1 APPLICATION OF STEM CELLS IN BIOMEDICAL RESEARCH.

C. N. Svendsen. *University of Wisconsin, Madison, WI.* Sponsor: J. Davila.

In recent years stem cells are a subject of increasing scientific interest because of their potential utility in numerous biomedical applications. Stem cell technology has provided unprecedented opportunities not only for studying and understanding human development but also for changing the way we potentially will discover and develop new drugs, as well as test them for safety. This presentation will provide an overview on the evolving concept of applying stem cell technology to biomedical research, derivation of diverse tissue-specific cell types, and specific example of stem cell applications in biomedical research. This mini-course will be of interest to all toxicologists and related scientists from industry, academia, and government who are interested in the application of *in vitro* approaches using stem cells to predict the impact of drug exposure in humans as well as the generation of cells and tissues that could be used as therapies.

2 ESSENTIAL INFORMATICS FOR TOXICOLOGISTS.

J. Fostel[4], R. Thomas[3], L. Burgoon[2] and W. B. Mattes[1]. *[1]Pharmacia Corporation, Kalamazoo, MI, [2]Michigan State University, East Lansing, MI, [3]Kalypsys, Inc., La Jolla, CA and [4]Pharmacia Corporation, Kalamazoo, MI.*

The combination of the Internet, automated data acquisition, and genomic information has transformed the role of the computer in the modern scientist's life. A familiarity with word processing and simple spreadsheets is simply not adequate preparation for dealing with large datasets such as those generated by toxicogenomics or high-throughput screens. Increasingly, the software tools used to deal with such data require an understanding of basic concepts in computer science, database design, bioinformatics and statistics. This basic level course hopes to provide the beginnings of such an understanding. Thus the first lecture will cover some of the essential concepts of operating systems, file and data concepts and programming concepts. This will be followed by a talk discussing the essentials of database design and use, contrasting flat-file and relational databases. A third lecture will provide an overview of how to work with protein and nucleic acid sequences: homology searching and sequence alignment. The final lecture will cover concepts of visual analysis of large data sets, and contrast some of the various approaches used. Hopefully after this course the student will be conversant in informatics to the level of effectively interacting with computer scientists, as well as collecting and manipulating datasets with reasonable skill. Exercises will be included that the attendee can review and practice on their own computer in order to better understand the principles discussed.

3 UNFOLDING THE SECRETS IN CULTURING BRAIN CELLS: THEORY, TECHNIQUES, AND BEYOND.

M. Noble[5], W. Zheng[4], M. Aschner[3], W. R. Mundy[2] and T. J. Shafer[1]. *[1]USEPA, Research Trangle Park, NC, [2]USEPA, Research Trangle Park, NC, [3]Wake Forest University School of Medicine, Winston-Salem, NC, [4]Columbia University, New York, NY and [5]University of Rochester Mecial Center, Rochester, NY.*

In vitro culture of selected cell types of the CNS is an indispensable tool in modern neuroscience research. Rapid development in theories and techniques has revolutionized the traditional way in culturing neurons, neuroglia, and brain barrier cells. For example, co-culture techniques make it possible to investigate molecular mechanisms underlying regeneration of neurons, interaction between neurons and neuroglia, and induction of brain barriers. Recent advancement in stem cell research provides an additional dimension toward the reproduction of nearly all brain cell types. The fast-paced progress in *in vitro* culture of brain cells has presented itself as the most dynamic and rapidly advancing field in neuroscience. It is for that matter that molecular mechanisms are rarely elucidated without evidence obtained from studies using cell cultures. This course will provide comprehensive reviews of cutting edge technology in culturing brain cells beginning with a brief introduction to tissue culture theory and practice. Subsequent lectures will focus on three major cell types of the CNS, *i.e.*, neurons, astrocytes, and barrier cells, and discuss in detail the techniques to establish a primary culture, to maintain an established cell line, and to create an immortalized cell line. The theory and practice of stem cell cultures in neurotoxicological studies will also be addressed. Application of these techniques in basic research, regulatory monitoring, and industrial R&D will be discussed. This course serves as an ideal introduction to students, postdoctoral fellows, and industrial researchers beginning in their culture research, and also is suitable to those who want to improve *in vitro* culture techniques in their own laboratories. For experienced researchers, the course will provide a comprehensive review of the most recent progress in cell culture techniques.

4 THE NUTS AND BOLTS OF GENETICALLY ENGINEERED MICE IN TOXICOLOGY.

B. Bolon[4], C. A. Montgomery[3], L. K. Riley[2] and N. W. Fox[1]. *[1]Lilly Research Laboratories, Indianapolis, IN, [2]University of Missouri, Columbia, MO, [3]ComPath, Conroe, TX and [4]Amgen, Inc., Thousand Oaks, CA.*

The recent advent of genetic engineering techniques has allowed intentional engineering of novel animal models for human diseases. This has had a profound impact on basic biomedical research and has accelerated the pace at which pharmaceutical and biotechnology firms can discover new targets and innovative drug candidates. In addition it has greatly enhanced the study of mechanisms of toxicity. This course will provide an overview of how genetic engineering is used to create such models, specific issues related to management of such animals, the identification of phenotypic alterations and their evaluation in the development of models, and the use of these models in the pharmaceutical industry for discovering new targets for therapy interventions and developing new drug candidates. The course will be presented at the basic level and will provide information for scientists of all toxicology disciplines who are considering the use genetically engineered models in their research or need to understand the information provided by the use of such models. It will especially be of use to those who are not currently working with whole animals or such genetically engineered models.

5 FUNDAMENTALS OF RISK ASSESSMENT AND APPLICATIONS OF RECENT METHODOLOGIES TO DIFFICULT PROBLEMS.

G. P. Broby[6], E. C. Hubal[5], J. S. Tsuji[4], T. E. Widner[3], D. J. Paustenbach[2] and P. Williams[1]. *[1]Exponent, Inc., Boulder, CO, [2]Exponent, Inc., Menlo Park, CA, [3]ENSR International, Alameda, CA, [4]Exponent, Inc., Bellevue, WA, [5]National Exposure Research Laboratory, Research Triangle Park, NC and [6]Exponent, Inc., Oakland, CA.*

The field of risk assessment has evolved at a fairly rapid pace over the past 4-5 years. Fifteen years ago, it was not uncommon for risk assessments to be conservative descriptions of the plausible risks posed by chemicals; often the approach was dictated by regulatory guidance or criteria. Today, the approach to characterizing risks is more flexible than in years past. This course will include an introductory lecture on the fundamentals of risk assessment with an emphasis on the changes in risk assessment procedures that have occurred over the past five years (*e.g.*, new EPA cancer guidelines, children's health guidelines, monte carlo techniques, aggregate and cumulative risk, etc.). The four basic parts of a risk assessment will be described (hazard identification, dose-response assessment, exposure assessment, and risk characterization) and state-of-the-art approaches to each will be presented. This lecture is followed by three case studies. The first will discuss one of the most complex risk assessments ever conducted. It involves a former government facility which used and emitted both chemical and radiological agents. The second will present an analysis of the risks to children posed by CCA treated wood. The last case study will present several examples of how to evaluate some of the hazards posed by consumer products. Applicable regulatory guidance (both domestic and international) will be cited in the various talks.

6 CUTANEOUS TOXICITY-CURRENT METHODS AND CONCEPTS IN SAFETY EVALUATION AND RELEVANCE TO HUMAN EXPOSURE.

A. C. Jacobs[5], R. C. Wester[4], C. S. Auletta[3], C. A. Ryan[2] and N. A. Monteiro-Riviere[1]. *[1]North Carolina State University, Raleigh, NC, [2]Procter & Gamble Company, Cincinnati, OH, [3]Huntingdon Life Sciences, East Millstone, NJ, [4]Universtity of California at San Francisco, San Francisco, CA and [5]USFDA, Rockville, MD.*

Humans are exposed to a large number of potentially toxic substances through the skin. Cutaneous exposure may occur intentionally, as with use of pharmaceuticals and consumer products, or accidentally, as a result of industrial or environmental exposure. Evaluation of the safety of these substances is an important function of toxicologists. It has been several years since SOT presented a continuing education course on this topic. The course will provide presentations and discussions of the current status of cutaneous toxicity safety evaluation, using *in vitro* and *in vivo* (animal model) systems as well as clinical evaluations in humans. Areas covered will include irritation, toxicity and phototoxicity. Regulatory aspects, current protocols, guidance on study design and interpretation of results will be discussed as will the relevance to human exposure. This would be a basic course of interest to toxicologists who may work with materials with a potential for cutaneous exposure (pharmaceuticals, consumer products, chemicals). It will provide an overview of the topic for those with little or no experience in this area and will provide updates, with information on current ideas and methods in the field, for those currently working in dermal toxicology. The presentation on *in vitro* assays will be of special

interest to scientists specializing in this area. Presentations on human testing and CDER/U.S. FDA practice will be of interest to those with concerns in the areas of drug development and regulatory affairs.

7 MEDICINAL HERBALS AND DIETARY SUPPLEMENTS.

G. N. Scott[4], J. Betz[3], E. A. Yetley[2] and C. S. Smith[1]. [1]*National Institutes of Environmental Health, Research Triangle Park, NC,* [2]*USFDA, College Park, MD,* [3]*NIH, Bethesda, MD and* [4]*Eastern Virginia Medical, Norfolk, VA.* Sponsor: A. Fuciarelli.

Medicinal herbals and other dietary supplements are consumed by an estimated one-third of the US population. Over 1500 botanicals are sold as dietary supplements or ethnic traditional medicines. Their use has increased substantially since passage of the 1994 Dietary Supplement Health and Education Act. Herbal formulations are not subjected to FDA pre-market toxicity testing to assure their safety or efficacy. However, there is an increased public awareness of the need to conduct toxicity studies on herbs and herbal ingredients and many government and private laboratories are contributing to this effort. Perhaps the largest single effort in this area is being conducted by the National Toxicology Program where studies are being conducted on the following medicinal herbals and compounds found in herbs: aloe vera gel, black cohash, comfrey, ginseng and ginsenosides, goldenseal, kava kava, pulegone, thujone, and extracts of grape seed, pine bark, black walnut, *Echinacea purpurea, Ginkgo biloba* and milk thistle. In this course, speakers will present information relevant to toxicity testing for safety and efficacy. Presentations describe the on-going efforts in chemical analyses and dosing/formulation issues; safety assessment including carcinogenicity, reproductive toxicity, immunotoxicity, neurotoxicity, and effects associated with acute exposure to high doses and chronic exposures to low doses; adverse human health effects with an emphasis on circumstances under which the adverse reactions may occur; interactions with pharmaceutical products; and perspectives on research needs and priorities for safety assessment of herbal medicines and dietary supplements.

8 GENOMIC AND PROTEOMIC ARRAY FORMATS ON THE CUTTING-EDGE.

S. Mousses[4], P. Bertone[3], M. Madou[2] and D. Walt[1]. [1]*Tufts University, Medford, MA,* [2]*University of California, Irvine, CA,* [3] *Yale University, New Javen, CT and* [4]*NIH, Bethesda, MD.* Sponsor: M. Cunningham.

Microarrays are now being used to explore gene expression from a variety of tissues and cells on the scale of tens of thousands of genes. They have been used in toxicology over the past three to four years to investigate and predict toxic effects and explore the mechanisms of action by which compounds cause these effects. Several past courses and seminars have detailed the most common formats: oligonucleotide and cDNA arrays. In this course, new formats which are on the cutting-edge and in some cases, in development, will be explored. These formats include optic fiber, electronic, tissue and protein microarrays. Each format presented has its own advantages and limitations but can offer a more defined look at gene and protein expression compared to the current common formats. Optic fiber and electronic arrays offer instantaneous hybridization and detection. Protein arrays offer a quicker scan of protein activity with better resolution than the more traditional method of performing two-dimensional electrophoresis and annotating by mass spectroscopy. Tissue arrays are essentially a microarray of histology and can be used to detect DNA, RNA or protein. Each format will be presented in detail with how it is applied to current genomic and proteomic issues. Specific applications or perceived applications to issues in toxicology will be presented

9 INTEGRATING TOXICOLOGIC PATHOLOGY INTO COMPOUND EVALUATION AND RISK ASSESSMENT II.

R. L. Peiffer[4], A. Fix[3], W. Kerns[2] and P. Mann[1]. [1]*Experimental Pathology Laboratory Northeast, Galena, MD,* [2]*Pharmacology Consulting Inc., Harvard, MA,* [3]*Procter & Gamble Company, Cincinnati, OH and* [4]*Merck Research Laboratories, West Point, PA.*

The contribution of pathology assessment to toxicity assessment is invaluable but often not clearly understood. Pathology endpoints are the central response around which human health risk assessment is determined. Therefore, it is important that the general toxicology community understands current concepts and nomenclature of toxicologic pathology. Toxicologic pathology is a discipline that changes and adapts over time including methods of analysis and nomenclature of lesions. As risk assessments are reevaluated and updated on commodity chemicals, frequently the older literature must be evaluated. This course will present ideas on how to evaluate terminology and diagnoses in light of current standards, diagnostic drift, and changed interpretation. Then a continuation of a systems approach to toxicologic pathology assessment will continue with a review of the cardiovascular system, neuropathology, and the eye. Lectures will cover normal structure, function, diagnostic terminology, and specific case examples.

10 CHOICE AND APPLICATION OF CLASSICAL, POPULATION OR PHYSIOLOGICALLY-BASED PK FOR CHEMICAL ASSESSMENT AND PHARMACEUTICAL DEVELOPMENT.

D. R. Plowchalk[5], H. A. Barton[4], S. Gupta[3], R. Dixit[2] and J. C. Lipscomb[1]. [1]*USEPA, Cincinnati, OH,* [2]*Merck Research Laboratories, West Point, PA,* [3]*Schering-Plough Research Institute, Kenilworth, NJ,* [4]*USEPA, Research Triangle Park, NC and* [5]*Pfizer Inc., Groton, CT.*

Both toxicity and therapeutic effectiveness are dictated by the delivery of a chemical to its target (pharmacokinetics, PK) and the response (pharmacodynamics, PD) which follows the molecular interaction between xenobiotic and target molecule. This session will instruct participants in proper methods to conduct investigations and interpret PK findings. It will contain an overview of PK in risk and safety assessment and four lectures on topics critical to the identification of PK models and their proper application to derive toxicologically, risk and safety-relevant measures. Lecture content will be aimed at instructing the selection of therapeutic doses; identification of margins of safety; methods applicable to the extrapolation of doses; the separate benefits of classical versus physiologically-based PK models; and proper methodology to collect, interpret and employ measures of population PK variance. PK is a critical modulator of toxicity, and is a fundamental component in risk assessments, safety assessment and drug development. This advanced level course is intended to educate professionals who are considering or have recently begun to increase their studies of PK; it will guide the development of toxicity studies which can also collect useful PK information. The course has been designed to address the interests of scientists involved in the design of basic toxicity and pharmacokinetic studies, preclinical and clinical studies, and those scientists conducting safety and/or risk assessments.

11 EVALUATION OF IMMUNOMODULATION IN SAFETY ASSESSMENT.

K. Hastings[4], J. Bussiere[3], R. V. House[2] and J. Dean[1]. [1]*Sanofi-Synthelabo, Malvern, PA,* [2]*Dynport Vaccine Company, Frederick, MD,* [3]*Immunex Corporation, Seattle, WA and* [4]*USFDA, Rockville, MD.*

Assessment of adverse effects on the immune system is of considerable importance in the safety evaluation of investigational new drugs. This course will cover the practical aspects of immunotoxicology for pharmaceutical development and is targeted to toxicologists in the industry. Although it will focus on safety assessment of therapeutics, the concepts discussed are also applicable to a variety of test materials. The course will be introduced with a session on the historical role that immunotoxicology has played in drug development, the types of adverse events that have been reported in both clinical trials and non-clinical toxicology studies and the growing importance of this field of study in safety assessment. The second speaker will discuss basic methods for assessing immune function in rodents, including which tests may be combined with standard 28-day toxicity studies, assays to evaluate specific immune targets, as well as special studies that may be informative or necessary to conduct when immune effects are observed. The third speaker will cover immune assessment in non-human primates, and will focus on species selection, testing strategies, and technical issues specific to primates. The final speaker will discuss the current international regulatory requirements for immunotoxicology in submission of new drugs. Although this is a basic course, it is assumed that the participants will have a basic knowledge of immunology.

12 THE EFFECTS OF NON-REPRODUCTIVE HORMONES ON THE REPRODUCTIVE SYSTEM AND THE IMPLICATIONS FOR TOXICOLOGY.

R. J. Witorsch[4], P. Cooke[3], P. Morris[2] and J. Meredith[1]. [1]*Schering-Plough Research Institute, Lafayette, NJ,* [2]*The Population Council, New York City, NY,* [3]*University of Illinios, Urbana, IL and* [4]*Medical College of Virginia, Richmond, VA.*

More and more, we are coming to understand the degree of interconnectedness that ties together organ and hormone systems that were previously thought to be separate. This interconnectedness is important in both human health and in animal toxicology studies. The mammalian reproductive system undergoes basic activation events during development, and then constant fine-tuning as adults. This activa-

tion and fine-tuning rely on hormones and growth factors which can have effects both subtle and profound. This course is designed to give both the general and specialist audience a better appreciation of the impact of several different hormonal systems on male and female reproduction, and how we can use these to explain mechanisms of toxicity in the reproductive systems. John Meredith will provide a background understanding of the signaling events in reproductive tissues by reviewing normal mechanisms of endocrine interaction and signaling. Patricia Morris will then describe the complex and intriguing world of cytokines, with their pleiotropic effects on all aspects of mammalian reproduction. Paul Cooke will show how the thyroid hormones significantly impact the reproductive system both developmentally and in adults. Finally, Raphael Witorsch will explore what is known about the effects of glucocorticoids on various stages of reproduction. At the end of the course, the student will have an improved understanding of how these other hormone systems impinge on reproduction, and will be better able to determine their involvement in a lesion when puzzling out mechanisms of toxicity.

13 EPIGENETICS OF CANCER.

R. Roberts[4], J. Moggs[3], J. Goodman[2] and J. Trosko[1]. *[1]Michigan State University, East Lansing, MI, [2]Michigan State University, East Lansing, MI, [3]Syngenta Central Toxicology Laboratory, Macclesfield, United Kingdom and [4]Aventis Pharmacology, Vitry sur Seine, France.*

For the past few decades, research has focused on understanding the mechanisms of genotoxic or nongenotoxic carcinogenesis. However, recent evidence suggests that gene expression can be markedly altered *via* several epigenetic mechanisms that can lead to permanent or reversible changes in cellular behavior. Thus, cancer may develop as a result of interplay between genetic alteration and epigenetic changes. Developing an understanding of the role played by epigenetic modulation of gene expression is a key element in understanding the response of cells and organisms to toxicants, in particular carcinogens. This course will bring together several leading speakers in this area to address the different aspects of epigenetics ranging from methylation through to proposed non-genomic modes of action for transcription factors such as ER and PPAR. This is of interest to all toxicologists, particularly those interested in the mechanisms of rodent and human cancer. This basic course is intended to assist investigators who may want to incorporate a consideration of epigenetics into their research and/or teaching. Through the use of appropriate examples, emphasis will be placed upon the conceptual and theoretical basis of epigenetics. Furthermore, there will be a focus on practical aspects concerning safety assessment, *e.g.*, how an epigenetic mechanism of action might provide information concerning extrapolation from species to species and the shape of the dose-response curve at low doses.

14 UNDERSTANDING MECHANISMS OF TOXICITY OF IMMUNOSUPPRESSIVE DRUGS TO IMPROVE THEIR SAFETY PROFILES AND BROADEN THE SCOPE OF USE.

U. Christians. *Anesthesiology, University of Colorado Health Sciences Center, Denver, CO.* Sponsor: T. Kawabata.

Organ transplantation requires life-long prophylaxis with immunosuppressants to avoid rejection of the transplant organ. Today, calcineurin inhibitors are still the cornerstone of most immunosuppressive protocols. The propensity of these agents to ultimately damage the very organs they were intended to protect, especially the kidney, was always recognized, but largely tolerated due to the impressive ability to improve short-term outcomes. With mycophenolic acid and the TOR (target of rapamycin) inhibitor sirolimus, equally potent immunosuppressants that themselves are lacking the most important side effects of calcineurin inhibitors, such as nephrotoxicity and neurotoxicity, have become available. Although devoid of nephrotoxicity when administered alone, TOR inhibitors unexpectedly enhanced cyclosporine nephrotoxicity in clinical studies. Until recently, the biochemical mechanisms underlying immunosuppressant toxicity alone and in combination were poorly understood. Immunosuppressive drugs used in the prevention of transplant rejection have limited application in other fields such as autoimmune diseases due to the severe toxicities produced. Progress in pharmacogenomics, proteomics, and analytical technology such as magnetic resonance spectroscopy has led to a better understanding of the mechanisms of immunosuppressant toxicity and variability of their pharmacokinetics. The cyclosporine derivative ISATX247 is a good example for how the understanding of molecular toxicity mechanisms can result in the design of a calcineurin inhibitor with a significantly improved therapeutic index. Better knowledge of immunosuppressant pharmacodynamics will lead to (a) more effective clinical long-term management strategies of toxicity in transplant patients, (b) the development of potent immunosuppressants with better safety profiles, and (c) broadening of the scope of use of immunosuppressants used mainly in transplantation.

15 PHARMACODYNAMIC, PHARMACOKINETIC AND PHARMACOGENOMIC INVESTIGATIONS OF IMMUNOSUPPRESSANTS PROVIDE THE BASIS FOR SAFER AND MORE EFFECTIVE REJECTION PROPHYLAXIS.

L. M. Shaw. *Department of Pathology and Laboratory Medicine, University of Pennsylvania Medical Center, Philadelphia, PA.* Sponsor: T. Kawabata.

The efficacious and safe use of the "critical-dose" immunosuppressive drugs (ISDs) cyclosporine, tacrolimus, mycophenolic acid and rapamycin requires drug concentration-guided dosing in the individual transplant recipient. Retrospective and prospective investigations of the relationship between active immunosuppressive drug concentration and clinical effects are the basis for current protocols used in transplant centers worldwide. Recognition of significant clinical pharmacodynamic variables or risk factors and adjustment of the immunosuppressive regimen, both the agents selected and the target concentration range used, is essential in order to obtain the best possible outcome. Among the most important immunologic and non-immunologic pharmacodynamic variables are: the occurrence of acute rejection, inadequate immunosuppression, degree of HLA mismatch, previous transplant, poor early graft function, infection, chronic nephrotoxicity, cold ischemia time, donor age and ethnicity. Thus the selection of a particular combination of ISDs and the corresponding target concentration range is based in part on the presence of particular clinical pharmacodynamic variables. The pharmacokinetic parameter that best reflects drug exposure is not necessarily the trough, Co value, in every case. The preferred pharmacokinetic parameter and the experimental basis for each of the ISDs will be described. The identification and use of cellular pharmacodynamic factors, illustrated by calcineurin phosphatase, the enzyme inhibited by the complex of cyclosporine or tacrolimus with either cyclophilin or FKBP12, respectively, and inosine monophosphate dehydrogenase, the enzyme inhibited by mycophenolic acid and the current status of incorporation of pharmacogenomics in clinical trials will be critically reviewed. The experimental basis for current "best practice" control of pharmacodynamic and pharmacokinetic variability of ISDs will be presented.

16 GENOTYPIC AND PHENOTYPIC EVALUATIONS IN CONNECTION WITH AZATHIOPRINE TOXICITY.

M. Oellerich, N. von Ahsen, M. Shipkova and V. W. Armstrong. *Department of Clinical Chemistry, George-August-University, Göttingen, Germany.* Sponsor: U. Christians.

Azathioprine is a pro-drug that is converted *in vivo* to 6-mercaptopurine (6-MP), which is subsequently metabolised to the pharmacologically active 6-thioguanine nucleotides (6-TGN). The latter are also responsible for the toxic side effects associated with this drug. Thiopurine-S-methyltransferase (TPMT) plays an important role in the catabolism of 6-MP, thereby opposing its transformation to 6-TGN. Patients with TPMT deficiency are at high risk for thiopurine drug-induced toxicity. TPMT is subject to a genetic polymorphism that leads to a heterozygous deficiency of this enzyme in 11 % of the Caucasian population and a homozygous deficiency in 0.3 %. If patients with a homozygous deficiency of TPMT are given thiopurine derivatives at a standard therapeutic dosage 6-TGN accumulate resulting in severe myelosuppression and possible life-threatening pancytopenia. Identification of such individuals through measurement of TPMT phenotype is essential. TPMT activity can be determined in a cytosolic preparation of erythrocytes. Genotyping is a further option. Out the 10 TPMT gene mutations TPMT *2, *3A, *3C account for > 90 % of cases with TPMT deficiency. Genotyping with conventional methods is hampered by the fact that not all TPMT mutations are known. There is also the possibility of a pseudo-heterozygosity, in which TPMT*3B / *3C cannot be discriminated from TPMT*3A / *1, the former bearing the consequence of complete TPMT deficiency. Such a patient has a high risk of developing toxicity but would be falsely categorized by routine genotyping as having a moderate or low risk. Novel haplotyping methods can overcome this problem. Genotyping is mandatory in patients who have recently received blood transfusions. In most other clinical situations phenotyping is the superior approach to exclude homozygous deficiency. In addition, monitoring the pharmacologically active 6-TGN metabolites in a cytosolic preparation of erythrocytes is recommended to optimise therapy during treatment with azathioprine.

17 MAGNETIC RESONANCE SPECTROSCOPY AS A TOOL TO IDENTIFY MECHANISMS OF IMMUNOSUPPRESSANT TOXICITY.

N. J. Serkova and U. Christians. *Anesthesiology, University of Colorado Health Sciences Center, Denver, CO.* Sponsor: K. Thomas.

The clinical use of the immunosuppressant cyclosporine is limited by its toxicity, mainly nephrotoxicity, and narrow therapeutic index. Although cyclosporine has been the basis for most immunosuppressive protocols in transplantation for two

decades, the exact molecular mechanisms of its toxicity remain unknown. The reason was limitations of the existing experimental methods to the evaluation of only selected biochemical pathways. In the last decade, MRS (magnetic resonance spectroscopy) has shown great promise in toxicology, drug discovery, pre-clinical drug-development and in hypothesis-driven biomedical research. MRS allows for the simultaneous assessment of all important metabolic pathways in cells including lipid (1H-MRS), glucose (13C-MRS) and high-energy phosphate metabolism (31P-MRS). We applied MRS to systematically evaluate the effects of immunosuppressants and their combinations on cell and organ metabolism *in vitro* and *in vivo* and used a novel dual lipid/ perchloric acid (PCA) extraction procedure. In rats treated with 10 mg/kg/d PO for 6 days, cyclosporine significantly inhibited high-energy metabolism: ATP: 57% of control (kidney, P<0.001), 62% (liver, P<0.01), 83% (heart, P<0.01). Also, concentrations of glutamate (mitochondrial Krebs cycle: 78% in kidneys, P<0.02) and NAD+ (mitochondrial oxidative phosphorylation: 52% in kidneys, P<0.0003) were significantly reduced. Our results showed that cyclosporine inhibits the Krebs cycle and oxidative phosphorylation in the mitochondria. As a compensatory effect, ATP production by anaerobic glycolysis was increased (elevated lactate concentrations) in all tissues. The negative effects of cyclosporine on cell metabolism were antagonized by oxygen radical scavengers indicating that oxygen radical formation plays a key role in cyclosporine-induced mitochondrial dysfunction. Our studies demonstrate that MRS is a powerful tool for pre-clinical toxicology screening of immunosuppressants and their combinations.

18 DEVELOPMENT OF THE NOVEL IMMUNOSUPPRESSIVE AGENT ISATX247 USING A PHARMACODYNAMIC APPROACH.

D. G. Freitag[1], M. D. Abel[1], L. J. Aspeslet[1], D. J. Trepanier[1], P. R. Mayo[1], P. F. Halloran[2], N. T. Kneteman[2], R. E. Morris[3], C. R. Gregory[4], R. T. Foster[1] and R. W. Yatscoff[1]. *[1]Isotechnika, Edmonton, AB, Canada, [2]University of Alberta, Edmonton, AB, Canada, [3]Stanford University, Stanford, CA and [4]University of California, Davis, CA.* Sponsor: U. Christians.

As the mechanism of action for various immunosuppressive drugs becomes understood, it is possible to utilize pharmacodynamic (PD) data with toxicokinetics to discover new drug candidates. This approach was used by Isotechnika to develop the novel immunosuppressant ISATX247 (ISA) which was found to be a more potent inhibitor of calcineurin (CN) in whole blood than cyclosporine A (CsA). Initially, several compounds were evaluated *in vitro* using the CN assay. Candidates with increased activity were tested further *in vivo* using a rat heart transplant model. The final candidate, ISA, was found to be 2.5 fold more potent than CsA *in vitro* and 3-fold more effective in promoting graft survival. Flow cytometric studies on T cell markers further characterized the immunosuppressant effects in non-human primates. These investigations determined that ISA was up to 6 times more potent at inhibiting immune functions than CsA. Based on this data a study was conducted to compare the survival times of renal allografts in non-human primates treated with either ISA or CsA. The results showed that the group receiving ISA survived significantly longer (p = 0.0036). An increase in potency could be associated with increased toxicity. Therefore, renal toxicity was evaluated in a rabbit model. The CsA treated animals had a 33 % increase in serum creatinine concentration over the treatment period. In Phase I trials, pharmacokinetic/PD correlation allowed for the determination of dose and a therapeutic window much earlier in the drug development process. Based on these correlations, ISA was used in Phase II trials, in stable renal transplant patients, at 1/3 trough concentration to CsA because the increased potency was demonstrated. Therefore, PD data may greatly accelerate the development of novel compounds.

19 USE AND APPLICATION OF STEM CELLS IN TOXICOLOGY.

G. N. Cosma[1], M. A. Thiede[2], S. Strom[3], J. A. Johnson[4] and J. E. Trosko[5]. *[1]Investigative Toxicology, Pharmacia Corporation, Kalamazoo, MI, [2]Discovery, Pharmacia Corporation, St. Louis, MO, [3]Pathology, University of Pittsburgh, Pittsburgh, PA, [4]Pharmacy School, University of Wisconsin, Madison, WI and [5]Pediatrics and Human Development, Michigan State University, East Lansing, MI.*

Recent published reports on the isolation and culturing of stem cells have created a great deal of interest and excitement in both the scientific and the public community. Stem cell technology holds great promise for advances in biomedical research, and will allow us to understand the complex events that occur during human development, provide new platforms for drug discovery and development, and replace organ-specific cell populations damaged by diseases. Embryonic stem cells are pluripotent cell populations with the ability to give rise to differentiated cells of the human body such as brain, heart, liver, bone and blood cells. Other stem cell types have been derived from fetal tissues, blood and bone marrow. Most isolated stem cells are capable of limitless division and undergo self-renewal. Thus, the cells can be maintained for extended periods of time in tissue culture making them a vital resource for biomedical research. The objective of this symposium is to provide information on the current status of efforts focused on derivation of stem cells and the application of tissue-specific stem cell types in toxicology. This symposium will be of interest to all toxicologists and related scientists from industry, academia, and government who are interested in the application of *in vitro* approaches using stem cells to predict the impact of drug exposure in humans as well as the generation of cells and tissues that could be used as therapies.

20 EXPLOITING MARROW-DERIVED ADULT STEM CELLS FOR PRE-CLINICAL SAFETY EVALUATION.

M. A. Thiede. *Discovery, Pharmacia Corporation, St. Louis, MO.* Sponsor: J. Davila.

The preclinical safety evaluation of drug candidates in cultures of human primary cells is limited by the availability of healthy donor tissue and the difficulties of maintaining the human cell isolates in culture. While Primary human hepatocyte or cardiomyocyte cultures provide an important surrogate for preclinical evaluation of liver and cardio-toxicities these cell types are particularly difficult to propagate in culture and therefore their use is greatly limited. Recent advances in stem cell biology offer the possibility of creating unlimited supplies of cell types, which can be used for research and even therapeutic purposes. While embryonic cells isolated from the pre-implantation blastocyst perhaps offer the greatest potential for producing every cell type found in the adult body, their general use for research purposes remains controversial. Alternatively, adult stem cells present in many adult tissues and which are critical to tissue repair and homeostasis, possess the unique capacity for self-renewal and differentiation into one or more specialized cell types. Furthermore, methods have been developed for isolating adult stem cells from tissue sources such as bone marrow aspirates adipose tissue recovered during liposuction procedures. Early stem cell research demonstrated that adult stem cells cultured under specific conditions could differentiate into several lineages including cells that produce bone, cartilage and fat. Recent advances in stem cell research have revealed an even greater differentiation potential for adult stem cells isolated from bone marrow. Culture conditions have now been developed to induce these adult stem cells into a vast spectrum of differentiated cell types including neurons, endothelial cells, hepatocytes and cardiomyocytes. The potential use of adult stem cells a as an alternative source of critical cells required to perform needed safety evaluation in human cells will be discussed.

21 PRODUCTION OF HEPATOCYTES FROM HUMAN AMNIOTIC STEM CELLS FOR DRUG METABOLISM AND TOXICITY STUDIES.

S. Strom, T. Miki and H. Cai. *Pathology, University of Pittsburgh, Pittsburgh, PA.* Sponsor: J. Davila.

Isolated human hepatocytes have been shown to be useful for both basic and clinical science. Hepatocyte transplantation has been shown to be an effective treatment for liver disease, and isolated human hepatocytes have been shown to be a useful model for drug metabolism, CYP450 induction or toxicology assays. The availability of sufficient numbers of hepatocytes with which to conduct the basic research or the clinical studies limits the numbers of studies which can be conducted. Stem cells could provide a new source of liver cells for cell transplantation studies or basic research. Human amniotic epithelial (AE) cells were isolated from term placenta following live birth. By immunohistochemical analysis amniotic tissue was found to react with cytokeratin antibodies AE1/AE3 and with specific antibodies to cytokeratins (CK) 18 and 19 and the hepatocyte marker Alpha 1-antitrypsin (A1AT). In addition, AE tissue showed significant reaction with antibodies to c-kit. Epithelial cells isolated from the amniotic tissue can be propagated in culture and react positively with the pan-cytokeratin AE1/AE3 and specific antibodies to CK 18, CK19, Thy-1, c-kit, A1AT and Alb. Albumin mRNA and protein were detected in extracts from cultured AE cells by RT-PCR and Western blot, respectively and A1AT protein was detected in cells by Western blot. The liver enriched transcription factor, HNF4, was detected in cultured AE cells by immunohistochemical analysis and by RT-PCR and HNF4 expression is increased under conditions which favor differentiation. Taken together these data indicate that AE tissue contains stem cells which under appropriate conditions are able to differentiate into cells with characteristics of hepatocytes. Amniotic stem cells may be useful for clinical hepatocyte transplantation and for the production of human hepatocytes for basic research such as drug metabolism and toxicology.

22 ANTIOXIDANT RESPONSE ELEMENT DRIVEN GENE EXPRESSION IN MULTIPOTENT HUMAN NEURAL PROGENITORS AND THE DIFFERENTIATED CELLS ARISING FROM THESE PROGENITORS.

J. A. Johnson[1,2,4], J. Li[1], D. A. Johnson[1], L. S. Wright[2] and C. N. Svendsen[2,3]. *[1]School of Pharmacy, University of Wisconsin, Madison, WI, [2]Waisman Center, University of Wisconsin, Madison, WI, [3]Center for Neuroscience, University of Wisconsin, Madison, WI and [4]Molecular and Environmental Toxicology Center, University of Wisconsin, Madison, WI.*

Multipotent neural progenitors can be obtained from the developing human brain and expanded *in vitro* as neuroshperes. To determine the changes in human antioxidant response element (ARE)-driven gene expression, neurospheres were treated with tert-butylhydroquinone (tBHQ), a potent activator of the ARE. Microarray analysis revealed that tBHQ could significantly upregulate ARE-driven genes such as NAD(P)H:quinone oxidoreductase (NQO1), glutathione reductase, heme oxygenase 1(HO1), thioredoxin reductase (TR), ferritin heavy and light chains, and gamma-glutamylcysteine ligase regulatory (GCLR) and catalytic (GCLC) subunits. Addition of LY294002, a selective inhibitor of phosphatidylinositol 3-kinase (PI3K), 30 min prior to tBHQ treatment, inhibited this induction by tBHQ and reduced basal levels of gene expression for most genes, except TR, GCLR, and GCLC. After neural progenitors were dissociated and plated down to promote differentiation, dynamic changes in gene expression of NQO1 were observed. NQO1 histochemistry demonstrated that NQO1 activity in well-differentiated neurons had been decreased dramatically relative to their progenitors (neuroblasts). Whereas NQO1 activity in well-differentiated glia cells was consistent with their progenitors. tBHQ also increased ARE-driven gene expression in well-differentiated cells. The extent to which was dependent on the expression of Nrf2. These data are the first to show the dynamic changes in ARE-driven gene expression during development of human neural progenitor cells. Since increased expression of these genes has been shown to protect cells from oxidative stress-induced apoptosis, it will be of great interest to correlate the dynamic changes described here with differential sensitivities to stress. *Supported by NIEHS, the BWF New Investigator Award, and the University of Wisconsin Foundation*

23 USE OF HUMAN ADULT PLURIPOTENT STEM CELLS TO SCREEN FOR GENOTOXIC/EPIGENETIC TOXICANTS.

J. E. Trosko. *Pediatrics and Human Development/ National Food Safety Toxicology Center, Michigan State University, East Lansing, MI.*

Understanding the mechanisms by which physical/chemical mutagenic, cytotoxic or epigenetic toxicants lead to death, teratogenesis, carcinogenesis, atherogenesis, cataractogenesis, immuno-, reproductive-, and neuro-toxicities, as well as premature aging and other diseases, requires knowledge of the homeostatic regulation of cell proliferation, differentiation, apoptosis, and senescence of cells. In the developing, mature and aging organisms, pluripotent stem cells, by symmetrical (self-renewal) and asymmetric (differentiation) processes, provide cells for growth, cell replacement and wound repair. The micro-environment (niche) of the pluri-potent stem cells in each organ, influenced by cell-matrix, cell to cell adhesion and extra- and inter-cellular communication, the net affect which determines intra-cellular signaling of the stem cell, determines whether the cell stays quiescent, apoptosis, divides asymmetrically or symmetrically. Upsetting this niche-micro-environment can alter homeostatic regulation, adaptively or mal-adaptively, the quality and quantity of the stem cell pool, their progenitor daughter cells or the terminally differentiated cells in any tissue. Mono-clonally-derived abnormal tissues found in organs, such as tumors and atherosclerotic plaques, are hypothesized to arise from single stem cells whose critical genes have been altered by either mutagenic or epigenetic mechanisms. Reduction of the stem cell pool might be responsible for the aging process of any organ, hence ultimately the organism. With the ability to isolate the few stem cells in any tissue and the availability of modern molecular biological tools such as DNA micro-array analyses, the goal of toxicology will be to characterize these stem cells and compare their sensitivity/resistance to physical/chemical toxicants to those of their progenitor and differentiated daughters.

24 BIOTERRORISM AND ITS TOXICOLOGICAL EFFECTS.

D. B. Warheit. *DuPont Haskell Laboratories, Newark, DE.*

The workshop is designed to present a basic primer on the timely topic of biological warfare agents. The first presentation will provide an overview of the major aspects of biological terror/warfare agents. A Center for Disease Control's classification of biological warfare agents will be presented, followed by a brief listing of 1) biological agents - including bacterial agents such as anthrax, cholera toxin, pneumonic plague and brucellosis; 2) viruses- such as smallpox, ebola, VEE, and VHF; 3) biological toxins - such as botulinum, Staph entero-B, ricin, and T-2 mycotoxins. In the second talk, Dr. Aileen Marty, a long-standing pathology expert (pre 9/11) on bioterrorism/ infectious disease will discuss the development of plans and methods for defending against the deliberate use of biological agents. Dr. Marty has been presenting a course on bioterrorism at her institution for several years and, in addition to her expertise on infectious diseases, is an expert on forensic and legal issues related to bioterror agents. In the 3rd presentation, Dr. Elliott Kagan, will discuss bioregulators as naturally occurring compounds that regulate physiological processes and their potential for misuse in bioterrorism - included in this category are cytokines, eicosanoids, neurotransmitters, hormones, and plasma proteases. The final presentation will focus on current concepts related to the pathogenesis of infectious agents such as inhalation anthrax and smallpox disease. For example, the talk will discuss inhalation anthrax, a deadly disease in which spores attack the lung macrophage *via* a number of novel proteins, including protective antigen (misnamed), lethal factor and edema factor, which hijack the macrophage's defensive functions and direct the cellular machinery to secrete destructive levels of cytokines. This Workshop should provide basic information on the infectious agents that pose a potential threat in a bioterrorist attack.

25 BIOTERRORISM: AN OVERVIEW.

D. K. Bhalla. *Wayne State University, Detroit, MI.*

This presentation provides an introductory primer on the classification of biological agents associated with potential uses in bioterrorism. The Federal Centers for Disease Control has recently evaluated some bioactive agents for potential bioterror attack and has classified many of these agents into priority categories (e.g., A, B, C) in order to forecast public health preparedness requirements. Agents assigned to the A Category are regarded as having the greatest potential for adverse public health impact with significant numbers of casualties. Included in this category are bacterial-derived products of anthrax, plague, botulism and tularemia. Viral agents in this category include viral hemorrhagic fevers (e.g. Ebola and Marburg viruses) and the smallpox virus. Anthrax is an acute infectious disease caused by the spores of *Bacillus anthracis* and is manifested in oral, cutaneous and inhalation forms of the disease. The inhalation form of anthrax is known to be lethal if antibiotic therapy is not initiated in a timely fashion. Plague is a historical disease caused by the bacteria *Yersinia pestis*. In 541 AD, the first plague pandemic occurred in Egypt and spread throughout the world for the next 4 years, resulting in 50-60% fatalities. Inhalation of aerosolized plague particles leads to pneumonic plague, a highly lethal and potentially contagious form. Botulinum toxin is derived from the genus of anaerobic bacteria named *Clostridia*. The toxin binds irreversibly to peripheral cholinergic synapses, inhibiting the release of the neurotransmitter acetylcholine from motor neurons and results in muscle paralysis. Smallpox is considered to be one of the most serious bioterrorist threats to the civilian population. Smallpox spreads directly from person to person, primarily as droplet nuclei expelled from the oropharynx of the infected person or by aerosol. Viral hemorrhagic fever viruses are a diverse group of viruses that cause clinical disease associated with fever and bleeding disorders. Most Category B agents also have potential for large-scale dissemination but generally have a reduced likelihood for causing illness and death.

26 RECENT CHALLENGES IN INFECTIOUS DISEASE: BIOLOGICAL PATHOGENS AS WEAPONS AND EMERGING ENDEMIC THREATS.

A. M. Marty. *Department of Pathology, Uniformed Services University of the Health Sciences, Bethesda, MD.*

This presentation will put in perspective emerging infections with the biological agents whose characteristics make them likely potential threat agents. It introduces the pathobiological, biochemical, molecular, and medical laboratory aspects of living agents or organic products of potential use in warfare, terrorism, or criminal activities. The talk then provides an understanding of the clinicopathologic features of potential threat agents and their toxins. Routes of host entry, the pathophysiology of host reactions, the specific cellular, biochemical, and molecular pathology in target organs and diagnostic techniques for living agents or organic products are discussed. Environmental & agricultural issues of biological agents and toxins are included. Mechanisms for providing a rapid clinicopathologic diagnosis of animal and zoonotic diseases used by terrorist are addressed. New equipment for rapid detection, including molecular techniques, and hand-held equipment are introduced. Mention of techniques to distinguish innocent from questionable use of dual-use high tech equipment will be discussed. Forensic investigation and the function of the pathologist, microbiologist, and toxicologist in chain of custody, legal, and political issues is explained. An understanding of the policy & decision-making issues will be addressed.

27 BIOREGULATORS AS INSTRUMENTS OF TERROR.

E. Kagan. *Department of Pathology, Uniformed Services University of the Health Sciences, Bethesda, MD.*

Bioregulators are naturally occurring organic compounds that regulate diverse cellular processes, such as bronchial and vascular tone, muscle contraction, blood pressure, heart rate, temperature and immune responses. They are produced in very small quantities in a variety of living organisms and are essential for normal homeostasis. These substances can be harmful, however, in large concentrations or if modifications to them bring about changes in the nature and duration of their action. Unlike traditional disease-causing bioterrorism agents that take hours or days to act, many bioregulators act within minutes of administration. Depending on factors such as dosage and route of administration, the action of several bioregulators may be lethal. If exploited for the purpose of bioterrorism, they could potentially cause profound physiological effects such as rapid loss of consciousness, fever, dyspnea, hypoglycemia, disseminated intravascular coagulation, heart failure, paralysis, shock, or hypertension. Other effects may be more subtle (e.g., exaggerated fear and pain). The main groups of bioregulators to be discussed comprise cytokines (IL-1, IL-6, TNF-alpha), eicosanoids (PGD2, LTC4), proteolytic enzymes (kallikrein), neurotransmitters and hormones (catecholamines). As advances continually are being made in their development, bioregulators should be considered as weapons with increasing bioterrorism potential.

28 CURRENT CONCEPTS ON THE PATHOGENESIS OF SELECTED INFECTIOUS AGENTS.

D. B. Warheit. *Pulmonary Toxicology, DuPont Haskell Lab., Newark, DE.*

Four biological agents of greatest concern are smallpox virus, botulinum toxin, and anthrax and plague bacteria. This presentation focuses on current concepts on the pathogenesis related to two of the infectious agents, namely smallpox and anthrax. Smallpox has traditionally been feared as the most devastating of all the infectious diseases. An aerosol release of smallpox virus is easily disseminated and spreads directly from person to person, primarily by droplet nuclei expelled from the oropharynx of the infected person or by aerosol. Natural infection occurs following implantation of the virus on the oropharyngeal or respiratory mucosa. The smallpox virus enters the respiratory tract, infecting the mucous membranes and transmigrating rapidly into the local lymph nodes. After a brief period of viremia, there is a latent period of 4 to 14 days, during which the virus multiplies in the reticuloendothelial system. Inhalation anthrax is initiated by endospores of *B anthracis*, a gram-positive soil organism. The major target of the anthrax spores is the alveolar macrophage. After phagocytosis, a number of proteins including protective antigen, lethal factor and edema factor cause the macrophages to significantly increase secretion of TNF-α and IL-1β, resulting in immunopathological effects and subsequent death. Specifically, anthrax bacilli secrete two exotoxins that are active in host cells. Edema toxin is a calmodulin-dependent adenylate cyclase that increases intracellular levels of cAMP on entry into most types of cells and alters water homeostasis, resulting in massive edema. Lethal toxin is a zinc metalloprotease that causes a substantial inflammatory response by activating the oxidative pathways leading to massive production of TNF-α and IL-1β. Macrophages containing anthrax migrate to the regional lymph nodes. Vegetative anthrax bacilli grow in the lymph node, creating regional hemorrhagic lymphadenitis. Bacteria spread and proliferate through the blood and lymph, causing severe septicemia. High levels of endotoxins are produced that are responsible for overt symptoms and death.

29 CUMULATIVE RISK ASSESSMENT: GETTING FROM TOXICOLOGY TO QUANTITATIVE ANALYSIS.

H. A. Barton[1] and C. N. Pope[2]. *[1]ORD/NHEERL/ETD/PKB, US Environmental Protection Agency, Research Triangle Park, NC and [2]Department of Physiological Sciences, Oklahoma State University, Stillwater, OK.*

Assessment of the cumulative risk posed by exposure to multiple chemicals is a problem the USEPA's Program and Regional Offices confront regularly. This session will focus on the interplay of toxicology studies and quantitative analysis to assess cumulative risk using a variety of case studies. The Food Quality Protection Act of 1996 directs the Office of Pesticide Programs to include in its assessments the risk associated with the cumulative effects of pesticides that have a common mode of action. Organophosphorus pesticides (OPs) have been the first class addressed, based on the common mechanism of acetylcholinesterase inhibition. The toxicology and mode of action of these compounds will be described, noting factors that may confound the assessment of cumulative effects. The quantitative cumulative risk analysis of OPs based on anticholinesterase relative potency will then be presented. The Air Office is concerned with mixtures of criteria air pollutants and volatile organic compounds. Physiologically based pharmacokinetic modeling of multiple volatile chemicals provides an example of a biologically-based approach to cumulative analysis. The Office of Water is concerned with risk from mixtures of disinfectant byproducts and balancing that risk, either as single chemicals or mixtures, against the risk associated with microbial agents in water. Development of toxicity study designs to address interactions of chemicals in mixtures of increasing complexity is a critical part of developing improved evaluations of cumulative risk, so recent developments will be described. This workshop provides an opportunity for toxicologists and others involved in experimental studies and the development and application of quantitative analytical methods to discuss recent and ongoing efforts in this important and challenging area. (This abstract does not reflect EPA policy.)

30 TOXICITY STUDIES OF MIXTURES IMPACTING MULTIPLE TARGET ORGANS.

J. P. Groten, R. Stierum, D. Jonker and B. van Ommen. *Department of Biomolecular Sciences, TNO Nutrition and Food Research, Zeist, Netherlands.*
Sponsor: H. Barton.

Toxicity studies focussing on component-based analysis of mixtures indicated that for chemicals not sharing the same target and mechanism, the type of combined action or interaction found when each chemical in the mixture was present at clearly-toxic-effect levels did not predict the response when each chemical was present at or below the lowest observed adverse effect level (LOAEL). Moreover, mixtures of chemicals produced toxicity only for those chemicals that showed the same toxic effect on the same target organ when given singly at doses above the LOAEL values (simple similar action or similar joint action). However, end-points chosen in these (routine) toxicity studies do not offer a wide dynamic range of testable, significant responses around and above the NOAEL. Therefore, small effects that might have indicated similar joint action instead of independent joint action have not been detected, a problem inherent in toxicity testing. Sensitive methods that detect low level changes have not been employed in mixtures testing protocols. Also, interactions at the mechanistic level are not studied because, until recently, information on the mechanism of action of a single chemical, let alone a mixture, could only be obtained by studying the response of genes or proteins a priori suspected to be involved in a particular toxic response. Technologies based on the progress in functional genomics now enable the determination of the expression of thousands of genes (transcriptomics) and proteins (proteomics) in a single experiment. Toxicogenomics integrates functional genomics with classical toxicology and we believe that it has great potential to revolutionize mixtures research, since it will generate new hypotheses on combined mode(s) of action within one study. Studies applying transcriptomics are carried out at TNO to obtain new mechanism-derived biomarkers to assess e.g. hepatoxicity of combined exposure to food additives or environmental toxicants. Mechanism-based analysis, including principal component analysis, are discussed for its applicability in mixtures research.

31 INTERACTIVE TOXICITY OF ORGANOPHOSPHORUS INSECTICIDES.

C. N. Pope. *Physiological Sciences, Oklahoma State University, Stillwater, OK.*

The Food Quality Protection Act requires consideration of risk from cumulative effects of multiple pesticides acting through a common mechanism. The organophosphorus insecticides initiate toxicity through a common mechanism by inhibiting the enzyme acetylcholinesterase. Extensive inhibition of this enzyme leads to elevated acetylcholine levels in synapses of the central and peripheral nervous systems, with consequent signs of cholinergic toxicity including autonomic dysfunction, involuntary movements, cardiovascular alterations, dyspnea and in severe cases respiratory depression. Some OPs have additional sites of action, however, that can modify cholinergic toxicity or affect processes outside the cholinergic synapse. It has been known for decades that some OPs can markedly enhance the toxicity of others by blockade of detoxification pathways. Maturational expression of some of these same pathways appears critical in the higher sensitivity of younger individuals to some OPs. Most OPs in use today are phosphorothioates requiring metabolic activation by the cyp450s, thus concurrent exposures can lead to competition for activating pathways. Recent studies suggest that anticholinesterases may induce the synthesis of acetylcholinesterase, potentially altering the availability of target enzymes for subsequent OP exposures. Some OPs have selective, differential actions on presynaptic cholinergic processes, i.e., acetylcholine synthesis and release, that could alter toxic responses to other OPs. In some cases, these toxicokinetic/toxicodynamic interactions may only occur with combined high dose exposures. The determination of relative potencies of individual OPs may not, however, provide sufficient information to adequately estimate risk from cumulative exposures. While acetylcholinesterase inhibition represents the common mechanism of toxicity and thus the basis for the cumulative risk assessment, consideration of these other sites of action for some OPs, where such information is available, may strengthen the predictability of cumulative risk models.

32 CUMULATIVE RISK ANALYSIS FOR ORGANOPHOSPHORUS PESTICIDES.

R. W. Setzer. *NHEERL MD-74, USEPA, Research Triangle Park, NC.* Sponsor: H. Barton.

The USEPA has recently completed a risk assessment of the effects of exposure to 33 organophosphorous pesticides (OPs) through the diet, water, and residential exposures. Oral, dermal, and inhalation routes were considered, but the oral route has by far the richest data set, and is the route discussed in detail here. The risk assessment combined a relative potency factor (RPF) approach to dose-response assessment with a probabilistic exposure assessment to estimate distributions of margins of exposure in the US population. RPFs for the oral route of exposure were based on benchmark doses (BMDs) calculated as the expected daily dose that would result in a 10% inhibition of brain acetylcholinesterase (AChE) in rats. For almost all of the 33 OPs considered, multiple dose-response data sets were available. The data sets formed a nested hierarchy: major studies conducted by different laboratories or the same laboratory at different times, and observations from serial sacrifices within major studies. Dose-response models were fit to all the data for each OP using a hierarchical model to account for variation in both levels of the hierarchy. Two interesting aspects of the dose-response shape complicated the modeling. The dose-responses for about half of the chemicals had a "shoulder" at the low-dose end: the steepness of the response increased with increasing dose. At the other extreme of dose, for many OPs, as dose increased, AChE activity decreased asymptotically to a non-zero level that varied among OPs. The RPF approach applies strictly only when dose-additivity applies, and dose-additivity applies strictly only when dose-responses can be superimposed by rescaling dose. Thus, these observations question the quality of the approximation to risk that the RPF approach provides for these data. Reliable pharmacokinetic and pharmacodynamic models of the distribution and metabolism of the OPs and of their effects on AChE would have facilitated the interpretation and use of the data base by providing an estimate of the precision of the RPF approach. [This is an abstract of a presentation and does not necessarily reflect EPA policy.]

33 PHYSIOLOGICALLY-BASED PHARMACOKINETIC MODELING FOR MIXTURES.

K. Krishnan. *Occupational and Environmental Health, Universite de Montreal, Montreal, QC, Canada.*

The available data on pharmacokinetic and pharmacodynamic interactions are not used in the context of cumulative risk assessments. Physiologically-based models represent an unique framework for integrating data on binary interactions, on the basis of quantitative nature of interaction mechanisms. Physiologically-based modeling also facilitates the prediction of the consequences of interactions in more complex mixtures on the basis of mechanistic considerations. The state-of-the art of this methodology consists of: (i) developing physiologically-based pharmacokinetic (PBPK) models for individual chemicals, (ii) interconnecting the individual chemical PBPK models at the level of binary chemical interaction mechanisms (e.g., competitive, uncompetitive, or noncompetitive metabolic inhibition in liver), and (iii) comparing a priori predictions of the interaction-based model to corresponding experimental data. This methodology was validated using quaternary mixtures of aromatic hydrocarbons [benzene (B), toluene (T), ethylbenzene (E), and m-xylene (X)] and a quiternary mixture [BTEX + dichloromethane]. The binary interaction-based mixture PBPK model adequately predicted the kinetics of all componenets of the mixtures in rats and humans. The results of these modeling studies suggest that data on interactions at the binary level alone are required for predicting the kinetics and tissue dose of components of complex mixtures. By taking into account the change in tissue dose of toxic moieties of mixture components during combined exposures (i.e., the output of the mixture PBPK model), the cumulative risk associated with multiple chemicals can be assessed. These methodological approaches, together, facilitate the consideration of pharmacokinetic interactions at a quantitative level for purpose of cumulative risk analysis.

34 DESIGNING STUDIES AND COLLECTING DATA USEFUL FOR CUMULATIVE RISK ASSESSMENT.

J. Simmons[1], C. Gennings[2], M. Casey[2], M. J. Plewa[3], E. D. Wagner[3], W. H. Carter[2], A. McDonald[1], Y. M. Sey[1] and L. K. Teuschler[4]. *[1]NHEERL/ORD, USEPA, Research Triangle Park, NC, [2]VCU, Richmond, VA, [3]University Illinois, Urbana, IL and [4]NCEA/ORD, USEPA, Cincinnati, OH.*

Humans are exposed to very complex environmental mixtures. In contrast to this reality, most laboratory investigations of mixtures, with the exception of mutagenicity assays, have focused on mixtures comprised of a few chemicals. Over the past decade, great advances have been made in component-based assessment of simple mixtures with development of appropriate, efficient and novel experimental designs, statistical methods and risk assessment techniques. These gains have increased greatly our ability to collect data useful for risk assessment. Additionally, these methods and approaches have been used to assess experimentally the validity of risk assessment assumptions. This is illustrated by experiments with the four trihalomethanes - chloroform, bromoform, bromodichloromethane and chlorodibromomethane - disinfection byproducts (DBPs) formed during chemical disinfection of drinking water. In low-dose regions, dose-additive hepatotoxicity was observed in mice; in high-dose regions, the mixtures were additive or antagonistic, but not synergistic. Similar gains need to be made for complex mixtures. Component-based approaches that use information on the individual chemicals contained in the mixture are not by themselves sufficient for complex, environmental mixtures because significant portions of the mixture mass are unidentified. Joint theoretical and experimental work to extend these methods is needed and can only be successful by the combined collaborative efforts of toxicologists, statisticians and risk assessors. An effort is in progress for a more complex chemical mixture, including power and sample-size estimates, and methods to determine the portion of any observed toxicity attributable to the unidentified fraction of the mixture. In summary, experimental methods and techniques are described and illustrated for collection of data useful for risk assessment. (This abstract does not reflect EPA policy.)

