB correlated to elevated p53 levels in the same cells in a concentration and time dependent manner. Although DEB-induced apoptosis was observed in the p53 proficient TK6 lymphoblasts, it failed to occur in the p53 deficient NH32 lymphoblasts under the same experimental conditions. Our results demonstrate the occurrence of DEB-induced apoptosis in human lymphoblasts for the first time. In addition, our results reveal that DEB-induced apoptosis is mediated by the tumor suppressor p53 protein. Collectively, this DEB-induced p53 mediated apoptosis may explain butadiene induced bone marrow depletion, as well as spleen and thymus atrophy in exposed animals(supported by grant# ES10018, funded by NIEHS).

1737 THE ROLE OF TNF-α RECEPTOR 2 IN BLEOMYCIN-INDUCED APOPTOSIS IN ALVEOLAR MACROPHAGES.

H. W. Zhao[1], S. Y. Hu[2], M. W. Barger[1], J. K. Ma[2], V. Castranova[1] and J. Y. Ma[1]. *[1]HELD, NIOSH, Morgantown, WV and [2]School of Pharmacy, WVU, Morgantown, WV.*

Activation of alveolar macrophages (AM) in the production of tumor necrosis factor (TNF)-αby bleomycin (BLM) is linked to AM apoptosis and the development of pulmonary fibrosis. AM may contribute to their own death through expression of TNF receptor (TNFR) 1 and 2. The present study was carried out to characterize the role of the TNFR in the mechanism(s) of BLM-induced apoptosis in AM. Sprague-Dawley rats were instilled intratracheally with saline or BLM at 1 mg/kg body weight. At 1, 3, or 7 days post-exposure, AM were isolated by bronchoalveolar lavage, and apoptosis was determined by ELISA. The activation of caspases 3, 8, and 9, the release of cytochrome c from mitochrondria, the cleavage of nuclear poly(ADP-ribose) polymerase (PARP), and the amount of TNFR1 and TNFR2 in AM were monitored by immunoblotting. The results showed that BLM treatment significantly induced AM apoptosis at all exposure time points, with peak apoptosis occurring at 1 day post BLM exposure. BLM treatment, at 1, 3 or 7 days post exposure, significantly increased active caspase 3 level with enhanced caspase 3 activity and increased PARP cleavage in AM in comparison to the control. The maximum activation of caspase 3 and PARP fragmentation occurred in AM from rats exposed to BLM for 3 days. The amount of cytochrome c released into cytosol was gradually increased with time after BLM treatment and peaked on day 7. This coincides with expression of TNFR2, which was significantly induced in BLM-exposed AM with a peak level at 7-day post exposure. In contrast, BLM treatment did not affect AM expression of TNFR1. BLM exposure also significantly activated caspase 9 but not caspase 8 in AM. These results show that BLM-induced apoptosis is TNFR1/caspase-8 independent, but involves over-expression of TNFR2, the release of cytochrome c from mitochondria, activation of caspases 9 and 3, and the cleavage of the DNA repair protein PARP.

1738 APOPTOTIC ALVEOLAR MACROPHAGES PLAY A ROLE IN THE DEVELOPMENT OF PULMONARY INFLAMMATORY DISEASE IN RATS.

L. Wang[1], J. Scabilloni[1], J. Antonini[1], Y. Rojanasakul[2], V. Castranova[1], B. Lu[2] and R. R. Mercer[1]. *[1]PPRB, NIOSH, Morgantown, WV and [2]West Virginia University Health Sciences Center, Morgantown, WV.*

Increasing evidence suggests that apoptosis plays an important role in pulmonary diseases; however, the molecular mechanism underlying this relationship is unclear. Previous studies from our laboratory have shown that pulmonary instillation of dimethyl sulfoxide (DMSO) induced apoptotic alveolar macrophage (AM) resulted in pulmonary inflammation and fibrosis. In this study, we further investigated the effect of intratracheal instillation of DMSO or UVB induced apoptotic AM and documented the time course of the resulting inflammatory and fibrotic responses in the Brown Norway rat lung. Morphological and immunohistochemical analyses of lung tissues showed an inflammatory response and increased connect tissue in the treatment groups, but not in control groups which were instilled with normal non-apoptotic AM. Instilled apoptotic cells were cleared at 4 weeks post-treatment, but the number of apoptotic lung cells was still higher than those in the control rats. Caspase 8 was elevated in the treatment group at 4 weeks post-treatment, suggesting a continuous induction of apoptosis *in vivo* via the death receptor-mediated pathway. Consistent with this finding, we observed a concomitant increase in TNF-α expression in treated lung tissues. *In vitro* studies also showed an increase in TNF-α production by naive AM incubated with apoptotic AM, but not when exposed to untreated AM. Together, our results indicate a role for AM apoptosis in the induction of inflammatory and fibrotic lung disorders, which may be mediated though cytokines, such as TNF-α.

1739 C2-CERAMIDE *VS.* TNF-α INDUCED CYTOTOXICITY AND APOPTOSIS IN A RAT HEPATOMA (H4IIE) CELL LINE.

J. F. Pregenzer, P. C. Wilga, D. K. Petrella, R. K. Patel and J. M. McKim, Jr.. *Investigative Toxicology, Pharmacia, Kalamazoo, MI.*

Understanding the various mechanisms of cellular toxicity and cell death can aid in drug design. Previously, we noted that TNF-α and C2-ceramide produced different toxicity and apoptosis profiles in rat hepatoma (H4IIE) cells. Tumor necrosis factor alpha (TNF-α) is a cytokine involved in certain apoptotic pathways and can stimulate the hydrolysis of sphingomyelin to ceramides. Ceramides are putative lipid second messengers implicated in apoptotic responses. In this study, the effects of TNF-α and ceramide on toxicity and apoptosis were investigated in H4IIE cells using multiple biochemical markers. H4IIE cells were exposed to ceramide (0-300 μM) or TNF-α (0-150 ng/mL, specific activity 1000 University/ng) for 24 hours. Changes in general cell health were determined by monitoring mitochondrial function, membrane leakage, and cell proliferation. Oxidative stress was assessed by measuring changes in reduced glutathione (GSH) and membrane lipid peroxidation. Apoptosis was evaluated by caspase (3, 8, and 9) activity, DNA fragmentation, and using a Cellomics™ ArrayScan®: mitochondrial mass potential, f-actin levels, and nuclear condensation/fragmentation. Cellular calcium changes were measured for up to 2 hours after treatment using Fluo3-AM dye and fluorescence microscopy or a Molecular Devices FLIPR system. As expected, TNF-α caused a marked increase in caspase 3, 8, and 9 activities as well as DNA fragmentation and f-actin content. TNF-α was cytotoxic above 5ng/mL, however, no significant change was observed in GSH or in membrane lipid peroxidation prior to toxicity. In contrast, ceramide caused a significant increase in membrane lipid peroxidation and DNA fragmentation but had no effect on caspase 3, 8, and 9 activities. Ceramide increased intracellular calcium levels while TNF-α did not produce significant calcium influx. These data suggest that apoptosis induced by TNF-α occurs through caspase dependent pathways whereas exogenous C2-ceramide induced cell death involves calcium influx, oxidative stress, or other caspase independent pathways.

1740 MECHANISMS OF OCHRATOXIN A-INDUCED INHIBITION OF HUMAN LYMPHOCYTE PROLIFERATION.

H. Assaf[1,2], H. Azouri[2] and M. Pallardy[1]. *[1]Faculty of Pharmacy, INSERM U461, Châtenay-Malabry, France and [2]Faculty of Pharmacy, Laboratory of Toxicology, Beyrouth, Lebanon.*

Ochratoxin A (OTA) is a fungal secondary metabolite produced in agricultural commodities by Aspergillus and Penicillium fungi species. Human exposure to OTA is both due to consumption of directly contaminated food or of food products derived from animals consuming contaminated feedstuffs. OTA was implicated in the pathogenesis of Balkan endemic nephropathy due to its nephrotoxicity ; in addition, it is hepatotoxic, genotoxic, carcinogenic and immunosuppressive. This latter toxicity has been widely studied in experimental animals such as mice and chickens. In this study, we investigated the effects of OTA on human peripheral blood mononuclear cells (PBMC). PBMC stimulated with phytohaemagglutinin (PHA) and incubated with OTA at different concentrations for 48 h showed an inhibition of proliferation at $5x10^{-6}$ M and 10^{-5} M of OTA as measured by ^{3}H-thymidine uptake. However, IL-2 secretion was not affected for all concentrations tested as determined by ELISA. In addition, exogenous IL-2 added to cell culture at 1 and 10 ng/ml did not overcome the inhibition of lymphocyte proliferation. A slight decrease in CD25 (IL-2R alpha) surface expression at $5x10^{-6}$ M of OTA was observed compared to control cells (60 vs 73 % and 47 vs 72 % at 24 h and 48 h respectively). Moreover, stimulated and unstimulated PBMC incubated with OTA entered apoptosis in a time and concentration-dependent manner. The mechanism is likely to be mediated by caspases since the pan-caspase inhibitor VAD reduced apoptosis induced by OTA. Our results suggest that downregulation of CD25 and induction of apoptosis are involved in OTA inhibition of lymphocyte proliferation. The role of cell cycle proteins such as cdk2 and cyclin E, as well as Bcl-2 family proteins, are currently under investigation.

1741 CHANGES IN LYMPHOCYTE SUBSETS AND APOPTOSIS IN LYMPHOID TISSUES OF NIVALENOL-TREATED MICE.

A. Poapolathep[1], T. Nagata[1], Y. Sugita-Konishi[3], S. Kumagai[2] and K. Doi[1]. *[1]Department of Vet. Pathol., The University of Tokyo, Tokyo, Japan, [2]Division of Microbiol., National Inst. of Health Sciences., Tokyo, Japan and [3]Department of Vet. Public Health, The University of Tokyo, Tokyo, Japan.* Sponsor: K. Ebino.

Nivalenol (NIV) is the major group B trichothecene mycotoxin and NIV widely contaminates agricultural commodities. In this study, ICR mice were orally administered with 15 mg/kg of NIV to elucidate the development of apoptosis and

changes in lymphocyte subsets in lymphoid tissues. The TUNEL-positive cells showing ultrastructural characteristics of apoptosis, were observed in lymphoid tissues, and the ladder pattern was detected by agarose gel electrophoresis on DNA extracted from thymus. Moreover, FACS analysis revealed that NIV attacked Peyer's patches first and thymus most severely, and the selective damage in CD4+CD8+ cells in thymus while CD4+ and CD8+ cells were unexceptionally reduced in other lymphoid tissues. As to B cell subsets, all B cell subsets, especially IgA+ cells showed significant increase in Peyer's patches while B cell subsets generally decreased in spleen and mesenteric lymph nodes. These results indicate that NIV induces apoptosis and changes in lymphocyte subsets in lymphoid tissues of mice.

1742 EFFECTS OF T-2 TOXIN ON KERATINOCYTE PRIMARY CULTURES.

S. M. Albarenque, K. Suzuki, H. Nakayama and K. Doi. *Veterinary Pathology, The University of Tokyo, Tokyo, Japan.*

T-2 Toxin (12-13 epoxytrichothecene mycotoxin) induces apoptosis in basal keratinocytes when topically applied on the dorsal skin of Wistar-derived WBN/ILA-*Ht*rats. In the present study, effects of T-2 toxin on keratinocyte primary cultures were examined. Cells which were obtained from newborn Wistar rats and cultured by the method of Reynwald and Green were used after the third passage. Keratinocyte medium containing 0.25μg/ml of T-2 Toxin dissolved in DMSO or solvent alone was added to four-days-cultures and incubated at 37°C. At 0.5, 1, 3, 5, 7, and 9 hours after treatment (HAT), feeder layer was separated from T-2 toxin-treated and control flasks, and cells were trypsinized. Cell viability was estimated by trypan blue exclusion method. In addition, RNA was obtained and RT-PCR was perfomed. Samples obtained from slides cultures at 3, 6, 9 and 12HAT were fixed in 4% paraformaldehide or 2.5% glutaraldehide for morphological studies. After T-2 toxin application, cell viability decreased to 40% at 12HAT. Pyknotic and karyorrectic nuclei with shrinkage of cell body were found in small keratinocytes at 6HAT, and there number increased until 12HAT. At the same points, large squamous keratinocytes showed degeneration characterized by intracytoplasmic edema. The number of PCNA-positive cells dramatically decreased from 3 to 12 HAT. Apoptosis related genes expression (*c-fos* and *c-jun* oncogenes) and cytokines (TNF-α) mRNA expression markedly increased at 0.5 HAT and drecreased thereafter. These findings were also observed in our previous *in vivo* studies suggesting that *c-fos* and *c-jun* oncogenes and TNF-α have some relation to the mechanisms of wich T-2 toxin-induced apoptosis in basal keratinocytes.

1743 SUBCYTOTOXIC INORGANIC ARSENIC AFFECTS MITOCHONDRIA IN HK-2 HUMAN PROXIMAL TUBULAR CELLS: POTENTIAL FOR APOPTOTIC CELL DEATH.

M. A. Peraza, D. E. Carter and A. Gandolfi. *Pharmacology and Toxicology, University of Arizona, Tucson, AZ.*

The kidney is a known target organ for arsenic (As) and is critical for both As biotransformation and elimination. Previous studies have demonstrated that at high doses (ppm) inorganic As is toxic to mitochondria primarily by affecting cellular respiration. However the effect of As on mitochondria after low level exposures is not known, particularly in the kidney. Thus the mitochondrial toxicity of low level inorganic As was investigated in a human proximal tubular cell line, HK-2. Subcytotoxic concentrations of arsenite (1-10 μM) and arsenate (<25 μM) were found to affect MTT processing by mitochondria in the HK-2 cells. Therefore, even at low concentrations, the mitochondria are a primary target for inorganic As toxicity. Mitochondrial injury was further assessed by examining the alteration of the mitochondrial membrane potential using Mito Tracker Red, a mitochondrion selective dye, with detection of staining by confocal microscopy. Mitochondrial staining was punctate in untreated cells, indicative of selective uptake by actively respiring mitochondria. Following 24 h exposure to As concentrations as low as 100 nM, changes in the membrane potential were evident by alterations in staining patterns. Fluorescence became more intense and eventually more diffuse throughout the cytoplasm with concentrations in the μM range. In general, arsenite effects were seen at a lower concentration than for arsenate, which confirms data from the MTT studies. Disruption of mitochondrial membrane potential by low-level inorganic As exposure could initiate cell death *via* apoptosis. To determine apoptosis, the presence of plasma membrane phosphatidyl serine was measured by Annexin-V-FLUOS labeling with detection by fluorescence microscopy. Apoptotic cells were observed with 100 nM arsenite exposures and a concentration-response increase was seen up to 10 μM. Therefore, the induction of apoptosis *via* the action of low-level As on mitochondria could contribute to the pathogenesis of renal tubular injury. (NIH Superfund ES 04940)

1744 ARSENITE STIMULATES APOPTOSIS IN MYELOID LEUKEMIA CELLS DURING G2/M PHASE.

G. McCollum and M. J. McCabe. *Department of Environmental Medicine, University of Rochester, Rochester, NY.*

Arsenic, notorious for its toxic and carcinogenic properties, may also be effective in the treatment of a variety of cancers. Arsenite (As(III)) is thought to be the most bioactive form of arsenic. As(III) is cytostatic and induces apoptosis in the myeloid leukemia cell line U937. We used analysis of 5-bromo-2′-deoxyuridine (BrdU) incorporation together with propidium iodide (PI) staining to test the hypothesis that As(III) induces apoptosis in G2/M phase cells. U937 cells were exposed to $NaAsO_2$ (0-10 μM) for 24-48 h and pulsed with BrdU for 15 min. Anti-BrdU labeling and PI staining were measured *via* flow cytometry. As(III) induced apoptotic DNA degradation in cells with G2/M DNA content as shown by the dose-dependent appearance of a population of BrdU-negative cells with sub-G2 DNA content. This population represents cells triggered by As(III) to undergo apoptosis after entering G2/M phase. These cells do not stain with BrdU, so although they have an S phase DNA content, they are not active S phase cells. Therefore, it may not be possible to define the cell cycle status of cells with S phase DNA content by PI staining alone. To clarify the source of the sub-G2 cell population, we used a BrdU pulse-chase technique. Following a 15 min pulse with BrdU, cells were treated with $NaAsO_2$ (0-10 μM) for 0-24 h. Cells were assayed as described above. A distinct population of BrdU-positive cells with G1 DNA content developed in untreated samples after 8 h, indicating that these cells have moved from S phase through G2/M phase and back to G1. The hypothesis that As(III)-treated cells undergo apoptosis during G2/M phase predicts that fewer cells will transit from S phase through G2/M to G1. Indeed, the population of BrdU-positive cells with G1 DNA content decreases in a dose-dependent manner with As(III) treatment. Also, As(III)-treated BrdU-positive cells undergo DNA degradation only after they attain G2/M DNA content. We conclude that As(III) targets U937 cells for apoptosis during G2/M phase. Supported by NIH grants P30 ES01247 and T32 ES07026.

1745 COPPER-INDUCED CASPASE-3 ACTIVATION AND APOPTOSIS IN RAT HEPATOMA CELL LINE (H4IIE).

R. Nino-Fong[1], C. Fuentealba[1], A. Cribb[2], B. P. Esparza-Gonzalez[1] and M. Cherian[1]. *[1]Pathology, University of Western Ontario, London, ON, Canada and [2]Anatomy and Physiology, University of Prince Edward Island, Charlottetown, PE, Canada.*

Increased hepatic copper (Cu) accumulation in Wilson's disease and Indian Childhood Cirrhosis cause severe liver damage. Although these changes can result in cirrhosis and hepatocellular carcinoma, the mechanisms involved in the pathogenesis of Cu-induced damage are not well understood. In order to study the initial changes on Cu-induced DNA damage and apoptosis, the present study was undertaken in rat hepatoma cell line (H4IIE) after exposure to Cu salts (250 to 1000 μM). The cell viability was not affected at 8 hrs of Cu exposure but was markedly reduced at 12 hrs with Cu concentration >750 μM. More apoptotic cells were observed by TUNEL staining at 8 hrs of exposure to Cu (> 500 μM) than control cells. This was confirmed by changes in DNA ladder formation. TNF alpha was not detected in the cells. There was an increase in Caspase-3 activity at 4 hrs of incubation with more than 750 μM of Cu exposure. The results suggest that Caspase-3 activation is an early event in Cu-induced injury *in vitro*. Therefore, Caspase-3 activation plays an important role in the Copper induced apoptosis. (Supported by a Grant from CIHR).

1746 EFFECTS OF DIETHYDITHIOCARBAMATE (DDC) ON RAT HIPPOCAMPAL ASTROCYTES ON CASPASE-1, C-MYC, BCL-2 AND P53 WITH AND WITHOUT GLUTATHIONE (GSH).

L. D. Trombetta and J. A. Mlockier-Audrain. *St John's University, Jamaica, NY.*

Diethyldithiocarbamate (DDC), a potent metal chelator, is a carbamate derivative. It has been documented that DDC binds and redistributes copper in a lipophilic complex to the central nervous system. Apoptosis is a morphologically defined process in which cells die in a controlled manner. Previously, we have demonstrated by TUNEL and DNA laddering techniques that 35 μg/ml and 350 μg/ml DDC induced apoptosis or programmed cell death in rat hippocampal astrocytes treated for 1hr. Caspase-3 was also shown to be induced. This study investigates the activation of 4 apoptotic genes in astrocytes, caspase-1, c-myc, bcl-2 and p53, following the recovery from DDC treatment with and without glutathione (GSH). Caspase-1 belongs to the cysteine protease family and plays a major role in apoptosis. It mediates inflammatory response through cleavage activation of IL-1β and IFN-γ promolecules. c-myc is a proto-oncogene documented to play a role in the induction of apoptosis. Bcl-2 blocks cell death following a variety of stimuli. Induction of p53 protein expression is usually considered as one of the primary events involved in the

apoptotic reaction cascade following DNA damage. Rat hippocampal astrocytes grown in Dulbecco's modified Eagle's essential media were treated with 35 and 350 μg/ml DDC at subconfluency for 1 hr. Astrocytes were then left to recover with or without 10mM glutathione in DMEM for 24 hr at which time cells were collected for RT-PCR. Caspase-1 was significantly activated in astrocytes treated with 35 and 350 μg/ml DDC in a dose dependent manner. Glutathione post-treatment prevents the activation of caspase-1 in both treatment groups. c-myc was significantly induced but not in a dose dependent manner. Bcl-2 and p53 did not show any significant induction or inhibition of apoptosis.

1747 EFFECT OF ACUTE MERCURY VAPOR EXPOSURE TO MURINE THYMUS.

M. Sawada[1], Y. Sunagawa[1], A. Shimada[1], T. Morita[1] and M. Yoshida[2]. *[1]Department of Veterinary Pathology, Tottori University, Tottori, Japan and [2]Department of Chemistry, St. Marianna University, Kawasaki, Japan.*

Elemental mercury is a toxic metal which causes various health effects. Acute poisoning causes pulmonary damage that is characterized by edema and hyaline membrane formation. However, toxic effects of mercury vapor *in vivo* on immune system are not well understood. Therefore, this study was performed to examine the *in vivo* toxic effect of mercury vapor exposure to thymus. Sixteen C57BL/6J Jcl mice were exposed to mercury vapor at 2.71 to 3.74 mg/m^3 for 1 hour. Mice were killed under diethylether anesthesia at 24 hours after exposure. The liver, spleen, kidney, heart, lung, brain and thymus were taken from each mouse. Histopathological examinations including autometallography for mercury distribution were performed. Mercury concentrations in the lung, thymus, kidney, brain and liver were measured by cold vapor atomic absorption method. The highest mercury concentrations were detected in the kidney, followed by the lung. Mercury concentration in the thymus was not significantly different from that in the liver. Mercury granules were demonstrated in the histological sections of the all organs examined. In the thymus, mercury granules were seen in the phagocytic cells and vascular endothelial cells. Histopathological changes were restricted to the lung and thymus. In the lung, mild inflammation and edema were observed. In the thymus, there was an increase of the number of phagocytic cells containing apoptotic lymphocytes compared with control mice. Agarose gel electrophoresis of the thymuses showed a ladder pattern that indicating the presence of fragmented DNA. These results suggest that apoptosis of lymphocytes may be caused by the mercury vapor in the thymus. Mechanisms of apoptosis induced by mercury vapor are to be elucidated.

1748 POSSIBLE INVOLVEMENT OF CALPAIN/P35/CDK5 CASCADE IN METHYLMERCURY-INDUCED DEATH OF CEREBELLAR NEURONS.

M. Kunimoto, M. Okazaki and M. Sakaue. *Kitasato University School of Pharmaceutical Sciences, Minato-ku, Tokyo, Japan.* Sponsor: N. Imura.

It has been shown that methylmercury-induced death of cerebellar granule neurons is apoptotic both *in vitro* and *in vivo* (Kunimoto (1994) Biochem Biophys Res Comm. 204, 310-317: Nagashima et al (1996) Acta Neuropathol 91, 72-77). To clarify the molecular mechanism for the induction of apoptosis in cerebellar neurons by methylmercury, several lines of experiments have been performed using rat cerebellar neurons in primary culture. Cerebellar neurons prepared from neonatal rats were exposed to methylmercury at very low concentrations (up to 30nM) *in vitro* and possible involvement of calpain/p35/cdk5 cascade in the death process was examined, since the cascade is shown to be activated during the neuronal death in Alzheimer?s disease. Calpain inhibitor and cdk5 inhibitor (butyrolactone I) were both effective in preventing or delaying the methylmercury-induced death of cerebellar neurons. In addition, 440 kD ankyrinB, an axonal protein and a substrate for calpain, was degraded in the cerebellar neurons treated with methylmercury. These results suggest that methylmercury-induced activation of calpain plays important role in the death process of cerebellar neurons.

1749 TRAIL AND DEATH RECEPTOR RESPONSE IN RODENT TESTIS AFTER CISPLATIN EXPOSURE.

P. Sawhney, C. J. Giammona, F. C. Seaman, Y. Ye and J. H. Richburg. *College of Pharmacy, The University of Texas at Austin, Austin, TX.*

Testicular germ cell tumors are extremely vulnerable to elimination by cisplatin-based chemotherapeutics. Non-cancerous germ cells are also sensitive to cisplatin and undergo apoptotic death following chemotherapy. However, the mechanism(s) responsible for initiating apoptosis in germ cells is still unclear. Here, we evaluate the response of death receptors and their cognate ligands in the testis following cisplatin treatment and analyze the correlations between death receptor changes and our previously reported massive apoptotic die-off of germ cells. Adult (11wk) C57/BL/6 mice were exposed to a single acute dose of cisplatin (5 mg/kg I.P.). Western blots from testis homogenates revealed a marked increase in membrane levels of DR4, DR5 and TRAIL by 3 h after cisplatin exposure. Exposure the TM4 Sertoli cell line to 150 micromolar cisplatin demonstrated increased levels of TRAIL by western blot analysis similar to those seen *in vivo*. Alterations in TRAIL protein expression were not observed in the F9 germ cell line. Pro-caspase-8 processing was also observed *in vivo* and in F9 cells after cisplatin treatment. Immunohistochemical analysis of frozen rat testis cross-sections suggests membrane localization of TRAIL in both Sertoli cells and germ cells and localization of the death receptors DR4 and DR5 in germ cells alone. Finally, an increase in NF-κB DNA binding activity was seen in both TM4 and F9 cells following cisplatin treatment. Up-regulation of DR5 occurs in germ cell concomitantly with TRAIL up-regulation in Sertoli cells. These data suggest that TRAIL-dependent signaling in germ cells is regulated by Sertoli cells in response to cisplatin treatment. Whether this pathway is an active participant in germ cell apoptosis or elicits another response in germ cells remains to be tested. (Supported, in part by grants from NIH/NIEHS ES09145, ES07784 and from the Lance Armstrong Foundation).

1750 6(5*H*)-PHENANTHRIDINONE ATTENUATES THE HEPATOTOXICITY OF CARBON TETRACHLORIDE.

T. Stedeford[1,2,4], M. Banasik[1,4], P. Su[1], D. I. Mosquera[2], C. Muro-Cacho[3], J. Sanchez-Ramos[2,5] and R. D. Harbison[1]. *[1]Department of Environmental and Occupational Health, University of South Florida, Tampa, FL, [2]Department of Neurology, University of South Florida, Tampa, FL, [3]Department of Interdisciplinary Oncology, H. Lee Moffitt Cancer Center and Research Institute, Tampa, FL, [4]ICC, Polish Academy of Sciences, Gliwice, Poland and [5]Research Services, James A. Haley Veterans' Hospital, Tampa, FL.*

Carbon tetrachloride (CCl_4) is routinely used as a model for eliciting centrilobular (zone 3) hepatotoxicity. CCl_4 is bioactivated to the trichloromethyl radical, which causes extensive lipid peroxidation, and ultimately cell death by necrosis. Poly(ADP-ribose) polymerase-1 (PARP-1) is a nuclear enzyme involved in the identification of DNA strand termini. Extensive cellular damage can overactivate PARP-1, which rapidly depletes the cellular stores of NAD^+ and ATP, resulting in necrotic cell death. The purpose of the present study was to determine whether 6(5*H*)-phenanthridinone (10 mg/kg, i.p.), a potent inhibitor of PARP-1, could attenuate the toxicity of CCl_4 (572 mg/kg, i.p.; LD_{50}) in male ICR mice. Animals treated with CCl_4 exhibited severe necrotic centrilobular lesions and significantly elevated serum glutamic pyruvic transaminase (GPT), glutamic oxalacetic transaminase (GOT), and lactate dehydrogenase (LDH) levels. In contrast, the histopathology and serum biochemistry (GPT, GOT, LDH) of animals treated concomitantly with CCl_4 and 6(5*H*)-phenanthridinone were not significantly different versus controls. The results of this study demonstrate that the hepatoxicity of CCl_4 can be blocked independently of its metabolism, and further indicate the role of PARP-1 in chemical-induced toxicity. (Supported in part by the Department of Defense)

1751 QUANTIFICATION OF HEPATOCYTE PROLIFERATION AND APOPTOSIS IN RATS TREATED FOR FIVE DAYS WITH VARIOUS HEPATOCARCINOGENS.

E. Blomme[1], J. Kramer[2], S. Williams[1], R. Duan[1], R. Bunch[1] and K. L. Kolaja[1]. *[1]Global Toxicology, Pharmacia, Skokie, IL and [2]Global Toxicology, Pharmacia, St. Louis, MO.* Sponsor: M. Schlosser.

Increased hepatocyte proliferation and apoptosis are common responses to various hepatic toxicants, especially nongenotoxic carcinogens. Cell proliferation and apoptosis are traditionally evaluated by histologic examination, but can also be quickly quantified using immunohistochemistry in combination with computer-assisted image analysis. The purpose of this study was to evaluate and validate a method for the quantification of hepatocyte proliferation and apoptosis following a 5-day daily treatment with various genotoxic or non-genotoxic carcinogens. Male CD IGS rats were treated orally for 5 days with vehicle, methapyrilene at 35, 70 or 140 mg/kg/day, phenobarbital at 60, 100 or 200 mg/kg/day, clofibrate at 200, 400 or 800 mg/kg/day, 2-AAF at 8, 50 or 100 mg/kg/day, 4-AAF at 8, 50 or 100 mg/kg/day, or tamoxifen at 25, 100 or 200 mg/kg/day. Livers were collected for histology and immunohistochemistry. Hepatocyte proliferation and apoptosis were quantified using computer-assisted image analysis following immunohistochemical staining for PCNA and activated caspase 3. As previously reported, treatment with the three non-genotoxic carcinogens (methapyrilene, phenobarbital and clofibrate) caused a dose-dependent increase in hepatocellular proliferation at all dose levels, but no changes in the apoptosis labeling index. In contrast, 4-AAF, a non-genotoxic and non-carcinogenic compound, only caused a minimal increase in hepatocyte proliferation at the high dose only. 2-AAF, a potent genotoxic carcinogen, induced apoptosis at the low- and mid-dose, but decreased cell proliferation at all doses. Tamoxifen, a carcinogenic agent potentially by hormonal mechanisms, did not affect apoptosis, but slightly decreased hepatocyte proliferation. Collectively, these results correlate with previously reported data and indicate that our method to quantify hepatocyte proliferation and apoptosis is suitable for the quantification of changes in cellular kinetics after a short-term treatment with hepatotoxicants.

1752 ACUTE ETHANOL (ETOH) EXPOSURE *IN VIVO* POTENTIATES ACETAMINOPHEN (AAP)-INDUCED HEPATOCELLULAR APOPTOSIS BY MODULATING OXIDATIVE STRESS AND EXPRESSION OF BCL-XL AND P53 GENES IN THE LIVER.

S. Phadke, R. Raje and S. Ray. *Molecular Toxicol. Program, A& M Schwartz College of Pharmacy and Health Scs., Long Island University, Brooklyn, NY.*

As modes of cell death induced by AAP have been undergoing intense debate in recent years, the effect of EtOH on AAP-induced liver injury has been the focus of investigation for many decades. Although EtOH-potentiated AAP hepatotoxicity has been primarily attributed to bioactivation by CYP450-IIE1, this study, for the first time, examined whether majority of the hepatocellular biochemical events are surrendered to apoptotic pathways, and if so, whether potentiation is due to accelerated induction of apoptotic death. Since, oxidative stress, genomic DNA fragmentation, and select expression of bcl-xl and p53 are considered instrumental to apoptotic process, these parameters were analyzed in the mouse liver. Male ICR mice (3 months old) were orally administered two consecutive doses of ethanol on Day-1 and Day-2 (7.6 ml/kg; 10% solution), followed by AAP on day-4 (300 and 400 mg/kg; ip). Animals were sacrificed after 18-hrs of AAP exposure. Serum ALT, and liver histopathology were considered key markers for the potentiation reaction. Lipid peroxidation, DNA fragmentaion (quantitative and qualitative) and expression of bcl-XL and P53 genes in the livers were compared in various groups to assess the extent of apoptosis. Data show that EtOH significantly potentiated AAP-induced liver injury coupled with massive genomic DNA fragmentation and oxidative stress (malondialdehyde formation). Expression of bcl-XL was considerably reduced (compared to AAP alone), and the p53 level was relatively higher in EtOH+AAP group (compared to AAP alone). No major changes were noted in the control and EtOH-alone groups. Histopathological evaluation of PAS-stained liver sections revealed, EtOH significantly potentiated AAP-induced apoptotic death in addition to necrotic death of hepatocytes. However, it is unclear whether both apoptogens acted synergistically, or orchestrated the suicidal process independently. [supported by Division of Pharmacology/Tox]

1753 DIFFERENCES IN ACUTE TOXICITY SYNDROMES OF TCDD AND HEXACHLORODIBENZO-*p*-DIOXIN IN RATS.

U. Simanainen[1,2], M. Niittynen[1], J. T. Tuomisto[1], R. Pohjanvirta[1,3], M. Viluksela[1] and J. Tuomisto[1,2]. *[1]Environmental Health, National Public Health Institute, Kuopio, Finland, [2]University of Kuopio, Kuopio, Finland and [3]National Food and Veterinary Research Institute, Kuopio, Finland.*

2, 3, 7, 8-Tetrachlorodibenzo-*p*-dioxin (TCDD) is the most potent congener of polychlorinated dibenzo-*p*-dioxins. The potency of 1, 2, 3, 4, 7, 8-hexachlorodibenzo-*p*-dioxin (HxCDD) is only 10 % of that of TCDD for typical Ah receptor (AhR) -mediated effects. Han/Wistar (Kuopio), (H/W) rats are exceptionally resistant to TCDD and the resistance is related to the mutated AhR. However, in terms of acute lethality, HxCDD is more potent than TCDD in H/W rats. Acute lethality and macroscopical effects of HxCDD and TCDD were compared in male rats of strain H/W, line A, and line B. H/W and line A rats are very resistant to TCDD due to an altered AhR, while line B rats are moderately resistant. The rats received 10000 and 2000 μg/kg of either TCDD or HxCDD i.g. Additionally line B rats received 1000, 600 or 200 μg/kg of TCDD or HxCDD. Body weight loss and mortality were monitored for 42 or 46 days. In H/W and line A rats the estimated LD50 values were 1500-12000 μg/kg and >10000 μg/kg for HxCDD and TCDD, respectively; for line B rats they were 1200-2000 μg/kg and 200-600 μg/kg, respectively. Necropsies revealed a severe liver toxicity syndrome. All rats that died from HxCDD had an exceptionally pale liver. TCDD caused a similar pale liver syndrome only in line B rats and only at the highest dose. In addition, HxCDD reduced body weight more rapidly than TCDD and caused diarrhea. The mean time to death was only 14 days for HxCDD compared with 33 days for TCDD. Interestingly, 10000 μg/kg HxCDD caused this syndrome in TCDD-resistant H/W and in line A rats, while the same dose of TCDD did not. The differences in toxic effects between HxCDD and TCDD suggest that the molecular mechanisms by which HxCDD causes lethality are different from those of TCDD. (Supported by the Academy of Finland, Project 42551, and the European Commission, Contract QLK4-CT-1999-01446.)

1754 DIFFERENTIAL REVERSIBILITY OF CYP1A1 INDUCTION IN TCDD VERSUS HxCDD TREATED RATS.

C. R. Croutch[1], M. Lebofsky[1], N. J. Cherrington[1], C. D. Klaassen[1] and K. K. Rozman[1,2]. *[1]University of Kansas Medical Center, Kansas City, KS and [2]GSF-Institut fur Toxikologie, Neuherberg, 81, Germany.*

2, 3, 7, 8–tetrachlorodibenzo–*p*–dioxin (TCDD) and 1, 2, 3, 4, 7, 8–hexachlorodibenzo–*p*–dioxin (HxCDD) were chosen for this study because of their differential half lives (20 and 60 days, respectively). An aim of this study was to elucidate the contribution of pharmacokinetics vs. pharmacodynamics in the recovery of CYP1A1 in TCDD vs. HxCDD treated animals. Female Sprague-Dawley rats were administered a loading dose of either TCDD or HxCDD in corn oil *via* oral gavage (n=5); controls were dosed with only vehicle. For the next 64 days, animals were dosed with maintenance doses of TCDD or HxCDD every third or ninth day, respectively, to maintain pharmacokinetic steady state. Iso–effective doses of TCDD/HxCDD (0.0125/0.3125 and 0.05/1.25 μg/kg) were selected based on their toxic equivalence. Following the 64 day dosing period, rats were allowed to recover. Rats were terminated on recovery days 2, 4, 8, 16, 32, 64, 128, and 256 after the final day of dosing (day 64). Livers were removed, weighed and snap frozen. The relative liver weight for each treatment remained constant throughout the recovery period. Hepatic EROD activity, measured fluorometrically, decreased in a dose– and time–dependent manner during the recovery period. The EROD activity of the TCDD treated rats declined more than that of the HxCDD treated rats during the recovery period. Liver samples were also analyzed for CYP1A1 and CYP1A2 mRNA and CYP1A1 protein expression by the branched DNA (bDNA) signal amplification assay and Western blotting, respectively. Semiquantitation of Western blots were obtained using GelPro image analysis. Both CYP1A1 mRNA and protein decreased in a dose– and time–dependent manner. In conclusion, these data demonstrate a differential reversibility of EROD activity, CYP1A1 mRNA and protein in TCDD vs. HxCDD treated rats. Moreover, there is a lack of complete reversibility of EROD induction in TCDD treated rats even after the elapse of almost 7 half–lives.

1755 THE EFFECT OF TCDD AND LEPTIN ON mRNA EXPRESSION OF NEUROPEPTIDES REGULATING FOOD INTAKE IN HYPOTHALAMUS.

J. Lindén[1,2], S. Lensu[3,4], M. Korkalainen[4], J. Tuomisto[4] and R. Pohjanvirta[1,2]. *[1]Department of Food and Environmental Hygiene, University of Helsinki, Helsinki, Finland, [2]Veterinary and Food Research Institute, Helsinki, Finland, [3]Department of Pharmacology, University of Kuopio, Kuopio, Finland and [4]Department of Environmental Health, National Public Health Institute, Kuopio, Finland.*

A complex and only partially known CNS network controls food intake and body weight. This control is based on integration of sensory input from external environment and from internal energetic state using leptin as the major peripheral adiposity signal. The main integrative centre of appetite control is hypothalamus with a large array of neurotransmitters involved. Wasting syndrome precedes lethality in 2, 3, 7, 8-tetrachlorodibenzo-p-dioxin (TCDD)-treated laboratory animals and seems to be caused by a derangement of a fundamental mechanism controlling body weight. Here, we examined the effects of TCDD and/or leptin on mRNA expression levels of hypothalamic neuropeptides and their receptors by real-time quantitative RT-PCR in two rat strains. The dose of TCDD employed (50 μg/kg ig.) is lethal to one of the strains but nonlethal to the other. The rats were killed by decapitation 6, 24 or 96h after TCDD exposure and were further treated with leptin (1.3 mg/kg ip.) or saline 2h before termination. Total RNA was isolated from the hypothalami of the rats. Every neuropeptide mRNA fragment measured (over 20) was cloned, sequenced and used as an external standard in real-time RT-PCR (LightCycler). The concentrations were normalized to beta-actin and the results evaluated by two-way ANOVAs. TCDD induced a drastic increase in hypothalamic expression of the positive control mRNA, CYP1A1, but the changes in neuropeptides and their receptors were smaller and dependent on time and strain. At the first time-point (6h), TCDD potentiated the effects of leptin on CART, insulin receptor and CRF receptor in the TCDD-sensitive rat strain alone. At later time points, TCDD elicited a different pattern of responses in the two strains. These findings suggest involvement of hypothalamic control centres in the wasting syndrome.

1756 2, 3, 7, 8-TETRACHLORODIBENZO-*p*-DIOXIN (TCDD)-INDUCED ACCUMULATION OF BILIVERDIN AND HEPATIC PELIOSIS IN RATS.

M. Niittynen[1], J. T. Tuomisto[1], S. Auriola[2], R. Pohjanvirta[1,3,4], P. Syrjälä[3], U. Simanainen[1], M. Viluksela[1] and J. Tuomisto[1]. *[1]Department of Environmental Health, National Public Health Institute, Kuopio, Finland, [2]Department of Pharmaceutical Chemistry, University of Kuopio, Kuopio, Finland, [3]National Food and Veterinary Research Institute, Kuopio, Finland and [4]Department of Food and Environmental Hygiene, University of Helsinki, Helsinki, Finland.*

2, 3, 7, 8-Tetrachlorodibenzo-*p*-dioxin (TCDD) is a widespread, persistent and highly toxic environmental pollutant. The most TCDD-sensitive and the most TCDD-resistant rat strains [Long-Evans (*Turku/AB*) and Han/Wistar (*Kuopio*), respectively] were cross-bred to separate the alleles of two genes (*Ahr* and an unidentified gene "*B*") mediating resistance against TCDD toxicity. During cross-breeding, a new type of toxicity in livers of both sexes was detected characterized macroscopically by intense dark green to black color and swelling that appeared most frequently after a large dose (300 μg/kg or more as a single i.g. dose) and a follow-up period of more than three weeks. Therefore, studies were undertaken to identify the causative pigment chemically and to examine the hepatotoxicity histologically. The pigment fractions were separated by thin layer chromatography and

then analyzed by HPLC and electrospray mass spectrometry. The pigment was found out to consist of biliverdin and several biliverdin-related compounds. In liver histopathology carried out on male rats, progressive sinusoidal distension and hepatic peliosis with membrane-bound cysts were seen. The clinical manifestations of pigment accumulation were recorded most often in intermediately resistant rat lines such as line B (homozygous for the gene *B*), but never occurred in rats expressing only the Han/Wistar (*Kuopio*)-type Ah receptor with an altered transactivation domain structure. (Supported by the Academy of Finland, the Finnish Research Program on Environmental Health, Project 42551 and the European Commission, Contracts ENV4-CT96-0336 and QLK4-1999-01446).

1757 CHARACTERIZATION OF BRONCHIAL METAPLASIA IN RATS EXPOSED TO 3, 3, 4, 4, 5-PENTACHLOROBIPHENYL (PCB 126).

A. E. Brix[1], M. P. Jokinen[3], N. J. Walker[2], D. M. Sells[5] and A. Nyska[2]. *[1]Laboratory of Experimental Pathology, NIEHS, Research Triangle Park, NC, [2]Pathology Associates - A Charles River Company, Durham, NC, [3]EPL, Research Triangle Park, NC, [4]NIEHS, Research Triangle Park, NC and [5]Battelle Columbus, Columbus, OH.*

The National Toxicology Program has conducted a series of two-year rat bioassays on dioxin-like compounds. One of the effects observed after exposure of Harlan Sprague-Dawley female rats with PCB 126, by gavage, was a dose-related increase in bronchiolar metaplasia. This lesion was found at the junction of terminal bronchioles and alveolar ducts throughout the lung. Alveolar epithelium in this location was replaced by cuboidal to columnar ciliated cells. Scattered among these were cells that lacked cilia and had a smooth apical surface that protruded into the alveolar space. To help elucidate the character of this lesion, staining was done with Periodic Acid Schiff (PAS), Alcian blue (AB) and immunohistochemistry [glutathione S-transferase Pi (GSTPi)]. Both PAS and AB staining were more positive in areas of bronchiolar metaplasia than alveolar hyperplasia (+1.7 of 4 vs. +0.8 for PAS, +2 of 4 vs. +1 for AB), indicating the presence of more mucus with bronchiolar metaplasia. Lung slides from 17 control and 17 treated rats were stained with GSTPi. Normal lung tissue exhibited intense positivity in the bronchiolar epithelium, with Clara cells staining the most intensely (+2.6 of 4). Diffuse, light staining (+1.1) occurred in alveolar epithelial type I cells. Foci of chronic inflammation with alveolar epithelial type II hyperplasia were positive in 5 of the 8 animals with this lesion, with an average score of +1.3. Areas of bronchiolar metaplasia stained with greater intensity than foci of inflammation and alveolar epithelial type II hyperplasia (average score +1.8). These areas also contained cells consistent with Clara cells that stained more intensely than the remainder of the cells. These results provide evidence that this lesion is actually metaplasia (considered an adaptive response), from typical alveolar to bronchiolar epithelium and should not be confused with alveolar epithelial hyperplasia.

1758 EXPOSURE TO TCDD RENDERS VIRUS-SPECIFIC CD8+ T CELLS UNRESPONSIVE DURING PRIMARY INFECTION AND DELAYS THEIR EXPANSION FOLLOWING REINFECTION.

K. A. Mitchell, J. A. Cundiff, B. A. Vorderstrasse and B. Lawrence. *Phar Sciences, Pharmacology/Tox Prog., Washington State University, Pullman, WA.*

Numerous studies implicate a role for impaired T cell function in the immune suppression resulting from exposure to 2, 3, 7, 8-tetrachlorodibenzo-p-dioxin (TCDD). To elucidate mechanisms by which TCDD drives T cell dysfunction, we use a murine model of infection with human influenza A virus. Cell-mediated immunity to influenza virus depends on the activation, differentiation and proliferation of CD8+ T cells into cytotoxic T lymphocytes (CTL). Exposure to TCDD suppresses the proliferation of CD8+ T cells, reduces their production of IFNg, and impairs the generation of virus-specific CTL. We atribute this to impaired activation of CD8+ T cells. To examine this further, we tested the hypothesis that treatment with TCDD induces anergy, characterized by the inability of antigen-specific T cells to respond under optimal conditions. Mice were gavaged with TCDD (10 ug/kg) or vehicle control one day prior to intranasal infection with a sublethal dose of influenza virus. Following infection, mediastinal lymph node (MLN) cells were restimulated *in vitro* with an immunodominant influenza virus peptide and IL-2. Stimulation of CD8+ cells from vehicle-treated mice induced proliferation and IFNg production. However, optimal stimulation conditions did not fully restore these responses in CD8+ cells from TCDD-treated mice, suggesting they are anergic. To study this unresponsive state *in vivo*, we tested the ability of virus-specific CD8+ T cells to respond to a second encounter with antigen. Eight weeks after primary infection the number of residual virus-specific memory cells was diminished 50% in the TCDD-treated mice. In response to re-infection, the expansion of virus-specific CD8+ T cells was delayed in mice treated with TCDD, such that 70% fewer cells were detected in the MLN three days after secondary challenge. These findings indicate that a single dose of TCDD induces anergy in CD8+ T cells during a primary response, diminishes the size of the memory T cell pool and delays the recall response.

1759 THYMOCYTE ALTERATIONS IN CD2-DRIVEN CONSTITUTIVELY ACTIVE ARYLHYDROCARBON RECEPTOR (AHR) TRANSGENIC MICE.

K. Nohara[1,2], S. Tsukumo[1,2], T. Ito[1,2], M. Yamamoto[2,3], H. Motohashi[3], A. Hida[3], Y. Fujii-Kuriyama[2,3], K. Inouye[1,4], H. Nagai[1,5] and C. Tohyama[1,2]. *[1]Environmental Health Sciences Division, National Institute for Environmental Studies, Tsukuba, Japan, [2]CREST, JST, Kawaguchi, Japan, [3]TARA Center, University of Tsukuba, Tsukuba, Japan, [4]JSPS, Tokyo, Japan and [5]RIBS, Science University of Tokyo, Noda, Japan.*

Arylhydrocarbon receptor (AhR) is the transcription factor that mediates the toxic effects of dioxin. Upon binding dioxin, AhR in the cytoplasm is activated and translocated to the nucleus, where it heterodimerizes with another transcription factor, arylhydrocarbon receptor nuclear translocator (ARNT). The AhR/ARNT complex binds to the specific DNA sequence, the xenobiotic responsive element (XRE), and alters the expressions of various genes. These AhR-dependent alterations in gene expressions are thought to be involved in the majority of adverse effects, including the immunotoxicity of dioxin. In order to clarify the cellular targets and mechanisms of dioxin-induced immunotoxicity, we generated transgenic (Tg) mice expressing constitutively active (CA) mutants of AhR in T cells using a CD2 promoter. We used a CA-AhR mutant having a deletion in the PAS B domain, which constitutively activated AhR/ARNT-dependent transcription, independently of ligands. Expression of CA-AhR mRNA was detected in the thymus and spleen of Tg mice. Furthermore, expression of CYP1A1, one of the genes activated by the AhR/ARNT heterodimer, was detected in the thymus and spleen without exposure to ligands. In these Tg mice, the weight of and total cell number in the thymus were decreased. In addition, the ratio of CD8 single positive/CD4 single positive cells in the thymus was elevated when compared with wild-type mice, just as observed in dioxin-treated wild-type mice. These results demonstrate that the changes in thymocyte population induced by dioxin are solely dependent on activation of AhR in T cells

1760 INDUCTION OF OXIDATIVE STRESS IN THE REPRODUCTIVE SYSTEM OF RATS AFTER SUBCHRONIC EXPOSURE TO 2, 3, 7, 8-TETRACHLORODIBENZO-P-DIOXIN.

O. S. El-Tawil and E. M. Elsaieed. *Toxicology and Forensic Medicine, Faculty of Veterinary Medicine, Cairo University, Cairo, Egypt.*

2, 3, 7, 8-tetrachlorodibenzo-p-dioxin (TCDD) is a persistent environmental contaminant. TCDD is formed as a by-product in the manufacture of chlorinated hydrocarbons and in the emissions from steel foundries and motor vehicles. TCDD is classified as a classic reproductive toxicant. It causes oxidative stress in a variety of animal tissues. The ability of TCDD to induce reproductive toxicity in both males and females after exposure during pregnancy, lactation or before puberty has been reported. However, its effect on mature animals is not clear. This study was conducted to assess the health risks associated with exposure to TCDD on testicular function of mature male rats and to assess *in vivo* its effect on the oxidative enzymes in mitochondrial and microsomal fractions of testis. Mature male Sprague-Dawley rats were orally administered 50, 100 or 200 ng/kg/day TCDD for 60 days. TCDD has no effect on the body weight and food intake during the course of the study. TCDD significantly reduced the relative weight of testis, epididymis, seminal vesicles and prostate. The number of the epididymal sperm count and the percentage of sperm motility were decreased. There was a significant increase in both percentages of sperm mortality and abnormality associated with testicular histopathological alterations. TCDD induced oxidative stress in both mitochondrial and microsomal fractions of testis. There was a significant decrease in the activities of superoxide dismutase (SOD), glutathione perioxidase (GPX) and catalase (CAT) and a significant increase in the level of thiobarbituric acid reactive substances (TBARS) as a measurement of lipid peroxidation. These changes were more prominent in microsomal than mitochondrial fraction. This study may suggest that TCDD caused exhaustion of antioxidant defense system in rat testis inducing an oxidative stress, which could explain the disruption of the testicular functions.

1761 BONE STATUS AND ALL-TRANS-RETINOIC ACID (ATRA) HOMEOSTASIS IN MICE LACKING CELLULAR RETINOL-BINDING PROTEIN I (CRBPI-KO) BEFORE AND AFTER CHEMICAL INSULT BY TCDD.

P. Hoegberg[1], M. Lind[1], N. Stern[1], A. Thomassen[2], R. Blomhoff[2], T. Jämsä[3], J. Tukkanen[3], N. B. Ghyselinck[4] and H. Håkansson[1]. *[1]Environmental Medicine, Karolinska Institute, Stockholm, Stockholm, Sweden, [2]Institute for Nutrition Research, University of Oslo, Oslo, Norway, [3]Department of Anatomy and Cell biology, University of Oulu, Oulu, Finland and [4]CNRS-INSERM-ULP, Illkirch, France.*

Dioxins are known to affect retinoid homeostasis, but the toxicological consequences are unknown. To clarify the link between vitamin A homeostasis and dioxin toxicity, we studied bone status (pQCT and three-point-bending tests of

tibia and femur), hepatic retinoid levels (HPLC of total retinyl ester, all-trans-retinol, and atRA levels), and CYP1A1/2, 1A2, and 2B1/2 activities (E/P/MROD assay) in adult male CRBPI-KO mice before and after a single dose of TCDD. Wildtype (WT) mice of the same strain background were used as controls. We saw no differences in bodyweight or bone length between untreated CRBPI-KO and WT mice. However, bone mineral density (BMD) and strength were lower in CRBPI-KO mice. After TCDD exposure, CRBPI-KO bones were unaffected, whereas WT bones displayed reduced BMD and strength. Retinyl esters in CRBPI-KO livers were significantly lower than WT at all times and doses. After TCDD exposure CRBPI-KO mice lost nearly all their retinyl ester stores, whereas WT mice were almost unaffected. TCDD-treated CRBPI-KO livers displayed reduced atRA levels, whereas atRA levels in WT were unchanged. Baseline CYP1A activities were lower in CRBPI-KO than in WT but after TCDD exposure, CYP1A was twice as much induced in the CRBPI-KO than in WT. This study clearly shows that a binding protein specific for the vitamin A system plays a role not only for proper retinoid storage as earlier shown but also for bone status and for the homeostasis of the hormone RA. The effects of TCDD on bone could however not be associated with an altered RA homeostasis. Nonetheless, the absence of CRBP I was indeed protective against the bone-disrupting effects of TCDD and the role of this protein in bone homeostasis must therefore be further explored.

1762 REGULATION OF CYCLIN D1 GENE EXPRESSION IN THE MOUSE UTERUS BY ESTROGEN AND 2, 3, 7, 8-TETRACHLORODIBENZO-*P*-DIOXIN.

K. B. Walker[1], R. C. Burghardt[2] and S. Safe[1]. [1]*Veterinary Physiology & Pharmacology, Texas A&M University, College Station, TX and* [2]*Veterinary Anatomy & Public Health, Texas A&M University, College Station, TX.*

Induction of uterine cyclin D1 mRNA levels was investigated in 25 day-old B6C3F1 mice treated with 200 ng of 17β-estradiol (E2) for 1, 3, 6, and 12 h followed by *in situ* hybridization of uterine sections. Increased cyclin D1 mRNA staining was observed in the luminal epithelium 6 and 12 h after treatment, whereas background cyclin D1 mRNA staining in stromal cells was observed in solvent (corn oil)-treated animals and was not increased after 6 and 12 h treatment with E2. Comparable hormone-responsiveness was observed in wild-type estrogen receptor α (ERα) knockout (αERKO)+/+ and aryl hydrocarbon receptor knockout (AhRKO) mice, whereas responsiveness was not observed in homozygous αERKO-/- mice, confirming the role of ERα in E2-induced cyclin D1 expression in the uterus. Moreover, since previous studies indicate that induction of uterine cyclin D1 mRNA is not affected by cycloheximide, our results suggest that induction of this gene in luminal epithelial cells is a direct effect of E2 and not related to induced stromal factors. Inhibition of E2-responsiveness in the uterus by the AhR agonist 2, 3, 7, 8-tetrachlorodibenzo-*p*-dioxin (TCDD) is well established. TCDD alone does not affect stromal or epithelial expression of cyclin D1; however, in B6C3F1 mice cotreated with E2+TCDD, there was a decrease in E2-induced uterine cyclin D1 mRNA expression in the luminal epithelial cells. This inhibitory TCDD-ERα crosstalk on cyclin D1 mRNA was not observed in AhRKO mice confirming the role of the AhR in mediating this response which was similar to inhibitory AhR-ER crosstalk observed in breast cancer cells and rodent mammary tumors. (Supported by NIH ES09106 and ES04176)

1763 HEPATIC RETINOID LEVELS IN A TCDD-SENSITIVE (LONG-EVANS) AND TCDD-RESISTANT (HAN/WISTAR) RAT STRAIN FOLLOWING LONG-TERM LOW-DOSE TCDD EXPOSURE.

N. Fletcher[1], C. Schmidt[4], N. Stern[1], M. Viluksela[2], J. T. Tuomisto[2], R. Pohjanvirta[3], J. Tuomisto[2], H. Nau[4] and H. Håkansson[1]. [1]*Institute of Environmental Medicine, Karolinska Institutet, Stockholm, Sweden,* [2]*Department of Environmental Health, National Public Health Institute, Kuopio, Finland,* [3]*Department of Food and Environmental Hygiene, University of Helsinki, Helsinki and* [4]*Department of Food Toxicology, School of Veterinary Medicine, Hannover, Germany.*

2, 3, 7, 8-Tetrachlorodibenzo-p-dioxin (TCDD) is a potent environmental contaminant that alters retinoid homeostasis by mechanisms believed to be mediated by the aryl hydrocarbon receptor (AhR). In this study we investigated whether the noted structural differences between the AhRs of Long-Evans (L-E) and Han/Wistar (H/W) rat strains influenced polar and apolar retinoid homeostasis following long-term TCDD treatment. Female L-E and H/W rats were given TCDD by s.c. injection once per week at calculated daily doses of 0, 1, 10, 100, or 1000 (H/W only) ng/kg bw/day for 20 weeks. Total hepatic retinoid levels were dose-dependently decreased in both strains. However, effects were seen at 1 ng/kg bw/day in the L-E strain whereas significant effects were observed at 10 ng/kg bw/day in the H/W strain. BMD05 levels, defined as a 5% change from mean control values, were approximately 140 and 1400 pg/kg bw/day for L-E and H/W rats respectively. Preliminary analyses of hepatic polar retinoid levels showed no change in retinoic acid levels of either strain. On the other hand, a recently discovered retinoic acid metabolite, 9-cis-4-oxo-13, 14-dihydro-retinoic acid was all but eliminated in the liver of both strains at the low-dose. Thus the data suggest that long-term low-dose TCDD exposure markedly increases hepatic retinoid turnover without significant effects on hepatic retinoic acid levels. Moreover, the 10-fold difference between the L-E and H/W strain provide further support for a role of the AhR in TCDD altered retinoid homeostasis.

1764 USE OF CYP1A2 (-/-) KNOCKOUT AND CYP1A2 (+/+) C57BL/6N PARENTAL STRAINS OF MICE TO COMPARE METABOLISM OF 2, 3, 7, 8-TETRACHLORODIBENZO-P-DIOXIN (TCDD).

J. J. Diliberto[1] and H. Hakk[2]. [1]*PKB, ETD, NHEERL ORD, USEPA, Research Triangle Park, NC and* [2]*BRL, ARS, USDA, Fargo, ND.* Sponsor: L. Birnbaum.

The most toxic dioxin congener, TCDD, induces hepatic cytochrome CYP1A2 to which it subsequently binds, resulting in whole body half lives of 5-11 years in humans and 30 days in rats. Metabolism of TCDD is very limited in both species. Whether TCDD is a poor substrate for metabolizing enzymes or is unavailable for metabolism due to its strong affinity to CYP1A2 has not been firmly established. Thus, we tested the hypothesis that sequestration of TCDD by CYP1A2 makes TCDD unavailable for metabolism that would readily occur in the absence of CYP1A2. Male C57BL/6N mice which possess or lack the CYP1A2 gene were given a single oral dose of 156 ug[14C]TCDD/kg. After 4 days, the mice (housed in metabolism cages with separate collection of urine and feces every 24h) were killed and tissues collected. Tissue deposition and overall metabolism in urine and feces were quantitated. Similar to previously reported studies, liver:fat ratio of the two groups was vastly different, i.e. 4.09 (C57BL/6N) vs. 0.57 (knockout, KO). Slightly higher levels of 14C-derived TCDD were excreted in urine and feces of the parental strain at each time point when compared to KO mice. The overall level of metabolism of TCDD was determined as sum of 14C in 0-96h urine, non-extractable feces, and metabolites in extractable feces. The parental strain of mice had greater overall metabolism than the KO mice, i.e. 11.1% vs. 6.5% of the dose, respectively. The lower overall metabolism in the KO than the parental strain of mice is probably due to low hepatic retention and rapid redistribution of TCDD into lipophilic tissues for storage, which made the TCDD unavailable to hepatic metabolizing enzymes. In conclusion, the data presented in this study contradicts the original hypothesis and confirms that TCDD has an inherently slow metabolism in mammals, perhaps *via* the inducible CYP1A1, 1A2, and 1B1 isozymes and/or non-P450 dependant mechanisms. (This abstract does not reflect USEPA and USDA policies.)

1765 A COMPARISON OF THE METABOLISM OF METHOXYRESORUFIN, ACETANILIDE AND CAFFIENE IN RAT AND HUMAN CYP1A2 SUPERSOMES AND THEIR INHIBITION BY 2, 3, 7, 8-TETRACHLORODIBENZO-P-DIOXIN (TCDD).

D. Staskal[1], D. G. Ross[2], L. S. Birnbaum[2] and M. J. DeVito[2]. [1]*Curriculum in Toxicology, UNC- Chapel Hill, Hillsborough, NC and* [2]*ETD, NHEERL, ORD, USEPA, Research Triangle Park, NC.*

CYP1A2 is highly expressed in both rats and humans. TCDD and related chemicals induce and bind to these proteins. The binding of TCDD and related chemicals to CYP1A2 leads to their sequestration in hepatic tissue. The present study compares the metabolism of prototype CYP1A2 substrates in rat and human CYP1A2 + P450reductase SUPERSOMES (GenTest Corporation, Woburn, MA) and the ability of TCDD to inhibit these reactions. For the O-demethylation of methoxyresorufin, the K_M was similar between human and rat CYP1A2, 0.10 and 0.09 nM respectively. Rat supersomes had a slightly higher V_{max} than human supersomes, 3.5 and 2.4 pmol/min/mg CYP1A2. TCDD inhibited methoxyresorufin metabolism with $K_I$values of 0.3 and 0.06 μM in the human and rat supersomes respectively. Caffeine was metabolized by both human and rat CYP1A2 supersomes. The estimated V_{max} was higher in the human compared to the rat supersomes, 5.0 and 2.2 nmol/min/mg CYP1A2, respectively. The Km was also higher in the human (6.5 mM) compared to the rat (0.9 mM) supersomes. The metabolism of acetanilide to 4-hydroxy acetanilide was similar in the human and rat supersomes. The Vmax was 2.8 and 5.9 nmol/min/mg protein, in human and rat supersomes, respectively. The K_M was 19.1 mM in human supersomes and 74.5 mM in rat supersomes. Initial studies indicate that TCDD inhibits both caffeine and acetanilide metabolism in rat and human supersomes. These data demonstrate that the *in vitro* metabolism of prototype substrates is similar between the rat and human CYP1A2 supersome preparations and that TCDD inhibits the metabolism of these substrates by both rat and human CYP1A2. Because of the potential for inhibition of CYP1A2 activity by TCDD, studies examining CYP1A2 induction in TCDD exposed populations using these substrates should be viewed cautiously. (This abstract does not reflect EPA policy)

1766 INFLUENCE OF DIABETES, OBESITY AND 2, 3, 7, 8-TETRACHLORODIBENZO-P-DIOXIN (TCDD)EXPOSURE ON THE EXPRESSION OF HEPATIC CYP1A2 IN A MURINE MODEL OF TYPE II DIABETES.

S. J. Godin[1,2], V. M. Richardson[2], J. J. Diliberto[2], L. S. Birnbaum[2,1] and M. J. DeVito[2]. [1]*Curriculum in Toxicology, University of North Carolina at Chapel Hill, Chapel Hill, NC and* [2]*ETD/NHEERL/ORD, USEPA, Research Triangle Park, NC.*

Recent epidemiology studies indicate an association between TCDD exposure and an increased incidence of type II diabetes. One criticism of these results is that diabetes and/or body fat composition may influence the disposition and/or elimination of TCDD. In the present study the influence of body fat composition and type II diabetes was examined on the expression of CYP1A2, a major determinant of the disposition of TCDD. In this study a high fat, high simple carbohydrate (HFHSC) diet was used to develop murine models of type II diabetes and obesity. After exposure to the HFHSC diet for 13 weeks, C57BL/6J mice develop obesity, hyperinsulinemia and hyperglucosenemia, consistent with type II diabetes. Following 13 weeks on the HFHSC diet AJ mice develop greater body fat mass without developing hyperinsulinemia or hyperglucosenemia. These models have allowed us to compare the influence of diabetes, body fat composition and TCDD exposure on the expression of CYP 1A2. Following 13 weeks on either a normal or HFHSC diet animals were exposed to 0, 0.1 or 5 ug/kg of 3H-TCDD by oral gavage and killed 1, 30 and 40 days later. Hepatic CYP1A2 was determined using western blot analysis. Initial results indicate that on day 1, animals on the normal diet have a greater fold induction of CYP1A2 than those on the HFHSC diet. This effect is more pronounced at the higher dose. For example in C57 mice on the normal diet, CYP1A2 is induced 3 and 43 fold by 0.1 and 5 ug/kg TCDD while in C57 mice on the HFHSC diet CYP1A2 is induced 2 and 13 fold at these same doses. On days 30 and 40, fold induction of CYP1A2 by 5 ug/kg TCDD is approximately 7-10 fold greater in the animals on the HFHSC diet. These data suggest that diet can influence the response to TCDD. This influence may be related to alterations in body fat composition. (This abstract does not represent USEPA policy. SJG supported by NIEHS training grant T32 ES07126)

1767 INFLUENCE OF TYPE II DIABETES AND OBESITY ON THE DISPOSTION AND ELIMINATION OF TCDD IN MICE.

M. J. DeVito[1], J. J. Diliberto[1], D. G. Ross[1], C. Emond[2], V. M. Richardson[1] and L. S. Birnbaum[1]. [1]*ORD/NHEERL/ETD, USEPA, Research Triangle Park, NC and* [2]*National Research Council, National Academy of Sciences, Washington, DC.*

One possible explanation for the relationship between TCDD exposure and diabetes in some epidemiological studies may be that diabetics have slower elimination of TCDD compared to non-diabetics. The present study examines the effects of type II diabetes and body fat mass on the elimination of TCDD in mice. A high fat, high simple carbohydrate (HFHSC) diet was used to develop murine models of type II diabetes and obesity. After exposure to the HFHSC diet for 13 weeks, C57BL/6J mice develop obesity with signs of type II diabetes, while AJ mice develop greater body fat mass without alterations in serum glucose or insulin. Thus we can compare the effects of diabetes and body fat mass on the elimination of TCDD. After 13 weeks on either a normal or HFHSC diet male mice were exposed (po) to 5 ug 3H-TCDD/kg. Mice were killed 1, 3, 10, 20, 30, 40 and 60 days later and concentrations of TCDD were determined in blood, liver and fat. The elimination half-life of TCDD from the blood was similar in the C57 and AJ mice on the normal diet and the AJ mice on the HFHSC diet, 15.9, 17.9 and 14.9 days, respectively. C57 mice on the HFHSC diet had a blood half-life of 36.5 days. The HFHSC diet increased the liver half-life of TCDD from 9.8 to 23.8 days in the C57 mice, but did not significantly affect the hepatic elimination in the AJ mice. The half-life of TCDD from adipose tissue was slightly elevated by the HFHSC diet in C57 mice, 16.8 vs. 23.8 days, in the normal vs. the HFHSC diet. The HFHSC diet had no effect on the half-life of TCDD from adipose tissue in the AJ mice. These data suggest that type II diabetes may influence the half-life to TCDD and that this is independent of body fat composition. This work was funded in part by an Interagency Agreement with the USAir Force # FQ7624-00-YA085) and a cooperative agreement (CR 828790) with NRC. (This abstract does not represent USEPA policy).

1768 COMPARING ENVIRONMENTALLY RELEVANT PCBs TO TCDD.

D. E. Burgin[1,2], J. J. Diliberto[2] and L. S. Birnbaum[2]. [1]*Toxicology, UNC, Research Triangle Park, NC and* [2]*ETD/NHEERL/ORD, USEPA, Research Triangle Park, NC.*

Environmental exposures to 2, 3, 7, 8-tetrachlorodibenzo-p-dioxin (TCDD) always occur as part of a complex mixture. In order to assess the potential risk associated with these exposures, the Toxic Equivalency Factor (TEF) method was developed, and uses toxic equivalents (TEQ) to relate a chemical to TCDD. While this method adequately accounts for the effects of mixtures of TCDD or dioxin-like (DL) chemicals, there are almost always non-dioxin-like (NDL) chemicals present, in particular, the NDL polychlorinated biphenyls (PCBs). To examine the interactions of TCDD with NDL PCBs, the present study compared the effects on multiple responses of different laboratory-defined mixtures, based on mass ratios found in food, of TCDD and NDL PCBs in both wildtype C57BL/6J (WT) and CYP1A2 null (KO) male and female mice. These chemical groups are: TCDD alone; DL Mix A; NDL Mix B; and Mix C - a combination of Mixes A and B. No effects were seen in body weight or other tissues, in male or female WT or KO mice. Although we expected an increase in liver weights in Mix B and Mix C, liver weight was increased only in Mix C in both male and female, WT and KO. No effects were observed in levels of glutathione or uric acid, markers of oxidative stress. Both male WT and KO showed greater decreases in levels of total triiodothyronine (TT3) while Mix A and Mix C resulted in a 50% reduction in levels of total thyroxine in all groups. With exposure to TCDD and DL mixes, but not to NDL PCBs, there is an increase in ascorbate levels. Based on these findings, there does not appear to be a strain difference in response to chemical exposure, indicating CYP1A2 is not necessary for these responses. There does appear to be a gender difference, reflecting a possible endogenous estrogenic component to maintenance of levels of TT3 and ascorbic acid cycling. Based on these findings, it appears that these mixtures have a synergistic effect greater than the sum of the individual congeners, or TCDD alone. (This abstract does not reflect EPA policy. DB supported by EPA CT902908 and NIEHS T32-ES07126)

1769 EVALUATION OF PCB EXPOSURE ROUTES IN ANNISTON, ALABAMA: ASSESSMENTS OF FISH CONSUMPTION USING PBPK MODELING OF PCB CONGENERS IN LOCALLY-CAUGHT FISH.

C. J. Welsh, D. Moffett, H. El-Masri, D. Fowler and S. Moore. *ATSDR, Atlanta, GA.* Sponsor: J. Wheeler.

The forty-year history of polychlorinated biphenyls (PCB) production in Anniston, Alabama was associated with releases of PCBs to the local watershed. Although PCB contamination in the Anniston area is well documented, the PCB exposure pathway(s) are not well characterized. This investigation examined a likely PCB exposure pathway: the consumption of PCB contaminated fish taken from a local waterway. To evaluate PCB exposures, physiologically based pharmacokinetic (PBPK) models were used in conjunction with knowledge of fish consumption behavior and serum PCB levels found in Anniston residents. The model parameters included physiological and biochemical factors, parameters affecting exposure duration, the distribution of PCB congeners in specific tissues, the PCB congener patterns from local fish, and serum PCB congener patterns from area residents who participated in an exposure investigation. PCB congener analysis of locally-caught fish showed the Anniston-area fish contain appreciable levels of higher chlorinated PCB congeners. Simulations from the model provided estimates of levels of PCBs in blood under exposure scenarios based on fish consumption rates that vary between demographic groups. The modeled estimates indicate that, for demographic groups that consume large amounts of local fish, the fish-eating pathway could contribute significant amounts of higher chlorinated PCBs to an individual's body burden.

1770 ACUTE EFFECTS OF *ortho*-PCB CONGENERS ON THE HYPOTHALAMO-PITUITARY-THYROID AXIS.

M. A. Khan and L. G. Hansen. *University of Illinois, Urbana, IL.*

ortho-Substituted polychlorinated biphenyl (PCB) congeners represent a large proportion of total PCBs in the environment and produce, resulting in episodes of exposure. Information is scanty regarding the effects of these PCBs on the hypothalamo-pituitary-thyroid (HPT) axis in developing animals. Acute effects of ortho-PCB congeners, 95 (2, 3, 6-2', 5'), 101 (2, 4, 5, -2', 5'), 110 (2, 3, 6-3', 4'), 149 (2, 3, 6-2', 4', 5'), and PCB153 (2, 4, 5-2', 4', 5') were investigated on the HPT-axis. Weanling female Sprague-Dawley rats were given a single ip dose of chosen PCB congeners at 16 or 32 mg/kg for 2 days. Selected endpoints were examined 48 hr after the last dose. Serum thyroxine (T4) levels decreased in PCB 95, 101, or 149 treated rats as compared to the respective controls. No changes were seen in serum triiodothyronine (T3), thyroid stimulating hormone (TSH), and prolactin (PRL) levels. PCB 110 exposure did not reduce serum T4, but increased serum T3 levels. PCB 153 exposure elevated serum T4 levels, but serum T3, TSH, or PRL levels did not change. Hypothalamic dopamine (DA) levels decreased following PCB 95, 101, 149, or 153 treatment, but did not change after PCB 110 exposure. The thyrotropin releasing hormone (TRH) test was administered to investigate the functionality of HPT-axis following exposure to PCB 95 or 101 at 32 mg/kg (as described above). Synthetic TRH was administered to weanling rats ip 30 min or 2 hr before decapitation. Serum T4 levels decreased following PCB 95

treatment at both times, but only at 2 hr after PCB 101 exposure as compared to control. Serum TSH levels were lower than control in PCB 95 treated rats, but did not change after PCB 101 exposure. No changes were seen in serum PRL and hypothalamic DA levels after exposure to TRH, or PCBs 95 or 101. These results indicate that acute exposure to ortho-PCB congeners cause changes in the HPT-axis, probably through multiple mechanisms. A less than maximal response of the pituitary and thyroid to TRH suggests an inhibition of T4, TSH, and PRL release.

1771 LIPID PEROXIDATION AND ANTIOXIDANT ENZYMES IN TESTES OF RATS TREATED WITH 2, 2', 4, 4', 5, 5'-HEXACHLOROBIPHENYL (PCB-153) AND EFFECTS OF CORN OIL, MEDIUM-CHAIN TRIGLYCERIDE (MCT) OIL AND OLIVE OIL.

Z. A. Fadhel, P. R. Bunaciu, H. P. Glauert, L. W. Robertson and G. Ludewig. *University of Petra, Amman, Jordan.*

The testes are vulnerable to injury by various chemicals, including polychlorinated biphenyls (PCBs). This damage may be mediated in part through oxidative stress. PCBs cause oxidative stress in liver and other organs. To study the effect of PCB-153 on oxidative stress and antioxidant enzymes in testes, and to account for the influence of different vehicles on these parameters, we measured thiobarbituric acid-reactive substances [TBARS] and the activities of antioxidant enzymes in rat testes after one i.p. injection of PCB-153 (300 umol/kg) dissolved in 3 different vehicles [corn oil, olive oil, and MCT oil; 1 ml/kg rat] or vehicle alone. Control animals received no injection. All animals were euthanized 2 days after treatment and testes subcellular fractions were prepared by differential centrifugation. Our preliminary results show that PCB-153 treatment in any vehicle produced an increase in TBARS level in testes cytosols and homogenates. The oils alone had no effect on TBARS compared to control. All PCB-treatment groups showed reduced catalase activity, but a reduction in activity was also seen in rats that received corn oil or olive oil alone. Similarly total glutathione peroxidase activity was lower in animals treated with corn oil, olive oil, or PCB-153 in olive oil. However, treatment with MCT oil, or PCB-153 in MCT or in corn oil had no effect. Glutathione reductase activity was at the control level in all vehicle treatment groups, but was increased in rats receiving PCB-153 in MCT oil and decreased in rats injected with PCB-153 in corn oil or olive oil. Glutathione S-transferase activity was not affected by any treatment. This study shows that PCB-153 may induce oxidative stress in testes, possibly in part through a reduction in antioxidant enzyme levels. It also shows, however, that the choice of vehicle may have an influence on enzyme activities in testes. (Supported by ES07380 and DAMD17-02-1-0241)

1772 COMPARATIVE STUDY OF PCB, PBB, AND PBDE MIXTURES ON SERUM PARAMETERS IN THE RAT.

G. Ludewig, N. M. Tampal and L. W. Robertson. *Occupational & Environmental Health, University of Iowa, Iowa City, IA.*

Mixtures of polychlorinated biphenyls (PCBs), polybrominated biphenyls (PBBs) and polybrominated diphenyl ethers (PBDEs) were or are currently used by industry for multiple applications. Unfortunately these mixtures are released into the environment and enter the food chain. They are found in breast milk samples and in the serum and tissues of humans and animals where they may cause health problems. PCBs have been studied extensively, but very little is known about the replacement compounds, the PBDEs. To compare the toxic potentials of these compounds, we treated male and female Sprague-Dawley rats (5 weeks old, about 150g) with weekly injections of equimolar amounts (0.765 mmol/kg rat/injection) of the PCB mixture Aroclor 1254, the PBB mixture Firemaster BP-6, the PBDE mixture DE-71, or vehicle alone (corn oil, 1 ml/100 g rat). One week after the second injection serum was collected. Results from the serum analysis show that male and female rats may have different sensitivities. For example, triglycerides were reduced by all three mixtures in male rats, whereas uric acid was reduced by all three mixtures in female rats. Differences were also found in the order of potency of the three mixtures. All three mixtures increased cholesterol and HDL levels in both geners with the order of potency being PBB > PCB >> PBDE, whereas the PCB mixture had the strongest effect on the levels of total triiodothyronine, total thyroxine and free thyroxine. In addition there was a difference in sensitivity to these mixtures between the sexes. In males the order of potency was PCB > PBB > PBDE, whereas in females the PBDE mixture caused a stronger reduction of all three thyroid hormone levels than the PBB mixture. These first results show that PCBs, PBBs, and PBDEs may cause adverse health effects as shown here for lipids and thyroid hormone levels, but that the degree in sensitivity towards the different mixtures varies from end point to end point and between the two genders. 1773 CONTAMINATION OF DIOXINS AND CO-PLANAR PCBS IN WHALE MEAT PRODUCTS FROM JAPANESE MARKET.

K. Haraguchi[1] and T. Endo[2]. *[1]Clinical Toxicology & Metabolism, Health Sciences University of Hokkaido, Ishikari-Tobetsu, Hokkaido, Japan and [2]Clinical Toxicology & Metabolism, Health Sciences University of Hokkaido, Ishikari-Tobetsu, Hokkaido, Japan.*

Whale meat products in Japanese market were surveyed for contamination of dioxins and co-planar PCBs for human consumption. The TEQ levels (pg/g wet wt) in fresh meats from Antarctic and Northern Pacific minke whales ranged from 0.02 to 0.25 (mean, 0.07, n = 6) and from 0.16 to 0.34 (mean, 0.26, n = 6), respectively. Meat products of small cetaceans (pilot whales, Risso's and bottle-nosed dolphins) from Japanese coastal water were highly contaminated with dioxin-like PCBs at the range of 1.0 - 51 pg-TEQ/g wet wt (mean, 12.3, n = 13). The concentrations on lipid weight basis corresponded to 82 - 240 pg-TEQ/g, which were comparable to the levels in small cetacean blubbers. Relative contribution of dioxins and co-planar PCBs to the total toxic potencies accounted for 1-12% and 78-99%, respectively. The major contributors were 2, 3, 4, 7, 8-pentaCDF for dioxins, and 3, 4, 5, 3', 4'-pentaCB (#126), 2, 4, 5, 3', 4'-pentaCB (#118) and 2, 3, 4, 5, 3', 4'-hexaCB (#156) for co-planar PCBs. The TEQ levels and their composition in meats were species-dependent and variable according to the lipid contents. Human consumption of lipid-rich products from small cetaceans in the market would exceed the TDI (4 pg-TEQ/kg bw/day) set by Japanese authorities and lead to increase in body burden of the contaminants. (Supported by IFAW)

1774 INCREASED LEVEL AND ASYMMETRICAL LOCALIZATION OF SECRETED FRIZZLED-RELATED PROTEIN 2 (SFRP2) MRNA IN THE MURINE FETAL BRAIN PERINATALLY EXPOSED TO 2, 3, 7, 8-TETRACHLORODIBENZO-*p*-DIOXIN.

H. Zaha[1,2], H. Sone[1,2], J. Yonemoto[1,2], S. Hisano[4], S. Maeda[2,3] and C. Tohyama[1,2]. *[1]Environmental Health Sciences Division, National Institute for Environmental Studies, Tsukuba, Ibaraki, Japan, [2]CREST, Japan Science and Technology Corporation (JST), Kawaguchi, Saitama, Japan, [3]The First Department of Biochemistry, Yamanashi Medical University, Nakakoma, Yamanashi, Japan and [4]Laboratory of Neuroendocrinology, University of Tsukuba, Tsukuba, Ibaraki, Japan.*

Exposure of 2, 3, 7, 8-tetrachlorodibenzo-*p*-dioxin (TCDD) to rodents is known to exert various biochemical alterations in central and peripheral nervous systems. To investigate possible changes in TCDD-dependent gene expression in the brain, we have first identified up- and down-regulated genes by using differential mRNA display techniques. Pregnant C57BL/6N mice were given an oral dose of 5 μg TCDD/kg bw on gestational day 12.5 (GD12.5) or an equivalent volume of corn oil as vehicle control. Fetal brains were collected on GD18.5, postnatal day 5 (PND5), and PND21. Two genes were found to be up-regulated by perinatal exposure of mice to TCDD, one was secreted frizzled-related protein 2 (sfrp2) that encode a Wnt modulator and the other was c-myc, a Wnt target gene. Next we utilized *in situ* hybridization and analyzed the expression profile of sfrp2 gene in the total brains collected on GD18.5. We found that sfrp2 mRNA was localized asymmetrically around the ventricular zone of the third ventricle in the brain from TCDD-exposed fetuses in contrast to the symmetrical localization in the brain from the vehicle-control fetuses. We suggest that perinatal exposure to TCDD may cause defects in development and function of the mouse brain *via* the Wnt signal transduction pathway.

1775 DIOXIN ALTERS DEVELOPMENT OF THE COMMON CARDINAL VEIN IN THE ZEBRAFISH EMBRYO.

S. M. Bello, W. Heideman and R. E. Peterson. *Pharmacy, University of Wisconsin - Madison, Madison, WI.*

A role for the aryl hydrocarbon receptor (AHR) pathway in vascular development has been implicated by studies in AHR null mice. Certain fetal vascular structures that normally regress during development fail to regress in AHR null mice. Therefore, we hypothesized that dioxin alters vascular remodeling and maturation. We chose to use the developing common cardinal vein (CCV) in the zebrafish embryo as a model to investigate this hypothesis. The CCV emerges from the junction of the anterior and posterior cardinal veins, grows across the yolk eventually connecting to the heart, and is extensively remodeled during its development. Fli1-eGFP transgenic zebrafish*, in which the vascular endothelium expresses GFP, were used for this study. The development of the CCV was followed from 27-74 hours post fertilization (hpf) in control or dioxin (10 ng/ml) exposed embryos. A significant reduction in the area of the CCV was detected as early as 44 hpf. The CCV area was reduced to 63% of control at 62 hpf. The dioxin dose-response curve for this reduction in area was similar to those for pericardial edema and reduction in

body length (determined in the same fish). There was no significant effect of dioxin on the time at which maximal CCV area occurred. Thus dioxin reduces the total area of the CCV but does not alter the time at which the maximal size is reached. The dependence of this effect on AHR2 was investigated using a zebrafish AhR2 specific morpholino to knockdown expression of AhR2. No significant effect of the AHR2 morpholino was found on the dioxin induced reduction in area of the CCV. This suggests that this is not an AHR2 dependent process, because both pericardial and yolk sac edema were completely blocked by the AHR2 morpholino in the same fish. This effect of dioxin on the CCV occurs well before overt signs of dioxin developmental toxicity are manifested, suggesting that alteration of vascular development may play a role in dioxin developmental toxicity in zebrafish. (UW SeaGrant, NRSA) Provided by B. M. Weinstein and N. D. Lawson, NIH.

1776 MORPHOLINO KNOCKDOWN OF AHR2 IN THE ZEBRAFISH EMBRYO PROTECTS AGAINST TCDD DEVELOPMENTAL TOXICITY.

A. L. Prasch, S. A. Carney, W. Heideman and R. E. Peterson. *Pharmacy, UW-Madison, Madison, WI.*

TCDD (2, 3, 7, 8 tetrachlorodibenzo-p-dioxin) is an environmental contaminant known to cause developmental toxicity in fish, mammals, and birds. In mammals it has been demonstrated that TCDD causes its toxicity by activating the AHR signaling pathway. Zebrafish have been found to express two forms of the AHR, zfAHR1 and zfAHR2, with zfAHR1 being most closely related to the mammalian AHR. Interestingly, *in vitro* molecular evidence has suggested that zfAHR2 is the form involved in mediating TCDD toxicity in zebrafish, however this has not been demonstrated *in vivo*. We have used an antisense morpholino to knockdown expression of the zfAHR2 protein in order to test the hypothesis that zfAHR2 is in fact responsible for mediating the developmental toxicity of TCDD. Embryos were microinjected with a morpholino targeted against zfAHR2 or a control morpholino immediately after fertilization and then exposed to TCDD within 4 hours. Embryos were then observed for endpoints of TCDD developmental toxicity to determine which were dependent on zfAHR2 signaling. The presence of the zfAhR2 morpholino produced a significant decrease in the ability of TCDD to induce transcription of cyp1A mRNA through at least 96 hpf. The morpholino was also able to protect the embryos from TCDD induced pericardial and yolk sac edema, craniofacial malformations, and anemia. The presence of the morpholino was initially able to protect against TCDD induced reduction in peripheral blood flow. However, the embryos still develop reduced blood flow at later times likely due to the persistence of TCDD and the decreasing effectiveness of the morpholino. Similarly, the morpholino provided minimal protection against TCDD's block on swim bladder inflation which also occurs at a later time. No effect of the zfAHR2 morpholino could be seen on normal development. These results support previous *in vitro* studies and demonstrate that zfAHR2 is the receptor involved in mediating several endpoints of TCDD developmental toxicity in the zebrafish embryo. Supported by UW Sea Grant.

1777 INVOLVEMENT OF HEDGEHOG SIGNALING IN IMPAIRED JAW DEVELOPMENT BY 2, 3, 7, 8-TETRACHLORODIBENZO-P-DIOXIN IN DEVELOPING ZEBRAFISH.

H. Teraoka[1], W. Dong[1], H. Iwasa[1], Y. Okuhara[1], A. Kawakami[2], N. Ueno[3] and J. J. Stegeman[4]. *[1]Department of Toxicology, Rakuno Gakuen University, Ebetsu, Japan, [2]Department of Biological Science, University of Tokyo, Tokyo, Japan, [3]Department of Developmental Biology, National Institute for Basic Biology, Okazaki, Japan and [4]Department of Biology, Woods Hole Oceanographic Institution, Woods Hoole, MA.*

Previously, we reported that 2, 3, 7, 8-tetrachlorodibenzo-p-dioxin (TCDD) retarded lower jaw development with only a minor inhibitory effect on total body length (Teraoka et al., 2002). Jaw growth retardation was significant long before circulation failure in lower jaw primordia emerged, suggesting direct effects of TCDD on jaw primordia. In the present study, the mechanism of impaired jaw development was investigated with special reference to the involvement of hedgehog signaling. Lower jaw primordia expressed sonic hedgehog (shh), tiggy-winkle hedgehog (twhh) and their receptors (patched 1, 2), as well as their transcription factors (gli1, 2). Shh function defective mutant embryos (Sonic you) with relatively normal circulation around jaw primordia showed marked retardation of jaw growth. When cyclopamine, an inhibitor for hedgehog signaling, was applied from 48hpf, lower jaw growth was significantly inhibited. On the other hand, embryos treated with TCDD showed marked reduction of shh and twhh expression in lower jaw primordia at 48 and 54hpf, while both patched expressions were not affected at all. Furthermore, zebrafish aryl hydrocarbon receptor 2 (zfAHR2) mRNA was strongly expressed in lower jaw primordia at 48 hpf. Injection of morpholino antisense oligo against zfAHR2 (zfAHR2-MO) but not its negative homologue with 4 different nucleotides (4-Mis) in two cells stage embryos inhibited reduction of hedgehog expressions and these toxic effects induced by TCDD. These results suggest the involvement of hedgehog signaling in lower jaw growth retardation by TCDD in zebrafish embryos.

1778 MICROARRAY ANALYSIS FOR MOUSE FETUS GENES ALTERED BY 2, 3, 7, 8-TETRACHLORODIBENZO-P-DIOXIN (TCDD) EXPOSURE ON GESTATIONAL DAY 13.

S. Ohsako[1,2], R. Ishimura[1,2] and C. Yohyama[1,2]. *[1]Environmental Health Sciences Division, National Institute of Environmental Studies, Tsukuba, Ibaraki, Japan and [2]CREST, JST, Kawaguchi, Saitama, Japan.*

A relatively low dose of 2, 3, 7, 8-tetrachlorodibenzo-*p*-dioxin (TCDD) exposure during pregnancy has been reported to result in developmental defects in reproductive organs on male offspring, e.g., delay of prostate development. In the mouse, the magnitude of the effect is more severe on gestational day 13 (GD13)-exposure than on the later stage, suggesting that this stage fetus is more sensitive to TCDD (Lin, T.M., *et al.*, 2002). In the present study, we exposed pregnant C57BL/6J mice to TCDD (10 μg/kg, p.o.) or vehicle (oil) on GD13 or GD17 and collected fetuses 24-hours post-administration. Total RNAs from fetal whole body were extracted and 5 male fetuses from each group were combined and analyzed by Atlas Mouse Glass 3.8I microarray (BD Biosciences Clontech, CA, USA). Among 3, 756 genes in the array, 822 genes were counted as detectable spots either of the 4 treatment groups. Among them, 146 genes and 239 genes were detected as genes up (ratio > 1.5)- and down (ratio < 0.67)-regulated by GD 13-TCDD treatment, respectively. Interestingly only 14 and 38 genes were also detected as altered genes by GD17-TCDD treatment. Semiquantitative RT-PCR analysis clearly showed that CYP1A1, 1A2, and 1B1 mRNA levels were increased in all fetuses exposed TCDD on both GD13- and GD17, however, CYP1A2 was classified as non-detectable level even in TCDD-exposed groups in the microarray. Above results suggested that GD13 mouse fetuses have a different set of genes from GD-17 fetuses in terms of specific response to TCDD.

1779 TEMPORAL EFFECTS OF AH RECEPTOR LIGANDS ON CH12LX MURINE B-CELL LYMPHOMA CELL GENE EXPRESSION: CDNA MICROARRAY ANALYSIS, REAL-TIME PCR VERIFICATION AND BIOINFORMATIC ASSESSMENT.

M. R. Fielden, D. R. Boverhof and T. R. Zacharewski. *Biochemistry & Molecular Biology, National Food Safety & Toxicology Center, and Institute for Environmental Toxicology, Michigan State University, East Lansing, MI.*

The B-cell, a major component of humoral immunity, is a sensitive target for the immunotoxic effects of 2, 3, 7, 8-tetrachlorodibenzo-p-dioxin (TCDD) possibly by rendering B-cells less responsive to antigen or mitogen stimulation. The potential mechanisms of TCDD action on B-cells were examined in murine B-cell lymphoma cells (CH12LX) treated with 3 nM TCDD or DMSO vehicle for 0, 2, 4, 6, 8, 12 and 24 hrs using a sequence verified cDNA microarray representing 3068 genes/ESTs. Quantitative real-time PCR was used to verify the microarray results and statistical significance was determined using the t-test ($p<0.05$). Cyp1a1 and Cyp1a2 displayed characteristic induction profiles with maximum induction of 300- and 6-fold, respectively, at 4 hrs. Semaphorin 3b (Sema3b), phosphitidyl-inositol-3-kinase delta (pik3cd), signal transducer and activator of transcription 1 (Stat1), and an EST similar to T-cell surface glycoprotein CD1.2 precursor exhibited similar induction profiles and were maximally induced 6-, 2.3-, 1.8- and 10-fold, respectively. A 5000 bp region upstream of the transcriptional start site was extracted from the UCSC Genome Browser database. Putative DREs were identified within the promoter regions that had position weight matrix scores comparable to 15 bona fide functional DREs suggesting that Sema3B, pik3cd and Stat1 may be regulated by the AHR. Induction by structurally diverse AHR ligands further implicated regulation by the AHR. These genes are involved in mitogen-stimulated signaling pathways and therefore, may play a role in the compromised responsiveness of B-cells following treatment with TCDD and related ligands.

1780 TRANSCRIPTIONAL REGULATION OF THE HS4 DOMAIN THROUGH A DRE AND κB MOTIF.

C. Sulentic[1], Y. Na[2], S. Fintushel[1] and N. Kaminski[1]. *[1]Pharmacology & Toxicology, Michigan State University, East Lansing, MI and [2]Korea Advanced Institute of Science and Technology, Daejon, South Korea.*

The B-cell is a sensitive cellular target of 2, 3, 7, 8-tetrachlorodibenzo-*p*-dioxin (TCDD) with the inhibition of immunoglobulin (Ig) secretion being a sensitive endpoint of TCDD toxicity. Our previous results describing the CH12.LX (AhR-

expressing) and BCL-1 (AhR-deficient) B-cell lines have supported an AhR/dioxin-responsive enhancer (DRE)-mediated mechanism for TCDD-induced inhibition of μ heavy chain expression and thus of IgM secretion. Transcriptional regulation of the Ig heavy chain genes involves several regulatory elements including the 3'α enhancer, which is composed of four regulatory domains. One of these domains, hs4, contains a DRE overlapping a κB motif. We have previously demonstrated binding of the AhR nuclear complex and NF-κB proteins to these motifs as well as TCDD and LPS-induced transcriptional activity through the hs4 domain. To determine if the DRE and κB motifs contribute to this enhancer activity, a luciferase reporter gene containing a variable heavy chain (V_H) promoter and a 42 bp fragment of hs4, which contains the overlapping DRE and κB motifs or mutations of these motifs, was transiently transfected into the CH12.LX or BCL-1 cells. In the CH12.LX cells, TCDD and/or LPS modestly affected promoter activity. Addition of the hs4 fragment resulted in a significant increase in activity following TCDD or LPS treatment with the cotreatment inducing the greatest activity. Mutation of either or both of the DRE and κB motifs diminished the effect of TCDD and LPS, resembling the effect of these treatments on the promoter alone. In the BCL-1 cells, only LPS activated the V_H promoter and addition of the hs4 fragment with or without mutations of the DRE and κB motifs did not alter this profile of activity. These results suggest that binding to both the DRE and κB motifs is necessary for enhancement of promoter activity by the hs4 fragment and perhaps activity of the entire hs4 domain. (Supported by NIH ES02520 and NIEHS ES05914)

1781 THE VASCULAR ENDOTHELIUM OF THE BLOOD-BRAIN BARRIER AS A TARGET FOR DIOXIN TOXICITY.

C. R. Filbrandt and T. A. Gasiewicz. *Environmental Medicine, University of Rochester, Rochester, NY.*

Numerous functions regulated by the central nervous system are targeted by 2, 3, 7, 8-tetrachlorodibenzo-p-dioxin (TCDD), demonstrating its potential neuroactivity. Due to its highly lipophilic structure, TCDD should transverse the vascular blood-brain barrier (BBB), enter the brain parenchyma and elicit damage. However, *in vivo*, TCDD distribution and accumulation into the brain is unexpectedly low. As a result, it is hypothesized the barrier endothelial cells play a role in mediating dioxin penetration, and by doing so are an initial cellular target of TCDD neurotoxicity. The goal of these studies was to characterize TCDD toxicity in the cells types comprising the blood brain barrier, namely endothelial cells and supporting astrocytes. Primary cortical culture models of these cell types, characterized by cell specific markers, have been established for these studies. Western blot analysis has localized the expression of the aryl hydrocarbon receptor (AhR), the predominant modulator of TCDD toxicity, in both endothelial cells and astrocytes. In addition, the prototypical CYP1A1 and CYP1B1protein induction in response to TCDD treatment has been characterized. While both CYP1A1 and CYP1B1 are induced in endothelial cells after four and eight hours respectively, CYP1B1 is the predominant CYP450 isoform induced in astrocytes at twenty-four hours. The CYP450 protein induction in both cell types is sustained for greater than 72 hours and is mediated by the AhR as indicated by co-treatment of cells with the receptor specific antagonist, 3-methoxy-4-nitroflavone. These data indicate endothelial cells and astrocytes are responsive to TCDD through the AhR mediated pathway. It is further hypothesized that CYP450 induction and consequential enzymatic activity is a mechanism for TCDD toxicity in these cells and may lead to vascular breakdown and potentiate neurotoxicity. (Supported by NIH grant ES09430, Training Grant ES07026, and Center Grant ES01247)

1782 ARYL HYDROCARBON RECEPTOR GENE SILENCING WITH SMALL INHIBITORY RNA DIFFERENTIALLY MODULATES Ah-RESPONSIVENESS IN MCF-7 AND HEPG2 CANCER CELLS.

M. Abdelrahim[1], R. Smith[2] and S. Safe[1]. *[1]Veterinary Physiology & Pharmacology, Texas A&M University, College Station, TX and [2]Veterinary Pathobiology, Texas A&M University, College Station, TX.*

Sequence-specific small interfering RNA (siRNA) duplexes can be used for gene silencing in mammalian cells and as mechanistic probes for determining gene function. Transfection of siRNAs for the aryl hydrocarbon receptor (AhR) and AhR nuclear translocator (ARNT) mRNAs in MCF-7 breast cancer cells resulted in a 60-80% decrease in levels of AhR and ARNT proteins in whole cell extracts and decreased binding of nuclear extracts to ^{32}P-labeled dioxin responsive element (DRE). siRNA for the AhR also decreased 2, 3, 7, 8-tetrachlorodibenzo-*p*-dioxin (TCDD)-induced CYP1A1 protein, CYP1A1-dependent activity, and luciferase activity in cells transfected with an Ah-responsive construct containing three tandem DREs linked to a bacterial luciferase gene. 17β-Estradiol (E2) induces proliferation of MCF-7 cells through enhanced G_0/G_1 to S phase progression, and this response is inhibited in cells cotreated with E2 plus TCDD. The effects of TCDD on E2-induced cell cycle progress were partially blocked in MCF-7 cells transfected with siRNA for AhR. The results also indicated that siRNA-dependent decreases in AhR protein in MCF-7 cells were accompanied by increased G_0/G_1 to S phase progression, suggesting a growth inhibitory role for the "endogenous" AhR. Surprisingly, TCDD alone induced G_0/G_1 to S phase progression and exhibited estrogenic activity in MCF-7 cells transfected with siRNA for the AhR. In contrast, degradation of the AhR in HepG2 liver cancer cells resulted in decreased G_0/G_1 to S phase progression, suggesting that in the absence of ligand, the AhR enhances growth of this cell line.

1783 A CONSTITUTIVELY ACTIVE ARYL HYDROCARBON RECEPTOR INDUCES GROWTH INHIBITION BY CELL CYCLE ARREST AND APOPTOSIS IN JURKAT T CELLS.

T. Ito[1,2], S. Tsukumo[1,2], M. Yamamoto[2,3], H. Motohashi[3], N. Suzuki[3], Y. Fujii-Kuriyama[2,3], J. Mimura[3], C. Tohyama[1,2] and K. Nohara[1,2]. *[1]Environmental Health Sciences Division, National Institute for Environmental Studies, Tsukuba, Japan, [2]CREST, JST, Kawaguchi, Japan and [3]TARA Center, University of Tsukuba, Tsukuba, Japan.*

2, 3, 7, 8-Tetrachlorodibenzo-p-dioxin (TCDD) is known to suppress T cell-dependent immune reactions, such as antibody production, in an aryl hydrocarbon receptor (AhR)-dependent manner. We previously reported that TCDD exposure inhibits T cell expansion prior to suppression of T cell-dependent antibody production in mice. However, the mechanism by which TCDD affects the growth of T cells remains to be clarified. In this study, we investigated the effects of AhR activation on the growth of Jurkat T cells by transiently transfecting them with an expression vector for green fluorescence protein (GFP) alone or GFP-constitutively active AhR (CA-AhR) fusion protein. We used a CA-AhR mutant lacking the minimal PAS B motif, which constitutively existed in the nucleus and activated AhR-dependent transcriptions independently of the ligand. GFP-positive cells were sorted out 2 days after transfection and cultured in order to measure cell growth. The growth of Jurkat T cells was completely inhibited by expression of CA-AhR whereas it was not affected by expression of GFP alone. In order to elucidate the mechanism of inhibition of T cell growth by CA-AhR, cell cycle stage and apoptosis in the transfected cells were investigated. Expression of CA-AhR increased the percentage of cells in G1 phase and decreased the percentage of cells in S phase, indicating that CA-AhR induced G1 arrest. In addition, expression of CA-AhR increased the population of Annexin V-positive apoptotic cells when compared to expression of GFP alone. These results suggest that activated AhR modulates T cell growth *via* cell cycle arrest and apoptosis, and thus prevents T cell expansion.

1784 THE ARYL HYDROCARBON RECEPTOR MEDIATES DEGRADATION OF THE ESTROGEN RECEPTOR α THROUGH ACTIVATION OF PROTEASOMES.

M. Wormke[1], M. Stoner[1], B. Saville[1], K. B. Walker[1], M. Abdelrahim[1], R. Burghardt[2] and S. Safe[1]. *[1]Veterinary Physiology & Pharmacology, Texas A&M University, College Station, TX and [2]Veterinary Anatomy & Public Health, Texas A&M University, College Station, TX.*

2, 3, 7, 8-Tetrachlorodibenzo-*p*-dioxin (TCDD) and other aryl hydrocarbon (AhR) ligands suppress 17β-estradiol (E2)-induced responses in the rodent uterus and mammary tumors and in human breast cancer cells. Treatment of ZR-75, T47D and MCF-7 human breast cancer cells with TCDD induces proteasome-dependent degradation of endogenous estrogen receptor α (ERα). The proteasome inhibitors MG132, PSI and PSII ablate the proteasome-dependent effects induced by TCDD, whereas the protease inhibitors EST, calpain inhibitor II and chloroquine do not affect this response. ERα levels in the mouse uterus and breast cancer cells were significantly lower after cotreatment with E2+TCDD than after treatment with E2 or TCDD alone. Our results indicate that AhR-mediated inhibition of E2-induced transactivation is due to limiting levels of ERα in cells cotreated with E2+TCDD as measured by both transient transfection and Western blot analysis. Gene silencing by RNA interference assays using small inhibitory RNA molecules demonstrate that the AhR is required for TCDD-induced degradation of ERα. TCDD alone or in combination with E2 increases formation of ubiquitinated forms of ERα, and both coimmunoprecipitation and mammalian two hybrid assays demonstrate that TCDD induces interaction of the AhR with ERα in the presence or absence of E2. In contrast, E2 does not induce AhR-ERα interactions. Thus, inhibitory AhR-ERα crosstalk is linked to a novel pathway for degradation of ERα in which TCDD initially induces formation of a nuclear AhR complex which coordinately recruits ERα and the proteasome complex resulting in degradation of both receptors. (Supported by NIH ES09106 and ES04176)

1785 ARYL HYDROCARBON RECEPTOR AGONISTS INHIBIT HORMONE-INDUCED TRANSACTIVATION IN PROSTATE CANCER CELLS.

D. Morrow and S. Safe. *Veterinary Physiology & Pharmacology, Texas A&M University, College Station, TX.*

2, 3, 7, 8-Tetrachlorodibenzo-*p*-dioxin (TCDD) and 6-methyl-1, 3, 8-trichlorodibenzofuran (6-MCDF) are ligands for the aryl hydrocarbon receptor (AhR), where 6-MCDF is a weak AhR agonist for several TCDD-like toxic responses. This study investigated the interactive effects of AhR ligands and steroid hormones on receptor proteins, hormone-induced transcriptional activation, and proliferative responses in human prostate (LNCaP and 22RV1) cancer cells. Both LNCaP and 22RV1 cells express the androgen receptor (AR), and after treatment with 10 nM dihydrotestosterone (DHT), significant 2- to 4-fold upregulation of immunoreactive AR protein is observed within 3 h, and remains elevated for up to 24 h. DHT-induced upregulation of AR is inhibited in cells treated with TCDD or 6-MCDF. In prostate cancer cells transfected with a construct (PB-luc) containing an androgen-responsive probasin gene promoter insert, both TCDD and 6-MCDF significantly inhibited DHT-induced reporter activity, whereas this activity was not inhibited in cells transfected with a construct containing only the strongly androgen responsive region (ARR3TK-luc). Ten nM 17β-estradiol (E2) also upregulated AR levels in LNCaP and 22RV1 prostate cancer cells and E2 significantly induced reporter gene (luciferase) activity in cells transfected with PB-luc or ARR3TK-luc. TCDD and 6-MCDF inhibited E2-induced activity only in cells transfected with PB-luc. E2-induced activity in cells transfected with PB-luc was inhibited by the estrogen receptor β (ERβ) antagonist 2, 2-bis(*p*-hydroxyphenyl)-1, 1, 1-trichloroethane (HPTE) and the pure antiestrogen ICI 182, 780, whereas the latter compound did not inhibit DHT-mediated transactivation. These studies indicate that AhR-AR crosstalk is dependent on promoter context (i.e. PB vs. ARR3TK). Moreover, our results also suggest that E2-responsiveness of probasin may be ERβ-dependent and the inhibitory effects of TCDD and 6-MCDF indicate that the AhR may inhibit ERβ-induced genes in prostate cancer cells. (Supported by DAMD17-02-1-0147 and NIH ES09106)

1786 CROSS TALK BETWEEN DIOXIN AND HYPOXIA SENSING PATHWAYS: A GENE ARRAY STUDY.

K. N. De Abrew[2,1] and K. K. Graven[1,2]. [1]*Medicine, University of Wisconsin, Madison, WI and* [2]*Molecular and Environmental Toxicology Center, University of Wisconsin, Madison, WI.*

Although the cellular responses to 2, 3, 7, 8-tetrachlorodebenzo-p-dioxin (TCDD) and the environmental stress of hypoxia are well studied investigations of potential cross talk are limited. The endothelial response to these combined stresses is unknown. Aryl hydrocarbon receptor nuclear translocator is a common dimerization partner for both aryl hydrocarbon receptor and hypoxia inducible factor. Possible cross talk between these two pathways was studied using gene array technology. Human lung microvascular endothelial cells were exposed to 10nM TCDD, hypoxia (0%O2) or both TCDD and hypoxia for 24 hrs and resulting RNA was analyzed using Affymetrix gene arrays. Statistical analysis of triplicate studies was performed using Affymetrix microarray suite and Affymetrix data mining tool. Ten genes were upregulated during exposure to TCDD alone and 194 genes were upregulated during exposure to hypoxia alone. A total of 147 genes were upregulated during exposure to both TCDD and hypoxia combined. The 6 genes that were upregulated only during TCDD exposure (i.e. hypoxia prevented their upregulation) encoded proteins involved in oxidant stress response, certain growth factors and cellular receptors. The 76 genes that were upregulated only during hypoxia (i.e. TCDD prevented their upregulation) encoded proteins involved in cell adhesion, extracellular matrix formation, histone binding and certain cellular receptors. The common genes upregulated under TCDD alone and in combination with hypoxia represented members of the cytochrome p450 family. The common genes upregulated under hypoxia alone and in combination with TCDD represented a wide variety of genes involved in the endothelial hypoxic response. These results demonstrate that there is cross talk between the TCDD and hypoxia sensing pathways.

1787 ARYL HYDROCARBON RECEPTOR-MEDIATED INHIBITION OF ESTROGEN RECEPTOR-NEGATIVE BREAST CANCER CELL GROWTH.

L. Kotha and S. Safe. *Veterinary Physiology & Pharmacology, Texas A&M University, College Station, TX.*

The mechanisms of inhibitory aryl hydrocarbon receptor (AhR)-estrogen receptor α (ERα) crosstalk in breast cancer cells have been extensively investigated, and selective AhR modulators (SAhRMs) have been developed for inhibition of ER-positive breast cancer cell/tumor growth. MDA-MB-453 and BT-474 human breast cancer cells are ER-negative and their growth is due, in part, to overexpression of the oncogene, epidermal growth factor receptor 2 (EGFR2/ErbB2/neu). In these cell lines, there is constitutive activation of the mitogen-activated protein kinase (MAPK) and phosphatidylinositol-3-kinase (PI3-K) signaling pathways. Treatment of these cells with 1 or 10 nM 2, 3, 7, 8-tetrachlorodibenzo-*p*-dioxin (TCDD) induces CYP1A1- or dioxin response element (DRE)-dependent activities confirming that both cell lines are Ah-responsive. Treatment of these cells with 25 μM LY294002 or 10 μM U1026 which inhibit PI3-K or MAPK signaling also inhibits growth of both cell lines. Growth inhibition of these cells is also observed after treatment with 10 nM TCDD, 1 - 5 μM 6-methyl-1, 3, 8-trichlorodibenzofuran (6-MCDF) and other SAhRMs. These AhR-mediated growth inhibitory responses are also accompanied by alterations of cell cycle progression. The effects of TCDD and SAhRMs on MAPK and PI3-K signaling pathways were investigated by determining phosphorylation of MAPK and Akt. After short term (3 hr) treatment with LY294002 or U1026, there was significant inhibition of both MAPK- and PI3-K-dependent phosphorylation, whereas inhibitory effects were not observed for SAhRMs. In contrast, after treatment for up to 72 hr, SAhRMs significantly decreased activity of both kinases pathways, and the mechanisms of this response are currently being investigated. 1788 TCDD INDUCES A SUPPRESSION OF PPARγ EXPRESSION THAT INHIBITS ADIPOCYTE DIFFERENTIATION.

M. Cimafranca[1] and C. R. Jefcoate[2]. [1]*Molecular & Environmental Toxicology Center, University of Wisconsin, Madison, WI and* [2]*Pharmacology, University of Wisconsin, Madison, WI.*

C3H10T1/2 cells (10T1/2) are a multipotential mouse embryo fibroblast cell line that can differentiate into adipocytes when administered insulin, dexamethasone, and isobutylmethylxanthine at 100% confluency; the PPARγ ligand BRL46593 increases this differentiation. We have previously shown that PPARγ expression is inhibited and subsequent lipid droplet accumulation is greatly diminished if TCDD is administered 48 hours prior to hormonal stimulation. Here we demonstrate that changes in TCDD-induced AhR activation positively correlate with TCDD-mediated inhibition of PPARγ. The down regulation of AhR induction of Cyp1B1, suppression of PPARγ expression, and suppression of the transformation into adipocytes each show a similar dependence on TCDD concentration (EC_{50} < ~ 2 — 5pM). TCDD suppressed PPARγ in an equally effective manner whether it was added 48 hours prior to or up to 12 hours after hormonal stimulation; however, if TCDD is administered 24 hours after the hormonal stimulation, suppression of PPARγ does not occur. We have also shown that the PPARγ suppression, whether TCDD treatment was initiated 48 hours prior to or 12 hours after hormonal stimulation, depended on MEK/ERK activation within the same time period of 6 – 16 hours post hormonal administration. The AhR antagonist 3'-methoxy-4'-nitroflavone (3-MNF) similarly antagonizes TCDD activation of AhR, as measured by inhibition of Cyp1B1 protein expression and suppression of PPARγ expression. In order for 3-MNF to antagonize the TCDD effect on PPARγ, 3-MNF must be present during the period of TCDD/MEK activity prior to the onset of PPARγ stimulation. We conclude that TCDD induces a protein that, in conjunction with MEK activity, suppresses PPARγ expression.

1789 TCDD INDUCES INCREASED EXPRESSION OF RETINOIC ACID METABOLIZING GENES: POSSIBLE ROLE IN ALTERING PROLIFERATION AND DIFFERENTIATION IN HUMAN KERATINOCYTES.