35 BIPHASIC INFLUENCE OF ALCOHOL ON ESTROGEN-MEDIATED PERTURBATION OF THE CELL CYCLE IN BREAST CANCER CELLS.

A. Sharga, Q. Felty, J. DuMond and D. Roy. *Environmental Health Sciences, UAB, Birmingham, AL.*

Alcohol consumption has been implicated to increase the risk of breast cancer. Experimental results indicate that ethanol is a tumor promoter, and chronic ethanol exposure enhances metastasis and growth of breast cancer. The exact mechanisms by which chronic alcohol intake supports the development of cancer are not clear. The metabolism of ethanol leads to the generation of acetaldehyde and free radicals, which may lead to instability in the genome. The present study used an *in vitro* model to investigate the mechanism(s) underlying tumor promoting effects of ethanol. Low doses of alcohol (1-3 ul/ml) stimulated the growth of MCF7 cells and increased S phase while high doses of alcohol (5-10 ul/ml) significantly inhibited the growth of MCF7 cells. Low doses of alcohol when cotreated with 17-beta-estradiol or diethylstilbestrol increased the growth stimulatory effect of estrogen in these cells. In addition, the growth inhibitory effects of high alcohol doses (5-10 ul/ml) were reduced by the cotreatment of 17-beta-estradiol or diethylstilbestrol (1-100 ng/ml). Our results suggest a biphasic influence of alcohol on the growth of breast cancer cells. Alcohol induced perturbation of cell cycle and genetic instability may add to estrogen-induced genotoxic as well as proliferative stresses and thus mediate the promoting effects of alcohol on breast cancer development.

36 ROLE OF THE PEROXISOME PROLIFERATOR-ACTIVATED RECEPTOR ALPHA IN MODULATING THE EFFECTS OF FUMONISIN B1 IN MOUSE LIVER.

K. Voss[3], J. R. Owen[3], A. Laughter[2], C. Dunn[2], S. P. Anderson[5], R. Riley[3], D. Miller[4] and J. C. Corton[1]. *[1]ToxicoGenomics, Chapel Hill, NC, [2]CIIT, Research Triangle Park, NC, [3]USDA, Athens, GA, [4]Carleton University, Ottawa, ON, Canada and [5]GlaxoSmithKline, Research Triangle Park, NC.*

Fumonisins are mycotoxins produced by Fusarium verticillioides that induce a broad spectrum of responses in animals and are suspected human esophageal carcinogens. Exposure of rodents to fumonisins causes liver and kidney toxicity and cancer. These effects are likely triggered through inhibition of ceramide synthase by fumonisins resulting in disrupted sphingolipid metabolism and accumulations of the lipids sphingosine and sphinganine in tissues. As fumonisin B1 can act as a weak peroxisome proliferator (PP), we hypothesized that fumonisin toxicity may be partly mediated through the PP-activated receptor alpha (PPAR), an important regulator of lipid metabolism in the liver. Wild-type and PPAR-null mice were fed the PPAR agonist WY-14, 643 (WY) (0.05% w/w in the diet), fumonisin-containing (300 ppm fumonisin B1) culture material (CM), or purified fumonisin B1 (300 ppm) in the diet for 8 days. Wild-type and PPAR-null mice responded similarly to the CM and fumonisin B1 diets, exhibiting almost identical hepatic pathology and increases in liver weights, hepatocellular apoptosis, hepatocellular mitoses, sphinganine to sphingosine ratios and tumor necrosis alpha mRNA levels. PPAR-null mice lacked WY-induced liver weight increases and cell proliferation as expected. Using Affymetrix gene chips containing ~9000 mouse genes, transcript profiles of liver gene expression in the wild-type mice showed that the CM and fumonisin B1 treatments exhibited similar profiles that were different than the profile altered by WY and did not alter genes typically associated with peroxisome proliferation. These results demonstrate that PPAR alpha does not mediate the effects of fumonisin.

37 ABERRANT DNA METHYLATION IS A MECHANISM INVOLVED IN TUMOR PROMOTION.

R. E. Watson[2], G. M. Curtin[1], D. J. Doolittle[1] and J. I. Goodman[2].
[1]Pharmacology & Toxicology, Michigan State University, East Lansing, MI and [2]Toxicology Division, R.J. Reynolds, Winston-Salem, NC.

DNA methylation (ME) is an epigenetic mechanism regulating normal gene expression, and aberrant ME is causally involved in carcinogenesis. Hypermethylation can silence tumor suppressor genes, while hypomethylation may facilitate expression of oncogenes and/or transposons normally silenced by ME. The objective of this study was to test the hypothesis that aberrant ME is a mechanism underlying the promotion stage of tumorigenesis. Hallmarks of promotion include clear dose-response relationships, existence of thresholds and reversibility. We used a SENCAR mouse skin initiation/promotion model of tumorigenesis that permits clear demarcation of these stages. Animals were initiated with one dermal application of 75 [mu]g dimethylbenzanthracene (DMBA) and promoted with 9, 18, 27, or 36 mg cigarette smoke condensate (CSC) thrice weekly for various time periods, up to 29 weeks. Global ME and ME of GC-rich regions were assessed using SssI methylase and arbitrarily primed PCR procedures, respectively. We report that GC-specific ME increases in a dose- and time-dependent manner. CSC doses necessary to detect these changes were between 18 and 27 mg at 6 wks, and between 9 and 18 mg and at 9 wks. Further examination of animals promoted for 9 wks indicated similar changes in the absence of initiation, and ME changes were reversible following cessation of promotion. Administration of 27 mg CSC for 29 wks led to increased ME of GC-rich regions for tumor vs. non-tumor tissue, with changes in global ME observed only in tumors. Compared to non-initiated counterparts, initiated animals promoted with 27 mg CSC for 29 wks exhibited a very substantial increase in tumor number. Summary: multiple changes in ME are observed during CSC tumor promotion; increased ME of GC-rich regions precedes global decreased ME. Significance: CSC acts as a classic promoter, and ME changes in a threshold-exhibiting, progressive and reversible manner, as expected for a mechanism underlying tumor promotion.

38 GLOBAL GENE EXPRESSION COMPARISONS AND PATHWAY ANALYSIS OF NONGENOTOXIC CARCINOGENS WITH DIFFERENT MECHANISMS OF ACTION.

M. F. DeCristofaro[1], D. A. McCabe[1], O. R. Crasta[1], R. W. Gerwien[1], B. Wahle[2], B. Stuart[2], T. A. Mansfield[1] and M. McKenna[1]. *[1]Pharmacogenomics, CuraGen Corporation, New Haven, CT and [2]Toxicology, Bayer Corporation, Stilwell, KS.*

Nongenotoxic chemical carcinogens are those chemicals that induce tumor formation by mechanisms that do not directly change cellular DNA. Therefore, changes in the regulation of cell growth and gene expression are important factors in tumor formation. The goal of this study was to compare gene expression profiles of two nongenotoxic chemicals, WY-14643 and thioacetamide (TAA), that differ in their mechanism of carcinogenicity. TAA induces hepatocellular neoplasms in male rats due to chronic cellular injury. WY-14643 is a peroxisome proliferator (PP) that causes hepatocellular carcinoma in susceptible species such as rodents. TAA and WY-14643 were delivered orally on a daily basis at a dose previously shown to result in tumor formation (19.2mg/kg/d for TAA and 60mg/kg/d for WY-14643) as well as a 1/10 low dose for 14 days. Five male rats/dose/time were randomly assigned to sacrifice on days 1, 3, 7, and 14. Gene expression analysis was achieved with an open analysis platform (GeneCalling ®) on all rat livers. Gene dysregulation was observed in a number of biological pathways including lipid and protein metabolism, xenobiotic metabolism, and cellular signaling and proliferation. The use of global gene expression methodology enables researchers to compare and contrast the entire transcriptome at one time. This analysis permits us to delineate genes and pathways that appear to be common to nongenotoxic carcinogens and some that are specific to classes of nongenotoxic carcinogens.

39 TOXICOGENOMICS OF HUMAN CARCINOGENS.

W. Luo[2,1], H. Xie[1], P. Vouros[2] and H. Zarbl[1]. *[1]Fred Hutchison Cancer Research Center, Seattle, WA and [2]The Barnett Institute of Chemical and Biological Analysis, Boston, MA.*

The objective of this study was to profile gene expression changes in response to carcinogen exposure using cDNA microarray technology, and correlate these with mutagenesis and toxicity. We used the human lymphoblast cell line TK6 as an *in vitro* model system, and reactive metabolites of human environmental and food carcinogens, benzo(a)pyrene (BP) and 4-aminobiphenyl (ABP) as model compounds, We first, measured the mutagenicity and toxicity of the model compounds N-hydroxy-4-acetylaminobiphenyl (N-OH-AABP) and Benzo(a)pyrene diol epoxide (BPDE) in TK6. We then chose three doses that resulted in low, medium and high toxicity to treat the cells and harvested cells at different time points. RNA extracted from treated cells or untreated cells was then labeled by reverse transcription in the presence of either fluorescence-labeled Cy5-dUTP or Cy3-dUTP. The labeled cDNAs were then co-hybridized human cDNA microarrays comprised of ~18, 000 genes/ESTs. Experiments were performed in triplicate, including one dye flip. The fold change in expression for each probe was determined as the mean ratio of fluorescence intensities relative to the reference sample (i.e. Cye5/Cye3). The normalized data were then analyzed using various clustering algorithms, The resulting analyses indicated a correlation between gene expression profiles and mechanisms of toxicity and mutagenicity. We found a subset of genes with decreased expression after exposure to N-OH-AABP or BPDE at all concentrations, which may indicate general response to toxicity. In contract, we also discovered a subset of genes that were highly decreased in BPDE treated cells, but not in N-OH-AABP treated cells. The latter group included DNA repair and replication genes, transcription factors, etc., which may help to explain why OH-AABP is about 1000 times less toxic and mutagenic than BPDE in the cell line TK6. Microarray technology is a power technology to provide the insight into the mechanism of toxicity and mutagenesity.

40 MICROARRAY ANALYSIS OF COMMON GENE EXPRESSION CHANGES IN THE HUMAN KERATINOCYTE CELL LINE RHEK-1 MALIGNANTLY TRANSFORMED BY MULTIPLE CHEMICAL AGENTS.

J. A. Campain[1], W. H. Hanneman[1], J. S. Rhim[2], R. S. Thomas[3], R. S. Yang[1] and D. Bae[1]. *[1]Environmental and Radiological Health Sciences, Colorado State University, Fort Collins, CO, [2]Center for Prostate Disease Research, Bethesda, MD and [3]Kalypsys, Inc., La Jolla, CA.*

We are interested in developing a predictive resource for hazard identification of carcinogenic chemicals and chemical mixtures. To this end, we are utilizing microarray analysis of chemically-induced gene expression alterations; genes commonly regulated by multiple carcinogenic agents may be useful predictive markers for detection of new and novel chemicals with transforming potential. RHEK-1, the human keratinocyte cell line used in our studies, was previously transformed with MNNG (at 0.01 and 0.1 mg/ml), TCDD, and 4-nitroquinoline oxide to a fully tumorigenic phenotype. Analysis of global gene expression alterations in the four malignant lines was carried out using the Clontech 3.8 II Human Microarray. Expression data was analyzed with ScanAlyze and Cluster. We applied stringent conditions that required alteration of the gene in triplicate samples from each cell line and a cut-off of 2-fold change in expression between the chemically-treated line and its control. Results of this analysis showed the following: 1) among genes with a known or putative function in the 3.8 II array, 11 were commonly up-regulated in all four transformed lines; 2) included in the genes commonly up-regulated are a member of the ras family, p21/cdc42, RNB6, a low fidelity DNA polymerase (k), and several genes involved in growth and differentiation; 3) a total of 23 genes showed decreased expression in all transformed lines versus control cells; 4) commonly down regulated genes include those encoding 5 membrane transporters, 2 Ser/Thr protein kinases involved in apoptosis, cadherin 12, and several novel proteins. Additionally, we were able to identify genes altered in their expression in a chemical-specific manner. These latter genes may give mechanistic clues as to chemical-class-specific toxicity in this cell type. This study was supported by ATSDR (Cooperative Agreement U61/ATU881475).

40a RECENT ADVANCEMENT IN *IN VITRO* METAL TOXICOLOGY FOR REGULATORY PURPOSE.

E. Sabbioni. *IHCP, European Commission, Ispra (VA), Italy.*

The European Centre for the Validation of Alternative Methods has been set up in order to coordinate, at European level, activities to promote the scientific and regulatory acceptance of alternative toxicity testing which are important to biosciences. In this context, advanced approaches that have less or no dependence on animal experimentation (cell cultures) represent the basis of *in house* projects concerning development and validation of mechanistically-based *in vitro* toxicity testing. One of these projects is IMETOX (In vitro MEtal TOXicology) that aims at integrating aspects of metal toxicity in the field of metabolism, immunotoxicity, neurotoxicity, nephrotoxicity, reproductive toxicity, carcinogenicity in relation to environmental and occupational exposure, drug therapy, and the use of foods, cosmetics and biomaterials for hard tissue substitute. This work reviews the current IMETOX research activities concerning metabolism, toxicological effects and carcinogenic potential of metal compounds as investigated by cell cultures (e.g. mouse fibroblasts BALB/3T3, immortalised human keratinocytes (HaCaT), rat pheochromocytoma (PC12) cell lines) in combination with radioanalytical, spectrochemical and bioanalytical techniques. Examples concerning arsenic, chromium, platinum and vanadium compounds are reported in relation to low dose exposure, metal uptake and intracellular distribution, the influence of the different chemical forms of metals and their cellular biotransformation on cytotoxicity.

41 NOVEL PHYSIOLOGICAL AND TOXICOLOGICAL ROLES FOR ENDOPLASMIC RETICULUM BOUND CA^{2+}-INDEPENDENT PHOSPHOLIPASE A_2 (ER-IPLA$_2$) IN THE KIDNEY.

B. S. Cummings[1], M. Jane[2] and R. G. Schnellmann[1]. *[1]Pharmaceutical Sciences, Medical University of South Carolina, Charleston, SC and [2]Pathology, St. Louis University, St. Louis, MO.*

We recently identified an 85 kDa, plasmalogen selective, Ca^{2+}-independent phospholipase A_2 (ER-iPLA$_2$) in rabbit renal proximal tubule cells (RPTC). ER-iPLA$_2$ inhibition with bromoenol lactone (BEL) potentiated oxidant-induced RPTC oncosis and lipid peroxidation suggesting that ER-iPLA$_2$ protects against oxidant-induced lipid dysfunction. To test this hypothesis RPTC phospholipid content was determined after *tert*-butylhydroperoxide (TBHP) exposure in the presence and absence of BEL. Twenty five individual phospholipid molecular species, differing in chain length and number of double bonds in the *sn-1* and *sn-2* fatty acids on the glycerol backbone, were identified and quantified in choline (phosphatidylcholine, PC and plasmenylcholine, PlasC) and ethanolamine (phosphatidylethanolamine, PE and plasmenylethanolamine PlasE) phospholipids. Treatment of RPTC with BEL (5 μM) for 1 hr caused 45% decreases in (18:0, 18:1)- and (18:2, 20:4)-PlasC compared to controls. Treatment of RPTC with TBHP (200 μM) for 1 hr resulted in 35% decreases in (16:0, 20:4)- and (18:0, 18:1)-PlasE, a 30% decrease in (16:0, 18:3)-PlasC, and a 25% decrease in (18:0, 20:4)-PE. In contrast, treatment of RPTC with BEL prior to TBHP exposure decreased the content of 10 phospholipids, decreasing all PlasE phospholipids an average of 60%, and 5 of the 8 PlasC phospholipids 40%, while PC and PE were essentially unaffected compared to TBHP. These data suggest a physiological role for ER-iPLA$_2$ in the maintenance of PlasC phospholipids. These data also demonstrate that ER-iPLA$_2$ inhibition increases oxidant-induced RPTC phospholipid loss, suggesting that ER-iPLA$_2$ has a role in the protection of RPTC against oxidant-induced toxicity.

42 INTERACTIVE TOXICITY BETWEEN TRICHLOROETHYLENE AND INORGANIC MERCURY IN RAT AND HUMAN KIDNEY PROXIMAL TUBULE.

L. H. Lash, D. A. Putt, S. E. Hueni, S. G. Payton and J. Zwickyl. *Pharmacology, Wayne State University, Detroit, MI.*

To test the hypothesis that prior exposure of rat or human kidney to subtoxic concentrations of either trichloroethylene (TRI), its metabolite *S*-(1, 2-dichlorovinyl)-L-cysteine (DCVC), or inorganic mercury (Hg) alters the toxic response to subsequent exposures, male Fischer 344 rats were given i.p. injections of either saline (= Control) or a subtoxic dose of $HgCl_2$ (0.5 μmol/kg) and 24 and 48 hr later, activities of several glutathione (GSH)-related enzymes and protein expression of GSH *S*-transferase alpha (GSTα) were determined. Pretreatment with Hg increased activities of GSH-related enzymes by 35-90% and increased expression of GSTα1 by 33%. Similar experiments in primary cultures of rat proximal tubular (rPT) cells showed preincubation with 0.5 or 1 μM $HgCl_2$ increased activities of GSH-related enzymes. *In vivo* treatments of rats with 0.5 μmol $HgCl_2$/kg increased rates of GSH conjugation of TRI, showing that these effects on GSH status influence TRI bioactivation. Pretreatment of primary cultures of human proximal tubular (hPT) cells for 24 hr with 0.25-1 μM $HgCl_2$ markedly enhanced acute cytotoxicity (lactate dehydrogenase release or inactivation) of 1 mM TRI and 50 or 200 μM DCVC. In contrast, pretreatment of hPT cells with 0.25 μM $HgCl_2$ markedly decreased apoptosis induced by either 1 mM TRI or 50 μM DCVC. This suggests that prior exposure of hPT cells to Hg shifts the cytotoxic response from apoptosis to necrosis. Pretreatment of hPT cells for 24 hr with either 1 mM TRI or 50 μM DCVC markedly diminished acute cytotoxicity due to 0.25-5 μM $HgCl_2$, decreased apoptosis due to Hg at 1 hr, but increased apoptosis by as much as 5-fold after 2- and 4-hr incubations. Pretreatment of hPT cells for 24 hr with 50 μM DCVC increased intracellular GSH content by more than 100%. These results show that prior exposure of either rat or human PT cells with low or subtoxic doses of TRI, DCVC, or Hg markedly alters cellular susceptibility to injury, in part due to changes in cellular GSH status. (Supported by NIH Grant ES08828.)

43 DICHLOROVINYL-L-CYSTEINE (DCVC) CAUSES G2/M CELL CYCLE ARREST IN RENAL PROXIMAL TUBULAR CELLS.

C. H. Reich and R. G. Schnellmann. *Pharmaceutical Sciences, Medical University of South Carolina, Charleston, SC.*

We have demonstrated that primary cultures of renal proximal tubular cells (RPTC) proliferate following sub-lethal injury induced by the model oxidant t-butylhydroperoxide (TBHP), but proliferate poorly following sub-lethal injury produced by the nephrotoxicant DCVC. In the current study we used both model compounds to investigate the mechanisms of the differential proliferative responses. Treatment of RPTC with DCVC (200 μM, 90 min) or TBHP (250 μM, 30 min) decreased monolayer protein and DNA contents by 40% after 48 hr. TBHP injured monolayers increased their DNA content by 67 ± 14 % on day 6, while DCVC injured cells only increased their DNA content by 31 ± 7 % on day 6. Cell cycle status was determined at various times following toxicant exposure using flow cytometry. Cell cycle analysis revealed that 88% of control RPTC were in G0/G1, 6% in S and 5% in G2/M phase and that this ratio did not vary over time. In TBHP treated RPTC, 75% were in G0/G1, 15% in S and 10% in G2/M phase, and these ratios were maintained over 48 hr. Twenty-four hr after DCVC treatment, 71% of DCVC treated cells were in G0/G1, 23% in S and 6% in G2/M phase. Forty-eight hr after DCVC treatment, 43% of the cells were in the G0/G1, 23% were in the S and 34% were in the G2/M phase. These results demonstrate that RPTC monolayers regenerate following TBHP exposure through proliferation. In contrast, RPTC regenerate poorly following DCVC exposure due to cell cycle arrest in the G2/M phase.

44 DOSE RESPONSE EFFECTS OF EICOSAPENTAENOIC ACID ON EXPERIMENTAL IGA NEPHROPATHY INDUCED BY THE TRICHOTHECENE DEOXYNIVALENOL.

Y. Shi[1], J. J. Pestka[1,2,3] and Q. Jia[1]. *[1]Food Science and Human Nutrition, Michigan State University, East Lansing, MI, [2]Microbiology and Molecular Genetics, Michigan State University, East Lansing, MI and [3]Institute for Environmental Toxicology, Michigan State University, East Lansing, MI.*

Immunoglobulin A nephropathy (IgAN), characterized by diffused kidney mesangial deposition of IgA, is now recognized as the most common form of primary glomerulonephritis in many parts of the world. However the pathogenesis of this disease remains obscure and there exists no effective treatment for it. A murine IgA nephropathy model induced by the trichothecene mycotoxin deoxynivalenol (DON) has been established in our lab. Fish oil has been demonstrated to attenuate the elevation of serum IgA and IgA deposition in the kidney mesangium in this model. In this study, we evaluated the dose-response effects of eicosapentaenoic acid (EPA), one of the major components of omega-3 polyunsaturated fatty acids in fish oil, on serum IgA and IgA-immune complexes, mesangial IgA deposition and other pathological changes. B6C3F1 mice were fed for 12 wk with AIN-93G diets containing 1g/100 g corn oil and 6g/100g oleic acid (CONTROL group), 1g/100g corn oil and 6g/100g oleic acid and 20ppm DON (DON group), 1g/100g corn oil and 0.2g/100 g EPA and 5.8g/100g oleic acid and 20ppm DON (0.2%EPA+DON group), 1g/100g corn oil and 1g/100g EPA and 5g/100g oleic acid and 20ppm DON (1%EPA+DON group) and 1g/100g corn oil and 6g/100g EPA and 20ppm DON (6%EPA+DON group). After 8 wk, DON significantly increased serum IgA (6 times higher than CONTROL group) ($P<0.05$). Mice fed with the 6%EPA+DON diet exhibited a significantly increased IgA concentration (3 fold) ($P<0.05$) compared to CONTROL group, however this IgA level was significantly lower than that of DON group($P<0.05$). Serum IgA concentrations in mice fed with 0.2%EPA+DON and 1%EPA+DON were not significantly different from that of DON group ($P>0.05$). We got similar results after 12 wk. The results suggest that there is a threshold of EPA consumption required for ameliorative effects on DON-induced IgAN. (Supported by NIH grant DK58833)

45 MECHANISMS OF STIMULATED TISSUE REPAIR IN SURVIVAL FROM ACUTE RENAL TUBULAR NECROSIS: ROLE OF MAPK PATHWAY.

V. S. Vaidya[2], K. Shankar[2], D. Dixon[3], E. A. Lock[1] and H. M. Mehendale[2]. *[1]Department of Toxicology, The University of Louisiana at Monroe, Monroe, LA, [2]Laboratory of Experimental Pathology, NIEHS, Research Triangle Park, NC and [3]Syngenta, CTL, Macclesfield, Cheshire, United Kingdom.*

Our earlier studies with S-(1, 2-Dichlorovinyl)-$_L$-cysteine (DCVC) showed that a priming/low dose (15 mg DCVC/kg, ip) given 72 h before administration of a normally lethal dose of DCVC (75 mg/kg, ip) to mice led to massive injury, but sustained renal tubular repair allowed recovery and survival. The objective of present study was to investigate whether this autoprotection was associated with upregulation of the mitogen activated protein kinase pathway (MAPK). Following the priming dose of DCVC, renal IL-6 protein (ELISA) and mRNA (RTPCR) levels increased as early as 1 h after dosing and declined by 24 h. EGFr {by immunohistochemistry (IHC)}, mainly localized in renal cortex and collecting ducts, peaked at 3 h returning to control by 9 h whereas the expression of its ligands, HB-EGF (IHC) and TGF-α (IHC) remained elevated from 3 to 36 h. Significantly higher expression of Grb-2 {IHC, (at 3, 9 and 36 h)} and ERK1/2 {IHC, (at 3, 9, 12, 24 and 36 h)} was observed selectively in the outer stripe of outer medulla (OSOM) and the papilla coincident with maximal S-phase DNA synthesis as assessed by proliferating cell nuclear antigen (PCNA) IHC. In contrast, increasing the dose to 75 mg DCVC/kg produced an increase in renal IL-6, HB-EGF and EGFr at earlier time points (3 to 12 h)-which then declined at 24 and 36

h along with Grb-2 and ERK1/2. Renal S-phase DNA synthesis in these mice was minimal and most of the mice died within 48 h of dosing. Prior treatment with a low dose of DCVC not only stimulated the renal MAPK pathway but also increased the expression of HB-EGF, TGF-α, EGFr, Grb-2 and ERK1/2 which was sustained even after administration of the normally lethal dose of DCVC, leading to augmented tissue repair and recovery from acute renal failure. These results suggest that the sustained activation of MAPK pathway may underlie protection from DCVC-induced acute renal tubular necrosis in the mouse.

46 EFFICACY AND TOXICITY STUDY OF VANADIUM NICOTINATE IN ALLOXAN INDUCED DIABETIC RATS.

S. L. Bodhankar, K. Rameshkumar, S. N. Shah, D. B. Goswami and V. Mohan. *Pharmacology, Poona College of Pharmacy, Pune, Maharashtra, India.* Sponsor: H. Mehendale.

Vanadium compounds regulate blood glucose (BG) in Type 1 and 2 diabetes mellitus. Animal data indicate that high dose of vanadium can be harmful to renal tubules. Vanadium compounds are used as nutraceuticals in health food formulation. The objective of the present study was to evaluate whether vanadium nicotinate (VN) administration may be used to control BG in diabetic rats and to evaluate its potential toxicity. VN was synthesized by combining vanadium and niacin. Male Wistar rats (150 to 200 g) were made Type 1 diabetic by a single i.v injection of alloxan (70 mg/kg in saline). Diabetes was confirmed after 48 h later by estimating BG (303± 56 mg/dl). The diabetic rats received either VN (100 mg/kg/day, p.o as a suspension in 7% gum acacia solution, n=7) or gum acacia (vehicle, n=7) for 21 days. Rats were maintained for additional 7 days without administration of VN. On day 28 rats were sacrificed and hepatic as well as renal injury was examined in H & E stained sections under a light microscope. Blood samples were withdrawn retro orbitally and were analyzed for glucose on days 0 (314 ± 62 vs 377 ± 36), 7, 14, 21 and 28. VN was very effective in decreasing BG on day 21 of therapy (140 ± 30 vs 385 ± 43) and the hypoglycemic effect of VN continued even after cessation of treatment for 7 days (148 ± 54 vs 380 ± 34). Maximum reduction in BG (55.21%) was observed on 21st day. The drug showed late onset and prolonged duration of hypoglycemic effect. No abnormality was detected in liver while focal tubular necrosis with severe cloudy changes were seen in kidney in VN treated groups as compared to the vehicle treated group after 21 days administration of VN. The mechanisms of VN's hypoglycemic and nephrotoxic effects are worthy of further investigation. It is concluded that VN (100 mg/kg) has significant hypoglycemic activity. However, this hypoglycemic effect was not without the liability of nephrotoxic injury. (Supported by Indus Biotech Pvt. Ltd., India)

47 MITOCHONDRIAL OXIDATIVE STRESS IS CAUSED BY NUCLEOSIDE REVERSE TRANSCRIPTASE INHIBITOR (NRTI) STAVUDINE (D4T) IN HEPG2 CELLS.

B. J. Day[1,2], M. Kovacevic[1], M. Goldstein[1], W. Lewis[3] and L. W. Velsor[1]. *[1]Medicine, National Jewish Medical & Research Ctr, Denver, CO, [2]Pharmaceutical Sciences, University of Colorado Health Sciences Ctr, Denver, CO and [3]Pathology, Emory University, Atlanta, GA.*

The toxicity of NRTI is linked to altered mitochondrial DNA (mtDNA) replication and resultant mitochondrial dysfunction. Clinically this is manifested by elevated plasma lactate, mitochondrial myopathy, and cardiomyopathy. However, the subcellular mechanisms that relate changes in mtDNA replication to mitochondrial dysfunction remain elusive. We hypothesize that mitochondrial oxidative stress (MOS) links NRTI-induced changes in mtDNA replication to mitochondrial dysfunction. To test the hypothesis, cultured human hepatoma cells (HepG2) were treated for 48 hours with stavudine (d4T). Changes in mitochondrial function (using lactate/pyruvate ratio in medium), mtDNA amplification efficiency (using PCR method), and oxidative stress to mtDNA (using 8-hydroxy-2-deoxyguanosine (8-OHdG) abundance in mtDNA) were determined. Results showed d4T up to 500 uM did not produce cell death in HepG2 cells over 48 hours. However, lactate/pyruvate ratios from medium were doubled compared to control values after 48 hours. d4T produced a dose-dependent decrease in mtDNA amplification efficiency and this inversely correlated with a doubling in the levels of 8-OHdG in mtDNA samples. All of d4T deleterious effects were ameliorated by concomitant treatment with the catalytic antioxidant, MnTBAP (100 uM). Data from these studies suggest that NRTI treatment elevates mitochondrial reactive oxygen species resulting in MOS and this contributes to NRTI-induced toxicity. In turn, MOS from NRTIs may be amplified by aging and alcohol in which MOS has also been invoked mechanistically. In patients, it may be possible to ameliorate MOS from NRTIs with catalytic antioxidants. (supported in part by NIH grants HL59602(BJD), HL31992(BJD), HL63666(WL) and AA13551(WL)).

48 ROLE OF LIPID PEROXIDATION AS MECHANISM OF LIVER INJURY AFTER ACETAMINOPHEN OVERDOSE IN MICE.

T. R. Knight[1], M. W. Fariss[2] and H. Jaeschke[1]. *[1]Pharmacology and Toxicology, University of Arkansas for Medical Sciences, Little Rock, AR and [2]Pharmaceutical Sciences, Washington State University, Pullman, WA.*

Acetaminophen (AAP) causes mitochondrial reactive oxygen (ROS) and peroxynitrite formation (Knight et al., Toxicol Sciences 62: 212-220, 2001). Thus, we tested the hypothesis that ROS-induced lipid peroxidation (LPO) is an important component of the injury mechanism by comparing AAP-induced injury in mice fed a high vitamin E-diet (1 g dl-alpha tocopheryl acetate (TA)/kg diet) compared to a control diet (35 mg TA/kg diet). Results: Male C3Heb/FeJ mice fed the vitamin E-diet for 1 week had higher tocopherol levels in the liver (28 ± 6 nmol/g liver) than animals on the control diet (8.2 ± 0.1 nmol/g). AAP (300 mg/kg) caused centrilobular necrosis with high plasma alanine aminotransferase (ALT) activities at 6 h (3280 ± 570 University/L). Liver malondialdehyde (MDA) content as indicator of LPO did not increase compared to untreated animals (9.9 ± 0.9 nmol MDA/mg protein). However, all necrotic cells in the centrilobular region stained positive for nitrotyrosine, an indicator of hepatocellular peroxynitrite formation. There was no significant difference in AAP-induced liver injury or hepatic nitrotyrosine staining between animals on the vitamin E diet compared to mice on the control diet. To verify a potential effect of the vitamin E-diet on drug-induced liver injury, animals were pretreated with 100 mg/kg phorone and 0.35 mmol/kg $FeSO_4$ before receiving 0.6 mmol/kg allyl alcohol. Massive LPO and liver injury was observed in livers of animals on the control diet as indicated by a 32-fold increase in MDA levels and plasma ALT activities of 2310 ± 340 University/L. Animals on the vitamin E-diet had 40% lower MDA levels and 84% lower ALT values. Conclusions: Despite ROS formation, AAP overdose did not cause LPO and consequently, enhancing hepatic vitamin E levels did not prevent liver injury. These results are consistent with our recent findings (Knight et al., J Pharmacol Exp Therap 303: in press, 2002) that peroxynitrite but not reactive oxygen formation per se is responsible for AAP-induced liver injury.

49 OXIDANT STRESS PRECEDES LIVER INJURY AFTER ACETAMINOPHEN IN CULTURED MOUSE HEPATOCYTES.

H. Jaeschke[1], T. R. Knight[1], J. J. Lemasters[2] and M. Bajt[1]. *[1]Pharmacology and Toxicology, University of Arkansas for Medical Sciences, Little Rock, AR and [2]Cell and Developmental Biology, University of North Carolina, Chapel Hill, NC.*

The role of reactive oxygen species (ROS) in the pathophysiology of acetaminophen (AAP)-induced liver injury is controversial for many years. Superoxide can function as precursor for peroxynitrite formation or can dismutate to molecular oxygen and hydrogen peroxide, which can be reductively cleaved to the highly reactive hydroxyl radical. We identified mitochondria as the source of ROS formation after AAP treatment *in vivo* by monitoring the cellular and mitochondrial glutathione disulfide (GSSG) levels and the GSSG-to-GSH-ratio (Knight et al., Toxicol Sciences 62:212-220, 2001). A concern with this approach is the initial severe depletion of hepatocellular glutathione, which makes the quantitative assessment of the oxidant stress difficult. Therefore, we tested the hypothesis that mitochondrial ROS formation precedes the onset of cell injury in a cell culture model using 2, 7-dichlorodihydrofluorescein diacetate (DCFH) as marker for an intracellular oxidant stress. Hepatocytes were isolated from fasted C3Heb/FeJ mice. After adherence in collagen-coated wells, AAP was added (final conc.: 5 mM) and DCFH fluorescence, lactate dehydrogenase (LDH) release and trypan blue uptake were determined from 0 to 12 h. Fluorescence began to increase at 3 h (1, 640 ±390 % of baseline), reached a maximum at 6 h (2, 410 ± 490 % of baseline)and was still high at 9 h (1, 510 ±250 % of baseline). Cell injury, as indicated by increased cellular release of LDH and uptake of trypan blue, was not evident at 1.5 or 3 h. However, a significant release of LDH was observed at 6 h (19 ± 11 % release of total cellular LDH), at 9 h (39 ± 7 % release) and at 12 h (53 ± 11 % release). Co-treatment with 500 nM cyclosporin, an inhibitor of the mitochondrial membrane permeability transition, attenuated the fluorescence increase by 62 %. Conclusions. A substantial mitochondrial oxidant stress is an early event in AAP-induced cell damage that precedes the onset of injury by several hours.

50 DIVERGENT EFFECTS OF HYPEROXIA ON CC10 AND GLUTATHIONE REDUCTASE MESSENGER RNA LEVELS IN LUNGS OF MICE.

S. E. Welty, M. Park, L. K. Rogers, T. N. Hansen and C. V. Smith. *Pediatrics, Columbus Children's Research Institute, Columbus, OH.*

Levels of Clara cell secreted protein (CC10) in trachael aspirate fluids (TAFs) increase in prematurely born human infants who survive and do not develop bronchopulmonary dysplasia (BPD), but not in infants who die or develop BPD

[Ramsay, AJRCCM 164:155, 2001]. Oxidative modifications of CC10, indicated by reactivities with 2, 4-dinitrophenylhydrazine (DNPH), appear to account for some of the decreases in TAF concentrations of CC10. The present studies were to test the hypothesis that hyperoxia also exerts pretranslational effects that may contribute to the diminished CC10 levels. Adult male ICR mice were placed in greater than 95 percent O2 for up to 96 h. Increases in lung weight-to body weight ratios were not observed through 72 h of hyperoxia, thus indicating minimal lung injury through this duration of exposure. Levels of CC10 mRNA were assessed by real time PCR, with 18S as reference. By 48 h of hyperoxia, lung levels of CC10 mRNA decreased to less than half of the levels observed in air-breathing control animals, and by 96 h, CC10 message levels were less than 5 percent of controls. In contrast, message levels of glutathione reductase in the lungs of animals in hyperoxia increased through 72 h to levels five times the levels in air-breathing control animals, then declined sharply between 72 and 96 h of hyperoxia. Lung GR activities were not increased in animals exposed to hyperoxia. The data indicate that hyperoxia can exert pretranslational effects that may contribute to the diminished levels of CC10 that we observed in premature human infants. The marked differences betwteen CC10 and GR mRNA responses indicate gene-specific effects and/or selective and early damage to the Clara cells in the lungs of animals and possibly in humans exposed to hyperoxia. Supported in part by GM44263.

51 HYPEROXIC LUNG INJURY IN MICE WITH GENETIC DEFICIENCIES IN GLUTATHIONE REDUCTASE ACTIVITIES.

C. V. Smith, L. K. Rogers, M. Park, T. N. Hansen and S. E. Welty. *Pediatrics, Columbus Children's Research Institute, Columbus, OH.*

Glutathione-dependent mechanisms are vital to antioxidant defense mechanisms, and we have demonstrated previously that transgene-driven enhancement of glutathione reductase (GR) activities can increase dramatically cell resistance to oxidant toxicities *in vitro*. Conversely, enhanced sensitivities to oxidants are observed in cells with attenuated GR activities from antisense expression of the GR transgene. The toxicological relevance of GR *in vivo* is attributed to the effects on toxicities of BCNU, which inhibits GR *in vitro* and *in vivo*, but the specificity of BCNU is less than is often assumed. In the present studies, we investigated the susceptibilities to hyperoxic lung injury of a line of mice that exhibit GR activities in livers and lungs that are less than 10% of the respective activities observed in the parent strain (C3H) of mice. The founder mouse of this GR hypomorph strain was generated by administration of isopropyl methanesulfonate, and the trait bred to homogeneity (Pretsch, Genet Res Camb 73:1, 1999). The GR hypomorph animals do not exhibit any remarkable phenotype, and the trait has remained stable for over 20 generations. We obtained breeding pairs and re-derived progeny at our institution. Lung and liver GR activities in the GR hypomorph mice were 6 and 9% of control C3H mice, whereas respective glutathione peroxidase activities and GSH levels were not different. Adult male mice of the GR hypomorph strain (Gr1a1Neu) exposed to greater than 95 percent O2 exhibited increases in lung weight to body weight ratios by 72 h of exposure, whereas increased lung weights in the wild type C3H mice were observed only after 96 h of continuous exposure to hyperoxia. The greater susceptibility of the Neu than of the C3H mice to hyperoxia is consistent with significant contributions of GR to antioxidant functions, but the modest effects on injury of such marked differences in GR activities suggest compensatory responses. Supported in part by GM44263.

52 EXPRESSION AND LOCALIZATION OF P70 ALBUMIN PRECURSOR PROTEIN AND PHI AP3 IN OXIDATIVELY STRESSED VASCULAR SMOOTH MUSCLE CELLS.

M. T. Holderman, C. R. Partridge, R. Barhoumi and K. S. Ramos. *Center for Environmental Health, Texas A&M University, College Station, TX.*

Redox signaling by benzo(a)pyrene (BaP) in vascular smooth muscle cells (vSMCs) involves activation of protein binding to a DNA regulatory sequence termed the antioxidant response element (ARE). ARE sequences (RTGAYNNNGCR) are similar to consensus TPA-response elements (RTGACTCA), cyclic AMP response elements (TGACGTCA) and Maf-response elements (TGCTGAGTCA), evidence of functional overlap in redox signaling among multiple cellular pathways. Recently, this laboratory identified p70 albumin precursor protein (APP) and Phi AP3 as novel components of the redox sensing machinery in vSMCs. The present studies were conducted to characterize the expression and cellular localization of these proteins in BaP-treated cells. Affinity-purified IgG was generated against APP and Phi AP3 peptide antigens. Two immune-reactive bands of Mr of 35- and 70-kDa were detected for APP in extracts of the cytosolic and nuclear compartments of vSMCs. Short-term oxidant treatment (0.5 hr) selectively increased p70 expression in the cytosolic compartment, while the p70 immune-reactive protein accumulated in the nucleus within 0.5 - 1 hr, along with a concomitant increase in p35 immunoreactivity. Anti-Phi AP3 immunoreactivity was detected at Mr 18-, 40 and 65-kDa in the nuclear fraction, while Mr 18- and 40- and 42-kDa proteins were predominant in the cytosolic fraction. Treatment of vSMCs with 3uM BaP abolished the nuclear p65 Phi AP3 signal and enhanced the appearance of p40 immunoreactivity. Fluorescence microscopy of BaP-treated cells showed diffuse Phi AP3 cytosolic staining, while APP immunofluorescence was confined to the nucleus. These results suggest that BaP alters the expression and localization of APP and Phi AP3, and implicate these proteins in redox signaling in vSMCs. (Supported by NIH Grants ES04849, ES04917, and ES09106).

53 NF-KB DYSREGULATION IN ATHEROSCLEROTIC VASCULAR SMOOTH MUSCLE CELLS: COMPLEX COMPOSITION AND REDOX SENSITIVITY.

E. S. Williams, E. Wilson and K. S. Ramos. *Center for Environmental and Rural Health, Texas A&M University, College Station, TX.*

Repeated exposure to chemical oxidants leads to induction of atherogenic vascular smooth muscle cell (vSMC) phenotypes. These cells are characterized by heightened proliferative activity, altered integrin expression, and upregulated NF-κB activity. NF-κB, a dimer of Rel proteins, is a transcription factor typically located in the cytoplasm *via* association with an inhibitory protein IκB. After phosphorylation by the IKK complex, IκB is ubiquitinated and destroyed, allowing NF-κB dimers to translocate to the nucleus and effect transcriptional regulation of a variety of gene targets, including osteopontin, a cytokine implicated in the maintenance of atherogenic vSMC phenotypes. In the present studies, male Sprague-Dawley rats (175-200g) were gavaged once daily for 20 consecutive days with 70 mg/kg allylamine, a vascular specific pro-oxidant. Aortic smooth muscle cells were isolated by enzymatic digestion and maintained in serial culture. Cells were seeded at 100 cells/mm2, growth arrested for 72 hours, and then released into growth by addition of serum mitogens. Immunoprecipitated IKKa was phosphorylated to a greater extent in allylamine cultures than controls, indicating a higher level of NF-κB activation. Rel A/p65 proteins were phosphorylated to a lesser extent in allylamine cultures, suggesting changes in the ability of this protein to regulate gene induction. The levels of other NF-κB constituent proteins in nuclear extracts were altered, with p52 levels increased and RelB levels decreased, in the nuclei of allylamine cells relative to controls. Gel shift analysis using nuclear proteins from control and allylamine cultures treated with PDTC or N-acetyl cysteine showed that NF-κB activity in allylamine cells was more sensitive to antioxidant inhibition than respective controls. These results implicate altered redox homeostasis as a key regulator of NF-κB activation in chemical atherogenesis. (This work was supported in part by NIH grants HL62539 and ES09016).

54 ROLE OF BIP/GRP78 IN 11-DEOXY-16, 16-DIMETHYL PROSTAGLANDIN E2 MEDIATED CYTOPROTECTION IN RENAL EPITHELIAL CELLS.

Z. Jia[1], M. D. Person [1], J. Shen[2], S. C. Hensley[2], J. L. Stevens[3], T. J. Monks[1] and S. S. Lau[1]. *[1]Center for Molecular and Cellular Toxicology, The University of Texas at Austin, Austin, TX, [2]UTMDACC, Science Park - Research Division, Smithville, TX and [3]Eli Lilly and Company, Greenfield, IN.*

Treatment with 11-Deoxy-16, 16-dimethyl prostaglandin E_2 (DDM-PGE_2), a stable synthetic analog of PGE_2 protects renal proximal tubule epithelial cells (LLC-PK_1) against oncotic/necrotic cell death induced by hydrogen peroxide (H_2O_2), iodoacetamide (IDAM), and 2, 3, 5-tris(glutathion-S-yl)hydroquinone (TGHQ), but not against cisplatin or mercuric chloride induced apoptotic cell death. Utilizing mass spectral and western blot analyses we showed that cytoprotection was associated with the up-regulation of at least six proteins, including the major endoplasmic reticulum (ER) chaperone, glucose-regulated protein 78 (Bip/Grp78). To elucidate the role of Grp78 in cell injury, we investigated cytoprotection using LLC-PK_1 cells in which induction of *grp78* expression was disrupted by stable expression of an antisense *grp78* RNA (pkASgrp78). As anticipated, DDM-PGE_2 failed to induce Grp78 in pkASgrp78 cells, with a concomitant inability to provide cytoprotection against TGHQ, H_2O_2, or IDAM. In contrast, DDM-PGE_2 induced Grp78 and afforded cytoprotection against all three toxicants in cells transfected with empty vector (pKNEO). These data suggest Grp78 plays an important role in DDM-PGE_2 mediated cytoprotection. Furthermore, using 2D gel electrophoresis coupled with MALDI-TOF peptide mass mapping and post source decay, we compared the pattern of protein induction in pkASgrp78 and pKNEO cells following DDM-PGE_2 pretreatment. Our results revealed that DDM-PGE_2 induced several proteins in pKNEO cells, but not in pkASgrp78 cells, including S100 calcium binding protein A2, proteasome subunit C2, galectin-1, galectin-3, myosin light chain, and molecular chaperones such as heat shock protein 27 and chaperonin 10. The findings suggest that these proteins may act in concert with Grp78 during DDM-PGE_2 mediated cytoprotection against oncotic/necrotic cell death. (GM56321, ES07784).

55 TBHQ PROTECTS NEURONAL CELLS FROM OXIDATIVE INJURY THROUGH UPREGULATION OF THE ANTIOXIDANT RESPONSIVE ELEMENT.

A. D. Kraft[1], D. A. Johnson[1] and J. A. Johnson[1,2,3]. *[1]School of Pharmacy, University of Wisconsin, Madison, WI, [2]Molecular and Environmental Toxicology Center, University of Wisconsin, Madison, WI and [3]Center for Neuroscience, University of Wisconsin, Madison, WI.*

Activation of a cis-acting response element known as the antioxidant responsive element (ARE) has been shown to increase the expression of many phase II protective genes such as NAD(P)H:quinone oxidoreductase 1 (NQO1) and Glutamate-cysteine ligase (GCL). A transgenic reporter mouse line was previously derived by insertion of a 51 base pair segment of the rat NQO1 promoter containing the core ARE coupled to a heat-stable human placental alkaline phosphatase (hPAP) reporter gene construct. To determine if activation of the ARE confers protection against oxidative stress-induced cytotoxicity, primary mouse cortical neuronal cultures were pretreated with tert-butylhydroquinone (tBHQ). TBHQ is a potent activator of the ARE through its stimulation of NF-E2-related factor 2 (Nrf2, the major transcription factor required for ARE binding and activation) nuclear translocation. Pretreatment of cortical cultures for 48 hours with tBHQ attenuated oxidative stress-induced apoptosis resulting from both hydrogen peroxide and L-glutamic acid treatments in a dose-dependent manner. This protective effect directly correlated with the amount of ARE activation in the cultures as measured by an increase in hPAP reporter activity. TBHQ-pretreated cultures showed reduced numbers of TUNEL-positive cells and fewer nuclei displaying condensed or fragmented chromatin visualized by Hoescht 33258. The doses of H2O2 and L-glutamic acid used in this study selectively killed the neurons (β-tubulin III-positive) of this mixed culture system. TBHQ pretreatment caused a significant decrease in this neurotoxicity. Furthermore, preliminary studies suggest that treatment of immature cultures (3 DIV) with L-glutamic acid is attenuated by tBHQ and leads to NMDA receptor-independent toxicity. These results lend further support to the idea that activation of gene expression *via* the ARE increases the resiliency of cells against multiple insults known to cause programmed cell death.

56 DEVELOPMENT OF A MICROARRAY ELISA FOR CHARACTERIZING POTENTIAL MARKERS OF BREAST CANCER IN NIPPLE ASPIRATE FLUID.

R. C. Zangar[1], R. L. Woodbury[1], S. M. Varnum[1], C. C. Covington[2] and R. D. Smith[1]. *[1]Pacific Northwest National Laboratory, Richland, WA and [2]University of California School of Nursing, Los Angeles, CA.*

Nipple aspirate fluid (NAF) is obtained from nonlactating women and is likely to be a rich source of protein markers for breast cancer. Analysis of NAF is difficult due to small sample volumes (typically 10-50 μL) and a rudimentary knowledge of its protein composition. To address these problems, we have taken a dual approach of characterizing the NAF proteome and of developing a microarray ELISA. Using trypsin digestion and LCQ tandem mass spectrometry, 64 proteins were identified in NAF. At least 15 of these proteins have been reported to be altered in serum or tumor tissue from women with breast cancer. Using the microarray ELISA, hepatocyte growth factor (HGF) was quantitatively detectable to the sub-pg/mL level. Significant differences between HGF concentrations in sera of breast cancer patients was detected and the serum HGF values correlated (r2 = 0.90) with those obtained using a commercial 96-well ELISA assay. In multiplex studies, we simultaneously assayed 5 potential markers at biologically relevant levels. These studies indicated that excellent signal-to-background ratios could be obtained for each assay even though the concentrations of the different antigens varied 3000-fold. Overall, this research provides an initial characterization of the NAF proteome and develops a microarray ELISA that appears suitable for the high-throughput evaluation of potential cancer markers in NAF. This research was supported by the US Army's Breast Cancer Research Program, award #DAMD17-00-1-0132.

57 FINDING NON-INVASIVE BIOMARKERS USING MICROARRAY TECHNOLOGY.

T. P. Ryan, W. H. Jordan, B. R. Berridge, P. C. May, D. O. Calligaro and G. H. Searfoss. *Lilly Research Labs, Greenfield, IN.* Sponsor: C. Thomas.

Finding non-invasive biomarkers of toxicity using microarray technology can be a challenge. Profiling of target organ toxicities often requires invasive procedures to obtain mRNA, gene expression changes are often transient, and differentially expressed transcripts often encode proteins that cannot be detected in accessible fluids, such as blood or urine. However, if expression data are mined with the intent of identifying biomarkers, these hurdles can be overcome. Here, we present a case study whereby microarray technology was utilized to identify a differentially expressed transcript that encodes a protein that is premonitory for a gastrointestinal toxicity observed in rat upon compound treatment. Analysis of microarray data identified the secreted serine protease adipsin as a transcript that was up-regulated early and whose expression levels were sustained throughout the compound treatment period. Expression changes in adipsin two hours post-treatment preceded gross pathological effects that required four days to manifest in the ileum of treated animals. Adipsin has previously been determined to encode an adipocyte-specific component of the alternative complement cascade. In investigating adipsin as a toxicity biomarker, however, we have identified a new regulatory mechanism for this gene that places it as a downstream target of the notch cell fate signaling pathway. Promoter analysis and protein expression using peptide antibodies confirm the array findings and mechanistically link this biomarker to off-target effects of adipsin. Furthermore, *in vitro* models used to confirm adipsin gene regulation and expression now allow screening for molecules for *in vivo* gastrointestinal effects using an *in vitro* transcription-based screen. In summary, we have employed a predetermined microaray data mining approach to identify a non-invasive toxicology biomarker using invasive microarray technology. Follow up studies have not only confirmed biologically what was observed transcriptionally, but identified a new regulatory control mechanism for the adipsin gene.

58 HIERARCHICAL CLUSTERING ANALYSIS OF 2-DIMENSIONAL PROTEIN GEL IMAGES: CORRELATION WITH TESTICULAR TOXICITY IN BEAGLE DOGS.

P. Liu, J. W. Davis, G. Mandakas, J. M. McNulty, L. A. Obert, R. J. Smith, F. M. Goodsaid and I. Y. Rosenblum. *Schering-Plough Research Institute, Lafayette, NJ.*

Changes in protein expression that correlate with onset of histopathology are potentially useful as indicators, and possibly as early markers of target organ toxicity. The use of 2-dimensional (2D) gel electrophoresis for the examination of global changes in an organism's proteome has great potential to aid in the identification of novel markers of toxicity. However, this approach has proven to be difficult due to the immense amount of data obtained from individual gels. We investigated a statistical approach where hierarchical clustering methods were used to correlate the changes of individual protein levels across a number of gels. Male beagle dogs were dosed with ketoconazole, a potent anti-fungal with noted testicular toxicities, (40 mg/kg) for 1, 7 or 25 days. Testicular degeneration occurred as early as day 7 and continued through day 25. Cellular proteins were extracted from the testes and separated by 2-D protein gel electrophoresis. Proteins whose abundance was significantly changed as compared to control testes ($p<0.05$) were identified and subjected to hierarchical clustering analysis. Two different software packages clustered proteins according to the similarity of their expression profiles. Clusters of proteins whose expression pattern correlated with or preceded the onset of the lesion were identified. These protein spots will be selected for mass spectrometry identification and further analysis. By using hierarchical clustering, the number of protein spots analyzed from 2D gels was reduced from over 2000 to less than 150. This approach will allow us to focus on specific clusters of proteins based on their correlation with the development of drug-induced histopathological lesions.

59 USE OF GENE EXPRESSION PROFILING TO UNDERSTAND THE TRANSCRIPTIONAL PROGRAMME ASSOCIATED WITH ESTROGEN-INDUCED UTERINE GROWTH: IMPLICATIONS FOR THE USE OF SURROGATE MOLECULAR MARKERS IN TOXICOLOGY.

G. Orphanides, J. G. Moggs, T. Spurway, H. Tinwell, J. Ashby and I. Kimber. *HAES Research, Syngenta CTL, Macclesfield, Cheshire, United Kingdom.*

Toxicogenomics, the measurement of gene expression changes in toxicant-exposed biological materials, is beginning to have a significant impact on toxicological research. The use of gene expression data in mechanistic and predictive toxicology is hindered by a lack of information on the relationships between transcriptional events and physiological and pathological changes. We have analysed this relationship using the rodent uterotrophic response as a model experimental system. Immature mice were administered with a single dose of estradiol (400 mg/kg) sufficient to induce a sustained increase in uterine weight, or with vehicle alone (corn oil), by sub-cutaneous injection. Uterine weight, histopathological parameters and gene expression levels were measured 1, 2, 4, 8, 24, 48, and 72hr after injection. Greater than 1, 000 of the 12, 500 genes analysed showed altered expression in response to estradiol treatment. Hierarchical clustering was used to group these genes into co-regulated gene clusters. By comparing the kinetics of gene regulation of each cluster with uterine weight and histopathological measurements, we were able to assess the contribution made by each cluster to the overall physiological response of the uterus. Using this approach, we have identified groups of co-regulated genes that may be involved in early (e.g. induction of growth-promoting transcription

factors, fluid imbibation), mid (e.g. increases in mRNA and protein metabolism) and late (e.g. induction of DNA replication and cell division) events. This study reveals novel insights into the molecular mechanisms that accompany estrogen-regulated uterine growth. Furthermore, by correlating gene expression and physiological changes we have identified alterations in gene regulation that may be used as molecular markers for early, mid and late uterine responses.

60 PROTEOMIC INVESTIGATION OF BODY FLUIDS.

H. Licea-Perez[1], R. F. Henderson[1], S. I. Rennard[2] and R. W. Rubin[1]. *[1]Lovelace Respiratory Research Institute, Albuquerque, NM and [2]University of Nebraska Medical Center, Omaha, NE.*

The use of surface-enhanced laser desorption ionization (SELDI) linked to time of flight (TOF) mass spectroscopy to determine protein expression profiles of body fluids is proving useful in informing diagnostic and therapeutic approaches to respiratory disease. Prior to initiation of such studies at the Lovelace Respiratory Research Institute, we developed standard protocols for the preparation of body fluid samples for analyses on the five major commercially available chips (anionic, cationic, hydrophobic, normal phase and metal affinity surfaces). As expected, there was considerable variation in the proteins bound by each chip type. Using these protocols we determined the reproducibility of the results between the eight surface areas on each chip, and between different chips with the same surface. Some variation was observed, suggesting that replicate analyses are advisable and internal standards are needed as reference values for quantitative analyses. We also determined the effect of large amounts of albumin (commonly present in body fluids) on the binding of other proteins to the surfaces. Albumin binding can prevent the binding of other proteins and mask their presence. Sample treatment including freeze/thawing and trichloracetic acid precipitation can produce apparent artifacts in the patterns of peaks seen in the TOF analyses. Preliminary analyses of human bronchoalveolar lavage fluid (BALF) suggested that a biomarker of developing chronic obstructive pulmonary disease (COPD) could be detected in smokers. Under conditions of the assay (SAX2 chip protein array, pH 7.0), the biomarker protein (Mw about 5 kDA) was not seen in BALF from non-smokers, variably seen from smokers without COPD, and present in large amounts from smokers with COPD. Additional samples are being analyzed to determine the consistency of this result. The results of these studies provide valuable information for the design of future investigations using proteomic analysis of body fluids. Research supported by the Lovelace Respiratory Research Institute.