J. Zhang, S. Ray and H. I. Swanson. *Molecular and Biomedical Pharmacology, University of Kentucky, Lexington, KY.*

The aryl hydrocarbon receptor (AhR), is thought to mediate most of the carcinogenic and toxic effects of TCDD and related chemicals through the formation of a heterodimer with its DNA binding partner, ARNT and transcriptional regulation of AHR/ARNT target genes. We have previously shown that administration of TCDD to primary, human keratinocytes results in an immediate increase in proliferation, and a decrease in replicative senescence and a subsequent increase in late differentiation. In an effort to identify the gene pathways that regulate proliferation and differentiation and may be modified by TCDD and the AHR/ARNT heterodimer, we have performed similar experiments and analyzed the TCDD-induced changes in gene expression using microarray and western blot analysis. We have found that TCDD induces the mRNA expression levels of a number of genes involved in retinoic acid metabolism (i.e., retinol and retinoic acid dehydrogenases) in a time dependent manner. In addition, significant changes in retinoic acid receptor (RAR) isoforms were observed in the TCDD-treated cells. Given that retinoic acid is a powerful modulator of proliferation and differentiation, we suggest that the ability of TCDD to alter proliferation and differentatiation in these cells may involve the alteration of retinoic acid homeostasis.

1790 EFFECT OF ARYL HYDROCARBON RECEPTOR (AhR) AGONISTS ON THE ACTIVATION OF TELOMERASE IN HUMAN MAMMARY EPITHELIAL CELLS.

R. M. Audet[1], S. Girard[1], G. Lassonde[1], D. Desaulniers[2] and M. Charbonneau[1]. *[1]INRS-Institut Armand-Frappier, INRS, Université du Québec, Montreal, QC, Canada and [2]Health Canada, Ottawa, ON, Canada.*

Telomerase, a reverse transcriptase inactive in normal somatic tissue, permits indefinite cell growth *via* the elongation and maintenance of telomeres, the repetitive sequence capping chromosome ends. Epidermal Growth Factor markedly stimulates telomerase activity in keratinocytes and 2, 3, 7, 8-tetrachlorodibenzodioxin (TCDD) prevents this effect. Telomerase is increased in the vast majority of human mammary tumors. Thus, the effects of TCDD and other AhR agonists on telomerase activity in human mammary epithelial cells were evaluated in order to assess the role of AhR agonists in breast carcinogenesis. Telomerase was measured using a quantitative PCR-based method (telomerase repeat amplification protocol). MCF-7 cells were exposed to 4 nM TCDD or the vehicle alone for a period up to 25 days. Compared to controls a larger proportion of cells exposed to TCDD detached from the Petri dish after 6 to 8 days in culture, but no reduction in cell proliferation was observed throughout the study. A marked reduction of telomerase activity was measured in all viable floating cells in comparison to adherent cells. TCDD did not change telomerase activity in the latter. In another series of experiments, a mixture of 16 AhR agonists (3 coplanar PCBs, 7 PCDFs and 6 PCDDs) was tested for up to 25 days in the non tumorigenic human mammary cell line, MCF-10A. The AhR-mixture caused a progressive reduction in telomerase activity from day 0 to day 3, whereas after day 6 no more activity was detected. A very small fraction of cells became floating and this was not influenced by TCDD treatment. A gradual growth arrest was observed from day 9 to day 25. Thus, a reduction of telomerase activity preceded the marked reduction in cell proliferation demonstrating a strong link between telomerase and proliferation. The effect of AhR agonists on telomerase activity in human cell lines does not support a role for these compounds in breast tumor development. (Supported by TSRI and PREECAN)

1791 THE ROLE OF DNA OXIDATION IN TCDD-INDUCED HOMOLOGOUS RECOMBINATION.

C. Y. Chan[1], P. M. Kim[1,2] and L. M. Winn[1,2]. *[1]Pharmacology and Toxicology, Queen's University, Kingston, ON, Canada and [2]School of Environmental Studies, Queen's University, Kingston, ON, Canada.*

The environmental toxicant 2, 3, 7, 8-tetrachlorodibenzo-p-dioxin (TCDD) elicits a spectrum of deleterious biological responses. One of the toxic effects of TCDD is carcinogenicity, but the molecular mechanism by which TCDD exerts its tumorgenic effects is unclear, since it is not directly genotoxic. Therefore, the molecular mechanism leading to the development of cancer as a result of TCDD exposure needs to be elucidated. DNA damage, including DNA oxidation, can induce DNA double-strand breaks (DSB), which can be repaired through homologous recombination (HR). Excessive DSBs may promote aberrant DNA recombination, which can mediate detrimental genetic changes. We hypothesize that these genetic changes lead to increased genomic instability and ultimately TCDD-induced carcinogenesis. To investigate this hypothesis we used a Chinese hamster ovary (CHO) cell line containing a neo direct repeat recombination substrate (CHO3-6) to determine whether TCDD-induced HR is initiated by DNA oxidation. CHO 3-6 cells were exposed to TCDD (50, 500 or 1000 pM) for 6 or 24 hr and 2 weeks later HR frequencies were determined by counting the number of functional neo expressing, G418-resistant colonies per live cells plated. TCDD-initiated DNA oxidation was determined by measuring the formation of 8-hydroxy-2'-deoxyguanosine *via* HLPC and electrochemical detection. While TCDD did not increase HR after the 6 hr exposure period, exposure to 500 pM TCDD for 24 hr significantly increased HR frequency. DNA oxidation was not increased in cells exposure to TCDD for either 6 or 24 hr. Therefore, our results suggest that TCDD-initiated HR in CHO 3-6 cells is not mediated by oxidative DNA damage. (Supported by the Canadian Institute of Health Research and Queen's University ARC)

1792 METABOLIC DEGRADATION OF A SUGGESTED ENDOGENOUS ARYLHYDROCARBON RECEPTOR LIGAND, THE TRYPTOPHAN PHOTOPRODUCT 6-FORMYLINDOLO[3, 2-B]CARBAZOLE.

A. Rannug[1], L. Bergander[2], W. Alworth[3] and U. Rannug[2]. *[1]Institute of Environmental Medicine, Karolinska Institutet, Stockholm, Sweden, [2]Department of Genetic and Cellular Toxicology, Stockholm University, Stockholm, Sweden and [3]Department of Chemistry, Tulane University, New Orleans, LA.* Sponsor: G. Johanson.

Purified extracts of irradiated tryptophan exhibit 4- to 7-fold higher binding affinity to the arylhydrocarbon receptor (AhR) compared to TCDD. In different cells, *in vitro*, the synthesized pure photoproduct 6-formylindolo[3, 2-b]carbazole (FICZ) as well as extracts of UV-irradiated tryptophan induce a rapid and transient expression of AhR-regulated genes. The transient induction suggests that the biotransformation gene battery induced *via* AhR activation takes part in a metabolic degradation of the ligand. The *in vitro* metabolism of the tryptophan photoproduct FICZ has been characterized by LC-MS and NMR spectroscopy. Five metabolites have been identified and their structures elucidated. In the present study, using rat hepatic S9 incubation and specific enzyme inhibitors, the involvement of different phase I and phase II metabolizing enzymes were investigated. The P4501A1enzyme is the most important enzyme for the first step in the metabolism of FICZ. Monohydroxylated metabolites seem to be formed by both CYP1A1 and CYP1A2, although with slower kinetics by CYP1A2. Dihydroxylated secondary metabolites were also identified. By use of specific inhibitors, the enzymes CYP1A1, CYP1A2, and CYP1B1 were indicated to participate in the formation of three different dihydroxylated compounds. The conjugating enzymes SULT and UGT take part in the further metabolism as indicated by decreased levels of the dihydroxylated metabolites after addition of the necessary conjugating cofactors PAPS and UDPGA, respectively. Our experimental data on the metabolism of the tryptophan derived AhR ligand FICZ by the battery of AhR-regulated enzymes explain the important role of the functional CYP1A1 enzyme in the autoregulatory feedback loop that has been proposed to exist for controlling transcription of AhR-regulated genes.

1793 2, 3, 7, 8 TETRACHLORODIBENZO-P-DIOXIN (TCDD) INCREASES MITOMYCIN C (MMC) TOXICITY AND ALTERS METABOLISING ENZYMES THROUGH ARYL HYDROCARBON RECEPTOR (AHR) INTERACTION.

A. C. Collier[1,2] and C. A. Pritsos[1,2]. *[1]Nutrition, University of Nevada, Reno, NV and [2]Environmental Sciences and Engineering, University if Nevada, Reno, NV.*

Selective manipulation of metabolic enzymes and intracellular events to increase drug efficacy is currently an area of much interest. Commonly the compounds used, such as broussochalcone, are AhR agonists. It is the relative induction of activation and detoxification enzymes which determines the efficacy of the agonist-AhR interaction to modulate drug toxicity. We have investigated the toxicity of the enzyme-activated prodrug MMC when TCDD, a prototypical AhR agonist, is co-administered. Human mammary carcinoma cells (MCF7) were maintained in MEM with non essential amino acids, 10% FBS, 1 mM sodium pyruvate and 10 μg/mL bovine insulin and were co-treated with TCDD (10 nM) and MMC (0, 1, 10 or 100 μM) for 2h or pre-treated with TCDD then MMC for 2h each in 95% air/5% CO2. Cells were subsequently assessed for viability or enzyme activity with S9 protein prepared by differential centrifugation. In clonogenic assays significantly more cell death was observed with TCDD and MMC co-treatment at 1 and 10 μM compared to cells treated with MMC alone although no significant differences in cell death were observed with TCDD pre-treatment. Enzyme activities increased by TCDD when compared to vehicle were DT-diaphorase (NQO1), xanthine dehydrogenase (XDH) and cytochrome P450 reductase (CYPR) in both pre- and co-treated cells. With TCDD pre-treatment, XDH activity when compared to both vehicle and 1 μM MMC increased as opposed to MMC alone, while CYPR activity increased at all doses when compared to MMC alone. The activities of xanthine oxidase and glutathione-S-transferase were not altered. Dose-dependent decreases in NQO1 and XDH activity were observed as MMC concentration increased. Co-administration of MMC and AhR agonists may result in greater toxicity through increased activity of activation enzymes, particularly XDH and CYPR without a concomitant increase in detoxification enzymes.

1794 AGONISTIC AND ANTAGONISTIC EFFECTS OF POLYBROMINATED DIPHENYL ETHERS (PBDE) IN MCF7 CELLS.

L. Peters[1], T. Sanderson[1], A. Bergman[2] and M. van den Berg[1]. *[1]Institute for Risk Assessment Sciences, University Utrecht, Utrecht, Netherlands and [2]Department of Environmental Chemistry, University of Stockholm, Stockholm, Sweden.*

Polybrominated diphenylethers (PBDEs) are used as flame-retardants in consumer products to reduce the chances of ignition and burning. Levels of some PBDE congeners have been increasing in fish, wildlife, and in human tissues. Certain PBDEs have been found to be highly lipophilic and persistent, resulting in bioaccumulation in the environment. The structural similarity of PBDEs to other polyhalogenated aromatic hydrocarbons has raised concerns that PBDEs might act as agonists for the aryl hydrocarbon (Ah) receptor. To study the possible dioxin-like effects of the environmentally relevant PBDEs (BDE47, 77, 99, 100, 153, 154, 183, 209), the Ah receptor-mediated induction of the cytochrome P450 enzyme CYP1A1 was studied in human breast carcinoma cells (MCF7). 7-Ethoxyresorufin-O-deethylase (EROD) was used as a marker for CYP1A1 activity. MCF7 cells (ATCC) were exposed to several concentrations (0.01-25 μM) of these PBDEs (Å Bergman, Sweden). Positive controls were 2, 3, 7, 8-TCDD (0.001-2.5 nM) and PCB126 (1-100 μM). EROD activity was measured after 72 hours. None of these

PBDEs was capable of inducing EROD activity. However, when the cells were exposed to BDE153 (2, 2', 4, 4', 5, 5'-hexabromodiphenyl ether) in combination with TCDD, there was a strong concentration dependent antagonistic effect. The positive control TCDD caused maximal EROD induction at 1 nM (100% efficacy). In the presence of BDE153 at concentrations of 2.5 and 10 μM, the maximum efficacy of TCDD was reduced to 38% and 23%, respectively. Similarly, 10, 25 and 50 μM PCB153 reduced the efficacy to 53%, 38% and 2%, respectively. At the present, these PBDEs are tested in either human and mammalian *in vitro* systems for possible Ah receptor agonistic and antagonistic properties. Whether or not this antagonism is due to direct interaction with the Ah receptor or some other unknown mechanism of downregulation will be further assessed.

1795 SPECTRAL INTERACTIONS OF POLYCHLORINATED BIPHENYLS (PCBS) WITH RAT HEPATIC MICROSOMAL CYTOCHROME P450 ENZYMES.

S. M. Bandiera and E. G. Hrycay. *Faculty of Pharmaceutical Sciences, University of British Columbia, Vancouver, BC, Canada.*

Rat hepatic microsomes contain multiple cytochrome P450 (CYP) enzymes that interact with xenobiotics to produce a type I spectral change indicative of a CYP-substrate complex. The purpose of this study was to determine whether the tetrachlorobiphenyls (PCB 47, 52, 54, and 77) elicit type I spectral changes with microsomal CYP and if so, which CYP forms are involved. Rats were treated with phenobarbital (PB) (75 mg/kg/day), dexamethasone (DEX) (100 mg/kg/day), or 3-methylcholanthrene (MC) (25 mg/kg/day) given i.p. once daily for 4 days. Hepatic microsomes were prepared for subsequent CYP determination, spectral binding, antibody inhibition studies, gel electrophoresis, and CYP immunoquantitation. All 4 PCBs elicited a type I difference spectrum with microsomal CYP showing an absorbance maximum and minimum at approximately 390 and 420 nm, respectively. The apparent spectral binding constant (Ks) and maximum absorbance change (ΔAmax) were derived from double reciprocal plots. Apparent Ks values of 67, 53, 11, and 5 μM were obtained for PCB 47, 52, 54, and 77, respectively, with control microsomes; 11, 18, 2, and 7 μM with PB microsomes; 78, 52, 9, and 12 μM with DEX microsomes; and 270, 469, 47, and 7 μM with MC microsomes. PCB 47, 52 and 54 bound avidly to PB microsomes with a binding efficiency (ΔAmax/Ks) that was on average 137 and 7 times greater, respectively, than that obtained with MC and DEX microsomes. The absorbance change elicited by PCB 54 in PB microsomes was decreased by 37, 29 and 3%, respectively, in the presence of antibodies against CYP2B, CYP3A and CYP 2C enzymes, and in control microsomes by 52 and 38% in the presence of antibodies against CYP3A and CYP2C enzymes. In conclusion results of antibody inhibition and CYP immunoquantitation experiments suggest that CYP2B and to a lesser extent CYP3A enzymes bind the non-coplanar PCBs (47, 52 and 54) in PB and DEX microsomes whereas CYP1A enzymes bind the coplanar PCB 77 in MC microsomes. CYP2C enzymes also bind PCB 47, 52 and 54 but only in control microsomes.

1796 CYP1B1 INDUCTION BY TCDD OR CELL SUSPENSION REQUIRES SMALL PROPORTION OF NUCLEAR AHR IN MEF 10T1/2 CELLS.

Y. Cho[1]. [1]*Pharmacology, UW-Madison, Madison, WI and* [2]*Pharmacology, UW-Medical School, Madison, WI.* Sponsor: C. Jefcoate.

Cytosolic AhR translocates to the nucleus after binding ligand, such as TCDD. A portion of nuclear AhR acquires transcriptional capability by forming a heterodimeric complex with the ARNT and, thereby, induces target genes. We hypothesize that only a small portion of AhR, translocated to the nucleus following treatment with 1 to 10 nM TCDD is utilized for target gene induction. Therefore, the concentration dependence for AhR translocation, turnover, and Cyp1B1 induction was compared. Gene induction was still maximum at 10 pM TCDD even though nuclear translocation and turnover of AhR were substantially decreased. This result suggests, first, that the quantity of nuclear translocation at 1 nM TCDD far exceeds the level required for target gene induction. Second, that the nuclear AhR that is unbound to DNA is immediately targeted for nuclear export and degradation. This nuclear export is, therefore, increased in proportion to the capacity of TCDD to generate this nuclear excess of AhR as seen in ER (Alarid, Mol Endocr 1999). AhR-mediated transcription is activated not only by TCDD, but also by cell suspension. Cytosolic AhR is complexed with Hsp90. When AhR is activated by TCDD or by suspension, the translocation of AhR to the nucleus is accompanied by translocation of Hsp90. Translocations of AhR and Hsp90 were comparable for TCDD and suspension activations. Geldanamycin, an inhibitor of Hsp90 ATPase, caused a large loss of AhR and prevented translocation of Hsp90 to the nucleus in each process. AhR turnover was also similar and equally inhibited by MG132, a proteosome inhibitor. A major difference between these two, otherwise very similar processes of AhR turnover, was that suspension induction of Cyp1B1 was insensitive to αNF, a competitive inhibitor of TCDD activation. This suggests that the suspension activation does not involve an endogenous AhR ligand. In conclusion, AhR activation by either TCDD or by cell suspension is equally effective and both require a low proportion of nuclear AhR for target gene induction where its down-regulation is slow.

1797 THE EFFECTS OF GREEN TEA CATECHINS ON ARYL HYDROCARBON RECEPTOR-MEDIATED GENE REGULATION.

C. M. Palermo and T. A. Gasiewicz. *Department of Environmental Medicine, University of Rochester, Rochester, NY.*

Green tea (GT) has been implicated in affording protection against cancer in numerous animal models of chemical carcinogenesis. The active constituents and mechanisms responsible for these observations are not fully understood. Among the proposed mechanisms is one involving inhibition of carcinogen activation by modulating bioactivating enzymes, such as CYP1A1, through an interaction with the AhR pathway. Previous investigations in our laboratory have shown that treatment of mouse hepatoma cells with GT extracts results in inhibition of 2, 3, 7, 8-tetrachloro-p-dioxin (TCDD) induced activity of a DRE-dependent luciferase reporter gene. Further fractionation of GT led to the identification of epigallocatechin gallate (EGCG) and epigallocatechin (EGC) as the catechins responsible for this inhibition. From this data, it was hypothesized that EGCG and EGC function as AhR antagonists. However, due to the high (uM) concentrations of catechins used as well as their strong antioxidant activity, it is possible that this decrease in luciferase activity resulted from some indirect, non-AhR effect. Further studies demonstrated that neither cytotoxicity nor antioxidant activity contribute to this decrease in TCDD induced luciferase activity. Furthermore, western blotting of mouse hepatoma cells treated with TCDD together with either EGCG or EGC showed a concentration dependent decrease in both luciferase and CYP1A1 protein levels, strongly supporting a role for the AhR in this inhibition. Interestingly, although both catechins inhibited TCDD induced luciferase with equal potency, EGCG was a much more potent inhibitor of CYP1A1. Further insight into the mechanism of action revealed that although EGCG inhibits TCDD induced DRE binding in cell free systems EGC does not. Identical results were observed in whole cell DRE binding assays indicating the parent compounds are responsible for the antagonist activity. Together, these data suggest that EGCG and EGC function as AhR antagonists through different mechanisms resulting in differential inhibition of AhR mediated gene induction.

1798 CHARACTERIZATION OF REGULATORY ELEMENTS IN THE HUMAN AH RECEPTOR PROMOTER.

J. Racky, H. Kauffmann, H. Schmitz and D. Schrenk. *Food Chemistry and Environmental Toxicology, University of Kaiserslautern, Kaiserslautern, RLP, Germany.*

The Aryl hydrocarbon receptor (AhR) is a ligand-activated transcription factor belonging to the PAS protein family of transcription factors. It mediates biological and toxic responses of e. g. halogenated aromatic hydrocarbons and certain indole derivatives. In the absence of a ligand, the AhR is located in the cytoplasm in a complex with a dimer of heat-shock protein 90 and XAP2 (X-associated protein 2). After ligand binding, AhR translocates to the nucleus where it heterodimerizes with the PAS protein Arnt (Ah receptor nuclear translocator). The AhR-Arnt heterodimer is able to activate specific xenobiotic regulatory elements (XREs) in enhancers of target genes. In many vertebrate as well as in invertebrate species the AhR or homologues have been identified. In humans, it has been found in various tissues such as lung, liver and placenta. Although much is known about the biochemical and molecular mechanisms of AhR action, little is known about the control of the expression of the AhR gene itself. In the present study, we aimed at the identification and characterisation of regions important for constitutive AhR gene expression. We generated a luciferase reporter gene construct including 2.7 kb of the 5'-flanking region of the AhR. Reporter gene assays demonstrated that this part of the AhR promoter strongly activates the reporter gene compared with the empty reporter vector. Reporter gene assays with deletion mutants led to the identification of a region containing putative binding sites for Sp1, c-myc and CREB. Interestingly, reporter gene activities of two constructs with a deletion in this region differed significantly. The functional relevance of putative regulatory sequences was investigated by gel mobility shift analysis and site-directed mutagenesis. Summarizing, our results indicate that a Sp1-site contributes to AhR regulation. Further experiments including super shift assays and investigation of the influence of Sp1 expression plasmids are necessary to reveal the regulatory relevance of the region identified in the present study.

1799 ROLE OF PEROXISOME PROLIFERATOR-ACTIVATED RECEPTOR β (PPARβ) IN MOUSE KERATINOCYTE PROLIFERATION AND DIFFERENTIATION.

D. J. Kim[1,2] and J. M. Peters[1,2]. [1]*Department of Veterinary Science and The Center for Molecular Toxicology and Carcinogenesis, Pennsylvania State University, University Park, PA and* [2]*Graduate Program in Cellular and Molecular Mechanisms of Toxicity, Life Sciences Consortium, Pennsylvania State University, University Park, PA.*

Previous work has shown an enhanced epidermal hyperplastic response induced by the tumor promoter 12-O-tetradecanoylphorbol-13-acetate (TPA) in PPARβ-null mice, suggesting a critical role of PPARβ in attenuating epidermal cell proliferation. In this study, the functional role of PPARβ in keratinoctye proliferation and differentiation was investigated using primary keratinocytes from wild-type and PPARβ-null mice. Differentiation induced by the classical method of increasing culture medium Ca^{++} level resulted in induction of atypical mRNA markers of differentiation and morphological changes including the formation of cornified cells in both genotypes, independent of PPARβ. Differentiation induced by TPA also resulted in induction of standard mRNA markers of differentiation in both genotypes, and the hallmark morphological features of dendritic cell-like appearance in keratinocytes from both genotypes. Despite induction of a known TNFα-responsive gene (mtCLIC) in both genotypes, induction of known mRNA markers of differentiation and atypical morphological changes associated with differentiation were not found in TNFα-treated cells from either genotypes. PPARβ-null keratinocytes showed high expression of cyclin B1 and PCNA mRNA compared to wild-type keratinocytes in low calcium medium. In addition, expression of both mRNAs initially decreased, following by a significant increase, after 1hr pulse treatment of TPA in PPARβ-null keratinocytes, whereas their expression was gradually decreased in wild-type keratinocytes during the same time frame. These results show that PPARβ does not regulate keratinocyte differentiation induced *in vitro*, consistent with previous *in vivo* results. These studies also provide strong evidence that PPARβ attenuates cell proliferation consistent with previous *in vivo* data. (Supported by NIH, CA89607)

1800 THE ROLE OF PEROXISOME PROLIFERATOR-ACTIVATED RECEPTOR ALPHA IN CELL CYCLE REGULATION.

K. A. Burns. *Center for Molecular Toxicology and Carcinogenesis, The Pennsylvania State University, University Park, PA.* Sponsor: J. Vanden Heuvel.

Peroxisome proliferator-activated receptors (PPARs) are ligand-activated transcription factors belonging to the nuclear receptor family. PPARs can be activated by a large group of chemicals called peroxisome proliferators (PPs) that include industrial pollutants and hypolipidemic drugs. It has been shown in murine models that administration of PPs results in hepatomegaly, mitogenesis, and eventually carcinogenesis. PPs are thought to cause cancer by altering gene expression of the target cell and, ultimately, affect cell cycle regulation. To study the role of PPAR alpha-dependent regulation of the cell cycle, hepatoma cell lines from the PPARα wild type and knockout mice were developed. The immortalized hepatoma cells reflect the PPARα-dependent mitogenic response to PPs. The activity, phosphorylation status, and expression of key cell cycle regulatory proteins were examined in these immortalized hepatocytes treated with Wy 14, 643. A significant difference in p53 and pRb activity between phenotypes, but not upon Wy 14, 643 treatment was observed. Similarly, the phosphorylation status of pRb, CDK4, CDK6, p21, and GSK3α/β was affected by PPARα status, but not by Wy 14, 643 treatment. Through quantitative RT-PCR, we are currently examining the role of PPARα in regulating the expression of cyclin dependent kinase inhibitors such as p15, p16, p18, p19, and p21. Although we have shown that PPARα affects the constitutive activity of certain cell cycle regulatory proteins, the key genes involved in the PP-dependent mitogenic response need to be determined.

1801 THE PROTECTIVE EFFECT OF GW4064X ON ALPHA-NAPHTHYLISOTHIOCYANATE (ANIT)-INDUCED HEPATOTOXICITY IN MICE: ROLE OF ACTIVATED FXR.

Y. Liu[1], S. A. Jones[1] and J. Binz[2]. [1]*High throughput Biology, GlaxoSmithKline, Research Triangle Park, NC and* [2]*Metabolic Diseases, GlaxoSmithKline, Research Triangle Park, NC.*

ANIT is a well-known hepatotoxicant that induces obstructive cholestasis in rodents. GW4064X, a farnesoid X-activated receptor (FXR; NR1H4) agonist, has been shown to protect against bile-duct ligation induced hepatotoxicity in rats. This study was designed to determine whether GW4064X is also effective in reducing ANIT-induced hepatotoxicity in mice. Adult CD-1 mice were given vehicle (Veh) (10 ml/kg, ip) or GW4064X (50 mg/kg, ip) daily for 4 days. Two hours after the second dose of Veh or GW4064X, mice were orally dosed with ANIT (150 mg/kg). Hepatotoxicity was assessed 48 hours after ANIT administration. GW4064X treatment significantly decreased ANIT-induced hepatotoxicity, as determined by serum activities of alanine aminotransferase, aspartate aminotransferase, lactate dehydrogenase and alkaline phosphatase. Serum levels of total bilirubin and bile acid were also significantly decreased by GW4064X treatment. Histopathological analysis of hepatocellular necrosis indicated GW4064X-treated mice had fewer and smaller necrotic areas than Veh-treated mice. To examine the mechanism of the protection, total RNA from livers was extracted and subjected to real time quantitative RT-PCR analysis. Compared to Veh, GW4064X treatment resulted in an enhanced expression of small heterodimer partner (SHP) and bile salt export pump (BSEP). ANIT treatment decreased cytochrome P450 7a (CYP7A) and cytochrome P450 8b (CYP8B) expression by 95% and 70%, respectively. GW4064X treatment had no further suppression in both CYP7A and CYP8B. In summary, GW4064X protected against ANIT-induced liver injury in mice. This provides additional evidence that FXR agonists may be useful in the prevention of hepatic damage during conditions of cholestasis.

1802 INDUCTION OF THE TRUNCATED ERYTHROPOIETIN RECEPTOR BY CHLORAMPHENICOL IN MOUSE BONE MARROW.

M. Otieno, A. Katein, L. Foster-Brown, D. Bounous and F. Pognan. *Safety Assessment US, AstraZeneca Pharmaceuticals, Wilmington, DE.* Sponsor: P. Ciaccio.

Interaction between erythropoietin (Epo) and its surface receptor EpoR plays a fundamental role in erythropoiesis. Erythropoiesis is a multi-stage process requiring proliferation and differentiation of erythroblasts to form mature erythrocytes, which repopulate the circulating erythroid pool. There are two forms of EpoR: a full length (EpoR-F) expressed predominantly in mature erythroids and a truncated receptor (EpoR-T) expressed predominantly in immature erythroids. Expression of EpoR-T is thought to have a dominant-negative effect on EpoR-F thus regulating erythropoiesis depending on circulating Epo levels. Chloramphenicol is a broad-spectrum antibiotic used in the treatment of serious infections including typhoid fever and meningitis. However, chloramphenicol is hematotoxic in humans and animals causing reversible anemia, but in extremely rare cases a more serious irreversible aplastic anemia may occur. The aim of our work was to study the mechanism by which chloramphenicol is hematotoxic. We hypothesised that chloramphenicol partially mediates its bone marrow toxicity by modulating the expression of EpoR in erythroblasts. In our studies, treatment of mice with 3000 mg/kg/day chloramphenicol resulted in a 50% or more decline in blood reticulocytes, which was preceded by a depletion of erythroid precursors in bone marrow as determined histochemically in sternums. Immunoblot analysis of bone marrow showed a time-dependent elevation of EpoR-T that corresponded temporally to reticulocyte decline. The overall increase in EpoR levels after treatment was also confirmed by immunofluorescence in bone marrow smears. Although the presence of EpoR-T is physiologically important to maintain tight regulation of erythropoiesis, increased expression of EpoR-T by chloramphenicol may deregulate erythropoiesis and perhaps contribute to the erythroblast-specific toxicity observed with chloramphenicol.

1803 SNURF AND MMS19 AS COACTIVATORS OF ESTROGEN RECEPTOR α-MEDIATED GENE EXPRESSION IN BREAST CANCER CELLS.

K. J. Higgins[2], B. Saville[1] and S. Safe[1]. [1]*Biochemistry & Biophysics, Texas A&M University, College Station, TX and* [2]*Veterinary Physiology & Pharmacology, Texas A&M University, College Station, TX.*

At least two mechanisms of 17β-estradiol (E2)-induced transactivation have been identified in human breast cancer cell lines. These include estrogen receptor α (ERα) interactions with estrogen response elements (EREs) and ERα/Sp1 interaction with GC-rich motifs in promoters of E2-responsive genes. ERα-dependent transcriptional activation of genes through interaction with EREs is dependent upon activation function 2 (AF2) in the ligand binding domain of ERα which specifically interacts with steroid receptor coactivators and other coactivators containing LXXLL motifs. Preliminary studies demonstrated that AF2-interacting coactivators do not enhance ERα/Sp1-mediated transactivation. This study reports the effects of SNURF, a DNA binding domain (DBD) interacting protein, and MMS19, an activation function 1 (AF1)-interacting protein on coactivation of ERα in ZR-75 human breast cancer cells. SNURF cooperatively coactivates ERα through recruitment and interaction with TATA-binding protein (TBP). SNURF coactivates E2-mediated induction by 4- to 5-fold in ZR-75 cells transfected with an ERE promoter construct ($pERE_3$) and ERα. Our results also indicate that interaction of SNURF with DNA is not sufficient, and that SNURF must recruit TBP for efficient coactivation by SNURF. SNURF-mediated coactivation of ERα/Sp1 in cells transfected with a GC-rich promoter ($pSp1_3$) was approximately 2-fold;

however, the mechanism for this coactivation has not been determined. Peptide competition studies using an AF1 peptide resulted in complete inhibition of E2-induced reporter activity in ZR-75 cells transfected with $pSp1_3$. Only minimal decreases were observed using a GRIP NR-box peptide that contains an LXXLL motif. These results demonstrate that ERα/Sp1-mediated transactivation is primarily AF1-dependent. AF1-interacting coactivator MMS19 coactivates ERα 2- to 3-fold in ZR-75 cells cotransfected with $pERE_3$. In contrast, MMS19 does not significantly coactivate ERα/Sp1 in ZR-75 breast cancer cells. (Supported by NIH ES09106 and CA76636)

1804 VITAMIN D RECEPTOR INTERACTING PROTEIN 150 (DRIP 150) AS A COACTIVATOR OF ESTROGEN RECEPTOR α

J. Lee and S. Safe. *Veterinary Physiology & Pharmacology, Texas A&M University, College Station, TX.*

Estrogen-induced gene expression is dependent on hormone interactions with the estrogen receptor α (ERα) and recruitment of nuclear cofactors that facilitate transactivation. Vitamin D receptor interacting protein 150 (DRIP 150) is a component of the mediator complex of nuclear cofactors, and in ZR-75 human breast cancer cells, DRIP 150 enhances 17β-estradiol (E2)-induced transactivation in cells transfected with a construct ($pERE_3$) containing 3 tandem estrogen response elements (EREs). In experiments using wild-type and variant ERα mutants, it was shown that DRIP 150 coactivation was dependent on the C-terminal activation function 2 (AF2) of ERα. DRIP 150 did not coactivate a variant ERα construct that contained mutations in helix 12 (D538A, E542A and D545A) that are required for interactions with coactivators that contain LXXLL motifs. Moreover, DRIP 150-mediated coactivation of ERα was blocked in cells cotransfected with an NR-box peptide containing LXXLL box motifs. DRIP 150 contains N- and C-terminal LXXLL motifs at aa 69-73 and 1182-1186, respectively; however, C-terminal deletions of DRIP 150 which did not contain the latter motif (aa 1-1144, 1-976, 1-885, 1-869, and 1-864) enhanced ERα-mediated coactivation. Amino acids between 864 and 789 were essential for coactivation of ERα by DRIP 150, and the specific sequences responsible for coactivation are currently being characterized. (Supported by NIH ES09106 and CA76636).

1805 PREGNANE X RECEPTOR (PXR) INTERACTS WITH THE NUCLEAR COREPRESSOR SMRT TO REPRESS BASAL CP3A4 GENE EXPRESSION.

D. R. Johnson[1], L. Chen[2], J. H. Li[2], D. Kupfer[2] and D. Chen[2]. *[1]Medicine, University Massachusetts Medical School, Worcester, MA and [2]Biochemistry and Molecular Pharmacology, University Massachusetts Medical School, Worcester, MA.*

The Pregnane X Receptor (PXR; NR1I2) is a member of the nuclear receptor superfamily that heterodimerizes with the Retinoid X Receptor (RXR) on numerous nuclear receptor response element DNA motifs, resulting in the transactivation of target genes. PXR is found primarily in liver and intestine, and is primarily responsible for the tissue-specific up-regulation of Cytochrome P450 3A4 (CYP3A4) in humans by numerous inducer chemicals. Recent PXR knockout mouse studies suggest that PXR may repress basal expression of target genes. We therefore examined whether PXR repressed basal gene expression, and whether the nuclear receptor corepressor SMRT plays a role in such repression. PXR binds to SMRT *in vitro* at the ID2 region. The interaction between PXR and SMRT also occurs *in vivo* in a ligand-dependent manner. SMRT interacts with the PXR ligand-binding domain (LBD), and this interaction is specifically regulated by the AF2-helix. Gal4-PXR-mediated repression of reporter activation appears to be due to an interaction with endogenous SMRT. Furthermore, SMRT represses PXR-mediated activation of the 13-kb CYP3A4 promoter, yet the addition of ligand abrogates this effect. These data demonstrate that PXR interacts with SMRT in the absence of ligand to repress basal expression of target genes.

1806 RESISTANCE TO SILICA-INDUCED LUNG FIBROSIS IN SENESCENT RATS: ROLE OF TNF-ALPHA AND FAS-L.

C. L. Galli[1], L. Lucchi[1], P. Sergio[2], B. Viviani[1], M. Marinovich[1] and C. Emanuela[1]. *[1]Department Pharmacological Sciences, University of Milan, Milan, Italy and [2]RBM, Ivrea, Italy.*

Aging is associated with a progressive decline in the ability of alveolar macrophages to produce TNF-a in response to LPS, which reflects a defective protein kinase C (PKC) translocation due to decreased expression of its anchoring protein RACK-1 (1). The purpose of the present study was to investigate the immunotoxicological consequences of this defective activation in an experimental model of silicosis. Young and old rats were intratracheally instilled with silica (30 mg) or saline as control. In young animals, as expected, silica induced a significant increase in bronchoalveolar lavage fluid (BAL) of TNF-alpha, lactate dehydrogenase and cell numbers, which correlated with increased collagen deposition and silicotic nodule formations. In old rats no changes in BAL fluid or lung parameters were observed, indicating that senescent rats are resistant to silica-induced lung toxicity. These *in vivo* results were confirmed *in vitro*, where silica failed to induce TNF-alpha release in alveolar macrophages obtained from old animals. This could be explained with a defective PKC translocation in aged macrophages. Use of RACK-1 antisense oligonucleotide reduced the response of young macrophages to silica, demonstrating its role in silica-induced TNF-alpha production. Furthermore, a decrease in FAS-L expression and silica-induced apoptosis in old macrophages were observed, supporting the idea that age-associated alterations in signal transduction pathways contribute to decreased sensitivity to silica-induced lung fibrosis in old animals. References 1. J. Immunol. 163: 3468-3473, 1999.

1807 IMMUNOGLOBULIN RESPONSE TO SILICA EXPOSURE IN LUPUS PRONE NEW ZEALAND MIXED MICE.

J. Brown, M. Hassani, J. C. Pfau and A. Holian. *CEHS, University of Montana, Missoula, MT.*

Crystalline silica exposure in New Zealand mixed (NZM) mice leads to an exacerbated autoimmune disease measured by increases in autoantibodies, immune complexes, proteinuria and pulmonary fibrosis. To determine the effect of long-term silica exposure on immunoglobulin responses in autoimmune prone mice, NZM mice were intranasally instilled with saline or saline suspensions of 1 mg silica. Immunoglobulin levels were measured by ELISA 14 weeks following instillation of silica. IgM levels were slightly elevated in silica exposed NZM mice compared to saline exposed mice (979 μg/ml ± 213 vs 792 μg/ml ± 104). IgG levels were significantly decreased in silica exposed mice compared to saline exposed mice (1639 μg/ml ± 193 vs 3024 μg/ml ± 501 $p<0.05$). IgG2a levels were similar between silica and saline treated mice (864 μg/ml ± 133 vs 920 μg/ml ± 203). IgG2b and IgG3 levels were also similar between silica and saline exposed mice (246 μg/ml ± 29 vs 227 μg/ml ± 52 and 160 μg/ml ± 37 vs 203 μg/ml ± 42). IgG1 levels were significantly lower in silica exposed mice compared to saline exposed mice (650 μg/ml ± 204 vs 1104 μg/ml ± 224 $p<0.05$). Due to these decreases in immunoglobulin, B cell numbers were examined by flow cytometry in NZM mice following silica exposure. B cell numbers in the spleen and the superficial cervical lymph nodes were decreased 58% and 10% respectively in silica exposed NZM mice 14 weeks following exposure. The immunoglobulin isotype pattern suggests silica leads to a Th1 type immune response with a decrease in total IgG due to decreased B cell numbers. This work was supported by NIH grant ES-04804.

1808 IMMUNOREGULATORY ADJUVANT EFFECT OF NO IN DRUG-INDUCED IMMUNOSENSITIZATION.

R. Pieters and S. Nierkens. *IRAS-IT UU, Utrecht, Utrecht, Netherlands.* Sponsor: M. van den Berg.

Many drugs elicit autoimmune-like features in susceptible patients. The chemodrug streptozotocin (STZ) is commonly used as a diabetogenic compound in animals. STZ-induced diabetes resembles immune-dependent diabetes as it involves macrophages, CD8+ cells and high production of IFNγ. STZ contains a nitrosamine-group and releases nitric oxide (NO) *in vivo*. Previous studies suggested that NO is responsible for inducing type-1 immunological features and activity of macrophages by STZ. We further investigated this hypothesis using the reporter antigen popliteal lymph node assay (RA-PLNA) by testing the effects of modulation of NO-production and macrophage depletion on STZ effects and also on the effects the type-2 drug (D-penicillamine, D-pen). This assay is particularly suitable to study the adjuvant and immune deviating activity of compounds, using the same antigen (TNP-OVA) and mouse strain (BALB/c). Mice were s.c. injected with the compounds and 7 days later the PLN was excised and we measured antibodies, cytokines and performed flowcytometry. We found that NO-free STZ was ineffective in eliciting a response. Additionally, methylnitrosurea (MNU, i.e. STZ without sugar moiety), but not NO-free MNU, also induced a type-1 response. However, a non-related NO-donor S-nitroso-N-acetylpenicillamine (SNAP) induced a clear type-2 response to TNP-OVA and SNAP shifted the response induced by STZ towards a type-2 phenotype. The D-pen-induced response was also elevated after SNAP-treatment. As STZ causes a marked influx of macrophages, iNOS-derived NO may also affect the T and B cell responses. The iNOS inhibitor aminoguanidine inhibited both type-1 and type-2 drug-induced responses, whereas *in vivo* depletion of macrophages resulted in a decrease in type-1 features (IgG2a) but an increase in type-2 (IgG1) in STZ-induced responses and no change at all in D-Pen responses. Together, both endogenous and exogenous NO adjuvate drug-induced type-2 responses, whereas it shifts STZ-induced type-1 responses to type-2. The type-1 deviating capacity of STZ may thus not be due to NO per se but may rather result from STZ-dependent activation of macrophages.

1809 COSTIMULATORY CD80, CD86 AND CTLA-4 SIGNALING ARE REQUIRED IN TYPE-2 BUT INDISPENSIBLE IN TYPE-1 IMMUNE RESPONSES ELICITED BY AUTOIMMUNOGENIC DRUGS.

S. Nierkens[1], M. Aalbers[1], L. Boon[2] and R. Pieters[1]. *[1]IRAS-IT, Utrecht, Netherlands and [2]MacroZyme, Amsterdam, Netherlands.* Sponsor: M. van den Berg.

Some pharmaceutical drugs provoke autoimmune-like derangements in susceptible subjects. Sensitization responses by these chemicals can broadly be subdivided in two types. Type-1 responses, elicited by the diabetogen streptozotocin (STZ), are characterized by macrophages, CD8+ cells, IFN-γ and IgG2a whereas the anti-rheumatic drug D-Penicillamine (D-Pen) induces B cells, IL-4, IL-5, IgG1 and IgE; features of type-2 responses. Besides the specific recognition of antigens, costimulatory signals (CD80, CD86, CTLA-4) between immune cells are required to regulate the response and they contribute to deviation of responses in type-1 or type-2. In this study we used STZ and D-Pen in the reporter antigen popliteal lymph node assay (RA-PLNA) to create typical type-1 or type-2 features in responses to TNP-OVA in BALB/c mice. The PLN was excised 7 days after s.c. exposure. We observed an increase in CD86+ B cells in the type-2 response and less CD86+ but far more CD80+ non-B cells (macrophages, dendritic cells) and CTLA-4 expression in the type-1 response. When treating D-Pen-exposed mice with anti-CD80, anti-CD86 or both, IL-4, IgG1, IgE, IgM and ICAM-1 expression were decreased. Anti-CLTA-4 increased all these type-2 parameters. On the contrary, STZ-induced type-1 features were not influenced or even slightly increased after anti-CD80 and/or anti-CD86 or anti-CTLA-4 treatments. In this STZ-induced response CD80 and CD86 might preferentially bind to CTLA-4, which is significantly upregulated, and may therefore provide a downregulating signal. Additionally, we showed the lack of a type-2 response in CD80/CD86 KO mice whereas the STZ-induced type-1 phenomena were still operational in these mice. In summary, we conclude that interactions between CD28/CTLA-4 and CD80/CD86 are highly balanced and crucial in eliciting a D-Pen-induced type-2 response. The STZ-induced type-1 features, however, are indisputably operational when blocking these molecules or in CD80/CD86 KO mice and thus not dependent on this costimulatory interaction.

1810 PENICILLAMINE (PA)-INDUCED AUTOIMMUNITY: NEW INSIGHT INTO THE MECHANISM OF COVALENT BINDING *IN VIVO*.

B. Seguin[1], C. Ju[2], L. Pohl[2] and J. Uetrecht[1]. *[1]Pharmaceutical Sciences, University of Toronto, Toronto, ON, Canada and [2]NIH, Bethesda, MD.*

BACKGROUND: Protein covalent binding of drugs/reactive metabolites has been associated with idiosyncratic drug reactions (IDRs). To study the mechanism of IDRs, and the role of covalent binding *in vivo*, we use an animal model in which Brown Norway (BN) rats develop an autoimmune syndrome after exposure to PA. We have shown covalent binding in BN rats that developed signs of autoimmunity. Moreover, immunohistochemistry (IHC) revealed a pattern of binding to collagen-like fibers. **OBJECTIVES**: (1)perform a time course for binding in BN rats before they develop signs of the syndrome. (2)test for covalent binding in Lewis rats (LW), a strain that is not susceptible to PA-induced autoimmunity. (3)determine if the binding involves a disulphide or thiazolidine link. **METHODS**: Covalent binding studies were done with anti-PA rabbit immune serum by Western Blotting (WB) and IHC. Male rats were treated with PA and tested for covalent binding on days 3, 7, and 14 (BN) or 3 weeks (LW). For *in vitro* studies, liver, skin and spleen from control were incubated with PA at 37°C for 24 hours. WB under reducing versus non-reducing conditions was compared to our results from *in vivo* covalent binding studies. **RESULTS and CONCLUSIONS**: Binding was present by 3 days but was greater in sick animals than in animals that did not get sick. Binding was as great in LW rats as in BN rats. *In vitro* binding was absent (skin/liver) or low (spleen) suggesting that the equilibrium with protein disulfides favors the native disulfide; yet, binding was eliminated under reducing conditions which suggests that most of the binding detected involves a disulfide bond. In contrast, *in vivo*, binding in spleen was not eliminated under reducing conditions suggesting thiazolidine linkage is involved. Since BN (day 3) and LW rats displayed the same pattern of covalent binding, we suspect that binding is required but not sufficient to cause an IDR. We cannot determine with these experiments whether increased binding in sick animals contributes to sickness or is a result of unmasking of antigen during inflammation.

1811 EFFECT OF TWO PEDIATRIC VACCINES ON INSULIN-DEPENDENT DIABETES MELLITUS (IDDM) IN FEMALE NOD MICE.

G. Ravel[1,2], M. Christ[1], R. Burnett[1] and J. Descotes[2]. *[1]MDS Pharmacology Services, l'Arbresle and [2]Poison Center, E.Herriot Hospital, Lyon, France.*

The induction or exacerbation of autoimmune diseases is a potential adverse effect of immunostimulating drugs. Vaccines have been suspected to increase the incidence of, or reveal autoimmune diseases, even though epidemiological studies have so far failed to demonstrate any causal relationship between vaccination and autoimmune diseases. In this study, groups of 15 female NOD mice received three intraperitoneal injections of the multivalent diphtheria, tetanus, pertussis, poliomyelitis, haemophilus vaccines DTaP-IVP or DTaP-IVP/Hib (1/100 the human dose) at 2-week intervals from 10 weeks of age. The immunostimulant tilorone hydrochloride (2 mg/mouse) was used as a positive control. Both vaccines and tilorone had a similar effect on IDDM as evidenced by a significant reduction in blood and urinary glucose levels. At the end of the study, 90 % of control mice had elevated blood glucose levels in contrast to 60 % of mice treated with either vaccine. Positive urinary glucose levels (according to a standard dipstick) were noted in 15 %, 40 %, and 33 % of mice treated with DTaP-IVP, DTaP-IVP/Hib and tilorone respectively, and in 53 % of control mice. A slight prolongation in survival was noted in mice treated with either vaccine. This study is the first report of a possible protecting effect of pediatric vaccines in IDDM-prone mice.

1812 HCB-INDUCED IMMUNOPATHOLOGY IS PARTLY MEDIATED BY T CELLS.

J. Ezendam, J. G. Vos and R. Pieters. *IRAS, Utrecht, Netherlands.*

Hexachlorobenzene (HCB) is a persistent environmental pollutant with (auto)immune effects in man and rat. The Brown Norway (BN) rat is susceptible to HCB and oral exposure causes inflammatory skin and lung lesions, splenomegaly, lymph node (LN) enlargement and increased serum levels of IgE and autoantibodies. Whether this is caused by HCB or by its metabolites and if T cells are involved is unknown. By using thymectomized BN rats it was shown that induction of lung lesions was thymus-independent, but the induction of skin lesions was delayed and seemed partly T cell dependent (TAP, 1999, 161(2):180). Since there were still functional T cells present in these rats, the role of T cells needed further investigation. To elucidate the role of T cells we used Cyclosporin A (CyA) to inhibit T cell function. BN rats were exposed to either a control diet or a diet supplemented with 450 mg/kg diet HCB for 21 days. CyA treatment started 2 days prior to HCB exposure. Rats were injected daily with 20 mg/kg bwt CyA. Treatment with CyA diminished the HCB-induced immunopathology significantly. Development of skin lesions was delayed and the severity was also strongly decreased. Also, CyA declined the HCB-induced increase in liver, spleen and LN weights. T cell dependent processes like increases in serum IgE and autoantibodies were reduced to background levels. Lungs were still infiltrated by macrophages, but the perivascular eosinophilic infiltrate was greatly reduced. Together, our results indicate that T cells seem to play a prominent role in HCB-induced skin lesions, the enlargement of spleen and LN, the increase in serum IgE and autoantibody levels and the attraction of eosinophils into the lungs. However, macrophage infiltration into the lungs is T cell independent. We hypothesize that HCB initially attracts phagocytes which adjuvates an adaptive immune response. The interplay of both macrophages and T cells in the HCB-induced immunopathology needs further investigation.

1813 ACCELERATION OF THE DEVELOPMENT OF LUPUS IN NZBXNZWF1 MICE BY CHLORDECONE.

S. M. Roberts and E. Sobel. *University of Florida, Gainesville, FL.*

Systemic lupus erythematosus (SLE) is a debilitating disease affecting women nearly nine times as often as men. Previously, we reported the ability of three organochlorine pesticides with estrogenic effects (methoxychlor, 50 mcg/day; chlordecone, 30 mcg/day; and o, p-DDT, 15 mcg/day) to accelerate the onset of disease in lupus-prone (NZBxNZW)F1 mice. Ovariectomized female mice treated continuously with any of these pesticides experienced earlier mortality from immune glomerulonephritis, the most severe manifestation of SLE in this mouse strain, compared with placebo controls. The most pronounced effect was observed for chlordecone. In follow-up studies reported here, lower doses of chlordecone (0.167 to 16.7 mcg/day) were tested in ovariectomized female (NZBxNZW)F1 mice. Chlordecone was administered in continuous-release pellets implanted subcutaneously. Mice treated with pellets without chlordecone served as controls. All doses of chlordecone decreased the time to onset of clinical SLE, defined for the purposes of this experiment as significant renal impairment. The decrease in time to onset in the highest dose group (16.7 mcg/day) was statistically significantly. Titers of serum anti-dsDNA were increased in a dose-related manner from 0.167 to 8.3 mcg/day chlordecone, with a drop-off in titers at the 16.7 mcg/day dose. Chlordecone did not produce detectable estrogenic effects in this dose range, as assessed by measurement of uterine hypertrophy. Also, when higher doses of methoxychlor, chlordecone, and o, p-DDT from previous experiments were compared, their effects to accelerate lupus were not in concordance with their estrogenic effects on the uterus. This apparent absence of concordance may indicate that these pesticides affect SLE through a mechanism unrelated to estrogenicity, or that estrogenic effects may be responsible, but occur at lower doses in the immune system as compared with the uterus. Supported by ES07375.

1814 OMEGA-3 FATTY ACIDS FROM FISH OIL SUPPRESS IGA NEPHROPATHY INDUCED BY THE MYCOTOXIN DEOXYNIVALENOL.

Q. Jia[1], H. Zhou[1], Z. Islam[1] and J. J. Pestka[1,2,3]. *[1]Food Science and Human Nutrition, MSU, East Lansing, MI, [2]Department of Microbiology and Molecular Genetics, MSU, East Lansing, MI and [3]Institute for Environmental Toxicology, MSU, East Lansing, MI.*

Primary IgA nephropathy (IgAN) is an autoimmune disease which has as its hallmarks, elevated serum IgA level and kidney mesangial IgA deposition. Fish oil can retard the progression of IgAN in humans and in a mouse model induced by feeding the trichothecene deoxynivalenol (DON, vomitoxin) In this study the effects of docosahexaenoic acid (DHA) and eicosapentaenoic acid (EPA), the two main omega-3 polyunsaturated fatty acids in fish oil, on DON-induced IgAN were observed. Mice were fed for 18wk with AIN-93G diet containing 1g/100 g corn oil and 6g/100g oleic acid (CONTROL) or 1g/100g corn oil and 6g/100g oleic acid and 10ppm DON (CONTROL+DON) or 1g/100g corn oil and 2.5g/100 g DHA and 3.5g/100g oleic acid and 10ppm DON (DHA+DON) or 1g/100g corn oil and 2.7g/100g EPA and 3.3g/100g oleic acid (EPA+DON) or 1g/100g corn oil and 2.3g/100g DHA/EPA and 3.7g/100g oleic acid and 10ppm DON (DHA/EPA+DON). DON significantly increased serum IgA, serum IgA immune complexes and kidney mesangial IgA deposition. DHA, USEPA and DHA/EPA treatment significantly attenuated all three immunopathological parameters as compared to CONTROL+DON group. Furthermore DHA, USEPA and DHA/EPA significantly reduced IgA secretion by spleen cells suggesting that systemic IgA production was depressed. Taken together, the results suggest that both DHA and EPA can impair DON-induced IgAN. (Supported by NIH grants DK58833 and ES03358)

1815 SUPPRESSION OF DEOXYNIVALENOL-INDUCED IL-6 BY FISH OIL AND RELATIONSHIP TO MITOGEN-ACTIVATED PROTEIN KINASE ACTIVATION.

Y. Moon and J. J. Pestka. *FSHN, MSU, East Lansing, MI.*

Dietary fish oil has been shown to block progression IgA nephropathy in human clinical studies as well as in a murine model induced by the trichothecene mycotoxin deoxynivalenol (DON, vomotoxin). Among possible mediators of this disease, interleukin-6 (IL-6) may play a pivotal role in IgA elevation and disease aggravation. Therefore, IL-6's potential as a target for the therapeutic effects of fish oil was assessed in both *in vivo* and *in vitro* models employing DON. Mice were fed with corn oil (CO)- or fish oil (FO)-containing diet for 8 wk and then acutely exposed to DON. Serum IL-6 was significantly elevated in CO-fed mice administered DON and this effect was suppressed in FO-fed mice. IL-6 mRNA levels of spleen were similarly affected. Prostaglandin E2, another proinflammatory mediator reportedly by FO, was measured but no significant differences were found between CO- and FO-fed groups. Mitogen-activated protein kinases (MAPKs), crucial signal-transducing mediators in induction IL-6 and other inflammatory genes, are activated by DON *in vivo* and *in vitro*. DON-induced phosphorylation of ERK1/2 and JNK1/2 in spleen were significantly suppressed by dietary FO. In contrast, DON-mediated activation of p38 MAPK was slightly enhanced in FO-fed mice. To further confirm *in vivo* data, two omega-3 polyunsaturated fatty acids that are specific components of FO, eicosapentaenoic acid (EPA) or docosahexaenoic acid (DHA), were added to RAW 264.7 macrophage cells that were treated with lipopolysaccharide (LPS) and DON. DON superinduced LPS-driven IL-6 production but this was suppressed by EPA and DHA. DON-activated ERK1/2 and JNK1/2 phosphorylation were also reduced when cells were pre-treated with EPA and DHA. Taken together, FO retarded IL-6 production and ERK1/2 and JNK1/2 activation in spleens of mice exposed to DON. Moreover, omega-3 PUFA similarly repressed DON-mediated ERK1/2 and JNK1/2 activation, which appeared to contribute to decrease DON-induced IL-6 superinduction in macrophage cells (supported by Public Health Services Grants DK 588833, ES 03358 and ES 09521).