61 USE OF PROTEOMIC TECHNOLOGIES FOR DISCOVERY OF NEW MARKERS OF SKIN IRRITATION *IN VITRO.*

S. T. Fletcher[1] and V. A. Baker[2]. *[1]SEAC, Unilever, Bedfordshire, United Kingdom and [2]CuDoS Cellular Development Systems Ltd, Nottingham, United Kingdom.* Sponsor: C. Atterwill.

The development of predictive *in vitro* test systems for the identification of skin irritation hazards relies on a greater understanding of the mechanistic basis of the human skin irritation response. Proteomic technologies now allow investigation of important biochemical events in the processes of skin irritation and the discovery of potential new markers. This study was designed to profile and identify proteins involved in the skin irritation response, following exposure of a reconstructed human skin model (EpiDerm™ (MatTek)) to a range of skin irritants: sodium lauryl sulphate (SLS), benzalkonium chloride (BKC), nonanoic acid (NAA) and phenol. EpiDerm™ cultures were exposed (15min-24h) in triplicate to non-cytotoxic doses of the skin irritants (0.1mg/ml SLS, 0.01% (v/v) BKC, 0.025% (v/v) NAA and 0.25% (v/v) phenol) as determined by MTT assay and histological examination. Proteomics was performed using SELDI-TOF to investigate protein expression profiles following exposure to skin irritants. A number of proteins (MW 6-52kD) were found to be differentially expressed when profiled using a range of ProteinChip® arrays (Ciphergen). For example, proteins of MW 9.9 and 12.9kD exhibited upregulation following exposure to skin irritants at the majority of time points tested, while some protein changes were chemical specific (e.g. 13.7kD protein upregulated following 4h exposure to phenol). In addition, differential phosphorylation (80D mass shift) patterns correlating with exposure to skin irritants were also identified. 2D-gel electrophoresis was also used in combination with MALDI-TOF and a number of proteins including heat shock proteins, metallothioneins, calmodulin-like skin protein and involucrin demonstrated differential expression/post-translational modification following exposure to skin irritants. In conclusion, these results demonstrate the potential of proteomic technologies to investigate the differential regulation of proteins in response to skin irritants, some of which could represent potential new *in vitro* markers of skin irritation.

62 CHARACTERIZATION OF A BILIARY PROTEOMIC INJURY SIGNATURE IN RATS EXPOSED TO 1, 1-DICHLOROETHYLENE.

J. A. Jones[1], D. C. Liebler[1] and M. T. Moslen[2]. *[1]College of Pharmacy, University of Arizona, Tucson, AZ and [2]University of Texas Medical Branch, Galveston, TX.*

Previous work has described the hepatotoxicity and metabolism of 1, 1-DCE, which causes a selective injury to the canalicular membrane. Bioactivation of 1, 1-DCE results in formation of reactive electrophilic intermediates that, in turn, are capable of protein alkylation. Protein alkylation following DCE treatment ultimately results in formation of S-carboxymethylated proteins. Proteins are excreted into the bile *via* the canalicular membrane. Analysis of biliary proteins provides insight into both intracellular and canalicular membrane changes. Bile was collected from rats both prior to and 3h after exposure to 50 mg/kg 1, 1-DCE. Proteins were separated by 1D-PAGE and subjected to in-gel digestion. Samples were analyzed by LC-MS-MS on a ThermoFinnigan LCQ-DECA mass spectrometer. Each sample was subjected to multiple analyses over 300 to 2000 amu, 300 to 700 amu, 700 to 1200 amu and 1200 to 1800 amu. Proteins were identified with the aid of SEQUEST and BLAST database searching, and verified by interpretation of the corresponding spectra. Moslen et al. observed a decrease in protein content after exposure to 1, 1-DCE; however, our data show a marked increase in the number of different proteins. Twenty-one proteins were identified in the control samples, whereas 40 were identified in the post-exposure samples. In addition, several S-carboxymethylated peptides were identified in samples collected after exposure. Since this modification does not occur endogenously, these modified peptides provide evidence for protein covalent modification by mechanisms previously proposed. This work describes the first comprehensive characterization of the rat biliary proteome both before and after exposure to a hepatotoxic chemical. (This work was supported by NIH Grants ES10056 and ES06694.)

63 A PROTEOMIC APPROACH TO IDENTIFY THE MOLECULAR TARGETS OF LEAD AND ACRYLAMIDE NEUROTOXICITY IN THE NEURONAL SNARE PROTEIN CIRCUITRY THAT UNDERLIES NEUROTRANSMITTER RELEASE.

M. Gillespie. *St. John's University, Jamaica, NY.* Sponsor: F. Schanne.

Our lab has developed a series of proteomic systems to identify protein:protein interactions that are affected by a toxin or drug. Here we present potential targets of the neurotoxins lead (Pb^{+2}) and acrylamide (ACR) identified from a library encoding millions of individual proteins. Our search was anchored by the neuronal SNARE protein complex, specifically SNAP-25. The system described is a proteomic approach to molecular toxicology based on the two-hybrid screen. The system is divided into three steps, the first screen identifying potential protein:protein complexes from the large human neuronal cDNA libraries. Secondary and tertiary screens are then used to limit artifacts and identify protein complexes that are disrupted by neurotoxin. The neuronal SNAREs are a special class of SNARE proteins, involved in the trafficking and calcium dependant fusion of neurotransmitter containing vesicles to the presynaptic neuronal membrane. Our approach, an intersection of proteomics, neuroscience, and molecular toxicology, is robust and inexpensive, providing a method to identify the molecular targets of a toxin or drug from complex libraries of proteins. For this study the neurotoxins Pb^{+2} and ACR provide excellent model systems, being associated with dysfunctions in neurotransmitter release, and membrane trafficking. We hypothesized that the neuronal SNARE protein circuitry (the neuronal SNARE complex and its associated proteins) was involved in this dysfunction. The experimental range of Pb^{+2} and ACR concentrations used had no toxic effects on the growth of control strains in the study. The primary and secondary screens of the cDNA library encoded proteins identified 43 potential protein:protein complexes. The tertiary neurotoxicity screen identified 12 candidate clones that were selected for sequencing and were independently tested for self-activation. Of the 12 candidate clones, 4 were previously identified as SNAP-25 partner proteins, 2 were SNARE proteins, 4 were known proteins, and 2 were unknown sequences.

64 BIOMARKERS OF HUMAN GLIOMA CELL EXPOSURE TO ELECTROMAGNETIC FIELDS.

E. M. Hennessey[1], L. W. U'Ren[1], R. E. Savage[2], M. H. Kanitz[2], W. G. Lotz[2] and W. H. Hanneman[1]. *[1]Department of Environmental & Radiological Health Sciences, Colorado State University, Fort Collins, CO and [2]NIOSH, Cincinnati, OH.*

Several recent reviews on the potential health effects of electric and magnetic fields (EMFs) have concluded that power frequency EMF exposures are potentially carcinogenic to humans. Similarly, recent pooled analyses examining the relationship between magnetic fields (MF) exposure and childhood cancer indicate that exposure to residential MF exceeding 3 or 4 milligauss (mG) are associated with a 70-100% increased risk of acute lymphocytic leukemia, the most common form of

cancer in children. In light of these data, the National Institute for Occupational Safety and Health (NIOSH), together with Colorado State University (CSU) are investigating the effects of putative occupational carcinogens on cancer-linked molecular events in appropriate cellular systems. We are currently interested in the biological plausibility of EMFs as a putative carcinogen in SF767 human glioma cells. Here we study the effect of short-term environmental-level EMF exposure using cDNA microarrays. Following a 3 hr exposure we investigate changes in gene induction to determine appropriate genetic biomarkers of effect of exposure to EMF. At 70% confluence SF767 are exposed in the presence or absence of either epidermal growth factor (EGF) or melatonin, to a 12 mG, 60 Hz EMF. Ambient field strength in the cell culture incubator is maintained at 2 mG, 60 Hz. Total RNA was then isolated for use on the PerkinElmer oncogene array. Computer analysis and comparison of gene up and down regulation is performed across groups. These data suggest a limited yet complicated response of glioma cells to environmental field exposure. The number of oncogenes induced by EMF alone and in the presence or absence of melatonin and/or EGF range from 8 to over 40. The number of suppressed oncogenes ranges from 7 to more than 20. Current cluster analysis of this data may offer preliminary evidence of the possible role of EMF as a carcinogen in human glioma cells.

65 ORAL EXPOSURE TO INORGANIC MERCURY ALTERS T-LYMPHOCYTE PHENOTYPES AND CYTOKINE GENE EXPRESSION IN BALB/C MICE.

S. Kim[1], V. J. Johnson[2] and R. P. Sharma[1]. *[1]Physiology and Pharmacology, University of Georgia, Athens, GA and [2]Toxicology and Molecular Biology Branch, NIOSH, Morgantown, WV.*

Mercury is a well recognized health hazard and an environmental contaminant. Mercury is known to suppress immune responses, but the mechanisms responsible for this effect are still unclear. The aims of this study were to investigate the effect of mercury on immune parameters, such as hematology, lymphocyte phenotypes and cytokine gene expression. Male BALB/c mice were exposed continuously to 0, 0.3, 1.5, 7.5, or 37.5 ppm of mercury in drinking water for 14 days. Food and water consumption decreased in a dose-dependent manner in mice exposed to mercury. Body weight was reduced at the highest dose of mercury whereas the relative kidney and spleen weight were significantly increased. The dose-range of mercury used did not cause hepatotoxicity as indicated by circulating alanine aminotransferase and aspartate aminotransferase. Circulating blood leukocytes were elevated in mice treated with the highest dose of mercury. Single-cell splenocyte cultures were used to determine the effects of mercury treatment on mitogen-induced lymphocyte blastogenesis. Mercury at 1.5 ppm increased the PHA and LPS stimulation indices for T and B lymphocytes, respectively reflecting the observed decrease in basal splenocyte proliferation in mercury-treated mice. Exposure to 7.5 and 37.5 ppm of mercury decreased the CD8+ T lymphocyte population in thymus, whereas double positive CD4+/CD8+ and CD4+ thymocytes were not altered. Mercury ranging from 1.5 to 37.5 ppm dose-dependently decreased CD3+ T lymphocytes in spleen; both CD4+ and CD8+ single positive lymphocyte numbers were decreased. The population of CD45+ B lymphocytes was not changed. Mercury altered the expression of cytokines (tumor necrosis factor α, interferon γ, interleukin-12), c-myc, and major histocompatibility complex II in various organs. Results indicated that decreases in T lymphocyte populations in immune organs and altered cytokine gene expression may contribute to the immunosuppressive effects of inorganic mercury.

66 INDUCTION OF HEPATIC METALLOTHIONEIN BY VANADIUM.

T. Hasegawa[1], K. Kobayashi[2], M. Satoh[3,4], S. Himeno[5] and Y. Seko[1]. *[1]Environmental Biochemistry, Yamanashi Institute of Environmental Sciences, Fujiyoshida, Yamanashi, Japan, [2]Kissei Pharmaceutical Co. Ltd.,, Hotaka, Nagano, Japan, [3]Hygienics, Gifu Pharmaceutical University, Gifu, Japan, [4]Environmental Health Sciences, National Institute for Environmental Studies, Tsukuba, Ibaraki, Japan and [5]Public Health and Molecular Toxicology, Kitasato University, Tokyo, Japan.*

We have previously shown that the induction of hepatic metallothionein (MT) in mice by manganese (Mn) administration is entirely dependent on the production of inflammatory cytokine, interleukin-6 (IL-6). It is known that IL-6 is one of the mediators of MT induction. In the present study, we investigated the induction mechanism of MT synthesis by vanadium (V) in mice. Male ICR mice were injected subcutaneously with ammonium metavanadate (V[5]; 0.05-0.3 mmol/kg) and sacrificed 24 h after the injection. Although hepatic total vanadium concentration was lower than that in kidney, MT concentration was increased dose-dependently in the liver by V[5] administration, but not in the kidney. HPLC/ICP-MS analysis on the distribution of the metals in hepatic cytosol of V[5]-treated animals showed that the major metal bound to MT-I and MT-II was not vanadium, but zinc. A time-course study showed that hepatic total vanadium content, serum alanine aminotransferase (ALT) activity and serum IL-6 concentration reached the peak at 4-6 h after V[5] (0.3 mmol/kg) injection, and then declined quickly. Concentration of serum amyloid A (SAA), an acute-phase protein that is induced by IL-6, increased at 24 h after the injection. To confirm the involvement of IL-6 in MT induction by V[5], IL-6 null and control mice were administered with V[5]. In IL-6 null animals, no increase in SAA was observed, and MT induction by V[5] was significantly decreased to about 55 % of control animals. These data suggest that both IL-6-dependent and independent mechanisms are involved in MT induction by V[5] in mice.

67 ENHANCED GENOTOXICITY BY DIMETHYLARSINIC ACID IN METALLOTHIONEIN-I/II NULL MICE.

M. Satoh[1,2], J. Guang[2], N. Nishimura[2,3], C. Tohyama[2] and H. Sone[2]. *[1]Department of Hygienics, Gifu Pharmaceutical University, Gifu, Japan, [2]Environmental Health Sciences Division, National Institute for Environmental Studies, Tsukuba, Japan and [3]Japan science and Technology Corporation, Kawaguchi, Japan.*

To elucidate the protective role of metallothionein (MT) in the genotoxicity of dimethylarsinic acid (DMA), we examined the sensitivity of MT-I/II null mice to the genetic damage and the induction of apoptosis caused by DMA. Eight-week-old female MT-I/II null mice and wild-type mice were given p.o. injection of DMA (188, 375, 750 mg/kg). The blood, urine and liver were removed from each mouse under ether anesthesia at 24 hr after the injection. The DNA strand breaks in the peripheral blood cells and the 8-hydroxy-deoxyguanosine (8-OHdG) in the serum and urine were determined as indicators of genetic damage. The production of DNA strand breaks in both MT-I/II null mice and wild-type mice was elevated by DMA treatment in a dose-dependent manner. The increased the production of DNA strand breaks in MT-I/II null mice at 750 mg/kg DMA was significantly higher than that of wild-type mice. Moreover, 8-OHdG levels in the serum and urine of MT-I/II null mice were also increased by DMA treatment and they were significantly higher than those of wild-type mice. On the other hand, the DMA-induced apoptosis in the liver was not different between MT-I/II null mice and wild-type mice. MT concentrations in the liver of wild-type mice were increased by DMA treatment in a dose-dependent manner. There were no detectable amounts of hepatic MT in untreated MT-I/II null mice, and they could not be induced by DMA treatment. These results suggested that MT plays an important role in defense of DMA-caused genotoxicity.

68 METAL INDUCED ACTIVATION OF METALLOTHIONEIN GENE EXPRESSION.

E. S. Craft and J. H. Freedman. *Nicholas School of the Environment, Duke University, Durham, NC.*

Metallothionein (MT) transcription is induced following exposure to elevated concentrations of a variety of transition metals. Metal-activated transcription is controlled *via* interactions between metal response elements (MREs) and the metal response element-binding transcription factor, MTF-1. It has been proposed that metals can initiate intracellular signaling cascades that result in altered states of MTF-1 phosphorylation, ultimately leading to the activation of MT transcription. COS-7 cells were transfected with one of three fusion chloramphenicol acetyltransferase (CAT) reporter genes: p-42-CAT (minimal mouse MT-1 promoter); pMREd5'-CAT (5 tandem copies of MREd' inserted upstream of the TATA box in p-42-CAT); or p-153-CAT (intact mouse MT-1 promoter). Cells were co-transfected with a β-galactosidase reporter plasmid, pSV-β-gal to control for transfection efficiency. Following a 4 hr metal exposure, the level of CAT protein was determined by a CAT-ELISA. Results were normalized with respect to the level of β-galactosidase activity. Of metals tested, only cadmium, copper, mercury, arsenic, antimony, silver, gold, and zinc were able to activate MT transcription *via* the MRE, while aluminum, indium, selenium, beryllium, tin, iron, cobalt, manganese, bismuth, molybdenum, lead, titanium, vanadium, chromium(III and IV), and nickel were not. CAT assay results were verified using reverse transcription PCR (RT-PCR) with MT primers and total RNA isolated from COS-7 cells exposed to the various metals for 4 hours. All real-time MT data was normalized to an actin standard. Of metals tested, cadmium, copper, zinc, mercury, silver, and arsenic exposures caused an increase in the steady state levels of MT mRNA. Inhibition studies were completed in order to test the hypothesis that phosphorylation of MTF-1 is involved in activation of MT gene transcription. These studies involved pre-treating cells for 30 minutes with 100μM of a broad range protein kinase C (PKC) inhibitor, H7. Inhibition results suggest that MT transcription induced by these metals occurs *via* a convergent signal transduction pathway involving PKC.

69 MT-3 OVEREXPRESSION INCREASES CHEMOTHERAPEUTIC RESISTANCE AND AFFECTS THE GROWTH OF BREAST CANCER CELL LINES.

M. Sens, V. Gurel, S. Somji, S. H. Garrett and D. A. Sens. *Pathology, University of North Dakota, Grand Forks, ND.*

The third isoform of the human metallothionein (MT) gene family is unique compared to the 1 and 2 isoforms in that it has a more restricted pattern of tissue distribution. This laboratory has previously shown that overexpression of MT-3 in the

prostate cancer cell line PC-3 and in the breast cancer cell line MCF-7, inhibited the growth of these cells and increased their resistance to certain chemotherapeutic drugs. Since estrogen receptor (ER) status is a prognostic marker in the diagnosis of breast cancer, we were interested in determining the effect of overexpression of MT-3 in ER positive and ER negative cell lines. For this purpose, the MT-3 gene was stably transfected under the control of the CMV promoter in ER positive cell lines (MCF-7 and T-47D) and ER negative cell lines (MDA-MB-231 and Hs578T). Our previous work has shown that the MT-1E isoform is expressed in ER negative cells and not in ER positive cells. Therefore the MT-1E gene was transfected into the two ER positive cell lines. The expression of MT-3 and MT-1E gene and protein was confirmed in five independent clones using RT-PCR and immuno-blot analysis respectively. MT-3 overexpression decreased the growth rate of MCF-7 and Hs578T cells, whereas the growth rate of T-47D and MDA-MB-231cells was not affected. Overexpression of MT-3 also conferred resistance to the chemotherapeutic drugs cisplatin, doxorubicin, paclitaxel, 5-Fluorouracil and methotrexate. However, overexpression of MT-1E did not affect the growth rate of the cells but did confer drug resistance. This data suggests that the growth inhibitory activity is a function of MT-3 and is not dependant on the ER status of breast cancer cells but rather, it subdivides ER positive cells into subcategories based on the expression of MT-3 which may be important factor in the prognosis of the disease.

70 THE INABILITY TO PRODUCE THE MAJOR FORMS OF METALLOTHIONEIN RENDERS MICE HYPERSENSITIVE TO THE CHRONIC TOXIC EFFECTS OF LEAD, INCLUDING RENAL HYPERPLASIA, WHILE PREVENTING INCLUSION BODY FORMATION.

B. A. Diwan[1] and M. P. Waalkes[2]. *[1]SAIC, Frederick, MD and [2]Inorganic Carcinogenesis Section, LCC, NCI at NIEHS, Research Triangle Park, NC.*

Lead (Pb) is a high priority environmental hazard and defining factors that predispose populations to the chronic Pb toxicity is a key research issue. Recently, we found that mice unable to produce the major forms of the metal-binding protein metallothionein, specifically MT-I/II knockout (MT-null) mice, are hypersensitive to the subchronic toxic effects of oral Pb, like diminished renal function and nephromegaly, compared to wild type (WT) mice that express MT normally. The MT-null mice accumulated less tissue Pb and did not form Pb inclusion bodies. Since the MT-null phenotype reduces tissue Pb accumulation, it is unclear how this might impact chronic Pb toxicity. Thus, chronic Pb toxicity was compared in MT-null and WT mice. Male MT-null and WT mice (n = 25) received Pb (as Pb acetate) in the drinking water at 0, 1000, 2000, 4000 ppm for up to 104 weeks. Reduced survival occurred at 2000 and 4000 ppm in MT-null mice but only at 4000 ppm in WT mice. Renal preneoplasia (cystic hyperplasia) was much more common and severe in Pb-exposed MT-null mice (up to 60%) than WT mice (up to 21%). A metastatic renal carcinoma occurred in a Pb-treated MT-null mouse while no renal tumors occurred in WT mice. Chronic Pb-induced nephropathy, including tubular degeneration, necrosis and interstitial fibrosis, did not occur to a significant extent in WT mice, but was common (up to 72%) and dose-related in both incidence and severity in MT-null mice. MT-null mice did not form renal Pb-containing nuclear inclusion bodies (NIBs), which are thought to mitigate Pb toxicity, whereas NIBs were common in WT mice. Thus, the MT-null phenotype is unable to form NIBs even after protracted Pb exposure and this increases chronic Pb toxicity. Overall, MT appears to have an important role in chronic Pb toxicity and NIB formation, and the inability to produce MT may predispose populations to chronic Pb toxicity. (Funded in part by DHHS #NO1-CO-12400.)

71 EFFECT OF METALLOTHIONEIN-3 EXPRESSION ON CADMIUM TOXICITY IN THE HUMAN PROXIMAL TUBULE CELL LINE HK-2.

S. Somji[1], S. H. Garrett[1], M. Sens[1] and D. A. Sens[2]. *[1]Pathology, University of North Dakota, Grand Forks, ND and [2]Surgery, University of North Dakota, Grand Forks, ND.*

The kidney and the proximal tubule in particular are the organ and cell type critically affected by chronic exposure to cadmium. Numerous studies have shown that metallothionein (MT) 1 and 2 family members play an important protective role against the chronic nephrotoxicity classically elicited by cadmium exposure. The third isoform of metallothionein, MT-3 can also bind and sequester cadmium similar to that of the MT-1 and 2 isoforms, and could have the potential to play a role in mediating toxicity that cadmium elicits on the renal proximal tubule cell. Previous work by this laboratory has shown that the immortalized human proximal tubule cell line HK-2, does not express the MT-3 gene. The goal of this study was to determine if over-expression of MT-3 in the HK-2 cell line would increase the resistance of these cells to the toxic effects of cadmium. The HK-2 cell lines and the MT-3 transfected cells were exposed to lethal and sub-lethal concentrations of cadmium chloride for various time periods. The effect of cadmium treatment on cell viability was determined by the automated counting of the cell nuclei stained with the nuclear binding dye, 4', 6-diamidino-2phenylindole (DAPI). Continuous exposure of HK-2 cells to various concentrations of cadmium for 8 to 48 hr resulted in cell death with extensive chromatin condensation and DNA fragmentation, features typical for cells undergoing apoptosis. This was further confirmed by agarose gel electrophoresis and caspase-3 assay. The MT-3 transfected cells did not show any increased resistance to cadmium compared to the HK-2 parental cells with very few cells showing morphological changes typical for apoptosis. Extended exposure of the parental and transfected cells for 16 days to cadmium had a similar effect. These results indicate that MT-3 expression may have a minimal role in providing protection against the toxic effects of cadmium.

72 EXPRESSION OF THE MT-3 PROTEIN IN THE NORMAL BREAST EPITHELIAL CELL LINE MCF-10 IS DEPENDANT UPON THE PRESENCE OF THE HEAVY METAL CADMIUM.

V. Gurel, M. Sens, S. Somji, S. H. Garrett and D. A. Sens. *Pathology, University of North Dakota, Grand Forks, ND.*

Metallothioneins (MT) are a family of low molecular weight (6Kb) cysteine rich proteins that participate in a variety of functions such as detoxification of heavy metals and homeostasis of essential metals. They can also act as scavengers of free radicals. MT-1 and 2 isoforms are ubiquitously expressed, whereas the expression of the third isoform is limited to the neural tissue. Our laboratory has recently shown that MT-3 is not expressed in normal breast tissue, but is overexpressed in certain breast cancers and that the overexpression is associated with tumors having a poor prognosis. The goal of this study was to determine the effect of MT-3 overexpression in breast epithelial cells using a cell culture model. For this purpose, the normal breast epithelial cell line MCF-10 was stably transfected with the MT-3 gene under the control of the CMV promoter. Expression of MT genes and protein were determined by RT-PCR and immuno-blot analysis respectively. The MT-3 transfected cells expressed the MT-3 mRNA but surprisingly did not express any MT-3 protein. In order to explain this finding, the MT-3 transfected cells, vector only transfected cells and the parental MCF-10 cells were exposed to various concentrations of cadmium chloride from 4 to 48 hours. Exposure to cadmium resulted in a significant increase in the gene expression of MT-1E, 1X and 2A isoforms in all the cell types. As expected, there was no expression of MT-3 in the parental or the vector only transfected cells. However, in the MT-3 transfected cells exposure to cadmium caused a 10 fold induction in MT-3 protein levels. This data suggests that the MT-3 protein is highly unstable in the absence of heavy metals and is rapidly degraded. However, heavy metals such as cadmium bind to the protein, stabilize it and prevent their degradation.

73 CADMIUM OR ZINC IS REQUIRED FOR THE EXPRESSION OF MT-3 PROTEIN IN THE MT-3 GENE TRANSFECTED UROTSA CELL LINE.

S. Park, S. H. Garrett, S. Somji, M. Sens and D. A. Sens. *Pathology, University of North Dakota, Grand Forks, ND.*

Metallothioneins (MT) are cysteine rich intracellular proteins that bind transition metals with high affinity and have a wide pattern of tissue distribution. However the third isoform of metallothionein, MT-3 is shown to have a restricted pattern of tissue distribution with expression confined to the neural tissue. Previous work done by this laboratory has shown that MT-3 is not expressed in the normal bladder but is over-expressed in bladder cancer with levels correlating to the type and grade of tumor. Recently, a new bladder epithelial cell line UROtsa has been characterized that does not express the MT-3 gene and may serve as a useful invitro model system of the normal human urothelium. The goal of this study was to see the effect of MT-3 over expression in the normal human bladder epithelial cell line. For this purpose, the UROtsa cell line was stably transfected with the MT-3 gene under the control of the CMV promoter, or the blank vector without the MT-3 gene. The MT-3 gene expression was determined by RT-PCR and the protein levels were detected by immuno-dot blot. The MT-3 transfected cells expressed the mRNA for the MT-3 gene but did not express any protein. One hypothesis to explain why the over expressed RNA does not result in increased protein level is that the protein is rapidly degraded if it is not saturated with heavy metal. To test this hypothesis, the parental cell line UROtsa, the vector blank and the MT-3 transfected cells were exposed to 1, 5 and 9mM cadmium chloride for 4 to 48 hr and MT-3 levels were determined. Treatment with cadmium did not increase the level of MT-3 mRNA or protein in the parental cell as well as the blank vector control. However, in the MT-3 transfected cells, the protein levels increased from 1.5 ng to 6ng/mg of the total protein. Exposure to zinc sulfate had a similar effect on these cells. This data suggests that the MT-3 protein is highly unstable and heavy metals such as cadmium and zinc could stabilize the protein and prevent it from undergoing rapid degradation.

74 EXPRESSION OF METALLOTHIONEIN ISOFORMS IN THE NORMAL HUMAN PROSTATE EPITHELIAL CELL LINE, 267-B1, EXPOSED TO CADMIUM.

S. H. Garrett, S. Han, M. Neriyanuri, S. Somji, M. Sens and D. A. Sens.
Pathology, University of North Dakota, Grand Forks, ND.

Cadmium is a known prostate carcinogen. The assessment of this metal's ability to transform epithelial cells of the prostate is complicated by the presence of metallothionein (MT). This protein can protect against the toxic effects of cadmium by metal sequestration, and exposure to this metal can drastically increase the cellular levels of MT. To study the involvement of MT in the genesis of prostate cancer, the expression profile of the MT isoforms was characterized in the normal human prostate cell line, 267-B1, in response to cadmium exposure. 267-B1 cells were exposed to 18 μM cadmium for up to 4 hr and recovered in normal growth medium for 24 hr, or cells were exposed to 8 μM cadmium continually up to 16 days. Cultures were harvested at various time points and the levels of MT isoform mRNA were assessed by reverse-transcription polymerase chain reaction (RT-PCR), and the levels of MT protein were measured by immuno-dot blot. Basal expression of MT-2A, -1E, and -1X mRNA was detected at levels near that of the house-keeping gene glyceraldehyde phosphate dehydrogenase whereas the levels of MT-3 mRNA were considerably lower. This was similar to the expression profile found previously in normal human prostate tissue. Cadmium increased the levels of MT-1E, 3 fold, and 1X slightly, but there was no induction of MT-2A. Cadmium elicited the expression of -1F in both exposure protocols, whereas the expression of MT-1A and -1G appeared only in the exposure and recovery protocol. Cadmium was unable to induce the levels of MT-3 mRNA or protein in either cadmium exposure protocol. The total MT-1 and -2 protein level was increased from 2.59 +/- 0.45 ng/ μg protein to a transient level of 16.11 +/- 2.85 ng/ μg protein during the exposure and recovery protocol, and to a level of 25.46 +/- 0.38 ng/ μg protein after 16 days of continuous exposure to cadmium.

75 LEAD MODULATES BOTH OSTEOBLAST AND OSTEOCLAST ACTIVITY: A PARADIGM FOR ENHANCED BONE LOSS.

J. E. Puzas, R. J. O'Keefe, E. M. Schwarz, M. J. Zuscik and R. N. Rosier.
Department of Orthopaedics, University of Rochester School of Medicine, Rochester, NY. Sponsor: T. Gasiewicz.

Many adults over the age of fifty have a substantial bone lead burden. This is due to the long half life of lead in the skeleton and to the sequestration of lead in the mineral compartment of bone. While the concern over lead toxicity in soft tissues may be decreasing, the cells in the bone compartment remain exposed to high levels. Our findings document that both osteoblast and osteoclast activity is depressed under the influence of lead. Primary cultures of osteoblasts and osteoclasts isolated from neo-natal rat calvaria and long bone marrow aspirates (respectively) were used for these experiments. Osteoblasts cultured in the presence of lead demonstrated a dose and time dependent decrease in alkaline phosphatase activity and collagen synthesis, both hallmarks of bone formation. The effect was statistically significant at 0.1uM and higher. This effect is mediated by a decrease in the mRNA levels for the requisite osteoblast transcription factor Runx2. Also, we have shown that lead rapidly and potently decreases TRIP-1 mRNA levels. TRIP-1 is a key effector in the TGF beta pathway which controls osteoblast differentiation. The effect of lead on osteoclast function is also inhibitory. This was demonstrated by a decrease in total surface area resorbed by isolated osteoclasts. The effect is mediated by a decrease in RANK ligand (the final paracrine factor involved in osteoclast activation) production and an increase in OPG (osteoprotegerin, a decoy receptor for RANK ligand) levels. A meta analysis of all of the osteoblast and osteoclast data indicate that the effect on osteoblasts occurs at a lower lead level than on osteoclasts. This implies that bone formation is more adversely affected than bone resorption. Lead exposure to bone cells in culture depresses both bone formation and resorption. However, bone formation is more profoundly affected than resorption. If this qualitative difference exists *in vivo*, then it might explain the decrease in skeletal density seen in animals and humans exposed to lead.

76 URANIUM AND CELL DEATH IN THE RAT KIDNEY.

M. Pomeroy[1], B. Jortner[1], M. Ehrich[1], J. Robertson[1] and D. Barber[2]. *[1]Department of Biological Sciences and Pathobiology, Virginia Tech, Blacksburg, VA and [2]Department of Physiological Sciences, Center for Environmental and Human Toxicology, University of Florida, Gainesville, FL.*

We investigated the histopathological course of uranium-induced acute tubular necrosis in adult male Sprague-Dawley rats, focusing on pathogenic events. Rats were sacrificed 8 hours, 24 hours, and 168 hours following intraperitoneal administration of 0, 1 or 10 mg/kg of uranium given as uranyl acetate in saline. Mean total uranium concentration (in ng/ml, n = 3-5) in serum was as follows: 1 mg/kg dose- 20.9 at 8 hours, 4.5 at 24 hours; 10 mg/kg dose- 200 at 8 hours, 30.5 at 24 hours. Light microscopic studies revealed diffuse brush border loss and necrosis of renal proximal tubular epithelium, most marked in rats given 10 mg/kg, confirming earlier work documenting the toxic effect of uranium (Sanchez et al., Biol Trace Elem Res 84:139; Lim et al., Yonsei Med. J 28:38). This lesion was notable at 8 hours post-dosing in the outer stripe of the medulla, and extended through the cortex by 24 hours, best seen in rats given 10 mg/kg. We have demonstrated that apoptosis is a feature of this event, most prominent at 24 hours post-dosing, using the TUNEL assay (1:25) (TUNEL Label, Roche Diagnostics). Glomeruli appeared intact. By 168 hours, proximal tubular epithelial regeneration was evident in the cortex and outer medullary stripe, more prominent in the 1 mg/kg dosage group. This was characterized by cells having basophilic cytoplasm and not infrequently, mitotic figures. We demonstrate that apoptotic events occur during uranium-induced renal tubular injury and that regeneration is a prominent sequel to such a heavy metal effect. (Supported by: US Army Medical Research and Materiel Command DAMD17-01-1-0775. This abstract does not necessarily reflect the position or policy of the US Government.)

77 ARSENIC ALTERS HORMONE-MEDIATED POSITIVE, BUT NOT NEGATIVE, REGULATORY EFFECTS OF STEROID RECEPTORS.

J. W. Hamilton, J. E. Bodwell, L. A. Kingsley, C. S. Barnet and J. C. Davey.
Pharmacology & Toxicology, Dartmouth Medical School, Hanover, NH.

Arsenic (As) is an agent of considerable human health concern in the US and worldwide. We previously reported that As+3 (arsenite) can act as a potent endocrine disruptor, inhibiting hormone-mediated gene activation by glucocorticoid receptor (GR) and estrogen receptor in cultured cells and *in vivo*. We have investigated these effects further in the current work. Expression constructs for GR, mineralocorticoid receptor or androgen receptor were co-transfected into EDR3 hepatoma cells along with luciferase expression constructs containing appropriate hormone receptor DNA binding sites. As altered the ability of each of these steroid receptors to activate expression of receptor-regulated gene constructs following treatment with dexamethasone, aldosterone or testosterone, respectively. As had little or no effect on basal expression of these constructs in the absence of hormone. The lowest doses of As used (0.1 - 0.5 μM) potentiated the hormone-induced gene expression by 2- to 3-fold over that with hormone alone. In contrast, slightly higher doses of As (1-3 μM) caused a dose-dependent suppression of induction. These results in combination with previous studies indicate that As has quantitatively and qualitatively similar effects on the entire family of steroid hormone receptors. GR can also act as a negative regulator of gene expression through both DNA-dependent and -independent mechanisms. In the latter case, hormone-activated GR can inhibit AP-1 or NF-κB gene activation in a dominant negative manner. Using several different cell culture systems we observed that activated GR suppressed AP-1 and NF-κB-mediated gene induction by phorbol ester (TPA) or TNFα, respectively. However, As treatment of cells had no effect on GR negative regulation in these systems. These results indicate that As affects DNA-dependent gene activation by GR but not its DNA-independent negative regulatory effects, suggesting that the endocrine disrupting effects of As occur primarily at the level of hormone receptor-mediated gene transcription (NIEHS ES07373).

78 ROLE OF THE CALPAIN PATHWAY IN ARSENITE-MEDIATED DECREASES IN CYP3A IN CULTURED RAT HEPATOCYTES.

T. L. Noreault[1], B. Dwyer[5,2], R. Nichols[5,3], H. Trask[4], S. Wrighton[6], P. Sinclair[5,4,1] and J. Sinclair[5,4,1]. *[1]Pharmacology & Toxicology, Dartmouth Medical School, Hanover, NH, [2]Neurology, Dartmouth Medical School, Hanover, NH, [3]Microbiology/Immunology, Dartmouth Medical School, Hanover, NH, [4]Biochemistry, Dartmouth Medical School, Hanover, NH, [5]VA Medical Center, White River Junction, VT and [6]Lilly Research Laboratories, Indianapolis, IN.*

We have previously shown that arsenite decreases CYP3A inductions by both Dexamethasone (DEX) and phenobarbital post-transcriptionally in cultured rat hepatocytes, by a mechanism not involving decreased availability of heme. Here we investigated, in primary cultures of rat hepatocytes, whether arsenite decreased CYP3A by increasing degradation of the protein. Three possible routes of protein degradation are the lysosomal, proteosomal and calpain pathways. CYP3A does not contain the pentapeptide consensus sequence recognized by the lysosomal pathway. The ubiquitin-dependent proteosomal pathway has been shown to play a role in the degradation of inactivated CYP3A in rat hepatocytes However, arsenite has been shown to inhibit the ubiquination pathway. Therefore, we first investigated the role of the calpain pathway in arsenite-mediated decreases in CYP3A protein. We established conditions for monitoring calpain activity in intact cells in serum-free medium, using t-butoxycarbonyl-Leu-Met-7-amino-4-chlorimethylcoumarin as a substrate. CYP3A protein induced by DEX was increased further in the pres-

ence of calpeptin, an inhibitor of the calpain pathway. These results suggest that CYP3A is partially degraded *via* the calpain pathway. Combined treatment with DEX, arsenite and calpeptin resulted in greater decreases in CYP3A protein compared to treatment without calpeptin. None of the treatments altered protein synthesis or reduction of MTT, indicating no toxicity. The results indicate that arsenite is not increasing CYP3A protein degradation *via* the calpain pathway. The results also suggest that a labile protein potentiates the effect of arsenite to decrease CYP3A. This work was supported by NIH-ES10426(JS) and the Department of Veterans Affairs.

79 INORGANIC ARSENIC INCREASES VASOCONSTRICTION THROUGH CALCIUM-SENSITIZATION IN VASCULAR SMOOTH MUSCLES.

J. Chung[1], M. Lee[1], Y. Lee[2], S. Chung[1] and O. Bae[1]. *[1]College of Pharmacy, Seoul National University, Seoul, South Korea and [2]College of Medicine, Yonsei University, Seoul, South Korea.*

Chronic exposure of arsenic is well known to be the cause of cardiovascular disease such as hypertension. In order to investigate the effect of arsenic on blood vessels, we examined whether arsenic affected agonist-induced contraction of aortic rings in organ bath system. Treatment with arsenite increased vasoconstriction induced by phenylephrine or serotonin in a concentration-dependent manner. Similar effects were also shown in the aortic rings without endothelium, suggesting that vascular smooth muscle played a key role in enhanced vasoconstriction induced by arsenite. Arsenite is the most potent form among arsenic species tested. These alterations were well correlated with myosin light chain (MLC) phosphorylation induced by arsenite in smooth muscles. Direct calcium measurement using fura-2 dye in aortic rings revealed that arsenite enhanced contraction by high K+ without further increase in intracellular calcium levels. Calcium-sensitization of contractile machinery, therefore, may contribute to the enhanced vasoconstriction by arsenite. Consistent with these *in vitro* results, intravenous administration of 1.0 mg/kg arsenite augmented blood pressure increase induced by phenylephrine in conscious rats. These results suggest that arsenite increases agonist-induced vasoconstriction and calcium-sensitization in smooth muscles was one of the key mechanisms for the arsenite-induced hypercontraction in blood vessels.

80 ARSENIC-INDUCED DYSFUNCTION IN RELAXATION OF BLOOD VESSELS.

M. Lee, B. Jung, S. Chung, O. Bae and J. Chung. *College of Pharmacy, Seoul National University, Seoul, South Korea.*

Several epidemiological studies have suggested that exposure to arsenic is strongly correlated with the development of cardiovascular diseases such as hypertension. To determine whether arsenic affects vasomotor tone in blood vessels, we investigated the effect of arsenic on vasorelaxation using isolated rat aortic rings in an organ bath system. Treatment with arsenite inhibited acetylcholine-induced relaxation of the aortic rings in a concentration-dependent manner, while several other arsenic species did not have any effect. Consistent with these findings, the levels of cGMP in the aortic rings were significantly reduced by arsenite treatment. In cultured human aortic endothelial cells, treatment with arsenite resulted in a concentration-dependent inhibition of endothelial nitric oxide synthase (eNOS). In addition, higher concentrations of arsenite decreased the relaxation induced by sodium nitroprusside (a NO donor) and 8-Br-cGMP (a cGMP analog) in aortic rings without endothelium. These *in vitro* results indicate that arsenite is capable of suppressing in blood vessels by inhibiting eNOS activity in endothelial cells and by impairing the relaxation machinery in smooth muscle cells. *In vivo* studies revealed that the reduction of blood pressure by acetylcholine infusion was significantly suppressed after arsenite was administered intravenously to rats. These data suggest that an impairment of vasomotor tone due to arsenite exposure may be a contributing factor in the development of cardiovascular disease.

81 CLONING, EXPRESSION, AND CHARACTERIZATION OF RAT S-ADENOSYL-L-METHIONINE: ARSENIC(III) METHYLTRANSFERASE (CYT19).

S. B. Waters[3], F. Walton[2], K. M. Herbin-Davis[1], M. Styblo[2] and D. J. Thomas[1]. *[1]ORD/NHEERL/ETD/PTB, USEPA, Research Triangle Park, NC, [2]Pediatrics, University of North Carolina, Chapel Hill, NC and [3]Curriculum in Toxicology, University of North Carolina, Chapel Hill, NC.*

S-adenosyl-L-methionine: arsenic(III) methyltransferase, an enzyme purified from rat liver, catalyzes the formation of methyl and dimethyl arsenic from trivalent inorganic arsenic. Because the predicted amino acid sequence of this enzyme resembles those of predicted products of cyt19 genes in the human and mouse genomes, the rat protein is designated cyt19. Rat, mouse, and human cyt19 contain common amino acid motifs of non-nucleic acid methyltransferases. Expression of cloned rat cyt19 yields a protein that methylates trivalent inorganic arsenic, producing methyl and dimethyl arsenic as minor and major metabolites, respectively. Omission of S-adenosyl-L-methionine or of a reductant abolishes its catalytic activity. Dithiothreitol and tris-(2-carboxyethyl)phosphine are approximately equipotent as reductants. A thioredoxin-thioredoxin reductase generation system can also function as a reductant. The capacities of rat cyt19 to catalyze both the oxidative methylation of arsenicals and the putative reduction of arsenicals to the trivalent oxidation state suggest that this protein has both methyltransferase and reductive functions. Selenite and methylselenol are potent inhibitors of cyt19-catalyzed formation of methylated arsenicals from inorganic arsenic. Selenite (Ki = 1.4 μM) is a more potent inhibitor than is methylselenol (Ki = 19 μM) and neither dimethylated or trimethylated selenium compounds inhibit cyt19. Alteration of cyt19-catalyzed production of methylated arsenicals by selenium-containing compounds could be a locus of interaction between these metalloids. (This abstract does not necessarily reflect EPA policy.)

82 INORGANIC AND METHYLATED TRIVALENT ARSENICALS INHIBIT GLUCOSE UPTAKE BY MURINE ADIPOCYTES.

F. S. Walton, D. S. Paul, A. W. Harmon, Y. M. Patel and M. Styblo. *Departments of Pediatrics and Nutrition, University of North Carolina, Chapel Hill, NC.* Sponsor: D. Thomas.

Chronic exposures to inorganic arsenic (iAs) are associated with increased incidence of various forms of cancer and noncancerous diseases, including non-insulin dependent (Type 2) diabetes mellitus. Although mechanisms by which iAs induces diabetes have not been identified, the nature of the disease indicates that iAs or its metabolites may interfere with insulin signaling or with critical steps in glucose metabolism. We have examined effects of iAs and methylated arsenicals on basal and insulin-stimulated glucose uptake by cultured 3T3-L1 adipocytes. Inorganic and methylated pentavalent arsenicals did not affect either basal or insulin-stimulated glucose uptake. Trivalent arsenicals, arsenite (iAsIII), methylarsine oxide (MAsIII), and iododimethylarsine (DMAsIII), inhibited insulin-stimulated glucose uptake in a concentration-dependent manner. Exposures to 20 μM iAsIII, 1 μM MAsIII or 2 μM DMAsIII decreased insulin-stimulated glucose uptake by 35 to 45% but did not affect cell viability. Basal glucose uptake was significantly inhibited only in cells exposed to MAsIII. All three trivalent arsenicals suppressed expression of protein kinase B (PKB/Akt), a component of insulin-activated signal transduction pathway. In addition, iAsIII and MAsIII, but not DMAsIII, inhibited phosphorylation of PKB/Akt. Notably, exposures to methylated trivalent arsenicals, but not to iAsIII, decreased the intracellular concentration of glutathione (GSH). Treatment of adipocytes with GSH-ethylester increased cellular GSH levels and prevented MAsIII- and DMAsIII-induced inhibition of glucose uptake. In contrast, treatment with GSH-ethylester did not prevent the inhibition of glucose uptake by iAsIII. These results suggest that trivalent arsenicals inhibit the PKB/Akt-dependent activation of glucose uptake by insulin. This mechanism may be, in part, responsible for the development of Type-2 diabetes in individuals chronically exposed to iAs.

83 COMPENSATORY HEME PATHWAY RESPONSES IN INTERACTION STUDIES OF LEAD, CADMIUM AND ARSENIC TOXICITY.

G. Wang. *Toxicology Program, University of Maryland, Baltimore, MD.* Sponsor: B. Fowler.

In addition to dose, duration of exposure is a critical determinant in assessing the toxicity of chemicals. This factor is particularly important for low-dose, chemical mixture situations such as those found near Superfund sites. The present studies were undertaken to evaluate changes in a number of parameters in rats exposed to lead, cadmium and arsenic combinations in deionized drinking water at empirically determined LOEL dose levels (Pb, 25ppm, Cd, 10ppm, As(As^{3+}), 5ppm). These studies employed a factorial statistical design to evaluate interactive effects at 30, 90 or 180 day (in progress) sacrifice time points. Histopathological evaluation of kidneys from animals in all treatment groups showed an absence of marked changes relative to controls at the 30 and 90 day time points. However, marked, statistically significant, inhibition of the heme pathway enzyme, delta-aminolevulinic acid dehydratase (ALAD) activity was observed in blood and kidney. Erythrocyte zinc-protoporphyrin (ZPP) concentrations were also observed to be statistically increased at 30 days for all treatment groups relative to controls. In contrast, at 90 days, blood ZPP were not statistically different from controls. In general, ALAD activities in the mixture treatment groups were more markedly different from controls at 30 days than at 90 days although all treatment groups were statistically different from controls at both time points. Interaction treatment group-specific differences

and kidney versus blood differences were also observed for this parameter. These data suggest differential *in vivo* compensation in response to these treatments for several heme pathway parameters by the hematopoietic system and kidneys at the 90 day intermediate time point and underscore the need for a detailed consideration of exposure duration in chronic low-dose mixture studies. It will be of interest to evaluate whether rats in the ongoing 180 day study are able to maintain this compensatory response or crossover into more overt toxic responses. (Supported in part by EPA STAR grant # 827161).

84 SUBLETHAL ARSENIC EXPOSURE ALTERS FOCAL ADHESION AND CYTOSKELETAL ORGANIZATION IN CULTURED H9C2 CELLS.

S. L. Yancy[1], E. A. Sheldon[2] and M. J. Welsh[2]. *[1]Toxicology, University of Michigan, Ann Arbor, MI and [2]Cell and Developmental Biology, University of Michigan Medical School, Ann Arbor, MI.*

Focal adhesions are sites where the extracellular matrix is connected to the actin cytoskeleton *via* integrins. They play an important role in cell morphology and migration. Alterations in the balance of cytoskeletal and focal adhesion protein expression and phosphorylation have been shown to affect many cellular processes including migration, proliferation and death. Changes in cytoskeletal and focal adhesion organization of cultured H9C2 cells that were exposed to a sublethal dose of sodium arsenite for 48 hours were observed. Arsenic reduced the amount of total F-actin content present in the cells. Immunolocalization of actin stress fibers and focal adhesions showed fewer focal adhesions present and a disorganization of the actin cyotskeleton in arsenic treated cells. When arsenic exposed cells were incubated with magnetic beads coated with a RGD peptide to promote integrin binding and the subsequent formation of an artificial focal adhesion, there was a delay in the recruitment of the focal adhesion proteins FAK, vinculin and paxillin. Immunoprecipitation using a phospho-tyrosine antibody showed that arsenic was able to dephosphorylate several focal adhesion proteins. Time-lapse video microscopy showed a reduction in the rate of cell motility and cell spreading in response to arsenic treatment. These data imply that arsenic disrupts focal adhesion and cytoskeleton organization and subsequently interferes with the cellular processes that rely on the proper organization of these structures.

85 ARSENITE INHIBITION OF THE HOMOLOGS α-KETOGLUTARATE DEHYDROGENASE AND PYRUVATE DEHYDROGENASE.

E. R. Berquist[1], K. D. Sugden[1,2] and B. Martin[1,2]. *[1]Chemistry, University of Montana, Missoula, MT and [2]Center for Environmental Health Sciences, University of Montana, Missoula, MT.* Sponsor: H. Beall.

The toxicity and carcinogenicity of arsenite have been ascribed to its ability to bind protein sulfhydryls, notably the pyruvate dehydrogenase (PDH) enzyme complex. One of the subunits of this complex is post-translationally modified by the addition of lipoic acid cofactors. The adjacent 1, 3-sulfhydryls of this cofactor are believed to provide an arsenite binding moiety. Against this background of literature, we have studied the ability of arsenite to inhibit the highly homologous α-ketoglurate dehydrogenase (KGDH) enzyme complex. This enzyme complex contains fewer subunits that have been modified by the addition of lipoic acid and fewer lipoic acid cofactors added to each subunit that is modified. This enzyme is, however, a control point for the citric acid cycle. Classic inhibition kinetic studies were performed on the purified enzymes. Both enzymes were inhibited in the low micromolar range. Mechanistically, arsenite inhibited PDH in an uncompetitive manner but KGDH exhibited mixed inhibition. Loss of dithiobisbenzoic acid reactivity indicated that inhibition was due to a modification of sulfhydryl groups, however probing the enzyme with a lipoic acid polyclonal antibody did not indicate sufficient modification at this site to be detected by this assay. The lipolylated peptide fragment could be detected by high resolution capilliary mass spectrometry. This fragment was diminished upon arsenite treatment. Western blot analysis indicated a change in mobility of the arsenite-treated protein subunit, indicating a significant change in charge of the protein. It is anticipated that the characterization of these modifications will provide a potential biomarker of arsenic toxicity.

86 CADMIUM PERTURBATION OF MICROTUBULES THROUGH ITS INTERACTION WITH PROTEIN SULFHYDRYLS.

Y. Zhao[1], W. Li[2] and I. Chou[1]. *[1]Microbiology, Boston University School of Medicine, Boston, MA and [2]Biochemistry, Boston University School of Medicine, Boston, MA.*

Previous studies demonstrated cadmium (Cd) depolymerization of microtubules (MT), a key element of the cytoskeleton. Certain cysteine residues of tubulin, the principal protein of MT, are critical for MT assembly. To further explore mechanisms of Cd damage to MT, we have examined effects of this metal ion on the sulfhydryl status of tubulins in MT polymerization *in vitro* and in cultured cells. Preincubation of "pure" tubulins free of MT associated proteins (MAPs) with $CdCl_2$ inhibited the binding of [^{3}H]-N-ethylmaleimide (NEM), a potent sulfhydryl(—SH) group reagent, to tubulins in a dose-dependent manner indicating Cd^{2+} binding to tubulins through—SH groups. Turbidity assays of MT assembly *in vitro* at 27°C in a reaction mixture containing 3.5 mg/ml tubulin, 1 mM GTP, 0.175 mM Mg^{2+}, 0.175 mM EGTA, and 0.1 M Pipes, pH, 6.6, showed that the initial rates of MT assembly were decreased to 44%, 29% and 12%, respectively, of the control in the presence of 15, 45 and 75 mM $CdCl_2$. Importantly, adding 1 mM dithiothreitol, a potent thiol reducing agent, to the Cd-pretreated tubulin mixture markedly blocked the Cd inhibitory effects on MT assembly *in vitro*. These results were further confirmed by EM examination of the polymerization products taken at the reaction plateau. Moreover, we also demonstrated using ^{109}Cd and [^{3}H]-NEM as probes, that taxol, an agent promoting MT assembly and stability, protected tubulin—SH groups from Cd and NEM binding thus antagonizing the Cd or NEM-induced MT disassembly *in vitro* and in cells. (Supported in part by an NIH grant, R01-ES 11164.)

87 DOWNREGULATION OF TUBULIN AND MICROTUBULE-ASSOCIATED PROTEINS (MAPS) IN CULTURED LUNG FIBROBLASTS EXPOSED TO CADMIUM.

W. Li[1], Y. Zhao[2] and I. Chou[2]. *[1]Biochemistry, Boston University School of Medicine, Boston, MA and [2]Microbiology, Boston University School of Medicine, Boston, MA.*

Cadmium (Cd) is an established human lung carcinogen and induces severe injury to pulmonary cells. Our previous studies demonstrated that Cd targeted the microtubules (MT) system causing their depolymerization in exposed cells. To further understand the mechanisms of Cd damage to MT, we have examined Cd binding to tubulin proteins, tubulin synthesis and its mRNA expression, and the calcium (Ca)-released MAPs in Cd treated lung fibroblasts (RFL6 cells). ^{109}Cd labeling assays with isotope-pulsed cells showed Cd binding to tubulin proteins isolated by the Vallee's taxol assembly method such that 70-80% of total tubulin-bound radioactivities were associated with the free tubulin fraction while 20-30% remained in the MT polymers fraction. High concentrations of Cd also induced decreases in [^{109}Cd]-labeled tubulin polymers reflecting strong disassembly of MT in these cells. Immunoprecipitation of [^{35}S]-methionine-labeled proteins using an anti-βtubulin antibody revealed a dose dependent inhibition by Cd of newβtubulin synthesis in RFL6 cells. Further, northern blots indicated the inhibition of newβtubulin synthesis was concomitant with downregulation ofβtubulin RNAs in Cd exposed RFL6 cells. In addition, 2-D gel analysis of detergent-extracted and Ca-released cytoskeletal proteins in [^{35}S]-methionine labeled RFL6 cells illustrated significant reductions in MAPs of 53/5.9, 53/6.5, 55/6.3, 56/6.6 and 86/8.5 (apparent MW in kDa/isoelectric point) by 51%, 56%, 61%, 64% and 88%, respectively, in addition to markedly deminished levels ofαandβtubulins in Cd-treated RFL6 cells. In view of the feedback inhibition exerted by free tubulin pools in tubulin synthesis and MT stabilization by MAPs, these results suggest that downregulation of tubulin (at both protein and mRNA levels) as well as MAP proteins may be an important mechanism for further injury to MT following the initial Cd binding to and disassembly of this key cytoskeletal element. (Supported in part by an NIH grant, R01-ES 11164.)

87a CYTOTOXIC POTENTIALS OF NICKEL COMPOUNDS FOLLOWING| *BITAL*|IN VITRO *EXPOSURE OF HUMAN BLOOD LYMPHOCYTES: ROLE OF SPECIATION.*

P. M'Bemba-Meka and S. K. Chakrabarti. *Environmental and Occupational Health, Universite de Montreal, Montreal, QC, Canada.*

Although nickel and its compounds are known to be toxic and carcinogenic, the information regarding the effects of nickel speciation on such toxicities is very limited at present. Therefore, the present investigation was carried out to evaluate the cytotoxic potentials of different nickel compounds using human blood lymphocytes from normal healthy volunteers. Isolated human lymphocytes in RPMI-1640 medium were exposed *in vitro* for 0-4h at 37° C to either nickel carbonate hydroxide (0-1 mM), or nickel subsulfide (0-2 mM), or nickel sulfate (0-4 mM), or nickel oxide (0-6 mM) in an atmosphere of 95% oxygen and 5% CO2. The cytotoxicity (cell death) was evaluated by trypan blue exclusion test. All these nickel compounds showed both concentration- and time-dependent cytotoxic potentials. Furthermore, the extent of such cytotoxicity was found to depend on the chemical form (speciation) of nickel. Thus, after a 4-hr treatment of human lymphocytes the percent of cell death (or, cytotoxicity) were 100, 67.66, 61.33 and 68.36% with 1 mM nickel carbonate hydroxide (2NiCO3.3Ni(OH)2.4H2O), 1 mM nickel subsulfide (Ni3S2), 2 mM nickel sulfate (NiSO4.6H2O), and 6 mM nickel oxide (NiO), respectively. The preliminary results suggest that the cytotoxic potency of

nickel decreases in the following order: nickel carbonate hydroxide > nickel subsulfide > nickel sulfate > nickel oxide. Such cytotoxic potency follows the same order as the nephrotoxic potency of these nickel compounds previously observed in our laboratory (Toxicol. Lett. 122:235-244, 2001).