1816 EFFECTS OF DIETARY OMEGA-3 FATTY ACIDS ON DEOXYNIVALENOL-INDUCED GLOBAL GENE EXPRESSION *IN VIVO*.

S. Kinser[1], Q. Jia[1], A. Laughter[2], P. Cornwell[2], C. Corton[2] and J. Pestka[1]. *[1]Department of Food Science, Michigan State University, East Lansing, MI and [2]CIIT Centers for Health Research, Research Triangle Park, NC.*

Dietary omega-3 fatty acid supplements have been reported to inhibit immune and inflammatory responses. Deoxynivalenol (DON), a trichothecene mycotoxin, upregulates inflammatory gene expression *in vivo*. Interestingly, chronic DON administration induces IgA nephropathy in mice, which can be attenuated by omega-3 fatty acid supplementation. In this study, cDNA arrays were used to characterize the effects of omega-3 fatty acid supplements on DON modulation of global gene expression in lymphoid tissue. Mice were fed diet containing corn oil (CO) or a diet containing 1% docosahexaenoic acid and 1% eicosapentaenoic acid (DHA/EPA) for 12 wk. Mice were treated with 25 mg/kg DON p.o. and 2 hr later, spleen samples were collected. The mRNA was extracted from spleen samples for analysis on mouse cancer 1.2 cDNA arrays (Clontech). Spot intensities were normalized using a local linear regression model. Of 1200 genes on the array, 386 genes were significantly increased or decreased above average expression levels in all treatment groups. Genes were arranged into an ontology tree using GeneSpring software to help compare expression profiles between treatment groups. IL-6 expression was highly expressed in DON-treated CO-fed mice and this was drastically repressed in DON-treated DHA/EPA-fed mice. Furthermore, basal IL-6 expression was much lower in DHA/EPA-fed mice than CO-fed mice. Eight other genes were found to have a greater than 0.9 correlation to the expression profile of interleukin 6. These included interleukin 1 alpha, small inducible cytokine subfamily (member 2), FBJ osteosarcoma oncogene, pigment epithelium-derived factor, fos-like antigen 2, DNAJ-like 2 heat shock protein, cysteine rich protein 61, and Jun oncogene. The results suggest that DON affects expression of multiple genes that may contribute to its immunotoxic effects and this expression profile can be affected by diet. (supported by Public Health Services Grants DK 588833 and ES 03358)

1817 DEVELOPMENTAL EXPOSURE TO DI-n-BUTYLTIN DICHLORIDE (DBTC): IMMUNOTOXIC AND NEUROTOXIC EVALUATION.

B. Luebke[1], S. Barone[2], C. Copeland[1], L. White[2] and S. Jenkins[1]. *[1]Immunotoxicology Branch, USEPA, ORD, NHEERL, ETD, Research Triangle Park, NC and [2]Cellular and Molecular Toxicology Branch, USEPA, ORD, NHERL, NTD, Research Triangle Park, NC.*

Organotins are incorporated as stabilizers in PVC water supply pipe. Particularly when new, mono- and di-substituted methyl- and butyltins leach from the pipe and are thus of regulatory concern to EPA. These contaminants have adverse effects on both the immune and nervous systems under laboratory conditions. The toxicity of other members of this class, tributyltin and dioctyltin, is greater in the immature immune system; thus, DBTC was evaluated following combined gestational and lactational exposure in offspring of Wistar rats exposed by gavage with 0 (olive oil), 2.5 or 5.0 mg DBTC/kg/d from gestational day 6 until weaning on post-natal day (PND)21. Separate groups of pups born to normal dams were exposed to the 10 doses of the same concentrations by gavage, 3 time/wk from PND3 through PND22. Immune system endpoints included body, spleen and thymus weights, antibody responses to a T-dependent antigen and delayed hypersensitivity responses. Potential neurotoxicity was evaluated by measuring brain weight. Immune function was not affected by either exposure regimen, although lower body weights and increased spleen and thymus weights were noted on PND38 in nonimmunized rats at the highest dose, suggesting that an earlier decrease in lymphoid organ weight may have occurred. Normal immune function, particularly in the directly-dosed pups, was an unexpected finding, given the demonstrated immunotoxicity of organotins in adult rats. Direct exposure to DBTC caused a dose-related delay in brain weight gain on PND38 at both exposure levels. Brain weights were similar in control and low dose pups on PND48; however, there was essentially no increase in brain weight in higher dose-group pups between PND30-PND48, in spite of a 25% increase in body weight. Based on these data, it appears that the developing nervous system may be more sensitive to DBTC than is the immune system. (This abstract does not reflect EPA policy.)

1818 DEVELOPMENTAL IMMUNOTOXICITY OF COCAINE AND KETAMINE IN POSTNATAL RATS.

H. Rofael[1], R. Turkall[1,2] and M. Abdel-Rahman[1]. *[1]Pharmacology & Physiology, GSBS, UMDNJ, Newark, NJ and [2]Clinical Laboratory Sciences, School of Health Related Professions, UMDNJ, Newark, NJ.*

The abuse of cocaine (COC) with ketamine (KET) among pregnant women was shown to be high. Transplacental exposure is not the only route by which a newborn may be exposed to these agents, they can distribute into breast milk. Chronic COC exposure is associated with immunological modulation in humans and animal models. The effect of sub-chronic exposure to COC and KET alone and in combination on the developing immune system was assessed in postnatal male rats. To simulate the route of exposure during lactation, newborn male rats were orally treated with saline, COC (20 mg/kg), KET (50 mg/kg) or KET followed 15 min later by COC (50/20 mg/kg) from day 1 to 21 of life. Male rat pups were sacrified 30 min following the last treatment. Total circulating leukocyte and lymphocyte counts were decreased with relative neutrophilia while; spleen/bodyweight ratios and IgM antibody response to sheep erythrocytes (SRBCs) were increased in animals treated with COC. Moreover, COC produced a shift in T-helper 1/T-helper 2 (Th1/Th2) balance promoting Th2 type response. On the other hand, KET treat-

ment did not produce any significant change of any of these parameters. However, when co-administered with COC these immunotoxic effects were antagonized. Studying the possible mechanisms of COC-induced immunotoxicity revealed that COC caused a significant increase in serum corticosterone concentration. Co-administration of KET effectively blocked the stimulatory effect of COC on serum corticosterone without any significant change of plasma and tissue concentrations of norcocaine (NC). The results of this study indicate that exposure to COC in early postnatal period can induce immunotoxic reactions which were antagonized by KET most likely through neuroendocrinal mechanisms.

1819 LIFETIME EXPOSURE TO TRICHLOROETHYLENE (TCE) MODULATES IMMUNE FUNCTION.

C. Adams[2], D. Keil[1,2], K. Meyers[2], A. EuDaly[2], J. Smythe[2], J. EuDaly[2], G. Gilkeson[3] and M. M. Peden-Adams[2]. *[1]NIOSH, Morgantown, WV, [2]Department of Health Professions, Medical University of South Carolina, Charleston, SC and [3]Department of Rheumatology, Medical University of South Carolina, Charleston, SC.*

Trichloroethylene (TCE) is an industrial solvent used in the cleaning and degreasing of metal components in various machine industries. Not only is it commonly inhaled during occupational situations, but its widespread use has resulted in groundwater contamination leading to human exposure *via* drinking water. It has been reported, in murine studies, that TCE can both exacerbate autoimmune disease and suppress immune function. While these studies have addressed effects in adult rodent models, none have explored immunological effects during developmental stages. To determine the immunological effects of TCE in B6C3F1 mice, exposure to TCE in drinking water (1000 ppb or 10, 000 ppb) began when pairs were mated (female C57 and male C3H mice) and continued through weaning (21-day old) or adulthood (56-days old). The vehicle control group was administered emulphor-treated water. Endpoints assessed included splenic and thymic weights and cellularity, natural killer cell (NK) activity, antibody plaque forming cell (PFC) response, lymphocyte proliferation, and T-cell immunophenotypes. At 21 days of age, alterations were evident. Body weight and length were significantly decreased by the 10, 000 ppb treatment. NK cell activity and T- and B-cell proliferation were not altered. IgM antibody responses to sRBC challenge were suppressed in both male and female pups by 10, 000 ppb TCE and by 1000 ppb TCE in the male pups only. Additionally, there was a distinct decrease in splenic CD4+CD8- T-cells resulting in a concomitant decrease in the CD4+:CD8+ ratio. At 56-days of age, the most striking effect was noted with increased NK cell activity in both treatment groups. Currently studies are being conducted to verify the PFC response and T-cell immunophenotypes in the adult mice. These data suggest that lifetime exposure to TCE modulates both innate and adaptive immune responses and this should be considered when assessing health risks to TCE.

1820 IMMUNOTOXICOLOGICAL ASSESSMENT OF A P38 MAP KINASE INHIBITOR.

S. M. Furst[1], W. J. Komocsar[1], F. C. Burleson[2] and V. Peachee[3]. *[1]Pharmacia Corporation, Skokie, IL, [2]BRT Inc., Raleigh, NC and [3]Immunotox Inc., Richmond, VA.*

The p38 MAP kinase signaling pathway plays a pivotal role in the initiation and progression of inflammation. Compounds that inhibit this kinase inhibit the production of inflammatory cytokines and are potential therapies for inflammatory diseases. A p38 kinase inhibitor was tested to evaluate its effects on the net health of the immune system using the mouse sheep red blood cell (SRBC) antibody forming cell response and host resistance model to influenza virus. Female B6C3F1 mice were administered the p38 kinase inhibitor by oral gavage for 28 days at doses of 0, 3, 30 and 300 mg/kg/day. Animals were immunized with SRBC and the number of splenic cells producing antibody (AFC) to SRBC was quantitated through the production of hemolytic plaques. Cyclophosphamide was administered as a positive control. In the influenza host resistance model, Balb/c mice were administered the p38 kinase inhibitor at doses of 30 and 150 mg/kg/day or anti-TNFα antibody at 250 μg/week, 7 days prior to a mouse-adapted influenza virus intranasal infection. Administration of the compound continued post-infection for 21 days. Dexamethasone was used as a positive control. Analyses included the measurement of the clearance of infectious influenza virus on Day 2, 6, 8, 10 and 21, and influenza specific IgG in the lung on Day 2, 10 and 21. Results of the studies were as follows: A decrease of 48% and 70% in the antibody forming cell response was observed with the p38 kinase inhibitor at a dose of 30 and 300 mg/kg/day, respectively. The compound did not affect any of the parameters evaluated in the influenza host resistance model. A significant decrease in AFC response was observed with cyclophosphamide and dexamethasone significantly reduced viral clearance and IgG production. A small decrease in influenza specific IgG production was noted with the anti-TNFα antibody on Day 21. In conclusion, although modulation of the immune response was observed with the p38 kinase inhibitor this did not affect the ability of the host to clear or eliminate a viral infection.

1821 EFFECT OF DIESEL EXHAUST PARTICULATE (DEP) ON BACILLUS CALMETTE-GUERIN (BCG) LUNG INFECTION IN MICE.

D. M. Lewis[1], Q. B. Saxena[3,1], D. N. Weissman[1], J. P. Simpson[1], T. A. Bledsoe[1] and R. K. Saxena[2,1]. *[1]ASB/HELD, NIOSH, Morgantown, WV, [2]School of Life Sciences, Jawaharlal Nehru University, New Delhi, India and [3]Indian Council of Medical Research, New Delhi, India.* Sponsor: P. Siegel.

The effect of exposure to diesel exhaust particulate (DEP) on Bacillus Calmette-Guerin (BCG) lung infection in mice was studied. C57Bl6 female mice were infected with BCG (2.5x10^4 bacteria/mouse) by tracheal aspiration with or without co-administration of DEP (100 mcg/mouse). Five weeks later, mice exposed to DEP+BCG had about four-fold higher BCG load in lungs than mice exposed only to BCG ($p<0.05$). DEP treatment alone had no effect on the total number of lung lymphocytes or numbers of T, B or NK cells recovered from lungs. In contrast, BCG infection significantly increased recovery of all types of lymphocytes from lungs. Co-exposure to DEP+BCG further increased the recovery of lymphocytes from lungs of BCG infected mice. The pulmonary lymphocyte subpopulation expressing the greatest levels of mRNA for IFN gamma after BCG infection was CD4+ T cells and expression levels were similar in mice exposed to BCG or BCG+DEP. Recovery of IFN gamma secreting T cells was significantly higher ($p<0.05$) from lungs of BCG and BCG + DEP infected mice as compared to control or DEP only exposed mice, but BCG and BCG+DEP groups of mice were not significantly different. These results indicated that co-exposure to DEP+BCG did not significantly affect the level of IFN gamma response of mice to BCG infection. However, *in vitro* studies demonstrated DEP treatment inhibited IFN gamma induced nitric oxide secretion by mouse alveolar macrophages. Thus, DEP exposure did not alter the IFN gamma response to BCG infection, but reduced a key microbiocidal response of macrophages to IFN gamma. Reduced responsiveness of DEP exposed macrophages to IFN gamma may contribute to a less efficient clearance of BCG from the lungs of BCG infected mice.

1822 ROLES OF REACTIVE OXYGEN SPECIES, HEME OXYGENASE-1, AND NITRIC OXIDE IN DIESEL EXHAUST PARTICLE-MEDIATED PULMONARY IMMUNE RESPONSES TO *LISTERIA MONOCYTOGENES* IN RATS.

X. Yin[1], J. Ma[2], J. M. Antonini[2] and J. Ma[1]. *[1]School of Pharmacy, West Virginia University, Morgantown, WV and [2]NIOSH, Morgantown, WV.*

This study examines the hypothesis that diesel exhaust particles (DEP) suppress pulmonary immunity to *Listeria monocytogenes (Listeria)* through the induction of reactive oxygen species (ROS), heme oxygenase-1 (HO-1) and altered cytokine production by alveolar macrophages (AM) and lymphocytes. Cells were isolated from Brown Norway rats intratracheally inoculated with saline or 100, 000 *Listeria* at 7 days post-infection. The *Listeria*-infected AM showed increased production of IL-6, IL-10, IL-12, and TNF-α over the saline control in response to lipopolysaccharide (LPS), whereas the *Listeria*-infected lymphocytes showed increased production of IL-2, IL-10, and IFN-γ when challenged with concanavalin A (ConA) or heat killed Listeria (HKLM). DEP or DEP extract, but not the washed DEP, inhibited AM secretion of IL-6, IL-12, and TNF-α and lymphocyte production of IL-2 and IFN-γ, but enhanced AM production of IL-10. The effect of the DEP extract on cytokine production was preceded by a time-dependent induction of ROS and ROS-induced HO-1 protein and activity in AM. α-Naphthoflavone (ANF), a CYP 1A1 inhibitor, partially inhibited DEP-induced ROS and HO-1 expression and reversed the DEP effect on cytokine secretion. L-NAME (N-nitro-L-arginine methyl ester), a NO synthase inhibitor, inhibited the DEP-induced ROS generation and HO-1 induction, but augmented the DEP-induced IL-10 production by *Listeria*-infected AM, suggesting that NO down-regulates IL-10 production. Similar to DEP extract, hemin induced HO-1 expression, an increase in IL-10 and a decrease in TNF-α production by AM. In comparison, DEP extract at a level that induced less HO-1 than hemin, showed greater effect on IL-10 secretion. These results show that both HO-1 and NO play a role in AM production of IL-10, and that due to its organic content, DEP suppress the host immune responses by inhibiting the innate and T cell-mediated immunity and augmenting AM production of IL-10 (NIH HL-62630).

1823 EXACERBATION OF RESPIRATORY SYNCYTIAL VIRUS INFECTION BY ULTRAFINE CARBON BLACK PARTICLE EXPOSURE.

A. L. Lambert[1], J. B. Mangum[1], M. P. DeLorme[2] and J. I. Everitt[1]. *[1]CIIT Centers for Health Research, Research Triangle Park, NC and [2]DuPont Haskell Laboratory for Health and Environmental Sciences, Newark, DE.*

Exposure to particulate matter (PM) may exacerbate preexisting respiratory diseases such as asthma, chronic obstructive pulmonary disease (COPD), bronchitis and pneumonia, however few experimental studies have addressed the effects of PM on

lower respiratory tract (LRT) viral infection. Respiratory syncytial virus (RSV) is a major etiological agent for LRT infections in infants, the elderly, and the immunocompromised, and may lead to chronic wheezing and the development of asthma in children. In this study we examined the effects of ultrafine particle exposure on RSV-induced pulmonary inflammation, chemokine and cytokine expression, and airway hyperresponsiveness in a mouse model of RSV. Female BALB/c mice were instilled *via* the trachea (i.t.) with 1x106 pfu RSV or with uninfected culture media. On day 3 of infection, mice were i.t. instilled with either 40 μg ultrafine carbon black (CB) particles or with saline vehicle. Endpoints were examined on days 4, 5, 7, and 14 of RSV infection. Viral titer and clearance in the lung were unaffected by CB exposure. Neutrophil numbers were elevated on days 4 and 7, and lymphocyte numbers were higher on days 4 and 14 of infection in CB-exposed, RSV-infected mice. CB exposure also enhanced RSV-induced airway hyperresponsiveness to methacholine, BAL total protein, and virus-associated chemokines MCP-1, MIP-1α, and RANTES. Immunohistochemistry and laser capture microdissection revealed that MIP-1α expression was localized to the alveolar epithelium, where ultrafine particles deposit in the lung. These data demonstrate a synergistic effect of particles on RSV infection, and suggest a mechanism for increased pneumonia in human populations after PM exposure.

1824 VARIED EXPOSURE REGIMES TO METHYL MERCURY (MEHG) DURING POSTNATAL DEVELOPMENT LEADS TO DIFFERENT IMMUNE RESPONSES.

M. M. Peden-Adams[1], C. Adams[1], K. Meyers[1], A. EuDaly[1], J. Smythe[1], J. EuDaly[1] and D. E. Keil[2,1]. [1]*Department of Health Professions, Medical University of South Carolina, Charleston, SC and* [2]*NIOSH, Morgantown, WV.*

Infantile autism (IA) is a neurodevelopmental syndrome with 1-5 cases found in every 10, 000 children. The spectrum of autism disorders includes a range of impaired communication and language development. Also reported are diverse immunological effects including decreased T-cell proliferative function and activation, increased serum IL-2 levels, decreased CD8+ cells, decreased NK cell function, and development of anti-neural autoantibodies. Several studies indicate that the etiology of IA is multi-factorial and includes exposure to environmental chemicals. In particular, Thimerosal, an adjuvant in vaccines that contains ethyl mercury, has been implicated in IA. This association has been criticized due to a lack of supportive experimental dose-response data. Consequently, this project was designed to compare dose-responsive immunological effects between Thimerosal and methyl mercury, a known immunotoxicant. In this phase of the study, B6C3F1 pups were exposed to MeHg (10 or 50 ug/kg) and two different exposure regimes were examined during postnatal development. Pups were exposed either on postnatal days (PND) 7, 10, and 12 or weekly on PND 7, 14, and 21. On PND 22, T-cell proliferation and the IgM plaque forming cell response were enhanced after exposure on PND 7, 14, and 21, but not affected after exposure on PND 7, 10, and 12. Weekly exposure to 50 ug MeHg/kg prior to weaning resulted in selective increases in CD8+ thymic T cells, whereas 10 ug MeHg/kg exposure on PND 7, 10, and 12 increased splenic CD4+ T-cell subpopulations. The exposure regime utilized during developmental periods must be considered when assessing mercury exposure, as this affects responses in immune parameters. This understanding may be useful when evaluating vulnerable periods of mercury exposure in children. Future studies will compare effects of Thimerosal with MeHg, and include assessment of cytokine levels, autoantibody production, serotonin levels and cognitive function.

1825 MERCURY (Hg) ACCELERATES AUTOIMMUNE DISEASE IN MICE.

E. K. Silbergeld[1], I. Silva[1], C. S. Via[3], M. Afanasyeva[2], J. Nyland[2], P. Nguyen[3] and N. R. Rose[2]. [1]*Environmental Health Sciences, Johns Hopkins University Bloomberg School of Public Health, Baltimore, MD,* [2]*Johns Hopkins School of Medicine, Baltimore, MD and* [3]*Medicine, University of Maryland School of Medicine, Baltimore, MD.*

Inorganic mercury (iHg) has a range of immunotoxic effects, including induction of autoimmunity in certain inbred strains of rats and mice. However, no associations between Hg and autoimmune disease have been shown in humans. We hypothesize that expression of frank disease may require interactions between Hg and other susceptibility factors, genetic or acquired. To test this hypothesis, we examined the effects of iHg pretreatment on the pathophysiology of experimental autoimmune disease in two well characterized models, the graft versus host disease (GVHD) model of chronic systemic lupus erythmatosis (SLE) and the cardiac myosin peptide (CMP) model of autoimmune myocarditis (AIM). We induced SLE by transfer of maternal splenocytes into C57Bl/6xDBA/2-F_1 hybrid offspring; and we induced AIM by immunization of A/J mice with purified murine CMP. In GVHD, both donors (female DBA/2) and hosts (female B6D2-F_1) were exposed to 20 or 200 mcg/kg $HgCl_2$ by s.c. injection every other day for 15 days; on day 20, GVHD was initiated by splenocyte transfer and disease was evaluated over 4 months. In the AIM model, male A/J mice were pretreated similarly with $HgCl_2$ at 10 or 100 mcg/kg; on day 20, mice were administered 100 nmol CMP s.c. and pertussis toxin i.p. Disease was monitored by observation, interim analyses of serum autoantibodies, and histopathological evaluation of the heart at sacrifice. The results are consistent with the hypothesis that Hg can interact with other risk factors to induce frank autoimmune disease, at low doses of Hg and in strains of mice (DBA/2, C57Bl/6) that are not susceptible to Hg immunotoxicity. *Research supported by the Arthritis Foundation and NIH (NIEHS, NHLBI).*

1826 EFFECT OF INORGANIC MERCURY ON PRIMARY MOUSE AND HUMAN MONOCYTE FUNCTION.

J. Koropatnick[1], W. Kennette[1] and R. K. Zalups[2]. [1]*Oncology, University of Western Ontario, London, Ontario, ON, Canada and* [2]*Division of Basic Medical Sciences, Mercer University School of Medicine, Macon, GA.*

Transition metal ions are toxic to human tissues and organs. Although they can be toxic to immune cells, they can also induce gene expression (including metallothioneins [MTs]) in the absence of toxic events. The consequences of non-toxic metal exposure on immune function are largely unexplored. Innate immune activation involves the acute phase response and respiratory burst of mononuclear cells (including monocytes) in response to extracellular signals. We have reported that *in vitro* treatment of immortalized human monocytes with zinc, cadmium, or mercury, at levels at least tenfold lower than that required to exert detectable cellular injury, significantly inhibits monocyte activation potential. We now report that that *in vitro* pre-treatment of primary human and mouse monocytes, isolated from peripheral blood, with low, non-cytotoxic levels of zinc (40 μM) or mercury (2 μM) have significantly decreased activation potential (assessed by reactive oxygen production and interleukin-1β [IL-1β] mRNA expression in response to phorbol myristate acetate [PMA]). In addition, pre-treatment of mice with low, non-toxic levels of inorganic mercury (0.2 - 1 μmole Hg/kg body weight, i.p.) had no effect on monocyte viability, but significantly inhibited the ability of primary peripheral blood monocytes to undergo LPS- or PMA-induced respiratory burst and differentiation into adherent macrophages. These data indicate that low level exposure to inorganic zinc or mercury inhibits primary monocyte activation potential (and, therefore, innate immune function) in the absence of cytotoxicity. The connection between low, non-toxic metal ion exposure and innate immune function, combined with the critical role of innate immunity in resistance to infection and tumour formation, highlight the potential importance of environmental metals in these pathological events.*Supported by grants from the NIEHS (ES11288) and CIHR*

1827 *IN VITRO* EXPOSURE TO SODIUM ARSENITE INCREASED INTRACELLULAR CA^{2+} LEVELS IN PHYTOHAEMAGGLUTININE STIMULATED HUMAN T LYMPHOCYTES.

R. C. Goytia-Acevedo[2,1], L. C. Acosta-Saavedra[1], M. E. Cebrián[1] and E. S. Calderón-Aranda[1]. [1]*Sección de Toxicología, CINVESTAV, México, D F, Mexico and* [2]*Facultad de Medicina, UJED, Gómez Palacio, Dgo, Mexico.*

Arsenic exposure inhibits murine and human T lymphocyte proliferation. Free intracellular ($[Ca^{2+}]i$) levels have been implicated as a regulatory signal for proliferation and death cell processes. This prompted us to investigate whether sodium arsenite ($NaAsO_2$)induced changes in $[Ca^{2+}]i$ of human stimulated human T lymphocytes and if this alteration was associated with the inhibitory effects of arsenic on T cell proliferation. We used mononuclear cells from healthy human subjects to measure free $[Ca^{2+}]i$ levels by spectrophotofluorometry using Fluo-3AM label. Proliferation was determined by [methyl-^{3}H]-thymidine incorporation. *In vitro* exposure to $NaAsO_2$ (1.0 to 7.5 μM) dose-dependently increased free $[Ca^{2+}]i$ in both PHA-stimulated lymphocytes and non-stimulated cells. However the effect was more pronounced in mitogen-activated cells simultaneously treated with $NaAsO_2$ at concentrations producing inhibition of T cell proliferation. In cells pretreated with a calcium ionophore (A23187) at concentrations able to increase $[Ca^{2+}]i$ to levels comparable to those induced by $NaAsO_2$, PHA-induced proliferation was similarly inhibited. These results suggest that increased free $[Ca^{2+}]i$ levels play an important role in the inhibitory effect of arsenic on human T cell proliferative response. Partially supported by CONACYT 34508-M to ESCA.

1828 ARSENIC-INDUCED ALTERATIONS IN CONTACT HYPERSENSITIVITY.

R. M. Patterson[1], L. Vega-Lloyo[2], K. J. Trouba[1], J. A. Teague[1] and D. R. Germolec[1]. [1]*LMT, NIEHS, Research Triangle Park, NC and* [2]*Cinvestav, National Polytechnical Institute, Mexico City, Mexico.*

Chronic exposure to arsenic contaminated drinking water has been associated with neoplasias in multiple organ systems, including the skin, liver, bladder and lung. Previous studies in our laboratory indicate that arsenic alters the levels of growth

promoting and inflammatory cytokines in the skin. These cytokines regulate the migration and maturation of Langerhans cells (LC) during allergic contact dermatitis. Therefore, we hypothesized that arsenic may modulate the response to cutaneous sensitizing agents by altering cytokine production, and subsequently, LC mobilization/migration, and T-cell proliferation. To investigate this hypothesis, we examined the induction and elicitation phases of dermal sensitization, using the local lymph node assay (LLNA) and mouse ear swelling test (MEST). Mice exposed to 50 mg/l arsenic in the drinking water for four weeks demonstrated a reduction in lymph node cell proliferation and ear swelling following sensitization with 2, 4-dinitrofluorobenzene (DNFB), compared to mice that received plain water. Cultured lymphocytes from arsenic treated animals sensitized with fluorescein isothiocyanate (FITC), exhibited reduced proliferative responses following antigen-specific stimulation *in vitro*. In contrast, lymphocytes from non-sensitized, arsenic treated mice showed no alteration in mitogen-stimulated proliferation as compared to controls, suggesting that arsenic-induced suppression of cell proliferation is antigen specific and not a general anti-proliferative effect. LC and T-cell populations in the draining lymph nodes of DNFB-sensitized mice were evaluated by fluorescence activated cell sorting. LC numbers were reduced in the cervical lymph nodes, suggesting that LC migration may be altered following arsenic exposure. These studies suggest that arsenic exposure may modulate antigen-presentation and cell migration leading to suppression of dermal sensitization.

1829 ALTERATION ON IMMUNE CELLS SUBPOPULATIONS AND LYMPHOCYTE PROLIFERATION BY ARSENIC EXPOSURE IN INFANT POPULATIONS.

G. Soto[1], A. Luna[1], L. Acosta-Saavedra[1], P. Conde[1], E. Vera[1], B. Cruz[2], M. Cebrián[1], E. Calderón-Aranda[1] and L. Vega[1]. *[1]Toxicology, CINVESTAV, México D.F, D.F, Mexico and [2]Coordinación de Investigación, SSA, Hidalgo, Mexico.*

Besides its carcinogenic effects, As has been described as immunotoxic. In animal models and human cells *in vitro*, As can modulate some transcription factors, cytokine secretion, and cell proliferation among other cellular activities (Germolec et al. 1996; 1998; Vega et al. 1999; 2001). Several human populations in the world are exposed to As *via* drinking water with high incidence of dermatological, vascular, neurological and carcinogenic affections. The effects of As exposure have been oriented to carcinogenic mechanisms and are mainly described in adults, no studies have been conducted with the aim of immunotoxic effects on humans neither in infant populations. We consider important to evaluate children populations since they could be more susceptible to As exposure effects. To address this question, we evaluated some parameters within the immunological status in an infant population exposed to As *via* drinking water. METHODS: PBMC from 80 children (6 to 10 years old) from an As exposed area were collected and stimulated with PHA for 72 h. Proliferation was evaluated by [^{3}H]-T incorporation, CD3, CD4, CD8, CD19 and CD57 subpopulations were determined by flowcytometry, IL-2, IL-4, IL-10, and IFN-γ secretion were evaluated by ELISA, As concentrations in urine were determined by HGAAS. RESULTS: Response to PHA lymphocyte stimulation and CD4/CD8 ratio were negatively associated with As exposure. Data obtained in this study indicate that the activation process on T cells could be altered, and thus represent an immunodepression status that could lead to an elevated incidence of opportunistic infections in children population. Study partially supported by CONACYT 34508-M to ESCA.

1830 FUNCTIONAL ACTIVITY OF TH1 AND MACROPHAGES FROM CHILDREN ENVIRONMENTALLY EXPOSED TO ARSENIC.

A. L. Luna[1], L. C. Acosta-Saavedra[1], P. C. Conde[1], E. Vera[1], M. B. Cruz[2], M. Bastida[2], A. Gómez-Muñoz[1], L. López-Carrillo[3], M. E. Cebrián[1] and E. S. Calderón-Aranda[1]. *[1]Sección de Toxicología, CINVESTAV, México, D.F., Mexico, [2]Secretaría de Salud, Pachuca, Hidalgo, Mexico and [3]Instituto Nacional de Salud Pública, Cuernavaca, Morelos, Mexico.*

Arsenic exposure has been associated with toxic effects at different levels including the immune system. Data from animal studies and scarce evidence from human adults, have shown that arsenic alters some immune system cells and affect T lymphocyte proliferation. However little is known about effects on children, a high risk group for the immunotoxicity of several chemicals. We studied the effect of arsenic exposure on Th1 and macrophage activation of children exposed to arsenic in drinking water (3.5 to 295.8 micrograms/L). We studied 87 children aged 6-10 years and having total urinary arsenic concentrations ranging from 12.3 to 1, 411 micrograms/L, determined by HGAAS. Th1 function was evaluated by measuring the capability of PHA-stimulated T lymphocytes to activate macrophages. Macrophage function was evaluated in the absence of T cells by direct activation with rhIFN-γ plus lipopolysaccharide. Macrophage activation was evaluated by superoxide anion and nitric oxide production. Superoxide anion production in directly activated macrophages was positively associated with total arsenic urinary concentrations whereas a negative association was observed with nitric oxide production. No significant association was found with macrophage activity in response to Th1 stimulation. These data suggest that macrophage activation in children is a relevant target for arsenic exposure. This effect could be related with a decreased resistance to those infections where macrophages play a protective role. Work supported by CONACYT 34508-M to ESCA.

1831 LEAD INTERACTION WITH ANTIGEN PRESENTING CELLS: A MECHANISM UNDERLYING Pb ALLO-ENHANCEMENT.

D. G. Farrer and M. J. McCabe. *Environmental Health and Science Center, University of Rochester, Rochester, NY.*

Adverse health effects due to lead (Pb) exposure continue to be a concern. Pb is immunotoxic as evidenced by increased susceptibility to pathogens in intoxicated animals. To explore mechanisms of Pb immunotoxicity, we utilized the mixed lymphocyte reaction (MLR). In this model, irradiated murine splenocytes of haplotype H-2^b serve as stimulators and are co-cultured with non-irradiated responder splenocytes of haplotype H-2^d. Proliferative expansion of murine alloantigen-reactive CD4$^+$ T cells is called an allogeneic response. In the presence of low levels of Pb, this response is markedly increased, a process termed Pb allo-enhancement. Although it has been thought that CD4$^+$ T cells are direct targets of Pb immunotoxicity, the possibility that allo-enhancement is mediated by the interaction of Pb with antigen presenting cells (APCs) has not been ruled out. In MLR, 1μM Pb enhances the proliferation of CD4$^+$ T cells but not when T cells are stimulated independently of antigen. We hypothesize that APCs are direct targets for Pb immunotoxicity and that its effects on CD4$^+$ T cells are indirect through modulation of antigen presentation. This hypothesis was tested in MLR using fixed or irradiated C57BL/6 (H-2^b) splenocytes as allogeneic stimulators and BALB/c (H-2^d) splenocytes as responders. Pb treatment enhanced responder splenocyte proliferation when stimulated by irradiated stimulators. Although fixed stimulators still elicited an allo-proliferative response, Pb treatment had no effect on the level of this proliferation. These findings suggest a role for Pb in altering antigen processing/presentation at the level of APC. Experiments also were conducted to identify APC populations that are responsive to Pb allo-enhancement. Allo-enhancement was observed using splenic adherent cells, peritoneal exudate cells, enriched B cells, and an I-A^b expressing cell line, PMJ-2, as stimulators. These findings suggest that APCs are targeted in Pb immunotoxicity and lay the groundwork for identifying its mechanism of action. Supported by R29 ES 07365 and T32 ES 07026.

1832 METALLOTHIONEIN INTERACTIONS AT LEUKOCYTE PLASMA MEMBRANES.

E. Canpolat[1], J. Pedersen-Lane[3], D. A. Lawrence[3], L. K. Silbart[2] and M. A. Lynes[1]. *[1]Department of Molecular and Cell Biology, University of Connecticut, Storrs, CT, [2]Department of Animal Sciences, University of Connecticut, Storrs, CT and [3]Wadsworth Center, NY State Department of Health, Albany, NY.*

Metallothionein (MT) is a small stress protein that can be induced by exposure to heavy metal cations, and oxidative stressors, and can contribute to changes in immune function. Previous work from our laboratory has shown that exogenous MT can affect cell proliferation, macrophage and T lymphocyte function, and humoral immunity to T-dependent antigens. An anti-MT monoclonal antibody (clone UC1MT) has been shown to enhance humoral immunity to T-dependent antigens by blocking the suppressive effects of metallothionein. We have found that metallothionein can be detected on the surfaces of splenocytes from congenitally autoimmune mice at higher levels than normal littermate controls. In the studies described here, we continue to explore the interaction of extracellular metallothionein with leukocyte plasma membrane. Our findings show that metallothionein can be detected on the surface of splenocytes from adjuvant-treated animals, but not on the surface of the splenocytes from unimmunized animals or animals immunized in the absence of adjuvant. Similar findings could be produced *in vitro* with primary human leukocyte cultures. Incubation of human leukocytes with LPS or PHA for 72 h induces increases in the levels metallothionein that can be detected on the surface of these cells. T cells are the lymphocyte populations with the highest increases in surface MT after exposure to mitogen. These results suggest that MT released as a consequence of immune activation or toxicant exposure will bind to plasma membranes, and can alter the course of the immune response. These findings suggest that extracellular MT interactions with immune effector cells may prove to be a useful therapeutic target for the manipulation of undesirable immune effects caused by toxicants and other stressful agents. Supported in part by NIH grant ES 07408.

1833 INHIBITORY EFFECTS OF NICOTINE ON INFLAMMATION AND LEUKOCYTE MIGRATION.

S. Razani-Boroujerdi, R. Kalra, C. Knall, F. F. Hahn, S. P. Singh, J. Pena-Philippides, R. J. Langley and M. L. Sopori. *Asthma and Pulmonary Immunology Program, Lovelace Respiratory Research Institute, Albuquerque, NM.*

Cigarette smoking is a major cause of morbidity and mortality worldwide; additionally, smokers take longer to recover from injuries. Conversely, smokers have a lower risk for some inflammatory diseases and nicotine may have a therapeutic potential in some inflammatory diseases. We have reported that nicotine, a major component of cigarette smoke, suppresses the antibody response and T cell function. Using the turpentine-induced sterile abscess model, where inflammation is accompanied with increase in body temperature (fever), we show that chronic treatment of LEW rats with nicotine suppresses the fever response as well as the accumulation of leukocytes at the site of turpentine injection. Thus, in addition to adaptive immunity, chronic nicotine also suppresses the innate immune responses (i.e., inflammation and fever). To understand the mechanisms underlying the anti-inflammatory effects of nicotine, PBMCs from control and 3-wk nicotine-treated animals were analyzed for migratory responses to chemotactic stimuli in the transwell system. Our results show that, cells from nicotine-treated animals exhibit significantly lower migration in response to the neutrophil chemoattractant, formyl-methionyl-leucyl-phenylalanine (fMLP), or the lymphocyte chemoattractant, monocyte chemoattractant protein-1(MCP-1). Thus, chronic nicotine exposure inhibits the migration of leukocytes toward the site of inflammation. This effect might stem from the inability of leukocytes to respond to chemoattractants. Because inflammation is critical for wound healing process, the property of nicotine to moderate leukocyte migration might explain the suppressive effects of smoking in some inflammatory diseases and wound repair, and the therapeutic potential of nicotine in moderating some inflammatory diseases. Supported by a grant from NIDA (DA04208).

1834 ROLE OF P38 MAP KINASE IN REGULATING THE INHIBITORY EFFECTS OF UVB LIGHT ON CYCLOOXYGENASE-2 EXPRESSION IN MOUSE MACROPHAGES.

J. D. Laskin[1], R. Sur[1], T. M. Mariano[1], L. L. Debra[2] and D. E. Heck[2]. *[1]Environmental & Comm. Medicine, UMDNJ-Robert W Johnson Med. Sch, Piscataway, NJ and [2]Pharmacology & Toxicology, Rutgers University, Piscataway, NJ.*

Ultraviolet light of high energy and shorter wavelengths (UVB, 290-320 nm) is toxic to the skin. In normal skin, UVB light can induce an inflammatory response while in diseased tissue, it exhibits anti-inflammatory and immunosuppressive activity. It is well recognized that cells in the skin release lipid mediators, including prostaglandins (PGs) and leukotrienes that promote inflammation. The synthesis of PGs is dependent on the activity of cyclooxygenase (COX), an oxidoreductase that converts arachidonic acid into the common PG precursor, PGH_2. An inducible form of the enzyme known as COX-2 is expressed in the skin during inflammation. In earlier work we reported that UVB light is a potent inhibitor of lipopolysaccharide (LPS)-induced COX-2 expression in macrophages, a cell type known to mediate inflammation in diseased tissue. In the present studies, we examined the mechanism. Using RAW264.7 macrophages, we found that UVB light (2.5-25 J/cm^2) rapidly phosphorylates and activates the c-Jun-NH_2-terminal kinase (JNK), p44/42 mitogen-activated protein (MAP) kinase [extracellular signal-regulated kinase 1/2 (ERK1/2)], and p38 MAP kinase. PD-98059, an inhibitor the ERK1/2 kinase, and SP600125J, an inhibitor of the JNK kinases, were effective inhibitors of UVB light-induced ERK1/2 and JNK phosphorylation, respectively, in the macrophages. However, the inhibitors did not alter UVB light-induced inhibition of COX-2 expression. Unexpectedly, SB-203580 [(4-(4-Fluorophenyl)-2- (4-methylsulfinylphenyl)-5-(4-pyridil)imidazole], a p38 kinase antagonist, was found to block UVB light-induced p38 phosphorylation and inhibition of LPS-induced COX-2 in the macrophages. Taken together, these data indicate that activation of p38 MAP kinase plays an important role in mediating UVB light phototoxicity. Selective modulation of p38 MAP kinase may be an important target for treating epidermal inflammatory diseases. Support: NIH ES06897, ES03647 and ES05022

1835 COMPARISON OF THE ALLERGENIC POTENCY OF ALPHA-HEXYLCINNAMALDEHYDE (HCA) AND 2-MERCAPTOBENZOTHIAZOLE (MBT) IN SIX STRAINS MICE IN MURINE LOCAL LYMPH NODE ASSAY (LLNA).

L. G. Ullmann, S. J. Corney, G. Arcelin and W. Wang-Fan. *Toxicology Division, RCC Ltd, Itingen, Switzerland.* Sponsor: K. Sachsse.

Keyword LLNA The Murine Local Lymph Node Assay (LLNA), which has been accepted by the OECD since 2000 as a stand alone alternative to the Guinea Pig Maximization Test (GPMT), has been largely used for assessing the allergic contact dermatitis potential of chemicals. According to OECD Draft Guideline No. 429 [November 2000] the animal species of choice are CBA/Ca or CBA/J mice. To test and compare the suitability of these and other mouse strains for assessing the allergenic potency of a chemical, two positive-control chemicals (HCA and MBT) were tested at three doses in the following six mouse strains at RCC: CBA/CaOlaHsd, CBA/Ca (CruBR), CBA/Jlbm (SPF), CBA/JNCrj, Balb/c and NMRI. For each strain, test groups of four mice were topically treated with HCA or MBT at 5%, 10% or 25% (w/w) in acetone:olive oil, 4:1 (v/v) on three consecutive days. A control group for each strain of mouse was treated with vehicle only. Five days after the first topical application the proliferation capacity of the lymph node cells was determined by their incorporation of 3HTdR, which was measured in a beta-scintillation counter, compared with that recorded in negative control groups. The experimental results are briefly summarized in Table 1. The test results indicate that CBA/CaOlaHsd mice should be the first choice for assessing allergenic potency. Balb/c mice are also a potential test strain for LLNA tests. CBA/Ca (CruBR) and NMRI strains of mice are not suitable for assessing the allergenic potency of chemicals.

Strain	HCA			MBT		
	5% (w/v)	10% (w/v)	25% (w/v)	5% (w/v)	10% (w/v)	25% (w/v)
CBA/CaOlaHsd	5.0	10.5	44.7	5.3	8.6	6.6
CBA/Ca (CruBR)	1.4	1.3	2.6	1.2	2.3	4.1
CBA/Jlbm (SPF)	1	1.8	8.5	1.3	8	5.4
CBA/JNCrj	2.3	4.5	8.2	1.7	3.6	0.6
Balb/c	6	3.8	9.6	6.1	9.6	7.5
NMRI	0.8	1.9	3.5	1.2	1	1.2

1836 INFLAMMATORY RESPONSE AND FREE RADICAL FORMATION IN SKIN OF B63CF1 MICE WITH DIMINISHED LEVELS OF GLUTATHIONE AFTER PHENOL EXPOSURE.

A. A. Shvedova[1,2], E. R. Kisin[1], A. R. Murray[1], C. Kommineni[1], M. R. Gunther[2], M. K. Rao[1] and V. Castranova[1]. *[1]NIOSH, Morgantown, WV and [2]West Virginia University, Morgantown, WV.*

A number of phenolic compounds that are utilized in industry (e.g., for production of resins, paints, lacquers, cosmetics and pharmaceuticals) are toxic to skin (i.e., can cause rash, dermal inflammation, contact dermatitis, leucoderma, and/or cancer promotion). The biochemical mechanisms of dermal toxicity of phenolic compounds are not well understood. We observed alpha-phenyl-N-*tert*-butylnitrone (PBN) spin-trapped free radicals generated in the skin of female B6C3F1 mice after topical exposure to phenol (3.5 mmol/kg, 100 µL, 1 h). The exposure also resulted in oxidation of GSH and protein thiols, and decreased levels of total antioxidant reserves and vitamin E in the skin. We also compared the effects of phenol in mice with normal or diminished levels of GSH. The magnitude of phenol-induced PBN-spin-trapped radical adducts in skin of mice with diminished levels of GSH (either pre-treated with DL-buthionine sulfoximine, BSO, or 1, 3-bis(2-chloroethyl)-1-nitrosourea, BCNU) was remarkably higher as compared to those in mice treated with phenol alone. Topical exposure to phenol also resulted in increased inflammatory cell infiltration in the skin of mice pre-treated with BSO or BCNU. To identify mediators involved in skin inflammation after phenol and phenol plus BSO exposure, we used JB-6 mouse epidermal cells. Using ELISA, we found that phenol and BSO plus phenol induced increases in IL-1β and prostaglandin E_2 production in the cells as early as 1 h post-treatment. Real time PCR of ICAM-1 revealed mRNA expression starting at 3 h after exposure of the cells to phenol and BSO plus phenol. Additionally, western blot analysis showed higher expression of COX-2 in cells exposed to BSO plus phenol. In the skin, we also observed mRNA expression of COX-2 and IL-1β in mice treated for 2 h with phenol or BSO plus phenol. These data indicate that mediators, such as IL-1β, ICAM-1 and prostaglandin E_2, are involved in early stages of skin inflammation in response to phenol and phenol plus BSO.

1837 EVALUATION OF THE PHOTOTOXIC AND PHOTOALLERGIC POTENTIAL OF METHYL N-METHYL ANTHRANILATE.

C. Letizia and A. Api. *Research Institute for Fragrance Materials, Inc., Hackensack, NJ.* Sponsor: A. Api.

Methyl N-methylanthranilate, which occurs naturally in many citrus oils, is used in both fragrances and flavors. Earlier studies reported that methyl N-methylanthranilate was phototoxic in hairless mice at a concentration of 50% in methanol and in humans at a concentration of 5% in hydrophilic ointment. Further studies were conducted to determine if a no-effect level for phototoxic effects in humans could be established. Phototoxicity was evaluated using a 24-hour occluded application of

methyl N- methylanthranilate to naive sites on the back followed by immediate exposure of the test sites to UVB and UVA from a Solar Simulator. Phototoxic effects were observed in 14/35 female volunteers with 1% methyl N-methylanthranilate in 75% ethanol/25% diethyl phthalate; no phototoxic effects were observed in 29 volunteers with 0.1%, 0.3% or 0.5% in 75% ethanol/25% diethyl phthalate. A study to determine the photoallergic potential of methyl N-methylanthranilate was conducted in 26 female volunteers using a modified human photomaximization procedure (six 24-hour occluded induction applications with each application followed immediately by UVB/UVA exposure from a Solar Simulator; after a 2-week rest period, a 24-hour occluded challenge application was immediately followed by exposure to UVA/UVB); phototoxicity was also evaluated during the induction phase of this study. No photoallergic or phototoxic reactions were observed with 0.5% in 75% ethanol/25% diethyl phthalate. Based on the findings in these studies, it can be concluded that the NOEL for methyl N-methylanthranilate for phototoxic effects in humans is 0.5%; and under the conditions of the above study, methyl N-methylanthranilate is not photoallergic in humans at a concentration of 0.5%.

1838 GENE EXPRESSION IN RAT SKIN FOLLOWING CUTANEOUS EXPOSURE TO XYLENE, SODIUM LAURYL SULFATE AND LIMONENE.

J. N. McDougal[1], C. M. Garrett[2] and J. V. Rogers[2,1]. *[1]Pharmacology and Toxicology, Wright State University School of Medicine, Dayton, OH and [2]Geo-Centers Inc., Air Force Research Laboratory, Wright-Patterson AFB, OH.*

In the US, occupational skin disease is the second most significant cause of occupational disease, after accidents. Some of this disease is due to exposures to occupational chemicals such as solvents, fuels and surfactants. Understanding the mechanisms of acute irritation will assist in assessing risks to exposures as well as potential therapy and prophylaxis. Gene expression studies may provide useful information about normal processes in the skin and the responses of the skin to exogenous chemicals. We exposed rats, cutaneously, to m-xylene (pure liquid), sodium lauryl sulfate (1% & 10% aqueous solution) and d-limonene (pure liquid) for one hour and measured transcriptional responses at the end of the exposure and three hours later for comparison with untreated skin samples. Total skin RNA was isolated and analyzed using the Affymetrix RatTox U34 array. We found that 120 of approximately 850 genes were detected as present with Affymetrix software. The largest number of these genes was in the metabolism (19) and oxidative/cellular stress responsive (9) categories. Other transcripts present in untreated skin were categorized as cellular structure, signaling, hormones, extracellular matrix, differentiation/cell division, transporters/ligands and a receptor. We found that limonene treatment caused the largest change in mRNA levels with a total of 34 transcripts increased and 4 transcripts decreased at one or four hours. 10 % sodium lauryl sulfate caused 5 transcripts to increase and 17 to decrease at one or four hours. Xylene treatment resulted in 6 increased transcripts and 14 decreased transcripts at one or four hours. Differences in the skin responses to these 3 treatments may reflect different mechanisms of irritation. These changes in gene expression suggest some proteins that should be quantified as we investigate the time course of the irritant cascade. (supported by CDC/NIOSH R01 OH03654)

1839 VEHICLE COMPOSITION INFLUENCES THE PHARMACOLOGIC EFFECTS AND KINETICS OF CAPSAICIN IN HUMAN SKIN.

L. K. Pershing[1], C. A. Reilly[2] and D. J. Crouch[2]. *[1]Dermatology, University of Utah, Salt Lake City, UT and [2]Center for Human Toxicology, University of Utah, Salt Lake City, UT.* Sponsor: G. Yost.

Less-than-lethal pepper spray products are prepared by solubilizing capsaicinoids in various solvents, including alcohols and propylene glycol. Previous studies showed that capsaicin activity in human skin (erythema) was 3X greater in propylene glycol than isopropyl alcohol. This study investigated the uptake and elimination of capsaicinoids in human skin as a possible kinetic basis for the responses. Twelve sites on the volar forearms of twelve human subjects were exposed for 1, 5, 10 and 15 min to a single, nonoccluded 150 mcg dose of capsaicin prepared in either 70/30 (v/v) isopropyl alcohol/water (IPA), 80/20 (v/v) mineral oil/isopropyl alcohol (MO) and 80/20 (v/v) propylene glycol/isopropyl alcohol (PG). Skin capsaicinoid concentrations were quantified in stratum corneum harvested with ten 1.3 diameter adhesive discs applied and removed from each skin site either immediately after exposure (1, 5, 10 or 15 min) or 3, 6, 11 or 24 hrs after removal of a 15 min exposure. The samples from each skin site were combined, extracted and analyzed for capsaicin and dihydrocapsaicin concentration by LC-MS and the kinetic parameters Cmax, Tmax, AUC and Thalf determined. Both capsaicinoids were detected in stratum corneum within 1 min of exposure. Cmax for capsaicin in PG (5.6 mcg) was similar to MO (6.6 mcg), but 3X less than IPA (16.1 mcg). Differences in AUC between the vehicles reflected the rank order of Cmax. Dihydrocapsaicin concentrations were ~60% of capsaicin in all solutions and all skin samples at all time points, independent of vehicle. Tmax and Thalf of the capsaicinoids were similar in PG, MO and IPA. Thalf of capsaicin and dihydrocapsaicin in human stratum corneum was ~24 hrs. Thus, alcohols influenced the extent of capsaicinoid uptake, but not the rate of uptake or elimination kinetics in human skin *in vivo*. Therefore, the elevated potency of capsaicin in PG is likely due to a vehicle influence on the receptor-mediated pharmacologic effects of capsaicin.

1840 EVALUATION OF DERMAL ABSORPTION OF AQUEOUS TOLUENE IN F344 RATS USING REAL-TIME BREATH ANALYSIS AND PHYSIOLOGICALLY BASED PHARMACOKINETIC MODELING.

A. D. Woodstock and K. D. Thrall. *Battelle, Pacific Northwest Laboratory, Richland, WA.*

Toluene is a ubiquitous chemical commonly used for its solvent properties in industry and manufacturing, and is a component of many paint products. Because of its widespread use, there is potential for both occupational and non-occupational dermal exposure to toluene. To understand the significance of these exposures, the dermal bioavailability of toluene was assessed in F344 male rats using a combination of real-time exhaled breath analysis and physiologically based pharmacokinetic (PBPK) modeling. Animals were exposed to toluene at a 0.5 or 0.2 mg/ml aqueous concentration using a 2.5-cm diameter occluded glass patch attached to a clipper-shaved area on the back of the rat. Immediately following exposure, individual animals were placed in a glass off-gassing chamber and exhaled breath was monitored as chamber concentration in real time using an ion trap mass spectrometer. The exhaled breath profile clearly demonstrated the rapid absorption of toluene, with peak chamber concentrations observed within 1 hr from the start of exposure. The PBPK model describing the exposure and off-gassing chamber was used to estimate a dermal permeability coefficient (Kp) to describe each set of exhaled breath data. Regardless of exposure level, a single Kp value of 0.074 +/- 0.005 cm/hr provided a good fit to all data sets. These rat studies using aqueous toluene will form the basis for comparing the dermal bioavailability of toluene in various paint products and may ultimately aid in understanding human health risk under a variety of exposure scenarios. (Supported by NIOSH grant 1-RO1-OH03658-01A2).

1841 A MATHEMATICAL MODEL OF THE PERMEATION KINETICS OF THE MEMBRANE-COATED FIBER TECHNIQUE ACCOUNTING FOR PARTITION, DIFFUSION AND BOUNDARY LAYER FACTORS.

X. R. Xia, R. E. Baynes, N. A. Monteiro-Riviere and J. E. Riviere. *Center for Cutaneous Toxicology and Research Pharmacokinetics, North Carolina State University, Raleigh, NC.*

A mathematical model was developed to describe the permeation kinetics of the membrane-coated fiber (MCF) technique, which is used for *in vitro* assessment of dermal absorption of chemical mixtures. In addition to the basic percutaneous absorption factors, partition coefficient and membrane diffusivity, a boundary layer adjacent to the membrane was considered in the model. The cumulative amount permeated into the membrane was expressed as a function of permeation time in an exponential equation. The two constants introduced into the model, clearly defined with the physiochemical parameters of the system, can be obtained by regression of the experimental data sampled over a limited time. The partition and diffusion coefficients, as well as, the thickness of the boundary layer were calculated from the two constants. The mathematical model adequately described the permeation kinetics of the MCF technique. All of the theoretical predictions were supported by the experimental results. The measured partition coefficients were correlated well with the published octanol/water partition coefficient (R2=0.88). The thickness of the boundary layer was 5.2μm in a donor solution stirred at 400 rpm. The contribution of the boundary layer to the permeation kinetics is $2K$ times larger than that of the membrane, where K is the partition coefficient of a given compound. These results suggest that the permeation rate of a hydrophobic compound could be controlled by the boundary layer even though the diffusivity of the compound in the membrane is lower than that in the donor solution. Supported by NIOSH R01-OH 03669 and 07555.

1842 PHYSIOLOGICAL MODELING OF THE DERMAL ABSORPTION OF OCTAMETHYLCYCLOTETRASILOXANE (D4).

M. B. Reddy[1], R. J. Looney[2], M. J. Utell[2], M. L. Jovanovic[3], J. M. McMahon[3], D. A. McNett[3], I. D. Dobrev[1], K. P. Plotzke[3] and M. E. Andersen[4]. *[1]Quantitative and Computational Toxicology Group, Center for Environmental Toxicology and Technology, Colorado State University, Fort Collins, CO, [2]University of Rochester School of Medicine, Rochester, NY, [3]Toxicology, Health and Environmental Sciences, Dow Corning Corporation, Midland, MI and [4]CIIT Centers for Health Research, Research Triangle Park, NC.*

Studies on human dermal absorption of octamethylcyclotetrasiloxane, D4, through axilla skin *in vivo* and through abdominal skin *in vitro* recently have been completed. A mathematical model describing the dermal absorption of D4 was developed and combined with an inhalation PBPK model for this material. The model

includes volatilization of the chemical from the skin surface, evaporation of chemical out of the skin after the skin surface has been cleared of the chemical, and a deep skin compartment. An *in vivo* dermal absorption study of D4 in the rat provided evidence that a model structure including elimination from the skin by evaporation is appropriate. Concentrations of D4 in exhaled air and blood plasma from human, *in vivo* exposures were used to estimate the model parameters. Following either inhalation or dermal exposures, D4 blood plasma concentrations increased with time relative to exhaled air concentrations. The PBPK model for both dermal and inhalation exposures required the inclusion of a pool of unavailable D4 created in the liver, transported in the blood, and cleared in the fat to describe this behavior. Model calculations indicated that during the human, *in vivo* dermal exposures, more than 90% of the applied dose evaporated from the skin surface before it could be absorbed into the skin. Of the D4 absorbed into the skin, the majority was eliminated by evaporation before systemic absorption could occur. For men and women, respectively, about 0.1 and 0.5% of the applied dose of D4 entered the cutaneous blood within 24 hours of the exposure. M. Reddy is supported in part by NIEHS F32 ES11425-02.

1843 MEASUREMENT OF THE *IN VITRO* RATE OF PERCUTANEOUS ABSORPTION OF [^{14}C]DIOCTYL TEREPHTHALATE (DOTP) THROUGH HUMAN SKIN.

T. Guerin[1], L. M. Taylor[1], J. C. English[1] and K. M. Ruble[2]. *[1]Health and Environment Laboratories, Eastman Kodak Company, Rochester, NY and [2]Eastman Chemical Company, Kingsport, TN.*

Dioctyl terephthalate (DOTP) is a potential replacement for ortho-phthalate plasticizers. The rate of percutaneous absorption of [carboxyl-^{14}C]bis(2-ethylhexyl)-1, 4-benzenedicarboxylate through dermatomed sections of human skin was measured *in vitro*. An excess of DOTP was applied to sections of human skin contained in glass diffusion cells. Solubility of DOTP in receptor solution was determined not to be a rate-limiting step in skin absorption. The total recovery of the test substance was measured by determining the percentage ^{14}C-labeled test substance remaining in test system components for each test substance cell. The total mean (± SD) ^{14}C-labeled DOTP recovery was 104% ± 6%. The majority of ^{14}C was recovered from the donor cell and only 0.056% ± 0.032% was associated with the skin. The measured absorption rate (mean ± SD) was 0.103 ± 0.052 μg/cm^2/hr, and the permeability constant was $(8.39 \pm 2.17) \times 10^{-8}$ cm/hr. The integrity of each skin specimen was determined by measuring its permeability to tritiated water (^3H_2O) in Phase 1. The mean (± SD) ^3H_2O absorption rate for all skin specimens was 2.04 ± 0.95 mg/cm^2/hr, in agreement with historical and published values. The mean damage ratio, calculated from the rates of ^3H_2O before and after exposure of the skin to the test substance, was similar to the negative control (unexposed) values, indicating that exposure to the test substance for 29 hr did not significantly damage human skin. Applying the criteria of Marzulli, Brown, and Maibach (1969), DOTP absorption through human skin is classified as "extremely slow". These data allow the estimation of uptake in man following dermal exposure to the test substance, assuming that the skin absorption rate in man is similar to that observed in this *in vitro* study. For example, if excess test substance were to be in contact with an area of skin equivalent to both hands (approximately 720 cm^2, 70-kg human) continuously for 1 hr, the calculated internal dose would be 1.06 μg/kg.

1844 *IN VITRO* PERCUTANEOUS ABSORPTION OF ACRYLAMIDE AND STYRENE IN HUMAN SKIN.

M. E. Kraeling and R. L. Bronaugh. *USFDA, Laurel, MD.*

Polyacrylamide is formed from polymerization of acrylamide (ACR) monomers and is used in hair, nail and skin care products. Polystyrene is manufactured from styrene (STY) monomers and is used in personal care products as a thickening agent. Although most of the ACR and STY are converted to polymers, residual monomers are an impurity in the polymers formed. Polymers will not penetrate skin, but, the monomers may be substantially absorbed. ACR poses a concern because of neurotoxic effects in humans and carcinogenic, reproductive, developmental and neurotoxic effects in animals. Long term exposure to STY was reported to cause neurotoxic and carcinogenic effects in rodents. We initiated studies to measure the extent of ACR and STY absorption in human skin relevant to exposures from consumer products. Human skin was dermatomed (200 μm thick) and mounted in diffusion cells perfused with HHBSS + 4% BSA, pH 7.4. Formulations remained on skin for 24 h and the amount of ACR and STY absorbed in skin layers and receptor fluid was measured and expressed as the % of the applied dose absorbed. [14C]ACR (specific activity; 5 mCi/mmol) was applied to skin in an O/W emulsion at radiochemical doses of 0.01, 0.1 and 0.6 μCi. ACR was also applied in a 2% polyacrylamide gel cream at a dose of 0.01 μCi. ACR was rapidly absorbed from both formulations into receptor fluid with peak absorption occurring at 6 h. At 24 h, ACR absorption into receptor fluid from the O/W emulsion at the 0.01, 0.1 and 0.6 μCi dose levels was about 42, 46, and 53%, respectively. With the polyacrylamide gel cream, ACR absorption into receptor fluid was 33%. Receptor fluid values represent ACR levels available for systemic absorption. With both formulations, only about 4-7% ACR remained in skin after 24 h. [14C]STY (20 mCi/mmol) was applied to skin in the O/W emulsion at a radiochemical dose of 0.5 μCi. Only 1.2% of the applied dose of STY was absorbed into receptor fluid with 0.12% remaining in skin. The low absorption of STY is due predominately to the high volatility of this monomer.

1845 COMPARISON OF *IN VITRO* MODELS OF PERCUTANEOUS ABSORPTION.

G. Pugh[1], H. A. Raabe[2], G. O. Moyer[2], J. W. Harbell[2] and D. M. Bagley[1]. *[1]Colgate-Palmolive Company, Piscataway, NJ and [2]Institute for In Vitro Sciences, Inc., Gaithersburg, MD.*

As part of a Colgate-Palmolive sponsored program to validate an *in vitro* percutaneous absorption model, three reference materials with extensive *in vivo* human and *in vitro* (animal and human) data were evaluated in three *in vitro* models. The objective of this study was to determine if the results are consistent with data published in the literature. The test methods used in this study were based upon guidance by the US Food and Drug Administration, and are consistent with the Office of Economic Cooperation and Development Draft Test Guidelines (2000). The *in vitro* models evaluated were human donor skin, engineered human tissue (MatTek Corporation, Model EPI-606X) and slaughterhouse-derived pig skin. The reference materials in each model were testosterone (petrolatum vehicle), benzoic acid (petrolatum and acetone), and caffeine (ethanol). The octanol/water partition coefficients (log P_{ow}) for these materials are 3.32, 1.87, and -0.07, respectively. Each reference material was evaluated at least twice in each model. The tissues were mounted in flow-through diffusion cells (PermeGear, Inc., 0.64 cm^2 surface area), qualified for barrier function by $^3H_20$ passage, followed by the application of a finite dose of ^{14}C-labeled test material (~4 μg/cm^2). The study duration was 24 hours. The recovery of caffeine and testosterone was similar (typically > 90%) in all models (a slightly lower recovery was observed in one trial with testosterone in pig tissue [mean = 81%]). Recovery of benzoic acid was notably lower, probably due to sublimation, with the highest recovery in the petrolatum preparation, as compared to the acetone preparation. In human and pig skin, the rank order for skin penetration was benzoic acid (petrolatum) > testosterone > benzoic acid (acetone) > caffeine. In Model EPI-606X, the rank order of penetration was benzoic acid (petrolatum) > testosterone > caffeine > benzoic acid (acetone). The results of these studies were reproducible and consistent with data published in the literature.

1846 METHYLEUGENOL SKIN ABSORPTION IN HUMAN AND FUZZY RAT SKIN.

J. J. Yourick and R. L. Bronaugh . *Cosmetics Toxicology Branch, USFDA, Laurel, MD.*

Methyleugenol (ME) is used as a fragrance ingredient in perfumes, soaps, detergents, creams, and lotions. Methyleugenol is an allylbenzene that is structurally related to safrole, isosafrole and estragole. Concerns about ME safety have been raised by National Toxicology Program carcinogenicity testing in rodents. Therefore, we initiated studies to measure ME dermal absorption in human (*in vitro*) and fuzzy rat (*in vitro* and *in vivo*) skin. *In vitro* [^{14}C]ME (approx. 0.5 μCi/cell) skin absorption was measured using either ethanol or an emulsion dosing vehicle. *In vitro* absorption was measured for 24 h by using flow-through diffusion cells (0.64 cm^2) with a receptor fluid consisting of HHBSS (pH 7.4). *In vivo* ME rat skin absorption was determined from an ethanol vehicle applied to skin for 24 h. In human skin (n=3), the percentage of applied dose absorbed (%ADA) from an ethanol vehicle over 24 h was 9.3 ± 1.82 (mean ± SEM) with approximately 0.9% remaining in skin. In rat skin *in vitro* (n=3), the %ADA from an ethanol vehicle over 24 h was 34.2 ± 2.82 with approximately 1.3% remaining in skin. Absorption of ME from an emulsion vehicle resulted in similar receptor fluid and skin levels when compared to levels measured in human or rat skin with an ethanol vehicle. Occlusion of the diffusion cells resulted in significantly higher *in vitro* absorption of ME with receptor fluid %ADA values of 49.7 ± 16.9 and 77.3 ± 6.0 for human and rat skin, respectively. ME rapidly penetrated both human and rat skin *in vitro* with approximately 7 and 30%, respectively, of the absorbed dose found in the receptor fluid within 6 h. Use of a charcoal trap attached to the top of the diffusion cell improved the recovery of the volatile ME. *In vivo* absorption of ME in the rat resulted in systemic absorption of 19.8 ± 0.1 %ADA with 0.7 %ADA remaining in skin. These studies indicate there is considerable ME absorption in skin. Systemic ME absorption should be expected after dermal application of ME-containing consumer products.

1847 THE INFLUENCE OF STORAGE TIME AND ARTIFICIAL SWEAT ON THE ERCUTANEOUS ABSORPTION OF EXPLOSIVES FROM SOILS.

W. Reifenrath[1], G. Reddy[2], M. Major[2] and G. Leach[2]. *[1]Stratacor, Inc., Richmond, CA and [2]US Army CHPPM, Aberdeen Proving Ground, MD.*

We determined the influence of sample storage time on the percutaneous absorption of C-14 labeled hexahydro-1, 3, 5-trinitro-1, 3, 5-triazine (RDX), 2, 6-dinitrotoluene (26DNT) and 2, 4, 6-trinitrotoluene (TNT) from two soil types, Yolo having 1.9% carbon and Tinker having 9.5% carbon content. RDX soil samples stored at -20C for 27 months and 62 months were compared to freshly spiked soil samples. Similarly, 26DNT samples stored 35-36 months and TNT samples stored 18 months were compared to freshly spiked samples. Approximately 10 ug/cm2 of radiolabeled compound was applied in 10 mg/cm2 of soil to freshly excised pig skin pretreated with artifical sweat (5 ul) and mounted in skin penetration-evaporation chambers. Radiolabel recovered from the dermis and tissue culture media (receptor fluid) was summed to determine percent absorption from the soils. For each compound, percent absorptions of label were highest from Yolo soil. Storage did not significantly alter percutaneous absorption values for RDX, as values were all less than 1%, regardless of soil type or age. Similarly, 26DNT absorption was 1-2% for Tinker soil and 16-18% for Yolo soil, regardless of soil age. TNT absorption was approximately 0.5% from Tinker soil and 3-4% from Yolo soil for fresh and stored samples. HPLC analysis of 26DNT in receptor fluid at maximum flux indicated no metabolism or breakdown. For TNT, extensive conversion to monoamino derivaties and other metabolites was observed. The absorption of 26DNT from low carbon soil was reduced from 16-18% to near zero without sweat pretreatment, indicating that skin surface moisture was a critical variable in determining topical bioavailability.

1848 THE INFLUENCE OF SWEAT ON THE PERCUTANEOUS ABSORPTION OF CHLORPYRIFOS FROM NYLON CARPET FIBERS.

R. L. Williams[1], W. G. Reifenrath[2] and R. I. Krieger[1]. *[1]Entomology, University of California, Riverside, CA and [2]Stratacor, Inc., Richmond, CA.*

Enhanced absorption of chlorpyrifos following exercise and a correlation between moisture and pesticide transfer (Williams et al., 2002) have been observed. Chlorpyrifos was chosen as a surrogate for semi-volatile chemicals used indoors. The percutaneous absorption of 14C-ring-chlorpyrifos from nylon carpet fibers was measured in porcine skin penetration-evaporation cells from nylon carpet fibers. Prior to application, synthetic sweat was applied to the skin surface in half of the cells. Radioactivity was measured in receptor fluid, dermis, epidermis, tape stripping samples, and vapor trap samples from a 24-hour period. Chlorpyrifos was successfully measured from nylon carpet fibers in the penetration-evaporation cells. The sum of radiolabel recovered from the dermis and receptor fluid was considered to represent the absorbed dose. There was no significant difference ($p > 0.05$) in percutaneous absorption or evaporative loss between cells that received the synthetic sweat application and cells that were run "dry" (1.5 ± 0.45 and 28.1 ± 4.96 percent for percutaneous absorption and evaporative loss, respectively). There was significantly more ($p < 0.05$) radiolabel recovered from tape stripping (5.4 ± 2.12 vs. 2.8 ± 0.59 percent) and in the epidermis (4.5 ± 0.78 vs. 3.1 ± 0.34 percent) from cells that received the synthetic sweat application. The percutaneous absorption of chlorpyrifos was found to correlate with an empirical model previously developed with nitro-compounds from soil. The synthetic sweat treatment facilitated transfer of chlorpyrifos from a treated substrate to the skin surface, but did not effect the rate or magnitude of percutaneous absorption in this study. This work has been supported in part through the Colgate-Palmolive/SOT Award for Student Research Training in Alternative Methods

1849 DERMAL DISPOSITION OF TRIAZINE IN CUTTING FLUID MIXTURES.

R. E. Baynes, J. D. Brooks, B. M. Barlow and J. E. Riviere. *Center for Cutaneous Toxicology and Research Pharmacokinetics, North Carolina State University, Raleigh, NC.*

Triazine is often added as a biocide/preservative to cutting fluids formulations used in the metal machine industry. Workers involved in metal machining are not only exposed to components in these cutting fluids, but biocides such as triazine which have been implicated in occupational contact irritant dermatitis (OCID). Little is known about how these cutting fluids and their ingredients influence the dermal disposition of triazine. The purpose of this study was to assess C^{14}-triazine membrane transport when topically applied to inert silastic membranes and porcine skin in *in vitro* flow-through diffusion cell system as aqueous mineral oil (MO) or aqueous polyethylene glycol (PEG) mixtures. C^{14}-triazine mixtures were formulated with 3 commonly used cutting fluid additives; namely, 0 or 5% linear alkylbenzene sulfonate (LAS), 0 or 5% triethanolamine (TEA), and 0 or 5% sulfurized ricinoleic acid (SRA). Triazine partitioning from the formulation into the stratum corneum (SC) was significantly reduced by LAS, while SRA significantly reduced the pH of the formulation. Triazine absorption ranged from 2.24 to 3.9% dose in porcine skin and 12.61 to 18.63% dose in silastic membranes. In silastic membranes, the complete mixture significantly reduced triazine absorption in MO-based mixtures, while in PEG-based mixtures triazine absorption and apparent permeability were significantly increased. In porcine skin, triazine permeability was significantly increased for both MO- and PEG-based complete mixtures and the trend was for greater triazine absorption in more complex PEG-based mixtures. Interestingly, SRA or TEA alone significantly reduced triazine absorption in MO-based mixtures, and this interaction appears to be more additive than synergistic. Although the physiochemical experiments suggest otherwise, triazine readily permeates a homogenous lipid membrane such as the SC, while triazine permeability and absorption was significantly enhanced by the complete mixture especially in PEG-based mixtures. Supported by NIOSH Grant R01-OH-03669.

1850 ABSORPTION OF 14C- RDX FROM SOILS THROUGH HUMAN SKIN.

G. Reddy[1], N. A. Allen[2] and M. A. Major[1]. *[1]Health Effects Research Program, US Army Center for Health Promotion and Preventive Medicine, Aberdeen Proving Ground, MD and [2]Oak Ridge Institute for Science and Education, Aberdeen Proving Ground, MD.*

Cyclotrimethylenetrinitramine (RDX), a munition compound has been detected in water and soil as an environmental contaminant at production waste disposal sites and at certain military installations. The bioavailability of a chemical from soils depends on soil composition. We studied dermal absorption of 14C- RDX from two types of soils, Yolo (low carbon, 1.9%) and Tinker (high carbon, 9.5%), in human skin *in vitro* in flow-through diffusion cells. Soils (10 mg/cm2) containing a dose (10 mg/ cm2 / 0.05 m Ci) was applied to the skin and collected as diffused receptor fluid for every 6 hr up to 24 hrs. The soil content on the skin was washed with soap water and water with cotton swabs, and radioactivity present in washings was determined. The RDX absorbed in the skin (stratum corneum, epidermis and dermis) was also determined. Our results show that a total of approximately 2 .71 % (Yolo) and 2.24% (Tinker) of applied dose from soils was absorbed in the skin (receptor fluid and skin) in 24 hr. The absorption of RDX in the receptor fluid was about 1. 4 % (Yolo) and 0.66% (Tinker) soils in 24 hrs. The total recovery of applied dose (receptor fluid, skin and washings) was about 87 % (Yolo) and 94% (Tinker). The RDX absorption from soils in the skin was low when compared to RDX in acetone (6%) (Reddy et al., 2002). This shows that the bioavailability of RDX from soils is reduced considerably. The estimated levels of RDX absorption from soils can be used to evaluate health risks associated with dermal exposure (Supported by COE, abstract does not reflect US Army policy).

1851 DERMAL ABSORPTION OF TOLUENE FROM ENAMEL PAINT IN F344 RATS.

M. R. Kania[1], A. D. Woodstock[2] and K. D. Thrall[2]. *[1]Energy Research Undergraduate Laboratory Fellowship, University of Washington, Seattle, WA and [2]Battelle, Pacific Northwest Laboratory, Richland, WA.*

Toluene is a component of many paint products and there is potential for both occupational and non-occupational dermal exposure to toluene in various matrices. To understand the significance of these exposures, the dermal bioavailability of toluene was assessed in F344 male rats using a combination of real-time exhaled breath analysis and physiologically based pharmacokinetic (PBPK) modeling. Animals were exposed to toluene present in a commercial enamel paint using a 1.7-cm diameter occluded glass patch system attached to a clipper-shaved area on the back of the rat. Immediately following exposure, individual animals were placed in glass off-gassing chambers and exhaled breath was monitored as chamber concentration using an ion trap mass spectrometer (MS/MS). The exhaled breath profiles from treated animals clearly demonstrated the rapid absorption of toluene. Peak chamber concentrations, representing exhaled breath, were observed within 1 hr from the start of exposure. The PBPK model describing the exposure and off-gassing chamber was used to model the exhaled breath data. A dermal permeability coefficient (Kp) of 0.073 cm/hr was found to describe each set of exhaled breath data. In comparison, the Kp value determined for enamel paint was identical to the Kp value for aqueous toluene (0.074 cm/hr) although toluene concentrations differed significantly (25 mg/ml versus 0.5 mg/ml). To evaluate the impact of paint

constituents on the dermal bioavailability, additional dermal studies were conducted using reformulated enamel paint with the titanium dioxide and xylene cosolvent replaced by toluene. PBPK model simulation of the exhaled breath data from these exposures required a Kp value roughly half the value from the intact paint (0.032 cm/hr) although the toluene concentration was more than 12 times greater. These data suggest the permeability of toluene is influenced by the exposure concentration and less so by the exposure matrix. (Supported by NIOSH grant 1-RO1-OH03658-01A2).

1852 SKIN PENETRATION AND EVAPORATION OF p-MENTHANE-3, 8-DIOL IN ETHANOL AND IN LOTION FORMULATION AFTER TOPICAL APPLICATION TO EXCISED PIG AND RAT SKIN: A MODEL FOR HUMAN DERMAL ABSORPTION.

J. J. Olson[1], T. G. Osimitz[2], U. Vedula[1] and W. G. Reifenrath[3]. *[1]S. C. Johnson & Son, Inc., Racine, WI, [2]Infoscientific.com Inc., Charlottesville, VA and [3]Stratacor, Inc.., Richmond, CA.*

p-Menthane-3, 8-diol (3-8DIOL), a plant based product, was recently introduced as a topical insect repellent in the commercial product, "OFF! Botanicals" Lotion. The objective of this study was to provide an estimate of the potential for its systemic absorption in man. Carbon-14 labeled repellent formulated in the lotion or ethanol solution was applied to excised pig skin in an *in vitro* test system predictive of skin absorption in man. Twenty-four hours after application, radiolabel recovered from the dermis and receptor fluid was summed to determine percent absorption. At a dose of approximately 80 μg/cm^2 of 3-8DIOL in the lotion, a value of 3.5±0.8% was obtained with pig skin (N=6). The corresponding value for 3-8DIOL in ethanol was not significantly different (3.0±1.2%, N=6, $p>0.05$, ANOVA). For reference purposes, the pig skin absorption of piperonyl butoxide (PBO) at 100 μg/cm^2 and N, N-diethyl-m-toluamide (DEET) at 500 μg/cm^2 were significantly higher (15±6% and 23±3%, respectively, N=6, $p<0.05$, ANOVA). For additional reference, absorption of all compounds was found to be higher with excised rat skin ($p<0.05$, ANOVA) than with excised pig skin. Most of the applied dose of 3-8DIOL was found to evaporate from pig skin (77±8% for the lotion and 87±1% for ethanol solution), thus contributing to the relatively small percutaneous absorption values observed. Although methodological differences (such as contact time, etc.) need to be considered further, the absorption of DEET and PBO determined in the pig *in vitro* system is greater than what was determined previously in humans. This provides confidence that using the pig-derived dermal absorption value for 3-8DIOL does not underestimate systemic exposure and thus it would be appropriate for human exposure assessments.

1853 INDUCTION OF ADIPOSE DIFFERENTIATION RELATED PROTEIN AND NEUTRAL LIPID DROPLETS ACCUMULATION IN KERATINOCYTES BY SKIN IRRITANTS.

E. Corsini, O. Zancanella, L. Lucchi, F. Visioli, B. Viviani, S. Bartesaghi, M. Marinovich and C. L. Galli. *Department Pharmacological Sciences, University of Milan, Milan, Italy.*

Skin irritation is a complex phenomenon, and keratinocytes, owing of their anatomical location and production of inflammatory mediators, play an important role in it. We have recently identified by DD-PCR the upregulation by skin irritants of adipose differentiation related protein (ADRP) in reconstituted human epidermis. ADRP is a lipid storage droplet-associated protein, governing the deposition and release of lipids from droplets. The purpose of this study was to characterize in a human keratinocyte cells line (NCTC 2544) SDS-induced ADRP expression, to identify the biochemical events that lead to ADRP expression, and finally, to understand the function of ADRP in SDS cytotoxicity. SDS induced a dose and time related production of ADRP, which was associated with lipid droplets accumulation. Lipid accumulation following SDS treatment was likely to be due to intracellular redistribution rather that lipid neosynthesis, as indicated by equivalent 14C-oleate incorporation into di- and tri-acylglycerols. Other skin irritants, namely benzalkonium chloride, tributyltin, and phorbol 12-myristate 13 acetate, induce lipid droplets accumulation as well, indicating a common effect probably related to the essential role of lipid droplets in eukaryotic cells. SDS-induced ADRP expression and lipid droplets accumulation could be modulated by staurosporine, a broad spectrum protein kinases inhibitor, and by BAPTA, a calcium chelator, suggesting a role of calcium and protein phosphorylation in SDS-induced lipid accumulation. Modulation of SDS-induced ADRP expression by specific antisense oligonucleotide or by BAPTA resulted in increased cytotoxicity, indicating a protective role of ADRP and lipid accumulation in the process of cell damage induced by skin irritants.

1854 DERMAL ABSORPTION AND TOXICITY STUDY OF ACETONE-BASED SKIN COATINGS IN MINIATURE SWINE.

K. C. Norbury[1], B. Bhatt[1], M. Marshall[1], M. A. Hanes[2], M. Javors[2], G. Kennedy[1] and G. Siegel[1]. *[1]Biomedical Development Corporation, San Antonio, TX and [2]University of Texas Health Science Center, San Antonio, TX.*

Objective: This study was performed to evaluate both the systemic absorption of acetone and the potential for dermal toxicity from acute and chronic application of a skin coating material made from an acetone solution of polyvinylidene fluoride (PVDF) and acrylic polymers. Methods: Yucatan miniature pigs weighing 16-20 kg were topically administered a single dose of an acetone/PVDF/acrylic coating (3 animals per sex) or acetone alone (1 animal per sex) for acute evaluation. Acetone levels in blood were evaluated at regular intervals between 0 and 240 minutes. After a 3-4 day washout period, skin was abraded and a chronic 7-week study was completed with 2 daily applications (minimum of 6 hours between applications) of test material or acetone for 5 days per week. Trough blood acetone levels were taken before the first application of each week. Peak levels were taken after the second application on the last day of each week. Body weights and food consumption were recorded weekly. Clinical chemistry and hematologic parameters were evaluated. At necropsy, skin and major organs were removed for histopathological examination. Results: No evidence of toxicity was observed in any of the treatment groups. In the acute study, pigs either showed no perceptible elevation of acetone levels or slightly increased levels that would be considered non-toxic to humans. In addition, there was no evidence for elevated blood acetone levels after chronic treatment. There were no significant microscopic differences between any treatment or control groups. The most significant histopathological finding was minor disruption of the keratin layer, an observation that was also seen in untreated areas of skin. Conclusion: Repeated dosing of PVDF/acrylic coating formulations containing acetone are non-toxic and non-irritating.

1855 ACUTE TOXICITY ASSESSMENT OF BREAKFREE CLP®: A SMALL ARMS CLEANING COMPOUND.

D. P. Arfsten[1], E. W. Johnson[1], A. R. Thitoff[1], W. W. Brinkley[2], D. Schaeffer[3] and K. R. Still[1]. *[1]Toxicology Detachment, Naval Health Research Center, Wright-Patterson AFB, OH, [2]Operational Toxicology, Air Force Research Laboratory, Wright-Patterson AFB, OH and [3]University of Illinois, Urbana, IL.*

BreakFree CLP® ("BreakFree") is a weapons cleaning compound that is in use by the Armed Forces. BreakFree is a complex mixture made up of polyalphaolefin oil (65%), synthetic oils, esters and other synthetic proprietary ingredients (27%), isoparaffinic hydrocarbons (5%), and dibasic ester (3%). Like so many commercial mixtures, there is very little information available on the toxicity of BreakFree. Studies were conducted to characterize the dermal toxicity of BreakFree following single or repeat application. BreakFree was applied neat to the shaved backs of male and female CD-1 mice, 50 μL/application, 3 times/week for 2 weeks. Mice were then sacrificed 24 hours and 2 weeks after initiation of dermal applications. Final body, liver, and kidney weights, and blood chemistry and hematology profiles were compared with those of animals treated with deionized H_2O or acetone (negative controls) or 2.5% croton oil in acetone (positive control). Gross observations at 2 weeks included moderate dermal irritation (skin irritation) for BreakFree-treated animals and marked dermal irritation and scabbing in croton oil-treated animals. Final relative body and kidney weights were significantly lower for BreakFree-treated animals at 24 hours. There was evidence of epidermal acanthosis, and dermal inflammation in both 2 week BreakFree- and croton oil-treated animals, but differed in that serocellular crusts and multifocal ulceration was apparent for croton oil-treated skin. Blood concentrations of total protein, sodium, and alanine aminotransferase were significantly higher for BreakFree mice. Our findings indicate that repeat, unprotected handling of BreakFree could result in significant dermal irritation with possible histopatholgical damage to the epidermis and dermis. Blood chemistry profiles are suggestive of possible liver toxicity, but need to be confirmed.

1856 DERMAL PERMEATION OF THE SULFATED FATTY ACID, RICINOLEIC ACID, IS INHIBITED BY COMPLEX MIXTURE ADDITIVES.

J. E. Riviere, J. D. Brooks, B. M. Barlow and R. E. Baynes. *Center for Cutaneous Toxicology and Research Pharmacokinetics, North Carolina State University, Raleigh, NC.*

Performance of many cutting fluid formulations is dependent on its lubricant properties, which can often be improved by adding a sulfated fatty acid such as sulfated recinoleic acid (SRA). SRA like many of the other formulation ingredients are potential dermal irritants, yet little is known about its permeability in skin, and if other cutting fluid additives influence its dermal permeation. The purpose of this study was to assess H^3-SRA permeation when topically applied to inert silastic

membranes and porcine skin in *in vitro* flow-through diffusion cell system as aqueous mineral oil (MO) or aqueous polyethylene glycol (PEG) mixtures. H^3-SRA mixtures were formulated with 3 commonly used cutting fluid additives; namely, 0 or 2% triazine (TRI), 0 or 5% linear alkylbenzene sulfonate (LAS), and 0 or 5% triethanolamine (TEA). Formulation additives had little or no effect on SRA partitioning from the formulation into the stratum corneum (SC) in MO-based mixtures; However, in PEG-based mixtures the additives significantly decreased partitioning into the SC. The pH of SRA control and SRA+LAS mixture remained in physiological range (7.0 - 7.4), but all other mixtures were more basic pH (9.3 - 10.3). In silastic membranes, SRA absorption ranged from 1.22 to 12.84% dose and permeability and absorption were significantly reduced to one level by LAS and then another level by other additives or combination of additives in either MO- or PEG-based mixtures. In porcine skin, absorption ranged from 0.1 to 0.57% dose, and again formulation additives significantly decreased SRA absorption and permeability in both MO- and PEG-based mixtures. The observed decreasing trend of SRA permeation in both silastic and skin membranes is suggestive that this interaction is more physicochemical in nature than chemical-biological. The presence of other formulation additives that increased the pH of the mixture resulted in more charged SRA molecules that are not absorbed across the skin as readily. Supported by NIOSH Grant R01-OH-03669.

1857 PERCUTANEOUS ABSORPTION OF 2, 6-DI-*TERT*-BUTYL-4-NITROPHENOL (DBNP) IN ISOLATED PERFUSED PORCINE SKIN.

A. O. Inman[1], R. L. Carpenter[2], B. Briggs[2], J. D. Brooks[1] and N. A. Monteiro-Riviere[1]. *[1]Center for Cutaneous Toxicology and Research Pharmacokinetics, North Carolina State University, Raleigh, NC and [2]Naval Health Research Center Detachment, Wright Patterson Air Force Base, OH.*

DBNP (2, 6-di-*tert*-butyl-4-nitrophenol) has been reported as a potential contaminant in submarines. This yellow substance forms when lubrication oil mist containing the antioxidant additive 2, 6-di-*tert*-butylphenol passes through an electrostatic precipitator and is nitrated. Percutaneous absorption of ^{14}C-DBNP was assessed in the isolated perfused porcine skin flap (IPPSF). Four treatments were studied (n=4 flaps/treatment): 40.0mg/cm^2 in 100% ethanol; 40.0mg/cm^2 in 85% ethanol/15% water; 4.0mg/cm^2 in 100% ethanol; and 4.0mg/cm^2 in 85% ethanol/15% water. DBNP absorption was minimal across all treatment groups, with the highest absorption detected being only 1.08% applied dose in an aqueous ethanol group. The highest mass of ^{14}C-DBNP absorbed was only 0.5µg. The majority of the applied dose remained on the surface of the skin. This suggests that there is minimal dermal exposure of DBNP when exposed topically to skin. Supported by GEO-CENTERS, INC., Subcontract GC-3291-044-01-099 under SPAWAR SYSCEN NHRC Contract No. N66001-98-D-2600, D.O. 0044.

1858 ABSORPTION THROUGH PORCINE SKIN EXPOSED TO VARIOUS DOSES OF JET FUEL MARKER COMPONENTS DETERMINED WITH GC-FID USING HEAD SPACE SPME FIBER.

F. Muhammad, R. E. Baynes, N. A. Monteiro-Riviere, X. R. Xia and J. E. Riviere. *Center for Cutaneous Toxicology and Research Pharmacokinetics, North Carolina State University, Raleigh, NC.*

Jet fuels (mixture of aliphatic and aromatic hydrocarbons) have been found to be potentially toxic to skin. In the past, we have studied the percutaneous absorption and mixture effects of selected individual hydrocarbons of jet fuels. Recently, dose related IL-8 release from human epidermal keratinocytes by jet fuel aromatic hydrocarbons has been studied. The present study is an ongoing approach to simultaneously observe the dose related percutaneous absorption of a number of aliphatic and aromatic hydrocarbons. Mixtures containing undecane (4.1%), dodecane (4.7%), tridecane (4.4%), tetradecane (3%), pentadecane (1.6%), naphthalene (1.1%) and dimethyl naphthalene (1.3% of jet fuels) in hexadecane was used to dose porcine skin diffusion cells. Treatments (n=4 cells) were 1X, 2X and 5X concentrations. Perfusate samples were analyzed with GC-FID using head space solid phase micro-extraction fiber technique. We have standardized the assay to have good linear correlation for all the tested components in media standards. Dosed components from perfusate were detected even with the lowest dose except for tetradecane which was detected with the highest dose only. Data indicates a dose dependent increase in absorption for naphthalene, dimethyl naphthalene and lower molecular weight aliphatic hydrocarbons. Absorption parameters including diffusivity, permeability and steady state flux were determined. This approach provides a baseline to access component interactions among themselves and with the diluent (solvents). Supported by USAFOSR F49620-01-1-0080.

1859 THE CYTOTOXICITY OF JET FUEL AROMATIC HYDROCARBONS AND DOSE-RELATED INTERLEUKIN-8 RELEASE FROM HUMAN EPIDERMAL KERATINOCYTES.

N. A. Monteiro-Riviere, C. Chou and J. E. Riviere. *Center for Cutaneous Toxicology and Research Pharmacokinetics, North Carolina State University, Raleigh, NC.*

Many aromatic hydrocarbons are known carcinogens with the ability to readily penetrate the skin with high absorption flux and cause skin irritation. In order to evaluate the *in vitro* cutaneous toxicity of individual aromatic hydrocarbons and their potential in inducing skin inflammation, we evaluated the LD_{50}, highest non-cytotoxic (5% mortality) dose (HNTD) and IL-8 release of 9 aromatic hydrocarbons in human epidermal keratinocytes (HEK). LD_{50} ranged from 1.8 mM (0.03%) for cyclohexylbenzene to 82.9 mM (0.74%) for benzene with a rank order potency of cyclohexylbenzene> trimethylbenzene≥xylene>dimethylnaphthalene>ethylbenzene>toluene>benzene. The HNTD value ranged from 0.1 mM (0.001%) for cyclohexylbenzene to 48.2 mM (0.43%) for benzene. There was a dose-related differential response in IL-8 release at 24 hr. Toluene, xylene, trimethylbenzene, cyclohexylbenzene and dimethylnaphthalene significantly decreased IL-8 release at the HNTD, while IL-8 release did not continue to decrease or significantly increase (cyclohexylbenzene and dimethylnaphthalene) at LD_{50}. IL-8 significantly increased with both doses of methylnaphthalene and naphthalene. The presence of hexadecane and mineral oil greatly attenuated the cytotoxicity to HEK cells elicited by individual aromatic hydrocarbons. This work was supported by the US Air Force Office of Scientific Research F49620-01-1-0080.

1860 CYTOTOXICITY OF THE JP-8 JET FUEL COMPONENTS m-XYLENE, 1-METHYLNAPHTHALENE, AND n-NONANE IN KERATINOCYTES.

J. Rogers[1,4], G. Siegel[2], D. Pollard[3] and J. McDougal[4]. *[1]GEO-CENTERS, Inc., Wright-Patterson AFB, OH, [2]Operational Toxicology Branch, Wright-Patterson AFB, OH, [3]ManTech, Wright-Patterson AFB, OH and [4]Wright State University, Dayton, OH.*

Cell culture methods are being developed to assess the dermal toxicity of volatile chemicals. Such tests are useful in the ranking of chemicals for irritancy, but they are not useful for quantitative risk assessment for two reasons. First, the amount of volatile chemical in the exposure media may decrease with time. Second, EC50 are reported as the concentrations in the media and not the cells. We have recently developed an *in vitro* approach for toxicity testing of volatile chemicals that avoids these problems. This system was used to expose keratinocytes grown on a collagen matrix to culture medium containing m-xylene, 1-methylnaphthalene (1-MN), or n-nonane. Partition coefficients were measured and used to estimate the chemical concentration in the keratinocytes. The EC50 for m-xylene at 1, 2, and 4 hours were 1248.46 ± 78.01, 1028.88 ± 11.12, and 860.8 ± 84.6 µg m-xylene per gram of keratinocytes, respectively. The EC50 for 1-MN in the keratinocytes at 1, 2, and 4 hours were 6494.3 ± 460.1, 4319.82 ± 372.61, 2201.06 ± 196.27 µg 1-MN per gram keratinocytes, respectively. Although marginal cytotoxicity was observed at 1 hr, the EC50 for n-nonane at 2 and 4 hours were 915.6 ± 155.5 and 980.7 ± 139.5 µg n-nonane per gram cells, respectively. These results suggest a time- and dose-dependent effect of m-xylene and 1-MN of keratinocyte viability, with little cytotoxic effect by n-nonane. This study supports the potential use of our exposure system for determining equivalent external doses for toxic endpoints.

1861 SIX MONTH SAFETY AND IMMUNOLOGY STUDY IN BABOONS OF ALLOGENEIC BABOON MESENCHYMAL STEM CELLS LABELED WITH FLUORESCENT DYE.

A. V. Lyubimov[1], A. M. Bartholomew[2], K. R. McIntosh[3] and B. S. Levine[1]. *[1]Toxicology Research Laboratory, University of Illinois at Chicago, Chicago, IL, [2]Surgery, University of Illinois at Chicago, Chicago, IL and [3]Osiris Therapeutics, Inc., Baltimore, MD.*

The purpose of this study was to determine the safety and immunologic consequences of administering allogeneic baboon mesenchymal cells (MSCs) by routes of clinical significance. MSCs are rare cells found in bone marrow and other tissues that have the capacity to be expanded to large numbers for tissue repair. MSCs from male donors were labeled with fluorescent dye for tracking purposes and injected into female baboons as follows: group 1 control animals (n=3) received vehicle (95% plasmalyte:5% recipient plasma); group 2 (n=3) received DiI-labeled

MSCs (5 million MSCs/kg) intravenously followed by DiO-labeled MSCs (5 million MSCs/kg) by intramuscular (IM) injection from the same donor on day 42 (6 weeks later); group 3 (n=3) was treated similarly to group 2 except that the second IM injection of MSCs was from a 3rd party donor. No signs of toxicity were seen throughout the study as evaluated by body weights, food consumption, clinical pathology, organ weights, and histopathology data. Antinuclear antibodies, sedimentation rate, Ig panel (IgG and IgM), and most peripheral blood cell subsets (CD14+ monocytes, CD56+ NK cells, CD19+ B cells) were comparable between the treatment groups. The modest decrease in the percentage of CD3+CD8+ cells in group 2 and 3 animals was offset by a modest increase in the percentage of CD3+ CD4+ cells in weeks 5, 11 and 27 in these groups, thereby maintaining an unchanged total number of lymphocytes. Under conditions of this study, allogeneic MSCs administered either intravenously or intramuscularly to immunocompetent recipients did not induce toxicity in baboons.

1862 PAROTID GLAND BASOPHILIC FOCI IN MICE ADMINISTERED THE PEPTIDE AC2993 (SYNTHETIC EXENDIN-4) BY SUBCUTANEOUS INJECTION FOR PERIODS OF 13 TO 26 WEEKS.

R. Hiles[1], T. Slone[2] and D. Serota[2]. *[1]Amylin Pharmaceuticals, Inc., San Diego, CA and [2]MPI Research, Inc., Mattawan, MI.*

AC2993 (synthetic exendin-4; a 39-amino acid peptide) is under development for glucose control in patients with type 2 diabetes mellitus. As part of the development program, the peptide was evaluated in toxicity studies in mice with twice daily administration and exposure durations of 13 and 26 weeks. A histopatholgical alteration in the parotid gland described as basophilic foci was noted. The alteration was characterized as enlarged cells with increased cytoplasmic volume and finely vesicular basophilic contents. In the 13-week study, one control mouse exhibited a trace incidence. In this study the incidences in the combined sexes at a severity of trace to mild at 3, 34 and 380 mcg/kg/dose were 22 of 42, 39 of 42 and 35 of 42, respectively. In the 26-week study, no basophilic foci were observed in the control animals. The incidences in the combined sexes at a severity of trace to moderate at 9, 58 and 380 mcg/kg/dose were 43 of 47, 35 of 39 and 43 of 49, respectively. The severity appeared related to duration of exposure, but not to the dose level of AC2993 administered. No toxicities could be associated with this microscopic alteration in the salivary gland. Jackson and Blackwell reported parotid basophilic foci in rats exposed to doxylamine for 90 days (1) but not in mice (2). They also did not define any associated toxicities. Chiu and Chen reported on the spontaneous occurrence of this tissue alteration in rats and mice (3). 1. Jackson, C.D. & Blackwell, B-N (1988). Subchronic studies of doxylamine in Fischer 344 rats. Fund. Appl. Toxicology. 10, 243-253. 2. Jackson, C.D. & Blackwell, B-N (1988). Subchronic studies of doxylamine in B6C3F1 mice. Fund. Appl. Toxicology. 10, 254-261. 3. Chiu, T, & Chen H.C. (1986). Spontaneous basophilic hypertrophic foci of the parotid glands in rats and mice. Vet. Pathol. 23, 606-609.

1863 A REVIEW OF MORTALITY PATTERNS IN CD-1 MOUSE TUMORIGENICITY STUDIES CONDUCTED OVER THE PERIOD OF 1985 TO 2001.

W. N. Hooks. *Huntingdon Life Sciences, Huntingdon, Cambridgeshire, United Kingdom.* Sponsor: E. Blanchard.

The interest and available information on the mouse as a model for tumorigenicity assessment have tended to be marginalised due to the possibility that the assessment would be confined to the rat model only. Currently the consensus is that both species should be used until international agreement has been reached. However, interest in the mortality patterns of mice has been renewed because of the increasing trend towards conducting mouse tumorigenicity studies over 2 years, rather than over 18 months or to a percentage survival point. In this review, the mortality data have been analysed from the control groups of up to 120 tumorigenicity studies (dietary and oral gavage) using the Charles River Crl:CD-1 ® (ICR) BR mouse. These studies used low protein maintenance diet (Special Diets Services) and were conducted over the period of 1985 to 2001. The analyses did not reveal any major differences for the terminal mortality (at Weeks 80 or 104) for the routes of administration (values given below) or housing conditions, or in the patterns over 2 years. Also, the analyses did not indicate that single housing increased the terminal mortality values. Review of the terminal mortality against time indicated a slight but increasing trend towards higher values in the females. In conclusion, there were no major differences between the terminal mortality or mortality patterns over 2 years for the routes of administration or housing conditions, but the analyses of terminal mortality against time indicated a slight but positive trend towards higher values for the females.

Terminal mortality (%)

Week	Sex	Dietary			Oral gavage		
		Mean	SD	n	Mean	SD	n
80	Males	28	7.7	80	25	9.0	40
	Females	22	7.0	78	21	7.2	41

1864 EVALUATING HEALTH IMPLICATIONS OF LUBRICATING OIL ON ORTHOPEDIC MEDICAL IMPLANT DEVICES.

M. Seeley[1], T. A. Lewandowski[2] and B. D. Beck[1]. *[1]Gradient Corporation, Cambridge, MA and [2]Gradient Corporation, Seattle, WA.*

Certain orthopedic medical devices may contain small amounts of machine lubricating oil (up to 50 to 100 mg/per device) due to the manufacturing process. Machine lubricating oils consist primarily of a base oil, similar to mineral oil, and small amounts (< 1%) of various additives that enhance performance of the oil. We evaluated the potential for adverse health effects due to exposure to machine lubricating oil on orthopedic medical implant devices using a hierarchical approach, based on availability of data. Studies suitable for identifying effect levels for relevant health endpoints were only available for the base oil and two of the additives (butylated hydroxytoluene and Bimox M). For another additive, dioctylamine, we identified a health effect level for a surrogate compound, cyclohexylamine. For the remaining additives we did not locate any suitable toxicology studies either for the additive itself or an appropriate surrogate. For these additives we derived a health protective screening level based on FDA's threshold of regulation for substances used in food contact articles, which, in the absence of other toxicity information, makes the conservative assumption that the substances are carcinogens. Because exposure to machine lubricating oil on orthopedic medical implant devices is likely to be most similar to i.p. exposures, we extrapolated effect levels derived from oral exposures to i.p. effect levels, based on a comparison of oral vs. i.p. LD50s in mice. We found that potential exposure levels ranged from approximately 1.5-fold below the estimated health effect level, for an additive of unknown identity (based on FDA's threshold of regulation), to approximately 200 million-fold below the health effect level identified for Bimox M. Thus, based on this analysis, exposure to machine lubricating oil on orthopedic medical implant devices is not likely to be associated with adverse health effects.

1865 BLOOD CONCENTRATION AND TISSUE DISTRIBUTION OF 14C-DI(2-ETHYLHEXYL) PHTHALATE (DEHP) IN JUVENILE AND ADULT COMMON MARMOSET.

Y. Kurata[1], F. Makinodan[1], M. Okada[1], T. Kawasuso[1], R. M. David[2], G. Gans[3], J. F. Regnier[4] and M. Katoh[1]. *[1]Kashima Laboratory, Mitsubishi Chemical Safety Institute Ltd.,, Kashima, Ibaraki, Japan, [2]Consultant to Eastman Chemical Company, Rochester, NY, [3]BASF AG, Ludwigshafen, Germany and [4]Atofina SA, Paris, France.* Sponsor: M. Tsuchitani.

This study was conducted to characterize the blood concentration, tissue distribution and excretion of DEHP in juvenile and adult primates and to assess the effect of repeated DEHP-treatment on those parameters. Male and female (3 animals/sex/group) common marmosets aged 3 or 18 months (nive and pretreated repeatedly with 100 or 2500 mg/kg DEHP for 15 months) received a sigle dose of 100 or 2500 mg/kg DEHP by gavage which contained 14C-DEHP labeled in the phenyl moiety. The Cmax was achieved 1 to 4 hours after administration. Sex-related differences in Cmax and AUC were observed, and age dependent differences were seen in males and females. No significant age-related differences in Cmax were seen in males and females, but the AUC was higher in older females compared with

younger females. Repeated exposure resulted in lower pharmacokinetic parameters suggesting induction of enzymatic metabolism and/or excretion of DEHP. The difference was more evident in females than in males and at 2500 mg/kg than 100 mg/kg. In all experimental conditions, two hours after a single administration of 14C-DEHP, the tissue-to-plasma ratios for bile were 14.0 to 42.6 and for the kidneys were 1.7 to 3.0, probably associated with excretion. There were no apparent dose-dependent differences. Tissue-to-plasma ratio were 0.09 to 0.23 for testes and were <1.00 for all other organs except for 1.8 for seminal vesicle from older nive males treated with 100 mg/kg 14C-DEHP. The major excretion route was in feces (36-65% of the dose); however, substantial urinary excretion (10-22% of the dose) was noted. These data may serve to improve the pharmacokinetic models for humans predicting potential reproductive effects.

1866 TESTICULAR TOXICITY STUDY OF DI(2-ETHYLHEXYL)PHTHALATE (DEHP) IN JUVENILE COMMON MARMOSET.

Y. Tomonari[1], Y. Kurata[1], T. Kawasuso[1], R. M. David[2], G. Gans[3], M. Tsuchitani[1] and M. Katoh[1]. *[1]Kashima Laboratory, Mitsubishi Chemical Safety Institute Ltd.,, Kashima, Ibaraki, Japan, [2]Consultant to Eastman Chemical Company, Rochester, NY and [3]BASF AG, Ludwingshafen, Germany.*

Rats exposed to DEHP during the pre- and peri-adolescent period have been shown to be sensitive to testicular effects, hence this study was conducted to characterize the potential effects of DEHP on the reproductive organs in the juvenile primate. Male marmosets aged 3 months (5-6/group) were treated orally with 0 (corn oil), 100, 500, and 2500 mg/kg DEHP once per day for 15 months until sexual maturity. The reproductive organs (testis, epididymis, prostate, seminal vesicle), pituitary, thyroid, pancreas, liver, adrenal, kidney, and spleen were weighed and were examined microscopically. Testicular 3-beta hydroxysteroid dehydrogenase(3-beta HD) activity was determined histochemically. The testis was also subjected to electronmicroscopic examination and to a determination of mRNA expression of PPAR-alpha (peroxisome proliferator-activated receptor). Mean body weights of each DEHP-treated group were comparable to that of the control group. There were no differences in the mean organ weights in each DEHP-treated group. One male in each DEHP-treated group showed low values in testis, epididymis, prostate, and seminal vesicle weights corresponding to the low body weights. The animals exhibiting low testis, epididymis, prostate, and siminal vesicle weights had reterded growth in general. No treatment-related findings were observed microscopically in any organs except for above changes. No remarkable changes were observed electronmicroscopically in the testis. There were no differences in a 3-beta HD activity or mRNA expression of PPAR-alpha between animals in the control group and those in the each DEHP-treated group. In conclusion, exposure of juvenile marmosets (primates) to high dose levels of DEHP prior to and during adolescence (a sensitive period for testicular toxicity in rats) showed no evidence of testicular effects.

1867 COMPARATIVE TOXICITY STUDY OF 3-AMINOPHENOL IN NEWBORN AND YOUNG RATS.

M. Koizumi[1], N. Nishimura[2], T. Enami[2], M. Sunaga[3], H. Horikawa[3], E. Kamata[1], M. Ema[1] and R. Hasegawa[1]. *[1]National Institute of Health Sciences, Tokyo, Japan, [2]Bozo Research Center Inc., Gotemba Laboratory, Shizuoka, Japan and [3]Safety Research Institute for Chemical Compounds Co., Ltd.,, Sapporo, Japan.*

Comparison of the toxicological profiles and toxicity levels of chemicals in newborn animals with the routine test results using young animals will provide valuable information for risk assessment of chemicals in infants. Repeated dose toxicity of 3-aminophenol was examined on oral administration to newborn and young rats and susceptibility was analyzed in terms of the no observed adverse effect level (NOAEL) and the unequivocally toxic level. In the 18-day newborn rat study starting at postnatal day 4, tremors and depression of body weight gain were observed, as well as hypertrophy of thyroid follicular epithelial cells and increases of relative liver and kidney weights at 240 mg/kg. Increase of relative liver weights in males and decrease of blood sugar in females without any histopathological changes at 80 mg/kg were not considered to be adverse effects. No chemical-related changes were observed at 24 mg/kg. Abnormalities of physical development and reflex ontogeny in the newborn were not observed. In the 28-day study starting at 5 weeks of age, depression of body weight gain, tremors, anemia, and liver, kidney and thyroid toxicity were observed at 720 mg/kg. Although slight pigmentation in renal proximal tubular epithelium was observed in females at 240 mg/kg, this was not considered to be an adverse effect because of the lack of changes in related toxicological parameters. It was concluded that the NOAEL is 80 mg/kg/day in newborn rats and 240 mg/kg/day in young rats, with unequivocally toxic levels of 240 mg/kg/day and 720 mg/kg/day, respectively. Based on these two endpoints, the susceptibility of newborn rats to the chemical was approx. 3 times higher than that of young rats, consistent with our previous results for 4-nitrophenol and 2, 4-dinitrophenol.

1868 EVALUATION OF CO2/O2 ANESTHESIA DURING THE JUGULAR BLEEDING PROCEDURE IN RATS.

N. A. Sharpe[1], N. Collins[2], L. DeGroat[1], D. Sauer[1], E. Evans[2] and R. E. Morrissey[1]. *[1]Toxicology, Schering-Plough Research Insitute, Lafayette, NJ and [2]Clinical Pathology, Schering-Plough Research Insitute, Lafayette, NJ.*

The jugular bleeding procedure has been utilized at Schering-Plough for the collection of blood samples from rats, required during the conduct of toxicology studies for both clinical pathology and toxicokinetic evaluations. To refine the procedure, the feasibility of CO2/O2 anesthesia during jugular bleeding was assessed. Twenty rats (10 males and 10 females) were bled for hematology and serum chemistry, respectively, under CO2/O2 anesthesia (60:40 ratio) on Day 0 and unanesthetized on Day 4. Twenty additional rats (10 males and 10 females)were bled for hematology and serum chemistry, respectively, unanesthetized on Day 0 and under CO2/O2 anesthesia on Day 4. The predominant clinicopathologic changes associated with CO2/O2 anesthesia were consistent with hemodilution and/or intravascular volume expansion and included minimal decreases in red blood cell mass (erythrocyte count, hemoglobin concentration and hematocrit), platelet numbers and serum total protein (albumin and globulin) concentration in anesthetized animals on Day 4 compared to controls on Day 0. Additional findings in anesthetized rats, compared to unanesthetized rats included minimal leukocytosis, characterized by proportional increases in lymphocyte, neutrophil and monocyte counts, and minimally lower serum aspartate aminotransferase activity. Equivocal were several changes including higher mean corpuscular volume and lower mean corpuscular hemoglobin concentration and higher serum electrolyte (phosphorus, sodium, potassium and chloride) concentrations in CO2/O2-anesthetized rats. All effects on clinical pathology parameters attributed to the anesthesia procedure were minor and at no time resulted in values that were considered to be out of the range of physiologic variation. It can be concluded that CO2/O2 anesthesia is a suitable means of restraint for rats in toxicology settings and should have no meaningful impact on interpretation of clinical pathology parameters.

1869 CANINE PURKINJE FIBER ACTION POTENTIAL DURATION: INFLUENCE OF STIMULATION FREQUENCIES AND EFFECTS OF DMSO CONCENTRATIONS.

G. P. Thomas, B. P. Klatt and C. B. Spainhour. *Calvert Preclinical, Olyphant, PA.*

Purkinje fibers are highly sensitive to the influence of action potential duration (APD)-prolonging agents and are believed to be the source of early after depolarization, the stimulus that commonly triggers Torsade de Pointes (TdP) arrhythmias. Canine Purkinje fibers are routinely used as a screening model to detect the ability of agents to prolong the QT interval and cause TdP. However, the ideal stimulation frequency and solvent concentration to be used in these types of experiments are controversial. We examined the effects of dl-sotalol, a positive standard, on canine Purkinje fiber APD under different stimulation frequencies to identify the ideal stimulation frequency for these type of experiments. We have also studied the effects of different concentrations of DMSO, a commonly used solvent for these types of studies, on APD in these same tissues. Standard microelectrode techniques were utilized to record transmembrane action potentials from canine Purkinje fibers at 0.5, 1 and 3 Hz stimulation frequencies. Action potential durations were measured at 30, 50 and 90% repolarization (APD_{30}, APD_{50} and APD_{90}). Dl-sotalol (50μM), prolonged APD_{50} and APD_{90} without any significant effects on APD_{30}. While dl-sotalol-induced prolongation of APD_{50} and APD_{90} was observed at all the three stimulation frequencies, the effect was minimal at 3 Hz and maximal at 0.5 Hz. At concentrations of 0.01, 0.05, 0.1, 0.5 and 1%, DMSO was found to not produce any significant effects on APD_{30}, APD_{50} or APD_{90}. However, 5% DMSO caused significant abbreviation of APD_{50} and APD_{90}. In conclusion, a significant prolongation of APD_{50} and APD_{90} by dl-sotalol at 1 and 0.5 Hz stimulation frequencies indicate the suitability of these frequencies for APD prolongation studies. Furthermore, DMSO, up to a concentration of 1%, can safely be used as a solvent in this type of studies.