88 REGIONAL DISTRIBUTION OF URANIUM IN RAT BRAIN.

D. S. Barber[1] and M. J. Kopplin[2]. *[1]Center for Environmental and Human Toxicology, University of Florida, Gainesville, FL and [2]Pharmacology and Toxicology, University of Arizona, Tucson, AZ.*

It has been suggested that depleted uranium exposure contributed to symptoms of Gulf War Illness. Previous studies have demonstrated that depleted uranium alters hippocampal neuron function and indicate that uranium causes neurotoxicity. However, it is not clear to what extent uranium accumulates in various brain regions, which is likely to determine the pattern of neurotoxicity. The distribution of brain uranium was quantified in male Sprague-Dawley rats that were treated with a single injection of 1 or 10 mg uranium/ kg as uranyl acetate by intraperitoneal injection. To determine if physiological stress has an impact on uranium distribution or accumulation, a subset of animals underwent periods of forced swimming for 5 days prior to uranium injection. The concentration of uranium in serum, hippocampus, striatum, cerebellum, and frontal cortex was determined by ICP-MS at 8 hours, 24 hours, 7 days and 30 days after exposure. Both doses of uranium increased uranium content of all brain regions tested. In vehicle controls, uranium concentrations in cerebellum, cortex, hippocampus, and striatum were 0.18, 0.66, 2.0, and 1.4 ng/g respectively. Twenty-four hours after administration of 1 mg uranium/kg, values for these tissues were 17.8, 2.8, 8.9, and 3.7 ng/g, respectively, while in animals given 10 mg uranium/kg, tissue concentrations were 12.7, 13.3, 19.7, 9.9 ng/g respectively. In both dose groups, stress tended to reduce brain concentrations without markedly affecting serum values. These studies demonstrate that soluble uranium rapidly enters the brain and exhibits regional distribution. (Supported by: US Army Medical Research and Materiel Command DAMD17-01-1-0775. This abstract does not necessarily reflect the position or policy of the US Government.)

89 URANIUM UPTAKE IN RAT BRAIN ENDOTHELIAL CELLS AND THE POSSIBLE LINK TO DIVALENT METAL TRANSPORTER 1.

A. Lack, K. M. Erikson, A. W. Dobson and M. Aschner. *Physiology and Pharmacology, Wake Forest University School of Medicine, Winston-Salem, NC.*

Many causes of "Gulf War Syndrome" have been proposed including depleted uranium (DU). Given recent evidence suggesting uranium accumulation in the rat brain, as well as neurobehavioral changes in US veterans retaining DU shrapnel as a result of friendly fire injury, we embarked on a series of studies to identify a putative uranium transporter on blood-brain barrier (BBB) endothelial cells. We tested the hypothesis that transendothelial uranium transport is mediated through divalent metal transporter 1 (DMT1; also known as Nramp or DCT1). We conducted western blot analysis of DMT-1 in an immortalized cell line of the BBB referred to as rat endothelial cells 4 (RBE4). Addition of desferrioxamine (DFO), an iron chelator, to the medium for 24 hours lead to a significant increase in DMT1 expression (264% of control; $p<0.004$). The 15 and 30 minute uptake of uranium (8 mM) in DFO treated RBE4 cells was analyzed with neutron activation analysis (NAA). The studies confirm that RBE4 cells readily take up uranium (0.3 ug University/mg protein). There was no statistically significant difference in the uptake of uranium between the two time periods (15 and 30 min), and an 18.26% decrease in uptake for cells treated with DFO compared to RBE4 cells treated with regular media. The studies corroborate the expression of DMT-1 in RBE4 cells and that its level of expression is modulated by iron levels in the medium. Treatment with DFO upregulates the protein expression of DMT-1 in RBE4 cells, but it is yet to be determined whether this increase is associate with increased uranium uptake. Finally, DMT-1 transfected Chinese Hamster Ovary (CHO) CHO cells have been selected with G4-18 antibiotic and the forward clones express greater DMT-1 protein than reverse or control cells, allowing for future studies on the role of DMT-1 in uranium transport. (Supported by DOD Award 3 DAMD17-01-1-0685).

90 BRAIN REGIONAL UPTAKE OF MANGANESE (Mn) AS AFFECTED BY SUBCHRONIC *IN VIVO* MN EXPOSURE IN SPRAGUE-DAWLEY RATS.

R. Deane[1], D. J. Opler[2] and W. Zheng[2]. *[1]Center for Aging and Developmental Biology, University of Rochester Medical Center, Rochester, NY and [2]School of Public Health, Columbia University, New York, NY.*

Mechanism whereby Mn enters the brain remains uncertain. It has been suggested that Mn and/or its binding moiety with transferrin (Tf) may be transported into the brain, presumably by a saturable process. However, little is known about brain regional differences in uptake of Mn. This study aimed to compare properties of Mn transport by various brain regions. Brains of controls or rats received ip.-injections of 6 mg Mn/kg daily for 14 days, were dual-perfused with a Ringer solution containing trace of ^{54}Mn *via* common carotid arteries. Brain areas, e.g., cerebellum (CB), brain stem (BS), choroid plexus (CP), frontal cortex (FC), striatum (ST), and hippocampus (HP), were removed and cerebral capillaries obtained by a capillary depletion method. AAS of tissue Mn showed that Mn levels were significantly increased in all brain regions after Mn exposure with 2.1 fold increase in CP, 3.6 in CB, 4.5 in BS, 4.8 in FC, and 4.9 in ST as compared to controls ($n=8$-12, $p<0.05$). Mn exposure did not alter serum ferritin level, but increased serum transferrin by 16% ($p<0.001$). The temporal pattern of ^{54}Mn uptake in brain capillaries was linear up to 10 min. The uptake volume (Vi) following a 10-min perfusion was 5.01+/-0.09 ml/100g (mean+/-SEM) and 3.26+/-0.55 ml/100g in control and Mn-exposed rats respectively, a reduction of 34%. Accordingly, the uptake by parenchyma of the whole brain at 10 min was reduced from 0.06+/-0.02 ml/100g in controls to 0.02+/-0.001 ml/100g in Mn-dosed animals. Among brain areas studied, the uptake of ^{54}Mn by striatum was significantly diminished by 73% in Mn-treated rats. However, Mn exposure did not significantly alter the influx of Mn to other brain regions including CSF. These results indicate that there appeared to exist a region-specific down regulation of brain influx of Mn as a result of Mn exposure. (Supported in part by ES-08146 and Burrows-Wellcome Foundation)

91 HETEROGENEOUS MANGANESE ACCUMULATION IN THE IRON DEFICIENT DEVELOPING RAT BRAIN IS LINKED TO DIVALENT METAL TRANSPORTER LEVELS.

Q. Wu, K. M. Erikson and M. Aschner. *Physiology and Pharmacology, Wake Forest University School of Medicine, Winston-Salem, NC.*

Iron deficiency (ID) is a prevalent nutritional disorder affecting nearly 2 billion people worldwide. Recently, our laboratory showed that ID causes increased manganese (Mn) concentrations in several brain regions, with regional accumulation in the hippocampus, caudate putamen, globus pallidus and substantia nigra. We hypothesized that this ID-associated Mn accumulation corresponds with changes in iron associated proteins [transferrin receptor (TfR) and divalent metal transporter (DMT-1)]. Prior studies showed that the brain regions most susceptible to Mn accumulation are those that display the greatest response to ID (i.e., increased transferrin and TfR). Thus, we sought to test our hypothesis by examining brain regional levels of TfR and DMT-1 in rats exposed to dietary ID and varying Mn levels and correlating these changes with regional Mn concentration. Twenty-one day old male Sprague-Dawley rats were fed for 6 weeks one of four semi-purified diets (AIN-93-G), (CN n=7), (ID n=7), (IDMn+ n=7), and (CNMn+ n=7). After 6 weeks of dietary treatment the rats were euthanized, and the brains dissected into seven brain regions. Brain regions were analyzed for [Mn] with neutron activation analysis (NAA), and for DMT-1 and TfR levels *via* immunoblot analysis. While TfR levels are detectable in all the regions tested, DMT-1 is specifically detected in the caudate putamen and globus pallidus and to a lesser extent in the hippocampus and substantia nigra with a distinct band at approximately 66 kDa. ID increases both TfR and DMT-1 in most brain regions, however increases in DMT-1 correlate with ID-associated Mn accumulation in the caudate putamen and hippocampus, but this is not the case for TfR. These data suggest that increases in DMT-1 due to ID may be the likely facilitator in the region-specific Mn accumulation associated with ID. (Supported by NIEHS 10563).

92 INCREASED MANGANESE UPTAKE IN IRON DEPRIVED AND IRON OVERLOADED PRIMARY ASTROCYTE CULTURES IS DUE TO INCREASED DIVALENT METAL TRANSPORTER.

K. M. Erikson, A. W. Dobson and M. Aschner. *Physiology and Pharmacology, Wake Forest University School of Medicine, Winston-Salem, NC.*

Neurotoxicity due to excessive brain manganese (Mn) can occur due to environmental (air pollution, soil, water) and/or metabolic aberrations (decreased biliary excretion). The role of astrocytes in managing the levels of extracellular constituents in the brain is critical for normal functioning. Given the putative role of astrocytes in regulating the movement of metals across the blood brain barrier, we sought to examine the relationship between iron status and manganese transport in astrocytes. Furthermore, our study examined the effect of iron status on astrocytic transferrin receptor (TfR) and divalent metal transporter (DMT-1) levels and their relationship to Mn uptake. All experiments were carried out in primary astrocyte cultures after they reached full confluency (approx. three weeks). Astrocytes were incubated for 24 hours in astrocyte growth media (AGM) containing 200 uM desferroxamine (ID), 400 uM iron dextran (Fe3+), 300 uM MnCl2 (Mn2+) or AGM (CN). The next day, five minute 54Mn uptake was measured and protein was harvested from parallel culture plates for DMT-1 and TfR immunoblot analysis. Both

iron deprivation (ID) and iron overload (Fe3+) caused significant increases in 54Mn uptake in astrocytes. As expected, MnCl2 treatment caused a significant decrease in astrocytic 54Mn uptake. TfR levels were significantly increased due to ID and decreased in astrocytes exposed to Fe3+ and Mn2+ treatments. As expected, DMT-1 was increased due to ID and decreased due to Mn2+. Interestingly, DMT-1 levels were also increased due to Fe3+ treatment, but not to the extent of ID. The decreased TfR associated with Fe3+ treatment and the increased DMT-1 levels, suggest that DMT-1 is a likely transporter of Mn in astrocytes. (Supported by NIEHS 10563)

93 MOLECULAR MECHANISM OF MANGANESE-INDUCED DISRUPTION OF IRON TRANSPORT AT THE BLOOD-CSF BARRIER.

G. Li, Q. Zhao, J. Pilsner, G. A. Freyer and W. Zheng. *School of Public Health, Columbia University, New York, NY.*

Previous studies indicate that Mn exposure appears to induce a compartmental shift of iron (Fe) from the systemic circulation to the CSF, possibly by acting on Fe transport machinery localized at the blood-brain barrier and/or blood-CSF barrier. Since Mn exposure increases the amount of mRNAs encoding transferrin receptor (TfR), which possesses 3'-UTR stem sloops, we hypothesize that Mn may alter the binding affinity of iron regulatory protein-1 (IRP1) to TfR mRNAs thereby influencing Fe transport at the blood-CSF barrier. A primary culture of choroidal epithelial cells was adapted to grow on a freely permeable membrane sandwiched between two culture chambers to mimic blood-CSF barrier. Trace ^{59}Fe was added to the outer chamber and radioactivity in both inner and outer chambers monitored to determine ^{59}Fe transepithelial transport. Following Mn treatment (100 uM for 3 days), the initial influx rate constant (K_i) was increased from the controls (135 dpm/ml/min) to Mn-treated cells (156 dpm/ml/min), a rise of 16%. Accordingly, the Css of ^{59}Fe was increased by 10%. Mn exposure, however, reduced ^{59}Fe retained in cells by 58%. Gel shift assay using S100 cytosolic extracts indicated that Mn exposure (100 uM) caused a time-related alteration of binding IRPs to stem loop-containing mRNAs; the IRP1-mRNA binding was initially reduced following an 8-hr Mn exposure. It was subsequently increased at 24- and 72- hr exposure interval. The protein-mRNA interaction was reduced after 6-day exposure. Binding of IRP2 to mRNAs was increased following 6 day Mn treatment. Western blot showed a significant increase of cellular TfR in Mn treated group (100 uM) starting at 8 hr treatment. The increase of TfR continued even at 6-day treatment. The data suggest that Mn upon entering the cells appears capable of altering IRPs binding ability to mRNAs with 3' or 5' UTR-stem loops. The disrupted protein-mRNA interaction in choroidal epithelial cells may underlie the increased Fe transport by the blood-CSF barrier. (Supported by NIEHS RO1 ES08146)

94 CHARACTERISTICS OF CARRIER-MEDIATED BRAIN MANGANESE UPTAKE IN ENDOTHELIAL CELL CULTURES AND INTO PERFUSED RAT BRAIN.

J. S. Crossgrove[1], K. R. Deibel[2] and R. A. Yokel[2,1]. [1]*Graduate Center for Toxicology, University of Kentucky Medical Center, Lexington, KY and* [2]*College of Pharmacy, University of Kentucky Medical Center, Lexington, KY.*

Manganese (Mn) is essential to healthy brain development and function. High brain Mn concentrations are neurotoxic and can lead to manganism, a neuropathy with parkinson-like symptoms. Previous studies indicated that brain Mn^{2+} influx across the rat blood-brain barrier (BBB) is carrier-mediated. This study determined characteristics of $^{54}Mn^{2+}$ uptake to identify the possible transporter(s) at the BBB. It was hypothesized that Mn^{2+} brain influx occurs *via* one or more divalent metal transporters or channels. $^{54}Mn^{2+}$ uptake into bovine brain microvascular endothelial cells (bBMECs) was found to be concentrative after 30 minutes and increased with decreasing proton concentration. Ferrous (Fe^{2+}) iron (100 µM) did not inhibit Mn^{2+} (0.375 µM) influx into rat brain in experiments using the *in situ* brain perfusion method. This suggests that Mn^{2+} brain entry is not solely mediated by the divalent metal transporter 1 (DMT-1), which co-transports protons and for which Fe^{2+} is a competing substrate. Ouabain, a Na^+/K^+-ATPase inhibitor, did not affect Mn^{2+} uptake into bBMECs. Pretreatment with 1 mM vanadate, an inhibitor of P-type ATPases, decreased $^{54}Mn^{2+}$ uptake to 40% of control uptake into bBMECs in a 30-minute incubation. However, vanadate (1 or 10 mM) did not inhibit influx into brain tissue or the lateral ventricular choroid plexus within the short duration (90 or 180 seconds) of *in situ* brain perfusion. These results suggest that vanadate does not directly block the uptake of Mn^{2+} at the BBB. In conclusion, DMT-1 does not appear to be solely responsible for brain entry of Mn^{2+} in the absence of transferrin. A vanadate-sensitive divalent ATPase may play a role in Mn^{2+} brain influx, but does not exclusively mediate Mn^{2+} influx. Supported by Health Effects Institute Agreement #99-10.

95 THE DIVALENT METAL TRANSPORTER-1 IS NOT ESSENTIAL FOR BRAIN MANGANESE UPTAKE.

R. A. Yokel[1,2] and J. S. Crossgrove[2]. [1]*College of Pharmacy, University of Kentucky Medical Center, Lexington, KY and* [2]*Graduate Center for Toxicology, University of Kentucky Medical Center, Lexington, KY.*

Manganese (Mn) is an essential mineral in the brain, however excessive brain Mn is neurotoxic. Maintenance of brain Mn entry might depend on a process that can be regulated. Brain uptake of the Mn^{2+} ion, Mn transferrin and Mn citrate is carrier-mediated. It has been hypothesized that the divalent metal transporter (DMT-1) plays a role in brain Mn uptake, as it has been shown to mediate Mn uptake into DMT-1 transfected oocytes and to be expressed at the blood-brain barrier. To test this hypothesis, brain uptake of ^{54}Mn from an arterial perfusion containing the Mn^{2+} ion or Mn transferrin in ~ 60 day old Belgrade rats was compared to their sex-matched littermates and Wistar rats. Belgrade rats were derived from Wistar rats and are -/- for DMT-1. Their littermates are +/-. Mn in 9 brain regions and the choroid plexus was determined using the *in situ* brain perfusion method. One side of the brain was perfused for 90 seconds with a solution containing 0.375 µM Mn and ~ 2 µCi/ml ^{54}Mn (as the ion or as Mn transferrin) and 1 µCi/ml ^{14}C-sucrose, an indicator of vascular volume and brain entry by diffusion. All rats were maintained on a diet containing 210 mg Fe/kg for 2 weeks prior to study. Brain ^{54}Mn following perfusion with ^{54}Mn ion was not consistently lower in the Belgrade rats than their +/- littermates or the Wistar controls. ^{54}Mn was lower in some brain regions in Belgrade rats after ^{54}Mn transferrin perfusion than their +/- littermates but ^{54}Mn was seen in all brain regions. In summary, the absence of DMT-1 decreased Mn uptake from brain perfusate containing Mn transferrin. Mn was seen in the brain following perfusion of the Mn ion and Mn transferrin in Belgrade rats. These results suggest one or more carriers mediate Mn uptake into the brain that are not DMT-1 or DMT-1 linked. Partially supported by Health Effects Institute Agreement #99-10.

96 MANGANESE CELL CULTURE EXPOSURE PARAMETERS AND THEIR IMPLICATIONS FOR TOXICITY.

S. Gomes, C. Kwik-Uribe, S. Reaney and D. Smith. *Environmental Toxicology, University of California, Sanat Cruz, CA.*

Manganese (Mn) is an essential element that has been shown to be a neurotoxin at elevated exposures. Since Mn is an essential nutrient, studying fundamental mechanisms of toxicity can be difficult. In cell culture models of toxicity these difficulties have been confounded by a range of cell culture conditions (e.g. serum conc.) and manganese concentrations. These differences make inter-study comparisons difficult. To address these difficulties and to make dose-response relationships more relevant, total cellular accumulation should be assessed when doing cell culture. To demonstrate this fundamental consideration, we explored the hypothesis that lower cell culture medium protein levels and increased Mn exposure duration, combined with increases in Mn exposure magnitude would result in greater cellular Mn uptake. PC-12 cells were exposed to $MnCl_2$ (0 to 500µM), for 24 and 48-hours in RPMI 1640 growth medium supplemented with either 5% or 15% fetal bovine serum (FBS). Levels of lactate dehydrogenase (LDH) were measured as an indicator of overt cytotoxicity. Cellular Mn uptake was measured using GFAAS. As predicted, total cellular Mn uptake increased with exposure duration (2-fold at 10µM, and 6-fold at 200µM). The high Mn accumulation following 200µM exposure (e.g., 24hrs, 5% FBS) is attributed to overt cellular dysfunction and cytotoxicity, based on significant increases in medium LDH concentrations at this Mn dose. Cellular Mn levels also increased significantly (4-fold) for 200µM exposure for 24-hours in the 5% FBS supplemented medium compared to the 15% FBS medium. This is consistent with a greater bioavailability of Mn in the exposure medium supplemented with 5% FBS compared to 15% FBS, and is substantiated by a higher relative partitioning of Mn in the <3000mw fraction of exposure medium supplemented with 5% FBS. These data demonstrate the importance of cell culture conditions on the cellular accumulation of toxic metals, and they provide a fundamental framework to facilitate comparisons between studies that used different culture conditions.

97 2-D DIGE PROTEOMIC ANALSYES OF Mn EXPOSURE IN DOPAMINE AND GABA PRODUCING CELL LINES: IMPLICATIONS FOR M*N* NEUROTOXICITY.

D. R. Smith[2], S. Whitman[1], S. Reaney[1,2], C. Kwik-Uribe[2], C. Arnold[2], R. Gwiazda[2] and T. Holman[1]. [1]*Environmental Toxicology, University of California, Santa Cruz, CA and* [2]*Chemistry and Biochemistry, University of California, Santa Cruz, CA.*

There is substantial evidence demonstrating neurotoxicity of moderate to elevated manganese (Mn) exposures. While several underlying mechanisms of toxicity have been purported (e.g., mitochondrial effects, oxidative stress, dysregulation of cellu-

lar iron), the unequivocal identification of specific mechanisms operating *in vivo* remains unclear. This fact is due, in part, to the complex multi-factoral nature of Mn regulation, functionality, and toxicity within organisms and specific cell types. To better understand the complexity of cellular responses to elevated Mn exposures, we are utilizing a 2-dimensional (2-D) differential in-gel electrophoresis (DIGE) method to evaluate changes in proteome expression patterns in dopamine producing (PC12) and GABA producing (M213) cell types. These cell types were selected, since studies from our laboratory and others have suggested differential susceptibility of dopaminergic versus GABAergic systems to Mn toxicity. The 2-D DIGE approach relies on minimal labeling of cellular proteins from control and treated cells with distinct fluoroprobes (Cydyes, Amersham Biosciences), followed by 2-D electrophoresis on a common gel, and MALDI-TOF analyses. Multiplexing of 2-D gel experiments and the use of in-gel internal standards allows for statistical analyses of replicated treatments. Our preliminary studies (pH 3 to 10 IPG, 12% acrylamide gel) have indicated that Mn exposures (200uM) produce significant changes in protein expression patterns in PC-12 cells, as expected. However, experimental replication and statistical analyses markedly reduced the number of measurably affected proteins. Further analyses across various Mn doses in both PC-12 and M213 cells, and the MALDI-TOF identification of selected proteins are underway. These data will facilitate identification both of specific cellular targets, and changes in protein expression patterns due to elevated Mn exposure, thereby increasing our understanding of Mn neurotoxicity across target cells.

98 CHARACTERIZATION OF NIGRO-STRIATAL DEFICITS IN A MOUSE MODEL OF MANGANESE-INDUCED PARKINSONISM.

X. Liu, B. Lee and R. Tjalkens. *Toxicology Program, Department of Integrative Biosciences, Texas A&M University, College Station, TX.*

Chronic exposure to manganese (Mn) produces neurological deficits resembling those in idiopathic Parkinson's disease (PD). A mechanistic basis for Mn-induced neurodegeneration is not well established but involves excitoxicity and disruption of mitochondrial function within basal ganglia. The rationale of the present study was to develop a mouse model of Mn-induced parkinsonism to elucidate cellular and neurochemical targets of Mn in the nigro-striatal system. Female C57Bl/6J mice were exposed to saline or MnCl2 (50 or 100 mg/kg/day) by oral gavage once daily for 8 weeks. At the cessation of treatment animals were evaluated for locomotor activity, catacholamine levels, and histopathological changes in the striatum and substantia nigra. Locomotor activity was assessed by open field activity. DA and DOPAC were quantified by HPLC. Serial sections from the striatum and substantia nigra were analyzed for neuronal viability, expression of tyrosine hydroxylase (TH) and glial acidic fibrillary protein (GFAP), and for nitro-tyrosine protein adducts. Striatal DA content was decreased by 26% and 55% in animals exposed to 50 and 100 mg/kg/day, respectively. The ratio of DOPAC:DA increased by 43% in the 100mg/kg/day group. Animals treated with 100 mg/kg/day MnCl2 displayed a 40% decrease in locomotor activity and a 76% increase in margin time. 100 mg/kg/day MnCl2 caused a 55% decrease in nissl-positive neurons in the striatumand a concomitant increase in dying, fluorojade-positive neurons. The expression of GFAP was increased in both the striatum and substantia nigra in animals exposed to 100 mg/kg/day MnCl2 and was paralleled by increased nitro-tyrosine protein adducts. Decreased TH staining was only observed in the striatum of animals exposed to 100 mg/kg/day MnCl2. It is concluded from these studies that Mn-induced depletion of striatal DA levels occurs both from an increase in DA turnover as well as from degeneration of neurons and nerve terminals within the striatum subsequent to glial activation and overproduction of NO.

99 MANGANESE EXPOSURE INDUCES AN INCREASE IN INTRACELLULAR GABA IN IMMORTALIZED RODENT STRIATAL CELLS.

D. R. Crooks, N. Welch, S. H. Reaney, R. Gwiazda, C. M. Arnold and D. R. Smith. *Environmental Toxicology, UC Santa Cruz, Santa Cruz, CA.*

Chronic elevated manganese (Mn) exposure has been associated with neurological disorders. The introduction of the anti-knock additive MMT to gasoline has been approved in the US, leading to concern about the potential for Mn neurotoxicity in sensitive populations. Published whole animal rat studies from our laboratory have suggested that moderate Mn exposure causes a significant increase in striatal GABA levels, which may represent an important cell/tissue based outcome underlying Mn toxicity. To further explore this hypothesis, we investigated the toxic effects of Mn exposures on two immortalized rodent GABAergic striatal cell lines (M213-2O and M213-2O/clone 2, generously provided by W. Freed, NIH). These cells are similar except that M213-2O/clone 2 additionally contains the human glutamate decarboxylase (GAD)-67 gene. Cells were exposed to $MnCl_2$ (0, 10, 50, and 200 μM) in DMEM:F12 culture medium containing 5% FBS for 24 hours. Lactate dehydrogenase (LDH) activity was measured in the exposure medium, followed by measurement of intracellular Mn concentration, and HPLC analysis of intracellular amino acids γ-aminobutyric acid (GABA), glutamate, glutamine, and aspartate. Results show that only the 200μM Mn dose was cytotoxic, with LDH levels 200-300% of control ($p<0.001$). Intracellular Mn concentrations in M213-2O cells increased from a control level of 0.07±0.01 nmol Mn/mg protein (mean ± SE, n=3) to 0.18±0.01, 0.34±0.01, and 0.66±0.04 nmol Mn/mg protein in 10, 50, and 200 μM Mn exposed cultures, respectively. Consistent with *in vivo* observations, Mn exposure (10 - 50μM) significantly increased GABA levels by 200%±20 and 250%±26 of control in M213-2O and M213-2O/clone 2 cells, respectively. Intracellular Glu, and Asp levels in M213-2O cells increased a significant 170%±8, and 140%±18 of control respectively (10μM Mn dose). These results indicate significant modulation of amino acid metabolism in both cell lines in the presence of Mn concentrations well below levels that induce overt cellular toxicity.

100 THE RELATIVE EFFECTS OF Mn(II) AND Mn(III) ON CELL FUNCTION.

S. H. Reaney[1,2] and D. Smith[2]. *[1]Chemistry and Biochemistry Department, UCSC, Santa Cruz, CA and [2]Environmental Toxicology Department, UCSC, Santa Cruz, CA.*

Chronic elevated manganese (Mn) exposure has been associated with neurological disorders. The introduction of the anti-knock agent MMT to gasoline has lead to concern about the potential for increased Mn exposures and neurotoxicity. Since the combustion products of MMT include Mn-oxides and phosphates of various Mn oxidation states (Mn(II), Mn(III) and Mn(IV)), there is justifiable need to investigate how the oxidation state of Mn exposure mediates toxicity. Therefore, the objective of this study was to evaluate the relative metabolic and toxic effects of Mn(II) and Mn(III) on an established cell line (PC12s). Cells were exposed to Mn(II)-chloride or Mn(III)-pyrophosphate at doses of 0 to 200uM *via* culture medium for 24 hrs. Total cellular Mn concentrations(concs.) were measured *via* GFAAS to quantify the intracellular Mn dose. Cellular function following exposure was evaluated by measuring dopamine (DA) and its metabolites, serotonin (5-HT), and ATP cellular concs. Cell stress was evaluated by measuring lactate dehydrogenase (LDH), total 8-isoprostanes, and cellular levels of ROS enzymes. Results indicate that total cellular Mn increased in a dose-dependent fashion, as expected, although Mn(III) exposed cells accumulated significantly ($p<0.001$) more Mn compared to cells exposed to Mn(II) for a given Mn exposure dose. When compared based on total intracellular Mn concs., Mn(III) led to a significantly greater decrease (<20% of control, $p<0.001$) in 5-HT concs. compared to effects of Mn(II) (~70% of control) at the higher range of exposures. Cellular levels of DA were also reduced by Mn, though the effects of Mn(II) were slightly greater (~50% of control) than the effects of Mn(III) (~70% of control). Other cellular outcomes measured had less dramatic responses. We can surmise from this data that Mn(III) may have a greater effect on cellular function than Mn(II). Consistent with previous studies (Reaney et. al. 2002, Chem. Res. Toxicology.). Furthermore, the effects seen on DA and 5-HT are independent of more broad measures of toxicity and may be specific to Mn in PC12s.

101 MANGANESE AUGMENTS CYTOKINE- AND LPS-INDUCED NO PRODUCTION IN GLIAL CELLS THROUGH ACTIVATION OF MAP KINASE AND NF-κB.

R. Tjalkens, J. Faske, X. Liu, M. Zhao and R. Mounemne . *Toxicology Program, Department of Integrative Biosciences, Texas A&M University, College Station, TX.*

Activation of glial cells and subsequent production of inflammatory mediators contributes to the degeneration of dopaminergic neurons in idiopathic Parkinson's disease (PD). Injury to the nigro-striatal system in humans chronically exposed to manganese (Mn) involves mitochondrial dysfunction and increased production of nitric oxide (NO), though the mechanisms underlying these phenomena are unclear. We therefore postulated that Mn potentiates lipopolysaccharide- (LPS) and cytokine-induced expression of inducible nitric oxide synthase (iNOS) in glial cells through stimulation of protein tyrosine kinase signaling cascades and activation of the transcription factor NF-κB. Wide field fluorescence microscopy was used to assess NO production and mitochondrial function in live C6 glioma cells. Activation of NF-κB was determined by electrophoretic mobility shift assay using a consensus κB sequence. Expression of iNOS and phosphorylation of p44/p42 mitogen-activated protein kinase (MAPK) was determined by western immunoblotting. Exposure to 100 μM MnCl2 potentiated LPS-induced NO production in C6 cells 1.7-fold compared to LPS alone. The effect of Mn on mitochondrial membrane potential ($\Delta\Psi$mt) and mitochondrial calcium ([Ca2+]mt) levels was not altered by LPS. LPS-induced expression of iNOS was dramatically increased by Mn and required NF-κB (p65/p50) activation. Overexpression of a mutant IκB, the inhibitory subunit of NF-κB, blocked p65/p50 DNA binding, iNOS expression, and production of NO. Exposure to concentrations of Mn as low as 1 μM increased phosphorylation of p44/p42 MAPK and p65. Exposure to 1-10 μM MnCl2 synergistically increased TNFα- and IFNγ-induced MAPK and p65 phosphorylation. It is concluded from these studies that Mn-induced NO production in glial cells involves both direct effects on mitochondrial calcium and activation of MAPK signaling pathways that increases inducible expression of the iNOS gene through an NF-κB-dependent mechanism.

102 TEMPORAL RESPONSES IN THE DISRUPTION OF Fe REGULATION BY Mn.

C. Kwik-Uribe, S. Reaney, Z. Zhu and D. R. Smith. *Environmental Toxicology, University of California, Santa Cruz, CA.*

Previous work in our lab has shown that acute low level manganese (Mn) exposure interferes with cellular iron (Fe) regulation (Kwik-Uribe et al. 2002, Toxicology. Sciences. 66:204). To expand our understanding of these events, the effect of both Mn dose (1, 10, 50, and 200 uM Mn) and duration of exposure (12, 24, 36, and 48 hrs) on (i) total intracellular and labile iron concentrations, (ii) the cellular abundance of transferrin receptor (TfR), H- and L-ferritin, and mitochondrial aconitase proteins, and (iii) IRP binding activity were systematically evaluated in undifferentiated PC12 cells. While total intracellular Fe concentrations were largely unaffected, the Phen Green SK (Molecular Probes) sensitive labile Fe pool was dramatically increased by exposure to Mn. This increase occurred in concert with changes in the cellular abundance of TfR, ferritin, and mitochondrial aconitase, protein changes consistent with an Fe deficiency response which favored Fe uptake and increased intracellular availability. In addition, an analysis of IRP binding activity and abundance demonstrated that Mn could alter the dynamics of IRP-1 binding and the intracellular abundance of IRP-2. Notably, significant effects were observed as early as 12 hrs exposure and at Mn doses as low as 1uM. The overall pattern of effect suggests that Mn produced an inappropriate cellular response akin to Fe deficiency that the cells were able to mount a compensatory response, while the highest Mn dose (200uM) produced an Fe deficiency response that the cells were unable to compensate for. Together, these data show that dose and exposure duration significantly impact cellular Fe regulation, supporting that this dysregulation may be one contributory mechanism underlying Mn neurotoxicity.

103 INFLUENCE OF SUBACUTE AND SUBCHRONIC MANGANESE SULFATE ON GLIAL FIBRILLARY ACIDIC PROTEIN.

H. L. Komiskey[1], M. Choi[1,2], X. Chen[1], M. Zhou[1], V. Childress[1] and C. S. Mehta[1,2]. *[1]College of Pharmacy, Xavier University of Louisiana, New Orleans, LA and [2]College of Pharmacy & Health, Texas Southern University, Houston, TX.*

The potential of manganese sulfate (MnSO4), given daily by gavage for either 14 or 90 days, to alter the glial fibrillary acidic protein (GFAP), was studied in rats as an early sign of neurotoxicity. Male and female rats were randomly given suspensions containing 0.1, 1.0, 10, 30, or 100 milligrams of manganese/kg or the vehicle control. GFAP were performed with ELISA on the hypothalamus and corpus striatum. The results show that 10, 30, and 100mg/kg significantly elevated the GFAP levels in the hypothalamus of male rats after two weeks of daily gavage. Furthermore, the GFAP levels in the hypothalamus of male rats after 90 days of daily gavage with 30, and 100mg/kg were still significantly elevated relative to rats injected with 6mg/kg midazolam or 1mg/kg manganese. In female rats, 30 and 100mg/kg of manganese significantly elevated the GFAP levels in the hypothalamus after two weeks of daily gavage relative to rats injected with 6mg/kg midazolam. In contrast, the GFAP levels in the hypothalamus of female rats were not altered by 90 days of daily gavage with MnSO4. In addition, neither 14 nor 90 days of daily gavage with MnSO4 altered the GFAP levels in the corpus striatum of male and female rats. The above results indicate that an early sign associated with neurotoxicity, activation of glial cells in the hypothalamus, could be produced by just two weeks of oral exposure of 10 to 30 mg/kg manganese (from MnSO4), but not in the corpus striatum of rats. (Support by ATSDR grant U50/ATU398948).

104 DIFFERENTIAL INDUCTION OF DNA REPAIR CAPACITY AFTER ARSENIC EXPOSURE ALLOWS FOR REGIONAL SPECIFIC ACCUMULATION OF DNA DAMAGE.

F. Cardozo-Pelaez, M. Pershouse and C. Bolin. *Center for Environmental Health Science, University of Monatana, Missoula, MT.* Sponsor: A. Holian.

Although exposure to arsenic has been primarily associated with the incidence of skin, lung, and bladder cancers, recent reports indicate that exposure to arsenic may have detrimental effects on CNS function. Chronic consumption of arsenic causes defects in operant learning in adult and young rats, alters locomotor activity, and changes in brain neurochemistry. Arsenic, by virtue of its reactivity with sulfhydryl groups of enzymes involved in cellular respiration, can alter the redox status in the cell causing free radical accumulation with the subsequent damage to cell macromolecules. Cells have in place a set of defense mechanisms to ameliorate the nocive effects associated with elevated free radicals. Amongst these, DNA repair mechanisms have been shown to up-regulate in specific brain regions after induction of oxidative stress. The objective of this study was to evaluate the status of oxidative damage to DNA, assessed by determining the levels of 8-hydroxy-2-deoxyguanosine (8-oxodGuo), and the activity of the DNA repair enzyme 8-oxoguanine DNA glycosylase 1 (Ogg1), responsible for removing the 8-oxoGuo DNA lesion, in specific brain regions after chronic exposure to arsenic. Mice were given sodium arsenite in the drinking water for a period of 20 weeks. The levels of 8-oxodGuo were found to be elevated in hippocampus and cortex but not in cerebellum of animals exposed to arsenic. Arsenic exposure also led to a region-specific induction in the activity of Ogg1. Region specific elevation of Ogg1 activity was in inverse relationship to the regional specific elevation of 8-oxoGuo. These results could help explain the intrinsic factors that would enhance the vulnerability of specific neuronal populations, and shed light in the molecular events associated with toxic effects of arsenic to the CNS. Supported by: NSF-EPSCoR (EPS-0091995)

105 DIMERCAPTOSUCCINIC ACID IS INEFFECTIVE IN THE TREATMENT OF ACUTE THALLIUM POISONING.

D. E. Rusyniak[1], L. W. Kao[1], K. A. Nanagas[1], M. A. Kirk[2], B. R. Furbee[1], E. J. Brizendine[3] and P. E. Wilmot[4]. *[1]Emergency Medicine/Medical Toxicology, Indiana University, Indianapolis, IN, [2]Medical Toxicology, University of Virginia, Charlottesville, VA, [3]Biostatistics, Indiana University, Indianapolis, IN and [4]American Institute Toxicology, Indianapolis, IN.*

Introduction: Despite being banned as a pesticide, thallium still results in human and animal poisonings. Current recommended treatments include the use of the chemical Prussian Blue. Limitations in its availability may result in Prussian Blue not being obtainable in the thallium poisoned patient. The chelator 2, 3-Dimercaptosuccinic acid (DMSA) is currently FDA approved for use in childhood lead poisoning and has been reported to be beneficial in treating other heavy metal poisonings. The objective of this study was to determine the efficacy of DMSA as a treatment for thallium poisoning by studying reduction in mortality and whole brain concentrations in thallium poisoned rats. Material and Methods: Rats were gavaged with 30 mg/kg of thallium. After 24 hours they were randomized to DMSA (n=20) 50 mg/kg twice daily for 5 days, Prussian Blue (n=20) 50 mg/kg twice daily for 5 days or control (n=30). Animals were monitored twice daily for weight loss and mortality. Animals losing greater than 20% of their starting weight were euthanized and counted as a mortality. All surviving rats at 120 hours had their brains harvested and digested and underwent subsequent thallium analysis *via* atomic absorption spectrophotometry. Results: There was no difference in the rate of survival (45% vs 21%, p=0.07) or mean whole brain thallium concentrations (3.4 vs 3.0 μg/g, p=0.06) between DMSA and control rats Prussian Blue treated rats had significantly improved survival (70% vs 21%, p <0.01) and lower whole brain thallium concentrations (1.6 vs 3.0 μg/g, p<0.01 tissue) compared to controls. Conclusion: DMSA is ineffective in the treatment of acute thallium poisoning in rats.

106 DIFFERENT RESPONSES OF NEURONS AND GLIA TO Cu ELEVATION IN ROS GENERATION.

Y. Qian, L. Abraham, Y. Zheng and E. Tiffany-Castiglioni. *Veterinary Anatomy and Public Health, Texas A&M University, College Station, TX.*

Copper (Cu) is an essential trace element in the development and function of the central nervous system (CNS). Its high redox potential is a potential cause of cytotoxicity in various neurodegenerative diseases in which Cu homeostasis is disrupted, including Alzheimer's disease. Disturbances of reactive oxygen species (ROS) homeostasis are also associated with these diseases. Neurons and glia are two main types of cells in the CNS and may have different responses to Cu elevation due to their different structural and functional properties. In this report, we used human SY5Y neuroblastoma cells as a neuronal model and human CCF-STTG1 astrocytoma cells as a glial model. Both cell lines were exposed to CuSO4 (0-10 μM) in serum-free medium and ROS was measured with pro-fluorescent molecules. Data showed that glial ROS significantly increased by 50% when cells were exposed to 10 μM Cu for 1 hr and neuronal ROS showed no change at any Cu concentration tested. Similar results were observed in rat C6 glioma and PC12 cells. To address this difference, expression of genes that contribute to Cu buffering capacity (ATP7A and hCtr1) and superoxide dismutation (Mn-SOD) was profiled by quantitative PCR. Both SY5Y and CCF-STTG1 cells had the same level of hCtr1 expression. However, SY5Y had much higher ATP7A expression than did CCF-STTG1. In contrast, CCF-STTG1 had higher Mn-SOD expression than SY5Y cells. These data suggest that glia are more sensitive to Cu elevation than are neurons in ROS enhancement. Furthermore, ATP7A and Mn-SOD probably play roles in Cu-induced ROS generation.

107 AGE-RELATED VASCULAR CHANGES IN THE CEREBRAL WHITE MATTER OF DOGS.

T. Morita, Y. Mizutani, M. Sawada and A. Shimada. *Department of Veterinary Pathology, Tottori University, Tottori, Japan.*

Dogs are known to share a variety of morphological age-related brain changes with humans: the changes include neuronal loss and amyloidosis in the cerebral cortex, dystrophic axonal changes and ubiquitin deposition in the cerebral white matter.

Degenerative changes in the white matter appear to be more prominent than those in the cortex. Based on our recent observation of iron accumulation and ferritin immunoreactivity in the aged dog brain, we suspected that iron-induced oxidative injury may be related to pathogenesis of the severe age-related morphological changes in the cerebral white matter. In this study, we performed immunohistochemical analysis using antibodies against laminin and fibrinogen to determine whether age-related morphological changes of blood-brain-barrier (BBB) occur in the white matter, resulting in an exudation of serum materials (*ie.* iron) which may cause oxidative injury. In addition, we examined iron deposition and astrocytic reaction for oxidative stress with the use of Prussian blue DAB and post DAB enhancement (PBD-PDE) method and superoxide dismutase (SOD) immunohistochemistry (IHC). Brains from 9 young dogs, ranging in age from 6 months to 5 years, and 22 old dogs from 10 to 18 years, were used. In young dogs, there were no significant findings in histological and immunohistochemical examinations. In contrast, a decrease of laminin immunostains was shown in the basement membranes of some capillaries and venules in the white matter of aged dogs. Fibrinogen IHC showed positive immunoreactions in some macrophages accumulating in perivascular spaces and some astrocytes. PBD-PDE method technique for iron demonstrated positive stains in some macrophages and astrocytes. There were some astrocytic processes positive for SOD in the white matter. These results suggest a possibility that a collapse of vascular basement membranes may occur during aging, leading to a disturbance of BBB function and thereby to perivascular exudation of serum materials including an iron. The vascular changes may be related to severe degenerative changes in the white matter.

108 HEAVY METALS AND PCBS PROMOTE BETA-AMYLOID AGGREGATION AND ITS CYTOTOXCITY IN PC12 CELLS.

M. R. Basha, W. Wei and N. H. Zawia. *Biomedical Sciences, University of Rhode Island, Kingston, RI.*

Alzheimer disease (AD) is a gradual and irreversible, progressive neurodegenerative disorder which is characterized with the accumulation of amyloid fibrils. The major constituents of amyloid fibrils in the AD brain are 39-43 amino acid amyloid β (Aβ) peptides, which are protein fragments snipped from a larger protein called amyloid precursor protein (APP). The amyloid hypothesis states that Aβ deposition is a major causative factor for the onset of AD. This is further supported by other studies, which showed that Aβ is toxic only when it is aggregated. The factors that cause the aggregation of Aβ are not clearly known, however it has been proposed that exposure to environmental toxic agents such as heavy metals and persistent organic pollutants may exaggerate the aggregation of this peptide. The present study is aimed to screen the role of various environmental agents, which could influence Aβ aggregation. Synthetic Ab peptide (1-40) was dissolved in urea, diluted with PBS (pH 7.4) and incubated in the presence of 0, 0.1 μM, 1 μM and 10 μM of Ba/Hg/Pb/Zn/PCBs. Peptide aggregation was studied by fluorometric determination with bis-ANS as well as measuring the sedimentation of the aggregated peptide by a protein assay. The protein assay showed that Pb, PCBs and Zn significantly promoted the aggregation of Aβ, whereas Ba and Hg had minimal effects. Similar results were obtained with the bis-ANS studies. Control studies conducted using both techniques and another protein, bovine serum albumen (BSA), showed non-significant effects on aggregation. Furthermore, the cytotoxicity of the Abeta peptide in the presence of these toxicants was investigated in PC12 cells. It was observed that toxicants that promoted peptide aggregation also enhanced the cytotoxicity of Aβ. These findings suggests that environmental agents are potential risk factors for the development of AD by promoting the aggregation of Abeta and/or enhancing its cytotoxicity.

109 ALUMINUM MALTOLATE-INDUCED CYTOTOXICITY IN NEURO-2a CELLS INVOLVES APOPTOSIS AND NECROSIS.

R. P. Sharma[1] and V. J. Johnson[1,2]. *[1]Department of Physiology and Pharmacology, The University of Georgia, Athens, GA and [2]Toxicology and Molecular Biology Branch, Health Effects Laboratory Division, NIOSH, Morgantown, WV.*

Aluminum maltolate (Al-malt) has been shown to cause neurodegeneration following *in vivo* exposure and apoptosis plays a prominent role. The objective of this study was to define the mode of cell death induced by Al-malt. Neuro-2a cells were treated with Al-malt for 24 h in the presence or absence of pretreatment with a variety of pharmacological agents. Al-malt concentration-dependently increased cell death as indicated by lactate dehydrogenase (LDH) release and the appearance of cells with hypodiploid DNA content. Flow cytometry using acridine orange (high-live, low-apoptotic) and ethidium bromide (necrotic) dual staining showed that the mode of cell death was a combination of apoptosis and necrosis. Treatment with Al-malt resulted in caspase 3 activation and the externalization of phosphatidyl serine, both indicative of apoptosis. In addition, nuclear condensation and fragmentation were evident in Hoechst 33258 stained nuclei from Al-malt-treated cultures. Interestingly, pretreatment with cyclohexamide (CHX) markedly reduced Al-malt-induced apoptosis indicating that this mode of death is dependent on *de novo* protein synthesis in the current culture model. Necrotic cell death was not prevented by CHX suggesting that only apoptosis was dependent on gene expression. Pretreatment with antioxidants and kinase inhibitors (mitogen activated protein kinases and PKC) did not reduce Al-malt toxicity suggesting independence from oxidative stress and major kinase signaling pathways. The results provide insight into the mechanisms of Al-malt neurotoxicity and support the involvement of this metal in neurodegeneration.

110 ALUMINUM-INDUCED NEURODEGENERATION INVOLVES DIFFERENTIAL REGULATION OF PROINFLAMMATORY CYTOKINE AND NEUROTROPHIN GENE EXPRESSION.

V. J. Johnson[1,2] and R. P. Sharma[1]. *[1]Department of Physiology and Pharmacology, The University of Georgia, Athens, GA and [2]Toxicology and Molecular Biology Branch, Health Effect Laboratory Division, NIOSH, Morgantown, WV.*

The etiology of human neurodegenerative diseases including Alzheimer's disease (AD) is exceedingly complex and our understanding of the mechanisms involved is far from complete. The experimental neurotoxicology of aluminum has been shown to recapitulate virtually every pathophysiological feature of AD and therefore represents a useful model to study the mechanisms involved in neurodegeneration. The present study investigated the effects of aluminum maltolate (Al-malt) on the delicate balance that exists between pro-inflammatory cytokines and neurotrophins using primary brain rotation-mediated aggregate cultures. Aggregates were treated with Al-malt (5-150 μM) on day 15 *in vitro* for 72 h. Cell death increased in a time- and concentration-dependent manner reaching significance in aggregates treated with 150 μM Al-malt in 48 h and 50 μM by 72 h. Analysis of gene expression at 72 h revealed a concentration-dependent increase in tumor necrosis factor α and macrophage inflammatory protein-1α suggestive of a state of inflammation. In contrast, a dramatic concentration-dependent decrease in the expression of nerve growth factor (NGF) and brain derived neurotrophic factor was observed. In fact, NGF expression could not be detected in aggregates treated with 50 and 150 μM Al-malt. These changes in gene expression correlated with a decrease in aggregate size and an increase in neurodegeneration as indicated by Fluoro-Jade B staining. The results indicated a differential regulation of pro-inflammatory cytokines and neurotrophins in brain tissue following treatment with Al-malt. Such findings provide insight into the possible involvement of deregulation of the cytokine/neurotrophin balance in the etiology of neurodegeneration.

111 ALUMINUM IN DRINKING WATER PROMOTES NEURO-INFLAMMATORY INDICES *IN VIVO*.

A. Becaria, S. C. Bondy, K. Sharman and A. Campbell. *Community & Environmental Medicine, University of California Irvine, Irvine, CA.*

Several epidemiological studies indicate a positive relationship between the incidence of Alzheimer's Disease (AD) and aluminum (Al) concentration in drinking water. However, others have not found such an association and the controversy regarding the role of aluminum in AD is still ongoing and unresolved. Existing evidence suggests that Al is capable of causing inflammation systemically and in the central nervous system. In order to determine if a biologically relevant amount of Al is capable of producing neuroinflammation *in vivo*, we exposed mice for 10 weeks to Al lactate (0.01, 0.1, 1 mM) in drinking water. The pro-inflammatory cytokine TNF-α was increased in the brain of mice treated with the highest dose of Al lactate. The inflammation related transcription factor NF-κB was increased in the mice brains dosed with the lowest concentration of Al. NF-κB activation was not observed at the highest Al dose. This may be due to homeostatic processes which down regulate gene expression of pro-inflammatory elements by negative feedback. No effect on these inflammatory markers was seen in the liver or serum. Therefore, the effects of Al observed were not due to a systemic response, but rather, suggest a selective neurological reaction.

112 EFFECTS OF ALUMINUM ON MEMBRANE PROPERTIES AND BIOGENIC AMINE METABOLISM IN RESTING PC-12 CELLS.

M. Tsunoda[1,2], V. J. Johnson[2], T. F. Murray[2] and R. P. Sharma[2]. *[1]Department of Public Health, Fukushima Medical University, Fukushima, Japan and [2]Department of Physiology and Pharmacology, The University of Georgia, Athens, GA.*

Effects of aluminum (Al) on membrane properties of excitable cells are not fully understood. Evidence suggests that oxidative stress and membrane alterations play important roles in Al neurotoxicity. The present study was conducted to investigate

the relationship between membrane effects of Al and altered neuronal function, namely biogenic amine metabolism. Resting rat pheochromocytoma (PC-12) cells, a model that exhibits neuron-like properties, were used. Treatment of PC-12 cells with Al (>0.01 mM) resulted in a concentration-dependent decrease in membrane fluidity. Similar concentrations of Al increased the rate of extracellular acidification, measured by a cytosensor microphysiometer, indicating stimulation of proton extrusion from cells. Al caused a rapid and concentration-dependent hyperpolarization of the cell membrane as determined by decreased fluorescence of a potential-sensitive dye, *bis*-[12]trimethine oxonol [$Dibac_4$(3)]. These membrane alterations corresponded with an increased production of reactive oxygen species, indicated by increasing dihydrorhodamine 123 oxidation. We previously demonstrated a selective decrease in hypothalamic DA and metabolites in mice treated with different concentrations of Al in drinking water for 4 weeks. Therefore, it was desirable to relate the observed alterations in membrane properties caused by Al to metabolic function of PC-12 cells, a model previously employed for neurotransmitter synthesis and release. Incubation of PC-12 cells with up to 3 mM Al for 6 h caused no alterations in the production or release of neurotransmitters or their metabolites. Results indicated that acute exposure to Al modifies membrane properties of neuron-like cells but had no effect on neurotransmitter biogenic amine pathways under the current treatment conditions.

113 VANADIUM INHALATION INDUCES NEURONAL ALTERATIONS IN *CORPUS STRIATUM*. AN EXPERIMENTAL MODEL IN MICE.

Metals air pollution is a persistent problem world wide. In Mexico City, and maybe in other areas with high gasoline consumption, Vanadium (V) may be increased in air suspended particles. This element is more toxic when inhaled. Very little information is accessible about V and Nervous system modifications. Only relation of V exposure with a decrement in the catecholamines and with depression has been suggested. Here we report neuronal morphological changes found in an inhalation model in mice, looking for changes in those areas in the nervous system with high concentrations of catecholamines, such as the corpus striatum. CD-1 male mice 35g were exposed by inhalation to 0.02 micrometers V2O5, for 4 weeks, two hours twice a week. Mice were sacrificed after the 2nd, 4th, 6th, and 8th inhalation. The striatum was placed in Golgi stain for cytological analysis which consisted in counting the dendritic spines in 10 dendrites of 20 medium spiny neurons. Our results showed that there was a significant reduction of dendritic spines after the exposition during the different times; we found that the exposed groups had almost the half of dendritic spines than the control group. Our data reveal that the inhalation of this element causes severe neuronal damage in the corpus striatum.

114 DIBROMOACETIC ACID-INDUCED ELEVATIONS OF ESTRADIOL IN BOTH CYCLING AND OVARIECTOMIZED/ESTRADIOL-IMPLANTED FEMALE RATS.

J. M. Goldman and A. S. Murr. *Endocrinol. Br., RTD, NHEERL, ORD, USEPA.* Sponsor: A. Cummings.

Haloacetic acids are one of the principal classes of disinfection by-products generated by the chlorination of municipal drinking water. Two members of this class, dibromoacetic acid (DBA) and dichloroacetic acids, have been reported to affect sperm production and gonadal hormonal activity in the male rat. In females, 2 wk oral exposures have been found to disrupt estrous cyclicity, and an alteration in estradiol (E2) concentrations may underlie the effect. Using ovariectomized (OVX) Sprague-Dawley rats implanted with E2 capsules over the final 3 days of a 2 wk oral exposure to DBA (0-270 mg/kg), dose-related elevations in serum E2 were present that accompanied a reduction in the daily induced surge of luteinizing hormone seen in this type of protocol. For an evaluation of intact, regular 4-day cycles, females were again gavaged for 2 wks, this time at doses (0, 30, 60 or 120 mg/kg, in water, pH adjusted to 6.8) unlikely to impair estrous cyclicity. Over the last 4 days of dosing, daily tail nick samples of blood from each rat (1400-1500h) showed that while serum E2 on diestrus and proestrus were comparable to controls, rats in the 60 and 120 mg/kg groups had E2 levels that remained elevated on vaginal estrus instead of exhibiting the marked fall typical of 4-day cycles. Results from both intact and OVX rats also suggest that over time the extended elevations of E2 could have contributed to the disruptions in cyclicity previously noted. To explore further whether the elevation in E2 seen in the OVX/E2-implanted rats was due to an impairment in E2 metabolism, females were gavaged with DBA (0 or 270 mg/kg) for 2 wks. Over the final 3 days, they were given phenobarbital (PhB) either in the drinking water (0.1%) or by IP injection (20 mg/kg) to increase hepatic E2 metabolism. Neither PhB route caused a lowering of the DBA-induced E2 elevations, suggesting that the effects on E2 were linked to an alteration in clearance of the hormone or a suicide inhibition in hepatic P450 activity. (This abstract does not necessarily reflect EPA policy.)

115 THE EFFECTS OF CYCLOPHOSPHAMIDE (CPA) ON THE SYNTHESIS OF GLUTATHIONE (GSH) IN RAT OVARIES.

S. G. Lopez and U. Luderer. *Center for Occupational and Environmental Health, University of California, Irvine, Irvine, CA.*

GSH, the most abundant non-protein thiol in mammalian cells, plays many important roles, including cytoprotection against exogenous and endogenous toxicants. CPA is a widely used chemotherapeutic drug that causes premature ovarian failure in many women who are treated with it. Although the precise mechanism by which CPA causes ovarian failure is not known, CPA's active metabolites are conjugated by GSH. Therefore, this study examined the effects of CPA on GSH synthesis in rat ovaries. It was hypothesized CPA would deplete ovarian GSH and cause a compensatory upregulation of protein and mRNA expression of the rate limiting enzyme in GSH synthesis, glutamate cysteine ligase (GCL). Adult female rats were injected intraperitoneally with 300 mg/kg or 50 mg/kg of CPA in 0.9% saline with 10% DMSO or saline/DMSO alone on the proestrous stage of the estrous cycle, as determined by vaginal cytology. The animals were sacrificed 24 hours later and ovaries were extracted. One ovary from each animal was used for measurement of total ovarian GSH by a modified Tietze method. The other ovary was used for analysis of either protein or mRNA levels of the catalytic or modulatory subunits of GCL (GCLc and GCLm), by Western or Northern blot, respectively. Total ovarian GSH levels decreased significantly with increasing CPA dose (p=0.009). GCLc mRNA increased non-significantly with increasing dose. GCLc and GCLm protein levels were not affected by CPA administration. These results suggest that the ovary is not able to up-regulate GSH synthesis in the face of CPA depletion of ovarian GSH. GSH depletion may play a role in the ovarian toxicity of CPA. Supported by NIEHS K08-ES10963-01 and the Center for Occupational and Environmental Health, UC Irvine.