1870 COMPARISON OF LASER MICRODISSECTION TECHNIQUES FOR CELL COLLECTION AND MOLECULAR ANALYSIS.

M. Taurino, M. Wojke, X. Ying, Z. Jayyosi, P. Rao and T. Monticello. *Drug Safety Evaluation, Aventis Pharmaceuticals, Bridgewater, NJ.*

Laser microdissection allows for fine-dissection, at the light microscopic level, of specific cell populations of interest which can then be processed and analyzed by various molecular techniques. Currently, two major types of laser dissection techniques are available: near-infrared laser capture microdissection (e.g. LCM, Arturus Pixcell II), and ultraviolet laser light beam cutting (e.g. LMD, Leica AS). In this study we evaluated both laser techniques in order to determine which process was

more time-efficient in collection of cells and to determine which process obtained better quality RNA. Samples of male rat kidney and liver were collected under RNAase-free conditions and frozen in OCT blocks. Sections (8um thick) of liver and kidney were cryosectioned and stained with hematoxylin in an RNAase free environment, to aid in the identification of hepatocytes in the liver and tubular epithelial cells in the kidney. Approximately 10, 000 cell profiles were obtained each from the liver and kidney. Cells were processed by standard methods and total RNA isolated using commercially available kits. Quantity and integrity of RNA were determined using the Agilent 2100 Bioanalyzer (RNA 6000 Nano LabChip). RNA obtained by both techniques was assessed for quaility by measuring mRNA expression of selected genes with Q-RT-PCR (Taqman). The laser dissection process took approximately 60 min/organ with the Arcturus Pixcell II and 3 min/organ with the Leica AS system to collect the defined sample size. The quantity and integrity of RNA obtained from the two laser systems were similar in nature and of high quality. Results of this study indicate that the Leica laser light beam cutting technique provides a more time-efficient method for the collection of large numbers of cells as compared to the Pixcell II (20-fold reduction in time), and that the RNA obtained by this method is amenable for subsequent molecular analysis.

1871 INDUCTION AND CHARACTERIZATION OF GRANULOMAS INDUCED BY INTRATHECAL OPIATES IN DOGS.

J. W. Allen, D. Cizkova and T. L. Yaksh. *Anesthesiology, University CA-San Diego, La Jolla, CA.*

Chronic intrathecal (IT) infusions of morphine sulfate have been shown to produce aseptic inflammatory masses (granulomas) in both humans and laboratory animals. We examined the role of opiate receptors in granuloma formation by infusing other opiates delivered at the maximum tolerable dose (MTD). Purpose-bred beagle dogs were implanted with chronic IT catheters terminating at the L1-L2 region. Solutions were delivered *via* vest-mounted infusion pumps with an infusion rate of 40 ul/hour for 28 days. One group of dogs was infused with saline or high concentration (HC) morphine sulfate (12.5 mg/ml;12 mg/day). Additional dogs were infused with methadone HCl, hydromorphine HCl, or the mu antagonist naloxone HCl with dose escalation every 24 hours to determine the acute MTD. To examine the role of dose versus concentration, low concentration (LC) 1.5 mg/ml morphine was infused at 334 ul/hr (12 mg/day). The MTD for methadone and hydromorphone was 3 mg/day. No effects were seen for naloxone up to 10 mg/ml. Arousal, muscle tone and motor coordination were assessed daily. Dogs receiving the MTD of HC morphine, methadone or hydromorphone developed hind limb muscle stiffness and motor dysfunction, tactile hypersensitivity, allodynia, and in some cases paralysis. Histopathology revealed aseptic granulomatous masses localized at the catheter tip of dogs receiving HC morphine, methadone and hydromorphone producing significant spinal cord compression. These masses, evolving from the dura-arachnoid, contained extensive accumulation of macrophages (CD68, iNOS positive cells), lymphocytes (CD3) and neutrophils. Inflammatory cells expressing TNF-alpha were limited to granulomas and did not impinge upon spinal cord tissue. Infusions of LC morphine, naloxone or saline displayed no significant adverse events or pathology. These data suggest IT opiate induced granuloma formation is dependent upon opioid receptor activation and that formation is a factor of infusate concentration rather that total dose infused. (Supported by DA02110 (TLY), UCSD Cancer Center Lopicolla Foundation (JWA))

1872 TOXICITY OF THE FIBROBLAST GROWTH FACTOR RECEPTOR TYROSINE KINASE INHIBITOR, PD176067, IN 11-MONTH OLD FEMALE RATS.

A. P. Brown[1], C. L. Courtney[1], L. M. King[2], S. Groom[2] and M. J. Graziano[1]. *[1]Drug Safety Evaluation, Pfizer Global Research and Development, Ann Arbor, MI and [2]Drug Safety Evaluation, Pfizer Global Research and Development, Groton, CT.*

PD176067 is a reversible and selective inhibitor of the basic fibroblast growth factor receptor tyrosine kinase, and was in development as an anti-cancer agent. In a previous study, bidaily oral administration to 7-week old rats resulted in vascular mineralization and physeal changes. To determine if these changes are specific to young, rapidly growing animals, PD176067 was administered to approximately 11-month old rats. Female Wistar rats (5/group), received PD176067 by gavage (BID) for 14 days at total daily doses of 2.5, 5, and 10 mg/kg (15, 30, and 60 mg/m^2, respectively), and were necropsied on Day 15. Clinical signs of toxicity were seen at ∝5 mg/kg and one death occurred at 10 mg/kg. Physeal dysplasia occurred in all drug-treated animals and was characterized by dose-related increased thickness of the zones of chondrocyte proliferation and hypertrophy, and marked thickening of the zone of ossification. Cartilage hyperplasia was characterized by proliferation of chondrocytes along margins of the physis and body of the sternebra. Bone marrow hypocellularity occurred at ∝5 mg/kg. Serum phosphorus levels increased 47% and 166% at 5 and 10 mg/kg, respectively. Mineralization of cardiac myocytes, aorta, various arteries, renal tubules, and gastric mucosa and muscularis was seen at 10 mg/kg. PD176067 produced morphologically similar lesions in young and adult rats. Systemic mineralization was the most toxicologically significant change, and is consistent with hyperphosphatemia and calcium-phosphorus deposits.

1873 LIPOSOME BASED FORMULATION OF SN-38 (LE-SN38): A FOUR-CYCLE TOXICITY EVALUATION IN BEAGLE DOGS.

S. Khan, S. Ali, D. Carbonaro, A. Ahmad, A. Zhang and I. Ahmad. *R&D, NeoPharm, Inc., Waukegan, IL.*

SN-38 (7-ethyl-10-hydroxy camptothecin) is the active metabolite of CPT-11 (Irinotecan), a semi-synthetic antitumor derivative of camptothecin. Although SN-38 is 100-1000 times more cytotoxic than CPT-11, it has not been developed as anticancer drug due to its poor solubility in pharmaceutically acceptable solvents. We have developed a liposome based formulation of SN-38 (LE-SN38) with enhanced therapeutic efficacy in animal tumor models. In the present study, we have evaluated the toxicity of LE-SN38 in beagle dogs after intravenous (iv) bolus administration once every three weeks for four complete cycles (q3 weeks x 4). Eight groups (3 dogs /group) of male and female dogs received a single 0, 0.4, 0.8, or 1.2 mg/kg SN-38 (as LE-SN38) iv bolus dose on days 1, 22, 43, and 64. All of the animals survived to scheduled necropsy (days 84-85). No drug related effect on body weights was observed during the study with the exception of one male dog at 1.2 mg/kg dose group, which lost 17.4% of its initial body weight between week 1 and 2. Changes in group mean hematology parameters such as decrease in reticulocyte, lymphocyte, monocyte and eosinophil counts were noticed at approximately 72 hours after drug administration. Also, decreases in platelet, neutrophil, and WBC values were observed in LE-SN38 treated groups after the third or fourth dose cycle. However, these changes were reversible and reached within normal range after 20 days of drug administration. Clinical chemistry parameters were unchanged after LE-SN38 administration at all dose levels. There was no drug related changes in adrenals, brain, heart, kidneys, liver, lung, ovaries, pituitary, prostate, spleen, testes, thymus, thyroid: parathyroid and uterus weights of males or females. Also, no direct, drug related microscopic changes were noticed in all 50 organs collected after LE-SN38 administration. The results obtained after the initial dose of LE-SN38 at 1.2 mg/kg/dose indicated that this dose level might have been close to a maximum tolerated dose. This study was performed at Southern Research Institute, Birmingham, Alabama.

1874 TOXICITY OF THE FIBROBLAST GROWTH FACTOR INHIBITOR, PD 176067, IN JUVENILE AND ADULT DOGS.

K. Datta[1], M. J. Graziano[1] and C. L. Courtney[1]. *[1]Drug Safety Evaluation, Pfizer Global R&D, Ann Arbor, MI and [2]Drug Safety Evaluation, Pfizer Global R&D, Ann Arbor, MI.*

PD 176067 is a reversible inhibitor of basic fibroblast growth factor receptor (FGFR) tyrosine kinase that was in development for the treatment of cancer. To assess its toxicity, PD 176067 was administered by oral gavage to young adult (∽ 14 months) and juvenile (∽ 4 months) beagle dogs (1 dog/sex/dose) twice daily up to 2 weeks at 10, 40 and 100 mg/kg/day. Clinical signs and mortality occurred in both age groups at ≥40 mg/kg. Clinical signs included ataxia, hypoactivity, generalized tremor, abnormal gait, diarrhea, dehydration, salivation, fecal changes and reduced food consumption. Carpal swelling in the juvenile male at 40 mg/kg correlated with increased metaphyseal radiodensity and thickened growth plate. At 10 mg/kg, there were minimal clinical signs (fecal changes, reduced food consumption) and no significant findings in serum biochemistry or histology. At ≥40 mg/kg, serum osteocalcin, bone formation marker, decreased by >50% and serum phosphorus increased by >50% in both age groups. Urinary markers of bone resorption were elevated by ≥50% in juveniles at ≥40 mg/kg. Vascular and/or parenchymal mineralization occurred in heart, coronary artery, lung, kidney, parietal pleura and pancreas at ≥40 mg/kg in both age groups. Additionally, sporadic gastrointestinal mucosal ulceration and hyperplasia, hemorrhage and necrosis were observed at ≥40 mg/kg in both age groups. Physeal dysplasia characterized by chondrocyte proliferation and hypertrophy was more prominent in juvenile animals than adult. These findings show that PD 176067 causes widespread systemic mineralization of soft tissues in dogs independent of age and does not appear to be secondary to alterations in bone physiology.

1875 EXPERIENCES WITH VAGINAL OR PENILE ADMINISTRATION IN TOXICITY STUDIES.

E. M. Donald[1], A. Danks[1] and R. J. Greenough[1]. *[1]Inveresk Research Ltd, Tranent, East Lothian, United Kingdom, [2]Inveresk Research Ltd, Tranent, East Lothian, United Kingdom and [3]Inveresk Research Ltd, Tranent, East Lothian, United Kingdom.*

There are several instances where pharmaceuticals are administered by the vaginal route. These include spermicidal agents and anti-infective agents. There are also cases where pharmaceuticals come in contact with penile tissue. This may be by accidental exposure or by intention, for example materials for erectile dysfunction. It is, therefore, important that these are subjected to appropriate safety tests. There are a number of factors to consider when designing suitable studies. These include species, duration and the volume to be administered. Experiences at this laboratory are discussed.

1876 RARE GASTRIC MUCOSAL DAMAGE FOLLOWING ACUTE ADMINISTRATION OF MELANOCORTIN RECEPTOR LIGANDS IN FISHER 344 RATS.

T. M. Williams and K. B. Donnelly. *Lilly Research Laboratories, Eli Lilly and Company, Greenfield, IN.*

Since the melanocortin system is believed to play a role in the central control of feeding, it is possible that melanocortin receptor ligands could be used to treat human obesity. Eleven structurally similar ligands were evaluated in female F344 rats to determine the safety of this class of compounds. Rats were gavaged daily with 100, 250, or 500 mg/kg of compound in 10% Acacia/0.05% Antifoam in purified water (pH > 2) for 4 days (n = 3/dose group). In treated rats, notable clinical observations included a dose-dependent decrease in mean body weight and food consumption. Analysis of terminal blood demonstrated a dose-responsive inflammatory leukocytosis with superimposed stress leukogram as well as increased serum alanine and aspartate aminotransferase activity in all treatment groups. Important compound-related gross and histologic observations occurred in the gastric mucosa. With 6 compounds, fluid-filled stomachs with multiple, focal, small (1-2 mm), raised, sometimes ulcerated, white foci in the nonglandular portion of the gastric mucosa were observed. Histopathological evaluation of the mucosa revealed discrete, raised, intraepithelial vesicles with dense accumulations of neutrophils at the core. Advanced lesions penetrated the stratum basale and were associated with edema, lymphohistiocytic inflammation, and neovascularization of the immediate submucosa. Ruptured vesicles resulted in ulcers and occasionally gastric perforation. No other mucosal surfaces of the gastrointestinal tract were affected, including the glandular mucosa of the stomach. Although the pathogenesis of this rare lesion is unknown, it was not likely pharmacologically-mediated due to the gastroprotective effect of melanocortin-related systems. The risk associated with formation of this lesion in species without a nonglandular portion of the stomach mucosa, such as humans, is likely minimal.

1877 A COMPARATIVE TOXICITY EVALUATION OF MITOXANTRONE AND ITS LIPOSOME BASED FORMULATION IN BEAGLE DOGS.

S. Ali, S. Khan, A. K. Sarkar, S. Sheikh and I. Ahmad. *NeoPharm Inc., Waukegan, IL.*

Mitoxantrone (MTO), an anthraquinone is an anti-neoplastic agent and is used for the treatment of leukemia, lymphoma, breast and prostrate cancer. In clinical trials, mitoxantrone has shown to cause moderate gastrointestinal toxicity, alopecia and a dose limiting cardiotoxicity. To overcome these side effects we have developed a novel liposome based Mitoxantrone (LEM) that has shown significantly improved safety profile, pharmacokinetics and efficacy profile compare to free MTO in mice (Gokhale, et al. Anticancer Research 21:3313-3322, 2001). The improved safety profile in mice prompted us to evaluate the toxicity of LEM in a more relevant large animal model. The current study demonstrates a comparative toxicity of free MTO and LEM in male and female dogs. MTO (0.129 and 0.258 mg/kg/dose) or LEM (0.258, 0.580, and 0.869 mg/kg/dose) was administered intravenously to beagle dogs on Days 1, 23, 43, and 65. Animals that received MTO at 0.258 mg/kg/dose had gastrointestinal toxicity, cutaneous sores and swelling of limbs whereas only at highest 0.868 mg/kg/dose of LEM showed the similar level of toxicity in dogs. The dogs receiving the LEM at 0.258 and 0.580 mg/kg/dose, had no gastrointestinal toxicity. The animals receiving LEM at 0.258 mg/kg/dose level, had reduced toxicity associated with testicular degeneration, bone marrow hypocellularity and lymphoid depletion compared to dogs that received the same dose of MTO. The toxicokinteic data showed that plasma concentration of mitoxantrone in dogs was about 6 fold higher in LEM group compared to MTO. The results of the present study, demonstrates that LEM is more than two fold less toxic and has longer half life (t1/2) compared to MTO. Thus, liposome based formulation of mitoxantrone may be safe and have better therapeutic index as compare to MTO. Currently, phase I clinical trials are in progress. The study was performed at Southern Research Institute, Birmingham, Alabama. *Authors equally contributed.

1878 EFFECTS OF THE ADDITION OF LICORICE EXTRACT TO TOBACCO ON THE CHEMICAL COMPOSITION AND BIOLOGICAL ACTIVITY OF CIGARETTE SMOKE.

E. L. Carmines[1], R. Lemus[1], C. L. Gaworski[1], T. Meisgen[2], K. Rustemeier[2], E. Van Miert[3] and D. Veltel[2]. *[1]Philip Morris USA, Richmond, VA, [2]INBIFO - Institut fuer biologische Forschung, Cologne, Germany and [3]CRC - Contract Research Center, Zaventem, Belgium.*

Licorice extract (LE) is used as a flavoring material in cigarettes. As such, it is useful to determine if it has an effect on the chemical and biological activity of mainstream smoke. LE was incorporated into cigarettes at a targeted normal use level (1.25%; 1X), and at multiples of the use level, (3.75%; 3X), and (12.5%; 10X). A cigarette without LE served as a control. Smoke constituents analyzed included those proposed by the CPSC and those classified as carcinogens by the IARC. The results obtained for genotoxicity (Salmonella Reverse Mutation) and cytotoxicity (Neutral Red Uptake) were comparable to the control cigarette. Cigarette analysis showed that 10X displaced tobacco as indicated by a reduction in smoke nicotine. On an equal TPM basis, there was a statistically significant decrease in B(a)A (10 %) for the 1X level, and an increase in phenol (10 %) and catechol (5 %) for the 3X level. These values were within the normal range of variability of the assay and were not considered to be LE related. At the 10X level it appeared that LE has the potential to alter the measured smoke constituents (decreases in nicotine (6%), CO (14%), nitrogen oxides (16%), HCN (18 %), acetaldehyde (6%) and NNN (11 %); increases in formaldehyde (43 %), phenol (27 %), catechol (9 %), B(a)P (19 %), and indeno(1, 2, 3-cd)pyrene (14 %)). In the 90-d rat nose-only inhalation study, COHb was slightly lower in the LE groups. Histopathologic changes were comparable to those seen in previously reported 90-d cigarette smoke inhalation studies; addition of LE had no effect. The overall assessment suggests that LE did not increase the measured smoke constituents (beyond normal variation) nor biological activity of the cigarette smoke, even at 3X the normal use level. The 10X level changed some smoke constituents, but these changes did not affect the biological activity as measured by the tests used in this study.

1879 A SUMMARY OF THE TOXICOLOGICAL AND CHEMICAL DATA RELEVANT TO THE TOXICOLOGICAL EVALUATION OF DRY ICE EXPANDED TOBACCO (DIET).

E. H. Theophilus, D. B. Poindexter, D. R. Meckley, B. B. Bombick, P. H. Ayres, M. A. Higuchi, A. T. Mosberg and J. E. Swauger. *Research and Development, RJ Reynolds Tobacco Company, Winston-Salem, NC.*

RJRT has developed a tiered testing strategy to evaluate the potential for tobacco processes, ingredients, and other technological developments to increase or reduce the biological activity resulting from burning tobacco. The foundation of this strategy is comparative testing, typically including chemical and biological components. Expansion processes have a long history of use in food and tobacco manufacturing. DIET is an example of a tobacco expansion process currently used in the manufacture of cigarettes to increase the filling capacity of tobacco. As part of RJRT stewardship program, test cigarettes containing DIET were compared to control cigarettes containing tobacco expanded with a traditional expansion agent (Freon 11). Principal components of this program included chemistry studies using mainstream cigarette smoke (determination of selected constituent yields), *in vitro* studies using cigarette smoke condensate (Ames study in Salmonella typhimurium and sister chromatid exchange study in Chinese hamster ovary cells) and *in vivo* studies (13-week inhalation study of mainstream cigarette smoke in Sprague-Dawley rats and 30-week dermal tumor promotion study of cigarette smoke condensate in SENCAR mice). Comparisons between test and control cigarettes demonstrated that the inclusion of DIET in cigarettes had no significant impact on mainstream smoke chemistry. Also, biological tests indicated that the cigarettes containing DIET were not different from the cigarettes containing tobacco expanded using Freon 11. Collectively, these data demonstrate that the use of DIET in the manufacture of cigarettes is acceptable from a toxicological perspective.

1880 FOUR-WEEK TOXICITY STUDY OF A SURROGATE MURINE ANTI-CD11A ANTIBODY IN MICE.

B. Mounho[1], J. Beyer[1], S. Ortega[1], B. Wu[1], A. Hoberman[2], A. Brechbill[2] and J. Clarke[1]. *[1]Safety Assessment, Genentech, Inc., S. San Francisco, CA and [2]Argus Research, a Division of Charles River, Horsham, PA.*

Surrogate antibodies offer a potential solution to the limited preclinical safety testing possible with humanized monoclonal antibodies with restricted species crossreactivity. CD11a is a subunit of lymphocyte function antigen-1 (LFA-1), a cell surface protein expressed on leukocytes. The interaction between LFA-1 and its ligand,

intercellular adhesion molecule-1 (ICAM-1) mediates intercellular interactions important for immune responses and inflammation. Raptiva™ is a humanized anti-human CD11a monoclonal antibody that inhibits the binding of LFA-1 to ICAM-1, and is being developed for psoriasis. A chimeric rat/mouse anti-mouse CD11a antibody (muM17) was developed as a surrogate antibody for Raptiva. This study evaluated potential adverse effects of muM17 administered to C57BL/6 mice. Male and female mice were administered vehicle or muM17 (3, 10, or 30 mg/kg) *via* subcutaneous injection weekly for 4 weeks; all animals were terminated on Day 29. The 3 mg/kg/week muM17 dose was determined by previous studies as approximately equivalent to the clinical dose of Raptiva (1 mg/kg/week). Toxicokinetic analysis confirmed exposure in muM17-treated mice, and no anti-muM17 antibodies were detected. There were no treatment-related effects on mortality, clinical signs, body weight, clinical chemistry parameters, or macroscopic observations. Increased spleen weights and histologic findings of increased cellularity in spleens and reduced cellularity in lymph nodes were observed in treated mice in all dose groups. These findings are consistent with those demonstrated in LFA-1 deficient mice and studies using other anti-CD11a antibodies, and are likely a result of altered lymphocyte trafficking to the lymph nodes and spleen. In summary, muM17 was well tolerated in mice up to 30 mg/kg/week for 4 weeks, and treatment-related changes in the spleen and lymph nodes are likely the result of the pharmacological activity of the antibody.

1881 DEVELOPMENTAL TOXICITY TESTING OF FOUR VACCINES.

P. C. Barrow[1] and F. Verdier[2]. *[1]MDS Pharmacology Services, LArbresle, France and [2]Aventis Pasteur, Marcy LEtoile, France.*

There are currently no regulatory requirements for preclinical developmental toxicity studies with vaccines, but this is a current area of interest[1]. Potential risks result either from vaccine interaction with the maternal immune system or from the binding of maternal antibodies on embryonic or fetal tissues. The following strategy was adopted to screen four new vaccines against viral or bacterial diseases for developmental toxicity. A preliminary study was performed in the rat, mouse and rabbit to evaluate the induced maternal immune response and to compare pre- and post-natal antibody titres in the offspring. Twelve females of each species were vaccinated before and during gestation. Half of the pregnant dams were submitted to caesarean section; the other half were given a booster vaccination at the end of gestation and sacrificed on day 11 post-partum. Serum antibody titres were determined in the dams, fetuses and pups. The most appropriate species was then selected for a main developmental toxicity study. On the basis of acquired experience (particularly for post-natal examinations), the rat was the preferred species followed by the mouse and rabbit. As would be expected from the literature, the highest rate of prenatal antibody transfer was usually observed in rabbits. Nonetheless, the fetal antibody titres to two vaccines attained maternal levels in mice. In rats, the fetal antibody titres were consistently lower than maternal levels, but had equalised by post-natal day 11. Consequently, the mouse was selected for the main study with two vaccines, and the rabbit for the other two. The main studies comprised a single vaccinated group of 40 mice or 36 rabbits and a sham-treated control group. Where feasible, the vaccine was administered at the human dose level without scaling for body weight. Twenty-five mice or 20 rabbits were subjected to caesarean examination and fetal examinations. The remaining litters were used for post-natal assessments. No indications of developmental toxicity were found with the four vaccines tested. [1] http://www.fda.gov/cber/gdlns/reprotox.pdf.

1882 EVALUATION OF THE SUBCHRONIC, REPRODUCTIVE, AND DEVELOPMENTAL TOXICITY OF A FLUOROALKYLETHYL ETHOXYLATE SURFACTANT.

S. A. MacKenzie, E. Mylchreest, S. Munley, J. Stadler, J. Hansen and N. Everds. *DuPont Haskell Laboratory for Health and Environmental Sciences, Newark, DE.*

The objective of these studies was to evaluate the subchronic, reproductive, and developmental toxicity of a fluoroalkylethyl ethoxylate surfactant in rats. Test substance was administered by gavage at 0, 25, 100, or 500 mg/kg/day (90-day subchronic toxicity and one-generation reproduction), and at 0, 50, 100, or 400 mg/kg/day on gestation days 6-20 (developmental toxicity). The NOEL for subchronic toxicity was 25 mg/kg/day based on clinical signs, reduced body weight and nutritional parameters, thyroid follicular hypertrophy, and chronic progressive nephropathy at ≥100 mg/kg/day. Other adverse effects at 500 mg/kg/day were reduced red blood cell mass, increased liver enzyme activity, and reduced grip strength. Non-adverse liver hypertrophy and splenic effects were observed at ≥25 and ≥100 mg/kg/day, respectively. Except for effects on the thyroid at 500 mg/kg/day and kidney at ≥100 mg/kg/day, other effects were reversible after a 1- or 3-month recovery. No NOEL was determined for reproductive toxicity, based on reduced fertility in P1 rats at ≥25 mg/kg/day, which was of similar magnitude at all dose levels. Body weights, food efficiency, and number of implantation sites were reduced in P1 rats at 500 mg/kg/day, and viability and weights were reduced in F1 pups at ≥100 mg/kg/day. The reduced pup viability was relatively less severe and required much higher doses than the structurally related perfluorooctane sulfonate. Red blood cell and spleen effects were similar to those observed with ethylene glycol ethers, but there were no developmental or testicular effects as seen with glycol ethers. The mechanism for reduced fertility is not known. In the developmental toxicity study, the NOELs were 50 and 100 mg/kg/day for maternal and fetal toxicity, respectively, based on reduced maternal body weight and nutritional parameters, and clinical signs at ≥100 mg/kg/day and reduced fetal weight and increased fetal variations at 400 mg/kg/day. No fetal malformations were observed.

1883 A COMPARISON OF MULTIPLE TOXICITIES FOLLOWING DEVELOPMENTAL EXPOSURE TO PESTICIDES: NEUROTOXICITY, IMMUNOTOXICITY, AND REPRODUCTIVE TOXICITY.

V. C. Moser[1], S. Padilla[1], S. Barone[1], R. J. Smialowicz[1], M. W. Harris[2] and R. E. Chapin[3]. *[1]NHEERL, USEPA, Research Triangle Park, NC, [2]NTP, NIEHS, Research Triangle Park, NC and [3]Pfizer, Groton, CT.*

The NAS report (Pesticides in the Diets of Infants and Children, 1993) called for significant research effort into the long-term effects of perinatal pesticide exposure on the nervous, immune, and reproductive systems. In response, the USEPA and NIEHS collaborated on a series of multidisciplinary studies. The exposure paradigm was designed to encompass the development of all three organ systems (in the rat, mid-gestation through weaning and/or sexual maturity). Broad batteries of tests were used to evaluate the structure and function of each organ system in the offspring. Tissue levels of chemical and general pathology were also measured Where possible, littermates were used for the various endpoints, to draw stronger conclusions regarding relative organ system vulnerability. Five pesticides from different chemical classes, targeting different organ systems, were evaluated: methoxychlor (organochlorine), carbaryl (carbamate), chlorpyrifos (organophosphate), tebuconazole (triazole), and heptachlor (cyclodiene). A comparison of these data reveals two critical findings. First, no single organ system was consistently more sensitive than another. Developmental/reproductive measures were most sensitive to the effects of methoxychlor and carbaryl. The nervous system was most sensitive to tebuconazole, chlorpyrifos, and heptachlor, whereas the immune system was most altered by low doses of methoxychlor and heptachlor. Second, the lowest effective doses for methoxychlor and heptachlor were lower than those reported in the literature. Thus, adverse health effects following developmental exposure may occur at lower doses than previously expected. These multidisciplinary studies provide valuable and unique data; furthermore, this shows that these organ systems may be evaluated in a single combined study. This strongly supports the need for more thorough evaluation of the nervous, immune, and reproductive systems during development. This abstract does not necessarily reflect EPA policy

1884 MULTIDOSE TOXICITY STUDIES OF TNK-TPA IN NORMAL BEAGLE DOGS.

Q. Lu, L. Wen, Y. Li, Y. Chen and S. Guo. *Department of pharmacology, Beijing Institute of Radiation Medicine, Beijing, China.* Sponsor: P. Zhou.

To evaluate the safety of new thrombolytic TNK-tPA in dogs.TNK-tPA was administered intravenously, daily at 1.5mg/kg, 4.5mg/kg and 13.5mg/kg to Beagle dogs(2 dogs/sex/group) for 2 weeks. Daily intraveneous administration of TNK-tPA for 2 weeks produced expected effects on blood coagulation system in a dose-related manner (subcutaneous hemorrhage at the sites of injection, increased pothrombin time, actvated partial thromboplastin time, and decreased fibrinogen, plasminogen). At 13.5mg/kg the following additional effects were observed: mild decreases in red blood cell count, hemoglobin, and hematocrit, higher serum levels of asparate aminotransferase, and total cholesterol, hemorrhage and adipic degeneration in the livers. These findings were not unexpected based on the pharmacologic activity of TNK-tPA, and were consistent with the preclinical pharmacokinetic data (unpublished) indicating that the liver was the major organ for TNK-tPA clearance.

1884a EVALUATION OF INTRAVENOUS EXPOSURE TO DI-(2-ETHYLHEXYL)PHTHALATE IN MALE NEONATAL RATS.

J. N. Cammack[1], R. D. White[1], D. Gordon[1], J. Gass[1], L. Hecker[2], D. Conine[2], S. Uma[2], M. Friedman[2], C. Echols[3], T. Y. Yeh[3] and D. M. Wilson[4]. *[1]Baxter Healthcare Corporation, Round Lake, IL, [2]Abbott Laboratories, Abbott Park, IL, [3]Allegiance, McGaw Park, IL and [4]previously at Baxter Healthcare, Round Lake, IL.*

Di-(2-ethylhexyl)phthalate (DEHP) was administered intravenously for 21 consecutive days in neonatal rats to determine the potential for residual effects in sexually mature rats at 90-days of age. DEHP was administered to three- to five-day-old

Sprague-Dawley rats by daily injections of 60, 300, or 600 mg/kg/day or by daily oral gavage of 300 or 600 mg/kg/day for 21 days. Histopathological evaluation and organ weight measurements were performed on some animals after 21 days of dosing (primary group) and later on the recovery group animals that were held without further treatment until sexual maturity at approximately 90 days of age. No effects of any type were observed in animals treated intravenously with 60 mg/kg/day. Testicular changes, consisting of a partial depletion of the germinal epithelium and/or decrease in diameter of seminiferous tubules, were present in all animals of the 300 and 600 mg/kg/day groups after the 21-day dosing period. Testes weight decreased and liver weight increased in these animals. Testes changes were dose-related and generally more severe among animals dosed orally versus intravenously. In the recovery animals, a residual DEHP-induced decrease in seminiferous tubule diameter was present in the testis of several animals dosed orally at 300 and 600 mg/kg/day, but not in animals dosed intravenously. There was no germinal cell depletion or Sertoli cell alteration observed in any dose group at any time. Notably, no effects on sperm count, sperm morphology or sperm motility were observed at 90 days of age in any of the groups.

1885 BEEFING UP — REVISED BODY WEIGHTS AND SKIN SURFACE AREA ESTIMATES.

S. Roy[1], J. K. Tolson[1], K. M. Portier[2] and S. M. Roberts[2]. *[1]Center for Environmental & Human Toxicology, University of Florida, Gainesville, FL and [2]Department of Statistics, University of Florida, Gainesville, FL.*

Exposure parameters such as body weight and surface area are important inputs for both deterministic and probabilistic risk assessments. Currently, USEPA guidance for body weight is obtained from the 1997 Exposure Factors Handbook (EFH). The EFH developed body weights from data available in the second NHANES (National Health and Nutrition Examination Survey II, 1976-1980). Since that time additional information has become available from the third NHANES study (1988-1994). The goal of this analysis was to use the NHANES III data set to develop age-specific body weight estimates for male and female US residents along with ethnic group sub-populations. Maximum likelihood and minimum variance unbiased estimates were computed assuming that the body weights follow a lognormal distribution, and age-specific body weight percentiles were estimated to support future probabilistic risk assessments. Since body surface area can be calculated from an allometric relationship to body weight, revised surface area estimates were also developed. Our analysis indicates that Americans are growing heavier: the average body weight for adults (18-74 yrs) has increased from 71.8 kg to 82.11 kg. The mean body weight for white males (82.67 kg) is slightly greater than black males (82.00 kg). Black females (75.98 kg) have a greater mean body weight than white females (68.88 kg). Although these differences among ethnic groups and genders are qualitatively the same as in previous data from NHANES II, the extent of the differences has increased slightly. Use of updated body weight and surface area estimates will provide a more accurate and contemporary estimation of risk.

1886 ESTIMATION OF CHEMICAL-SPECIFIC INTERINDIVIDUAL UNCERTAINTY FACTORS USING PHYSIOLOGICALLY-BASED PHARMACOKINETIC (PBPK) ALGORITHMS.

A. Nong and K. Krishnan. *Occupational and Environmental Health, Universite de Montreal, Montreal, QC, Canada.*

In non-cancer risk assessments, an interindividual uncertainty factor of 10 is used as the default value. The numerical value for the pharmacokinetic component of the interindividual uncertainty factor (IUF) has been suggested to be 3.17. Steady-state algorithms, derived from PBPK models, can be used to derive the chemical-specific IUF, provided the distributions of the input parameters are known. The objective of this study was to estimate the magnitude of the pharmacokinetic component of the IUF for toluene (TOL), styrene (STY), m-xylene (XYL) and 1, 4-dioxane (DIO) using steady-state algorithms derived from PBPK models. The PBPK algorithms were used to calculate the steady-state arterial blood concentration (Ca) and rate of the amount metabolized (RAM) of chemicals in humans during chronic exposures. Following the specification of the characteristics (mean, SD) and distributions of input parameters such as the pulmonary ventilation rate (345.3, 102.1 L/hr; normal), cardiac output (342.8, 245.6 L/hr; lognormal), fractional hepatic blood flow (0.25, 0.06; normal), metabolic parameters [Vmax (mg/hr): XYL (192.6, 95.9), TOL (111.2, 55.5), STY (155.4, 78.0), DIO (147.1, 74.4); Km (mg/L): XYL (0.20, 0.04), TOL (0.55, 0.11), STY (0.36, 0.07), DIO (3.0, 0.6); lognormal] and blood:air partition coefficient [XYL (32.5, 1.6), TOL (19, 3), STY (62, 10), DIO (2905, 613); normal], 10, 000 iterations of Monte Carlo simulations were conducted to generate the output. The chemical-specific pharmacokinetic uncertainty factor was computed as the ratio of the simulated 95th and 50th percentile values of Ca and RAM. The resulting uncertainty factors for XYL, TOL, STY and DIO based on Ca were 2.52, 1.93, 2.61 and 2.23, respectively. The pharmacokinetic uncertainty factor for XYL, TOL, STY and DIO was 1.5, if the calculations were based on the rate of metabolism. These results suggest that the chemical-specific IUF calculated for TOL, STY, XYL and DIO, on the basis of mechanistic considerations, are within the currently used default value of 3.17.

1887 CHILDRENS HEALTH RISK CHARACTERIZATION FROM EXPOSURE TO TETRACHLORETHYLENE.

N. Beck[1] and B. Sonawane[2]. *[1]Office of Information and Regulatory Affairs, Office of Management and Budget, Washington, DC and [2]National Center for Environmental Assessment, USEPA, Washington, DC.*

In 1995 the US Environmental Protection Agency (EPA) established an agency-wide policy that calls for the consideration of the risks to infants and children in all risk assessments. We summarize the current state of the science regarding how children may differ from adults in their response to tetrachloroethylene exposures. Ideally, the uncertainty factors used to explain variability in a population could be data-derived numbers. To begin, a review of how a childs exposure may differ from an adults exposure was conducted. The primary routes of exposure include inhalation of vapor and ingestion of contaminated drinking water. Exposure through breast feeding was also considered as an exposure pathway for nursing infants. Further evaluation was carried out to determine how a childs toxicokinetic and toxicodynamic responses may differ from those of an adult. This included a review of differences in metabolism as well as other susceptibility factors that are specific to the life stage of a child. In an ideal situation, the data would allow for a quantitative understanding of these differences. However, the current knowledge base allows for only a qualitative discussion of the differences that may exist between children and adults. Attempts are made to understand these differences and data gaps are identified to better assess potential risks of tetrachloroethylene exposure to children. Disclaimer: The views presented in this abstract are those of the authors and do not necessarily represent views and/or policy of their affiliations.

1888 EMPIRICALLY IDENTIFYING AN INTERSPECIES UNCERTAINTY FACTOR FOR MILD ACUTE INHALATION EXPOSURES.

G. V. Alexeeff, R. Broadwin and D. Wang. *OEHHA, Cal/EPA, Oakland, CA.*

This analysis was conducted to evaluate the uncertainty in acute inhalation risk assessment and to better understand the interspecies variability in response to mild acute exposures. When using animal data in threshold-based risk assessments, the primary approach applies a 10-fold uncertainty factor (UF) to the animal data to estimate an average human response. We identified 318 data sets, for 66 hazardous air pollutants for which NOAELs and LOAELs were reported for mild effects from acute inhalation exposures. There were 208 animal-to-human data comparisons available for mild eye or respiratory irritation for ten chemicals. We evaluated the interspecies relationship for both LOAELs and NOAELs for each chemical. First we evaluated them assuming the effects were independent of exposure time. The animal-to-human ratios for LOAELs were 5.0 at the 50th percentile, and 100 at the 95th percentile. In contrast, the animal-to-human ratios for NOAELs were 4.0 at the 50th percentile, and 200 at the 95th percentile. The value of the standard UF (10) was approximately the 65-70th percentile. Exposure time was adjusted using a modification of Haber's Law, $C^n * T = K$, where C is concentration, T is time and K is a constant. The value "n" was obtained from the literature when available. Time adjustment of the data did not improve the animal-to-human correlation. When adjusted for exposure time, the animal-to-human ratios for LOAELs were 24 at the 50th percentile, and 1300 at the 95th percentile. The time-adjusted ratios for NOAELs were 29 at the 50th percentile, and 1700 at the 95th percentile. These data suggest a very large skew in the data. Finally, it must be emphasized that this analysis is reflective only of mild acute inhalation toxicity for a limited set of chemicals. For other exposure routes, subchronic or chronic exposures or more severe toxicity, the distributions are expected to be different.

1889 REFERENCE DOSES (RfDs): FACTORS IN THE SELECTION OF HUMAN INTRASPECIES UNCERTAINTY FACTOR (UFH) WHEN USING HUMAN DATA.

C. O. Abernathy[1], J. M. Donohue[1], J. Cicmanec[2] and K. A. Poirier[3]. *[1]HECD, University. S. EPA, Washington, DC, [2]NRMRL, ORD, USEPA, Cincinnati, OH and [3]TERA, Cincinnati, OH.*

There are 14 RfDs on the USEPA's Integrated Risk Information System (IRIS) based on human studies. Data from these RfDs are taken from epidemiological, clinical and nutritional studies and their UHFs range from 1 to 10. However, there

are no definitive guidelines for the selection of UFHs on IRIS. With human data, the choice for UFH may be affected by several factors and it is important to understand the rationale for the selection of the UFHs. for each compound. One subset of chemicals on IRIS is comprised of the essential trace elements (ETEs) and their UFHs range from 1 (F and Mn) to 3 (Se, Mo and Zn). For the ETEs, the major determining factor in the selection of the UFH was the presence of human nutritional data and the setting of Recommended Dietary Allowances (RDAs). The UFHs for the other chemicals range from 1 (benzoic acid and nitrate/nitrite) to 3 (As and Ag) to 10 (aldicarb, Cd, methyl mercury and 2, 4-dinitrophenol). Rationales for assignment of UFHs of less than 10 included one or more of the following reasons; 1. adequate peer-reviewed human studies (all), 2. presence of RDAs (Mn, Mo, Se and Zn), 3. exposure to a large human population (F and Mn), 4. most sensitive species exposed (nitrate/nitrite [Although nitrite has an UFH of 1, a 10-fold modifying factor was added for its greater toxicity as nitrate data were used in the RfD derivation.]), 5. end-point not based on an adverse health effect (F and Ag), and 6. data base uncertainties (As). [The statements and opinions expressed in this abstract are those of the authors and are not necessarily those of the USEPA.]

1890 USING TOXICOKINETIC DATA FOR KINETIC COMPONENTS OF THE INTERSPECIES AND INTERINDIVIDUAL UNCERTAINTY FACTORS FOR THE BORON REFERENCE DOSE.

C. L. Smallwood, J. C. Swartout and J. C. Lipscomb. *NCEA, ORD, US Environmental Protection Agency, Cincinnati, OH.*

Boron is a naturally-occurring element that is commonly found in food. Studies in rats fed boron in the diet during pregnancy indicate that decreased fetal body weight is the critical effect. A dose response analysis resulted in a benchmark dose (BMDL05) of 10.3 mg/kg-day. Inter- and intra-species uncertainty factors (UFA and UFH, respectively) used to extrapolate this dose from animals to humans and to the sensitive human subpopulation can be divided into toxicokinetic (TK) and toxicodynamic (TD) components. Toxicokinetics in rats and humans is markedly similar and renal elimination (filtration) accounts for differences in plasma half-life. Differences in urinary elimination of boron in pregnant rats and pregnant humans were used to quantify the inter-species TK variance as a replacement for the default value for the TK component of UFA. Differences in renal filtration (GFR) in normal pregnant women and at-risk pregnant women were used to quantify the intra-species TK variance as a replacement for the TK default value for the TK component of UFH. Together with default values for the TD components of the UF, these results suggest an overall adjustment factor for boron of approximately 50 to 60, which would replace a default uncertainty factor of 100.

1891 INTER-SPECIES DIFFERENCES IN SUSCEPTIBILITY TO PERCHLORATE: A CRITICAL CONSIDERATION FOR HUMAN HEALTH RISK ASSESSMENT.

T. A. Lewandowski, M. R. Seeley and B. D. Beck. *Gradient Corporation, Cambridge, MA.*

Due to the widespread occurrence of perchlorate as a groundwater pollutant, considerable research effort has been focused on understanding the toxicology of this chemical. A key concern involves understanding how to use rodent data to predict health effects in humans. While humans and rats exhibit similar dose-response relationships in terms acute inhibition of thyroidal iodide uptake, the two species exhibit notable differences in terms of thyroid hormone response, the downstream effect of ultimate interest. To explore this issue, data on changes in serum T3, T4 and TSH levels in response to increasing perchlorate doses were obtained from a number of studies in humans, rats, mice and rabbits. The studies were of subchronic duration (14 to 35 days). We found that the rat was strikingly more sensitive to perchlorate than any of the other species. Particularly in regard to serum TSH levels, rats exhibited a response at 0.1 mg/kg-day whereas other species remain unresponsive even at doses of 10 mg/kg-day. Perchlorate effects on serum T4 levels in the pregnant rat were also notable, although the male rat and fetal rat appeared to be less sensitive. T3 levels appeared to be less affected by perchlorate than T4 or TSH, although the rat still exhibited small decreases in T3, an effect not observed in the other species. The greater sensitivity of the rat (particularly the pregnant rat) to perchlorate compared to other species is consistent with greater rat sensitivities reported for other thyroid active agents such as amitrol or propylthiouracil. These cross-species comparisons provide strong evidence that data obtained from rat thyroid studies need to be critically judged for their quantitative relevance to humans. Direct application of rat dose-response relationships to humans would overestimate the potential human risks from perchlorate. We propose that the case of perchlorate is one of the rare situations where an inter-species uncertainty factor of less than one can be adequately supported.

1892 HIGHER SUSCEPTIBILITY OF NEWBORN RATS TO 3-METHYLPHENOL THAN YOUNG RATS.

R. Hasegawa[1], M. Koizumi[1], A. Noda[2], Y. Ito[2], M. Furukawa[3], S. Fujii[3], E. Kamata[1] and M. Ema[1]. *[1]National Institute of Health Sciences, Tokyo, Japan, [2]Research Institute for Animal Science in Biochemistry and Toxicology, Kanagawa, Japan and [3]Safety Research Institute for Chemical Compounds Co., Ltd.,, Sapporo, Japan.*

Considering higher susceptibility of infants to 3-methylphenol, the repeated dose toxicity study was conducted by oral administration in newborn and young rats. In the 18-day newborn study from postnatal days 4 to 21 at doses of 30, 100 and 300 mg/kg, various clinical signs including deep respiration, hypersensitivity at handling and tremors under the contact stimulus, and depressed body weight gain were observed at 300 mg/kg. At 100 mg/kg, hypersensitivity and tremors were also noted in a small number of males only at each single day during the dosing period. No other adverse effects were observed in 100 and 30 mg/kg groups. There were no abnormalities of physical development including sexual maturation and reflex ontogeny. The no observed adverse effect level (NOAEL) was considered to be 30 mg/kg/day and the unequivocally toxic level 300 mg/kg/day for newborn rats. In the 28-day study starting at 5 weeks of age, clinical signs and depression of body weight gain as observed in the newborn rats appeared in both sexes at 1000 mg/kg but not 300 mg/kg. The unequivocally toxic level and the NOAEL were 1, 000 mg/kg/day and 300 mg/kg/day, respectively. From these results, newborn rats were considered to be 3 to 10 times higher susceptible to 3-methylphenol than young rats. However, realistic no adverse effect dose for the newborn must be slightly lower than 100 mg/kg/day, at which the toxicity incidence was very low, rather than 30 mg/kg/day. Based on this speculation and the equal toxicity at the unequivocally toxic levels, the differences in the susceptibility to 3-methylphenol could be concluded to be 3 to 4 times. It is consistent with the results of our previous comparative studies on 4-nitrophenol, 2, 4-dinitrophenol and 3-aminophenol, which showed 2 to 4 times differences in the susceptibility between the newborn and young rats.

1893 ASSESSMENT OF THE SKIN ABSORPTION OF MALATHION.

J. Scharf[1], M. Martinez[2], T. Stedeford[2], G. Hahn[3] and R. Harbison[2]. *[1]Department of Anesthesiology, James A. Haley Veterans' Administration Hospital, Tampa, FL, [2]Center for Environmental/Occupational Risk Analysis & Management, College of Public Health, University of South Florida, Tampa, FL and [3]Ecology & Environment, Inc., Buffalo, NY.*

Malathion is a commonly used organophosphate pesticide on field crops, fruits, nut trees, vegetables, livestock, agricultural premises, and land. The approved uses also include mosquito and medfly control. These uses can result in human skin contact. The purpose of this study was to evaluate the human skin absorption of malathion for the purpose of assessing the risks associated with aqueous solution exposures following applications. Aerial applications can result in solubilized malathion in swimming pools and other waters that may be contacted. Human volunteers were selected and exposed to aqueous solutions of malathion at various concentrations. Participants submerged their arms or hands in a 10-gallon tank containing 20 liters of malathion in either a stagnant or moving environment. Malathion concentration in the water was determined before and after the human subjects placed their arms or hands in the water for various periods of time. Malathion was measured using Gas Chromatography. No measurable skin absorption was detected in 43% of the participants. Measurable skin absorption among some participants resulted in doses that were more than an order of magnitude less than the minimal dose necessary to cause a measurable change in blood cholinesterase. Extrapolation of these results to recreational exposure to swimming pool or surface water levels of malathion typically detected after application again are an order of magnitude below the doses needed to cause a detectable change in blood cholinesterase. These data indicate that exposure to aqueous malathion following usual aerial applications is not appreciably absorbed, and therefore, it is not a public health hazard. (Supported in part by the Department of Defense)

1894 PHYSICAL ACTIVITY PRIOR TO EXPOSURE INCREASES HUMAN ABSORBED DOSE TO SURFACE RESIDUES OF CHLORPYRIFOS (CP).

R. I. Krieger[1], L. S. Aston[2] and R. L. Williams[1]. *[1]Entomology, University of California, Riverside, CA and [2]Pacific Toxicology Laboratories, Woodland Hills, CA.*

To develop realistic and responsible estimates of human exposure and absorbed daily dosage (ADD), it is important to identify and evaluate potential determinants of exposure, and to clarify the extent of human exposure following pesticide applications. Transferable chemical residue rapidly declines following application (Krieger et al., 2001), correlated with a decline in carpet moisture (Williams et al,

2002). Skin moisture has also been shown to increase the dermal absorption of propoxur (Meuling et al., 1997). A structured activity program (SAP) was used to estimate human exposure potential (Jazzercise®; Ross et al., 1990; Krieger et al., 2000; Bernard et al., 2001). Participants were randomly divided into two groups. Group 1 participated in a warm-up exercise program in an untreated area, while group 2 remained sedentary. All participants completed the SAP in an area treated 24-hours earlier with CP. Each participant collected a morning urine specimen prior to the SAP and then for 5 subsequent days, that were analyzed for TCP. Two weeks later the study was repeated with group 2 participating in the warm-up exercise, while group 1 remained sedentary prior to the exposure period. Participants that completed the warm-up exercise (123 ± 39 and 88 ± 32 μg TCP excreted following exposure 1 and 2, respectively) had a significantly higher absorbed dose compared to those that rested prior to the SAP (84 ± 41 and 57 ± 22 μg TCP excreted following exposure 1 and 2, respectively). Estimates of absorbed dose made from environmental measurements, e.g. deposition (34 ± 4 and 31 ± 3 μg CP/cm2 for exposure 1 and 2, respectively), modified California roller (0.25 ± 0.07 and 0.23 ± 0.07 μg CP/cm2 for exposure 1 and 2, respectively), and personal dosimetry (0.6 ± 0.3 and 0.3 ± 0.1 μg CP/cm2 on shorts worn during exposure 1 and 2, respectively; (2.6 ± 1.1 and 0.7 ± 0.3 μg CP/cm2 on socks worn during exposure 1 and 2, respectively), overestimated the results of urine biomonitoring.

1895 ORGANOPHOSPHATE CUMULATIVE ASSESSESSMENT USING CARES (CUMULATIVE AND AGGREGATE RISK EVALUATION SYSTEM).

M. Pandian[1], J. L. Phillips[3], J. Driver[1], I. Kelley[3], G. Mihlan[3], C. Breckenridge[2], K. Schnelle[4] and J. Zabik[4]. *[1]infoscientific.com, Las Vegas, NV, [2]Syngenta, Greensboro, NC, [3]Bayer CropScience, Research Triangle Park, NC and [4]Dow AgroSciences, Indianapolis, IN.*

The Food Quality Protection Act mandates that the US Environmental Protection Agency evaluate both the aggregate and cumulative risks associated with pesticide use. CARES, a computer program developed by CropLife America (CLA) is designed to perform such analyses. CARES utilizes relevant databases to evaluate potential risk from dietary, drinking water, and residential sources *via* the oral, dermal, and inhalation routes of exposure for a single pesticide or multiple pesticides with a common mechanism of toxicity. A 365-day exposure profile for each individual in a population of interest is created and used to estimate acute, short term, intermediate term, and chronic risks according to the relevant toxicity profile of the pesticide(s). CARES allows identification of the factors contributing to the highest percentiles of risk. The organophosphate insecticides were the first group of pesticides to be evaluated by EPA for cumulative exposure. The Sound Science Policy Alliance and CLA undertook a parallel assessment utilizing CARES. The toxicity endpoints used in the assessment were Relative Potency Factors based on BMD10 21-day female rat brain choinesterase inhibition studies of 30+ organophosphates. The dietary exposure results are based on the USDA/EPA Food Consumption Intake Database, and the PDP food residue data supplemented by additional studies. Residential assessments within CARES were based on EPA Residential SOP algorithms and OP specific product use data. Drinking water was not included in the CARES assessment because it had previously been determined by EPA to be a non-significant contributor to overall risk. Results at various percentiles closely paralleled the EPA-derived Margins of Exposure. Results from the CARES assessment indicate that the overall safety of the US population is not threatened by the use of OP insecticides.

1896 METHYL ISOTHIOCYANATE (MITC): RISK TO HUMANS FOLLOWING AGRICULTURAL APPLICATIONS OF METAM SODIUM (MS).

A. L. Rubin[1], T. Thongsinthusak[2] and K. F. Pfeifer[1]. *[1]Medical Toxicology Branch, Department of Pesticide Regulation, Cal-EPA, Sacramento, CA and [2]Worker Health & Safety Branch, Department of Pesticide Regulation, California Environmental Protection Agency, Sacramento, CA.*

Metam sodium (MS; sodium N-methyldithiocarbamate) is a fumigant used in agriculture as a preplant biocide. The primary degradation product and pesticidal agent, methyl isothiocyanate (MITC), evolves as a gas after MS application. MS gained public attention following the spill of 19, 500 gallons into the Sacramento River in July 1991. Subsequent exposure to airborne MITC and other MS breakdown products caused an array of irritational health effects in local residents. Drift incidents following MS agricultural applications have also resulted in irritational injuries. We evaluated the risks to humans from MITC following normative agricultural use of MS. Exposure of workers and the public was documented in a series of MITC air monitoring studies conducted mainly in the southern Central Valley. The critical acute NOEL of 220 ppb was determined in a human eye-only exposure study, based on eye irritation at 800 ppb. The subchronic NOEL of 100 ppb was based on nasal epithelial atrophy in a 4-week rat inhalation toxicity study; it was estimated from the study LOEL of 1.7 ppm using Haber's Law. The chronic NOEL of 10 ppb was calculated by dividing the subchronic NOEL by a default uncertainty factor of 10. Acute margins of exposure (MOE=exposure dose/NOEL) for occupational and application site scenarios ranged between <1 and 59, with many scenarios <10, indicating an acute health concern. The acute MOE range for ambient air scenarios was 15-2200. The seasonal MOE range for occupational/application site scenarios was 1-250, also indicating a health concern. Seasonal ambient air MOEs were 28-166, 667. Annual MOEs were <1-143 for occupational/application site exposures and 5-25, 000 for ambient air exposures. While some monitoring studies were not done using currently approved application methods, this evaluation does indicate a clear health concern for individuals exposed to airborne MITC near fields under treatment with MS.

1897 FRAMEWORK FOR ASSESSING DIETARY CHEMICAL THREATS.

P. M. Bolger, C. Carrington and R. Canady. *Department of Health and Human Services, USFDA, College Park, MD.*

Safeguarding food supplies from the deliberate introduction of chemical agents is a major challenge, especially with the world-wide access to a range of raw and processed foods. Pre-farm, farm and slaughterhouse levels provide opportunities for chemical contamination. Trace-back and forward of contaminated products is very complex, particularly on an international level. Food production includes the following critical steps: agricultural production, storage and transport of commodities, processing, storage and transport of processed products, retail distribution, food service, and individual food preparation. In assessing a myriad of potential dietary chemical threats it is necessary that a threat assessment framework be used that considers critical salient factors. A multi-factorial framework was developed that included the following critical factors which were considered critical in identifying the most probable acute/short-term dietary threats: (1) well known historical use - name recognition - it has to be perceived as a threat by the public and the media, (2) accessibility of source material, (3) acute/short-term potency, (4) detectability - organoleptic or analytical, (5) stability and ease of handling and (6) transport stability in food. A wide-range of classes of potential chemical toxicants were assessed by an internal expert panel using this critical factors framework. The following classes were selected as the most pr obable threats on the basis of their numerical ranking: acetylcholine esterase inhibitors; (e.g., organophosphate pesticides), plant toxins - exquisitely potent and easy to work with in terms of stability and transport (e.g., ricin), pharmaceuticals - ease of availability and inherent toxicity, mushroom toxins - several classes demonstrate extreme toxicity, mycotoxins while more of a chronic issue several do demonstrate potent acute/short-term toxicity and marine toxins - while generally limited in their accessibility several are exquisitely toxic and are available (e.g., tetrodotoxin).