116 CIGARETTE SMOKE EFFECTS HAMSTER OOCYTE CUMULUS COMPLEX PICKUP RATE, ADHESION, AND CILIARY BEAT FREQUENCY.

C. Gieseke[1,2] and P. Talbot[2,1]. *[1]Environmental Toxicology Graduate Program, University of California, Riverside, CA and [2]Cell biology and Neuroscience, University of California, Riverside, CA.*

Maternal smoking is associated with adverse effects on reproduction. Women who smoke are at increased risk for decreased fertility and ectopic pregnancy. Our lab has shown that the hamster oviduct is a target of cigarette smoke and that oocyte pick-up rate (OPR) is decreased after acute *in vitro* exposure to mainstream or sidestream smoke. Oocyte pick-up requires both ciliary beating and adhesion between the oocyte cumulus complex (OCC) and oviductal cilia. Since inhibition of OPR cannot be explained by changes in ciliary beat frequency (CBF) alone, the purpose of this study was to test the hypothesis that cigarette smoke decreases OPR by altering adhesion between the OCC and oviductal cilia. An assay, developed to measure adhesion between the OCC and oviduct, was used in conjunction with *in vitro* assays to measure OPR and CBF. Experiments were done to determine the effect of mainstream and sidestream whole, gas, and particulate smoke solutions on OPR and adhesion before and after exposure of OCC or oviducts. CBF was measured before, during, and after oviducts were exposed. Results showed that all smoke solutions except sidestream particulate decreased OPR and increased adhesion when OCC were treated. All six types of smoke solutions decreased OPR and increased adhesion after oviducts were exposed. Mainstream whole had no effect on CBF, however, both mainstream gas (MSG) and particulate (MSP) decreased CBF during exposure. MSG, but not MSP, recovered to control levels after exposure. All sidestream smoke solutions increased CBF during exposure, and sidestream whole and gas recovered to control levels after exposure. The results show that pretreatment of either the OCC or the oviduct with mainstream or sidestream smoke solutions increases adhesion and that decreases in OPR correlate more closely with increases in adhesion than with changes in CBF.

117 LOCALIZATION OF GLUTAMATE CYSTEINE LIGASE CATALYTIC SUBUNIT (GCLC) PROTEIN IN IMMATURE RAT OVARY AFTER TREATMENT WITH PMSG.

M. M. Tsai-Turton and U. Luderer. *Center for Occupational and Environmental Health, University of California Irvine, Irvine, CA.*

Glutathione (GSH) is an antioxidant tripeptide that may play a protective role in ovarian follicles. We have previously observed that GSH and protein levels of the catalytic and modulatory subunits of the rate-limiting enzyme in GSH synthesis,

GCLc and GCLm, increase in immature rat ovaries after treatment with pregnant mare's serum gonadotropin (PMSG) in saline. The objective of this study was to localize GCLc protein in the rat ovary using immunohistochemistry. We hypothesized that gonadotropin treatment increases ovarian GSH synthesis by stimulating expression of GCLc protein in growing follicles. Six 25-day-old female Spraque Dawley rats were treated with 0.9% saline (n=3) or 10 IU PMSG in saline (n=3) subcutaneously. Animals were euthanized and both ovaries were dissected out at 24 hours after treatment. Immunohistochemistry with a polyclonal rabbit anti-GCLc antibody was performed on every 4th 8μm section of one ovary, and total GSH concentrations were measured in the other ovary using a modified Tietze assay. As has been previously reported, there were significant increases in ovary weight and GSH levels in PMSG-treated ovaries compared to saline-treated ones. Also, as expected, there were more large antral follicles in PMSG-treated ovaries. The GCLc staining was strongest in granulosa and theca cells of follicles in both saline and PMSG-treated groups. Moreover, there was a trend towards positive GCLc staining in a higher proportion of follicles in PMSG-treated ovaries than saline-treated. The trend was similar when follicles were categorized by type (primary, secondary, and antral). These results support the hypothesis that gonadotropin increases ovarian GSH synthesis by increasing GCLc subunit protein levels in granulosa cells of growing ovarian follicles. (Supported by NIEHS K08-ES10963-01 to UL).

118 BENZYL ISOTHIOCYANATE INDUCED FUNCTIONAL ABERRATION OF ISOLATED UTERINE STRIPS.

A. Adebiyi, R. Prasad and G. P. Adaikan. *Obstetrics & Gynaecology, National University of Singapore, Singapore, Singapore.* Sponsor: M. Ehrich.

Benzyl isothiocyanate (a chemopreventive phytochemical found in cruciferous vegetables) has also been used as an antibiotic for the treatment of urinary tract infections (UTI). In order to evaluate the potential hazard of benzyl isothiocyanate (BITC) on parturition, we studied its effect on uterine activity *in vitro*. BITC (5 mM) caused time dependent modulation of spontaneous contractions of myometrial biopsy specimens obtained from women undergoing lower segment caesarian sections (with approval). The modulating effect of BITC on human myometrial contractions was characterized by progressive reduction in the amplitude and at the same time, increase in the frequency and tone of contractions leading to irreversible uterine quiescence within 2 hours. Furthermore, on isolated whole uterus of non-gravid rats, BITC (10-320 $_{\mu}$M) caused irreversible, concentration-dependent inhibition of spontaneous, prostaglandin $F_{2\alpha}$ (5 $_{\mu}$g/ml) and oxytocin (10 mU/ml) induced contractions of the uterus. At 20 $_{\mu}$M of BITC, slight increase in the contractile tones was observed. Pre-incubation of the rat uterus in Ringer Locke solution containing 100 $_{\mu}$M of BITC (at 37^0C; gassed with carbogen for 1 hour) before suspension in tissue baths also caused significant depression of the maximum force of spontaneous and KCl (60mM) induced uterine contractions relative to the control (P<0.01). Cryosections of BITC-treated rat uterus (hematoxyline and eosin stained) examined under light microscope revealed structural disintegrity with marked cytoplasmic vacuolation. BITC- induced degenerative changes in the uterus could hence be responsible for the altered uterine functions. The present findings suggest that BITC could modify spontaneous and drug-induced uterine contractions. Should BITC alter uterine functions *in vivo*, normal/drug-induced labor will be impaired. Though the normal level of BITC in vegetables is believed to have no ill effect, concentrated BITC in dietary supplements or as a remedy for UTI during pregnancy could have deleterious effect on parturition.

119 NEONATAL ESTROGENIZATION INDUCES HYPOSPADIA AND INFERTILITY IN FEMALE RATS.

A. S. Faqi[1], N. Kozub[1], J. A. Crowell[2] and D. L. McCormick[1]. *[1]Life Sciences Operation, IIT Research Institute, Chicago, IL and [2]Division of Cancer Prevention, National Cancer Institute, Bethesda, MD.*

Emerging data from studies in both humans and experimental animals suggest that *in utero* or neonatal exposure to estrogens may induce adverse effects on later reproductive function in the mature female. The present study was designed to determine the effects of neonatal exposure to a model estrogen on fertility in female rats. Female Sprague-Dawley rats received subcutaneous injections of 25 ug estradiol benzoate (EB) at 1, 3 and 5 days of age. Rats were observed throughout juvenile development and into adulthood to identify gross alterations in reproductive anatomy. Fertility in adult female rats receiving neonatal EB was then compared to fertility in age-matched controls. Control and neonatally estrogenized females were individually co-habitated with untreated males for up to 8 weeks. After mating, all females were allowed to undergo natural parturition; dams that failed to deliver pups by gestation day 25 were evaluated for the presence of implantation sites. 29/29 female rats receiving neonatal EB exhibited hypospadia or malpositioning of the urethral opening. In comparison to age-matched controls, female rats receiving neonatal EB demonstrated significant decreases in the number of successful matings (defined as the number of pregnancies), and decreased fertility index. 28/30 mated female controls demonstrated live implants and successfully delivered pups. By contrast, 0/29 female rats that received neonatal EB delivered live pups. No implantation sites were present in any neonatally estrogenized female rat, suggesting a failure in the process of conception. Infertility in neonatally estrogenized females could result from hypospadia or other anatomic alterations in the genitalia; these alterations could interfere directly with mating and/or fertilization. Alternatively, the effects of neonatal estrogenization on fertility in adult animals could be secondary to long-term alterations in estrus cyclicity or other hormonal mechanism. [Supported by N01-CN-15110 from the National Cancer Institute.]

120 IDENTIFICATION OF COMPOUNDS IN CIGARETTE SMOKE THAT INHIBIT HAMSTER OVIDUCTAL FUNCTIONING.

K. Riveles, R. Roza and P. Talbot. *Cell Biology & Neuroscience, UC Riverside, Riverside, CA.*

Our past studies have shown that chemicals in cigarette smoke inhibit oviductal functioning *in vivo* and *in vitro*. The purposes of this study were to identify the individual toxicants in cigarette smoke solutions that inhibit oocyte pickup rate, ciliary beat frequency, and infundibular smooth muscle contraction and to determine their effective doses using *in vitro* bioassays. Solid phase extraction and gas chromatography-mass spectrometry were used to identify individual chemicals in the mainstream and sidestream cigarette smoke solutions that were active in the above assays. Pyridines, pyrazines, indoles, quinolines, and phenols were identified in the solutions of mainstream and sidestream cigarette smoke. Commercially available standards of the identified compounds were purchased, assayed for purity, and tested in dose-response studies on hamster oviducts. The lowest observable adverse effect level and efficacy were determined for each compound using the oocyte pickup rate, ciliary beat frequency, and infundibular muscle contraction assays. Previously, we have shown that several pyridine compounds including 2-methylpyridine, 4-methylpyridine, 2-ethylpyridine, 3-ethylpyridine, and 4-vinylpyridine were inhibitory at picomolar concentrations in all three bioassays. Further studies have shown that compounds in the pyrazine group: 2-methylpyrazine, ethylpyrazine, 2-methoxy-3-methylpyrazine, 2, 5-dimethylpyrazine, and 2, 3, 5-trimethylpyrazine, were inhibitory in pico or nanomolar doses. Both quinoline and isoquinoline were inhibitory in picomolar doses. 5-Methylindole showed inhibition in the nanomolar range. Indole, which is found in large quantities relative to other compounds in the smoke, showed inhibition at 10^{-15}M. The phenolic compounds were not as inhibitory as the other classes of compounds in the bioassays, although hydroquinone and 4-ethylphenol were inhibitory at nanomolar doses. This work is important because it shows that very low doses of cigarette smoke components significantly inhibit proper oviductal functioning raising questions regarding the safety of these compounds.

121 FOLLICLE GROWTH IN THE MOUSE OVARY IS MEDIATED BY THE ARYL HYDROCARBON RECEPTOR.

K. P. Miller[1], J. C. Benedict[1], C. Greenfeld[1], T. Lin[2], J. K. Babus[1], R. E. Peterson[2] and J. A. Flaws[1]. *[1]Program in Toxicology, University of Maryland-School of Medicine, Baltimore, MD and [2]University of Wisconsin-School of Pharmacy, Madison, WI.*

The ligand-activated aryl hydrocarbon receptor (AhR) binds various environmental contaminants, mediating toxic outcomes. A physiological role for the AhR has remained elusive, though AhR deficient mice (AhRKO) have helped to better understand its mechanisms. In the reproductive system, a lack of AhR results in mice with reduced litter sizes, and difficulties rearing pups to weaning and maintaining conceptuses. Previous laboratory studies have shown that the AhR regulates folliculogenesis, with AhR deficiency causing fewer preantral and antral follicles, without changes in primordial and primary follicle numbers in adult life. Our hypothesis is that AhR deficiency may cause fewer preantral and antral follicles by slowing follicular growth and/or inducing atresia, contributing to reduced ovulatory capacity from follicular growth changes. Follicular growth was compared in wild type (WT) and AhRKO ovaries using morphometric techniques and by measuring the ability of the ovaries and follicles to respond to pregnant mare's serum gonadotropin (PMSG). Atresia was compared using morphometric techniques, TUNEL assays, and 3' end-labeling of fragmented DNA. In addition, ovulation in WT and AhRKO mice was compared by assessing the number of corpora lutea per ovary. Our results indicate that follicle growth and ovulation were reduced in AhRKO ovaries compared to WT ovaries. AhRKO ovaries exhibited a 1.5-fold decrease in number of preantral and antral follicles between postnatal day (PND) 32 and PND 45, were less responsive to PMSG, and contained fewer corpora lutea than WT ovaries. No significant differences in follicular atresia or apoptosis were found in WT and AhRKO ovaries. These data suggest that the AhR regulates preantral and antral follicle growth and ovulation, but not atresia of preantral and antral follicles in the mouse ovary. (Supported by NIH grants HD38955, T32 ES07263-13, and ES01332).

122 GENE EXPRESSION PROFILE INDUCED BY 17-α-ETHYNYL ESTRADIOL IN THE PRE-PUBERTAL FEMALE REPRODUCTIVE SYSTEM OF THE RAT.

J. M. Naciff, G. J. Overmann, S. M. Torontali, G. J. Carr, J. P. Tiesman, B. D. Richardson and G. P. Daston. *Miami Valley Laboratories, Procter & Gamble, Cincinnati, OH.*

The various effects of 17 β-estradiol in the reproductive and other systems, are mediated mostly by the regulation of temporal and cell-type specific expression of different genes. To better understand the molecular events associated with the activation of the estrogen receptor (ER), here we have used microarray technology to determine the transcriptional program and dose-response characteristics of exposure to 17 α-ethynyl estradiol (EE), in the reproductive system of pre-pubertal rats. Changes in patterns of gene expression were determined in the uterus and ovaries of Sprague-Dawley rats on postnatal day 24, 24 h after exposure to EE, from 0.001 to 10 μg EE/kg/day (s.c.), for four days. Transcript profiles were compared between treatment groups and controls using oligonucleotide arrays to determine the expression level of approximately 7000 annotated rat genes and over 1740 expressed sequence tags. Quantification of the number of genes whose expression was modified by the treatment, for each dose of EE tested, showed clear evidence of a dose-dependent treatment effect that follows a monotonic response, concordant with the dose-response pattern of uterine wet weight gain and luminal epithelial cell height. At the highest dose tested of EE, we determined that the expression level of over 300 genes was modified significantly ($p \leq 0.0001$). A dose-dependent analysis of the transcript profile revealed a set of 88 genes whose expression is significantly and reproducibly modified (increased or decreased) by EE exposure ($p \leq 0.0001$). Our results demonstrate that, exposure to an ER agonist during pre-pubertal maturation changes the gene expression profile of estrogen-sensitive tissues. The product of the EE-regulated genes identified in these tissues, have a physiological role in different intracellular pathways, information that will be valuable to determine the mechanism of action of estrogens. Those genes could be used as biomarkers to identify chemicals with estrogenic activity.

123 ALTERED GENE EXPRESSION IN THE MURINE UTERUS FOLLOWING DEVELOPMENTAL TREATMENT WITH GENISTEIN, A SOY PHYTOESTROGEN.

W. N. Jefferson[1,2], E. Padilla-Banks[1] and R. R. Newbold[1]. [1]*Laboratory of Molecular Toxicology, National Institute of Environmental Health Sciences, Research Triangle Park, NC and* [2]*Department of Environmental and Molecular Toxicology, North Carolina State University, Raleigh, NC.* Sponsor: M. Cunningham.

Permanent alterations follow developmental exposure to synthetic and naturally occurring estrogens. Long-term consequences of diethylstilbestrol (DES) or genistein on days 1-5 include uterine carcinoma. Thus, the developing reproductive tract appears to be uniquely sensitive to environmental estrogens. To study mechanisms involved in genisteins toxic effects, estrogen-signaling pathways were examined in outbred CD-1 mice following treatment on days 1-5 with genistein (0.5-50 mg/kg). These dose levels span the range for infants consuming soy based infant formula. Expression of estrogen receptor (ER)α, ERβ, and estrogen responsive genes in the uterus including lactoferrin (LF) and c-fos were compared to untreated controls at 5, 12, and 19 days. Ribonuclease protection assays (RPA) and immunohistochemistry showed no expression of ERβin the uterus of control or genistein-treated mice; however, ERα was increased following the lowest genistein dose. LF was increased on day 5 following neonatal genistein in a dose dependent manner. LF induction was blocked by the anti-estrogen, ICI 182 780 suggesting LF expression was mediated through ERα since ERβ was not present; c-fos followed similar patterns as LF. Another group of mice was treated with genistein on days 1-5 and subsequently stimulated at 17 days with 3 daily injections of estrogen (DES; 10μg/kg/day). On the 4th day, uterine wt./body wt. ratios were determined. Mice exposed to the lowest dose of genistein showed an enhanced response while higher neonatal doses dampened the effects of estrogen at puberty; altered gene expression paralleled uterine wet weight response. Reproductive assessment at 2, 4, and 6 months showed alterations at all genistein doses. These findings suggest exposure to genistein during development alters estrogen responsive genes that may play a role in subfertility and long-term toxicity.

124 EXPOSURE TO 1-BROMOPROPANE DISRUPTS DEVELOPMENT OF OVARIAN FOLLICLES IN ADULT RATS.

T. Yamada[1], G. Ichihara[1], H. Wang[1], X. Yu[1], K. Maeda[2], H. Tsukamura[2], M. Kamijima[1], T. Nakajima[1] and Y. Takeuchi[1]. [1]*Occupational and Environmental Health, Nagoya University Graduate School of Medicine, Nagoya, Aichi, Japan and* [2]*Nagoya University Graduate School of Agricultural Sciences, Nagoya, Japan.*

Although 1-bromopropane has been used in chemical and electronic industries as an alternative to ozone layer-depleting solvents, its toxicity on female reproductive organs has not been fully elucidated. The aim of this experimental was to determine the effect of 1-bromopropane on female reproductive function in rats. Forty female Wistar rats were divided into four equal groups. Each group was exposed daily to 0, 200, 400, or 800-ppm 1-bromopropane for eight hours a day. After exposure for 7 weeks, all rats in the 800-ppm group became seriously ill and were sacrificed during the 8th week. The other dose groups were exposed for 12 weeks. In the 800-ppm group, but not in the other two exposed groups, body weight was significantly less than the control at each time point from 2 to7 weeks after the beginning of exposure. Tests of vaginal smears showed a significant increase in the number of irregular estrous cycles with extended diestrus in the 400 and 800-ppm groups. Histopathological examination of the ovary showed a significant dose-dependent reduction of the number of normal antral follicles and a decrease in the number of normal growing follicles in the 400-ppm group. No significant change was found in plasma concentrations of LH or FSH in any group compared with the control. Our results indicate that 1-bromopropane can induce a dose-dependent ovarian dysfunction in non-pregnant female rats associated with disruption in follicular growth process.

125 METHOXYCHLOR MAY REGULATE ESTROGEN RECEPTOR LEVELS IN THE MOUSE OVARY.

C. Borgeest[1], D. Tomic[2], C. Greenfeld[3], J. K. Babus[2], D. Symonds[2] and J. A. Flaws[1,2]. [1]*Program in Toxicology, University of Maryland, Baltimore, Baltimore, MD,* [2]*Epidemiology and Preventive Medicine, University of Maryland, Baltimore, Baltimore, MD and* [3]*Physiology, University of Maryland, Baltimore, Baltimore, MD.*

The effects of estrogenic pesticides on the female reproductive system are not well understood. We previously reported that the estrogenic pesticide, methoxychlor (MXC), increases the number of atretic ovarian follicles, alters ovarian estrogen receptor α (ERα) and bcl-2 levels, increases the thickness of the ovarian surface epithelium, and disrupts estrous cyclicity in mice. The purpose of the current study was to determine whether MXC alters the levels of both ERα and estrogen receptor β (ERβ) in the mouse ovary. To test this hypothesis, we dosed adult CD-1 mice (39 days) for 10 and 20 days with sesame oil (control) or MXC (8, 16, 32mg/kg/d). All animals were terminated during estrus because ER levels in the ovary differ throughout the estrous cycle and we wanted to minimize this variability. The ovaries then were removed and snap frozen for western blot analysis of ERα and ERβ levels. At the 10-day time-point, MXC (8-32 mg/kg/d) increased ovarian ERα levels compared to controls, but it did not appear to change ovarian ERβ levels. At the 20-day time-point, 8 mg/kg/d MXC increased ovarian levels of ERα, while 32mg/kg/d MXC decreased ovarian levels of ERα compared to controls. At this same time-point, MXC appeared to increase ovarian ERβ levels in a dose-response fashion. These studies suggest that MXC may differently affect the levels of ERα and ERβ in the mouse ovary. (Supported by NIH HD 38955 and the Women's Health Research Group at the University of Maryland).

126 EFFECTS OF BROMODICHLOROMETHANE (BDCM) ON *EX VIVO* LUTEAL FUNCTION IN THE PREGNANT F344 RAT.

S. R. Bielmeier[1], A. S. Murr[2], D. S. Best[2], J. M. Goldman[2] and M. G. Narotsky[2]. [1]*Curriculum in Toxicology, University of North Carolina, Chapel Hill, NC and* [2]*Reproductive Toxicology Division, NHEERL, ORD, USEPA, Research Triangle Park, NC.*

We have reported that BDCM, a drinking water disinfection by-product, causes pregnancy loss, i.e. full-litter resorption, in F344 rats when treated on gestation day (GD) 6-10, encompassing the luteinizing hormone (LH)-dependent period. BDCM-induced pregnancy loss was associated with reductions in serum progesterone (P) and corresponding decreases in LH on GD 10, suggesting BDCM disrupts the maternal hypothalamic-pituitary-gonadal axis. These and other data indicate that BDCM affects the hypothalamus or pituitary gland; however, an effect on luteal responsiveness to LH had not been definitively excluded. To address this data gap, we used an *ex vivo* approach to assess luteal function. Dams were dosed by gavage on GD 6-9 (plug day = GD 0) at 0 or 100 mg/kg/d (n=11, 12). One hour after the GD-9 dose, rats were sacrificed, blood was collected and corpora lutea (CL) were incubated with or without hCG, an LH agonist, to stimulate P secretion. During the 24 h incubation, media were periodically sampled for hormone analysis by dissociation enhanced lanthanide flouroimmmunoassay (DELFIA®). Luteal responsiveness was unaffected; both groups displayed a 2.4-fold increase in P secretion in response to hCG challenge. Paradoxically, the BDCM-exposed CL showed >2-fold increases in P secretion *ex vivo* regardless of the presence of hCG; whereas the same animals, i.e., the CL donors, had decreased serum P and LH levels *in vivo*. It is unclear if this 'rebound' effect reflects the removal of the CL from a possible direct inhibitory influence of BDCM, or a response to the diminished LH stimulation *in vivo*. Regardless, the lack of effect on luteal responsiveness is further evidence that BDCM-induced pregnancy loss in the rat is due to reduced pituitary LH

secretion. *Funded by the EPA/UNC Toxicology Research Program, Training Agreement CT827206 Curriculum in Toxicology, UNC-Chapel Hill. This abstract does not necessarily reflect EPA policy.*

127 FTIR PATTERN SHIFT IN TOXICANTS INDUCED CYTOSKELETON REARRANGEMENT CAN IDENTIFY *IN SITU* AND INVASIVE CARCINOMA OF CERVICAL CELLS.

P. Sinhaseni [1,2], R. Sindhuphak [1], T. Posayanonda[2], V. Taechakitiroj [2], T. Suramana [2], N. Nuntharatanapong [2], S. B. Chichareon [3], K. Peeyananjarassri [3] and N. Dusitsin [1]. *[1]The Institute of Health Research, Chulalongkorn University, Bangkok, Thailand, [2]Department of Pharmacology, Faculty of Pharmaceutical Sciences, Chulalongkorn University, Bangkok, Thailand and [3]Department of Obstetric & Gynecology, Faculty of Medicine, Prince of Songkla University, Songkla, Thailand.*

Cervical cells were swabbed and scanned on Fourier Transform Infrared (FTIR) Spectroscopy. FTIR spectrum shifts were compared between normal cells against in situ- and invasive-carcinoma cells. It was found that phosphodiester group in nucleic acid band significantly shifted from 1080 cm-1 in normal cells to 1085 cm-1 in invasive carcinoma cells. Glycogen band also found significantly shifted from 1025 cm-1 in normal cells to 1029 cm-1 in in situ carcinoma cells. Similar phosphodiester bond changes detected by FTIR were found in spleen cells of rats exposed to methomyl, a carbamate insecticide which could induce apoptosis and cell cycle arrest at G0/G1 phase in leukocytic cell lines *via* IL-6 regulation. Colchicine, an antitubulin, can also cause shifts in FTIR pattern of spleen cells. Cytoskeletal-dynamic polymerization provides cell shape control through cellular mechanotransduction, which involves the interconnection of mechanical load network among adhesion molecules and actin, microtubules, and intermediate filaments. It was proposed that mechanisms of signal transduction by local stress from epidermal growth factor to membrane were through adhesive molecules and various integrins, and/or compartmentalization of cAMP-signaling by cAMP phosphodiesterase isoenzymes. Regulation of capillary blood flow, uptake by phagocytosis and synthesis of extracellular matrix may also participate. We proposed that FTIR pattern shifts may provide additional tool for hazard identification of compounds having effects on cytoskeletal dynamic polymerization, as well as an innovative tool for separating in situ and invasive carcinoma of cervical cells.

128 *IN VITRO* BIOACTIVATION OF 4-VINLYCYCLOHEXENE MONOEPOXIDE IN CULTURTED OVARIES FROM B6C3F1 MICE.

K. Rajapaksa[1], E. A. Cannady[2,1], P. J. Christian[1], P. J. Devine[1], I. Sipes[2] and P. B. Hoyer[1]. *[1]Physiology, University of Arizona, Tucson, AZ and [2]Pharmacology and Toxicology, University of Arizona, Tucson, AZ.*

The occupational chemical, 4-vinylcyclohexene (VCH) causes loss of small preantral ovarian follicles in B6C3F1 mice. Structure activity studies have shown that VCH requires hepatic metabolism to the diepoxide (VCD) to cause ovotoxicity. Whether the ovary is also capable of this bioactivation is unknown. VCD is known to be metabolized to an inactive tetrol metabolite (4-[1, 2-dihydroxy]ethyl-1, 2-dihydroxycyclohexane) by microsomal epoxide hydrolase (mEH), and the mouse ovary has been shown to express high levels of mEH activity. Because VCH must be bioactivated by Cyp 450 enzymes to form the mono-epoxide (VCM) and subsequently the bioactive diepoxide form (VCD), the following study was designed to test whether VCM can cause ovotoxicity *in vitro* in cultured ovaries from neonatal mice. Whole ovaries from female post natal day 4 B6C3F1 mice were incubated (15d) in control medium or medium containing VCM (125, 250, 500, 750, and 1000mM) +/- the mEH inhibitor, cyclohexene oxide (CHE; 2mM), or VCD (15 and 30mM). Following incubation, ovaries were prepared for histological evaluation, and follicles were counted. VCD depleted ($p<0.05$) primordial (control, 554 ± 58; 15mM, 0; 30mM, 0.7 ± 0.7) and small primary (control, 84 ± 7; 15mM, 2 ± 2; 30mM, 0) follicles. VCM at higher concentrations reduced ($p<0.05$) the number of primordial (control, 554 ± 58; 750mM, 230 ± 84; 1000mM, 149 ± 81) and small primary (control, 84 ± 7; 1000mM, 22 ± 18) follicles, compared to control. Furthermore, inhibition of mEH by adding CHE along with VCM at 500mM caused loss of ($p<0.05$) primordial follicles (500mM VCM, 512 ± 77; 500mM VCM ± 2mM CHE, 258 ± 93). These results demonstrate that the mouse ovary can participate in the conversion of VCM to the ovotoxic form VCD. Future studies will utilize the ovarian culture system to demonstrate direct metabolism of VCM to VCD. (ES08979; Center Grant ES06694)

129 APOPTOSIS AS A MECHANISM OF 8-MOP-INDUCED OVARIAN TOXICITY.

D. S. McDermott[1], P. B. Hoyer[2] and M. M. Diawara[1]. *[1]Biology, University of Southern Colorado, Pueblo, CO and [2]Physiology, University of Arizona, Tuscon, AZ.*

Apoptosis, or programmed cell death, regulates the number of follicles ovulated through a distinct framework of gene regulation and signaling pathways. Previous experiments have demonstrated that foreign agents may induce apoptosis in a distinct follicular stage, depending on the inducing agent. Xanthotoxin, a naturally occurring photosensitizer and drug used to treat various skin disorders, has been implicated in a number of adverse reproductive effects in Wistar rats, including decreased birth rate as a direct result of decreased ovulations. Histological examination of ovaries in treated females determined that xanthotoxin targets the follicle and its granulosa cells at the antral stage and reduces 17-beta estradiol production. The present study investigates the potential for programmed cell death as the mechanism of xanthotoxin-mediated ovarian toxicity. Female Wistar rats were dosed (180 mg/kg, p.o.) for twelve weeks. Biomarkers of apoptotic activity were compared in control and treated subjects through Western Blotting. Levels of aromatase protein, (cytochrome P450 19), were measured as both a marker of follicular apoptosis and possible origin of decreased 17-beta estradiol. Levels of caspase 3 protein, the most common executioner of ovarian atresia, were also examined. A significant decrease in protein levels of both aromatase and caspase-3 was observed in xanthotoxin-dosed female rats compared with the control. Histological analysis also confirmed follicular damage typical of apoptotic-stimulating agents in antral follicles of xanthotoxin-dosed rats. These findings are consistent with increased levels of oxidative DNA damage and moreover, disruption of the hypothalamic-pituitary-gonadal axis. The significance of these results is far-reaching and may explain some adverse reproductive effects reported in humans undergoing psoralen photochemotherapy (PUVA).

130 HUMAN HEALTH RISK ASSESSMENT FOR PHENYL GLYCIDYL ETHER TO DETERMINE DRINKING WATER ACTION LEVELS.

C. D. Gillilland, G. L. Ball, C. J. McLellan and M. C. Sanders. *Toxicology Services, NSF International, Ann Arbor, MI.* Sponsor: M. Dourson.

A risk assessment to determine acceptable levels of phenyl glycidyl ether in drinking water was conducted according to Annex A of NSF/ANSI Standard 60/61. As the only repeated-dose studies suitable for risk assessment were conducted by the inhalation route, several long-term inhalation studies were reviewed. The critical study chosen was a two-year rat inhalation study, in which groups of 100 Chr-CD rats per sex per exposure level were subjected to whole-body exposure of phenyl glycidyl ether at human equivalent doses of 0, 0.08, or 1.0 mg/kg-day for females or 0, 0.13, or 1.5 mg/kg-day for males. At the high dose, rhinitis, squamous metaplasia of the nasal epithelium, and nasal tumors were observed, all of which likely developed due to the irritant and cytotoxic properties of phenyl glycidyl ether and its reactivity with biological macromolecules. These effects were not seen at the low dose. Results were positive in several mutagenicity assays but negative in *in vivo* mouse micronucleus assays. In deriving drinking water action levels, a margin-of-exposure approach was used because the data suggested that there was a threshold for the observed nasal tumors. Benchmark dose modeling, based on the initial tumor precursor effect of rhinitis, was used to determine a BMDL of 0.09 mg/kg-day (95% confidence level), using the gamma, logistic, quantal linear, and Weibull models. The margin-of-exposure calculation took into account uncertainties of 3x for interspecies extrapolation and 10x each for intraspecies extrapolation and database deficiencies, resulting in a total margin of 300x. Based on this, a maximum exposure level of 0.0003 mg/kg-day was calculated. The Short-Term Exposure Level was calculated to be 0.03 mg/L, and the chronic exposure levels of the Total Allowable Concentration and the Single Product Allowable Concentration were calculated to be 0.002 mg/L and 0.0002 mg/L, respectively.

131 RISK ASSESSMENT OF IODINE FOR THE DEVELOPMENT OF DRINKING WATER ACTION LEVELS.

A. D. Phelka, L. L. Bestervelt, C. J. McLellan and M. C. Sanders. *Toxicology Services, NSF International, Ann Arbor, MI.* Sponsor: M. Dourson.

A human health risk assessment was conducted by NSF International to determine safe short-term and long-term exposure limits for iodine in drinking water in accordance with NSF/ANSI Standard 60/61, Annex A. Very few applications have been authorized for the use of iodine outside of emergency drinking water and swimming pool applications even though the element is a proven effective water disinfectant. The use of iodine-containing products by international travelers, military personnel and the US Space Shuttle Program, has initiated a great deal of research on the ability of iodine to serve as a multi-purpose drinking water disinfectant. As an essential element, iodine intakes ranging from 40 to 200 μg/day are estimated to be necessary for maintenance of normal thyroid function. Longer-term exposure to iodine levels in excess of those necessary for normal thyroid function shows little visible effect on the thyroid in most individuals due to highly effective regulatory mechanisms. While individuals with preexisting thyroid conditions, as well as children and aged individuals, can be significantly more susceptible to elevated iodine levels, the presence of underlying thyroid disease and/or the age of an individual does not guarantee an adverse reaction to elevated iodine

concentrations. NSF has calculated an oral RfD of 0.01 mg/kg-day from the NOAEL of 1 mg/L (0.03 mg/kg-day) from an ongoing prison disinfection study initiated by Freund et al. (1966) and a total uncertainty factor of 3X. Because the response to excess iodine is highly individual, it is suggested that the risk values calculated by NSF be used with caution and only after consideration of the environment into which iodine supplementation is being introduced.

132 RISK ASSESSMENT OF ARSENIC IN DRINKING WATER FOR THE CALIFORNIA PUBLIC HEALTH GOAL.

J. P. Brown, R. A. Howd, A. M. Fan, A. Smith and P. Lopipero. *University of California, Berkeley, CA.*

Arsenic is known to be carcinogenic, atherogenic, genotoxic, and teratogenic, and may cause other adverse developmental effects in children. OEHHA has conducted a risk assessment of arsenic to support a public health goal for drinking water. Both cancer and noncancer endpoints were evaluated. Primary reliance was placed on human data in this assessment. The cancer risk estimate for arsenic in drinking water was based on mortality of arsenic-induced lung and urinary bladder cancers in studies of populations in Taiwan, Chile, and Argentina. Risks were determined from the equation Rx = R0(xB) where Rx represents the predicted risk to persons exposed to level x in drinking water, R0 represents the background lifetime risk of dying from lung or bladder cancer without arsenic exposure, and B is the slope or unit risk of the linear relative risk model. For lung and bladder tumors, the proposed unit risk estimate is 2.7x10-4 (micrograms/L)-1 based on a linear extrapolation of relative risks. The mode of carcinogenic action is not fully understood, but actual risks of low-level exposure are unlikely to exceed this value but could be lower or even zero. For noncancer effects, several studies were evaluated that indicated dose-response relationships between arsenic intake *via* drinking water and a variety of vascular and related diseases. A health protective value of 0.9 micrograms/L was developed based on one of these studies and endpoints, namely human cerebrovascular disease (Chiou et al., 1997). A benchmark dose approach was used with the quantal linear regression model and an overall uncertainty factor of 30 to account for interindividual variation and extrapolation from the lower bound on effect levels to negligible effect levels for the non-cancer effect.

133 HUMAN HEALTH RISK ASSESSMENT FOR t-BUTANOL TO DETERMINE DRINKING WATER ACTION LEVELS.

J. M. Russell, G. L. Ball, L. L. Bestervelt, C. J. McLellan, M. C. Sanders and A. P. Phelka. *Toxicology Services, NSF International, Ann Arbor, MI.* Sponsor: M. Dourson.

A risk assessment to determine acceptable levels of t-butanol in drinking water was conducted according to Annex A of NSF/ANSI Standard 60/61. A chronic oral study in rats and mice was used as the critical study, in which the key effects were absolute and relative kidney weight increases in female rats. t-Butanol was administered in drinking water to male and female F344/N rats (ten rats per sex per dose) at a dose range of 90-650 mg/kg-day, and to male and female B6C3F1 mice (60 mice per sex per dose) at a dose range of 510-2110 mg/kg-day. In female and male rats, kidney weights were affected, and in male rats, significant nonneoplastic and neoplastic lesions of the kidney were also observed. Male rat kidney effects were discounted due to the presence of α-2 microglobulin accumulation, an effect that is not relevant to human health. Male and female mice showed thyroid follicular cell hyperplasia, adenoma, and carcinoma in the chronic study, and also showed mild kidney effects in a separate subchronic study. Evidence suggested that t-butanol is neither genotoxic nor a developmental toxicant. A two-generation reproductive study of methyl t-butyl ether, which is metabolized to t-butanol and formaldehyde, showed no effects that could be attributed to t-butanol. The oral RfD based on kidney effects in female rats was used for the risk assessment calculations, because it was lower than the oral RfD based on thyroid effects in mice. Benchmark dose modeling resulted in a BMDL of 133 mg/kg-day based on the power model (95% confidence level). Uncertainty factors of 10x each for intraspecies and interspecies variability, resulting in a total UF of 100x, were used to calculate an oral RfD of 1 mg/kg-day (rounded). The calculated Short-Term Exposure Level was 40 mg/L. The calculated chronic exposure levels were the Total Allowable Concentration of 9 mg/L and the Single Product Allowable Concentration of 0.9 mg/L.

134 HEALTH RISK TO FETUSES, INFANTS AND CHILDREN FROM STAGE 1 DISINFECTANTS AND DISINFECTANT BY-PRODUCTS (D/DBPS).

A. T. Bathija. *Office of Water, University.S.EPA, Washington, DC.* Sponsor: E. Ohanian.

The Safe Drinking Water Act (SDWA) of 1996, mandates EPA to consider the effects of contaminants in drinking water on the general population and on sensitive sub-groups such as infants, children, pregnant women and the elderly. Under the Executive Order 13045 of April 21, 1997, the Federal Health and Safety Standards must include an evaluation of potential risks to children from microbes and D/DBPs. Before the D/DBP rule was finalized in December 1998, a report was developed on The Health Risk to Fetuses, Infants and Children. This report considered the following issues: whether the D/DBPs caused developmental or reproductive effects; for carcinogenic D/DBPs, are children more likely to be affected than adults; and for noncarcinogenic effects, are children more sensitive than the adults.To answer these questions we evaluated toxicology studies, developmental and reproductive studies, and carcinogenicity and other systemic toxicity studies for the D/DBPs. We also evaluated epidemiology studies for carcinogenicity and developmental and reproductive effects. For Chloroform, Bromodichloromethane, Bromoform, Dichloroacetic Acid and Bromate the MCLG of zero for carcinogenic effects is protective of children's health. The Chloramine NOAEL/LOAEL is lower than NOAEL/LOAEL for developmental effects. Chlorine Dioxide and Chlorite MCLGs are based on developmental toxicity. The MCLGs for Chlorine and Dibromochlorometane are based on other non-carcinogenic effects. Based on our evaluations, it was concluded that for the Stage 1 D/DBPs the MCLGs are "protective" for developmental and reproductive effects. (The opinions expressed in this abstract are those of the authors and not necessarily those of EPA).

135 THE CUMULATIVE RISK OF DRINKING WATER DISINFECTION BY-PRODUCTS: ADEQUACY OF DATA AND APPROACH.

J. C. Lipscomb, G. E. Rice and L. K. Teuschler. *ORD / National Center for Environmental Assessment, USEPA, Cincinnati, OH.*

Human exposure to chemicals is complex, involving mixtures of chemicals and multiple exposure routes. The cumulative relative potency factor (CRPF) approach is applied to mixtures of chemicals, when toxicity of at least one member is well-characterized. The toxic potency of other chemicals is scaled to that of the index chemical, taking into account the dose-response relationships evident. The disinfection of drinking water (DW) produces a myriad of chemicals (disinfection byproducts - DBP). Humans are exposed to DBP through the oral, dermal and inhalation routes, making the health risk issue one of cumulative risk. We have combined data on their concentration in DW, information on their physicochemical properties, human water use and activity patterns, indoor air flow modeling, and physiologically based pharmacokinetic (PBPK) modeling to derive internal doses for adults and children for trihalomethane, haloacetic acid and haloacetonitrile DBP. Fiftieth-percentiles for the 24-hr absorbed doses of dichloroacetic acid and bromodichloromethane in adult females, adult males and 6-year old children were 2.73, 3.14 and 1.12 E-2 mg; and 8.00, 8.43, 4.38 E-2 mg, respectively. This approach allows internal doses, rather than exposure concentrations, to be employed in the cumulative relative potency factor (CRPF) approach.

136 HEALTH RISK ASSESSMENT FOR MONOCHLOROACETIC ACID (MCA).

D. Wong. *Office of Water, OST/HECD, USEPA, Washington, DC.*

MCA is one of the five haloacetic acids considered for regulation under EPA's proposed Stage 2 Disinfectants and Disinfection Byproducts Rule. A risk assessment of MCA showed that MCA exposure induces cardiovascular, kidney, and liver damage in fatal cases of MCA poisoning in humans. Subchronic and chronic oral-dosing studies suggest that the primary targets for MCA-induced toxicity include the heart and nasal epithelium in rats. In a 104 weeks drinking water study in rats, DeAngelo et al. (1997) noted increased spleen weight at 3.5 mg/kg/day, while decreased body weight, decreased liver and kidney weights, and increased testes weight were observed beginning at 26.1 mg/kg/day. Based on a Lowest-Observed-Adverse-Effects-Level (LOAEL) of 3.5 mg/kg/day for increased spleen-weight changes (DeAngelo et al., 1997), and applying an uncertainty factor (UF) of 1000, the RfD is 0.004 mg/kg/day. The UF accounts for the following: a factor of 10 for inter-individual variability in humans; 10 for extrapolation from an animal study; as well as two factors of 3 for extrapolation from a minimal LOAEL; and inadequacy of the data base (including the lack of adequate developmental toxicity studies in two species, and the lack of multi-generation reproduction study). MCA has produced mixed results in genotoxicity assays, but has not produced a carcinogenic response in a chronic gavage study in rodents (NTP, 1992), and a more recent chronic study in rats (DeAngelo et al., (1997). EPA has classified MCA as Group D: not classifiable as to human carcinogenicity. Under EPA's 1999 Draft Guidelines for Carcinogen Risk Assessment, MCA can be best described as having "inadequate data for an assessment of human carcinogenic potential". (The opinions expressed in this abstract are those of the author and not necessarily those of EPA.)

137 REGULATORY DETERMINATION FOR MANGANESE IN DRINKING WATER.

J. T. Du. *Office of Water, USEPA, Washington, DC.*

As required by the 1996 Safe Drinking Water Act amendment, USEPA published a contaminant candidate list (CCL) in 1998 for the purpose of making regulatory determinations. Regulations are recommended only when all the following three

criteria are satisfied: 1) have adverse health effects, 2) occur or are likely to occur in drinking water at concentrations of health concern, and 3) regulation provides a meaningful opportunity to reduce human risk. Mn is ubiquitous in the environment, comprising about 0.1% of the earth crust. It is an essential trace element, necessary for normal growth and function of animals as well as human beings. Although high exposure *via* inhalation has been shown to cause CNS effect in miners, by the oral route, the available data do not show Mn in water presents a public health concern in the US Under normal circumstances, Mn intake is mainly from dietary sources, very little from water or air. Taking the median concentration of detections from the National Inorganic and Radionucleotide Survey data in drinking water (0.01 mg/L), and assuming a daily intake of 2 L of drinking water by an adult, the average daily dose would be 0.02 mg/person-day. The corresponding dose for a child consuming 1 L/day of drinking water would be 0.01 mg/child-day. These values are far below those expected from a normal diet. Further, Mn has a unique low staining threshold; it stains laundry at or below 0.05 mg/L (lower than the health reference level or HRL of 0.3 mg/L). Because of a lack of adequate epidemiological study, the HRL is based on dietary surveys showing no adverse effect at a daily dose of 10 mg/day or greater. Vegetarian diets can provide as high as 15 or 18 mg Mn per day for a long time with no adverse effect. Thus, regulation of drinking water for Mn does not provide a meaningful opportunity to reduce the risk of adverse health effects. The opinions expressed are that of the author and do not necessarily reflect USEPA policy.

138 EVALUATION OF THE ORAL REFERENCE DOSE FOR VANADIUM.

N. H. Chiu[1] and L. H. Moilanen[2]. [1]*Office of Water, USEPA, Washington, DC and* [2]*Syracuse Research Corp., Denver, CO.*

USEPA has recently reevaluated human and animal health effects data for vanadium. The current database for vanadium compounds has sufficient chronic and subchronic data for development of an oral reference dose (RfD). A provisional RfD of 8E-4 mg V/kg/day has been calculated based on a drinking water study in rats. This value was derived from a marginal NOAEL of 0.25 mg V/kg/d in rats exposed to sodium metavanadate for 3 months.The NOAEL is considered marginal because mild histological changes evident in the spleen, kidneys and lungs of all exposed animals in the study. These changes were mild at the low dose, but were more evident in animals receiving a higher dose of the compound. Selection of 0.25 mg V/kg-day for derivation of the RfD is supported by results of a human study which identified a LOAEL value of 0.32 mg V/kg-day based on gastrointestinal effects. A composite uncertainty factor of 300 was used in the calculation of the RfD for protection of potentially sensitive subpopulations, interspecies extrapolation, study duration, and use of a marginal NOAEL. Based on this provisional RfD value, the Lifetime Health Advisory for vanadium is 6 ug/L. This value can be compared to concentrations of vanadium in US drinking water. Nationally representative data from the National Inorganic and Radionuclide Survey indicate that vanadium was detected in approximately 15% of public water systems served by ground water (median concentration 0.01 mg/L), affecting 7 million people nationally. Average concentrations of vanadium in smaller studies ranged from 0.0043 to 0.0461 mg/L. These data indicate that the occurrence levels of vanadium in drinking water are comparable to the Lifetime Health Advisory level. Disclaimer: The opinions and conclusions expressed in this abstract are those of the authors and do not necessarily reflect those of the affiliated institutions

139 ATSDR'S ACUTE MINIMAL RISK LEVEL FOR COPPER.

L. Ingerman[1] and A. S. Dorsey[2]. [1]*Environmental Science Center, Syracuse Research Corp, Syracuse, NY and* [2]*ATSDR, Atlanta, GA.* Sponsor: P. McGinnis.

ATSDR is currently re-evaluating the noncancer toxicity of copper and has prepared a draft for public comment version of the toxicological profile for copper. One of the most commonly reported adverse health effects of copper is gastrointestinal distress. Most of the available data on gastrointestinal effects comes from case reports of individuals ingesting beverages stored in copper or untinned brass containers or first draw water. Vomiting, nausea, and/or abdominal pain are usually reported shortly after ingestion. These symptoms are not usually persistent or associated with other effects. The case reports provide limited information on exposure levels, however, recently conducted studies identify a threshold for gastrointestinal effects. These studies, as well as the case reports, provide a strong basis for an acute-duration oral minimal risk level (MRL) for copper. An acute MRL is an estimate of daily exposure to a substance that is likely to be without an appreciable risk of adverse effects over a period of 14 days or less. In studies involving a single exposure to copper, adverse gastrointestinal effects (nausea, vomiting, abdominal pain, and/or diarrhea) have been observed at copper concentrations of 4 mg/L and higher (=0.01 mg Cu/kg). In repeated exposure studies, vomiting, nausea, and/or abdominal pain have been observed at 5 mg Cu/L (0.073 mg Cu/kg/day); no adverse effects were observed at concentrations of 1 or 3 mg/L. Animal studies support the identification of the gastrointestinal tract as a sensitive target of toxicity. A 2-week human exposure study (Pizarro et al. 1999) was selected as the basis for the acute MRL. No adverse effects were observed in women ingesting 3 mg Cu/L (0.027 mg Cu/kg/day). To estimate total copper exposure, the copper in the drinking water was added to the reported average dietary copper intake of 0.0266 mg Cu/kg/day. The total copper dose of 0.0538 mg/kg/day was considered a NOAEL for gastrointestinal effects. The NOAEL was divided by an uncertainty factor of 3 (to account for human variability) to yield an acute-duration oral MRL of 0.02 mg Cu/kg/day.

140 SELECTION OF PRE-CONTAMINANT CANDIDATE LIST CHEMICALS FROM UNIVERSE OF DRINKING WATER CONTAMINANTS: A STRUCTURE-ACTIVITY APPROACH.

S. S. Kueberuwa. *Office of Water, USEPA, Washington, DC.* Sponsor: F. Adeshina.

The 1996 Safe Drinking Water Act (SDWA) established that regulations are recommended only for those drinking water contaminants that have adverse effects, occur or are likely to occur in drinking water at concentrations of concern, and for which regulation provides meaningful opportunity to reduce risk. To meet this need, the United States Environmental Protection Agency (USEPA) is directed to publish a list of contaminants (referred to as the Contaminant Candidate List, or CCL). The National Research Council (NRC) has advised that the EPA consider using a "prototype" computerized classification tool in conjunction with expert judgment to produce the CCL from a selected pre-CCL. The pre-CCL must be selected from the "universe" of all known contaminants based on the likelihood to occur or have the potential to occur in drinking water and cause or have the potential to cause adverse effects, using a priority screening criteria and expert judgment. Because this "universe" of potential hazardous drinking water contaminants may number in the tens of thousands, it is proposed that this priority screening criteria and expert judgment should be achieved with an objective and systematic tool for reproducibility and transparency. Structure-Activity Relationships (SAR) can be used for producing the pre-CCL from the "universe" of drinking water contaminants. SAR, as a tool to predict toxicity and exposure, is based on molecular structure and physico-chemical properties that provides a rapid and inexpensive method for screening data-poor contaminants for rule-making prioritization. The SAR method is an EPA approved practice and is the basis of the data found in the EPA's Assessment Tools for The Evaluation of Risk (ASTER) and toxicity equivalency factors (TEF) for chlorinated dibenzo-p-dioxins and -dibenzofurans (CDDs and CDFs). [The opinions herein are those of the author and do not necessarily reflect the opinions of the US Environmental Protection Agency (USEPA)].

141 REGULATORY DETERMINATION FOR NAPHTHALENE IN DRINKING WATER.

J. M. Donohue[1] and L. H. Moilanen[2]. [1]*Health and Ecological Criteria Division, US Environmental Protection Agency, Washington, DC and* [2]*Environmental Science Center, Syracuse, Denver, CO.*

The 1996 Safe Drinking Water Act established a new paradigm for determining the need for drinking water regulations. Under this new paradigm, regulations are recommended only for those drinking water contaminants that have adverse health effects, occur or are likely to occur in drinking water at concentrations of concern, and for which regulation provides a meaningful opportunity to reduce total risk. On June 3, 2002, the USEPA published a preliminary determination that naphthalene did not satisfy the criteria for regulation. This determination was based primarily on a low occurrence of naphthalene at the Health Reference Level (HRL) in representative cross-sections of monitoring data collected under the Unregulated Contaminant Monitoring Program. The HRL (140 mg/L) was derived from the Reference Dose (RfD) for naphthalene after determination that the data are inadequate for an assessment of human carcinogenic potential for the oral route of exposure. The national cross-sections were developed using data collected from public water systems in up to 24 states during the time periods from 1988 to 1992 and 1993 to 1998. During the time periods covered by the monitoring data, there were only two instances where naphthalene was present above the HRL or half the HRL. In fact, only 0.43 and 0.24 % of the drinking water samples collected for Round 1 and Round 2, respectively, exceeded the detection limit for the analytical method used. Additional consideration of environmental fate and potential impacts on sensitive populations, including infants and children with an inherited defect in glucose-6-phosphate dehydrogenase, supported the conclusion that regulation of drinking water for naphthalene did not provide a meaningful opportunity to reduce the risk of adverse health effects. [The opinions expressed represent those of the authors and do not necessarily reflect the opinions of the US Environmental Protection Agency.]

142 EXACERBATION OF CARDIOVASCULAR PATHOLGIES IN FEMALE SPRAGUE- DAWLEY RATS FOLLOWING CHRONIC TREATMENT WITH 3, 3, 4, 4, 5-PENTACHLOROBIPHENYL (PCB126) OR 2, 3, 7, 8-TETRACHLORODIBENZO-P-DIOXIN (TCDD).

M. P. Jokinen[1], N. J. Walker[5], A. E. Brix[2], D. M. Sells[3] and A. Nyska[4]. *[1]Pathology Associates- A Charles River Company, Durham, NC, [2]EPL, Research Triangle Park, NC, [3]Battelle Columbus, Columbus, OH, [4]LEP, NIEHS, Research Triangle Park, NC and [5]ETP, NIEHS, Research Triangle Park, NC.*

Epidemiologic studies have linked human dioxin exposure to increased severity and mortality of ischemic heart disease. The effect of chronic exposure to dioxin-like compounds on the cardiovascular system was investigated in female Harlan Sprague- Dawley rats as part of an ongoing NTP initiative to evaluate the relative potency of chronic toxicity and carcinogenicity of polychlorinated dioxins, furans, and biphenyls. Animals were treated by daily gavage with up to 1000 ng PCB126/kg/d or up to 100 ng TCDD/kg/d for up to 2 yr. Control animals received corn oil: acetone (99:1) vehicle alone. A stop-study group that received the highest dose of each chemical for 30 wk and then vehicle for the remainder of study was also included. A complete necropsy was performed on all animals, and a full list of tissues was collected and examined microscopically. Administration of each compound was associated with treatment-related increases in the incidence of degenerative cardiovascular lesions. Microscopically, incidences of cardiomyopathy, a degenerative myocardial change seen commonly in rats, and chronic active arteritis in a number of tissues were increased in a dose-related manner in all treated animals in both the PCB126 and TCDD studies. A trend for recovery was noted in the stop studies. Average severity of cardiomyopathy was minimal in all dose groups, including controls, in both studies. Chronic active arteritis occurred primarily in the mesentery and pancreas, although other tissues, including rectum, liver, heart, ovary, uterus, and glandular stomach in the PCB126 study and liver and ovary in the TCDD study were affected in a few dosed animals. Our investigations indicate that the rat cardiovascular system is a target for dioxin exposure, which increases the incidence and severity of spontaneous cardiomyopathy and arteriopathy.

143 BONE INJURY IN A CHEMICALLY INDUCED RAT MODEL OF HUMAN HEMOLYTIC DISORDERS ASSOCIATED WITH THROMBOSIS - COMPARATIVE PATHOLOGICAL AND MRI INVESTIGATION.

A. Nyska[3], S. Shabat[1], P. H. Long[2], N. Ezov[4], T. Levin-Harrus[4], S. Paddada[5], M. Rehdlich[6], S. Yedgar[7] and M. Nyska[1]. *[1]Laboratory of Experimental Pathology, NIEHS, Research Triangle Park, NC, [2]Orthopedic Surgery, Sapir Medical Center, Kfar - Saba, Israel, [3]Pathology Associates - A Charles River Company, West Chester, OH, [4]Harlan Biotech Israel Ltd, Rehovot, Israel, [5]Department of Statistics, University of Virginia, Charlottesville, VA, [6]Faculty of Dental Medicine, Hebrew University of Jerusalem, Jerusalem, Israel and [7]Department of Biochemistry, Hebrew University of Jerusalem, Jerusalem, Israel.* Sponsor: R. Maronpot.

Bone injury occurs in human hemolytic disorders associated with thrombosis, such as beta-thalassemia and sickle cell disease. Exposure of rats to 2-butoxyethanol (BE) has been associated with hemolytic anemia, disseminated thrombosis, and infarction in multiple organs including bones. This model apparently mimics acute thrombophilia in humans. To elucidate the extent of bone injury, male and female Fischer F344 rats were exposed to 4 daily doses of 250 mg BE/5ml water/kg BW and studied the tail vertebrae by histopathology and magnetic resonance imaging (MRI). Thrombosis and infarction were seen in both sexes with females more severely affected. Acute necrosis with little cellular reaction occurred at the epiphyseal, physeal, metaphyseal, and diaphyseal regions of the distal tail. Animals held untreated for an additional 24 days after the 4 daily treatments showed extensive areas of medullary fat necrosis, granulomatous inflammation with fibroplasia, and areas of new woven bone formation adjacent to necrotic bone trabeculae. Growth plate alterations were characterized by focally extensive degeneration of chondrocytes within the central region of the growth plate. MRI mean and standard deviation tissue-density data for both sexes indicated significant ($p \leq 0.05$) decrease following 4-days treatment and a significant increase ($p \leq 0.05$) following an additional 24 days without treatment. Thus, MRI was useful in predicting the BE-induced bone injury, being predominantly necrotic at the early sacrifice and regenerative with proliferation of connective tissue and bone following recovery.

144 EFFECT OF FAMOTIDINE, H2 HISTAMINE BLOCKER, ON HERG CURRENT AND ACTION POTENTIAL OF CARDIAC VENTRICULAR MYOCYTES.

R. Nagata, J. Matsuo, Q. Gong, N. Uchimura, K. Kuwano, S. Nagayama and G. Kito. *Shin Nippon Biomedical Laboratories (SNBL), Yoshida, Kagoshima, Japan.*

(Background) Numerous noncardiac drugs prolong QT interval in ECG, resulting in a distinctive polymorphic ventricular tachycardia. Furthermore, it is known that drug-induced QT prolongation and polymorphic ventricular tachycardia is more frequent in women than in men. Recently, it has been reported that a H2 histamine blocker, famotidine, causes QT prolongation leading to torsades de pointes in women. The present study was undertaken to determine whether famotidine has a cardiac proarrhythmic effect on HERG current in HERG (human ether a go-go related gene)-transfected cells and action potential duration (APD) in isolated guinea pig cardiac ventricular myocytes using the patch-clamp technique. (Methods and Results) Measurement of ion current: In HERG-transfected cells, ion currents were measured by the patch-clamp technique. Action potential: The hearts of male guinea pigs (4-12 weeks) were harvested and perfused with Ca2+ free Tyrode solution containing collagenase through the coronary artery using Langendorff apparatus. The left ventricle was cut out and dispersed to isolate ventricular myocytes. The AP of the ventricular myocytes (VM) was measured by the patch-clamp technique. Famotidine (10-100μM) prolonged APD90 by 15-46%, but had little effect on HERG current. Similarly, E-4031 (3 μM) prolonged APD90 by 40%, and inhibited on HERG current by 100%. 17β-estradiol (10 μM) did not prolong APD90. (Conclusion) These data indicate that prolongation of APD by famotidine might be not attributed to inhibition of HERG current, IKr. In conclusion, these results demonstrate that both evaluations in HERG current and APD of cardiac myocytes are very useful for assessment of cardiac proarrhythmic effect of new drugs.

145 THE ROLE OF GLUTATHIONE AND GLUTATHIONE S-TRANSFERASE INDUCED BY 3H-1, 2-DITHIOLE-3-THIONE IN PROTECTING RAT AORTIC SMOOTH MUSCLE CELLS AGAINST 4-HYDROXYNONENAL-MEDIATED CYTOTOXICITY.

Z. Cao, D. Hardej, L. D. Trombetta and Y. Li. *Pharmaceutical Sciences., SJU, Jamaica, NY.*

4-Hydroxynonenal (4HNE) is a major aldehydic product of lipid peroxidation and is believed to contribute significantly to the pathogenesis of cardiovascular diseases, particularly atherosclerosis. 4HNE adducts have been detected in atherosclerotic lesions. One of the major metabolic transformations of 4HNE involves conjugation with glutathione (GSH) catalyzed by GSH S-transferase (GST). In this study we have characterized the induction of GSH and GST by 3H-1, 2-dithiole-3-thione (D3T) and their protective effects against 4HNE-mediated toxicity in rat aortic smooth muscle A10 cells. Incubation of A10 cells with micromolar concentrations of D3T resulted in a marked concentration- and time-dependent induction of both GSH and GST. Consistent with the increased GSH level, enhanced mRNA expression of ~{&C-}-glutamylcysteine synthetase occurred prior to the significant increase of GSH. To examine the protective effects of D3T-induced GSH and GST against 4HNE-mediated toxicity, A10 cells were pretreated with D3T and then exposed to 4HNE. Pretreatment of A10 cells with D3T led to a marked decrease of 4HNE-induced toxicity as determined by MTT reduction assay as well as light and electron microscopy. To further demonstrate the involvement of GSH and GST in protecting against 4HNE-induced toxicity, buthionine sulfoximine (BSO) and sulfasalazine were used to inhibit cellular GSH biosynthesis and GST activity, respectively. Either depletion of GSH by BSO or inhibition of GST by sulfasalazine caused great potentiation of 4HNE-mediated toxicity. Moreover, D3T failed to protect A10 cells against the toxicity induced by 4HNE in the presence of BSO. Taken together, this study demonstrated that D3T can induce both GSH and GST in aortic smooth muscle cells, and that this augmented cellular defense affords protection against 4HNE-induced cardiovascular cell injury.

146 CHEMICAL INDUCTION OF ENDOGENOUS ANTIOXIDANTS IN RAT CARDIOMYOCYTES: PROTECTION AGAINST OXIDATIVE CELL INJURY.

X. Peng, S. Cheng, L. D. Trombetta and Y. Li. *Pharmaceutical Sciences., St. John, Jamaica, NY.*

It is well known that reactive oxygen species (ROS) are involved in the pathogenesis of many human diseases, including cardiovascular diseases. Accumulating evidence shows that exogenous antioxidative compounds provide protection against oxidative cardiac injury. However, whether induction of endogenous cellular antioxidants by chemicals (drugs) also offers protection against oxidative cardiac injury has not been carefully studied. In this study, we have investigated the induction of cellular antioxidants by the unique chemoprotective agent, 3H -1, 2-dithiole-3-thione (D3T) and the protective effects of the D3T-induced cellular antioxidants against oxidative cell injury in rat cardiomyocyte H9C2 cells. Incubation of H9C2 cells with 25-100uM of D3T for 24 h resulted in a significant induction of a series of cellular antioxidants, including reduced glutathione (GSH), GSH peroxidase, GSSG reductase, catalase and GSH S-transferase. To determine whether the induced endogenous antioxidants can protect against oxidative cell injury, H9C2 cells were pre-treated with D3T and then incubated with xanthine oxidase (XO) plus xanthine, a system that generates ROS, or 4-hydroxy-2-nonenal (HNE), a major lipid peroxidation product formed during oxidative stress. We observed that D3T pre-treatment of H9C2 cells led to significant protection against XO/xanthine- and HNE-induced cytotoxicity as determined by 3-[4, 5-dimethylthiazol-2-yl]-2, 5-diphenyltetrazolium bromide (MTT) reduction and morphological changes.

Moreover, immunoblot analysis showed that D3T-pretreatment of H9C2 cells resulted in a marked reduction of HNE-mediated protein adduct formation. Taken together, this study demonstrates that endogenous antioxidants in H9C2 cells can be induced by D3T, and that the induced antioxidant defenses afford significant protection against oxidative cardiac cell injury.

147 INHALATION TOXICITY OF BREVETOXIN 2 IN SPONTANEOUSLY HYPERTENSIVE AND F344 RATS.

B. M. Tibbetts[1], M. J. Campen[1], F. F. Hahn[1], T. F. March[1], A. J. Bourdelais[2], J. Narr[2], D. G. Baden[2] and J. M. Benson[1]. *[1]Lovelace Respiratory Research Institute, Albuquerque, NM and [2]Center for Marine Sciences, University of North Carolina at Wilmington, Wilmington, NC.*

Brevetoxins (PbTxs) are neurotoxins produced by the marine dinoflagellate, *Karenia brevis*. Acute exposure to PbTxs in sea spray is known to cause respiratory tract irritation and may induce broncho-constriction in asthmatic individuals. Histopathologic examination of manatees dying from repeated exposure to brevetoxins during red tide events suggests that the respiratory, nervous, hematopoietic, and immune systems are potential targets for toxicity. The purpose of this experiment was to evaluate the effects of repeated inhalation of brevetoxin 2 (PbTx-2) in the spontaneously hypertensive rat (SHR), a rodent model for pulmonary hypertension. Two groups of male SHR were exposed 2 hr/day, 4-5 days/wk for 3 wks to 0 or 250 to 500 ug PbTx-2/m^3. In-life endpoints included evaluation of ECGs, body temperature, and pulmonary function. At sacrifice, lavage fluid was analyzed for indicators of pulmonary toxicity and inflammation. Lung, brain, liver, kidney and spleen were taken for histopathological evaluation. PbTx-2 exposure resulted in small increases in heart rate and minute volume, but no pronounced effects on ECGs. There was a small, statistically significant increase in macrophages in lavage fluid, but no effect on differential cell counts, lactate dehydrogenase activity, or protein concentration. In a parallel experiment, F344 rats were exposed similarly for one week. Changes in lavage fluid were limited to increases in the numbers of macrophages. Results suggest that repeated inhalation exposure to concentrations of brevetoxin several orders of magnitude above that observed in the environment produced minimal effects in rodents. Long term effects on the nervous and immune systems remain to be evaluated. Research funded under NIH P01-ES10594.

148 PHYSICAL CONDITIONING MODULATES CARDIAC VEGF GENE EXPRESSION AND NITRIC OXIDE LEVELS IN NO-DEFICIENT HYPERTENSIVE RATS.

K. Husain[1], J. Matta[1], S. R. Hazelrigg[2], T. Boley[2] and S. M. Somani[3]. *[1]Pharmacology and Toxicology, Ponce School of Medicine, Ponce, Puerto Rico, [2]Surgery, SIU School of Medicine, Springfield, IL and [3]Pharmacology, SIU School of Medicine, Springfield, IL.*

Many individuals with cardiac diseases undergo periodic physical conditioning with or without medication. Therefore, this study investigated the interaction of physical training and chronic nitric oxide synthase (NOS) inhibitor (Nitro-L-Arginine Methyl Ester, L-NAME) treatment on blood pressure (BP), vascular endothelial growth factor (VEGF) gene expression and nitric oxide (NO) generating system in the heart of the rat. Fisher 344 rats were divided into four groups and treated as follows: 1) sedentary control, 2) Exercise training (ET) for 8 weeks, 3) L-NAME (10 mg/kg, s.c. for 8 weeks) and 4) ET + L-NAME. BP was monitored with tail-cuff method. The animals were sacrificed 24 hr after last treatments and hearts were isolated and analyzed. Physical conditioning significantly increased respiratory exchange ratio (RER), cardiac VEGF mRNA levels, NO level, NOS activity, endothelial eNOS and inducible iNOS protein expression. Training also caused depletion of cardiac malondialdehyde (MDA) levels. Chronic L-NAME administration resulted in depletion of cardiac VEGF mRNA levels, NO level, NOS activity, eNOS, neuronal (nNOS) and iNOS protein expression. Chronic L-NAME administration enhanced cardiac MDA levels. These biochemical changes were accompanied by increases in BP after L-NAME administration. Interaction of training and NOS inhibitor treatment resulted in the normalization of BP and the up-regulation of cardiac VEGF mRNA levels. The data suggest that physical conditioning attenuated the oxidative injury caused by chronic NOS inhibition by up-regulating the cardiac VEGF gene expression and NO levels and lowering the BP in rats(Supported by AHA/IA grant #0051395Z).

149 CONTROL REFERENCE DATA FOR DOPPLER ECHOCARDIOGRAPHY IN HEALTHY CYNOMOLGUS MONKEYS UNDER KETAMINE HYDROCHLORIDE SEDATION.

S. Mohr[1], U. Zuehlke[1], R. Strobel[2], U. Menzel[2], M. Bopst[2] and E. Schulze-Bahr[3]. *[1]Covance Laboratories GmbH, Muenster, Germany, [2]Hoffmann-La Roche Ltd, Basel and [3]Department of Cardiology, University of Muenster, Muenster, Germany.*

In addition to the routine electrocardiogram recording, echocardiography is a useful noninvasive technique that is commonly used to evaluate cardiac structure and function. The cynomolgus monkey is a frequently used nonhuman primate animal model of human cardiovascular disease because of anatomical and physiological similarity. Furthermore, cardiovascular toxicity is a key parameter in toxicity studies providing important information on the health status. However, whilst cynomolgus monkeys are frequently used in cardiovascular research and preclinical toxicity studies, standardized echocardiographic parameters generated from large numbers of healthy animals are not available. In the present study, echocardiographic investigations were undertaken on more than 100 untreated animals in order to obtain normal reference values for this species. The following standard views were determined: (1) Diameters and visual assessment of left ventricular (LV) function in LPQ (long parasternal heart axis), (2) Visual assessment of LV and (right ventricular) RV function in SPQ (short parasternal heart axis), and (3) Diameters and visual assessment of LV and RV function in 4KB (4-chamber view of the heart). In addition to these parameters, pump function was analyzed by heart rate, ejection fraction (EF), beat volume (together with heart rate and body weight for cardiac output determination) and the shortening fraction (FS; as a parameter of pump function) based on wall thickening properties and planimetric measurements ("Areas") during systole and diastole were determined. This historical control data base will allow a reasonable discussion of possible cardiologic findings in preclinical toxicity studies.

150 THE PROTECTIVE EFFECTS OF CHEMICALLY-INDUCED ENDOGENOUS GLUTATHIONE ON PEROXYNITRITE-MEDIATED TOXICITY IN VASCULAR CELLS.

Y. Li and Z. Cao. *Pharmaceutical Sciences, St. John's University, Jamaica, NY.*
Sponsor: L. Trombetta.

Accumulating evidence suggests that peroxynitrite generated from the reaction of nitric oxide and superoxide attributes to the pathogenesis of cardiovascular diseases, such as atherosclerosis. Reaction with glutathione (GSH) is believed to be a major detoxification pathway of peroxynitrite in biological systems. This study was undertaken to test the hypothesis that chemically-elevated intracellular GSH may afford protection against peroxynitrite-mediated toxicity in vascular cells. Incubation of rat aortic smooth muscle cells or human aortic endothelial cells with micromolar concentrations of 3H-1, 2-dithiole-3-thione, a unique chemoprotective agent, led to a concentration- and time-dependent elevation of cellular GSH. Increased gene expression of gamma-glutamylcysteine synthetase, the key enzyme involved in GSH biosynthesis, was also observed in D3T-pretreated cells. To examine the protective effects of D3T-induced cellular GSH on peroxynitrite-mediated toxicity, vascular cells were pretreated with D3T for 24 h and then exposed to either purified peroxynitrite or the peroxynitrite-generator, SIN-1. We observed that D3T-pretreatment of vascular cells resulted in a significant protection against purified peroxynitrite- or SIN-1-mediated toxicity, as assessed by MTT reduction and morphological changes. Conversely, depletion of cellular GSH by buthionine sulfoximine (BSO) caused a marked potentiation of purified peroxynitrite- or SIN-1-mediated toxicity. To further demonstrate the critical involvement of GSH induction in D3T cytoprotection, vascular cells were co-treated with BSO to abolish D3T-mediated GSH elevation. Co-treatment of cells with BSO was found to greatly reverse the protective effects of D3T on purified peroxynitrite- or SIN-1-mediated toxicity. Taken together, our results demonstrate for the first time that induction of endogenous GSH by D3T affords marked protection against peroxynitrite-mediated toxicity in vascular cells.

151 MESENTERIC AND PANCREATIC VASCULAR INJURY INDUCED BY FENOLDOPAM IN SPRAGUE-DAWLEY (SD) RATS: EVIDENCE FOR MAST CELL MEDIATED PATHOGENESIS.

J. Zhang, R. Honchel, E. H. Herman, J. L. Weaver, A. Knapton and F. D. Sistare. *Division of Applied Pharmacology Research, Center For Drug Evaluation and Research, USFDA, Laurel, MD.*

Fenoldopam (FP) has been shown previously to induce mesenteric and splanchnic arterial injury in rats. This toxicity is thought due to excessive vasodilation following sustained dopaminergic receptor stimulation. In the present study adult male SD rats were given a single s. c. injection of 60 (11 rats) or 120 (5 rats) mg/kg FP or saline (10 rats) and euthanized 24 hr later. At necropsy, the entire mesentery of each rat was spread out, divided into three ring-shaped sections, fixed, sectioned and stained with H&E, toluidine blue (for mast cells) and Luna's method (for eosinophils). Vascular alterations were similar to those observed in our previous studies with SK&F 95654. Two categories of vascular injury were again noted: (1) muscular arteries showed medial hemorrhage with smooth muscle cell apoptosis and necrosis and periadventitial inflammation; (2) small vessel (capillaries, venules, arterioles, and small veins) injury was characterized by inflammation, vascular congestion, and venous thrombosis. Endothelial cell activation and injury (denudation, vacuolization, apoptosis and necrosis) were found in all vessels. Degranulation of

mast cells, infiltration of eosinophils, macrophages and neutrophils, and fibrin exudate were present in the perivascular spaces and connective tissues of the mesentery. Dose dependent increases in serum alpha-2-macroglobulin were seen. Granulocytosis but not generalized activation was observed. Rats treated with 60 or 120 mg/kg FP had an average vascular injury score of 3.4 or 3.8 on a scale of 0 (unaffected) to 5 (most severe) with an average of 30% or 53% of mesenteric vessels showing hemorrhage, respectively. The acute phase response, findings of mast cell degranulation, accumulation of numerous eosinophils and widespread edema reinforce our previous hypothesis that a localized pseudoallergic reaction can contribute to drug-induced rat mesenteric vascular injury.

152 VALIDATION FOR QT PROLONGATION IN CONSCIOUS BEAGLE DOGS ADMINISTERED SOTALOL VIA THE ORAL ROUTE.

C. M. Kelly, M. Miyamoto and S. J. Gosselin. *Safety Assessment, Huntingdon Life Sciences, East Millstone, NJ.*

The purpose of this study was to evaluate the DSI (Data Sciences, St. Paul, MN) telemetry system in our Testing Facility environment with an agent known to cause QT prolongation. Eight adult beagle dogs (4 /sex) with implanted telemetry transmitters were used for this study. Pretest data was collected for a 24 hour period prior to initiation of dosing. Sotalol was administered orally in capsules in a dose escalation regimen. Doses of sotalol were 0, 8, 16, and 32 mg/kg, respectively with a 2-3 day washout period between each dose. ECG waveform, blood pressure, and heart rate (HR) were collected for 30 seconds intervals. Prior to dosing all parameters were collected every 15 minutes for 2 hours, and every 30 minutes for 24 hours following each dose. QT interval and mean HR were manually measured. The effect of sotalol on QT interval was assessed by several methods including QTcv (Van De Water), QTcr (separate regressions of QT on RR interval), %QTc change from baseline, comparison of absolute QT with similar HR, QT:HR outlier analysis, and the difference between postdose and baseline for QT and each QTc. Data was averaged over 0 to 3 hours, 3 to 6 hours, 6 to 12 hours and 12 to 24 hours. Analysis of covariance for repeated measures was used to test whether treatment effects varied during the above time intervals. Data was also analyzed to test whether the treatment had the same effect in males and females. Treatments were compared to control using Williams test. All levels of sotalol had a significant effect on QT, QTc and HR. QT prolongation started within 1 hour of dose with the peak effect occurring 3 to 4 hours later and lasting about 15 hours. The duration of the effect was dose related though not for the degree of the effect. Treatment effects were not different in between sexes in most parameters except for QTc between 3 to 6 hours. During this time, males had significantly longer QTc compared to females. In conclusion, we have demonstrated the suitability of using DSI telemetry systems to detect changes in QT interval in our Testing Facility environment.

153 THE EFFECT OF THE NONSELECTIVE NOS INHIBITOR, L-NITRO-ARGININE ON THE CANINE PANCREAS.

R. Bell[1], K. Kolaja[1], D. Jenssen[1], P. Manning[2] and N. Khan[1]. *[1]Global Toxicology, Pharmacia Corporation, Skokie, IL and [2]Discovery, Pharmacia Corporation, Chesterfield, MO.*

Nitric oxide (NO), generated by both constitutive (cNOS) and inducible (iNOS) isoforms of nitric oxide synthase (NOS), is a cell-signaling molecule involved in numerous physiological possesses including gastrointestinal (GI) functions. NO stimulates the release of gastric and pancreatic secretions and increases gastric motility and contractility. We therefore evaluated the effects of L-nitro-arginine (LNA), a NOS inhibitor that preferentially inhibits both constitutive isoforms, on the canine pancreas. LNA was administered orally for 4 weeks at doses of 10 and 30 mg/kg/day (6 female dogs/group). Doses of LNA were selected based on the upper limit of acceptable changes in blood pressure and overt toxicity. To evaluate whether pancreatic effects of LNA were related to the amino acid-like structure an additional group was given L-arginine (L-Arg). Treatment with both doses of LNA resulted in stool changes (decreased, watery, soft, mucoid and/or red-tinged), a reduction of ~40% in heart rate (possible vagal response to increased blood pressure) and elevations in pancreatic enzymes (amylase, lipase, or trypsin-like immunoreactivity (TLI)) in serum. After one week, there was a 2-10X dose-related increase in pancreatic enzymes in both LNA groups, which then declined to ~30% greater than control thereafter. No remarkable histological changes were found in the pancreas after 4 weeks. No effects of treatment with L-Arg were found. The results of this study indicate that the inhibition of constitutive NOS can lead to pancreatic effects, specifically elevations in serum levels of pancreatic enzymes. However, inhibition of constitutive NOS for up to 4 weeks does not result in any observable morphologic changes.

154 VALIDATION OF THE IL 682 CO-OXIMETER FOR EVALUATION OF METHEMOGLOBIN IN THE SPRAGUE-DAWLEY RAT.

T. P. O'Neill[1], C. P. Chengelis[1], S. C. Haley[1] and V. J. Piccirillo[2]. *[1]WIL Research Laboratories, Ashland, OH and [2]VJP Consulting, Ashburn, VA.*

Measurement of methemoglobin (MetHb) can play a valuable role in the determination of adverse effects caused by particular xenobiotics (example: nitrites). Methb decreases the oxygen capacity of the blood, which as a result can exert a dual effect of impairing the supply of oxygen to tissues. The purpose of this study was to validate methods of measuring MetHb levels in the Sprague-Dawley rat using the IL 682 Co-Oximeter System. Untreated rats (Crl:CD(SD)IGS BR) had blood samples collected from the lateral tail vein utilizing 21 gauge needles. Syringes, pretreated with heparin to prevent clotting, were attached to the needles. Exposure of the sample to air was avoided, as exposure to oxygen would decrease the ability to accurately measure MetHb. Evaluation of MetHb was performed on each sample utilizing the IL 682 Co-Oximeter System. An additional set of animals were assigned to two treatments groups; one group treated intraperitoneally with 21 mg/kg of sodium nitrite and one treated intraperitoneally with 42 mg/kg of sodium nitrite. These two groups of animals had blood collected in the same fashion as the untreated animals prior to treatment and approximately two hours post-dose and evaluation of MetHb performed. Mean MetHb values for the untreated rats were 0.7% (range 0.2-1.4%) which are within biological normal ranges for this species. There were no apparent differences noted between sexes. Mean values for the sodium nitrite treated groups at 2 hours post-dose were 5.3% (21 mg/kg) and 32.4% (42 mg/kg). It was concluded that the IL 682 Co-Oximeter System and the procedures utilized for blood collection were an accurate method for determination of methemoglobin in the Sprague-Dawley rat.

155 THE EFFECTS OF CISAPRIDE ON QT INTERVAL IN CONSCIOUS, TELEMETERED MALE BEAGLE DOGS.

B. M. Roche, L. R. Votaw and P. R. Atterson. *Safety Pharmacology, Quintiles, Inc., Kansas City, MO.* Sponsor: R. Long.

Torsades de pointes (TDP) is a rare but potentially fatal polymorphic ventricular tachycardia associated with prolongation of the QT interval primarily due to drug-induced delayed repolarization. Cisapride, a prokinetic agent, known to prolong action potential duration (APD) in canine purkinje fibers (Gintant et al, 2001) has also been reported to produce transient increases in QTc in anesthetized dogs (Crema et al, 1998). The present study was conducted in order to provide additional information regarding the potential arrhythmogenic effects of cisapride using a conscious model. Four male beagle dogs were surgically implanted with telemetry transducers, for the measurement of arterial blood pressure and lead II ECG. Cisapride, suspended in 1% w/v aqueous methylcellulose, was administered in an ascending dose regimen on days 1, 4, 7, 10 and 14 *via* oral gavage at doses of vehicle, 0.1, 1.0, 2.0 and 4.0 mg/kg, respectively. Measurements of systolic blood pressure (SBP), diastolic blood pressure (DBP), mean arterial blood pressure (MAP), heart rate (HR) and the lead II ECG variables (PR interval, RR interval, QRS duration and QT interval) were taken from each animal continuously for 1 hour before and six hours after dosing. Preliminary results indicate that oral administration of cisapride at 0.1, 1.0, 2.0, and 4.0 mg/kg tended to have no effect on arterial blood pressure (systolic, diastolic and mean) or heart rate when compared to vehicle. Furthermore, QTc (Fridericia) tended to increase from baseline to 90 min post dose for the 2.0 mg/kg dose. Data from the completed study and the successful use of this in-vivo assay to investigate QT prolongation will be described.

156 INDUCTION OF 5-LIPOXYGENASE IN VASCULAR ENDOTHELIAL CELLS IN RESPONSE TO ARSENIC EXPOSURE.

M. Bunderson[1,2], R. E. Hamilton[1,2], J. D. Coffin[1,2] and H. D. Beall[1,2]. *[1]Pharmaceutical Sciences, University of Montana, Missoula, MT and [2]Center for Environmental Health Sciences, University of Montana, Missoula, MT.*

Numerous epidemiological studies have linked arsenic in drinking water to cancer and more recently to cardiovascular disease. Although an association between arsenic exposure and atherosclerosis has been established, the mechanisms are primarily unknown. Atherosclerosis is an inflammatory disease so any agent that enhances the inflammatory state of the vasculature may perpetuate atherosclerosis. The proinflammatory leukotrienes are major products of the 5-lipoxygenase pathway. Patients with atherosclerosis are known to have increased leukotriene production, and a recent study identified the 5-lipoxygenase gene as a major contributor to the development of atherosclerosis in mice. Although 5-lipoxygenase is expressed primarily in leukocytes, there is also evidence for the presence of 5-lipoxygenase in endothelial cells. The goal of this study was to determine the effect of arsenic exposure on 5-lipoxygenase protein expression and leukotriene generation in endothelial cells. Bovine aortic endothelial cells (BAE) were used as a model to measure the induction of 5-lipoxygenase and production of the inflammatory mediator, leukotriene E4 (LTE4). Using Western immunoblots, we showed that 5-lipoxyge-

nase is upregulated in a time-dependent manner in response to arsenic exposure in BAE cells. Densitometry revealed a 3-4 fold increase in 5-lipoxygenase protein over controls after 72 h. LTE4 production was also measured using commercial ELISA kits and showed an increase in response to arsenic exposure concomitantly with induction of the 5-lipoxygenase enzyme. This study links arsenic to an inflammatory pathway that has been associated with atherogenesis and provides insight into the complicated mechanisms of arsenic-induced cardiovascular disease.

157 PEROXYNITRITE GENERATION IN AORTIC ENDOTHELIAL CELLS EXPOSED TO ARSENIC IS INCREASED BY MANGANESE.

R. E. Hamilton, M. Bunderson, J. D. Coffin and H. D. Beall. *Pharmaceutical Sciences, University of Montana, Missoula, MT.*

Long-term exposure to arsenic in drinking water has been linked to cancer and other health effects, including cardiovascular disease. Arsenic is found in combination with a range of metals that could influence its toxicity. Manganese is a metal that is typically found in conjunction with arsenic in contaminated groundwater. One possible mechanism for the cardiovascular toxicity of arsenic involves generation of peroxynitrite. Peroxynitrite is a powerful oxidant and a reactive nitrating agent, particularly in the presence of tyrosine residues. Nitrotyrosine, a biological marker for the presence of peroxynitrite, is found in high levels in the plaques of individuals with atherosclerosis. The goal of this study was to examine the effects of manganese on arsenic-induced toxicity and peroxynitrite formation in endothelial cells. The effect of manganese on arsenic toxicity was determined in bovine aortic endothelial (BAE) cells using the MTT assay. Arsenic toxicity was potentiated by the addition of manganese at manganese concentrations that were non-toxic when administered alone. BAE cells were also used to measure the generation of peroxynitrite in the presence of arsenic, manganese and arsenic-manganese mixtures. We have previously shown that arsenic increases peroxynitrite formation in this model. BAE cells were exposed to sodium arsenite, manganese chloride or an arsenite-manganese mixture for 1h. Peroxynitrite was measured using a published assay based on the conversion of hydroethidine to its fluorescent form, ethidium. Individually, arsenic and manganese enhanced peroxynitrite formation by approximately 1.5-fold each over controls at 5 μM arsenic and 25 μM manganese. However, when added together at the same concentrations, peroxynitrite formation was increased 2-fold versus controls. These data suggest that manganese may exacerbate the toxic effects of arsenic on the vascular system.

158 CELL TYPE DEPENDENT SIGNALING WEBS OF OXIDATIVE STRESS.

S. E. Purdom[1], J. R. Coronella-Wood[2] and Q. M. Chen[2]. [1]*Interdisciplinary Graduate Program for Genetics and Genomics, University of Arizona, Tucson, AZ and* [2]*Pharmacology, University of Arizona, Tucson, AZ.*

Heart disease is a major cause of natural death worldwide. The major cell types in the heart are cardiomyocytes (CMCs) and fibroblasts. While CMCs undergo apoptosis or hypertrophy during heart disease progression, fibroblasts often develop hyperplasia or malfunctions in protein production, causing alterations in the structure and texture of the extracellular matrix. Oxidants have been shown to activate three branches of MAPKs: ERKs, p38 and JNKs. The upstream regulators of oxidant-induced MAPKs have not been identified in CMCs and fibroblasts. We explore the hypothesis that oxidants may transactivate the insulin receptor, EGF receptor and Src tyrosine kinase, leading to activation of MAPKs. Measurements of insulin receptor substrate (IRS)-1 or IRS-2 phosphorylation in CMCs following H_2O_2 treatment yielded negative data. AG1478, a pharmacological inhibitor of EGFR, reduced the activation level of ERK1/2 and JNKs but not p38 in CMCs after oxidative stress. AG1478 did not block any of the three MAPKs in fibroblasts treated with the same dose of H_2O_2 as CMCs. Inhibiting Src family tyrosine kinases with PP2 blocks JNKs but not ERKs or p38 in CMCs. In contrast, PP2 inhibits ERKs and JNKs but not p38 in fibroblasts. Therefore, it appears that while EGFR-like signals may be activated by oxidants and contribute to ERK1/2 or JNK activation in CMCs, the Src pathways contribute to activation of JNKs in CMCs and to activation of ERKs and JNKs in fibroblasts. Neither EGFR nor Src pathways contribute to p38 activation by oxidants in CMCs or fibroblasts. In conclusion, although ERKs, p38 and JNKs are activated by many types of stress, the upstream regulators of these pathways differ depending on cell type.

159 cDNA SEQUENCE OF CHICK BETA-1-ADRENERGIC RECEPTOR MAY EFFECT RESPONSES TO CARDIOTOXIC XENOBIOTICS.

A. J. Hume[1], M. K. Walker[2] and R. J. Sommer[1]. [1]*Biology Department, Bates College, Lewiston, ME and* [2]*College of Pharmacy, University of New Mexico, Albuquerque, NM.*

It has been known for over three decades that the avian cardiovascular system is sensitive to halogenated aromatic hydrocarbon toxicity. Recently, research has demonstrated that 2, 3, 7, 8-tetrachlorodibenzo-*p*-dioxin (Toxicol Appl Pharmacol 167:210) inhibits the ability of isoproterenol, a β-adrenergic receptor (β-AR) agonist, to increase heart rate of day 10 and 12 chick embryos. This reduced response to β-AR stimulation may be mediated at the receptor level. Thus, we have cloned a nearly complete cDNA sequence of the chick β_1-AR by routine RT-PCR and RACE. One-day old chick heart total RNA was isolated, treated with RNase-free DNase, and used to synthesize cDNA. Initial PCR primers were designed based on turkey β_1-AR cDNA sequence (GenBank M14379) and subsequent primers were based on chick β_1-AR cDNA sequence cloned in our laboratory. The cDNA sequence of the chick β_1-AR is highly conserved with turkey, sharing 96% amino acid identity. In addition, the membrane spanning regions and short interspan loops of the chick β_1-AR shares 81-83% amino acid identity with the corresponding regions of the mouse, rat or human β_1-AR. However, the turkey β_1-AR has an alternative splice variant that is not found in mammals. The variant encodes a carboxyl-terminus with 59 additional amino acids that block agonist-promoted endocytosis and down-regulation of the β_1-AR. Expression of the variant is age- and tissue-specific providing avian species with an additional mechanism to regulate receptor levels following agonist exposure. Given the importance of β_1-AR regulation in progression and severity of cardiovascular disease, it is possible that differential regulation of β_1-AR between avian and non-avian species could result in varying sensitivity to cardiotoxic chemicals. Future research will continue to investigate the mechanisms by which developmental TCDD exposure decreases the response of the chick embryo heart to stimulation by β_1-AR agonist. Supported by NIH R15 ES011806.

160 ARE THERE SEX DIFFERENCES IN ACTION POTENTIAL DURATION RECORDED FROM CANINE PURKINJE FIBRES?

L. Patmore, K. Lansdell, S. Fraser, S. Laycock, D. Gallacher and A. Templeton. *Preclinical Safety and Efficacy, Quintiles Ltd, Edinburgh, United Kingdom.* Sponsor: D. Mitchell.

Two-thirds of the cases of drug-induced torsades de pointes occur in women. This gender-related risk of arrhythmia is associated with a longer corrected QT interval at baseline and a greater response to IKr blockers (Drici & Clement, Drug Saf., 2001, 24, 575). Sex differences in rabbit Purkinje fibre action potential have been reported by Lu *et al.* (J.Cardiovasc. Pharmacology, 2000, 36, 132). However, in the conscious dog this difference was not evident, QT interval being similar: 206 vs 203 ms in males and females respectively (Osborne & Leach, Fd. Cosmet.Toxicol., 1971, 9, 857); 233 vs 230 ms in males and females respectively (Quintiles telemetry data). Action potentials were recorded from Purkinje fibres isolated from the hearts of both male and female Beagle dogs according to Patmore *et al.* (Eur. J. Pharmacology, 2000, 406, 449). Values were compared to establish if there were baseline gender differences. Data are shown below for action potential duration (APD) recorded at 90% repolarization at stimulation frequencies of 1 and 0.5Hz. These values are from an extensive database of action potential parameters. No gender related differences in APD were evident. Exposure of fibres to 50 μM dl-sotalol resulted in comparable increases in APD indicating that the sensitivity of male and female dog Purkinje fibres to IKr blockers is not different. These data contrast those obtained for rabbit Purkinje fibres by Lu *et al.* but are consistent with a lack of difference in QT interval measured in conscious male and female Beagle dogs.

161 ENHANCEMENT OF NO RELEASE FROM S-NITROSOALBUMIN BY FATTY ACIDS: RELEVANCE TO OXIDATIVE/NITROSATIVE STRESS OF PREECLAMPSIA.

V. Tyurin[1], R. E. Gandley[2,1], C. A. Hubel[2], R. N. Taylor[3] and V. E. Kagan[1,2]. [1]*Environmental and Occupational Health, University of Pittsburgh, Pittsburgh, PA,* [2]*Magge-Womens Research Institute, University of Pittsburgh, Pittsburgh, PA and* [3]*Obstetrics/Gynecology and Reproductive Sciences, University of California, San Francisco, CA.*

S-nitrosothiols (RSNO), mainly S-nitrosoalbumin (NO-Alb), are potent plasma vasodilators whose action is associated with NO release. Release of NO requires the presence of a redox-active transition metal (copper) and a reductant (ascorbate).

Oxidative stress-induced ascorbate deficiency might result in decreased rates of decomposition of RSNO in disease conditions e.g., in preeclampsia, diabetes. Because free fatty acids (FFAs) affect redox activity of albumin-bound Cu, we studied the role of FFAs and ascorbate in the release of NO from NO-Alb in the presence of Cu/Alb using NO-sensitive electrode. No release of NO occurred in PBS solution. Cu/Alb (0.3:1 mole/mole) slightly stimulated decomposition of NO-Alb and ascorbate caused a strong concentration-dependent increase of NO release. Albumin/FFA complexes (oleic acid, linoleic acid, 1-6 mole/mole albumin) also increased the rate of ascorbate-dependent NO-Alb decomposition, particularly at FFA/albumin ratios >2-3. Thus two major factors - ascorbate and FFAs - regulate stability of NO-alb in plasma. To assess the relevance of these results to vasoactive properties of NO-Alb, the relaxation responses of isolated phenylephrine-preconstricted mouse mesenteric arteries (incubated in 1% plasma from women with normal or preeclamptic pregnancies) after exposure to 5.8 μM albumin with 0.5 μM NO-Alb were tested. To eliminate differences in the endogenous levels of ascorbate, the samples were spiked with exogenous ascorbate. Preeclamptic plasma that contains elevated levels of albumin-bound FFAs (so-called cytotoxic albumin with pI =4.8) caused a greater relaxation response (45.3±6.3%) than normal pregnancy plasma (22.7±5.8%, p=0.02). Thus enrichment of albumin with FFAs can enhance decomposition of NO-Alb if sufficient ascorbate is available in plasma. Supported by NIH HL64145.

162 OPENING OF MITOCHONDRIAL PERMEABILITY PORES CAUSES ISCHEMIA/REPERFUSION-INDUCED KILLING OF CULTURED ADULT RAT MYOCYTES.

J. Kim, Y. Jin and J. J. Lemasters. *UNC-Chapel Hill, Chapel Hill, NC.*

BACKGROUND: Mildly acidic pH is protective in toxic and hypoxic injury but the restoration of normal pH is an independent factor promoting cell death after reperfusion. Studies suggest that onset of the mitochondrial permeability transition (MPT) contributes to ischemic damage to heart and hypoxic injury to cardiac myocytes. The **AIM** of this study was to test the hypothesis that onset of the MPT underlies the pH-dependency of ischemia/reperfusion injury. **METHODS:** Overnight cultured adult rat myocytes were incubated in anoxic Krebs-Ringer-HEPES (KRH) buffer at pH 6.2 for 3h to simulate ischemia. Reperfusion was simulated by reoxygenating cells at pH 6.2 or 7.4 for 2h. Some myocytes were treated with 1.0μM cyclosporin A (CsA), a MPT blocker, 20min prior to reperfusion. Cell viability was determined by propidium iodide fluorometry and LDH release. To monitor mitochondrial Ca^{2+} and reactive oxygen species (ROS), myocytes were loaded with 2μM Rhod-2 and 10μM chloromethyldichlorofluorescin (DCF) diacetate for 20min at 37°C prior to reperfusion, respectively. Some cells were loaded with 1μM calcein for 20min at room temperature before ischemia to monitor onset of the MPT. DCF fluorescence was also assessed by a multiwell fluorometry. Confocal images of Rhod-2, calcein, DCF fluorescence were collected with a Zeiss LSM 410 microscope. **RESULTS:** Reoxygenation at pH 7.4 decreased cell viability to 40% after 2h (n=4). In contrast, reoxygenation at pH 6.2 or with CsA at pH 7.4 prevented cell killing. Confocal images of DCF and Rhod-2 revealed that mitochondrial ROS generation increased after reperfusion at pH 7.4 whereas mitochondrial Ca^{2+} remained unchanged. CsA did not block increased ROS formation after reperfusion, as measured by DCF fluorometry. The MPT occurred within 5min of reperfusion as assessed by confocal microscopy from the redistribution of mitochondrial calcein into cytosol, an event that was inhibited by CsA. **CONCLUSION:** The MPT is a key mechanism inducing pH-dependent reperfusion injury to myocytes. Mitochondrial ROS generation may also help trigger the MPT after reperfusion.

163 UPREGULATION OF ENDOTHELIN SYSTEM IS INVOLVED IN NICOTINE-INDUCED CARDIOTOXICITY IN RATS WITH ACUTE MYOCARDIAL INFARCTION.

Y. Li[1], L. Cai[1], Z. Zhou[1] and Y. Kang[1,2]. *[1]Medicine, University of Louisville, Louisville, KY and [2]Pharmacology & Toxicology, University of Louisville, Louisville, KY.*

The adverse effects of nicotine at the exposure level found in mild cigarette smokers on the pre-existing ischemic infarction myocardium are clinically concerned, but have received litter attention experimentally. Studies have shown that smokers had higher plasma concentrations of endothelins (ETs) than non-smokers, and ET elevation is implicated in heart failure in both humans and animal models. This study was undertaken to test the hypothesis that compromised heart has higher sensitivity to nicotine toxicity due to upregulation of the ET system. Adult rats weighing about 200 g were subjected to a surgery procedure of left coronary artery ligation to induce myocardial infarction (MI). A sham surgery was applied to control groups. Twenty-four hours after the surgery, a dose of 0.8 mg/kg nicotine, which has been shown to produce plasma concentrations of nicotine comparable to that found in mild cigarette smokers, was injected through tail vein in rats with acute MI along with sham-operated controls. The results showed that plasma total ET concentrations, determined by an ELISA assay, were significantly elevated in the nicotine-treated rats and ET receptor density, measured by an immunohistochemical assay, was markedly elevated in the MI heart. Importantly, a ventricular arrhythmia, in the form of premature ventricular complexes, occurred in the MI heart and nicotine significantly increased this incidence. Myocardial dysfunction as measured by an in situ cardiac performance analysis was also dramatically worsened in the MI rats after nicotine exposure. These results thus demonstrate that upregulation of ET system plays an important role in nicotine-induced cardiotoxicity and overexpression of ET receptors in the ischemic myocardium would make the heart more susceptible to the deteriorating effect of subsequent bursts of ETs by exposure to nicotine. (Supported in part by NIH grants HL 59225 and HL63760).

164 THE UTILITY OF THE HERG BINDING ASSAY TO ASSESS QT PROLONGATION AND A STRATEGY FOR THE DISCOVERY PROCESS.

E. Eddy. *Drug Safety and Disposition, Millennium Pharmaceuticals Inc., Cambridge, MA.* Sponsor: C. Alden.

Some drugs can cause QT prolongation, arrhythmias and occasionally torsades de pointes in humans. Drugs elicit QT prolongation by blocking the hERG channel carrying the IKr current.In vitro assays are currently utilized in preclinical studies to assess a compounds potential to interact with the hERG channel, the hERG binding assay being one. The objective was to test the utility of the hERG binding assay as a low-cost, high throughput screen to assess compounds with a potential to prolong QT *in vivo*. A set of 207marketed compounds were selected at random based on availability and purity. Membranes from HEK-293 cells stably transfected with hERG cDNA(from the University of Wisconsin, Zhou et al, 1998)were prepared and incubated with compounds ranging from 0.0016 uM to 10uM and ligand (3H-Dofetilide, 4 nM) in duplicate 96-well plates for 80 minutes at 22C. The percent inhibition of ligand uptake by the test compound was assessed by counting radioactivity in a Packard Topcount and an inhibiton Ki value determined. Of the 207 compounds, 181 (87%) were weak binders of the hERG channel (Ki>5uM) and except for four, did not have reports of QT prolongation in pateints (PDR). The four compounds were associated with rare incidences of QT prolongation (PDR) and thus false negatives (2%) in the hERG binding assay. Eleven of the 207 compounds were potent hERG binders (Ki <1 uM) and were associated with adverse QT prolongation problems in patients. The 14 compounds that were moderate binders (Ki's of 1 -5 uM) were associated with QT prolongation (PDR), and had other complexing factors such as other ion channel activity. Verapamil is a false positive in the assay as it also is a Ca++ channel blocker negating the hERG binding effects *in vivo*. Thus, with a concordance rate of >96%, the hERG binding assay is a useful tool as a first level high throughput screen to assess QT issues early in discovery and reduce attrition in development due to QT issues. A testing strategy was developed based on these results.

165 CYCLOSPORIN A PROTECTION AGAINST pH-DEPENDENT ISCHEMIA/REPERFUSION INJURY TO NEONATAL MYOCYTES: ROLE OF Ca^{2+} AND GLYCOLYSIS.

J. R. Blattner[1], W. E. Cascio[2] and J. J. Lemasters[1]. *[1]Curriculum in Toxicology, University of North Carolina, Chapel Hill, NC and [2]Department of Medicine, University of North Carolina, Chapel Hill, NC.*

In cardiac ischemia, ATP hydrolysis and lactic acid production by glycolysis cause a naturally occurring acidosis that protects against onset of necrotic cell death. pH protection is lost after reperfusion as pH returns to physiologic levels. Here, our aim was to assess the ability of cyclosporin A (CsA), an inhibitor of the mitochondrial permeability transition (MPT), to prevent pH-dependent ischemia/reperfusion (I/R) injury in isolated neonatal rat cardiomyocytes. Myocytes (4 to 8 days in culture) were exposed to 4 h of anoxia at pH 6.2 in Krebs-Ringers-HEPES (KRH) buffer to simulate ischemia. After anoxia, myocytes were re-oxygenated with KRH at pH 7.4 or 6.2 to simulate reperfusion. Cell killing was monitored by propidium iodide fluorometry using a fluorescence plate reader. At 1 mM Ca^{2+}, cell killing did not increase during ischemia but progressively increased to 47 ± 7% during 2 h of reperfusion. Reperfusion-induced killing was strongly dependent on Ca^{2+}, being nearly negligible with 0.2 mM Ca^{2+} and maximal with 1 mM Ca^{2+}. CsA blocked most I/R killing of myocytes in 0.5 to 1 mM Ca^{2+} but was only weakly effective at 1.5 and 2 mM Ca^{2+}, although reperfusion at pH 6.2 completely prevented cell killing at 2 mM Ca^{2+}. However, when myocytes were reperfused with CsA plus 20 mM glucose during reperfusion, protection against cell killing became virtually complete at all Ca^{2+} concentrations examined. This enhanced protection was lost if 2-deoxyglucose was used during the ischemic phase only to inhibit glycolysis. These results suggest that a CsA-sensitive MPT contributes to pH-dependent killing in

this model for I/R injury to neonatal cardiomyocytes, at least at $Ca^{2+} \leq 1$ mM. At higher Ca^{2+}, an unregulated, CsA-insensitive MPT may be occurring. Glucose may add to the protection afforded by CsA by decreasing intracellular ADP and Pi, compounds that promote MPT onset.

166 CONSIDERATIONS FOR ANESTHETIZED CARDIOVASCULAR SAFETY PHARMACOLOGY STUDIES: EFFECT OF ISOFLURANE ANESTHESIA ON HEART RATE AND QT INTERVAL IN THE CYNOMOLGUS MONKEY.

M. Vézina, C. Copeman and P. Shaver-Walker. *Infusion, Pharmacology and Neurotoxicology, CTBR, Senneville, QC, Canada.* Sponsor: D. Jones.

Isoflurane is a common anesthetic used in preclinical laboratories due to its relative safety and rapid recovery time. Though the current ICH S7a guidelines recommend use of a conscious model for cardiovascular safety pharmacology, there are instances where an anesthetized model is appropriate. In this comparison, systemic blood pressure and ECG (modified lead II) were obtained from 5 cynomolgus monkeys on 2 occasions using a DSI telemetry system or Schiller ECG recorder. On the first occasion, unrestrained animals were monitored in the conscious state for 24 hours and ECGs recorded every 30 minutes. On the second occasion, the same animals were anesthetized with Isoflurane/oxygen and ECGs were recorded every 15 minutes for 2 hours. As expected, heart rates (HR) were reduced and QT interval prolonged in the anesthetized state compared to the conscious state. However, the heart rate reductions and QT interval lengthening were not static during the 2 - hour anesthetized state. Over the course of 2 hours HR progressively declined by approximately 25% and QT progressively increased by 21%. The magnitude of these changes was relatively consistent between animals. This anesthetic-related effect can impact directly on the outcome of a study and should be considered when designing and interpreting anesthetized cardiovascular safety pharmacology studies. Using the anesthetized model over the course of several hours can lead to progressive cardiac depression that may obscure or enhance an effect on the QT interval, or the risk of an adverse reaction to a test material.

167 HOMOCYSTEINE INDUCES PROLIFERATION, STIMULATION OF ERK1/2 AND CALCIUM INFLUX IN VSMC, WHICH ARE INHIBITED BY THE NMDA RECEPTOR ANTAGONIST MK801.

G. Bennett, M. Solomon and T. H. Rosenquist. *Genetics, Cell Biology and Anatomy, University of Nebraska Medical Center, Omaha, NE.*

Homocysteine(HYC) is recognized as an independent risk factor for the development of atherosclerosis. However, the mechanism by which HYC acts remains unknown and controversial. Recent reports have suggested that the NMDA receptor may play a pivotal role in homocysteine-induced vascular effects. The current investigation was undertaken to better define the relationship between NMDA receptors and homocysteine in cultured vascular smooth muscle cells (VSMC). In these experiments VSMC were obtained from the thoracic aorta of male New Zealand White rabbits (2-4 months of age). Smooth muscle cells were cultured in supplemented media (M199 with Earle salts with L-glutamine and 10% FBS), which was changed every other day, and the cells were maintained at 37°C and 5% CO2. Initially it was determined that the NMDA receptors were present on VSMC. It was then demonstrated that HYC induced the proliferation of these cells, in a dose dependent manner. Experiments that were performed in the presence of MK801, an antagonist of the NMDA receptor, demonstrated a significant reduction in the amount of proliferation. One transduction pathway that mediates mitogenic activity is the mitogen-activated protein kinase (MAP-kinase) pathway. Therefore, we examine whether HYC could stimulate ERK1/2. VSMC were exposed to various concentrations of HYC (0-50uM) with or without 10uM MK801 for various durations (2, 30, 60 seconds, or 2, 5, 10 minutes). These experiments demonstrated that every concentration of HYC tested stimulated the phosphorylation of ERK1/2 at all time points. The activation of ERK1/2 was inhibited by PD98059, a specific inhibitor of ERK1/2 phosphorylation. Similarly, the phosphorylation of ERK1/2 was inhibited by MK801. HYC also stimulated an influx of Ca+2 in VSMC, which was inhibited by MK801. Therefore, HYC induces proliferation of VSMC *via* the MAP-kinase pathway, which appears to be mediated by NMDA receptors. Support for this research was provided by NHLBI grant # 5RO1HL58969-03

168 BACKGROUND HEART RATE AND QT INTERVAL DATA IN THE ANESTHETIZED BEAGLE DOG.

P. Shaver-Walker, M. Vézina and C. Copeman. *Infusion, Pharmacology and Neurotoxicology, CTBR, Senneville, QC, Canada.* Sponsor: D. Jones.

The use of an anesthetized model for cardiovascular safety pharmacology can lead to confounding results. For this reason, the ICH S7a guideline thus suggests the use of a conscious model, however, if a test material is intended to be administered under anesthetic, or severe clinical signs prevent the achievement of a suitable safety factor in the conscious model, the anesthetized model can be considered a suitable alternative. Typically, the anesthetized model requires the animals to be under anesthetic for a considerable amount of time to allow for instrumentation, stabilization and several doses of control and test material (eg up to 12 hours). This background data represents 8 beagle dogs that had been under Isoflurane/oxygen anesthesia for approximately 6 hours prior to 4 further hours of monitoring. ECGs were obtained at 15-minute intervals for the first hour, followed by 30 minute intervals for the remaining 3 hours. The effects on heart rate and QT interval over the 4 hour monitoring period were quite variable among dogs. Some individuals exhibited little cardiac depression and remained stable - even comparable to conscious dogs but the majority exhibited varying magnitudes of slowly progressive heart rate reduction and QT interval prolongation. The impact of long-term anesthesia on these critical safety parameters should be considered when choosing a conscious or anesthetized model and also when designing and interpreting data from anesthetized dogs.

169 MECHANISMS OF ARSENIC TOXICITY IN VASCULAR DEVELOPMENT.

W. He, M. Bunderson, H. D. Beall and J. D. Coffin. *Center for Environmental Health Sciences, The University of Montana, Missoula, MT.*

Arsenic is an abundant toxin in ground water and soil around areas with extractive industries. Exposure to arsenic is linked to several developmental defects in the nervous system and limbs, pregnancy complications and miscarriage. Vascular defects are often the underlying basis for limb deformations and developmental anomalies in other systems and vascular abnormalities often form the basis for placentation defects linked to miscarriage. The overall goal of this project was to define the developmental mechanisms for how arsenic exposure causes developmental defects and miscarriage, and to characterize the molecular mechanisms for arsenic mediated alteration of endothelial cell physiology. We hypothesize that arsenite toxicity causes defects in vascular development, predisposing the embryo to other developmental anomalies and miscarriage. The aims are: 1 Determine how arsenite exposure affects angiogenesis *in vitro*. Cultured bovine aortic endothelial (BAE) cells on Matrigel were exposed to 0, 10 um, 20 um, 50 um, 100 um arsenite for 7 days. The data suggest that increasing concentrations of arsenite inhibits angiogenesis *in vitro*. 2. Characterize the effects of arsenite exposure on embryonic mice and vascular development. Timed-pregnant FVB/NJ mice were exposed to 1 ppm, 75 ppm and 150 ppm arsenite in their drinking water for duration of pregnancy and until weaning (21 days). Litter size was recorded and pups were weighed weekly. The data suggest that there were no significant differences observed in either litter size or pup weight for arsenite exposures of 1 ppm. However, there were significant differences for 75 ppm exposures. Arsenite exposures of 150 ppm were toxic to pregnant females, but not control (non-pregnant) females; suggesting that pregnancy may cause increased sensitivity to arsenic exposure.

170 TELEMETRY MONITORING OF CARDIOVASCULAR AND RESPIRATORY FUNCTION IN MALE CYNOMOLGUS MONKEYS.

T. W. Beck, T. Kamenosono, D. Aïssat, S. Meyer, K. Fukuzaki and R. Nagata. *SNBL USA, Ltd.,, Everett, WA.*

A primate telemetry system (Open-A.R.T./Ponemah: DSI/Gould) was evaluated and compared to conventional systems for monitoring cardiovascular and respiratory function in male cynomolgus monkeys surgically implanted with a telemetry transmitter (TL11M2-D70-PCT). The animals were sedated, surgically prepared and maintained on isoflurane gas anesthesia. A calibrated transducer was used for direct blood pressure and heart rate comparisons. The transducer catheter was inserted through the contralateral femoral artery to approximately the same location in the dorsal aorta as the telemetry catheter. A Vetronics VitalScan system was used for ECG and temperature monitoring. All ECGs were over-read. A trained observer performed direct respiratory count. Each animal was subjected to the following stimuli: Elevated temperature, mechanical ventilation, epinephrine, Dopram V (R) and sodium pentobarbital. Parameters were evaluated before and after the various manipulations. Telemetry files were analyzed for systolic and diastolic blood pressure, heart rate, respiratory rate, temperature and ECG parameters. Blood pressure comparison revealed a high correlation coefficient (r=0.99) for both systolic and diastolic blood pressure with pressures fluctuating from 196 to 31 mmHg following epinephrine or sodium pentobarbital respectively. Heart rate was directly correlated to the transducer pulses (r=0.99). Printed ECG waves evaluated by a veterinary cardiologist revealed a high degree of accuracy on both systems used. All ECG parameters were highly correlated (r=0.90 to 1.00) to the manual measurements. The telemetry system accurately measured mechanical ventilation, hyperventilation, apnea, shallow respiration and transitory increase in respiratory rate following Dopram V (R) infusion. The overall correlation coefficient for respiration was r=0.95. In conclusion, the telemetry system was able to monitor and accurately report cardiovascular and respiratory parameters over the expected range of physiological values.

171 CARDIOTOXICITY STUDY OF NSC-638850 (UCN-01) AND CYTOSTAR (ARA-C) GIVEN ALONE OR IN COMBINATION TO BEAGLE DOGS.

M. Stonerook[1], C. Hassler[1], P. Tosca[1], J. Merrill[1], D. Vasconcelos[1] and A. Smith[2]. *[1]Battelle Memorial Institute, Columbus, OH and [2]National Cancer Institute, Bethesda, MD.* Sponsor: M. Brooker.

Combination chemotherapy with multiple drugs is commonly used in cancer therapy. This study evaluated the cardiotoxicity of the chemotherapeutics UCN-01 and Ara-C given individually or in combination. Pairs of dogs were infused intravenously for up to 96 hours with vehicle, 1.2 mg/kg UCN-01, 5.0 mg/kg Ara-C or combinations of UCN-01/Ara-C at 1.2/2.5 mg/kg, and 1.2/5.0 mg/kg. Caridiotoxicity parameters evaluated included blood pressure, heart rate, ECGs, body temperatures, clinical pathology, and histopathology. All but one of the dogs exposed to UCN-01 alone or in combination were euthanized in a moribund condition. Clinical signs included lethargy, thin, pallor and mucoid feces. Body temperatures were increased in all animals receiving UCN-01. Persistent post-exposure cardiovascular evaluations in animals exposed to UCN-01 or UCN-01/Ara-C included increased heart rate, attributed to a decrease in blood pressure, and decreased systemic blood pressures, possibly due to a negative inotropic effect, a decrease in preload or vascular resistance, venodilation or a combination thereof. ECGs of several animals exposed to UCN-01/Ara-C exhibited J-point depression, which has attributed to subendocardial changes noted in the ventricular free wall. The heart rate changes and decreased systemic blood pressure were not seen in the Ara-C group. No changes in ECGs were seen in the animals exposed to either the Ara-C or UCN-01 group. Histopathology revealed UCN-01-related necrosis and inflammation of veins, injection sites, and medium-sized arteries, which were possibly related to caustic action. Additional UCN-01-associated lesions included depletion of gut-associated lymphoid tissue, atrophy of lymph nodes, and infiltration of neutrophils in the mantle zone of splenic lymphoid follicles. Conducted under contract N01-CM-87028, Division of Cancer Treatment of the National Cancer Institute.

172 ALLYLAMINE INDUCES VASOSPASM IN HUMAN CORONARY ARTERY BYPASS GRAFT BLOOD VESSELS *IN VITRO*: ROLE OF SEMICARBAZIDE-SENSITIVE AMINE OXIDASE.