1898 RISK CHARACTERIZATION MODEL-1.1 AND AN ASSESSMENT AND CHARACTERIZATION FOR A RIOT-CONTROL AGENT.

M. Dourson[1], P. M. Nance[1], A. Maier[1], B. Hakkinen[1], P. Price[2], B. Klauenberg[3] and T. Dayton[4]. *[1]Toxicology Excellence for Risk Assessment (TERA), Cincinnati, OH, [2]LifeLine, Inc., Cape Elizabeth, ME, [3]USDoD/HEDR, Brooks AFB, TX and [4]Veridian Engineering, Brooks AFB, TX.*

Riot-control agents are important assets in nontraditional military operations, such as peacekeeping missions. DoD directives call for these weapons to achieve an appropriate balance between the competing goals of having a low probability of causing death, permanent injury, and collateral materiel damage, and a high probability of having the desired anti-personnel or anti-materiel effects. A conceptual framework for characterizing the risks of human effects from non-lethal weapons has been developed and applied to different types of weapon systems. From this framework a probabilistic software model illustrating how exposure and risk characterization modeling can be conducted for non-lethal weapons was developed. This Rick Characterization Model-1.1 was modified for use with the riot-control agent, o-chlorobenzylidene malononitrile (CS). The toxicity of this weapon, both mild and significant, has been characterized at a detailed level. However, aggregation of information is also given in order to compare the effectiveness and toxicity of this weapon in a limited number of different situations. The Risk Characterization Model (RCM-1.1) was modified to incorporate exposure variables and available data, and dose response information of CS to determine potential risks and benefits of its use. The human physiological measures of mild toxicity were the dose concentrations required to cause transient burning and pain of exposed mucous membranes and skin. The significant toxicity from possible longer-term exposure and possible high level exposure were included, as were the possible hazards from impact from the vehicle of CS delivery. This work was funded by Department of Defense under subcontract PO P66050-DSC0142.

1899 A RISK ASSESSMENT-BASED TOXICOLOGICAL WEIGHTING OF CIGARETTE SMOKE CONSTITUENTS.

C. Euchenhofer, J. Diekmann, B. Gerstenberg, R. Stabbert, K. Rustemeier and H. Haussmann. *INBIFO GmbH, Cologne, Germany.*

Characterization of the potential risks from chemicals are based on risk assessment, which deals with the qualitative classification of substances and/or the quantitative delineation of risk factors or reference concentrations thereof. To prioritize cigarette smoke constituents as targets for reduction, we applied the approach outlined in the USEPA guidelines for the comparative assessment of chemical mixtures (1986) and used published inhalation unit risks and reference exposure limits, e.g., Cal EPA (2002), for cancer and non-cancer risk estimates. Smoke constituent yields for the Reference Cigarettes 1R4F and 1R5F as well as 8 market brands were determined and weighted with the cancer and non-cancer risk factors. With this model, the ranking of calculated risks suggests that the major risk contribution comes from only a few gas phase constituents, e.g., 1, 3-butadiene and acrylonitrile for cancer and acrolein for non-cancer. This weighting approach can also be used in the comprehensive assessment of the smoke chemistry of new cigarette designs. In smoke from an electrically heated cigarette with ammonium magnesium phosphate in the overwrap, the yields of most smoke constituents were significantly reduced compared to the 1R4F, while a few were increased. Application of the weighting approach demonstrated an overall reduction in the calculated cancer and non-cancer risk estimates for the electrically heated smoking system compared to the 1R4F. Although this approach is somewhat limited by the uncertainty/lack of potency data and the inherent limitation of the chemical analysis of complex mixtures such as cigarette smoke, it can supplement the evidence obtained from experimental toxicological investigations for the overall evaluation of new cigarette designs.

1900 FEASIBILITY OF TESTING INGREDIENTS ADDED TO CIGARETTES.

D. M. Byrd, N. J. Emenaker, M. C. Falk, R. S. Feldman, C. J. Klein, K. D. Lewis, N. Pour-Moghaddam and J. Smith. *Life Sciences Research Office, Bethesda, MD.*

The Life Sciences Research Office (LSRO), a nonprofit, biological research organization, is currently reviewing the data relevant to testing ingredients added to cigarettes in order to ascertain their potential health risks, relative to cigarettes without the additives. The US Food and Drug Administration approved many of the nontobacco ingredients for use as food additives, often with Generally Recognized as Safe (GRAS) status. The Flavor and Extracts Manufacturers Association of the United States also recognizes many of these ingredients as safe for ingestion. However, few data exist concerning the toxicology of nontobacco ingredients when inhaled, either directly or as pyrolysis products. In addition, consumers inhale nontobacco ingredients (or their pyrolysis products) in combination with the combustion products of tobacco. LSRO assembled an Expert Committee of ten scientists, representing multiple disciplines to provide advice regarding the review, and divided the work into three phases: feasibility, scientific criteria, and detailed reviews. For the first phase of the project, LSRO's staff scientists have reviewed more than 1, 800 scientific publications and met with the Committee eight times to discuss and prepare a report about the feasibility of testing nontobacco ingredients added to cigarettes. The feasibility report will cover smoke generation, smoke properties, adverse health effects of smoking, testing principles, test data, and research recommendations. LSRO solicited public comments and held an open meeting in August 2002. Nontobacco ingredients added to cigarettes could change relative risks of smoking in any of three ways: (1) a direct effect of inhaling the additive (or its pyrolysis products) transferred in the smoke, (2) a change in the physics or chemistry of the smoke, or (3) a change in human smoking behavior. Transfer and pyrolysis of ingredients in smoke is crucial to the assessment of relative risks. Please see the LSRO web site at www.lsro.org for additional details. Work sponsored by Philip Morris USA.

1902 ACRYLAMIDE: A CASE STUDY IN HAZARD ASSESSMENT OF GENETIC TOXICITY.

S. H. Humphreys, P. M. Bolger and R. A. Canady. *Division of Risk Assessmente, Center for Food Safety and Applied Nutrition, College Park, MD.*

Recent discovery of acrylamide (A) in processed, carbohydrate-rich foods renews concerns initiated by its use as a flocculent in drinking water and as component of some plastics that could migrate into food. Exposure to A produced by processing of food is at much higher levels than A which migrates from wrappings, but still is orders of magnitude below most experimental dose levels. A is a reported animal mutagen and carcinogen and a human neurotoxin. Dose-response relationships for these endpoints are critical for policy and regulatory decisions for A. FDA concluded that A could be carcinogenic upon migration from plastic food-wrappings. In the case of germ cell mutagenicity, USFDA faces a particularly steep challenge in that widely accepted or standard extrapolation approaches are not available. Furthermore, general insight into the genotoxic potential of A through examination of mutagenicity data will be important in evaluation of mode of action for carcinogenicity. While positive results of A have been noted at some i.p. high doses, mutagenicity assays leave the scientific question of whether lower dietary doses would cause heritable mutations. Conversely, it is unclear whether doses sufficient to cause mutation will, without causing sterility, result in mutations conveying to offspring. Exposure timing is a critical factor for mutagenesis in mouse male germ cells. Exposure is most effective after the second meiotic division; continuous exposure would be required for continuous production of mutated sperm. The underlying policy question is how to appropriately consider this uncertainty in decision-making. A preliminary hazard analysis of dietary A shows potential hazard, but the relevance to human dietary exposure is equivocal. For risk assessment, further data are needed to justify extrapolations, such as *in vitro* to *in vivo* extrapolation, data which clearly define the dietary intake, effective human exposure from food matrices, and appropriate dose-response relationships.

1903 RISK ASSESSMENT OF ORAL EXPOSURE TO DIISONONYL PHTHALATE (DINP) FROM CHILDREN'S PRODUCTS.

M. A. Babich, M. A. Greene, S. Chen, W. K. Porter, C. T. Kiss, T. P. Smith and M. L. Wind. *US Consumer Product Safety Commission, Bethesda, MD.*

Diisononyl phthalate (DINP) is a plasticizer used in children's products such as soft plastic toys. DINP may be released when children mouth PVC products. The potential chronic health risks of phthalate exposure to infants have been investigated by regulatory agencies worldwide. Manufacturers voluntarily removed DINP from teethers and rattles in 1999, but DINP is still used in toys. This paper describes a CPSC staff risk assessment of DINP exposure from children's products. It has not been reviewed or accepted by the Commission. Key input data include DINP migration rates for a representative sample of soft plastic toys and an observation study of children's mouthing behavior. The acceptable daily intake (ADI) level of 120 μg/kg-d is based on chronic liver effects. Probabilistic risk assessment methods were applied. Mouthing behavior and, thus, exposure depend on the child's age. Estimated exposures for soft plastic toys (an estimated 42% of which contained DINP) by age are: 3 to 12 months old, mean, 0.07 (95% C.I. 0.03-0.13) μg/kg-d; 95th percentile, 0.44 (0.15-0.82) μg/kg-d; 12 to 24 months old, mean 0.08 (0.04-0.14) μg/kg-d; 95th percentile, 0.53 (0.24-0.89) μg/kg-d; and 24 to 36 months old, mean, 0.03 (0.01-0.06) μg/kg-d; 95th percentile, 0.12 (0.04-0.23) μg/kg-d. The authors conclude that oral exposure to DINP from mouthing soft plastic toys containing DINP is not likely to present a health hazard to children. Exposures were also estimated for several hypothetical cases, all assuming 100% prevalence of DINP. Estimated 95th percentile exposures for soft plastic toys; soft plastic toys, teethers, and rattles; all soft plastic objects; and all toys, teethers, and rattles for these hypothetical cases were below the ADI. (The opinions expressed by the authors do not necessarily represent the views of the Commission. This abstract is in the public domain and may be freely copied or reprinted.)

1904 CHEMICAL-SPECIFIC HEALTH CONSULTATION FOR CHROMATED COPPER ARSENATE (CCA) SPILL.

J. Colman[1], L. Ingerman[1], S. Chou[2] and C. Tylenda[2]. *[1]Environmental Science Center, Syracuse Research Corp, Syracuse, NY and [2]Agency for Toxic Substances and Disease Registry, Atlanta, GA.*

This health consultation was prepared to support assessment of the public health implications of leakage of large amounts of CCA from defective shipping containers to soil. Conclusions are applicable to other spills and releases of this chemical mixture. CCA, a wood-preserving pesticide, contains chromium(VI), arsenic(V), and copper(II) in an aqueous solution or concentrate. Concerns for long-term exposure to CCA included persistence in soil, potential runoff with consequent contamination of shellfish and fish, and leaching to sources of drinking water. Evaluation of experimental studies of CCA fate in soil and monitoring studies of wood-preserving facilities where CCA was spilled on the soil indicated that chromium(VI), arsenic, and copper can leach from soil into groundwater and surface water. Leaching potential decreased in the order chromium(VI)>arsenic>copper. CCA persisted in soil and remained leachable for years. Chromium(VI) is not likely to accumulate in fish and shellfish. Copper may accumulate in tissues of mussels and oysters. Arsenic may accumulate, primarily in a relatively nontoxic form, in tissues of fish and shellfish. Evaluation of health effects studies on CCA indicated little or no harm to workers exposed at low levels, but data were inadequate for derivation of a health guideline. Adverse effects in people and animals from high-level exposure were similar to those from the individual components of CCA. These effects included irritant or corrosive effects (all three components), dermal effects (arsenic), neurological effects [arsenic and chromium(VI)], hematological and renal effects (all three). Additional effects of concern for oral exposure to CCA include

hepatic effects (all three components) and cancer (arsenic). A weight-of-evidence analysis predicted that interactions among the components are likely to be less than additive or additive. Thus, no increase in toxicity beyond that expected from additive toxicity towards shared target organs is expected for CAA.

1905 COMPARATIVE EXPOSURE ASSESSMENT FOR THIMEROSAL MERCURY.

C. A. Williams[1], R. W. Freeman[1] and T. Herring[2]. *[1]Ecology & Environment, Inc., Tallahassee, FL and [2]Ecology & Environment, Inc., Lancaster, NY.*

Thimerosal (ethylmercurithiosalicyclic acid) is a mercury-containing preservative that has been widely used as a vaccine additive since the 1930s. Recent safety concerns and litigation over routine use of thimerosal-containing vaccines in infant immunization schedules have forced major manufactures of vaccine preparations to re-formulate their products or cease manufacturing, with unintended consequences including vaccine shortages and missed immunizations. Various agencies and organizations have developed exposure guidelines for methylmercury (but not for ethylmercury) ranging from 0.1 μg/kg/day (EPA reference dose) to 0.47 μg/kg/day (WHO daily tolerable intake). According to the immunization schedule recommended by the Centers for Disease Control and Prevention, infants may be exposed to a total mercury intake of 237.5 μg over the course of the first year and a half of life, or approximately 0.03 μg/kg/day. This is more than 3-fold lower than the EPA reference dose and more than 14-fold lower than the WHO daily tolerable intake. This is also from 2- to 70-fold lower than the daily dietary intake of mercury (1 - 30 μg). Repeated injections of thimerosal-containing gamma globulin have been reported to result in increases in blood mercury concentrations of 18 μg/L. This is only 9% to 36% of the background blood concentration found in consumers of mercury-containing seafood (50 - 200 μg/L). Thus, health threats from thimerosal-derived mercury exposure are more imagined than real and detract from far greater adverse public health consequences associated with missed vaccinations.

1906 ESTIMATED CHILDREN'S EXPOSURE TO DECABROMODIPHENYL OXIDE IN THE US.

C. A. Cushing[1], K. C. Holicky[1], D. W. Pyatt[1], D. Staskal[2], B. L. Finley[3], D. J. Paustenbach[4] and S. M. Hays[1]. *[1]Exponent, Boulder, CO, [2]Exponent, Oakland, CA, [3]Exponent, Santa Rosa, CA and [4]Exponent, Menlo Park, CA.*

The EPA's Voluntary Children's Chemical Evaluation Program (VCCEP) will provide information to the public on 21 chemicals, selected based on their presence in biomonitoring or environmental samples, by requesting that chemical manufacturers or importers quantify children's potential health risks from exposure. Included in the VCCEP is decabromodiphenyl oxide (DBDPO), one of the most widely used brominated flame retardants. The majority of DBDPO is used as a flame retardant for high-impact polystyrene products such as television cabinets. DBDPO is also applied to upholstery textiles as a back coat, to make the fabric flame retardant. Information from published literature and manufacturers about the uses and concentrations in various media was combined with data on the chemical and physical properties of DBDPO, and serum concentrations of DBDPO from workers exposed to DBDPO and blood donors thought to represent the general population, to characterize children's potential exposures to DBDPO. The exposure pathways evaluated were ingestion of breast milk, mouthing of consumer products containing DBDPO, and exposures *via* the general environment. Reasonable and upper estimates (REs, UEs) of intake were calculated for three different populations: 1) breast-feeding infants of mothers who manufacture DBDPO, 2) breast-feeding infants of mothers who disassemble T.V.s, and 3) a child's and adult's lifetime average exposures associated with DBDPO in the environment. The highest estimated exposure (representing a very conservative upper bound) was the UE for breast-feeding infants of mothers who manufacture DBDPO. The lowest was the RE for the lifetime environmental exposure scenario. The calculated exposures were combined with toxicity data to calculate non-cancer hazards. Exposures for all scenarios evaluated were significantly below the reference dose for DBDPO; therefore, based on this assessment, DBDPO is unlikely to pose a health risk to infants or children.

1907 DOSE-RESPONSE INVESTIGATION OF TRICRESYL PHOSPHATES POTENTIALLY PRESENT IN AIRPLANE CABIN AIR FROM JET ENGINE OILS.

G. M. Bruce, R. C. Pleus and M. K. Peterson. *Intertox, Inc., Seattle, WA.*

Tricresyl phosphate (TCP), a heterogeneous mixture of organophosphate aryl congeners, has been the subject of considerable toxicological interest due to its use in some synthetic jet engine oils to provide anti-wear properties and concerns regarding "incidents" of unintended venting of exhaust or vapors into aircraft cabins during flight. To assess possible toxicologic sequelae, we completed an exhaustive review of the scientific literature and a detailed dose-response assessment of TCPs under probable human exposure conditions. A primary effect of exposure to some TCP mixtures observed historically in some species, including humans, is organophosphate-induced delayed neuropathy (OPIDN), which manifests as a delayed neurological response up to two weeks after exposure. However, evaluation of this characteristic neuropathy reveals a striking dose-response threshold, dependent on the concentration of ortho-configured components in the mixture, below which toxicological effects are not observed. Unlike other organophosphates, toxic effects attributable to cholinesterase inhibition are not likely since the components of TCP are weak acetylcholinesterase inhibitors. Using dose-response data from exposure of the most sensitive animal species (chicken) to TCPs of differing ortho content, historical data from human accidental and occupational exposures, current engine oil compositional data, and assumptions about worst-case exposure conditions, the evaluation revealed that achievement of toxicological thresholds under probable exposure conditions in aircraft cabins is extremely unlikely.

1908 EPIDEMIOLOGICAL VALIDATION OF ENVIRONMENTAL CANCER RISK ASSESSMENTS: A CASE STUDY IN POPULATIONS EXPOSED TO POLYCYCLIC AROMATIC HYDROCARBONS.

M. Camus[2], A. Vyskocil[1] and C. Viau[1]. *[1]Environmental and Occupational Health, Université de Montréal, Montreal, QC, Canada and [2]Environmental Health Sciences Bureau, Health Canada, Montreal, QC, Canada.*

It has been proposed that epidemiological methods could validate locality-specific environmental cancer risk assessments (RA). We assessed the feasibility of this approach in populations exposed to polycyclic aromatic hydrocarbons (PAH) in 6 aluminium smelting and 4 other communities in Quebec. Lifetime lung cancer risks predicted for these communities on the basis of PAH and benzo(a)pyrene (BaP) levels measured in the early 1990s were converted to equivalent annual incidence rates among women. We compared these predictions with statistically detectable incidence rates based on a Poisson sample size formula. We then used robust weighted linear regression to estimate an exposure-response gradient between female lung cancer rates (1989-1993) and BaP exposure levels measured during those years. The highest upper bound estimate of the lifetime risk of lung cancer was 89 x 10^{-5}. The corresponding excess incidence rate (1 x 10^{-5} x $year^{-1}$) was 9 times smaller than what could be detected statistically over the 1989-1993 period in that community. Indeed 380 years of observation would be required for that excess to become statistically significant. If however exposures were 10 times higher before 1970, the predicted excess incidence of 10 x 10^{-5} x $year^{-1}$ today would require only 4 years of data (100 times less) to be significant. A linear regression model based on "dispersion-adjusted" exposure estimates showed an exposure-response gradient (P=0.035) across the 10 communities. This gradient would match the BaP-based RA if pre-1970 exposures had been 54 (95% CI 5-103) times higher than today, akin to Alcan's own guesstimate of 7 times. Although RAs may be the only option to assess health impacts of low levels of carcinogens in small populations, epidemiological studies may have the statistical power to assess impacts of past environmental exposures one order of magnitude higher than today under certain conditions.

1909 AN ESTIMATION OF CANCER RISKS POSED BY EXPOSURE TO PARTICULATE MATTER IN AIR IN SANTIAGO, CHILE.

H. Ochoa-Acuna and S. M. Roberts. *University of Florida, Gainesville, FL.*

The objective of this analysis was to conduct a two-dimensional probabilistic risk assessment for lung cancer from exposure to respirable particulate matter in Santiago, Chile. Small particulate air pollution in Santiago has increased dramatically since the 1980s due to an increase in the number of motor vehicles. The problem is particularly severe during the winter, when air dispersion of particulates is reduced. Lung cancer risks from inhalation of particulates were estimated using three different approaches based on the PM2.5, diesel exhaust (DE), and polycyclic aromatic hydrocarbon (PAH) composition of air. The DE concentration in air was estimated from PM10 measurements and previous analysis of the proportion of PM10 due to DE in Santiago. Annual average concentrations from 1996 were used, the most recent data set with information needed to derive all three air concentrations of interest (DE, PM2.5, and PAHs). Outdoor air concentrations were corrected to reflect personal breathing zone exposure using comparison data from children living in Santiago. For DE, cancer risks were estimated using two different inhalation unit risk (IUR) ranges, one developed by the CalEPA and the other from an exploratory analysis conducted by the USEPA. Cancer risks from PM2.5 were estimated using data from a large prospective mortality study focusing on PM2.5 (Pope et al., JAMA 287:1132-1141, 2002). Lung cancer risks for PAHs were estimated using an IUR for benzo(a)pyrene. Excess lung cancer risks from DE and

PM2.5 were both in the single-digit percent range. Predicted excess lung cancer risks from PAHs were orders of magnitude lower, suggesting that PAHs in DE and PM2.5 are not the primary source of the large lung cancer risks from particulates. Given the lag time for lung cancers, the full consequences of the recent deterioration in air quality in Santiago may not yet be apparent. However, it may be relevant to note that while mortality from most cancer types has decreased in Chile since 1970, mortality due to lung cancer has doubled.

1910 RISK COMPARISONS OF EXHAUST EMISSIONS FROM SCHOOL BUSES IN COMPRESSED NATURAL GAS, LOW-EMITTING DIESEL, AND CONVENTIONAL DIESEL ENGINE CONFIGURATIONS.

C. Lapin[1], T. W. Hesterberg[2], W. B. Bunn[2] and C. R. Clark[3]. *[1]Lapin and Associates, Glendale, CA, [2]International Truck and Engine Corporation, Chicago, IL and [3]ConocoPhillips, Tempe, AZ.*

This study compared the emissions profiles of three currently available school bus configurations: conventional diesel, low-emitting diesel and natural gas. The low emitting diesel engine used Green Diesel Technology® (catalyzed diesel particulate filter, a low nitrogen oxides (NOx) engine control module, and ultra-low-sulfur fuel). Each engine configuration was tested three times with each test consisting of three consecutive runs of the City-Suburban Heavy Vehicle Cycle. Regulated and unregulated emissions were analyzed using standard methods. Twenty-one of the 41 toxic air contaminants (TACs) listed by the California Air Resources Board as being present in diesel exhaust were not found in the exhaust of any of the vehicles tested despite very low detection limits. The conventional diesel had the highest emissions for five TACs. Natural gas exhaust had higher levels of six TACs (acetaldehyde, acrolein, benzene, formaldehyde, methyl ethyl ketone, propionaldehyde) compared to low-emitting diesel. None of the TAC emissions of the natural gas vehicle were lower than the low-emitting diesel. Low-emitting diesel had the highest emissions of nitrogen dioxide (NO2) and carbon dioxide (CO2); but had the lowest emissions of NOx, nitrogen oxide (NO), particulate matter (PM), soluble organic fraction of PM (SOF), total hydrocarbons (THC), non-methane hydrocarbons (NMHC), methane, and carbon monoxide (CO). Natural gas had the highest emissions of NOx, NO, THC, NMHC, methane and CO, but the lowest emissions of CO2 and lower emissions of NO2 than low-emitting diesel. Both the natural gas and low-emitting diesel buses had essentially no sulfate emissions. Both cancer and non-cancer potency weighted emissions were lowest for the low-emitting diesel vehicle. Overall, the low-emitting diesel technology had the lowest risk from emissions associated with EPA criteria pollutants and TACs.

1911 POTENTIAL HEALTH IMPACTS OF A MAJOR TIRE FIRE AT WESTLEY, CA IN SEPTEMBER 1999.

R. J. Blaisdell[1], M. Lipsett[1], M. A. Marty[1], K. Stroud[2] and G. Zimmerman[2]. *[1]Office of Environmental Health Hazard Assessment, Oakland, CA and [2]California Air Resources Board, Sacramento, CA.*

The California Air Resources Board conducted air monitoring during the Westley Tire Fire. Air monitoring data can be useful in prioritizing the potential health impacts from major tire fires and identifying appropriate public health responses and recommendations. PM-10, carbon monoxide, black carbon, 1, 3-butadiene, benzene, metals and PAHs were monitored for several weeks during the tire fire at populated sites. PAHs monitored include: benzo (b) fluoranthene, benzo (k) fluoranthene, benzo (a) pyrene, dibenz (a, h) anthracene, benzo (ghi) perylene and indeno (1, 2, 3-cd) pyrene. Elevated PM-10 levels were identified as posing the greatest risk to public health based in part on the air monitoring results. Airborne PAH levels monitored during the Westley tire fire did not appear to significantly increase lifetime cancer risk relative to routine exposures. Monitored levels of metals did not appear to pose a threat to public health based on comparison with California Reference Exposure Levels. Favorable meteorology and other factors ameliorated the potential public health impacts. However, a major tire fire under different circumstances could result in very serious public health impacts.

1912 RISK ASSESSMENT OF POLYCHLORINATED BIPHENYLS AT HAZARDOUS WASTE SITES.

M. J. Wade and B. K. Davis. *Department Toxic Substances Control, Cal EPA, Sacramento, CA.*

We recently reported on a hazardous waste site with polychlorinated biphenyl (PCB) vapors in indoor air in housing units built over soil contaminated with the PCB mixture Aroclor 1260. This poster illustrates chemistry, exposure assessment and toxicity issues associated with PCB risk assessment. Commercial mixtures of PCBs, e.g. Aroclors, consist of different combinations of the 209 individual PCB congeners. Environmental fate and transport processes change the congener composition following release into the environment. This was demonstrated by the preponderance of mono- and dichlorinated congeners in indoor air resulting from an Aroclor 1260 spill containing mostly penta- to octachlorinated congeners. Long term toxicity studies, and hence toxicity criteria, are only available for Aroclors rather than individual congeners. Our findings showed that PCB mixtures at a waste site may be quite different than mixtures on which toxicity criteria are based. USEPA currently provides three cancer slope factors ranging from 0.07 to 2.0 (mg/kg-day-1) based on bioassays of Aroclors 1260, 1254, 1242, and 1016 and the exposure route, exposure medium and congener makeup; Cal-EPA uses the same range of slope factors and slightly different selection criteria. Additionally, non-cancer toxicity is of concern at relatively low doses. For example, doses of Aroclor 1016 predicting a cancer risk above 5E-6 are associated with an unacceptable non-cancer hazard. Consideration of dioxin-like activity of individual congeners is also appropriate but consensus methods are unavailable. Exposure assessment of PCBs is complicated by the bioaccumulative properties, necessitating consideration of potential for food chain exposure and by the low-level ambient presence of PCBs in environmental media including air, soil and food and a paucity of physical chemical and physiological data needed to characterize the potential for other exposures such as infants exposed *via* breast milk.

1913 RISKS TO CHILDREN FROM EXPOSURE TO LEAD IN AIR DURING REMEDIAL OR REMOVAL ACTIVITIES AT SUPERFUND SITES: A CASE STUDY OF THE RSR LEAD SMELTER SUPERFUND SITE.

G. A. Khoury[1] and G. L. Diamond[2]. *[1]USEPA, Kansas City, KS and [2]Environmental Science Center, Syracuse Research Corp, Syracuse, NY.*

This study explored modeling approaches for assessing potential risks to children from air lead emissions during removal of a smelter facility. The EPA Integrated Exposure Uptake Biokinetic (IEUBK) model and the International Commission of Radiologic Protection (ICRP) lead model were used to simulate blood lead concentrations (PbB) in children, based on monitored air lead concentrations. Although air lead concentrations at monitoring stations located in the downwind community intermittently exceeded the NAAQ standard for lead (1.5 μg/m3), both models indicated that exposures to children in the community areas did not pose a significant long-term or acute risk. Long-term risk was defined as greater than 5% probability of a child having a long-term PbB that exceeded 10 μg/dL, the CDC and the EPA concern level. Short-term or acute risk was defined as greater than 5% probability of a child having a PbB on any given day that exceeded 20 μg/dL, the CDC trigger level for medical evaluation. The models were also used to estimate air lead levels for short- or long-term exposures that would not exceed specified levels of risk (risk-based concentrations, RBCs) for given daily exposure durations (3 or 8 hr/day) or frequencies (1-7 days/week). RBCs for long-term exposures, based on the ICRP model, ranged from 0.3 (7 days/week, 8 hr/day) to 4.4 μg/m3 (1 day/week, 3 hr/day) and were lower than those based on the IEUBK model (1.9-18 μg/m3). RBCs short-term exposures based on the ICRP model ranged from 3.5 to 29.0 μg/m3. Recontamination of remediated residential yards from deposition of air lead emitted during remedial activities at the site was also examined. The increase in soil lead concentration due to lead deposition in the community at large was predicted to be 3.0 mg/kg; this would be less than 1% increase when compared to the cleanup level of 500 mg/kg developed for residential yards at the site. (Views are those of the authors and not necessarily of any Federal agency or department.)

1914 HUMAN HEALTH RISK EVALUATION OF STRUCTURAL SURFACES CONTAMINATED WITH METALS.

K. W. DiBiasio and K. Klein. *Toxic Substances Control, CalEPA, Sacramento, CA.*

Contaminated surfaces, such as the walls and/or floors inside a former manufacturing facility, on occasion generate concern for potential human health risks. A responsible party may seek the consensus of a regulatory environmental agency on the potential human health risks and hazards from exposures to indoor structural surfaces by workers, or children residents as a conservative screening tool. The involvement of the Human and Ecological Risk Division in such cases has resulted in the development of spreadsheets to evaluate risks and hazards and calculate site-specific chemical-specific surface screening goals. The spreadsheets utilize exposure parameters based on professional judgment, since no regulatory guidance currently exists on the subject. The exposure parameters developed include skin surface area for dermal exposures as well as for inadvertent oral exposure, contact frequency, transfer efficiency from surface to skin, and fraction of contaminant transferred from skin to mouth. Analytical chemistry results from wipe samples of indoor building surfaces were the source of the exposure point concentrations and toxicity criteria recommended by the California Environmental Protection Agency were employed. The chemicals evaluated were arsenic, cadmium, chromium, copper, cyanide, nickel and zinc. The risk evaluations did not include potential exposures *via* other sources, such as soil or groundwater. Further research quantifying expo-

sure parameters from contact with structural surfaces will reduce the uncertainty in the risk estimates and likely generate less conservative structural surface screening goals.

1915 THE EFFECT OF CENSORED DATA ON THE PERFORMANCE OF TECHNIQUES FOR CALCULATING 95% UPPER CONFIDENCE LIMITS (95% UCLS) ON THE MEAN.

C. J. Saranko[1], C. F. Mills[1], J. K. Tolson[2], S. M. Roberts[2] and K. M. Portier[2].
[1]GeoSyntec Consultants, Tampa, FL and [2]University of Florida, Gainesville, FL.

The upper 95% confidence limit on the mean (95% UCL) is often used as an upper-bound estimate of average contaminant concentration for risk assessments at hazardous waste sites. Statistical techniques used to calculate 95% UCLs often rely on underlying distributional assumptions. However, sampling datasets from contaminated sites may contain a number of values below the detection limit. For the calculation of exposure point concentrations, these values are typically assigned a proxy concentration of one-half of the detection limit. This practice results in a left-censored dataset, and in some situations the extent of censoring can be substantial. Limited guidance exists for handling censored datasets. The most common approach is to calculate a 95%UCL from the full dataset, including the censored values. The effects of this approach on distributional tests and 95% UCL techniques were evaluated using simulated lognormal datasets with known distribution parameters and fixed levels of data censoring. Censoring was found to profoundly affect the ability of standard tests to correctly identify the underlying distribution. Several methods for calculating the 95% UCL also performed poorly with censored datasets. The extent of the effect of censoring on calculation of the 95% UCL depended upon the method of calculation and the sample size and skewness of the dataset. For example, the non-parametric bootstrap method performed well with sample sizes of 50 and mildly skewed data with no censoring, but underestimated the true mean 27% of the time (rather than the target 5% value for a 95% UCL) when 50% of the data were censored. Other methods performed better with censored data. The results of this analysis can be used to guide the selection of the distributional tests and UCL techniques depending on degree of censoring of site-specific datasets.

1916 COMPARISON OF TECHNIQUES FOR CALCULATING 95% UPPER CONFIDENCE LIMITS (95% UCLS) ON THE MEAN.

C. F. Mills[1], C. J. Saranko[1], J. K. Tolson[2], S. M. Roberts[2] and K. M. Portier[2].
[1]GeoSyntec Consultants, Tampa, FL and [2]University of Florida, Gainesville, FL.

Exposure point concentrations used in risk assessments should reflect the average contaminant concentrations encountered by a receptor at a site. This parameter is typically represented by the upper 95% confidence limit on the mean (95% UCL) of an often limited site dataset. Numerous statistical methods are available for the calculation of 95% UCLs, however, they often yield disparate results. There is currently little guidance related to their appropriate application. In the present analysis, we have systematically evaluated the performance of several 95% UCL techniques using simulated distributions with known population parameters. The UCL techniques evaluated were: central limit theorem (CLT), standard bootstrap, bootstrap-t, Students-t, H-statistic (Land's method), MVUE and MLE based, and Chebyshev's methods. For each method, 95% UCLs were calculated for simulated datasets of different sample sizes and skewness. By comparing the 95% UCLs with the underlying simulation expected value, the coverage of each technique (i.e., the proportion of times the true population mean lies at or below the 95% UCL) was evaluated. The extent to which the true mean was overestimated by the 95% UCL for each technique was also determined. The analysis revealed that small sample sizes and highly skewed data are particularly problematic, and depending on the technique, can result in poor coverage or significant over-estimation of true site contamination. For example, using a simulated lognormal distribution [LN (100, 200)] and a sample size of 10, the CLT method generated 95% UCLs that were, below the true mean from which the data were drawn 26% of the time. With the same simulated dataset, the H-statistic 95% UCL had better coverage (1% of means were under predicted) but some 95% UCLs calculated with this method exceed the true mean by more than 100-fold. The results of this analysis can be used to guide the selection of the best UCL technique depending on attributes of site-specific datasets.

1917 HEALTH RISKS FOR CONSTRUCTION WORKERS IN INDUSTRIAL REDEVELOPMENT: A MAJOR RISK DRIVER?

S. Schettler, M. R. Seeley and B. D. Beck. *Gradient Corporation, Cambridge, MA.*

Redevelopment of former industrial areas may result in exposure of construction workers to historical subsurface contamination. A human health risk assessment addressing such exposures was performed for a site near a former manufactured gas plant in Kansas City, MO. This site had unique construction-phase exposure scenarios because of proposed future residential and commercial uses, including potential construction of a Federal Reserve Bank building requiring excavation of contaminated soil to 40 feet below ground surface. The primary chemicals of concern (COCs) were volatile organic compounds (VOCs), polycyclic aromatic hydrocarbons (PAHs), coal tar, and a petroleum hydrocarbon (diesel). Because of the spatial heterogeneity of the soil and groundwater data for these COCs, we divided the site into six exposure zones and estimated risks for the two most contaminated zones. Exposure pathways included dermal contact with soil and groundwater; incidental soil ingestion; and inhalation of air in construction pits, trenches, and buildings. We estimated cancer risks and non-cancer hazards for construction and utility workers during the construction phase and for future residents and office workers in the post-construction phase. We also estimated risks for exposure to coal tar, which was noted in the soil boring logs, but not quantified analytically. Cancer risks for the construction and utility workers exceeded Missouri's acceptable risk of 1 x 10-5 in two exposure zones and non-cancer hazards exceeded 1.0 in one exposure zone. There were no unacceptable risks for either residents or office workers in the post-construction phase. Because estimated risks to the construction and utility workers exceeded state criteria, risk reduction measures prior to construction were recommended.

1918 DERIVATION OF AIR ACTION LEVELS FOR USE IN MONITORING DURING SITE REMEDIATION.

L. Beyer and B. D. Beck. *Gradient Corp., Cambridge, MA.*

Air monitoring is often conducted during site remediation to ensure that the surrounding community is not adversely affected by chemicals released during remediation. For this project, our goal was to identify air action levels, expressed in terms of air concentrations protective of subchronic exposures, that could be used as the basis of air monitoring during remediation at an inactive industrial property with a predominance of coal tar constituents. We identified the chemicals that are important contributors to risk at such properties, developed toxicity criteria for each, then calculated air action levels - levels that could be used as a basis for air monitoring and risk management actions during site remediation. An important challenge to this effort was the translation of the toxicity criteria based on subchronic exposures to shorter-term air action levels for use in decision-making. We evaluated two classes of compounds: volatile organic compounds (VOCs) and particulates. For VOCs we developed toxicity criteria for subchronic exposure based on a review of the primary literature for benzene, toluene, and xylene. For particulates we evaluated lead, benzo(a)pyrene, and naphthalene. We calculated action levels based on toxicity criteria, which were derived based on primary literature with adjustments to reflect an anticipated remediation schedule of 5 days per week, 10 hours per day. The action levels were then calculated based on frequency of continuous monitoring and the site remediation schedule. A particular action level could be exceeded during the monitoring period as long as the average value was in compliance. The point of compliance was conservatively chosen as the site boundary, where few residents would be exposed for continuous periods. We developed the following action levels for 15-minute measurement periods which are protective of subchronic exposures: benzene 0.5 ppm; toluene 7 ppm; xylenes 7 ppm; lead 4 mg/m^3; naphthalene 16 mg/m^3; and benzo(a)pyrene 1 mg/m^3.

1919 RISK-BASED ACTION LEVELS FOR FENCE-LINE MONITORING PROGRAMS.

L. J. Bradley and K. Sullivan. *ENSR, Westford, MA.*

Risk-based action levels (RBAL) for a fence-line monitoring program should adequately address both project needs and the protection of human health. Issues to be considered and addressed in the development of risk-based action levels include the following. 1) Receptors. Off-site receptors should be identified, and appropriate receptors should serve as the basis for the fenceline air standard. 2) Timeframe of remediation. RBALs for a fenceline program should be developed within the context of potential human exposure periods. In toxicology, appropriate exposure periods to consider are: Acute (less than 24 hours up to 3 months); Subchronic (3 months up to 7 years); and Chronic (greater than 7 years). RBALs should be developed to address each of these exposure durations, depending on the intended length of the remediation. Potential noncarcinogenic health effects should be considered for each exposure duration, however, chronic exposure durations are generally not anticipated for a remediation project. Potential carcinogenic effects are most appropriately considered for the chronic exposure duration, however, they can also be considered for the subchronic exposure duration. 3) Toxicity values. Appropriate chemical-specific toxicity values from the USEPA should be employed in the RBAL calculations. This includes the use of subchronic toxicity values. For benzene, the range of toxicity values provided by USEPA for addressing the potential carcinogenic effects at a given target risk level should be used in developing the RBALs; ideally a range of standards should be developed for benzene where any air monitoring data within that range would be considered to have not exceeded the RBAL.

4) Point of Exposure. Where potential receptors are not at the fenceline, air modeling should be used to calculate an RBAL to be protective of the receptors at the point of exposure.

1920 A SOIL CONCENTRATION LIMIT FOR LEAD BASED ON ACUTE EXPOSURE IN CHILDREN.

B. K. Gadagbui[1], J. G. Pounds[2], T. W. Simon[3] and S. M. Roberts[1]. *[1]University of Florida, Gainesville, FL, [2]Pacific Northwest Laboratory, Richland, WA and [3]USEPA Region 4, Atlanta, GA.*

Lead-contaminated soil is a potential public health problem in many parts of the United States. Current regulatory limits for lead in soil are based on chronic exposure. There are some situations, however, where exposure may be brief. Risk management for these situations would benefit from an assessment of lead concentrations in soil that pose a risk from acute exposure. This analysis was conducted in order to derive a concentration limit for lead in soil protective of acute exposure for a small child. Based on information in the USEPA Child-Specific Exposure Factors Handbook, a small child was assumed to be capable of ingesting, during a one-time pica episode, 10 g of soil. For this dose of soil, a concentration limit was sought that would result in a peak concentration of lead in blood no more than 60 mcg/dL, based on clinical observations of children with acute lead intoxication. The Leggett model was selected to model blood lead (PbB) concentrations resulting from acute lead ingestion. While several models predict PbB concentrations, the Leggett model has the critical features of scaling for children with the ability to model PbB concentrations after an acute dose. The dose-dependent oral bioavailability of lead in juvenile non-human primates was used to derive the estimate of gastrointestinal lead absorption. The baseline PbB concentration (before acute exposure) was defined as 2.5 mcg/dL. PbB concentrations were modeled with and without non-linear partitioning of lead into red blood cells. Assuming non-linear partitioning, the model predicted a peak PbB concentration matching the target limit of 60 mcg/dL for acute ingestion of 10 g of soil at 7, 800 mg lead/kg soil. Assuming linear partitioning, the soil lead concentration corresponding to the target peak PbB concentration was 6, 800 mg/kg. The results of this modeling exercise may be useful in evaluating risks posed by lead contaminated soils at sites where children may be present, but are not expected to have long-term contact.

1921 EVALUATING THE BIOAVAILABILITY OF METALS IN SOILS FOR USE IN HUMAN HEALTH RISK ASSESSMENT.

M. J. Beringer[1] and P. C. Grevatt[2]. *[1]USEPA, Kansas City, KS and [2]USEPA, Washington, DC.*

Site-specific bioavailability is an important consideration in determining potential threats to human health that are posed by metals-contaminated soils at waste sites. It is important to consider bioavailability because metals may be absorbed to a lesser or greater extent following ingestion of contaminated soils as compared to the fraction absorbed in the studies used to establish toxicity values, such as a reference dose or a cancer slope factor. USEPA's Office of Solid Waste and Emergency Response led an effort to develop additional guidance on evaluating and incorporating bioavailability adjustments into human health risk assessments. A decision framework was developed for data collection and utilization of bioavailability data at waste sites. The framework consists of a tiered approach which is intended to both improve risk estimates made at specific sites where the framework is applied, as well as to encourage the expansion of a knowledge base that can be applied to future assessments of bioavailability of metals in soils at all sites. Available bioavailability data on arsenic and other metals were also evaluated to determine if alternative default values for adjusting relative bioavailability could be derived. This paper summarizes these activities and other ongoing USEPA efforts on bioavailability.

1922 DEVELOPMENT OF CHILD-SPECIFIC HEALTH CRITERIA FOR SCHOOL SITE RISK ASSESSMENT.

S. A. Knadle[1], D. W. Chan[1] and K. E. Stewart[1,2]. *[1]Office of Environmental Health Hazard Assessment, California EPA, Sacramento, CA and [2]Environmental Toxicology, University of California, Davis, CA.*

The Office of Environmental Health Hazard Assessment (OEHHA) in the California Environmental Protection Agency (Cal/EPA) is responsible for evaluating health risks for environmental chemicals. Recent legislation has required development of health criteria for School Site Risk Assessment pursuant to California Health and Safety Code 901(g). The first part of the mandate is to identify chemical contaminants at school sites which may be of concern because of child-specific exposure and child-specific physiological sensitivities. OEHHA has identified a group of candidate chemicals that will likely include contaminants found at school sites (comprising approximately 200 chemicals), and another group that has the potential for causing adverse effects on school-age children (approximately 198 chemicals). This report is available on the OEHHA website at http://www.oehha.ca.gov. The second part of the mandate is to make available child-specific numerical health guidance values for five of the chemical contaminants each year. OEHHA selected the first five chemicals on the basis of: 1) those which had been identified by Department of Toxic Substance Control monitoring studies to be present at proposed school sites, 2) those for which review articles presented evidence of possible adverse effects in three or more of the systems that are undergoing critical development during childhood, 3) chemicals that other OEHHA programs had identified as a regulatory concern, and 4) carcinogens for which existing adult 1 x 10-4 cancer risk dose might not be protective of non-carcinogenic risks to children. After completing in-depth review of the scientific literature for relevant chemicals, OEHHA has proposed child-specific reference doses (RfDs) for cadmium, chlordane, heptachlor, methoxychlor, and nickel. OEHHA's process for approval of proposed child-specific RfDs is to undergo internal peer review, public comment, and external peer review with University of California faculty. The child-specific RfDs will be presented.

1923 MINERALOGICAL DILEMMAS IN EVALUATING THE HUMAN HEALTH IMPACTS OF ASBESTOS IN COMMERCIAL MINERAL DEPOSITS.

B. S. Van Gosen, G. P. Meeker, G. S. Plumlee and T. L. Ziegler. *USGS, Denver, CO.*

The term asbestos, a commercial-industrial term rather than a mineralogical term, refers to well-developed, long, thin (fibrous) particles and bundles of specific minerals that fulfilled particular industrial applications. Most commonly 6 mineral species are defined as asbestos in the US, including a member of the serpentine group (chrysotile) and 5 minerals of the amphibole group: asbestiform varieties of riebeckite (commercially called crocidolite), cummingtonite-grunerite (amosite), anthophyllite, actinolite, and tremolite. Recently, debate has focused on the potential health effects from airborne exposures to mineral particles that do not completely fit some definitions of asbestos. These particles include amphiboles that: a. produce an abundance of fibrous particles when crushed or b. display asbestiform textures, but do not have chemical compositions that fit the precise mineralogical definitions of the asbestos minerals listed above. Adding to the dilemma of classifying amphibole particles and their health effects is the difficulty of distinguishing, under high magnification, the difference between long, thin cleaved fragments formed by fracturing versus fibers formed by mineral growth. Much of the difficulty in determining the presence of asbestos in talc deposits centers on transitional fibers, which are fibrous mineral particles composed of talc and amphibole in various proportions. There is disagreement regarding the potential long-term health impacts resulting from airborne exposure to the various particles described above. Collaborative research is needed between the geosciences and biomedical/public health communities to refine the classification of asbestos minerals. This collaboration must include toxicological research that can identify the roles and processes responsible for deleterious effects to humans after exposure to amphibole-bearing materials. Such research should include mineralogical study to determine if the airborne particles can be effectively defined by chemical composition, geometry, or other means.

1924 DISSOLVED ORGANIC CONSTITUENTS IN COAL-ASSOCIATED WATERS, AND IMPLICATIONS FOR HUMAN AND ECOSYSTEM HEALTH.

A. B. Santamaria[2] and J. Fisher[1]. *[1]Environmental, Exponent, Tulsa, OK and [2]Health Risk Assessment, Exponent, Houston, TX.*

Decisions concerning the disposal or use of waters produced during the production of coalbed methane (CBM) are typically made based on water quality as expressed by the salinity and/or inorganic ionic constituency. The quality of CBM water is frequently evaluated in terms of its suitability for irrigation. Water that has acceptable salinity and sodium adsorption ratio is considered safe for surface discharge and for potential injection into a drinking-water aquifer. It is important to remember, however, that water associated with coal seams, independent of its inorganic constituents, may contain dissolved organics and other constituents at levels that may adversely affect human health and the environment. It is well known that coal, lignite, or coaly materials present in aquifers used as drinking-water supplies are associated with adverse or potentially adverse human health effects. Water produced from coal-associated aquifers has been linked, or is suspected to be linked, to goiter, Balkan Endemic Nephropathy (BEN), multiple sclerosis, and increased rates of cancer morbidity and mortality. Water-soluble organic compounds found in coals include goitrogens such as the hydroxyphenols resorcinol, 2-methyl resorcinol and 5-methylresorcinol (orcinol), and hydroxypyridines. Well waters containing poly-

cyclic aromatic hydrocarbons, aniline, aminophenols, and aromatic amines leached from low-rank Pliocene coals may be the cause of, or a contributing factor to, BEN, an incurable interstitial nephropathy that is believed to have killed more than 100, 000 people in the former Yugoslavia alone. There are few, if any, systematic and comprehensive analyses of dissolved organic compounds in CBM-produced water. Prudence suggests that the dissolved organic constituents in CBM-produced water should be systematically characterized, and their potential for harm to human health and the environment should be evaluated before potentially harmful chemicals are discharged to the environment or released to drinking-water aquifers.

1925 COMMUNICATION OF WORKPLACE HAZARDS - TOPIC CENTRE GOOD PRACTICE, SYSTEMS AND PROGRAMMES.

K. Savolainen[1], K. Kumpulainen[1], C. Roberts[2] and T. Tregenza[2]. *[1]Department of Industrial Hygiene and Toxicology, Finnish Institute of Occupational Health, Helsinki, Helsinki, Finland and [2]European Agency for Safety and Health at Work, Bilbao, Spain.*

The Topic Centre Good Practice, Systems and Programmes has been established in 2002 to promote the aims of the European Agency for Safety and Health at Work to collect, evaluate and disseminate relevant information on good practices at workplace level and occupational safety and health (OSH) systems and programmes in Europe. The Topic Centre, consisting of 14 European OSH institutes, is a part of the Agency's network build up on Focal Points in EU Member and Candidate States, Thematic Network Groups and expert groups. As an important part of its work, the Topic Centre aims to raise awareness of chemical safety at workplaces. In 2002, the Topic Centre disseminates and maintains Internet sites for several industries and topics, and studies the information needs of Fisheries sector and success criteria of assistance schemes for the small, and medium sized enterprises and integration of OSH, including prevention of chemical hazards into Education. In addition, material is provided to support the European OSH weeks. The Agency network provides the Topic Centre with examples and other material on workplace practices and OSH systems and programmes around Europe. The Topic Centre gathers material from the Internet and literature. Each product of the Topic Centre is validated within the Agency's network for relevance and suitability to its target group. For the promotion of chemical safety, the Topic Centre has provided evaluated and maintained the website on good practices related to dangerous substances. Articles, fact sheets and a report on communication of risks of dangerous substances have been produced. Studies on integration of OSH thinking, success criteria of assistance schemes and fisheries sector information needs have detected several new methods need to be utlised in the future for chemical safety promotion. The Topic Centre work has proven to be effective and efficient network, which can tackle communication of OSH with various aspects and methods.

1926 CATEGORIZATION OF THE ASSOCIATIONS BETWEEN EXPOSURE TO THE HERBICIDES USED IN VIETNAM OR THEIR CONTAMINANTS AND HEALTH OUTCOMES.

M. C. Catlin, J. A. Cohen and A. B. Staton. *Institute of Medicine, The National Academies, Washington, DC.*

Between 1962 and 1971 military forces sprayed herbicides over Vietnam. In 1991, because of ongoing uncertainty about the long-term health effects on Vietnam veterans of the herbicides sprayed, Congress passed the Agent Orange Act of 1991. That legislation directed the Secretary of Veterans Affairs to request the National Academy of Sciences, a non-profit organization that provides independent, objective advice on scientific issues, to perform a comprehensive review and evaluation of scientific and medical information regarding the health effects of exposure to Agent Orange, other herbicides used in Vietnam, and the various chemical components of those herbicides, including dioxin. In assessing the evidence of an association between exposure to the herbicides and their components and a health outcome, the committees responsible for the reports review the available literature and categorize the evidence as 1) sufficient of an association; 2) limited or suggestive of an association; 3) inadequate or insufficient to determine whether an association exists; or 4) limited or suggestive of NO association. In addition, conclusions regarding the biological plausibility of the health effects and the risk to Vietnam veterans are also made. Biennial updates are produced; the latest of those reports is Veterans and Agent Orange: Update 2002, which will be released in December 2002. The assessments in the reports are used by the Department of Veterans Affairs to make policy decisions regarding compensation to veterans for service-related illnesses. The methods used by the committee as well as the most recent conclusions made by the committee will be discussed.

1927 MORE THAN 10, 000 ANIMALS ARE REQUIRED FOR THE REGISTRATION OF A SINGLE PESTICIDE - THIS PARADIGM MUST BE CHANGED.

J. L. Mattsson[1], D. L. Eisenbrandt[1] and J. E. Doe[2]. *[1]Dow AgroSciences, Indianapolis, IN and [2]Syngenta CTL, Alderley Park, Cheshire, United Kingdom.*

More than 10, 000 mice, rats, rabbits, guinea pigs and dogs are used for toxicity studies to satisfy regulatory data requirements for the registration of a single pesticide product. Although data requirements depend upon use patterns, most of the focus of the toxicity testing is driven by concern for pesticide residues in food. On the other hand, analyses from the University. S. Department of Agriculture (PDP 2000) show that dietary exposures to pesticide residues in food are not measurable or are very small. In contrast, foods have hundreds of times more intrinsic self-defense chemicals (natural pesticides) than synthetic pesticide residues and, when tested, some of the natural pesticides are genotoxic, carcinogenic, developmental toxicants or cause other effects. Still, with few exceptions, there is a long history of food consumption without apparent harm, providing a practical demonstration of efficient detoxification mechanisms in real life. Obviously, our bodies do not distinguish between natural and synthetic chemicals, but only among chemical structures. These considerations have led to at least one approach that resulted in the reduction in the number of animals used in hazard evaluation. The University. S. Food and Drug Administration (FDA) evaluates the safety of food additives by assigning a concern level based on the additive's structural configuration and an estimation of exposure. Toxicology testing then is either expanded or reduced depending upon the concern level. Similarly, the low genotoxic potential and typically very low levels of pesticides in the diet would result in a low level of concern for many pesticides and could result in a significant reduction in the numbers of animals necessary for safety studies. A myriad of other strategies are possible and new thinking is required to address overall food safety and to "Reduce, Refine, or Replace" laboratory animals in the current regulatory requirements for registration of pesticides.

1928 EVALUATION OF HUMAN PESTICIDE NOAEL STUDIES FOR CONSISTENCY WITH US FEDERAL POLICY FOR THE PROTECTION OF HUMAN SUBJECTS (THE COMMON RULE).

J. Patterson[1] and G. Charnley[2]. *[1]Toxicology Excellence for Risk Assessment (TERA), Cincinnati, OH and [2]HealthRisk Strategies, Washington, DC.*

The US Environmental Protection Agency (EPA) recently suspended the use of toxicity data obtained from human studies for chemical assessments over concerns regarding ethics. One argument against the use of human pesticide toxicity data asserts that such data are obtained from studies that do not comply with the "Federal Policy for the Protection of Human Subjects, " (known as the "Common Rule"). The Common Rule provides ethical guidance for the conduct of studies using human subjects that are funded by federal agencies, including EPA. To determine whether contemporary pesticide studies funded/sponsored by registrants meet the criteria for ethical treatment of human subjects as specified by the Common Rule, we analyzed over a dozen pesticide studies that sought to identify oral no-observed-adverse-effect-levels (NOAELs). The studies chosen were identified primarily from a list of studies that were submitted to EPA's Office of Pesticides Programs since passage of the Food Quality Protection Act. Fundamental and detailed requirements of the Common Rule regarding informed consent and ethics committee review were identified, and copies of study reports, protocols, and ethics committee documentation were evaluated to determine whether the Common Rule requirements were met. We found all the studies analyzed complied with the fundamental requirements of the Common Rule, including an ethics committee review and approval of the study protocol, use of volunteer subjects for the study, and acquisition of written informed consent from the volunteers. We found a few deviations in some studies from specific detailed requirements of the Common Rule. Some of these deviations may have been due to absence of documentation available for our evaluation, and not necessarily to failure of the laboratory to fulfill the requirements. In the sub-set of studies we evaluated our results demonstrate that the fundamental ethical requirements of the Common Rule were followed.

1929 A COMPARISON OF THE NUMBER OF RISK VALUES DERIVED BY DIFFERENT ORGANIZATIONS FOR 20 PRIORITY HAZARDOUS SUBSTANCES AND FOR CHEMICALS IN THE INTERNATIONAL TOXICITY ESTIMATES FOR RISK *(ITER)* DATABASE.