D. J. Conklin[1], D. Kranig[1], H. Mueller[1], G. Johnson[2], R. Wiechmann[2], M. Trent[3] and P. J. Boor[3]. *[1]Biology, University of Wisconsin-Eau Claire, Eau Claire, WI, [2]Cardiothoracic Surgery, Luther Hospital, Eau Claire, WI and [3]Pathology, Uiversity of Texas Medical Branch, Galveston, TX.*

Allylamine (AA) is a cardiovascular toxicant that produces rat coronary artery vasospasm *in vitro*. To test the applicability of this model for human vasospasm, we exposed uncontracted and norepinephrine-precontracted (NE, 1 μM) human coronary artery bypass graft (CABG) blood vessels (internal mammary artery, IMA; radial artery, RA; saphenous vein, SV) to AA (1-1, 000 μM) *in vitro*. AA (1-100 μM) stimulated concentration dependent relaxations in precontracted IMA and RA or contractions in precontracted SV, but induced vasospasm at 1 mM in all three blood vessels. Vasospasm was defined as a sustained hypercontracture with intractability (inability to relax). About 5 min after addition of 1 mM AA, vessel tension increased rapidly and at times exceeded 300% of the NE-precontraction tension. Vasospasm was intractable as evidenced by significant maintenance of NE-induced tension following 3 buffer changes over >30 min. Vasospasm and intractability were both significantly blocked by the pretreatment of IMA with 1 mM semicarbazide implicating semicarbazide-sensitive amine oxidase (SSAO) enzyme activity in AA-induced vasospasm. The presence of CABG blood vessel SSAO activity was confirmed by radiometric assay. Naïve IMA were also exposed to either AA, benzylamine (BZA) or methylamine (MA) for comparison. Both BZA and MA are known SSAO substrates and each produced concentration dependent relaxations in NE-precontracted IMA without incidence of vasospasm or intractability. Thus, AA produces vasospasm in human CABG blood vessels *via* an SSAO-dependent pathway, and acrolein is a likely candidate for mediating vasospasm. This work supported by the ORSP at the UWEC and NIEHS #1 R15 ES011141-01.

173 INHIBITION OF PEROXYNITRITE-INDUCED DAMAGE IS INVOLVED IN METALLOTHIONEIN PREVENTION OF DIABETIC CARDIOTOXICITY.

L. Cai[1], X. Sun[1], Y. Li[1], L. Wang[1] and Y. Kang[1,2,3]. *[1]Medicine, University of Louisville, Louisville, KY, [2]Pharmacology & Toxicology, University of Louisville, Louisville, KY and [3]Jewish Hospital Heart and Lung Institute, Louisville, KY.*

Previous studies have shown that oxidative stress caused by superoxide accumulation and peroxynitrite-induced injury is a major cause of diabetic cardiotoxicity, and metallothionein (MT) protects the heart from various oxidative injuries. In the present study, cardiac-specific MT-overexpressing transgenic (MT-TG) mice were used to investigate the role of MT in prevention of diabetic cardiotoxicity. Diabetes was induced by streptozotocin (STZ). Both MT-TG and wild-type (WT) mice were induced the same diabetic manifestations including increased blood glucose, glycated hemoglobin (HbA1), serum lipid peroxidation, increased renal weight, and decreased body-weight gain. However, serum creatine phosphokinase (CPK) activity, an indicator of cardiotoxicity, was increased in the WT diabetic mice, not in the MT-TG diabetic mice. Myocardial pathological changes examined by light and electron microscopy, along with cardiac dysfunction assessed by cardiac hemodynamic analysis, were observed in the WT diabetic mice. These cardiac pathological and functional changes were almost completely inhibited in the MT-TG diabetic mice. Correspondingly, peroxynitrite-induced damage detected by 3-nitrotyrosine and the accumulation of superoxide also significantly increased in the WT-diabetic hearts, but not in the MT-TG diabetic hearts. Furthermore, *in vitro* studies have shown that MT directly interacts with peroxynitrite and prevents peroxynitrite-induced lipid and protein damage. These results thus demonstrated that MT prevents the early-phase diabetic cardiotoxicity most likely by suppression of oxidative damage in the myocardium. (Supported by NIH, ADA, Philip Morris, Jewish Hospital Research Foundation and University of Louisville School Medicine)

174 APPLICATION OF REACTION NETWORK MODELING TO A PRIORITY CARCINOGENIC ENVIRONMENTAL POLLUTANT, BENZO(a)PYRENE.

K. H. Liao[1,2], W. Wei[3], M. T. Klein[3], K. F. Reardon[1,2] and R. S. Yang[1]. *[1]Quantitative and Computational Toxicology Group, Center for Environmental Toxicology and Technology, Colorado State University, Fort Collins, CO, [2]Department of Chemical Engineering, Colorado State University, Fort Collins, CO and [3]Department of Chemical and Biochemical Engineering, Rutgers, The State University of New Jersey, Piscataway, NJ.*

Reaction Network Modeling (RNM) is a new approach for predicting the complex biotransformation pathways of xenobiotics. The reaction network is automatically generated based on the chemical structures of the parent compound and reaction rules. Graph theory is used to encode chemical structures and reaction rules at the molecular level. Benzo[a]pyrene (BaP) was used as the substrate for the first application of RNM to biochemical reactions since it is a human carcinogen as well as an ubiquitous environmental pollutant. The reactions used in this model include epoxidation of double bonds, epoxide hydrolysis, NIH shift of arene oxides to phenols, and oxidation of phenols to quinones. RNM provided good predictions for the time course profiles of BaP metabolites from data reported by Gautier et al. (*Chem Res Toxicol*, 1996, *9*:418-425). The rate constants of BaP RNM were further measured by biotransformation studies using purified human cytochrome P450 1A1 and epoxide hydrolase. HPLC methods were used to analyze 12 BaP metabolites including dihydrodiols, phenols, tetrols, and quinones with average detection limit in the nM range. The rate constants of BaP biotransformation measured by experiments were then used to establish quantitative structure/reactivity correlations (QSRCs). When RNM is applied to other chemicals, QSRCs can be used to predict their rate constants based on quantum chemistry. The top candidates for further application of RNM are the air pollutants benz[a]anthracene and benzo[b]fluoranthene. From there, RNM could be used to predict the complex reaction networks arising from exposure to mixtures of polycyclic aromatic hydrocarbon air pollutants that result from incomplete combustion of petroleum fuels. This work was supported by NIEHS Grant # R01 ES09655.

175 A REACTION NETWORK MODEL FOR CYP2E1-MEDIATED METABOLISM OF TOXICANTS.

B. Reisfeld[1,2], K. Reardon[2] and R. Yang[1]. *[1]Environmental and Radiological Health Sciences, Colorado State University, Fort Collins, CO and [2]Chemical Engineering, Colorado State University, Fort Collins, CO.*

One of the principal catalysts in the Phase I metabolism of toxicants is cytochrome P450-2E1 (CYP2E1). Substrates for this isozyme include low molecular weight, hydrophobic and carcinogenic species such as benzene, chloroform, carbon tetrachloride, vinyl chloride, and trichloroethylene. Metabolism of chemical substrates and substrate mixtures often involves complex reactions in which the species associated with one reaction are constituents of numerous other reactions. This interdependent, coupled set of reactions can be thought of as a 'reaction network', and can occur for even relatively simple systems. The objective of this project is to develop a computer-based biochemical reaction network modeling framework that can create detailed and accurate predictions of the interlinked networks and kinetics resulting from CYP2E1-mediated metabolism of both pure species and chemical mixtures. To carry out this task, the modeling tool comprises a number of software modules, each of which is responsible for a separate 'phase' of the simulation. These phases

include testing of substrate binding feasibility, performing virtual chemistry to predict intermediate and product species, formulating reaction rate equations, constructing the network topology, and computing the reaction kinetics and time-dependent species concentrations. To date, this framework has predicted the reaction networks for the metabolism of several of the compounds on the CERCLA Priority List of Hazardous Substances that are catalyzed by CYP2E1. When fully realized, we expect this modeling methodology to be an important addition to the toolkit for investigators seeking to quantify the impact of chemicals and chemical mixtures on human health. This work was supported by a Mentored Quantitative Research Career Development Award to B. Reisfeld from the National Institutes of Health (NIEHS K25 ES11146-02).

176 A MATHEMATICAL MODEL TO DETERMINE *IN VITRO* CLEARANCE IN THE SANDWICH RAT HEPATOCYTE CULTURE.

N. Treijtel[1], J. C. van Eijkeren[2], M. van den Berg[1] and B. J. Blaauboer[1]. *[1]Institute for Risk Assessment Sciences, Utrecht University, Utrecht, Netherlands and [2]National Institute of Public Health and Environment, Bilthoven, Netherlands.*

For risk assessment it is important to have knowledge of the kinetics of a compound. *In vitro* kinetics can be extrapolated to *in vivo*kinetics using physiologically based pharmacokinetic models. To determine the *in vitro* clearance of slowly metabolized compounds, long-term systems such as the sandwich hepatocyte culture are preferred over the more commonly used short-term systems, such as microsomes, liver slices, hepatocyte suspensions and primary cultures. Since the hepatocytes in a sandwich culture are located between two layers of collagen, the upper collagen layer will form a transport barrier between medium and cells. To determine *in vitro* clearance, these molecular diffusion coefficients as well as protein binding should be taken into account. A mathematical model was developed in which these processes were incorporated using a mechanistic approach. The 'non-stirred sandwich model' was evaluated using the slowly metabolized compound tolbutamide as a reference. Tolbutamide was added to the sandwich cultures; subsequently the decrease of tolbutamide and the increase of its metabolites were measured over time. Molecular diffusion coefficients and protein binding were determined in separate experiments. Using the non-stirred model *in vitro* clearance was calculated to be 2.4 µl/min. This finding was in accordance with experiments in which the clearance of tolbutamide was determined in liver slices using a similar approach. In conclusion, the *in vitro* clearance of tolbutamide can be determined in sandwich hepatocyte cultures using the mathematical approach described above.

177 PARAMETERIZATON OF A BIOLOGICALLY BASED KINETIC (BBK) MODEL OF THE ISOLATED PERFUSED RAT LIVER (IPRL): BROMOSULPHOPHTHALEIN (BSP) AND CADMIUM (CD) KINETICS.

J. Gearhart[1], B. Foy[2], A. Soto[1], E. Ebel[1] and J. Frazier[1]. *[1]AFRL/HEST, Dayton, OH and [2]Wright State University, Dayton, OH.*

A previously developed BBK model (Foy et al., Toxicol.Sci. 50:20-29, 1999) was parameterized with experimental studies of clearance for BSP, the BSP glutathione conjugate (BSP-GSH), or Cd, in the IPRL. The goal of this work is to provide a mathematical structure for exploring the mechanisms governing the kinetics of water soluble compounds, using the IPRL and *in vitro* data, to make predictions in the whole animal system. To parameterize the model, *in vitro* data were collected for the binding and S-9 metabolism of BSP to BSP-GSH. Proper incorporation of *in vitro* metabolic data into the IPRL BBK analysis required the determination of albumin binding of BSP. Also, non-enzymatic conjugation of BSP contributed significantly to the overall metabolism of BSP, and was incorporated into the enzymatic analysis. IPRL studies were conducted with BSP clearance under various physiological conditions, including a range of starting concentrations. To experimentally simulate choleostasis, the bile duct was ligated and the effects on BSP kinetics in the perfusate were followed over time. Cd kinetics in the IPRL were studied at two different albumin concentrations, 0.25% and 4%, to modulate the levels of free Cd available in *in vitro* and *in vivo* experiments. Starting concentrations for these studies ranged from 10 to 1000 µM, depending on the particular albumin concentration being employed. Comparison of the calculated free Cd in the perfusate and the onset and degree of cessation of bile flow, provided the basis for understanding critical mechanisms of Cd kinetics for BBK model development. IPRL kinetic studies starting with the BSP-GSH conjugate were conducted to allow for BBK model parameterization of the conjugate for better tracking of conversion of BSP parent to the metabolite. Parameterization of the BBK model for BSP and Cd allowed analysis of other IPRL studies with these compounds and provided verification of the general model structure.

178 A NONSTEADY STATE MODEL FOR THE TIGHT-BINDING INHIBITION OF THYMIDYLATE SYNTHETASE BY 5-FLUOROURACIL.

R. S. DeWoskin[1] and R. W. Setzer[2]. *[1]ORD/NCEA, USEPA, Research Triangle Park, NC and [2]ORD/NHEERL, USEPA, Research Triangle Park, NC.*

5-Fluorouracil (5-FU) is a widely used chemotherapeutic drug and teratogen that was chosen as a prototypic toxicant to construct a biologically based dose-response (BBDR) model (Setzer et al., 2001). Part of the BBDR model simulates the inhibition of thymidylate synthetase (TS), an essential enzyme for DNA synthesis. TS methylates deoxyuridine monophosphate (dUMP) to form thymidine monophosphate (dTMP). A metabolite of 5-FU, fluorodeoxyuridylate (FdUMP), inhibits TS by forming a tight-binding complex. The resulting low level of dTMP leads to adverse effects on cell growth and morphology. The FdUMP/TS inhibition model needed to: 1) account for an observed 3-5 hour delay between peak 5-FU blood concentration and peak TS inhibition; and 2) simulate the recovery of TS activity that occurs within 24-48 hours following a bolus 5-FU dose. A steady state model for a tight-binding inhibitor provided an initial simulation of both the delay in peak inhibition and the recovery of TS activity. The steady state model simulates the competition between FdUMP and the endogenous dUMP substrate for free TS binding sites. Nonsteady state conditions, however, result from a constitutive increase in TS and dUMP as well as potential up-regulation of TS. A nonsteady state model was developed that provided a better fit of the data. The nonsteady state model requires considerably more kinetic data to develop the microconstants for the different reaction rates, and the parameters for the constitutive increases in substrate and TS levels. The nonsteady state model, however, offers more heuristic value and insight into how alterations in enzyme and natural substrate levels affect the apparent rate of enzyme inhibition and recovery. The apparent concentration-time curve for the toxic metabolite, FdUMP, also depends upon dUMP and TS levels. Consideration of these variables leads to a better understanding of the mechanisms underlying nonlinear dose-response curves and thresholds for adverse effects. [This abstract does not necessarily reflect EPA policy.]

179 EVALUATION OF INTERSPECIES VARIABILITY DURING NEOCORTICAL NEUROGENESIS USING BIOLOGICALLY BASED COMPUTATIONAL MODELS.

J. M. Gohlke, W. C. Griffith and E. M. Faustman. *Institute for Risk Analysis and Risk Communication, University of Washington, Seattle, WA.*

From an evolutionary perspective, neocortical expansion is a hallmark of human speciation which has been functionally linked to the social and intellectual evolution of humans. We are investigating approaches for evaluating cross-species differences in neocortical development and its responsiveness to environmental injury. Neocortical neurogenesis is a critical sensitive window for numerous human neurodevelopmental toxicants including radiation, methyl mercury, and ethanol. The final number of neocortical neurons generated depends on several factors including the number of founder cells at the beginning of neurogenesis, the rate of cell division, the duration of neurogenesis, the modes of cell division (proliferative or terminal), and finally the extent of cell death. Here we build on a previously developed rodent neocortical neurogenesis computational model to quantitate the differences in rodent versus primate (rhesus monkey) neurogenesis to build our novel primate neocortical model. The genesis of neurons for the rodent neocortex takes approximately 6 days and 11 cell cycles, primate neocortical neurogenesis can span 60 days and 28 division cycles. Furthermore, while the rodent cell cycle lengthens as neurogenesis progresses, the cell cycle length decreases with time in the rhesus monkey. Simulations suggest the large increase in duration and total neuron output of neocortical neurogenesis in the primate model can increase the suseptibility of the primate neocortex to neurodevelopmental toxicants effecting neurogenesis. Adding mechanistic data on ethanol induced cell cycle inhibition into our primate neocortical neurogenesis models shows a greater deficit in total neuron number is predicted in the adult primate neocortex compared with the rodent neocortex. These preliminary results highlight the important role of computational modeling in quantitating interspecies differences in toxicodynamic processes.

180 EFFECTS OF DIFFERENCES IN NASAL ANATOMY ON AIRFLOW DISTRIBUTION: A COMPARISON OF THREE INDIVIDUALS.

R. Segal[1], G. M. Kepler[2], D. L. Kalisak[1], R. B. Richardson[1] and J. S. Kimbell[1]. *[1]CIIT Centers for Health Research, Research Triangle Park, NC and [2]Consultant, Chapel Hill, NC.*

Differences in nasal anatomy and respiratory airflow patterns between different human individuals may cause significant differences in the regional dose of inhaled gases in the nasal passages and subsequently the lung. For water-soluble, reactive gases, nasal surface area and volume may be predictors of nasal scrubbing efficiency,

which can be estimated using computational fluid dynamics (CFD) models. To construct such models, MRI scans of the head were digitized for a number of individuals in a study led by Dr. Ray Guilmette and the Lovelace Respiratory Research Institute, and nasal surface area and volume were calculated. Three individuals were selected whose ratio of nasal surface area to volume (SAVR) represented low and high values: Subject A = 0.74, Subject 14 = 0. 94, and Subject 12 = 1.03. Nasal CFD models for these individuals were constructed by a semi-automated process that provides input to a commercial mesh generator (Gambit, Fluent, Inc., Lebanon, NH). Steady-state inspiratory airflow at 7.5 L/min was calculated using commercial CFD software (FIDAP, Fluent, Inc., Lebanon, NH). Ventral, middle, and dorsal flow allocation percentages were computed for each subject. Flow in Subject 12 favored ventral over middle (48% versus 34%) whereas flow in Subjects A and 14 favored middle over ventral (55% and 58% versus 37% and 39%, respectively). In all three cases, dorsal flow was the lowest of the three regions. More swirling flow in both the vestibule and the nasopharynx was evident in Subjects A and 14 than in Subject 12. These simulations indicate that there are interindividual differences in bulk airflow patterns in the nose. Concurrent studies are focusing on the effects of inhaled gas uptake based on these flow simulations. These studies will test the dependence of potential regional dose differences and nasal uptake efficiencies on SAVR.

181 EFFECTS OF DIFFERENCES IN NASAL ANATOMY ON UPTAKE OF INHALED GASES: A COMPARISON OF THREE INDIVIDUALS.

J. S. Kimbell[1], R. A. Segal[1], D. L. Kalisak[1], R. B. Richardson[1] and G. M. Kepler[2]. *[1]CIIT Centers for Health Research, Research Triangle Park, NC and [2]Consultant, Chapel Hill, NC.*

Differences in nasal anatomy, airflow, and patterns of uptake and deposition among different human individuals may cause significant differences in the regional dose of inhaled gases, vapors, and particles in the nasal passages and subsequently the lung. Computational fluid dynamics (CFD) models can quantify the contribution of anatomical variation to risk assessment uncertainty and reduce the reliance on default uncertainty values. For water-soluble, reactive gases, nasal surface area and volume may be predictors of nasal scrubbing efficiency. To test this hypothesis, MRI scans of the head were digitized for a number of adult individuals by Dr. Ray Guilmette and the Lovelace Respiratory Research Institute, and nasal surface area and volume were calculated. Three subjects were selected whose ratio of nasal surface area to volume (SAVR) represented a range of values: 0.74, 0.94, and 1.03 for Subjects A (male), 14 (male), and 12 (female), respectively. Anatomically-realistic CFD models for the nasal passages of these individuals were constructed by a semi-automated process that provided input to a commercial mesh generator (Gambit, Fluent, Inc., Lebanon, NH). Steady-state inspiratory airflow at 7.5 L/min and inhaled gas uptake were simulated for a reactive, water-soluble, low-molecular-weight gas using commercial CFD software (FIDAP, Fluent, Inc., Lebanon, NH). Nasal uptake efficiency was estimated to be 95, 97 and 98% for the highest, middle, and lowest SAVR individuals, respectively, indicating that overall uptake was not highly sensitive to SAVR. Uptake efficiency in the nasal vestibule was higher in Subjects A and 14 than 12, and higher in the turbinate region in Subject 12 than Subjects A and 14, suggesting that SAVR should be calculated regionally. These studies and their extension to additional individuals form a basis for developing an empirical means of characterizing populations that may be at a higher risk for developing respiratory tract effects than the general population.

182 BUILDING BBDR MODELS FOR CELL SIGNALING PATHWAYS USING TRANSGENIC ANIMAL MODELS.

W. C. Griffith, J. M. Gholke, T. A. Lewandowski, M. C. Mendoza, R. A. Ponce and E. M. Faustman. *Institute for Risk Analysis and Risk Communication, University of Washington, Seattle, WA.*

We have developed a Biologically Based Dose-Response (BBDR) model utilizing stochastic processes to describe the interaction of p21 and contaminant exposure to methylmercury (MeHg) during fetal development. The model was developed using data from a previously published study (Mendoza, et al., TAP 178(2), 117-125, 2002) of transgenic mouse fetal fibroblasts, p21(+/+), p21(+/-), and p21(-/-), collected at gestation day 14 and cultured for 3-4 passages before exposure. The BBDR model examines the role of p21 cell signaling pathways in cell cycle checkpoints, and how the fraction of cells in different parts of the cell cycle are altered by doses of 0, 2, 4 and 6 μM MeHg at 24 and 48 hours after exposure. Multiple passages through the cell cycle after exposure to MeHg were measured by flow cytometry using double labeling with Hoescht 33258 and ethidium bromide. Cytoxicity was quantified using an LDH assay. The cell cycle is regulated by a number of proteins that have redundant and cross-talk pathways. Using a BBDR model of transgenic p21 animals allowed us to bound of the influence of p21 pathways on the the MeHg induced cell cycle inhibition. The results show that p21 alters the dynamics of MeHg inhibition of the cell cycle. After exposure to 6 μM MeHg the p21 null (-/-) cells had 85% lower rates of inhibition than the p21(+/+) cells and 65 % lower than the p21(+/-) cells at G1 checkpoints. Lower doses of MeHg had intermediate rates of inhibition in a dose dependent manner. However p21 status had no effect on G2/M accumulation induced by MeHg. 183 TUMOR INCIDENCE IN HUMANS AND RODENTS: EFFORTS TO RECONCILE THE OBSERVED DATA WITH BBDR MODEL PREDICTIONS.

C. S. Wells[1], L. R. Rhomberg[1] and T. A. Lewandowski[2]. *[1]Gradient Corporation, Cambridge, MA and [2]Gradient Corporation, Seattle, WA.*

Because human carcinogenic potency is most often estimated from animal bioassay data, understanding potential species differences in the carcinogenic process is a critical need in risk assessment. We compared human tumor incidence data from the Surveillance, Epidemiology and End Results (SEER) database of the National Cancer Institute to the incidence of spontaneous tumors in control animals reported in the Toxicology Database Management System (1974 to 1995) of the National Toxicology Program. Tumors strongly associated with environmental or lifestyle factors (e.g., lung or skin tumors) were not included. Rates of fatal tumors, which occurred prior to the conclusion of the rodent studies, were compared with lifetime tumor risks reported in humans, which are calculated as the primary cause of disease, death or disability. The tumor incidence in humans and laboratory rodents was found to be relatively similar. For example, the background lifetime probability of being diagnosed with a liver tumor in the US during 1997-1999 was approximately 0.6% whereas the corresponding probabilities in rats and mice were approximately 2% and 34%, respectively. The cross-species similarity was also observed for other tumor sites. These results are inconsistent with the results of biologically-based tumor incidence models. For example, when the approach of Kopp-Schneider et al. (1994) is used to predict tumor incidence in mice, rats and humans, the predicted lifetime probability of liver tumors in humans exceeds that in rodents by a factor of over 1 million. Previous work we have conducted suggests that model inputs (e.g., rates of cell division, death and mutation) are similar across species and would not reconcile model predictions with observed tumor incidences. We therefore consider information on other species-specific differences (e.g., telomere length, DNA methylation) which are not explicitly incorporated in most BBDR models but may be of use for explaining the observed inter-species patterns in tumor incidence.

184 QUANTITATIVE STRUCTURE ACTIVITY RELATIONSHIP (QSAR) EVALUATIONS OF THE PHARMACOLOGY AND TOXICOLOGY OF HISTONE DEACETYLASE INHIBITORS.

U. Schramm[1], H. Thomas[2], P. Atadja[2], S. Remiszewski[2] and A. Wolf[1]. *[1]Integrative Compound and Product Profiling, Novartis Pharmacology AG, Basel, Switzerland, Switzerland and [2]Oncology Research, Novartis Pharmacology AG, East Hanover, NJ.*

Histone deacetylation is a fundamental step in cancer cell division. Thus histone deacetylase inhibitors (HDAIs) are potential targets for cancer therapy. In order to gain more information on the correlation betweeen chemical structure and pharmacological and toxicological molecular mechanisms, experimental data were analysed by means of QSARISTM (SciVision). In this study data from 95 HDAIs were analysed concerning the pharmacological activities, HDA-enzymatic activity, p21 activation as well as growth inhibition of the tumour cell lines HTC116 and H1299. The impairment of the spontaneous frequency of contraction of rat cardiomyocytes and the ability of HDAIs to inhibit the Angiotensin II-induced contraction of rat thoracic aortic rings (RTAR) were used as *in vitro* toxicological endpoints. A maximum of 227 molecular 2D descriptors (e.g., topological and electrotoplogical indices) descriptors were employed with the generic algorithm function (GAF). All QSAR models were done *via* Multi-linear Regression (MLR) fitting except one, where Partial Least Squares (PLS) was employed. The resultant R2 values for four bioactivity parameters (HDA-inhibition, p21 activitation, RTAR IC25, and growth inhibiton of HCT116 cells) ranged from 0.75 to 93 with corresponding Q2 values of 0.69 and 0.9 respectively. Likewise, the analysis pinpointed important E-State atom types (9) as well important bulk descriptors (e.g. LogP). Use of an E-State similarity search based on one compound with high HDAI activity/low toxicity identified a grouping of four similar compounds with close similarity (i.e., cosine coefficient ranged from 0.91 to 0.98) as opposed to reduced similarity of four other compounds (0.74 to 0.88) with high toxicity and high activity. The results of the present study suggest that QSARISTM is a powerfull tool to analyse pharmacological-toxicological *in vitro* data in order to gain more insight into the underlying molecular mechanisms of action.

185 QUANTITATIVE MECHANISTIC MODELING OF MIXTURE INTERACTIONS: AN APPROACH FOR MANGANESE (Mn) AND ORGANOPHOSPHATES (OPs).

P. Robinson, J. M. Gearhart and E. A. Merrill. *ManTech GeoCenters Joint Venture, Air Force Research Laboratory, Dayton, OH.*

Traditional approaches to analyzing health effects of chemical mixtures often involve the prediction of interactions between more than one environmentally relevant chemical and their combined impact vis a vis exposure to the individual chemicals. These approaches center on dose-response analysis and lead to the development of such concepts as dose or response additivity, synergism and antagonism. While useful, such approaches have limitations, as discussed in the recent NIOSH/NORA Mixed Exposures Research Agenda (HHS/CDC, Draft July 2002). We propose an alternative approach beginning with the analysis of a specific multifactorial disease (such as gulf war syndrome or vCJD) of complex etiology with significant environmental or occupational influence. Key environmental components can be identified by from epidemiological studies, cluster analyses, and many other rapidly developing bioinformatics tools. An existing hypothesis for the ontogeny of BSE and vCJD is based on exposure to high levels of OP pesticides and Mn, together with low endogenous copper and other co-factors, which may lead to conformation changes in specific brain proteins (Purdey, Medical Hypotheses 57, 29-45, 2001). This model qualitatively explains a number of epidemiological observations, and is supported by *in vitro* studies (Brown et al., EMBO Journal 19, 1180, 2000). However, to further validate this model and to apply it to risk assessment, target site dosimetry of key components and chemical interactions must be quantitatively predicted. Only then can testable extrapolations to other exposure scenarios be made. Therefore, we have combined previously developed PBPK models for Mn and OPs in rodents and humans (Andersen et al., NeuroToxicology, 20, 161, 1999; Gearhart et al., Environ Health Perspect, 102 (Suppl 11), 51, 1994) and modified them to account for chemical interactions and multiple exposure scenarios. By including chemical and mechanistic information, these models can provide quantitative predictions of target site dosimetry and potential combined health effects.

186 FROM CONCENTRATION TO DOSE: FACTORS INFLUENCING AIRBORNE PARTICULATE MATTER DEPOSITION IN HUMANS AND THE RAT-HUMAN DOSE EXTRAPOLATION.

F. Cassee and R. de Winter - Sorkina. *Center for Environment and Health Research, National Institute for Public Health and the Environment, Bilthoven, Netherlands.* Sponsor: F. Cassee.

The Multiple Path Particle Dosimetry model (MPPD) allows calculation of PM deposition fractions and exposure doses for humans. Human regional and lobar depositions as well as alveolar deposition distributions for different particle sizes were calculated for an individual stochastic adult human lung. For coarse particles (>2.5 um) tracheobronchial and thoracic deposition fractions and dose as well as the doses per alveolus are significantly larger for children (<15 yr.) than for adults. Pulmonary exposure doses per unit surface area increase nearly linear between the ages of 20 and 80 years by approximately 30%. Pulmonary deposition fraction of ultrafine particles (<0. um) increases and of coarse particles decreases from rest to light exercise. Thoracic exposure dose increases with increasing physical exertion. The estimation of inhaled particulate matter (PM) dose and regional deposition patterns in the lungs is not only based on exposure concentrations, but also on physical characteristics of the particles, morphometry and breathing parameters is an essential part of the source-effect chain for risk assessment.

187 SEASONAL EFFECTS OF ULTRAFINE, FINE, AND COARSE PARTICULATE MATTER(PM) ON HUMAN PRIMARY AIRWAY EPITHELIAL CELLS.

L. Dailey and R. B. Devlin. *ORD/NHEERL/ETD, USEPA, Research Triangle Park, NC.*

Exposure of humans to PM results in increased mortality and morbidity. Recent toxicology studies have shown a number of pathophysiological pulmonary and cardiovascular changes following exposure to fine PM. However, the relative potency of ultrafine, fine, and coarse PM has not yet been characterized, nor is it well understood if PM emitted at different seasons of the year has different potencies. We have been collecting ultrafine, fine, and coarse ambient PM in Chapel Hill for the past year using the ChemVol High Volume Cascade Impactor developed by the Harvard School of Public Health. Samples were pooled into monthly batches to allow us to examine seasonal differences in PM effects on human airway epithelial cells. The fractions tested included coarse (2.5-10 microns), fine (0.1-2.5 microns), and ultrafine (<0.1micron). This abstract presents results from PM collected in October 2001 and April 2002. Human primary airway cells were exposed to equal masses (0, 25, 50, 100, and 250 ug/ml) of each PM fraction for 2 and 24hrs. Changes in expression of IL8, COX2 and heme oxygenase-1(HHOX1) genes were assessed at each time point. Exposure to October fine and ultrafine PM resulted in 5x and 9x greater increases in HHOX1 expression, respectively, compared with the corresponding April fractions; coarse PM from either month had a minimal effect on HHOX1 expression. In contrast, exposure to coarse PM collected in both October and April resulted in a 10 fold increase in COX2 expression while fine and ultrafine PM stimulated minimal expression of COX2. Increases in IL8 paralleled those seen for COX2. Detailed chemical analysis of each fraction will allow us to determine if the differential responses we have seen are associated with specific components present in each fraction. These data will provide useful information to the EPA on health effects associated with specific size fractions of PM. This is an abstract of a proposed presentation and does not necessarily reflect EPA policy.

188 AIRBORNE COARSE PARTICLES OF THE SAN JOAQUIN/SACRAMENTO VALLEY INDUCE INFLAMMATION IN THE LUNGS OF RATS.

K. R. Smith[1], S. Kim[2], C. Misra[2], J. J. Recendez[1], A. E. Aust[3], C. Sioutas[2] and K. E. Pinkerton[1]. *[1]Center for Health and the Environment, University of California, Davis, CA, [2]Civil and Environmental Engineering, University of Southern California, Los Angeles, CA and [3]Chemistry and Biochemistry, Utah State University, Logan, UT.*

Epidemiological studies have suggested particle size is an important determinant in adverse health effects. Particles less than 2.5 μm in diameter are considered to be the most deleterious, while particles with a mean aerodynamic diameter between 2.5 and 10 μm, referred to as coarse particles, are thought to produce less injury to the cardiopulmonary systems. Since the dominant PM fraction in the San Joaquin/Sacramento Valley is coarse particles, especially in the summer and fall seasons, we wished to examine the effects of exposure to ambient particles in the coarse mode on the lungs of healthy adult rats. Rats were exposed in Fresno, CA and Davis, CA to filtered air or the coarse fraction of PM enhanced approximately 40-fold over ambient levels with a particle concentrator system. Exposure to these particles was for 4 hours per day for 3 consecutive days. The mean mass of concentrated particles ranged from 0.2 to 1.1 mg/cubic meter. PM was composed primarily of nitrate, metals, sulfate, and organic carbon. Bronchoalveolar lavage (BAL) was performed on each group of rats following exposure. Total cells in BAL from rats exposed to concentrated PM were significantly increased during 1 of 2 weeks in Fresno and 2 of 2 weeks in Davis, compared to rats exposed to filtered air ($P<0.05$). BAL macrophages were increased during 1 of 2 weeks in Fresno and 2 of 2 weeks in Davis, neutrophils increased during all 4 weeks and lymphocytes during 2 of 2 weeks in Davis. The increase in macrophages, neutrophils, and lymphocytes in rats exposed to coarse PM indicates a significant inflammatory response with short-term exposure. These observations suggest that additional studies to elucidate potential mechanisms for possible health effects of coarse particles are warranted. Research supported by USEPA 827995 and NIEHS ES05707.

189 REGIONAL AND LOBAR DEPOSITION OF FINE AND COARSE PARTICLES IN THE LUNGS OF RATS AND MICE.

B. A. Wong, E. W. Tewksbury, J. T. Kelly and B. Asgharian. *CIIT Centers for Health Research, Research Triangle Park, NC.* Sponsor: O. Moss.

Inhalation toxicology studies have used various strains of rats as a surrogate for humans. Recently, attention has been focused on the use of mice for mechanistic inhalation studies because of the availability of transgenic mouse strains. There are always uncertainties for a given strain of animal regarding an appropriate exposure level to yield comparable doses in humans. Interspecies dosimetric comparison can help in reducing the uncertainties and improve risk assessment in humans from exposure to inhaled pollutants. Deposition of fine and coarse particles in the lungs of rats and mice was measured in this study. A condensation monodisperse aerosol generator was used to produce uniformly sized particles containing radiolabeled iron chloride ($^{59}FeCl_3$). Long-Evans rats and B6C3F1 mice were exposed in separate studies to radiolabeled monodisperse particles of different sizes using a nose-only exposure tower. Exposure concentration and animals' breathing parameters were measured and used in deposition calculations. The exposure durations were 10 to 15 min to reduce the impact of clearance processes. Deposition fractions in the head, lung lobar, and total lung were found by comparing measured deposition with that on a filter sampling from the Cannon nose-only tower. The results showed that total deposition fraction increased with particle size for both animals and reached a maximum value for particles 2 to 3 μm in size. For particles larger than 3 μm, total deposition fraction decreased with particle size, which stemmed mainly from the inability of the particles to enter the respiratory tract of the animal on inhalation (inhalability). Deposition fractions in mice were found to be larger than those in rats. By establishing the database for particle deposition in rats and mice in this study and linking them to responses from other studies, various dosimetrics can be developed for use in establishing safe exposure limits for humans. μ

190 THE COMPARATIVE TOXICITY STUDY OF KOREAN URBAN PM 2.5 AND PM 10 IN RAT LUNG EPITHELIAL CELLS.

J. Kim, J. Choi and M. Cho. *Toxicology, College of Veterinary Medicine, Seoul, South Korea.*

Air pollutants have long been recognized as a major problem for human health. A number of epidemiologic studies have been reported that elevated as well as ambient levels of PM10 were associated with increased frequencies of chronic cough, bronchitis, chest illness, hospital admissions, and mortality. Recent evaluation of the contribution of PM 2.5 to health outcomes has suggested that fine particles may be more closely associated with mortality and adverse respiratory health effects than particles of larger size. It has been hypothesized that PM 2.5 may cause more toxicity than PM 10 mediated through diverse mechanisms. This study was performed to find the toxic mechanism of especially Korean urban PM 2.5-induced toxicity in rat lung epithelial cell, and evaluate the risk of the exposure of PM 2.5. In the group treated with PM 2.5, the cytotoxicity by MTT assay was higher than in the group treated with PM 10. Also, in the group treated PM 2.5, the malondialdehyde was more produced than that in the same concentration of the group treated with PM10. In pBR322 DNA treated with 25 μg/ml of PM2.5, single strand breakage of DNA was higher than the DNA treated with 25 μg/ml of PM2.5. In electro mobility gel shift assay, both particles induced NF-kB activation, but only PM2.5-treated group induced AP-1 activation in rat lung epithelial cell significantly. These data suggest that PM2.5 rather than PM10 may induce more damage of DNA, oxidative damage and alteration of signal tranduction in NF-kB and AP-1 in rat lung epithelial cell and, and this may be associated with PM2.5-induced toxicity. Our data can be applicable for the risk assessment of PM2.5. Further PM2.5 related study for mechanism at the molecular level should be performed. Supported by Korean Deparment of Environment Grant

191 EVALUATION OF INORGANIC SOLUBLE SPECIES CONTENT IN PM10 FROM MEXICO CITY AND THEIR CYTOTOXICITY IN HUMAN BRONCHOEPITHELIUM CELLS.

M. E. Gutiérrez-Castillo[1], A. De Vizcaya-Ruiz[2], R. Ramos[3], A. Retama[3] and M. E. Cebrián[3]. *[1]CIIEMAD-IPN, México D.F., México D.F., Mexico, [2]CINVESTAV-IPN, México D.F., México D.F., Mexico and [3]SIMAT, SMA, GDF, México D.F., México D.F., Mexico.*

The debate over the scientific evidence for an underlying cause linking airborne particle levels to adverse health effects has intensified in major urban centers in recent years. However there are still uncertainties about the exact chemical and physical properties causative of the associated health effects and their toxicity mechanisms. In Mexico City the persistent high mass concentration of PM10 in the air has intensified research to elucidate the role of their chemical composition. Among the chemical components of PM10 inorganic species are important due to their high toxicity. The purpose of this study is to investigate if the water-leachable inorganic species contribute to the cytotoxic effects of PM10 in human bronchial epithelial cells (BEAS-2B). PM10 samples were collected over 24 hr from July to December 2000 from four different monitoring network stations from Mexico City (northern, central and sourthern regions). PM10 were suspended in deionized water, sonicated for 15 min, the soluble fraction was analyzed by HPLC and AAS to determinate anions (chloride, nitrate and sulfate), cations (ammonia, sodium and potassium) and ionizable transition metals. Trends in the concentration levels for soluble ions in the PM10 showed high amounts of sulfate (13.7-15.8ug/m3) and ammonia (2.4-3.5ug/m3) for the four regions in December. We used the soluble fraction of the highest concentration for colorimetric cytotoxicity assay (MTT method). Preliminary results showed that 48 hr *in vitro* exposure to 2.7-4.07ug/cm2 of NH4 and 15.8-18.3ug/cm2 of SO4 from the four regions of Mexico City produced 15% cell death associated to inorganic species. These data suggest that inorganic soluble constituents from PM10 could be responsible for the cytoxicity, yet additional information at a molecular level is needed and is currently in progress. (Study supported by the Financial Research Training Program from CIIEMAD/COFFA-IPN and CINVESTAV-IPN).

192 CONCENTRATED AMBIENT PARTICULATE STUDIES IN HEALTHY AND COMPROMISED RODENTS.

W. P. Watkinson[1], L. B. Wichers[2], J. P. Nolan[1], D. W. Winsett[1], U. P. Kodavanti[1], M. J. Schladweiler[1], L. C. Walsh[1], E. R. Lappi[1], D. Terrell[1], R. Slade[1], A. D. Ledbetter[1] and D. L. Costa[1]. *[1]ORD/NHEERL/ETD/PTB, USEPA, Research Triangle Park, NC and [2]SPH, UNC, Chapel Hill, NC.*

Epidemiological studies have reported a consistent association between exposure to higher concentrations of ambient particulate matter (PM) and excess cardiopulmonary-related morbidity and mortality. To further examine this phenomenon, we exposed various rodent models of cardiopulmonary dysfunction to Concentrated Ambient Particulates (CAPs) and monitored changes in indices of cardiopulmonary function and damage. Animal models used included young (3 mo) Spontaneously Hypertensive (Y-SH), old (11 mo) Spontaneously Hypertensive (O-SH), and healthy (SD) and monocrotaline-treated Sprague-Dawley (MCT-SD) rats. Subsets of animals were implanted with radiotelemeters to monitor (5-min intervals x 24h/d) electrocardiogram (ECG), heart rate (HR), systemic blood pressure (BP), and core temperature (T_{co}). Exposure protocols for Y-SH rats were either Continuous (4h/d x 2–3d/wk x 11wk) or Intermittent (4h/d x 1d/wk x 11wk) while SD, MCT-SD, and O-SH were exposed 4h/d x 2–3d/wk x 1wk. Pulmonary function tests (Buxco Electronics) were performed on all animals before, during, and after exposures. At the termination of the study, animals underwent bronchoalveolar lavage (BAL) and the BAL fluid was examined for biochemical indices of pulmonary damage and inflammation. Heart and lung tissues were harvested for histological and morphological analyses. PM exposure concentrations ranged from 135–1600μg/m^3. In general, despite the variety of exposure protocols and compromised animal models used, these studies demonstrated minimal adverse effects on cardiopulmonary and thermoregulatory function in cardiopulmonary-compromised rats after exposure to CAPs. Furthermore, these studies underscore the inherent complexities of conducting toxicology studies using "real-world" exposure atmospheres. (Abstract does not represent USEPA policy. This research was supported in part by EPA CT826513.)

193 EFFECTS OF EXPOSURE TO CONCENTRATED AMBIENT PARTICULATES ON INDICES OF CARDIOPULMONARY AND THERMOREGULATORY FUNCTION IN HEALTHY AND MONOCROTALINE-TREATED SPRAGUE-DAWLEY RATS.

L. B. Wichers[2], J. P. Nolan[1], U. P. Kodavanti[1], M. J. Schladweiler[1], D. W. Winsett[1], D. L. Costa[1] and W. P. Watkinson[1]. *[1]SPH, UNC, Chapel Hill, NC and [2]ORD/NHEERL/ETD/PTB, USEPA, Research Triangle Park, NC.*

Numerous epidemiological studies have reported a positive association between levels of ambient particulate matter (PM) and morbidity and mortality, noting higher correlations in persons with cardiopulmonary disease. Supporting data from animal studies are sparse and generally derived from exposures to large doses/concentrations of highly toxic PM surrogates. To investigate this phenomenon using a more environmental PM, we exposed healthy (SAL) and monocrotaline (MCT)-treated Sprague-Dawley (SD) rats to Concentrated Ambient Particulates (CAPs); paired groups were exposed to filtered air (AIR). Rats were implanted with radiotelemeters to monitor electrocardiogram (ECG), heart rate (HR), and core temperature (T_{co}). Animals were divided into four groups (SAL/AIR; MCT/AIR; SAL/CAPs; MCT/CAPs) and exposed (4h/d x 3d) to RTP CAPs. Telemetered rats were monitored continuously (4d preexposure-1d postexposure) and ventilatory function was examined daily (10 min; 1d preexposure-1d postexposure). At 24h postexposure, rats underwent bronchoalveolar lavage (BAL) to quantify biochemical indices of pulmonary injury and inflammation. On exposure Day 1, increases in HR (≈50 bpm) and decreases in T_{co} (≈1.0°C) were observed in all CAPs animals. Similar decreases in T_{co} occurred on Day 2. These effects do not appear to be associated with PM concentration *per se* but may be related to differences in composition. Protein and albumin in BAL fluid were elevated for rats receiving CAPs and appear exacerbated in MCT-pretreated animals. The above effects, while mild compared to those of previous studies that exposed MCT-SD to Residual Oil Fly Ash PM, nevertheless demonstrate a small toxic response in compromised rats following exposure to CAPs that, when projected over larger subject numbers, may help explain some of the reported epidemiological findings. (Abstract does not represent USEPA policy. This research was supported in part by EPA CT826513.)

194 CONSISTENT INFLAMMATORY RESPONSE FOLLOWING EXPOSURE TO CONCENTRATED AMBIENT PARTICLES (CAPs) DURING FALL SEASON IN WISTAR-KYOTO RATS.

U. P. Kodavanti, M. C. Schladweiler, A. D. Ledbetter, L. C. Walsh, P. S. Gilmour, M. I. Gilmour, W. P. Watkinson, J. P. Nolan, J. H. Richards, D. Andrews and D. L. Costa. *ETD/NHEERL/ORD, USEPA, Research Triangle Park, NC.*

Animal studies involving CAPs exposures have demonstrated variable pulmonary effects due likely, in part, to the animal model employed and the composition of ambient particulate matter (PM). To determine the consistency of CAPs response with repeated studies, we exposed male Wistar-Kyoto (WKY) and Spontaneously Hypertensive (SH) rats to CAPs in Research Triangle Park, NC (4h/d x 2 consecutive days) and measured pulmonary inflammation, cytokine levels, and changes in plasma fibrinogen and white blood cells. Seven replicates were conducted using the same exposure protocol during the period from August 27-October 24, 2001. The CAPS concentrations ranged from 145-2758 mg/m3, with the highest concentration achieved for the August 27-28 exposure period. After the first week of expo-

sure, the atmospheric temperature dropped significantly; the CAPs concentration also dropped significantly and both parameters remained low for the remainder of the study. There were consistent and significant changes in inflammatory cells in bronchoalveolar lavage fluid (BALF). All seven exposures resulted in significant decreases in total lavageable cells, and increases in neutrophils in WKY rats. The smallest increase was noted during the first week of exposure. The biochemical measures of BALF such as protein, albumin, lactate dehydrogenase and cytokines were variable. A small but consistent plasma fibrinogen increase was apparent only in SH rats at all exposures except the first. Plasma fibrinogen increases were not as consistent in WKY rats despite a significant inflammatory response in all replicates. This study demonstrates the potential variability between animal models and indicates that the season, and likely the composition of the atmospheric PM, may have a greater influence on CAPs-induced health effects than previously reported. (This abstract does not reflect USEPA policy).

195 DIFFERENTIAL PULMONARY INFLAMMATION AND *IN VITRO* CYTOTOXICITY BY SIZE FRACTIONATED PARTICLES COLLECTED FROM COMBUSTED COAL EMISSIONS.

I. Gilmour[2], S. O'Connor[1], C. Dick[4], M. Daniels[2], A. Miller[3] and W. P. Linak[3]. *[1]NHEERL, USEPA, Research Triangle Park, NC, [2]NRMRL, USEPA, Research Triangle Park, NC, [3]CEMLB, University of N Carolina, Research Triangle Park, NC and [4]Radiobiology, National Atomic Energy Commision, Buenos Aries, Argentina.*

Exposure to industrial and urban particulate matter (PM) has been associated with adverse health effects in humans. In the present study we examined pulmonary inflammatory responses in mice after intratracheal instillation of 25 or 100 micrograms of ultrafine, (<0.2uM), fine <2.5 uM) and coarse (2.5-10 uM) coal fly ash from a combusted Montana coal, and fine and coarse fractions from a combusted West Kentucky coal. CD1 mice (60 days old) were intratracheally instilled with either saline or saline suspensions of the different fractions of the coal emissions and the responses were compared to endotoxin as a positive control. After 18 hours, lungs were lavaged and bronchoalveolar fluid (BALF) was assessed for cellular influx. Biochemical markers including protein and albumin content, lactate dehydrogenase (LDH) and N-acetyl glucosaminidase (NAG) activity and pro-inflammatory cytokines (TNF-a, MIP-2 and IL-6) were also analyzed. The results show that on an equal mass basis, the Montana ultrafine particles induced a higher degree of neutrophil inflammation, NAG and cytokine levels than the fine or coarse particles. The Western Kentucky fine particles caused a moderate degree of inflammation and increased levels of protein content in BALF that was higher than the Montana fine particles. Coarse particles did not produce any significant effects. *In vitro* experiments with rat alveolar macrophages showed a similar ranking of potency with the Montana UF displaying the highest amount of cytotoxicity. In summary the Fine and Ultrafine fractions of CFA are capable of generating inflammation and lung injury. These effects were inversely related to particle size and were also associated with increased sulfur content and higher levels of trace elements. This abstract does not reflect EPA policy.

196 SPONTANEOUSLY HYPERTENSIVE RATS ARE SUSCEPTIBLE TO MICROVASCULAR THROMBOSIS IN RESPONSE TO PARTICULATE MATTER EXPOSURE.

P. S. Gilmour[1,2], M. C. Schladweiler[2], A. D. Ledbetter[2] and U. P. Kodavanti[2]. *[1]CEMLB, UNC, Chapel Hill, NC and [2]NHEERL, PTB, USEPA, Research Triangle Park, NC.*

Inhalation of environmental particulate matter (PM) is associated with cardiovascular (CV) health effects. These effects may be augmented by PM-induced thrombus formation in the vasculature. Tissue factor (TF) activation of coagulation, and reduction in thrombododulin (TM)-mediated inhibition of thrombin formation, may enhance thrombosis. The persistence of thrombi is regulated by fibrinolysis which is initiated by tissue plasminogen activator (tPA), and inhibited by plasminogen activator inhibitor-1 (PAI-1). To determine the role of thrombosis in PM-induced injury, we intratracheally (IT) instilled 3.3mg/kg oil combustion-derived PM into male Wistar-Kyoto (WKY) and Spontaneously Hypertensive (SH) rats. Pulmonary inflammation, changes in plasma fibrinogen, white blood cells (WBC), and expression of TF, TM, tPA, and PAI-1 were analyzed 24 h post IT. The combustion PM used in this study contained primarily zinc and nickel but not vanadium. Significant increases in BALF neutrophils and total cells occurred in the particle exposed WKY and SH rats, however, the SH rats showed greater increases than WKY rats. While BALF protein and LDH levels were increased with all particles versus control exposures, SH rats showed a greater increase. Plasma fibrinogen was significantly increased only in SH rats exposed to particles. Furthermore, the lung mRNA expression of TF was significantly increased, while TM and tPA mRNA decreased only in SH rats exposed to particles. TM protein was decreased in the SH rats following particle exposure. These data suggest that altered coagulation and fibrinolysis may play a critical role in PM-induced CV effects in susceptible individuals. This abstract does not reflect USEPA policy. Supported in part by #CR829522 between EPA and UNC.

197 EFFECT OF EXPOSURE TO PARTICULATE MATTER AND DIESEL EXHAUST PARTICLES ON THE FREQUENCY OF DNA DELETIONS *IN VIVO* IN MICE.

R. Reliene and R. Schiestl. *Pathology, UCLA, Los Angeles, CA.*

Particulate Matter (PM) and diesel exhaust particles (DEP) contain a staggering number of known carcinogens and there is some epidemiological indication that exposure to PM causes cancer in people. However, the increased risk is close to the limits of detection of classical epidemiology. For this reason, and to contribute to a mechanistic understanding of the effect of PM and DEP additional tools of investigation are required, such as animal studies based on biomarkers of genotoxicity. We have exposed animals to DEP under various exposure scenarios. As a cancer-related early genotoxic effect, we determined the frequency of DNA deletions on the offspring of exposed C57BL/6J-pun/pun mice. DNA deletions are scored as homologous recombination events between two copies of the partially duplicated pigmentation gene p (pun mutation) resulting in a deletion of one of the two copies. The deletion reconstitutes the wild type p gene visualized as black spots on the gray fur or patches of pigmented cells on the translucent retinal pigment epithelium. The frequency of deletions is measured as percentage of animals with fur spots or number of eye spots per retinal pigment epithelium. Preliminary data from mice exposed to DEP (500 mg/kg) by a single i.p. injection at 10.5 dpc, indicated that the offspring have a significantly higher frequency of eye spots (6.9±2.2; n=40) than those from unexposed mice (5.9±2.0; n=36) spots per retinal pigment epithelium ($P<0.05$). The fur spot assay did not reach statistical significance probably due to low number of animals analyzed. We have also launched a study on the effects of PM of concentrated urban air of the Los Angles basin, in collaboration with the UCLA Southern California Particle Center and Supersite. This study is supported by grants from the UC Toxic Substances Research and Teaching Program.

198 CARDIOVASCULAR EFFECTS OF DIESEL EXHAUST INHALATION IN SPONTANEOUSLY HYPERTENSIVE (SH) RATS.

M. J. Campen[2], A. Gigliotti[2], B. Tibbets[2], C. Elliott[2], E. B. Barr[2], S. Sielkop[1], M. D. Reed[2], J. L. Mauderly[2] and J. M. Benson[2]. *[1]Lovelace Respiratory Research Institute, Albuquerque, NM and [2]SKS Consulting, Siler City, NC.*

Particulate matter air pollution has been associated with increases in cardiovascular mortality in several epidemiological studies. The present study examined cardiac outcomes of exposure to diesel exhaust (DE) in a rodent model of systemic hypertension. SH rats (3 mo old, 6 males and 6 females/group) were exposed to either filtered air or one of four levels of DE (30, 100, 300, and 1, 000 μg particles/m^3, generated by a Cummins B 5.9L engine) for 7 d. Electrocardiographic (ECG) measurements were obtained by radiotelemetry (Data Sciences, Intl) at 15 min intervals from 3 d prior to exposure and ending 4 d following the cessation of exposure. Hearts were isolated following the monitoring period and fixed for morphological examination. Control rats displayed a reduction in daytime heart rate (HR) from the beginning of the protocol, while exposed rats maintained a significantly elevated HR throughout the exposure period. Daytime HR values for control rats averaged 265±5 bpm (mean±se), while values for exposed rats averaged 290±7 bpm. This difference persisted during the evening, but was not observed during the pre- or post-exposure periods. The P-Q interval, an index of AV node sensitivity, was significantly prolonged among exposed animals. No other significant ECG component alteration or arrhythmia induction was observed and no significant pathology was seen in hearts. However, increased HR with prolongation of AV-node activation (P-Q interval) represents a possible substrate for several major ventricular arrhythmias. These results concur with previous reports implicating particulate effects on the pacemaking system of rats, potentially involving alteration of the autonomic nervous system. Supported by the National Environmental Respiratory Center with support from multiple government and industry sponsors, including the USEPA. 199 COMPARISON OF PULMONARY RESPONSES TO AUTOMOBILE-GENERATED AND NIST STANDARD REFERENCE MATERIAL DIESEL PARTICULATE EMISSIONS IN MICE.

P. Singh[1], C. A. Dick[2], J. Richards[3], M. J. Daniels[3] and I. Gilmour[3]. *[1]NCSU, Raleigh, NC, [2]UNC, Chapel Hill, NC and [3]Experimental Toxicology Division, USEPA, ORD, NHEERL, Research Triangle Park, NC.*

Studies have shown that diesel exhaust particles (DEP) worsen respiratory diseases including allergic asthma. The adjuvant effects of DEP in the airways have been widely reported; however, the precise mechanisms of these effects remain ill defined. It is known that the composition of DEP may change with variations in conditions under which they are generated or collected. We hypothesized in this study that two different DEP samples, generated and collected under different condi-

tions, would produce different levels of pulmonary toxicity. CD-1 mice were intratracheally (IT) exposed to 25 or 100 μg of either automobile-generated DEP (A-DEP: dilution tunnel collection, from a 4 cylinder Isuzu engine) or standard reference material DEP (SRM-DEP: NIST SRM 2975, from a forklift) or saline, and brochoalveolar lavage (BAL) was performed 4 and 18 hr later. Both samples produced increased total inflammatory cells with only a moderate increase in microalbumin and total protein in the BAL fluid. SRM-DEP produced 4-5 fold greater increase in neutrophil influx and greater depletion of total antioxidant capacity in the BAL fluid than A-DEP. Both the low and the high doses of A-DEP increased MIP-2 and IL-6, while only the high dose of SRM-DEP increased levels of these proinflammatory cytokines. By contrast, TNFα and N-acetyl glucosamine were significantly increased only by the A-DEP. Percentages of extractable organic material (hydrocarbons) in the two DEP samples were determined by dichloromethane extraction followed by gravimetric analyses. A-DEP was composed of 60-71% hydrocarbons, while SRM-DEP was composed of 1.6-6% hydrocarbons. We suggest that the observed differences in proinflammatory profiles are related to the disparate amounts of organic chemical constituents in the two DEP samples. (Supported by NIH grant # ES11245-01) (This abstract does not reflect EPA policy.)

200 BAX EXPRESSION AND NITRIC OXIDE PRODUCTION IN MACROPHAGES J774A.1 AS BIOMARKERS OF GASOLINE EMISSION TOXICITY.

J. L. García-Tavera[1], F. Morales[1], R. A. Pérez[1], L. C. Acosta-Saavedra[1], A. Zambrano-García[2], J. L. Arriaga[2], U. González-Macías[2], M. E. Cebrián[1], E. S. Calderón-Aranda[1] and A. De Vizcaya-Ruiz[1]. *[1]Toxicology, CINVESTAV-IPN, México, D.F, Mexico and [2]Instituto Mexicano del Petróleo, México, D.F, Mexico.*

Extensive evidence supports that short-term exposure to elevated levels of atmospheric pollutants is associated with respiratory diseases. Although the known toxic effects of atmospheric pollutants results from the synergistic contribution between primary and secondary pollutants, in this study we investigate the contribution of primary pollutants from gasoline emission using an *in vitro* cell line model. We evaluate cytotoxic capability, Bcl-2/Bax ratio and p53 protein expression as cellular biomarkers of toxicity of vehicle emission extracts (VEE), on non-activated J774A.1 murine macrophages. In addition we evaluated the effect on IFNγ plus LPS activated macrophages through nitric oxide (NO·) and TNFα mRNA expression (evaluated by RT-PCR). The VEE were obtained from a 1.7 cc gasoline engine vehicle operated under the FTP-75 method using Mexican commercial gasoline and sampled under EPA/625/R-96/010b specifications. The organic extracts from gas and particle phases were tested at a dose equivalent to a 160 m of urban operation conditions. No cytotoxicity assayed by MTT was observed. Immunodetection after exposure to the particle and gaseous phase showed induction of Bax expression with an inversion on the Bcl-2/Bax ratio in both phases. At the time points evaluated no induction of p53 was observed. On activated-macrophages VEE inhibited NO· production and the TNFα mRNA expression a higher effect was observed in cells exposed to the particle phase extract. These results suggest that the increase in Bax expression with no proportional increase in Bcl-2 is a sensitive biomarker of VEE toxicity and that macrophage activation is an important target of VEE toxicity. Further studies are in course to elucidate on the mechanisms of these toxic effects. (Study supported by FIES-IMP 98-119-VI).