A. Wullenweber, A. Maier and M. Barkhurst. *Toxicology Excellence for Risk Assessment (TERA), Cincinnati, OH.*

Human health risk values are used by many organizations to make important public health decisions, and are developed by various organizations from around the world. Not all organizations derive risk values for the same chemicals, and even if

they do, the values may differ due to scientific judgments, the mission of the organization, or the use of more recently published data. This analysis used risk values derived by the Agency for Toxic Substances and Disease Registry, Health Canada, the National Institute of Public Health and the Environment (The Netherlands), the US Environmental Protection Agency, and independent parties to compare trends in the type and quantity of currently published risk values among organizations. For example, we find that there are risk values available from 3 or more organizations for 10 of the 20 Priority Hazardous Substances, often with different guidance values provided. We also find that for the majority of the roughly 600 chemicals in the International Toxicity Estimates for Risk *(ITER)* database, only a single organization has a risk value available. This analysis suggests the importance of being able to conduct side-by-side comparisons to both identify the availability of and to select risk values for application in public health decision-making. This analysis provides a significant update to previously reported results, as all of the ATSDR risk values have been added to *ITER* and included in the analysis.

1930 IDLH DOCUMENTATION REVIEW.

R. McCartney[1], L. Jackson[1], P. McGinnis[1], A. Maier[3] and H. A. Ahlers[2]. *[1]Environmental Science Center, Syracuse Research Corp, Syracuse, NY, [2]Toxicology Excellence for Risk Assessment, Cincinnati, OH and [3]National Institute for Occupational Safety and Health, Cincinnati, OH.*

Immediately Dangerous to Life and Health (IDLH) values have been established by the National Institute for Occupational Safety and Health (NIOSH) to protect workers against exposure conditions that may cause severe irreversible health effects or impair escape from exposure environments. Original assessments were used primarily as a tool to recommend respiratory protection and IDLH values were often based on limited scientific data, secondary source reported data, or safety considerations. In 1994, NIOSH reevaluated the IDLH values and developed more formal criteria for determining IDLH values. A review of the toxicological basis for 35 of a total 398 of the current IDLH values was conducted to determine if the existing IDLH recommendations were consistent with current toxicological data. For this critical analysis, a qualitative rating method was developed as a tool for conducting the evaluation. Technical guidelines were established for selection of experimental studies, evaluation of each study, and evaluation of the database for each substance. Experimental study protocol and methods were recorded into a customized database designed for tracking and sorting scientific data specific to acute exposures to hazardous substances. Two overall evaluations were made for each substance. The first evaluation rated the adequacy of the database to support the development of an IDLH value and classified each as adequate, marginally adequate, or inadequate. Out of a total 35 substance databases, approximately 50% were considered marginally adequate and 50% adequate. The second evaluation rated the degree to which the current IDLH value was likely to be protective against dangerous levels of exposure. Of the current 35 IDLH values reviewed, approximately 20% were considered more than adequately protective, 63% were considered protective, and 17% were considered inadequately protective.

1931 DATABASES YIELDING RISK ASSESSMENTS AS ONGOING PROCESSES.

C. N. Aldous. *Department Pesticide Regulation, Cal-EPA, Sacramento, CA.*

Regulatory agencies currently produce risk assessment (RA) documents as text files. Much of the input data in an RA comes from previously completed agency reviews of toxicity and exposure data, which must be incorporated into each RA version. Often RAs are initiated out of newly-recognized concerns, but substantial time is often required before an RA is drafted and peer reviewed for dissemination. Integration of endpoints from reviewed studies into RAs could be an ongoing process rather than an occasional event, if reviews and associated RAs are organized into an appropriate database (DB) format. Advantages of using DB approach include transparency, flexibility, utility to data providers and users, and real-time updates of critical derived values. Transparency suggests that a minimally-filtered public version of the DB should be accessible to all stakeholders. Agencies should define default assumptions in the DB design, and what data would displace default values. Key endpoints should be linked to associated data tables. Reviews should tabulate all plausibly treatment-related findings, then justify selection of relevant effects, as is currently done. When a review is finalized and incorporated into the DB, new endpoints of regulatory interest are considered in the re-calculation of reference doses for the associated duration of exposure. Any report bearing titles or keywords indicating plausible relevance to the subject chemical should be identified in the DB, indicating whether it was reviewed by agency. Data providers would benefit from real-time updates of critical derived values and the associated endpoints and uncertainty factors. Companies could then make economic decisions regarding future testing to reduce uncertainties which apply to regulatory reference doses. Challenges in moving to a DB system include cost factors, protecting data integrity, staff acceptance, transition time, coordination with other regulatory agencies, and decisions of whether and how extensively to retrofit existing data.

1932 THE ACTIVITIES AND PERSPECTIVES OF THE KOREAN NATIONAL TOXICOLOGY PROGRAM.

I. Yu[1], K. Yang[2], D. Cho[2], K. Kil[2] and Y. Chung[1]. *[1]Center for Occupational Toxicology, OSRHI/Korean OSHA, Daejeon, South Korea and [2]National Institute of Toxicological Research, Korea Food and Drug Administration, Seoul, South Korea.*

The Korean National Toxicology Program (KNTP) was established on 2001 as a multi-disciplinary program supported by the Korean Food and Drug Administration (KFDA). The objectives of KNTP are to prevent human health from toxic chemical exposure, and to provide science based toxicity information to citizens to keep any social disturbance from the invalid toxic information. The activities of the KNTP include: sponsoring chemical toxicity testing, establishing toxicity evaluation infra-structure, developing alternative testing methods, building toxicity database with integrated toxic chemical management program, organizing inter-ministrial cooperative program, and initiating toxicology research centers to evaluate toxic chemicals in depth and systemic. The toxic chemicals will be selected, tested, and monitored through the KNTP and finally utilized for assessing the risk of the chemicals. These activities to ensure valid toxic information coordinated by specialized government organization eventually will be helpful in improving public health and regulating policy cooperating with related government organization including Ministry of Labor, Ministry of Agriculture & Forestry, Ministry of Maritime Affairs & Fisheries and etc., sharing common toxic information for same chemicals. The KNTP is also interesting in establishing international cooperation program to share the toxicology program experiences with other countries and to collaborate toxicity assessment activities.

1933 PROMOTION OF CHEMICAL SAFETY AWARENESS: INTERNET DATABANK ON RISK MANAGEMENT TOOLS OF DANGEROUS SUBSTANCES.

K. Kumpulainen[1], T. Tregenza[2] and K. Savolainen[1]. *[1]Department of Industrial Hygiene and Toxicology, Finnish Institute of Occupational Health, Helsinki, Helsinki, Finland and [2]European Agency for Safety and Health at Work, Bilbao, Spain.*

Databank on hazardous substances has been established on the website of the European Agency for Safety and Health at Work in Bilbao, Spain. The goal of this project is to create a user-friendly information source on substitution, practical risk management of dangerous chemicals, and Occupational Exposure Limit (OEL) systems. The project is conducted by the Topic Centre Good Practice, Systems and Programmes. The target group of the databank includes health and safety professionals and other competent persons within small and medium sized enterprises. The core of the databank is substitution and risk management data on asbestos and organic solvents. This material is collected from the Internet outside the EU Member States, and evaluated for credibility, currency, relevance, usefulness, accessibility, and ethical appropriateness. The hyperlinks are written abstracts and defined keywords to facilitate Internet search. OEL systems are also included and written descriptions in co-operation with the authorities in these countries. The databank is maintained by continuos monitoring and maintenance of the descriptions and Internet references of the entered links. The search for information on risk management of asbestos and organic solvent has provided over 200 links covering various industrial sectors. International organisations and national institutes outside the EU provide most of the material. Additionally, the databank displays descriptions and reference for OEL systems in 27 countries, and the work of the EU Scientific Committee on Occupational Exposure Limits (SCOEL). Usability of the Good Practice website has been improved by a glossary of the applied terms, and two sets of Frequently Asked Questions on the definitions and use of the website, and risk management and substances. The goal is still to further develop and maintain the databank. The user-friendliness will be developed further according to feedback from user and focus group surveys.

1934 THE RELATIVE BIOAVAILABILITY OF METALS FROM SOIL TO ECOLOGICAL RECEPTORS.

Y. W. Lowney[1], M. V. Ruby[1], J. Salatas[2] and R. Pastorok[2]. *[1]Exponent, Irvine, CA and [2]Exponent, Bellevue, WA.* Sponsor: L. Yost.

Small mammals (e.g., short-tailed shrew and cottontail rabbit) are among the wildlife receptors for which ecological risk assessment models consistently indicate the greatest level of potential exposure to metals in soil. These small mammals receive much of their metals exposure either from direct soil ingestion during foraging or preening activities, or from consumption of soil-laden earthworm. In assessing risks to these receptors from soil contamination, the standard method is to assume that contaminants have a relative bioavailability of 100% (i.e., the efficiency of metals absorption from ingested soil is equal to that which occurred in the laboratory tests conducted to determine toxicity thresholds). However, a growing body of research indicates that many chemicals - including metals - are less bioavailable from ingested soil than from soluble forms (i.e., the forms typically used in labora-

tory toxicity tests), when dosed in a similar manner. Our research is designed to determine the relative oral bioavailability in shrew for arsenic, cadmium, chromium, and lead in several soils. To date, the research has involved determining the appropriate target metals for evaluation, the appropriate target species, and conducting feasibility studies for this novel small-mammal model. Results of soil dosing experiments will be presented, along with a preliminary interpretation of the implications for use in ecological risk assessment. A brief summary of other aspects of our research (including relative oral bioavailability of metals in soil to avian receptors and human receptors, as well as dermal absorption for humans) will also be provided, with an update on ongoing and planned research.

1935 THE TOXICITY OF LEACHATES FROM A MUNICIPAL SOLID WASTE LANDFILL IS DEPENDENT ON CADMIUM AND MODULATED BY NICKEL.

J. Olivero-Verbel and C. Padilla-Bottet. *Environmental and Computational Chemistry Group, University of Cartagena, Cartagena, Colombia.*

Landfills are used to dispose municipal solid wastes including food residues, used paper and both scrap metal and plastic. Although recycling in landfills is extensive, diverse materials release toxic metals and other contaminants that are incorporated into the leachate. The objective of this work was to determine the chemical source of the toxicity of leachates from the landfill of the city of Cartagena (Colombia), by using bioassays with the crustacean Artemia saline. Leachates were initially pre-filtrated and then passed through 0.45 micrometer membranes to remove most of the bacteria. This liquid was characterized physicochemically, and the concentration of several metals such as Cd, Ni, Hg, Mn, Cu and Pb were measured by atomic absorption spectroscopy. Bioassays were conducted using leachate dilutions with synthetic seawater, and the toxicity recorded as LC50 after 24 and 48 hours exposure. The LC50 values oscillated between 3.20% and 39.33% v/v. Multivariate analysis showed that toxicity was a function of both Cd concentration and chemical oxygen demand. Interestingly, the slope of the dose-response curve correlated with Ni concentration and this relationship was independent from toxicity. The results suggest that the toxicity of leachates from the landfill of Cartagena depends on the levels of Cd associated with organic matter, and also that this effect is modulated by Ni.

1936 RENAL TOXICITY IN RATS AFTER ORAL ADMINISTRATION OF MERCURY-CONTAMINATED BOILED WHALE LIVERS MARKETED FOR HUMAN CONSUMPTION.

T. Endo[1], K. Haraguchi[2], Y. Hotta[1] and M. Sakata[1]. *[1]Clinical Toxicology & Metabolism, Health Sciences University of Hokkaido, Ishirari-Tobetsu, Hokkaido, Japan and [2]Environmental Health & Chemistry, Daiichi College of Pharmaceutical Sciences, Fukuoka, Fukuoka, Japan.*

Some people living in Japan have traditionally eaten the internal organs of small cetaceans (toothed whales and dolphins), and a mixed package of boiled liver, kidney, lung and so on is still marketed for human consumption. Recently, we reported that these organs are highly contaminated with mercury. In this study, we investigated the absorption, distribution, excretion and biochemical parameters in serum and urine after a single oral administration of boiled whale liver containing 1980 $_{\mu}$g/g of total mercury and 23.5 $_{\mu}$g/g of methyl mercury to rats (0.2g boiled liver/100 g rat). The single administration of the boiled liver resulted in marked increases of the mercury concentration in the rat kidney, urinary volume, and the urinary excretion of N-acetyl-$_{\beta}$-D-glucosanidase, albumin and sodium, suggesting the renal toxicity caused by inorganic mercury. Furthermore, the administration increased lactate dehydrogenase activity and creatinine, potassium and phosphorus concentrations in serum. About 95% of total mercury dose was excreted in feces and less than 0.05% was excreted in the urine. Thus, the absorption rate of mercury from the boiled whale liver appears to be about 5 % or slightly higher. These data indicate that the human consumption of boiled whale liver may cause acute intoxication by the contaminated inorganic mercury.

1937 SKELETAL LEAD CAUSES AN ARTIFACT IN BONE MINERAL DENSITY MEASUREMENTS BY DEXA.

R. N. Rosier, J. Campbell, R. J. O'Keefe, E. M. Schwarz, M. J. Zuscik and J. E. Puzas. *Department of Orthopaedics, University of Rochester School of Medicine, Rochester, NY.* Sponsor: T. Gasiewicz.

No reports have documented the presence of low bone mineral density in patients exposed to significant sources of lead. This is surprising given the known adverse effects of lead on both bone formation and bone resorption. We believe we have discovered the reason for this discrepancy. Our findings indicate that even trace amounts of skeletal lead artifactually increase DEXA (dual energy x-ray absorptiometry) values. This finding suggests that the diagnosis of osteoporosis is under reported in patients with a history of lead exposure. Bone mineral density of bovine bone containing added amounts of lead that mimic human levels was measured with DEXA and ultrasound (US). Also, the calcaneus of 18 human subjects with differing lead-exposure histories were measured with both DEXA and US. The DEXA measurements were performed on both GE/Lunar and Hologic instruments. The range of lead levels found in the bone of adult humans causes an artifactual increase in bone mineral density. The artifact ranges from a 4% (10 ug Pb/g bone) to 11% (100 ug Pb/g bone) overestimate of bone density. The overestimate occurred with instruments from both GE/Lunar and Hologic. Ultrasound measurements of the same samples showed no such increase. A ratio of an US measurement to a DEXA measurement at the calcaneus in patients (N=18) showed a statistically significant inverse relationship with blood lead levels. We have used this relationship to calculate a correction factor for bone mineral density based on historic lead-exposure. A 4 - 11% overestimate of bone density can alter a patients t-score by as much as 1.0. and fracture risk by 150%. Thus, unless one knows the skeletal lead content of their patient, an accurate bone density cannot be determined. If this finding proves to be consistent throughout the population, then a large number of patients are being under-treated for their low bone density. This would contribute to a substantial morbidity in the post-menopausal population.

1938 PERINATAL LEAD EXPOSURE IN THE ROMAN EMPIRE: ARCHEOMETRIC EVIDENCE FROM ISOTOPE ANALYSIS.

F. A. de Wolff[1], E. Smits[2], J. L. Fischer[3,4], F. Vanhaecke[3] and L. Moens[3]. *[1]Toxicol Lab., Leiden University Med. Ctr, Leiden, Netherlands, [2]Amsterdam Archaeol Ctr, University Amsterdam, Amsterdam, Netherlands, [3]Lab. Anal Chem, Ghent University, Ghent, Belgium and [4]Department Chem Biochem, Rand Afrikaans University, Aucklandpark, South Africa.*

Lead (Pb) poisoning or 'plumbism' was a major public health issue in the Roman empire. Pb exposure in Rome has been attributed to Pb-contaminated drinking water, and Pb salts added as preservative to wine and stewed food. As excessive wining and dining was a privilege of the Roman upper class, Pb poisoning is an example of class-related disease at that time. Plumbism may well have lead to the rapid decline of the Roman empire in the first centuries. Earlier studies with Romano-British bones indicated that Pb-poisoning was not limited to Rome proper but also occurred in Romanized settlements throughout the empire. We studied Pb exposure in infants exhumated in the cemetery of the Roman settlement Praetorii Agrippinae (near Leiden, The Netherlands). Previously, we demonstrated with EAAS a high Pb concentration in femora of neonates. Although these results indicated a high perinatal exposure to Pb, uptake of Pb in bone from the surrounding soil could not totally be excluded. To discern between the origins of Pb in bone and soil, stable isotope analysis of Pb204, Pb206, Pb207 and Pb208 was performed with a single-collector sector field ICP-MS (Finnigan MAT Element). Total Pb in bone measured with ICP-MS correlated satisfactorily with EAAS-results. For 13 bone and 11 soil samples, the Pb207/Pb206 ratios were plotted against the Pb208/Pb206 ratios. Bone and soil ratios clearly form two different populations. The mean Pb207/Pb208 ratio for bone is 0.4054 ± 0.0007, for soil 0.4023 ± 0.0008 ($p < 0.01$). This strongly suggests that Pb in infant bone is from a different source than Pb in soil. This is the first study that convincingly shows that Pb in bone from a Roman cemetery is not concentrated from Pb in the surrounding soil, but must have been transmitted from the mother to the fetus. Future studies are aimed at defining the actual geographic and nutritional source of Pb in bone.

1939 A NOVEL ISOTOPIC APPROACH FOR DETERMINING THE CONTRIBUTION OF LEAD FROM BONE TO BLOOD IN CHILDREN.

C. Campbell[2], R. H. Gwiazda[1] and D. Smith[1]. *[1]Environmental Toxicology, University of California, Davis, CA and [2]Children's Hospital, Philadelphia, PA.*

Epidemiological studies have shown that household lead (Pb) abatement yields at most a 32% decrease in blood Pb (PbB) levels of children 3 to 6 months post-intervention. To evaluate the role of bone Pb release in supporting elevated PbB levels post-intervention we implemented a novel isotopic approach. Lead concentrations and isotopic compositions of blood and feces (4 consecutive daily collections) were determined for three children with PbB levels between 15 and 30 µg/dL. In addition, Pb levels and isotopic compositions of different environmental media in the children's homes were measured before and after a cleaning intervention. Through mass balance equations of Pb and Pb isotopes in blood we derived the endogenous Pb contribution to blood. The isotopic composition of most feces, a surrogate of the sources and magnitude of Pb ingested, agreed with the isotopic composition of

the household dusts exceeding EPA clearance levels. This underscores the importance of household dust as the direct pathway of Pb exposure. In case #1, intervention produced a small decrease in the child's PbB level (from 29 to 25μg/dL), even though fecal Pb levels suggested relatively low Pb exposures post-intervention (fecal Pb ~5μg Pb/day). Lead isotope data substantiated this, showing that the bone Pb contribution accounted for more than 95% of the Pb in blood. The other two children had slightly larger relative drops in PbB levels with intervention (20 to 15μg/dL, and 18 to 13μg/dL, respectively), and had higher fecal Pb levels suggesting higher on-going exposures (fecal Pb = 20 – 70μg Pb/day) post-intervention. The isotope results for these latter cases suggest that initially (pre-intervention) bone was accumulating (i.e., scavenging) Pb from blood equivalent to 3μg/dL, and releasing Pb to blood post-intervention equivalent to 4 μg/dL. These results highlight the importance of endogenous Pb sources and provide a blueprint for the utilization of Pb isotopes to quantify the toxicokinetics of this important source of Pb to Pb poisoned children.

1940 EFFECT OF OCCUPATIONAL EXPOSURE TO MANGANESE ON STEADY-STATE SERUM CONCENTRATIONS OF IRON, ZINC, COPPER, SOD, AND MDA AMONG WELDERS.

L. Lu[1,2], L. Zhang[1], P. Wu[2], J. Deng[2], W. Guo[1], G. Li[2,3] and W. Zheng[3]. *[1]Fengtai Distric Surveillance Station of Public Hygiene, Beijing, China, [2]School of Public Health & Family Medicine, Capital University of Med. Sciences, Beijing, China and [3]School of Public Health, Columbia University, New York, NY.*

Recent studies suggest that exposure to Mn alters homeostasis of trace elements such as iron (Fe) and copper (Cu). This study was performed to investigate if occupational exposure to Mn in welders was associated with distorted serum levels of Fe, Cu and zinc (Zn), all of which are important to CNS function. Thirty-seven welders (ave. 38.1 years old) who have been engaged in electrical arc welding with potentially high level of exposure were selected from about 500 welders in one factory as the exposed group. Welders worked 7-8 hours per day with the employment of 2-36 years. Control subjects consisted of 50 workers (ave. 34.2 years old), who were recruited from a nearby food factory with no history of Mn exposure. Ambient Mn levels in welders breathing zone had a geometric mean of 1.45 ug/m^3, while it was 0.11 ug/m^3 in the control breathing zone. Results showed that serum levels of Mn and Fe in welders were about 4 fold ($p<0.01$) and 1.9 fold ($p<0.05$), respectively, higher than those of controls. In contrast, serum Zn levels were significantly lower in welders than in controls, while serum Cu did not differ significantly between two groups. ANOVA analyses revealed the lack of association between serum levels of all four metals and the duration of employment. However, the latter was positively associated with urinary Mn among welders ($p<0.05$). In addition, biochemical assays showed that the activity of erythrocytic superoxide dismutase (SOD) in welders was reduced by 24% compared to controls ($p<0.05$), whereas the levels of serum malondialdehyde (MDA) was increased by 44% ($p<0.05$). These findings suggest that occupational exposure to Mn among welders disturbs the homeostasis of trace elements and induces oxidative stress. These factors may contribute to the etiology of Mn-induced Parkinsonism (Support in part by P30 ES-09089).

1941 DIETARY CADMIUM ABSORPTION IS ACCELERATED IN YOUNG WOMEN WITH LOW SERUM FERRITIN LEVELS AMONG FEMALE JAPANESE FARMERS.

H. Horiguchi[1,2], E. Oguma[1,2], S. Sasaki[3], K. Miyamoto[1], Y. Ikeda[1,2], M. Machida[1] and F. Kayama[1,2]. *[1]Health Science, Jichi Medical School, Tochigi, Japan, [2]CREST, JST, Kawaguchi, Japan and [3]National Institute of Health and Nutrition, Tokyo, Japan.* Sponsor: T. Yoshida.

Dietary absorption rate of cadmium (Cd) was investigated among 37 female farmers selected from the previously studied 596 participants, who have been exposed to Cd close to the current provisional tolerable weekly intake (PTWI). This study group consists of 7 diabetics and their 13 age-matched controls, and 5 anemic subjects and their 12 controls. With their informed consent, they were confined in an inn for 7 days in order to collect all the food duplicates consumed and their feces and urine. The absorption rate *via* gastrointestinal tract was calculated for each subject. The means and 95% confidence intervals of diabetic group and anemic group showed no significant differences from their respective controls. The anemic group and its control revealed higher absorption rate than diabetic group and its control group. Among all subjects, significantly higher Pearson's correlation coefficients were observed between Cd absorption rate and age, serum ferritin and iron levels, and both blood and urine Cd levels. However, multiple regression analysis revealed that only age and serum ferritin level were significant factors for Cd absorption rate. The mean value of Cd absorption in younger female (20s-30s) with iron deficiency was 30-40%, while elder people (60s-70s) without iron deficiency showed zero to negative value. These results demonstrate that the absorption rate of Cd is independent of the diagnostic criteria of anemia or diabetes, but decreases by aging, and increases by body iron deficiency. This research protocol was approved by the Committee on Medical Ethics in Jichi Medical School.

1942 AMINOLEVULINIC ACID DEHYDRATASE GENOTYPE DISTRIBUTION IN LEAD EXPOSED CHILDREN IN TORREON COAHUILA, NORTHERN MEXICO.

G. G. Garcia-Vargas[1,2], I. Mijares[1], P. Lopez[6], J. L. Rosado[4,6], J. Alatorre[5], B. Quintanilla-Vega[3] and M. E. Cebrian[3]. *[1]Facultad de Medicina, Investigacion, Universidad Juarez del Estado de Durango, Gómez Palacio, Durango, Mexico, [2]Facultad de Medicina, CIB, Universidad Autonoma de Coahuila, Gómez Palacio, Durango, Mexico, [3]Seccion Externa Toxicologia, CINVESTAV-IPN, Mexico, D.F, Mexico, [4]Universidad Autonoma de Queretaro, Queretaro, Queretaro, Mexico, [5]Universidad Autonoma de Mexico, Mexico, D.F., Mexico and [6]Instituto Nacional de Ciencias Médicas y Nutricion, Mexico, D.F., Mexico.*

Aminolevulinic acid dehydratase (ALAD) is a zinc containing enzyme which is part of the heme synthesis pathway. This enzyme has two alleles: ALAD-1 and ALAD-2, and has different distribution according with ethnic characteristics of populations. ALAD-2 allele has been associated, in epidemiological studies with people having higher lead concentrations in blood (PbB). The aim of this work is to assess the relationship between PbB and ALAD genotyope distribution in a children with chronic lead exposure, as well as, with an effect biomarker as is zinc protorporhyrin in blood (ZPP). Methods: 569 children were recruited from 9 primary schools around a smelter site. Selection was made taken all children in first degree in these schools. All parents children studied were informed and signed a consent form letter. PbB was made by atomic absorption spectrometry with Zeeman background correction. ALAD genotype was made according to Wetmur et al (1991). ZPP was made by direct fluorimetry in blood. Results: Geometric mean (range) of PbB in children was 10.25 μg/dL (2.0 to 47.9 μg/dL). The individuals (number; %) having different allele combination were: ALAD-1-1 (530; 93.15 %), ALAD1-2 (38; 6.67 %), and ALAD2-2 (1; 0.18 %). There were a significant relationship between PbB and ZPP. There were a significant direct relationship between the proportion of ALAD-2 and PbB. Individuals with ALA-2 allele had lower levels of ZPP ($p= 0.0512$). These results support the view that determination of ALAD genotype can be useful as susceptibility biomarker. Wetmur JG, et al (1991) Am. J. Human Genet. 49:757-763.

1943 TRANSPORT OF MERCURIC-THIOL CONJUGATES IN BASOLATERAL MEMBRANE VESICLES FROM RAT KIDNEY: EFFECT OF COMPENSATORY RENAL CELLULAR HYPERTROPHY.

D. A. Putt[1], S. E. Hueni[1], R. K. Zalups[2] and L. H. Lash[1]. *[1]Pharmacology, Wayne State University, Detroit, MI and [2]Basic Medical Sciences, Mercer University, Macon, GA.*

The susceptibility of developing renal injury induced by inorganic mercury (Hg) increases subsequent to the induction of compensatory renal growth. We hypothesize that this is related to increased rates of uptake of Hg into target proximal tubular epithelial cells. The goals of this study were 1) to determine the roles of specific transporters in the uptake of Hg, in the form of Hg-thiol conjugates, across the renal basolateral membrane (BLM) and 2) to assess the effects of compensatory renal cellular hypertrophy on each transporter involved in the uptake of Hg-thiol conjugates. BLM vesicles were isolated from kidney(s) of both control and uninephrectomized (NPX) rats. Non-specific binding of Hg accounted for 75 to 90% of total amount of Hg associated with membranes exposed to $HgCl_2$, which decreased with increasing Hg concentrations. The presence of sodium ions had little effect on the fraction of binding, but the presence of thiols (glutathione [GSH], L-cysteine [Cys], or *N*-acetyl-L-cysteine [NAC]) reduced binding by more than 70%. BLM vesicles from kidneys of NPX rats exhibited a much lower proportion of binding (only 20 to 45% of total). Of the Hg-thiol conjugates studied, transport of Hg-cysteine was fastest. Use of selective inhibitors of BLM carriers indicated involvement of system ASC and the organic anion transporters in the transport of Hg-$(Cys)_2$, the organic anion transporters and the sodium-dicarboxylate exchanger in the transport of Hg-$(GSH)_2$, and system ASC and the organic anion transporters in the transport of Hg-$(NAC)_2$. Transport of each Hg-thiol conjugate was higher in the BLM vesicles from the NPX rats, with specific increases noted in transport by the organic anion transporter, system ASC, and the sodium-dicarboxylate carrier. These results support the hypothesis associating increased cellular injury with increased Hg transport across the BLM. (Supported by NIH Grants ES05157, ES05980 and DK40725.)

1944 TRANSPORT OF DICYSTEINYLMERCURY IN MADIN-DARBY CANINE KIDNEY (MDCK) CELLS OVEREXPRESSING SYSTEM $b^{0,+}$.

C. C. Bridges[1], C. Bauch[2], F. Verrey[2], D. W. Barfuss[3] and R. K. Zalups[1]. *[1]Basic Medical Sciences, Mercer University School of Medicine, Macon, GA, [2]Physiology, University of Zurich, Zurich, Switzerland and [3]Biology, Georgia State University, Atlanta, GA.*

It has been suggested that dicysteinylmercury (Cys-Hg-Cys) can serve as a molecular homolog or "mimic" of the amino acid cystine at the site of one or more of amino acid transporters involved in the uptake of cystine. System $b^{0,+}$, which is a heterodimeric transport system comprised of $b^{0,+}$AT and rBAT, has been postulated to be one of these transport systems. The aim of the present study was to determine whether a line of renal epithelial cells (MDCK cells), which do not express system $b^{0,+}$, gain the ability to transport Cys-Hg-Cys after being stably transfected with the genes for this transport system. Kinetic analysis was performed by measuring the uptake of Cys-^{203}Hg-Cys or ^{35}S-cystine in the presence of unlabeled Cys-Hg-Cys (1, 10, 50, 100, 250, 500 nM, 1, 10 μM) or cystine (0.1, 1, 10, 100, 250, 500, 1000 μM), respectively. Substrate-specificity experiments were performed by adding 3 mM unlabeled amino acids. The uptake of cystine and Cys-Hg-Cys in the transfected cells was approximately 3-fold and 2-fold greater than that in wild-type cells, respectively. Kinetic analysis of the transport process demonstrated a 2-fold increase in Cys-Hg-Cys transport (Wild type, Vmax = 1.4 μM, Km = 0.8 μM; $b^{0,+}$, Vmax = 3.0 μM, Km = 0.5 μM). Transport of Cys-Hg-Cys was greatest during the initial hour of incubation. Uptake of Cys-Hg-Cys was inhibited by known substrates of system $b^{0,+}$ (cystine, Leu, Arg, Tyr, CycloLeu, His, Phe) as well as unlabeled Cys-Hg-Cys. Val, Ala, and Gly did not inhibit uptake. These studies demonstrated that system $b^{0,+}$ is capable of transporting Cys-Hg-Cys, and that this transport likely involves Cys-Hg-Cys acting as a molecular homolog or mimic of the amino acid cystine. This study is the first to implicate system $b^{0,+}$ in the transport of the biologically relevant thiol-conjugate of inorganic mercury, Cys-Hg-Cys, in renal epithelial cells.

1945 BASOLATERAL TRANSPORT OF THE MERCURIC CONJUGATE, CYS-HG-CYS, IN NON-PERFUSED S1, S2, AND S3 SEGMENTS OF THE RABBIT RENAL PROXIMAL TUBULE.

D. W. Barfuss[1], Z. Azarbaeijani[1] and R. K. Zalups[2]. *[1]Biology, Georgia State University, Atlanta, GA and [2]Division of Basic Medical Sciences, Mercer University School of Medicine, Macon, GA.*

Cellular uptake (bath-to-cell) of dicysteinylmercury (Cys-Hg-Cys) across the basolateral membrane was studied in non-perfused segments of the rabbit proximal tubule. Proximal tubular segments were selected and separated according to their morphological features and location in coronal sections of the kidney. Each isolated tubular segment was incubated for 20 minutes in a saline-based bathing solution containing 20μM 203Hg^{++} and 60μM L-cysteine. All segments took up Cys-Hg-Cys avidly at 38°C. Uptake was 2473 ± 31, 3340 ± 36 and 2154 ± 15 fmol (mm tubular length)$^{-1}$ (20 min)$^{-1}$ in the S1, S2 and S3 segments, respectively. In S2 segments, the only segment studied in the following experiments, the rates of uptake were reduced by about 80% when incubated at 12°C. When S2 segments were co-incubated with 200 μM PAH (para-aminohippurate) or 200 μM L-cystine, uptake of Cys-Hg-Cys was reduced to about the same level as incubating the tubular segments at 12°C. Co-incubation with PAH caused the rate of uptake to decrease to 710 ± 8 fmol (mm tubular length)$^{-1}$ (20 min)$^{-1}$ while co-incubation with L-cystine reduced uptake to 610 ± 12 fmol (mm tubular length)$^{-1}$(20 min)$^{-1}$. Since it has been observed that Cys-Hg-Cys is taken up most avidly at the basolateral membrane of the S2 segment, the segment that is known to contain the greatest activity of organic anion transport, and since PAH greatly inhibited the uptake of Cys-Hg-Cys, we conclude that Cys-Hg-Cys is transported by the organic anion transport systems. Also, since L-cystine effectively inhibited Cys-Hg-Cys uptake, we conclude that the Cys-Hg-Cys mercury conjugate can be transported by a mechanism that transports the amino acid cystine.

1946 MADIN-DARBY CANINE KIDNEY (MDCK) CELLS GAIN THE ABILITY TO TRANSPORT MERCURIC CONJUGATES OF CYSTEINE (CYS) OR N-ACTEYLCYSTEINE (NAC) AFTER BEING STABLY TRANSFECTED WITH OAT1.

D. K. Zalups[1], A. Aslamkhan[2], D. W. Barfuss[3] and S. Ahmad[1]. *[1]Basic Medical Sciences, Mercer University School of Medicine, Macon, GA, [2]NIEHS, Research Triangle Park, NC and [3]Biology, Georgia State University, Atlanta, GA.*

One of the main transporters implicated in the basolateral uptake of inorganic mercury (Hg^{++}) along the renal proximal tubule is the *p*-aminohippurate (PAH)- and probenecid-sensitive organic anion transport system. The primary aim of the present study was to provide direct molecular evidence that the organic anion/dicarboxylate exchanger, OAT1, is capable of transporting biologically relevant dithiol-conjugates of Hg^{++}. To that end, transport of radiolabelled PAH and the mercuric conjugates of CYS (CYS-Hg-CYS) or NAC (NAC-Hg-NAC) was studied and compared in two populations of MDCK cells; one which had been stably transfected with *hoat1*, and the other, which had been transfected with a control vector. Uptake of Hg^{++} during exposure to 5 uM CYS-Hg-CYS or NAC-Hg-NAC, or uptake of PAH alone, was significantly greater in hOAT1-expressing MDCK cells than in the corresponding control cells. The Km for the uptake of NAC-Hg-NAC in the hOAT1-expressing cells was determined to be 73.3 ± 2.9 uM. Transport of the mercuric conjugates or PAH was both time-dependent and temperature-sensitive. For example, uptake of NAC-Hg-NAC in the hOAT1-transfected cells decreased by 82% when temperature was decreased from 37°C to 25°C. Uptake of each mercuric conjugate or PAH was decreased significantly in the presence of probenecid (200 uM) or PAH (1 mM) only in the hOAT1-transfected cells. PAH also inhibited the uptake of NAC-Hg-NAC by the hOAT1-expressing cells in a concentration-dependent manner. Similarly, a decreased pattern of uptake of PAH was noted in the presence of increasing concentrations of NAC-Hg-NAC. These findings indicate clearly that OAT1 can efficiently transport certain dithiol-conjugates of Hg^{++}. Moreover, the activity of OAT1 is likely responsible for a significant component of the basolateral uptake of, and nephropathy induced by, Hg^{++} along the proximal tubule *in vivo*.

1947 ROLE OF ORGANIC ANION TRANSPORTER 1 (OAT1) AND AMINO ACID TRANSPORTERS IN THE UPTAKE OF THIOL-CONJUGATES OF METHYLMERCURY IN MADIN-DARBY CANINE KIDNEY (MDCK) CELLS.

S. Ahmad and R. K. Zalups. *Basic Medical Sciences, Mercer University School of Medicine, Macon, GA.*

Several sets of recent *in vivo* and *in vitro* findings have implicated OAT1 and certain amino acid transport systems in the basolateral and luminal uptake of inorganic forms of mercury by proximal tubular cells. By contrast, very little is known about the transporters involved in the uptake of methylmercury (CH_3Hg^+) by proximal tubular epithelial cells. Therefore, the principal aim of the present study was to investigate the potential role of OAT1 and amino acid transporters in the uptake of biologically relevant thiol-conjugates of CH_3Hg^+. Transport of the CH_3Hg^+ conjugates of cysteine (CYS) or N-acetylcysteine (NAC) was studied and compared in two populations of MDCK cells; one which had been stably transfected with *hoat1*, and the other, which had been transfected with a control vector. The uptake of CH_3Hg^+ during exposure to 5 uM CH_3Hg-CYS or CH_3Hg-NAC was significantly greater in the hOAT1-expressing cells than in the corresponding control cells. The Km values for transport of CH_3Hg-NAC in hOAT1-expressing and control MDCK cells were 42.8 ±+ 2.5 uM and 118 ±+ 17.8 uM, respectively. Transport of these conjugates was also time-dependent and temperature-sensitive. In both the hOAT1-expressing and control cells, the uptake of CH_3Hg-NAC was decreased by approximately 80% at 21°C and by 95% at 4°C. Similarly, the uptake of CH_3Hg-Cys was decreased by 60% at 21°C and 88% at 4°C. In the presence of L-type amino acids (such as Leucine, Isoleucine, Cystine, Histidine or phenylalanine), the uptake of CH_3Hg-Cys was significantly inhibited in both hOAT1-expressing and control MDCK cells. However, in the presence of well-established inhibitors of OAT1 (probenecid, *p*-aminohippurate, glutarate or adipate), the uptake of these complexes was significantly inhibited only in the hOAT1-transfected cells. These findings indicate that both OAT1 and amino acid transporters are capable of transporting thiol-conjugates of CH_3Hg^+ into cells containing these transporters.

1948 P-GLYCOPROTEIN MEDIATED TRANSPORT OF CADMIUM IN CULTURE RENAL EPITHELIAL CELL LINE, LLC-PK_1

O. Kimura, T. Endo, Y. Hotta and M. Sakata. *Clinical Toxicology & Metabolism, Health Sciences University of Hokkaido, Ishikari-Tobetsu, Hokkaido, Japan.*

The purpose of this study using the renal cultured epithelial cell lines, LLC-PK_1, and P-gp overexpressed cell lines, LLC-GA5-COL 150 cells was to investigate whether transepithelial transport of cadmium (Cd) is mediated by P-glycoprotein (P-gp). These cell monolayers cultured on permeable membranes were incubated at 37C for 60 min with 1_{μ}M $CdCl_2$ from either the apical or basolateral side. The transepithelial transport of Cd from the basolateral side was 1.7 times higher than that from the apical side in LLC-GA5-COL 150 cells, while that of Cd from the basolateral side was almost similar to that from the apical side in LLC-PK_1 cells at 60 min. Pretreatment with the P-gp antibody, UIC2, increased the apical-to-basolateral transport of Cd in LLC-GA5-COL 150 cells by 20%, while it decreased the basolateral-to-apical transport of Cd by 20%. On the other hand, the pretreatment increased the apical-to-basolateral transport of Cd in LLC-PK_1 cells by 20%, but it

did not decrease the basolateral-to-apical transport of Cd. The typical P-gp inhibitors, such as cyclosporin A, verapamil, nifedipine and quinidine, markedly decreased basolateral-to-apical transport of Cd in LLC-PK_1 and LLC-GA5-COL 150 cells. These results suggest that Cd is extruded from apical membrane of renal cultured epithelial cell *via* P-gp.

1949 EFFECT OF DMT1 KNOCKDOWN ON IRON, CADMIUM, AND LEAD UPTAKE IN CACO-2 CELLS.

D. I. Bannon[1], J. P. Bressler[3,2], R. Abounader[4] and P. S. Lees[3]. *[1]Center for Health Promotion and Preventive Medicine, US Army Aberdeen Proving Ground, Edgewood, MD, [2]Department of Neurology, Kennedy Krieger Institute, Baltimore, MD, [3]Department of Environmental Health Sciences, Bloomberg School of Public Health, Johns Hopkins University, Baltimore, MD and [4]Department of Neurology, School of Medicine, Johns Hopkins University, Baltimore, MD.*

DMT1 (divalent metal transporter) is a hydrogen-coupled divalent-metal transporter with a substrate preference for iron, which also transports a broad range of metals, including the toxic metals cadmium and lead. The intestinal cell line, Caco-2, which has been shown to express DMT1 at its apical membrane, was used to study the transport of iron, cadmium and lead. Wild-type Caco-2 cells displayed saturable transport of lead and iron that was acid-stimulated, a property of DMT1. Cadmium and manganese inhibited transport of iron whereas zinc and lead did not. The involvement of DMT1 in the transport of toxic metals was further examined by establishing clonal DMT1 knockdown and control Caco-2 cell lines. Knockdown cell lines displayed lower levels of DMT1 mRNA and a lower Vmax for iron uptake compared to control cell lines. The functional consequence of DMT1 knockdown was a 50% reduction in uptake of iron across a pH range from 5.5 to 7.4. Uptake for cadmium also decreased 50% across the same pH range. Lead was unaffected by DMT1 knockdown, even though uptake was acid-stimulated in wild type cells. These results show that DMT1 is important in iron and cadmium transport in Caco-2 cells, but that lead enters these cells through an independent hydrogen-driven mechanism.

1950 DIETARY IRON REGULATES INTESTINAL CADMIUM ABSORPTION THROUGH DMT1 IN RATS.

J. D. Park[1], M. Kwon[1], B. S. Choi[1], E. S. Park[2] and Y. P. Hong[1]. *[1]Preventive Medicine, Chung-Ang University, Seoul, South Korea and [2]Pathology, Chung-Ang University, Seoul, South Korea.*

The main exposure source of Cd is oral ingestion with food in general population. In previous study, the depletion of iron(Fe) up-regulated the expression of Divalent Metal Transporter 1(DMT1) and increased Cd absorption in intestine. However, it is not clear whether the dietary Fe plays a role of regulation Cd absorption in intestine through DMT1. This study has done to clarify the role of Fe in intestinal Cd absorption by control body Fe stores with diet. In first model, rats were fed with a Fe-deficient (FeD-, 2-6mg Fe/kg) or Fe-supplemented (FeS-, 120mg Fe/kg) diet for 4 wk, and followed single administration of 109CdCl2 orally. In the other model, rats were fed FeD- or FeS- diet for 4 wk, and replaced FeD-diet with FeS-diet (FeR-diet group) for 4 wk but kept FeS diet for 8wk, and followed single oral administraion of 109CdCl2. Animals of each model were killed at 24 hr after Cd administration. Body Fe status was evaluated and tissue Cd concentration was determined. The level of DMT1 mRNA in duodenum was analyzed by RT-PCR method. Feeding the FeD-diet for 4 wk produced Fe deficiency anemia in animals with findings of decreased serum total Fe, increased UIBC and hypochromic microcytic RBC. Tissue Cd concentration was significantly higher with 2-6 folds in FeD-diet rats than FeS-diet. Body burden of Cd in FeD-diet rats was 3 folds higher. Also, the level of DMT1 mRNA in duodenum was highly expressed in FeD-diet group than FeS-diet. In FeR-diet group, body Fe status returned to the control level. Tissue Cd concentration and body burden of Cd was not significant with FeS-diet fed rats for 8 wk. The level of DMT1 mRNA expression in FeR-diet rats was similar with control group. These findings support to understand more clearly the role of dietary Fe in the intestinal Cd absorption. Dietary Fe effects on the body Fe stores directly, follows the up- or down- regulation of DMT1 expression at transcription level, and results in the regulation of intestinal Cd absorption in mammalian.

1951 ZINC SUPPLEMENTATION MAY DECREASE HEPATIC COPPER ACCUMULATION IN LEC RAT: A MODEL OF WILSON'S DISEASE.

B. P. Esparza-Gonzalez, R. Nino-Fong, I. Fuentealba and M. Cherian. *Pathology, University of Western Ontario, London, ON, Canada.*

The Long-Evans Cinnamon (LEC) rat is an animal model for Wilson's disease where copper (Cu) accumulates in the liver with age. The condition in LEC rats is characterized by development of fulminant hepatitis, cirrhosis, and hepatocellular carcinoma. The defective Cu-transporting ATP7B gene is homologous to the gene responsible for Wilson's disease. The objective of this study was to evaluate the effect of Zinc (Zn) supplementation in the development of Cu-associated liver damage in LEC rats. Female, 4 weeks-old, LEC (N=48) and LE rats were divided in two groups. One group was fed a Zn-supplemented diet, and the other group was given a normal rodent diet. Four LEC rats in each group were sequentially sacrificed at 6, 8, 10, 12, 18, and 20 weeks of age. Controls were sampled at 6, 12, 18 and 20 weeks of age. Hepatocyte apoptosis was detected in LEC rats fed with Zinc-supplemented diet much later (20 weeks) than in LEC rats fed with normal diet (10 weeks). Metallothionein (MT) concentration in livers of LEC rats with Zn-supplemented diet increased after 12 weeks of age up to 20 weeks, while hepatic MT concentration in LEC rats fed a normal diet decreased after 12 weeks. Between 6-18 weeks of age, Cu concentration in the liver was higher in LEC rats fed a normal diet compared to that detected in rats fed a Zn-supplemented diet. After 8 weeks, serum levels of alkaline phosphatase (ALP) were increased only in LEC rats fed a normal diet. Hepatocyte Growth Factor (HGF) was detected by immunohistochemical staining in livers of all LEC rats with strong positive HGF staining in LEC rats over 12 weeks of age and fed a normal diet. The results suggest that Zn supplementation can reduce the hepatic Cu concentration and delay the onset of clinical and pathological changes of Cu toxicity in LEC rats. Although the actual mechanism of the protection in not known, it could be to sequestration of dietary Cu by intestinal MT, induced by high Zn diet in LEC rats. (Supported by a Grant from CIHR).

1952 EFFECT OF SELENITE ON THE DISPOSITION OF ARSENATE AND ARSENITE IN RATS.

Z. Gregus and I. Csanaky. *Department of Pharmacology and Pharmacotherapy, University of Pecs, Pecs, Hungary.*

Selenite (SeIV) and inorganic arsenicals counter the toxicity of each other. SeIV inhibits arsenic methylation in hepatocytes, however, it is unknown whether it decreases the formation of the highly toxic monomethylarsonous acid (MMAsIII). Therefore, we examined, in comparison with the methylation inhibitor periodate-oxidized adenosine (PAD), the effect of SeIV (10 μmol/kg, i.v.) on the appearance of arsenic metabolites in blood, bile and urine as well as the distribution of arsenic metabolites in the liver and kidneys in rats injected i.v. with 50 μmol/kg arsenite (AsIII) or arsenate (AsV). Arsenic metabolites were analyzed by HPLC-hydride generation-atomic fluorescence spectrometry. In rats given either arsenical, PAD decreased the excretion and tissue concentrations of methylated arsenic metabolites (MMAsIII, monomethylarsonic acid [MMAsV], and dimethylarsinic acid [DMAsV]), while increasing the tissue retention of AsV and AsIII. The effect of SeIV on arsenic disposition differed significantly from that of PAD. For example, both in AsIII- and AsV-injected animals, SeIV lowered the tissue levels of MMAsIII and MMAsV, but increased the levels of DMAsV. SeIV almost abolished the biliary excretion of MMAsIII in AsV-exposed rats, but barely influenced it in AsIII-dosed rats. The SeIV-induced changes in arsenic disposition may largely be ascribable to formation of the known complex containing trivalent arsenic and selenide (SeII), which not only depends on but also influences the availability and effects of these metalloid species in tissues. By such complexation SeII compromises monomethylation of arsenic when trivalent arsenic availability is limited (e.g. in AsV-exposed rats), but affects it less when the presence of AsIII is overwhelming (e.g. in AsIII-dosed rats). As an auxiliary finding, it is shown that DMAsV occurs in the blood of rats not injected with arsenic and that DMAsV formation in rats can be followed by measuring the build-up of blood-borne DMAsV. (Supported by OTKA and the Hungarian Ministry of Health)

1953 RELATION OF URINARY TRIVALENT METABOLITES OF INORGANIC ARSENIC WITH ARSENIC-SKIN LESIONS IN HUMANS.

O. L. Valenzuela[1], G. G. Garcia-Vargas[2], E. S. Calderon-Aranda[1], V. H. Borja-Aburto[3] and L. M. Del Razo[1]. *[1]Toxicology, Cinvestav-IPN, Mexico City, Mexico, [2]Medicine School, UJED, Gomez Palacio, Durango, Mexico and [3]Health in the Work, IMSS, Mexico City, Mexico.*

Chronic ingestion of arsenic (As) from drinking water is associated with the occurrence of skin cancer. Exposure of humans to inorganic As (iAs) results in the urinary excretion of iAs and two major methylated metabolites MAs and DMA. In experimental models, methylated and dimethylated arsenicals that contain As in the trivalent oxidation state (MAsIII and DMAIII) are more potent toxins than iAs. The aim of this study was to evaluate the pattern of urinary trivalent As species in people chronically exposed to iAs and the association of trivalent As species with the development of arsenic-skin lesions. A cross-sectional study was conducted in the central part of Mexico, in which 24 participants chronically exposed to water naturally contaminated with high arsenic content (363 micrograms/l) were evaluated by questionnaire and clinical examination. Participants provided drinking water and spot urine samples. Trivalent As compounds were quantified within the

first 6 hours of collection. Trivalent forms of As were the predominant species in urine (59.3 %). iAsIII accounted for 7.2 %, MAsIII for 9.1 % and DMAIII for 43% of the sum of all arsenic in urine. Content of urinary MAsIII and DMAIII were directly correlated with the iAs concentration in water. Individuals exposed with skin-lesions presented higher concentration of MAsIII and DMAsIII in urine than those without skin lesions. Characterization of the urinary excretion of MAsIII and DMAsIII may provide a new biomarker of the effects of chronic exposure to As. This study was supported by Conacyt-Mexico (grant 3871-M).

1954 DOSE-RESPONSE ALTERATION IN THE URINARY PATTERN OF TRIVALENT ARSENIC SPECIES IN MICE EXPOSED TO ARSENITE.

E. A. Garcia-Montalvo, C. Aguilar and L. M. Del Razo. *Toxicology, Cinvestav-IPN, Mexico City, Mexico.*

Biomethylation of arsenic (As) is the major process of metabolism of As. This procedure involves a stepwise reduction of pentavalent to trivalent arsenicals followed by oxidative addition of a methyl group to the trivalent As. Because methylated metabolites that contain trivalent As (MAsIII and DMAIII) are toxic intermediates in the metabolism of As, there is increasing interest in the determination of MAsIII and DMAIII in studies of As biotransformation. The purpose of this study was to determine As species, including the putative more toxic trivalent methylated As species, MAsIII and DMAIII, in mice exposed to inorganic As and its relation with toxic effects. Female C57BL/6 mice were orally administered with 3 or 6 mg arsenite/kg, daily for nine days. Because trivalent methylated species are unstable in urine, this was recollected during three periods, 0-4 h, 4-8 h and 8-24 hr after the last arsenite dose; during this process the urine was preserved on dry ice. After collection, the urine was immediately analyzed for As species. Hepatic lipoperoxidation was increased in dose-depend fashion. Concentration of urinary iAsIII, MAsIII and DMAIII were directly correlated with dose of arsenite. However, a significant decrease in the relative proportion of DMAIII and increase in the MAsIII and iAsIII were associated with magnitude of As exposure. These data showed a negative relationship between relative urinary proportion of DMAIII and hepatic lipoperoxidation.

1955 COMPARISON OF THIMEROSAL AND METHYL MERCURY DISTRIBUTION IN NEONATAL MICE.

G. Zareba[1], E. Cernichiari[1], R. Hojo[1], J. Kai[1], M. Mumtaz[2], D. Jones[2], B. Weiss[1] and T. Clarkson[1]. *[1]Department of Environmental Medicine, University of Rochester, Rochester, NY and [2]Agency for Toxic Substances and Disease Registry, Atlanta, GA.*

Thimerosal, which contains the ethyl mercury radical as the active species, has been used as a preservative in many currently marketed vaccines throughout the world. Because of the assumption that its toxicity is similar to that of methyl mercury, it is no longer incorporated in many vaccines in the United States. There are reasons to believe, however, that this assumption may not be correct; that is, the disposition and toxicity of ethyl mercury compounds, including thimerosal, may differ substantially from those of the methyl form. To further explore this question, the current study sought to compare, in neonatal mice, the tissue disposition of thimerosal with that of methyl mercury. Female ICR mice were given single intramuscular injections of thimerosal or methyl mercury (1.4 mg Hg/kg) on postnatal day 10 (PND 10). Tissue samples were collected daily on PND 11-14. Absorption from the application site was similar in both groups. In our study it has been documented that ethyl mercury accumulates in growing hair similarly to methyl mercury. Mean total mercury blood and brain levels were approximately two times lower in the mice treated with thimerosal than in the methyl mercury-treated group. In the brain, thimerosal-exposed mice showed a steady decrease of mercury levels following the initial peak, whereas, in the methyl mercury-exposed mice, concentrations peaked the second day after exposure. In the kidneys, thimerosal-exposed mice retained higher total mercury levels than methyl mercury-treated mice 4 days after exposure. These preliminary data on the toxicokinetic behavior of the chemicals challenge the assumption that ethyl mercury is toxicologically identical to methyl mercury. (Funded by Grant H75/ATH270795 from ATSDR.)

1956 (1795a) CYP1A2 IS NOT REQUIRED FOR 2,3,7,8-TETRACHLORODIBENZO-p-DIOXIN-INDUCED IMMUNOSUPPRESSION

R. Smialowicz[1], D. E. Burgin[1], W. C. Williams[1], J. J. Diliberto[1], and L. S. Birnbaum[1]. *[1]US EPA, Research Triangle Park, NC,and [2]UNC, Chapel Hill, NC.*

One of the most sensitive and reproducible immunotoxic endpoints of 2,3,7,8-tetrachlorodibenzo-p-dioxin (TCDD) exposure is suppression of the antibody response to sheep red blood cells (SRBCs) in mice. Immunosuppression occurs in concert with hepatomegaly and associated induction of several hepatic cytochrome P450 enzymes, including CYP1A2 which is responsible for the hepatic sequestration of TCDD. In this study, TCDD-induced immunosuppression was evaluated in CYP1A2 (-/-) knockout mice and compared with that of age-matched female C57/BL/6N CYP1A2 (+/+) wild-type, and CYP1A2 (+/-) heterozygote mice. Groups of mice were given a single gavage dose of 0, 0.03, 0.1, 0.3, 1.0, 3.0 or 10.0 μg TCDD/kg, followed seven days later by immunization with SRBCs. Serum was obtained five days after immunization and body, spleen, thymus and liver weights were measured. SRBC antibody titers were determined by an enzyme-linked immunosorbent assay (ELISA). Anti-SRBC titers were suppressed at 1.0, 1.0 and 0.3 μg TCDD/kg for CYP1A2 (+/+), CYP1A2 (+/-), and CYP1A2 (-/-) mice, respectively, which indicated a three fold increase in TCDD immuno-sensitivity for the CYP1A2 (-/-) mice. This increase in TCDD-induced immunosuppression may be due to the inability of CYP1A2 (-/-) mice to sequester TCDD in the liver, leading to a higher dose to the immune system. In CYP1A2(+/+) mice a dose of 0.3 μg TCDD/kg was sufficient to increase the liver-to-body weight ratio, while in CYP1A2 (-/-) mice a dose of 10 μg TCDD/kg was required. Nevertheless, calculated TCDD ED50 values of immunosuppression were no different across the three groups of mice examined (i.e., mean ±SEM of 0.98 ±0.32, 1.02 ±0.89 and 0.58 ±0.71 μg TCDD/kg for CYP1A2 (+/+), (+/-), and (-/-) mice, respectively). Thus CYP1A2 is not required for TCDD-induced immunosuppression. (This abstract does not reflect EPA policy.)

NOTE: This abstract will be presented as #1795a.