201 *MYCOPLASMA FERMENTANS* INFECTION AUGMENTS IL-6 RELEASE IN HUMAN LUNG CELLS EXPOSED TO RESIDUAL OIL FLY ASH (ROFA) AND TNF-β.

F. Gao and J. P. Fabisiak. *Environmental & Occupational Health, University of Pittsburgh, Pittsburgh, PA.* Sponsor: M. Karol.

Mycoplasma (MP) can establish chronic latent infections with little signs of disease. *M. fermentans* is a species of MP associated with arthritis, leukemia, and lung disease, but its presence in normal healthy individuals suggests it to be a co-factor for disease in concert with other stimuli. Particulate matter (PM) is a component of air pollution associated with adverse health effects. We hypothesize that MP modulate the inflammatory effects of chemical stress and alter cellular responses to promote lung disease upon exposure to PM. We assessed IL-6 release in response to PM and TNF-β in human lung epithelial cells (A549) and fibroblasts (HLF) deliberately infected with *M. fermentans* and uninfected controls. Exposure of uninfected HLF to 50 μmg/ml ROFA for 24 hrs increased IL-6 release from 54 ± 11 pg/10^5 cells to 603 ± 145 pg/10^5 cells. MP infection alone produced a similar 10-fold increase in IL-6 release and enhanced the ROFA response greater than that predicted by the sum of each stimulus alone (> 50-fold above uninfected control). A549 cells required 5-fold greater concentrations of ROFA, as well as TNF-β pretreatment to realize the synergistic interactions between ROFA and MP. In both cell types, MP and TNF-β together synergized to augment IL-6. ROFA and other PMs were compared by exposing HFL to 20 μg/ml of urban dust from Dusseldorf, Germany, Mt. St. Helen's ash, or aqueous extract of PM obtained from Provo Valley near Salt Lake City, Utah (SLC). Only ROFA and SLC increased IL-6 release in uninfected cells. None of the other PMs, including SLC augmented IL-6 above that seen with infection alone. Both ROFA and SLC are rich in redox-active metals, but differ in their relative elemental composition (high V in ROFA vs. high Cu in SLC). MP interacts with environmental and endogenous inflammatory stimuli to synergistically activate signaling pathways that control lung cell cytokine production and, thus, can potentially modulate the effects of various environmental chemicals. (Funded in part by EPA STAR Grant R827151)

202 CCSP DEFICIENCY ALTERS BASAL PULMONARY AND SYSTEMIC HUMORAL IMMUNITY.

T. M. Watson[1], S. D. Reynolds[2,1], J. N. Finkelstein[1] and B. R. Stripp[2,1]. *[1]Department of Environmental Medicine, University of Rochester, Rochester, NY and [2]Department of Environmental and Occupational Health, University of Pittsburgh, Pittsburgh, PA.*

Altered levels of Clara Cell Secretory Protein (CCSP), a major component of airway lining fluid, are associated with chronic airway disease in asthmatics, smokers, COPD patients and Silica exposed individuals. CCSP has been proposed to act as an immunoregulatory protein though the mechanism is unknown. We previously demonstrated that CCSP knockout (-/-) mice within a 129/J background possess elevated pulmonary IgA message and protein levels compared to wild type control mice, suggestive of an immunoregulatory defect. Numerous studies have demonstrated that immune responses can vary based on genetic background or strain. Comparison of C57BL/6J wild-type and CCSP -/- mice by northern hybridization revealed that pulmonary IgA message was undetectable in both groups. In contrast, flow cytometry of interstitial pulmonary lymphocytes determined that CCSP deficiency results in a decrease of pulmonary B-2 cells. A two fold increase of IgG1 immunoglobulin in the plasma was also detected, suggesting that the effects of CCSP at steady state are strain dependent and that CCSP deficiency may play a role in B cell population and locality. Evaluation of CCSP -/- B cell populations in the spleen did not reveal alterations to B cell number. These results confirm that CCSP deficiency is associated with immunoregulatory perturbations and that the nature of these alterations is strain-dependent. Acknowledgements: HL70575, ES08964, ES01247, and ES07026.

203 OVALBUMIN-INDUCED AIRWAY INFLAMMATION AND FIBROSIS IN INOS-DEFICIENT MICE: MECHANISMS AND CONSEQUENCES.

J. A. Last, N. J. Kenyon and K. Gohil. *Pulmonary/Critical Care Medicine, University of California, Davis, CA.*

We hypothesized that C57BL mice, a Th-1 responsive strain, would be relatively resistant to ovalbumin exposure as compared with the BALB/c strain, a Th-2 responder. Our results are consistent with this hypothesis, especially with respect to the accumulation of collagen in the airways of the mice exposed to ovalbumin and increased airway reactivity to challenge with methacholine, as measured by the Penh response. BALB/c mice demonstrate significant increases in accumulation of airway collagen after 4 weeks of exposure to ovalbumin aerosol under conditions identical to those used in the current study. Significant increases in airway collagen content were seen only after 6 weeks of exposure of the C57BL mice, as contrasted with 4 weeks in the iNOS knockout animals. At each time point examined, Penh values for the iNOS knockout mice exceeded those observed with the C57BL strain. Thus, responses to ovalbumin exposure of the Th1 responsive C57BL animals were significantly less (or slower) than those of the Th2 responsive BALB/c mice. We found the iNOS knockout mice to be more susceptible to ovalbumin-induced airway fibrosis than the C57BL strain, giving results intermediate between BALB/c and C57BL in the various assays performed. We also measured the response of C57BL and iNOS knockout mice to direct intra-tracheal challenge with TGF-B1. There was no apparent response of C57BL mice to TGF-B1 at 4 or 11 days after TGF-B1 challenge, as evaluated by bronchoprovocation testing. There were significant increases in Penh values measured in iNOS knockout mice exposed to serially increasing concentrations of methacholine, and the observed Penh values were significantly greater in mice that had also received TGF-B1. These results strongly support the hypothesis that the increased sensitivity of iNOS knockout mice to ovalbumin is at least partially dependent on pathways that come into play subsequent to the release of TGF-B1 by effector cells in the lungs of mice exposed to ovalbumin aerosol.

204 RESPONSES TO *MYCOBACTERIUM CHELONAE* FROM METAL WORKING FLUIDS DIFFER FROM *SACCHAROPOLYSPORA RECTIVIRGULA* IN A MURINE MODEL OF HYPERSENSITIVITY PNEUMONITIS.

P. S. Thorne[1], B. Lester[1], A. Dodd[1], M. E. O'Neill[1] and C. Duchaine[2]. *[1]College of Public Health, The University of Iowa, Iowa City, IA and [2]Laval University, Quebec, QC, Canada.*

Human cases of hypersensitivity pneumonitis (HP) have been reported among machinists for over ten years. Although *Mycobacteria* have been implicated as causal agents, the mechanisms leading to the development of this disease in machinists re-

main unclear. It is recognized that other constituents of in-use metal working fluids (MWF), such as endotoxins may contribute to lung inflammation and may act as adjuvants for the development of HP. Thus, we investigated the potential for microbial agents in MWF to induce HP in an established rodent model and characterized the physiologic and immunologic responses to these MWF exposures and appropriate positive and negative controls. Female C57Bl/6J mice were exposed by nasal instillation to live *Mycobacterium chelonae* (MC) bacteria (isolated from an in-use MWF sample), live *Saccharopolyspora rectivirgula* (SR) bacteria (positive control), saline (negative control), or endotoxin (inflammation control). Mice were exposed three consecutive days per week for three weeks and were necropsied on the fourth day after last treatment. SR-exposed mice demonstrated significantly more total cells, neutrophils, lymphocytes and monocytes in lung lavage; an increased CD4+/CD8+ ratio; and marked pulmonary lymphocytosis on histological exam when compared to saline-treated controls. The cytokine, interleukin (IL)-12 was significantly elevated but IL-6, IL-10 and interferon-γ (IFNγ) were not. Mice treated with MC had significantly elevated lung weights, total lavage cells, neutrophils, and CD4+/CD8+ ratio as compared to saline controls. However, when MC was administered at twice the dose of SR, cellular and cytokines responses were still lower than those observed in the SR-treated mice. These data suggest that MC produces HP-like changes in the mouse but with lower potency and different response profile than induced by SR. *(Supported by UAW-DaimlerChrysler National Training Center.)*

205 RESPIRATORY RESPONSE TO TOLUENE DIISOCYANATE AFTER DERMAL SENSITIZATION IN MICE.

J. Vanoirbeek, P. Hoet and B. Nemery. *Pathophysiology; Pneumology - Lungtoxicology, KULeuven, Leuven, Belgium.*

Aim: Occupational asthma is the principal cause of work-related respiratory disease in the industrial world. In the absence of satisfactory models for predicting the potential of low molecular weight chemicals to cause asthma, we have attempted to produce immunologically mediated respiratory responses in mice using toluene diisocyanate (TDI), a known respiratory sensitizer. Methods: BALB/C mice received TDI (20 µl per ear, 0.3 or 3% solution) or vehicle (acetone/olive oil) on each ear for three consecutive days. On day 7 the mice received a dermal boost of TDI (20 µl per ear, 0.3 or 3% solution). On day 10, they were intranasally challenged with TDI (0.1%, 10 µl per nostril) or vehicle. Lung function was monitored by whole body plethysmography for 40 min after intranasal challenge, and bronchial reactivity to methacholine (0, 10, 25, 50 and 100 mg/ml) was assessed 24 h later. Pulmonary inflammation was assessed by bronchoalveolar lavage (BAL) and histology. Results: Mice sensitized with TDI, boosted with TDI and challenged with TDI did not show a different breathing pattern after intranasal challenge compared to the control. One day later they did not show an increased reactivity to methacholine. However, mice that been "sensitized" with the vehicle and then "boosted" with TDI (0.3% or 3%), experienced marked bronchoconstriction immediately after the intranasal challenge with 0.1% TDI. 24 h later they had pronounced bronchial hyperreactivity and pulmonary inflammation [20% and 40% neutrophils; 1.5% and 2% eosinophils in BAL, for boosts with 3% and 0.3%]. Dry and wet lung weight were also significantly higher in this group compared to the control. Histologic examination revealed a minor influx of eosinophils round the blood vessels. Conclusion: We have been partially successful in our attempt to develop a model of chemical-induced asthma. The role of dermal sensitization and subsequent dermal boosting is proving to be one of the critical factors, the mechanisms of which remain to be explored. DWTC PS/01/43

206 PULMONARY FUNCTION FOLLOWING EXPOSURE TO CARBON-GRAPHITE/EPOXY COMPOSITE MATERIAL SMOKE.

E. C. Kimmel[1,2], J. E. Reboulet[2], D. L. Courson[3], G. S. Whitehead[4] and P. G. Reinhart[1]. *[1]Inhalation/Pulmonary Effects Laboratory, Naval Health Research Center (Toxicology), Wright-Patterson AFB, OH, [2]Geo-Centers Inc., Wright-Patterson AFB, OH, [3]ManTech Enviromental, Wright-Patterson AFB, OH and [4]Duke University, Raleigh, NC.*

Four groups of 28 male F-344 rats were exposed to smoke from pyrolysis of 0, 10, 55, or 100 g of carbon-graphite/epoxy composite material for 1 hour. Two groups of 28 animals were exposed to 100 g smoke for 2 hours. No deaths resulted from exposure to 10, 55 g smoke, 4/28 (14%) died immediately after 100 g smoke exposure for an hour, and 24/56 (43%) died during or shortly after 2 hour 100 g smoke exposure. Pulmonary function was assessed in 6 animals from each exposure group at 2, 7 and 14 days post exposure. Significant elevation of tidal volume and minute ventilation was observed 2 days following 2hr-100 g smoke exposure. Lung resistance was not altered in any of the animals, however both dynamic and quasistatic compliance were significantly lower at all post-exposure times in animals exposed to 100 g smoke regardless of exposure duration. Functional residual capacity (FRC), residual volume (RV), FRC/TLC, and RV/FRC were significantly elevated in 100 g animals regardless of exposure duration and post exposure time. Mid-mean expiratory flow and forced expiratory volume at 100 and 50 milliseconds (all normalize forced vital capacity) were significantly elevated at day 2 post-exposure in 100 g smoke regardless of exposure duration. These parameters were elevated at 7 and 14 days post-exposure in animals exposed to 100 g smoke for 2 hours. Diffusing capacity and diffusing capacity normalized to lung volume was significantly decreased at all post-exposure times in animals exposed to 100 g smoke regardless of exposure duration. The arithmetic mean alveolar septal thickness in these animals was significantly elevated at all post exposure times.

207 ACUTE TOXICITY OF CARBON-GRAPHITE/EPOXY COMPOSITE MATERIAL SMOKE: COMPARISON WITH N-GAS MODEL PREDICTIONS.

J. E. Reboulet[3], D. L. Courson[2], G. S. Whitehead[4], P. G. Reinhart[1] and E. C. Kimmel[1,3]. *[1]Inhalation/Pulmonary Effects Laboratory, Naval Health Research Center (Toxicology), Wright-Patterson AFB, OH, [2]Man Tech Environmental, Wright-Patterson AFB, OH, [3]Geo Centers Inc., Wright-Patterson AFB, OH and [4]Duke University, Raleigh, NC.*

One hour exposure to smoke (average nominal concentration (28.4 ±1.6 g/m3) from pyrolysis of 100 grams of carbon-graphite/epoxy composite material (cgeCM) used in the manufacture of military and civilian aircraft was 32% (34/107) lethal to F-344 rats. No lethality was observed from 1 hour exposures to smoke from pyrolysis of 55, 60, or 75 grams of cgeCM. Time weighted average concentrations of CO, CO2, HCN, NO2, SO2, and O2 in the 100 g smoke were 3282, 8932, 56, 254, 218, and 195000 ppm, respectively; and were used to predict acute cgeCM smoke toxicity using the N-gas model (Levin, 1996). The average N-gas number for five 100 g smoke exposures was 2.25 indicating a much higher than expected mortality. However, carboxyhemoglobin (COHb) level in the surviving animals was approximately 45% which was much lower than the 85 to 90% predicted by the Coburn-Forster-Kane equation. This was attributed, in part, to a reduction of the Haldane coefficient by a decrease in blood pH, with concomitant reduction of COHb formation. Adjusting the N-gas model proportionately resulted in an average N-gas number of 1.49. The N-gas model was further modified to remove CO and CO2 synergism because of the relative concentrations of these gases in the smoke and to reflect the non-linearity of CO2 stimulation of ventilation. The result was an additional small reduction of the N-gas prediction to 1.40 which also predicts greater lethality than observed. This suggested that other constituents in the smoke inhibited uptake of more toxic components, possibly by suppression of breathing from SO2 and particulate irritation of the airways.

208 INDUCTION OF STROMELYSIN BY PULMONARY INSTILLATION OF TOXIC DUST.

R. R. Mercer, L. Wang, J. M. Antonini, J. F. Scabilloni, V. Vallyathan and V. Castranova. *HELD, NIOSH, Morgantown, WV.*

Stromelysin is a collagenase of the matrix metalloprotease family that is involved in collagen remodeling of scar and wound tissues. It is not normally present in the lungs. In this study, we tested the hypothesis that the matrix metalloprotease, stromelysin, is induced by instillation of toxic particles into the lungs. Male, Fischer 344 rats (body weight 255±8 g, mean±SE, N=6) were intratracheally instilled with saline vehicle or 4 mg of either crystalline silica, titanium dioxide or particulates from air sampling of citrus and grape fields. After 4 weeks, rats were sacrificed and the lungs were analyzed for total lung collagenase activity using a fluorometric assay. Matrix metalloprotease 2 (MMP2, the principal form of collagenase normally present in the lungs) and stromelysin were localized using immunohistochemistry. Total lung collagenase activity was 407±130, 464±64, 644±110, 895±126 and 906±129 nmol substrate/min/lung (mean±SE, N=6) for saline, titanium dioxide, citrus, grape and silica treated lung, respectively. Total lung collagenase activities of citrus, grape and silica exposed lungs were significantly greater than saline and titanium dioxide treated lungs. Immunohistochemistry demonstrated significant expression of stromelysin in silica, citrus and grape instilled lungs. Stromelysin was not present in the saline controls or titanium dioxide treated lungs. MMP2 was significantly elevated above saline and/or titanium dioxide in silica, citrus and grape treated lungs. The results suggest that stromelysin may play a role in lung remodeling in response to toxic particles, and that it may be used to differentiate between toxic and non-toxic particles.

209 ASSESSMENTS OF THE BARRIER EFFECTIVENESS OF PROTECTIVE CLOTHING FABRICS TO AEROSOLS OF CHRYSOTILE ASBESTOS FIBERS.

K. L. Reed and D. B. Warheit. *Pulmonary Toxicology, DuPont Haskell Lab., Newark, DE.*

This study measured the performance of flashspun polyethylene clothing fabrics and the spunbonded polypropylene composite (spc) fabrics as barriers to chrysotile asbestos fibers. The spc fabric samples were taken from clothing samples obtained from several manufacturers. Ten fabric samples and two controls were concurrently exposed to chrysotile asbestos aerosols. Fibers that penetrated the fabric specimens were captured on sub-micron filters. These fibers were counted and sized from SEM micrographs of random sections of those filters. The aerosol challenge concentration was obtained from filters directly exposed to the asbestos aerosol without an intervening fabric. Penetration percentage was based on the number of fibers that penetrated the fabric versus the number of fibers observed on the uncovered filters. Five different exposures were performed. The penetration of chrysotile fibers through flashspun polyethylene fabrics ranged from 0.24% to 1.0%. In contrast, the penetration of chrysotile fibers through the commercial spc fabrics ranged from 13.4% to 26.8% under the conditions at which these evaluations were conducted. The results demonstrated that the method consistently differentiates performance of protective clothing materials to chrysotile fiber penetration and that flashspun polyethylene fabrics provide greater resistance to asbestos fiber penetration when compared to several different spc fabrics available from several manufacturers.

210 SILICA EXPOSURE *IN VITRO* STIMULATES THE ACTIVITY AND EXPRESSION OF MATRIX METALLOPROTEINASES IN MOUSE MACROPHAGES. .

S. Mowbray, M. Thibodeau and A. Hubbard. *University of Connecticut, Storrs, CT.*

Exposure of mouse macrophages *in vitro* to crystalline silica elicits numerous inflammatory mediators including the matrix metalloproteinases (MMPs) which participate in extracellular matrix remodeling. MMP activity has been implicated *in vivo* in the development of pulmonary fibrosis in rodents and humans. In a rat model of silicosis, MMP-2, -9, and -13 were found in silicotic granulomas (Perez Ramos et al:Am J Respir Crit Care Med. 160:1274, 1999). Furthermore, gene analysis of lungs of both humans and mice implicate MMP-7, matrilysin, as a mediator of fibrosis (Zuo et al: PNAS 99:6292, 2002). However, few studies have examined the profile and regulation of MMP expression *in vitro*. To investigate the expression and activity of MMP-2, -7, and-9, RAW 264.7 cells were stimulated with LPS (1 ug/ml), TNFα(20 ng/ml), crystalline silica (cristobalite), and amorphous silica for varying times and with different concentrations of particles. The results were analyzed using zymographic and western blot methods. The zymogram indicated constitutive levels of MMP-9 activity in cells stimulated with silica; no activity for MMP-2 was detected. Increased gelatinolytic activity was detected in the silica treated cells (25, 12, and 6 ug/cm2) after 48 hours of stimulation that was not apparent in the LPS, media, or amorphous silica treated groups. The apparent molecular weight of this active moiety was ~28kDa, consistent with that of MMP-7. Western blot analysis and further zymographic analysis will confirm the identity of this moiety. These data suggest that MMP expression and activity are integral to the cell's response to a silica insult. (Funded by R15ES09433 and the University of CT Research Foundation)

211 BIOMATHEMATICAL MODELS OF EXPOSURE-DOSE-RESPONSE TO RESPIRABLE QUARTZ IN FISCHER 344 RATS, CYNOMOLGUS MONKEYS, AND HUMANS.

E. D. Kuempel[1] and L. Tran[2]. *[1]CDC/NIOSH, Cincinnati, OH and [2]Institute of Occupational Medicine, Edinburgh, United Kingdom.* Sponsor: D. Dankovic.

A biomathematical model was developed to describe clearance and retention kinetics of respirable quartz and pulmonary responses, including the recruitment of alveolar macrophages (AMs) and polymorphonuclear leukocytes (PMNs) and the production of superoxide dismutase (SOD) in bronchoalveolar lavage (BAL) fluid, as well as hydroxyproline (HP) in lung tissue. The model was first calibrated in Fischer-344 rats exposed to respirable crystalline silica (15 mg/m^3 for up to 6 months) and validated using data from two additional rat studies (respirable quartz exposures 0.74 mg/m^3 for 2 years, and 10 mg/m^3 for 75 days). The model was then extrapolated to cynomolgus monkeys and humans by adjusting model parameters for species differences such as breathing rates, lung mass, and surface area. To evaluate model fit, BAL data and limited quartz lung burden data were available in cynomolgus (10 mg/m^3 quartz for up to 26 months) and in coal miners (<0.1 mg/m^3 mean quartz in respirable coal mine dust for 17 years). The model predicted well the end of study lung burden in monkeys and the lavageable quartz mass in two humans; however, it overpredicted the pulmonary cell responses by several fold. This was consistent with the observed dose-response, in which the rat PMN and AM counts were several times greater than those in monkeys at higher doses (cell counts relative to controls and normalized to lung surface area). Human predicted dose-response data were in the low dose region, where responses were similar across species, except for two individuals, whose PMN counts exceeded those expected from the rat data. The relative increases in SOD and HP were comparable across species. Despite some differences in magnitude, similar patterns of nonlinear dose-response were observed in all three species. These biomathematical models may be useful in risk assessment by providing a mechanistic basis for extrapolating rat responses to various inhaled particulates in humans.

212 EVALUATION OF THE CHEMICAL AND PHYSICAL PROPERTIES OF CELLULOSE INSULATION AEROSOLS AND THE POTENTIAL ACUTE PULMONARY TOXICITY.

D. L. Morgan[1], J. A. Dill[2], Y. Su[2], B. Westerberg[2], H. C. Price[3], C. J. Shines[1] and C. S. Smith[1]. *[1]NIEHS, Research Triangle Park, NC, [2]Battelle Pacific Northwest Laboratories, Richland, WA and [3]ManTech Environmental Technology, Inc., Research Triangle Park, NC.*

Cellulose insulation (CI) is a type of thermal insulation produced primarily from recycled newspapers. The newspapers are shredded, milled and treated with fire retardant chemicals. CI is installed by a blowing process that generates significant quantities of airborne material. These studies were conducted to characterize the chemical and physical properties of the CI aerosol and to evaluate the potential acute pulmonary toxicity of the respirable particles. An aerosol generation system was designed to simulate the process used during installation of CI at work sites and to separate CI particles based upon aerodynamic size. Aerosols were generated using CI from four different manufacturers. The mean equivalent diameter of aerosol particulates ranged from 3.5 to 11.4 microns in the cyclone collection bag and 0.6 to 0.7 microns in the sampling chamber. For all four CI samples, less than 0.1% was collected as the small respirable particle fraction. X-Ray diffraction analysis of the respirable particle fraction did not indicate the presence of any cellulose material. The fraction consisted mainly of fire retardants and smaller quantities of clays. Concentrations of the toxic elements lead, chromium, arsenic, and selenium were very low in all samples tested. The respirable fraction was administered by intratracheal instillation to male F344 rats at doses of 0, 0.125, 0.25, 0.5, and 1 mg/rat, and the bronchoalveolar lavage fluid (BALF) evaluated 3 days later. BALF was evaluated for cellularity and cell differentials. The total number of cells in the BALF was significantly increased only in the high dose group. The %PMNs was increased and the %AMs was decreased in a dose-related manner. These results indicate that few respirable particles or fibers are generated during the application of CI, and that intratracheal instillation of respirable particles in rats resulted in only a minimal inflammatory response.

213 PULMONARY TOXICITY OF CARBON NANOTUBES IN MICE 7 AND 90 DAYS AFTER INTRATRACHEAL INSTILLATION.

C. -. Lam[1,2], J. T. James[1], R. McCluskey[1] and R. L. Hunter[3]. *[1]Toxicology Division, Wyle Laboratories, Houston, TX, [2]Space Life Sciences, NASA Johnson Space Center, Houston, TX and [3]Department of Pathology, University of Texas Medical Center, Houston, TX.*

Single-walled carbon nanotubes (SWNT; individual tube: ~1 nm x 1, 000 nm) are a novel material possessing many desirable properties and potentially have widespread applications in the electronics, computer, and aerospace industries. NT are light and could become airborne. Little is known about the toxicity of this fiber/rope-like material. The pulmonary toxicity of three NT products, obtained from Rice University or Carbolex Inc. was investigated in mice by intratracheal instillation. These products were made by different methods, and contained different types or amounts of residual catalytic metals. Metal analysis showed that the Rice HiPco-prepared NT contained 27% (w/w) iron in the raw form, and 2% iron after purification; Carbolex electric-arc product contained 26% nickel and 5% yttrium. Male mice (B6C3F1, ca. 30 g, 4 to 5 per group) were each intratracheally instilled once with 0, 0.1 or 0.5 mg of NT suspended and ultrasonicated in 50 µl of mouse serum. Carbon black and quartz, two standard reference dusts, were prepared similarly for instillation. Carbon black elicited minimal effects and high-dose quartz produced moderate inflammation in the lung. All the NT products, regardless of the type or amount of metal, induced a dose-dependent formation of epithelioid granulomas in the centrilobular alveolar septa and, in some cases, interstitial inflammation in the animals of the 7-d groups. These lesions persisted and, in most cases, became worse in the 90-d groups. The granulomas in NT-treated mice consisted of aggregates of macrophages laden with black NT particles. Our results show that, for the test conditions described here, if SWNT reach the lung, they can be more toxic than quartz.

214 INFLAMMATORY EFFECTS OF QUARTZ SAMPLES AFTER INTRATRACHEAL INSTILLATION IN RATS.

O. Creutzenberg[1], G. Oberdörster[2], S. G. Ampian[3], W. F. Moll[3], R. Hamilton[4] and H. Muhle[1]. *[1]Toxicology, Fraunhofer Institute, Hannover, Lower Saxony, Germany, [2]Environmental Medicine, University of Rochester, Rochester, NY, [3]Sorptive Minerals Institute, Washington, DC and [4]Technical Center, Johns Manville Corp., Littleton, CO.*

Objectives: This 28-day study compared the inflammatory potential of quartz with geologically ancient surfaces to well-characterized reference quartz DQ 12 (RQ). A differentiation of subspecies of quartz dusts is important in regard to a wide exposure and a potential carcinogenicity. Methods: A quartz sample in a naturally occurring respirable size (quartz isolate-QI) was separated centrifugally from an unprocessed bentonite dispersion, as were clay minerals (clay isolate-CI). QI contained approx. 67% quartz with the remainder being predominantly clay minerals, and CI contained <0.035% quartz. Lung effects of QI and CI were evaluated in rats at 3 and 28 days after administering a total dose of 15.2 mg/kg in 4 equal doses. To rank the effects, a positive control (RQ) and a negative control (TiO2) were included. Results: Bronchoalveolar lavage showed a severe acute inflammatory effect in the CI group at 3 days after last dosing, which recovered mostly after 28 days. QI induced moderate inflammatory effects after 3 days, which did not change significantly by 28 days post treatment. In contrast, RQ showed a high acute inflammatory response on day 3, persisting through day 28. Histopathologically pulmonary inflammation in lungs at day 28 was most pronounced in the RQ group, whereas QI and CI showed significantly lower effects. In contrast to the quartz groups, inflammation in the CI group was not persistent or progressive but was a late recovery phase of a severe acute inflammatory effect. Conclusion: Pulmonary inflammatory effects of various quartz subspecies were significantly different.

215 PULMONARY TOXICITY OF ADVANCED COMPOSITE MATERIAL COMBUSTION ATMOSPHERES IN RATS.

P. G. Reinhart[1], E. C. Kimmel[2], D. L. Courson[3], J. E. Reboulet[2], A. E. Jung[2] and J. T. Murray[1]. *[1]Naval Health Research Center (Toxicology Detachment), Wright-Patterson AFB, OH, [2]Geo-Centers Inc., Wright-Patterson AFB, OH and [3]ManTech Environmental Technology Inc., Wright-Patterson AFB, OH.*

Advanced composite materials (ACM) provide a lighter alternative to their metal counterparts without compromising strength. A downside to the use of ACM is their ability to burn. To investigate the toxicity of ACM combustion atmospheres F-344 rats were exposed for 1 hour in whole-body chambers to the smoke produced from the pyrolysis of 60 g of carbon-graphite/epoxy material. Control rats were exposed to filtered air. After 1, 3, and 7 days post-exposure, the animals underwent bronchoalveolar lavage. The lavaged cells were quantitated and identified morphologically. The lavage fluid was analyzed for the inflammatory cytokines Interleukin-1 beta (IL-1β), IL-6, and Tumor Necrosis Factor-alpha (TNF-α) by ELISA. The results included significant increases in cell counts, polymorphonuclear leukocytes (PMN)s, IL-1β, IL-6, and TNF-α as compared to controls. In conclusion, exposure to ACM combustion atmospheres produces time-dependent pulmonary toxicity manifested by the recruitment of inflammatory cells, release of inflammatory cytokines and the development of pulmonary inflammation.

216 ACUTE PULMONARY RESPONSE OF INDUCIBLE NITRIC OXIDE SYNTHASE KNOCKOUT *VERSUS* WILD TYPE MICE FOLLOWING ASPIRATION OF LIPOPOLYSACCHARIDE PLUS INTERFERON-γ OR QUARTZ.

P. C. Zeidler, D. W. Porter and V. Castranova. *NIOSH, Morgantown, WV.*

Exposure of mice to lipopolysaccharide (LPS) plus interferon-γ (IFN-γ) or to quartz increases nitric oxide (NO) production, which has been proposed to play a role in the resulting pulmonary damage and inflammation. To determine the role of NO in these acute lung reactions, the responses of inducible nitric oxide synthase knockout (iNOS KO) versus C57BL/6J wild type (WT) mice to aspiration of LPS+IFN-γ or quartz were compared. Male mice (6-8 weeks) were exposed by aspiration to LPS (1.2 mg/kg) + IFN-γ (5000 University), quartz (40 mg/kg), or saline vehicle. At 24 hours post-exposure, lungs were lavaged with 10 aliquots (1 ml each) of Ca+2 and Mg+2 free phosphate-buffered saline. The acellular fluid from the first bronchoalveolar lavage (BAL) was analyzed for total antioxidant capacity, lactate dehydrogenase (LDH) activity, albumin, tumor necrosis factor-α (TNF-α) and macrophage inflammatory protein-2 (MIP-2). The cellular fraction of the total BAL fluid was assayed for alveolar macrophage (AM) and polymorphonuclear leukocyte (PMN) counts, and AM zymosan-stimulated chemiluminescence (AM-CL). Exposure to LPS + IFN-γ decreased total antioxidant capacity, increased BAL AMs and PMNs, LDH, albumin, TNF-α and MIP-2, and enhanced AM-CL to the same extent in both iNOS KO and WT mice. Exposure to quartz decreased AM yield, increased PMNs, LDH, albumin, TNF-α and MIP-2, and enhanced AM-CL. However, iNOS KO mice exhibited less AM activation (activation status was defined as an increased AM-CL and decreased AM yield) than WT mice. These data suggest that NO may play a role in the acute pulmonary response to quartz exposure; however, evidence for a role of NO in the acute reaction to LPS+IFN-γ was not obtained.

217 INTERACTION BETWEEN PRIMARY ALVEOLAR MACROPHAGES(AM) AND PRIMARY ALVEOLAR TYPE II (TII) CELLS UNDER BASAL CONDITIONS AND AFTER LIPOPOLYSACCHARIDE (LPS) OR QUARTZ EXPOSURE.

R. S. Kanj[1], J. L. Kang[2] and V. Castranova[1]. *[1]Physiology & Pharmacology, NIOSH and West Virginia University, Morgantown, WV and [2]Ewha Woman's University, Seoul, South Korea.*

This study evaluated the mutual interactions between AM and TII cells under unstimulated or LPS (10 μg/ml) or quartz (100 μg/ml) exposure conditions. AM were obtained by bronchoalveolar lavage of rats, while rat TII cells were isolated by enzymatic digestion and purified by panning (~20 million cells/rat, 95% pure). AM and TII cells were co-cultured either separated by transwell inserts or in a single well to allow physical contact. After an 18 hour culture period in the absence or presence of stimulant, the medium was assayed for tumor necrosis factor-alpha (TNF-α), macrophage inflammatory protein-2 (MIP-2), interleukin-6 (IL-6), interleukin-1 beta (IL-1β) and nitric oxide (NO). Cell viability, which was measured as lactate dehydrogenase (LDH) released from the cells into the medium, was not affected by either transwell or contact co-culture under basal or stimulated conditions. Under basal conditions, co-culture of AM and TII cells in transwells significantly potentiated the release of TNF-α, MIP-2, IL-6 and NO above the sum of the production by these cells cultured separately. Physical contact between AM and TII cells mitigated this potentiation, which was further decreased by exposure to LPS or quartz. Indeed, under stimulated conditions, physical contact actually decreased the production of some of these inflammatory products below the sum of the production by these cells cultured separately. These results indicate that cross-talk between AM and TII cells is complex. It appears to vary with the distance and/or contact between the two cell types, and with exposure to different stimulants.

218 CYTOTOXICITY OF SIZE-SELECTED MANVILLE CODE 100 (JM-100) GLASS FIBERS ON HUMAN ALVEOLAR MACROPHAGES.

V. Castranova[3], P. C. Zeidler[3], W. J. Calhoun[1], B. T. Ameredes[1], M. P. Clark[1], G. Deye[2], P. Baron[2] and T. Blake[3]. *[1]AAARC, Pulmonary, Allergy, and CCM, University of Pittsburgh, Pittsburgh, PA, [2]Division of Applied Research and Technology, NIOSH, Cincinnati, OH and [3]Health Effects Laboratory Division, NIOSH, Morgantown, WV.*

A previous study using rat alveolar macrophages (AMs) demonstrated that glass fibers > 17μm long were larger than these pneumocytes and resulted in frustrated phagocytosis, while fibers < 7μm long were completely engulfed. Frustrated phagocytosis was associated with a substantially greater cytotoxicity of long versus short fibers (Blake et al. J Toxicol Environ Health. Part A, 54:243, 1998). Human AMs are larger than rat AMs, approximately 18 and 13μm in diameter, respectively. Therefore, the objective of this study was to evaluate the cytotoxicity of fibers of different lengths on human AMs. JM-100 glass fiber samples of 8, 10, 16, and 20μm lengths were obtained by classification of airborne fibers by dielectrophoresis. Human AMs were obtained by segmental bronchoalveolar lavage of healthy, non-smoking volunteers. AMs were treated with three different doses (determined by fiber numbers) of the sized fiber samples for 18 hours *in vitro*. Cytotoxicity caused by the fiber samples was then determined by monitoring membrane damage (leak of lactate dehydrogenase [LDH]) and loss of function (decrease in zymosan-stimulated chemiluminescence [CL]). Microscopic analysis indicated that human AMs were large enough to completely engulf fibers which were 20μm long. All fiber length fractions tested exhibited equal cytotoxicity, i.e., increasing LDH and decreasing CL in the same dose-dependent fashion. The data indicate that because human AMs are larger than rat AMs they are able to phagocytize longer fibers and the absence of frustrated phagocytosis results in lower fiber toxicity in human AMs. These differences in the AM response to long fibers between human and rat phagocytes should be considered when designing *in vivo* exposures using the rat model.

219 SILICA-INDUCED TOXICITY: *IN VITRO* AND *IN VIVO* PROTECTIVE EFFECTS OF TAURINE.

V. Vallyathan, D. Pack and S. Patel. *NIOSH, Morgantown, WV.* Sponsor: V. Castranova.

Taurine has been suggested to have cytoprotective actions through different mechanisms including antioxidant effects. Taurine has been proposed to be a membrane stabilizer thereby preventing oxidative damage. The aim of the present studies was

to test whether taurine might act to attenuate silica-induced toxicity *in vitro* and *in vivo*. The presence of taurine resulted in a reduction of cytotoxicity with alveolar macrophages exposed to crystalline silica. To investigate further whether taurine would function effectively in the prevention of *in vivo* toxicity from exposure to silica we exposed rats by intratracheal instillation to a single dose of 5 mg silica coated with 100 mM taurine and compared the pulmonary response to rats exposed to silica or vehicle saline. Rats were sacrificed 1, 3, or 7 days postexposure, and lungs were lavaged to monitor inflammatory cells (alveolar macrophages, neutrophils, lymphocytes, eosinophils), leakage of albumin, protein and enzymes (LDH, NAG), and chemiluminescence as markers of inflammation, cytotoxicity and reactive oxygen species generated, respectively. Surface coating and coexposure of silica with taurine significantly decreased silica-induced lung injury. In conclusion, taurine showed beneficial effects in both *in vitro* and *in vivo* models of silica toxicity. This result confirms previous studies obtained in other models of lung injury.

220 ASBESTOS AND RADIATION AS COMBINED EXPOSURES IN PULMONARY FIBROSIS.

T. K. Takaro[1,2], W. C. Griffith[1,2], K. Omri[2], H. Checkoway[1] and E. M. Faustman[1,2]. *[1]Environmental Health, University of Washington, Seattle, WA and [2]CRESP, Institute for Responsible Management, New Brunswick, NJ.*

Worker protection standards are based upon single exposures and do not account for the constellation of exposures frequently encountered in the workplace. Workers exposed to asbestos may encounter radiation as radon or from other sources. Both asbestos and radiation are etiologic agents in pulmonary fibrosis. The aim of this study is to determine whether concomitant radiation exposure in asbestos exposed workers increases the incidence of fibrosis demonstrated by International Labor Organization (ILO) opacity profusion category on chest radiographs, or spirometric evidence of restrictive disease. 1037 asbestos exposed former nuclear weapons workers from a medical surveillance program make up the study cohort. Most are male (85.5%) with an average age of 64.9 years. 663 workers had complete work histories. The demographic and fibrosis endpoints did not differ significantly between groups. Asbestos exposure based upon years in a potentially exposed job was divided into low (less than 13 years) and high (> 13 years) dose groups. 8.0% of the high dose verses 3.6% of the low dose group had ILO scores >0/1 indicating pulmonary fibrosis while 29.3% of the high dose group verses 21.8% of the low dose group have spirometry indicating restrictive disease consistent with pulmonary fibrosis. In a 2 x 4 table analysis (binary fibrosis x binary asbestos and radiation exposure) 38.6% in the high asbestos/high radiation group met the cases definition for fibrosis vs. 25.4 % in the low/low group suggesting an additive effect. This publication was prepared with the support of the US Department of Energy, under Award No. DE-FG26-00NT40938. Opinions, findings, conclusions, or recommendations expressed herein are those of the author and do not necessarily reflect the views of the DOE. Additional support: Center for Ecogenetics and Environmental Health at the University of Washington and Center for Environmental Health Sciences at the University of Montana.

221 EFFECTS OF AVASTIN™, AN ANTI-ANGIOGENIC ANTIBODY TO VASCULAR ENDOTHELIAL GROWTH FACTOR, IN A RABBIT MODEL OF VENOUS THROMBOSIS.

C. L. Zuch[1], L. DeGuzman[2], S. Bullens[2], J. Beyer[1], W. J. Leach[1] and S. Bunting[2]. *[1]Safety Assessment, Genentech, Inc., San Francisco, CA and [2]Physiology, Genentech, Inc., South San Francisco, CA.*

Avastin™ (bevacizumab) is a recombinant humanized monoclonal antibody directed against vascular endothelial growth factor (VEGF). It blocks the interaction of VEGF with its receptors, thereby inhibiting angiogenesis. Avastin is intended as a treatment for various cancers. Several thrombotic episodes were observed in clinical trials of Avastin. This non-clinical toxicology study was performed to determine the effect of Avastin in a rabbit model of venous thrombosis. Adult male New Zealand White rabbits were given 75 mg/kg Avastin or Avastin vehicle intravenously daily for eight consecutive days. Following the final dose, a thrombus was induced in the jugular vein by application of a flow-reducing stricture proximal to the site of a clamp-induced damage. The presence or absence of occlusion was noted, as well as time to occlusion and weight of the excised clot. Cuticle bleeding time was measured. Coagulation and fibrinolysis assays were performed *ex vivo*: prothrombin time, activated partial thromboplastin time, whole blood recalcification time, activated clotting time, platelet aggregation to adenosine diphosphate, and d-dimer concentrations. Complete blood cell counts were measured. Immunohistochemical assay for von Willebrand Factor/Factor VIII complex was performed on sections of the jugular vein adjacent to the site of clot formation and on sections from the contralateral undamaged vessel. No differences were found in any of the parameters between Avastin- and vehicle-treated animals. These data suggest that rabbits subacutely treated with Avastin do not develop a prothrombotic or hyper-coaguable state in this venous thrombosis model nor is such a state demonstrable by the biomarkers measured.

222 TH9507: SAFETY STUDIES OF A GROWTH-HORMONE RELEASING FACTOR (GRF) ANALOGUE.

G. R. Washer[1], E. Ferdinandi[1], B. Procter[2], J. Praslicka[2], C. Parente[3], P. Dubreuil[4] and T. Abribat[1]. *[1]Theratechnologies, Inc., Montreal, QC, Canada, [2]ITR, Montreal, QC, Canada, [3]CTBR, Montreal, QC, Canada and [4]P. Dubreuil Services Inc., Montreal, QC, Canada.*

TH9507 is a GRF analogue which has been stabilized by anchoring a hydrophobic moiety to the peptide, while preserving its amino acid sequence. TH9507 is in Phase II trials (doses range from 1.7 to 33.3 µg/kg) for multiple indications (muscle wasting in COPD, recovery after hip fracture surgery, sleep maintenance insomnia and immune dysfunctions). The mode of action involves induction of growth hormone (GH) release, followed by GH-induced release of Insulin-like Growth Factor–1 (IGF-1). Acute to 4-month toxicology and safety pharmacology studies have permited continuation of ongoing clinical trials, and are presented below. Acute IV studies in rats & mice at doses of 100 & 200 mg/kg produced 80% mortality at 200 mg/kg and severe but transient clinical signs at 100 mg/kg. Range-finding 2-week IV studies in rats & dogs revealed no toxicity up to the highest dose (100 µg/kg/day). IND-enabling 4-week IV studies in rats & dogs employing doses of 100 to 600 µg/kg/day revealed no adverse effects; increased body weight, adrenals weight, food intake, bilirubin, triglycerides and/or cholesterol, were attributed to the pharmacological action of TH9507. Three- and 4-month SC studies (with 1-month recoveries) in rats & dogs, respectively, employing doses of 100 to 600 µg/kg/day, revealed increased body weight, food intake, reversible hepatocellular vacuolization and/or reversible increases in phosphorus, triglycerides, cholesterol and proteins. Dose-related injection site irritancy, common to peptides, was also observed. Toxicokinetic evaluations showed a dose-related increase in TH9507 plasma levels. Bioactivity was confirmed by increased rGH and cIGF-1, in rats & dogs, respectively. In conclusion, although no dose level was free of effects, with the exception of local irritancy, all effects were judged to be due to the pharmacological activity. Furthermore, single-dose SC respiratory and CNS safety pharmacology studies in rats at doses of 0.6 to 50 mg/kg, revealed no adverse effects.

223 TWENTY-EIGHT DAY TOXICITY STUDY OF THE CANCER CHEMOPREVENTIVE AGENT 4-BROMOFLAVONE IN RATS.

R. Krishnaraj[1], R. L. Morrissey[2], J. Crowell[3], B. S. Levine[1] and J. Pezzuto[1]. *[1]University of IL @ Chicago, Chicago, IL, [2]Pathology Associates, Chicago, IL and [3]NCI, Bethesda, MD.*

4-Bromoflavone (4BF) is being developed as a cancer chemopreventive agent. We have examined the toxicity of 4BF after 28 days of daily gavage administration to 4 groups of 20 CD® rats/sex at 0, 100, 300 and 1000mg/kg/day. No animals died. Clinical signs included dehydration and rough coat in a high dose group male (1000 mg/kg/day) and 5 males in mid dose group (300mg/kg/day) on days 1-3. Reduced total body weight gain with a corresponding reduction in food consumption was seen in all 4BF-treated groups except the low dose (100mg/kg/day) male group. Plasma levels of 4BF increased as a function of dose level, with male groups showing 2.1 & 1.5 times higher plasma drug levels than female groups at high and mid doses. Treatment-related ophthalmic lesions were absent. Non-hemolytic anemia was noted at high, mid and low dose groups due to reductions in one or more hematologic parameters (hematocrit, RBC count, MCV, hemoglobin, MCH) and increased no. of reticulocytes (high dose group only). The primary target tissues for 4BF were liver and thymus in both sexes, pituitary gland in males, and mammary gland in females. Dose-dependent hyperproteinemia, hypercholesterolemia and hypotriglceridemia were noted. These, accompanied by hepatomegaly and increased hepatocyte glycogen depletion in all 4BF-treated groups were suggestive of liver as a major target organ for the metabolic effects of 4BF rather than hepatotoxicity. Thymic lymphoid depletion in all 4BF-treated groups and hyperplasia/hypertrophy of clear cells of pituitary gland in all 4BF-treated male dose groups were also noted. Increased secretory activity of mammary glands (all doses of 4BF) and reduced weight of ovaries/fallopian tubes (at mid and high doses) were seen in female dose groups. The histopathologic changes were interpreted as related to the metabolic effects of 4BF on liver, pituitary and mammary glands (Support: NCI Contract N01-CN-85173).

224 STABILIZATION AND ANALYSIS OF PYROGALLOL (PG) IN RAT BLOOD AND IN RECEPTOR FLUID MEDIA.

J. Algaier[1], S. M. Barnes[1], B. A. Canham[1], K. Decker[1], A. J. Porter[1], R. K. Harris[1], A. P. Clark[1], D. Overstreet[2] and C. S. Smith[2]. *[1]Midwest Research Institute, Kansas City, MO and [2]NIEHS, Research Triangle Park, NC.* Sponsor: M. Cunningham.

Pyrogallol, (1, 2, 3-trihydroxybenzene, PG), a metabolite of plant hydrolysable tannin gallic acid, is used in hair dyes, as a mordant in wool dying, in the manufacture of pharmaceuticals and pesticides and in topical formulations. Because of its wide

spread use and lack of carcinogenicity data, PG has been selected for toxicological evaluation by the NIEHS. In this work a reverse phase HPLC/UV method was validated for both rat blood and receptor fluid media at pyrogallol concentrations of 4 to 200 μg/mL. Sample concentrations were determined using the peak area ratio, PAR, with resorcinol, 2 μg/mL, as the internal standard. In addition since resorcinol is a pyrogallol metabolite found in urine, sample concentrations may also be determined by peak area alone. During the development of the analysis method, it was observed that PG spiked into rat blood or into receptor fluid media, was rapidly lost. For pyrogallol in rat blood at 0.5 mg/mL, 10% of the initial concentration was lost within 0.4 hr. If spiked into pH 7 receptor fluid media at 0.1 and 0.5 mg/mL, 10% PG was lost within ~ 10 and ~ 30 hours, respectively. This indicated that, for a collected sample, a significant loss of PG in solution will occur prior to analysis if not stabilized. Here we report on the stabilization of PG in rat blood and receptor fluid media samples by adjusting the sample to pH 3 with phosphoric acid and by adding at least 1.5% ascorbic acid, final concentration, as an antioxidant. Once stabilized, spiked rat blood and receptor fluid media samples may be stored for at least 3 weeks under frozen conditions without significant PG loss, allowing for a reasonable time for analysis. Using direct injection mass spectrometry, identification of the PG degradation products was evaluated. Although no degradation components were observed using HPLC/UV, the MS data suggested the presence of a diol metabolite.

225 PHARMACOKINETICS OF GT56-252, A NOVEL ORALLY AVAILABLE IRON CHELATOR IN RAT, DOG AND CYNOMOLGUS MONKEY.

J. K. Marquis[1], R. Aoude-Dagher[1], M. Bree[1], T. Appelqvist[2], P. Guillaumat[2] and R. Forster[2]. *[1]GelTex Pharmaceuticals, Waltham, MA and [2]CIT, Evreux, France.*

GT56-252 is a novel orally-available iron chelator, under development for the primary treatment of iron overload. Pharmacokinetic studies were conducted as part of a preclinical programme to support Phase 1 clinical studies, and were complemented by toxicokinetic data. Single dose pharmacokinetic studies were performed with ^{14}C labeled and unlabeled compound in the rat and dog, and with ^{14}C-labeled compound in the monkey. Excretion balance, biliary excretion and tissue distribution were measured in the rat. GT56-252 was orally bioavailable in all three species, and measurements in the dog revealed a significant food effect. Elimination of GT56-252 from plasma was moderately slow in all 3 species, with terminal half-lives ranging from 3 hours in the rat to 7 or 8 hours in the dog. Overall exposure for unchanged drug in both species was lower than that for radioactivity. Tissue distribution in the rat was similar following oral gavage or IV administration. The organs with the highest concentrations were the adrenals and intestines, while drug levels were also measured in the kidneys and liver. Urinary excretion was the principal route of elimination in both the rat and dog, and more than 80% of the administered dose was eliminated in the urine within 24 hours. Faecal administration accounted for 10 to 20 % of the excreted material, whether given by the oral or IV route, suggesting the involvement of biliary excretion. This was confirmed by measurement of biliary excretion in the rat where 7-8% of an intravenously administered dose was found to be eliminated in the bile in the first 3 hours after dosing. Toxicokinetic data from 28 day oral toxicity studies were broadly consistent with the pharmacokinetic data. In both normal and iron loaded animals, the toxicokinetics data showed good proportionality between administered dose and systemic exposure. There was no evidence that systemic exposure was substantially modified as a result of repeated administration for 28 days.

226 THE PROTEASOME INHIBITOR PS-341 INDUCES COX-2 IN MURINE AND HUMAN ENDOTHELIAL CELLS.

V. Csizmadia, J. Rottman, P. Bouchard, A. Raczynski, M. Juedes, P. White and V. Sasseville. *Drug Safety and Disposition, Millennium Pharmaceuticals, Inc., Cambridge, MA.*

PS-341, a novel compound selectively inhibits the 26S proteasome that is integral in the proteolytic degradation of intracellular proteins. During preclinical safety studies, hypotension was observed in cynomolgus monkeys within hours after administration of an acutely toxic dose that caused >90% proteasome inhibition. Thus, we investigated the ability of PS-341 and lactacystin, a structurally unrelated inhibitor, to induce synthesis of vasoactive mediators in murine RAW 264.7 macrophages, human aortic endothelial cells (HUAEC), and murine b.END3 endothelial cells. Nitric oxide was not detected in endothelial cells, but was produced in LPS and IFN-γstimulated RAW 264.7 cells, which was completely abrogated by treatment with 10 μM PS-341 or 10 μM lactacystin. In HUAEC and b.END3 cells, both proteasome inhibitors induced a robust increase in levels of PGI2 and PGE2, and a mild increase in Thromboxane B2, but not Leukotriene B4. Lactacystin and TNF-α, had a similar but less robust effect. Northern analysis of treated HUAECs showed that PS-341and lactacystin induced Cox-2, but not Cox-1. TNF-α induced VCAM-1 expression was inhibited 83% and 47% by PS-341and lactacystin, respectively. In b.END3 cells Cox-2 mRNA appears by one-hour and peaks at 8 hours post-treatment with PS-341. By Western analysis there was an 11-fold induction of Cox-2 protein that was first detected at 4 hours and reaches a plateau by 24 hours post-treatment. Also, Hsp70 was induced ~12-fold by PS-341, which is a well-documented effect of proteasome inhibitors. To verify that PS-341-mediated Cox-2 upregulation was independent from Hsp70 induction, cells were heat shock treated, which induced Hsp70, but left Cox-2 expression unaffected. Cox-2 gene induction was confirmed *in vivo* by demonstrating strong induction of Cox-2 mRNA expression in peripheral blood mononuclear cells from cynomolgus monkeys administered PS-341. These data demonstrating that PS-341 induced Cox-2 and prostanoids suggest that a peripheral vasodilatory mechanism may mediate hypotension.

227 INVESTIGATIVE CARDIOVASCULAR STUDY OF THE PROTEASOME INHIBITOR PS-341 IN THE MOUSE.

J. Rottman, V. Csizmadia, E. Ozkaynak, V. Kadambi, K. Ganley, K. Cardoza, M. Juedes and P. Bouchard. *Millennium Pharmaceuticals, Inc., Cambridge, MA.*

During preclinical safety pharmacology studies in macaques with PS-341, acutely toxic IV doses (0.3 mg/kg) caused initial tachycardia, followed by progressive bradycardia, hypotension and death. To investigate mechanisms underlying these observations, PS-341 was given to Balb/c mice and ECG tracings using a free ranging remote ECG recording platform (AnonyMOUSE, Mouse Specifics, Inc., Boston MA). Following a single IV dose of 0.1, 0.3, 1.0, 3.0 or 10 mg/kg, at 10 mg/kg showed there was initial tachycardia, followed by a precipitous decrease in heart rate and moribundity. ECG tracings during the period of bradycardia revealed prolonged PR intervals and spiked T waves. No significant ECG changes were seen at ≦3.0 mg/kg. Increased parasympathetic vagal tone was not a considered a contributing factor to the bradycardia as atropine treatment had no effect on heart rate in PS-341 treated mice. Body temperature monitoring showed a decrease in body temperature coincident with decreased heart rates. To confirm a direct association, PS-341 treated animals had body temperature maintained by ambient temperature control and during this period, bradycardia was not seen. Using an *ex vivo* perfused heart preparation, hearts from PS-341 treated mice showed no difference in heart rate and force of contraction compared with untreated controls. In separate but parallel experiments, we investigated the possible role of PS-341 induced soluble vasoactive mediators in the hypotension observed in macaques (Csizmadia, SOT 2003). These experiments demonstrated that PS-341 promoted robust expression of the vasoactive mediators PGE2 and PGI2 by human aortic endothelial cells, which was associated with induction of Cox-2, but not Cox-1 mRNA and protein. Collectively, these data indicate acutely toxic doses of PS-341 had no direct effect on heart rate or contractility and that bradycardia was mediated indirectly through altered thermoregulation, which can be abrogated by maintenance of body temperature.

228 ENDOTHELIAL CELL-DERIVED NITRIC OXIDE MEDIATES SMOOTH MUSCLE CELL FAS EXPRESSION INDUCED BY PHOSPHODIESTERASE INHIBITION.

R. Slim , M. Albassam and L. A. Dethloff. *Drug Safety Evaluation, Pfizer Global Research and Development, Ann Arbor, MI.*

Using an established model of phosphodiesterase inhibitor-induced vasculopathy, we demonstrated increased levels of smooth muscle cell apoptosis in mesenteric vessels of female Wistar rats given 3 daily 750-mg/kg oral doses of the phosphodiesterase (PDE) subtype IV inhibitor CI-1018. Inducible nitric oxide synthase was observed by immunohistochemistry in vascular endothelium and inflammatory cell infiltrates in the vessel media. Because nitric oxide is a documented intercellular signaling molecule between vascular endothelial and smooth muscle cells as well as an initiator of apoptotic signaling pathways, we hypothesized that nitric oxide elaborated by endothelial cells may play a role in vascular smooth muscle cell apoptosis induced by CI-1018. We hypothesized further that nitric oxide release from endothelial cells upon treatment with CI-1018 induces vascular smooth muscle cell apoptosis *via* Fas-Fas ligand pathway. In the present study, human pulmonary artery smooth muscle cells (HPASMC) were cultured with or without overlying monolayers of human lung microvascular endothelial cells (HMVEC-L). Cultures were treated with vehicle or CI-1018 at 125 μM for 72 hours. RT-PCR analysis of smooth muscle cell lysates demonstrated that CI-1018 induced Fas expression in HPASMC only and only when co-cultured with HMVEC-L. Induction of Fas expression was accompanied by an increase in the levels of the nitric oxide metabolites nitrate and nitrite in the shared medium. Pretreatment of HPASMC/HMVEC-L co-cultures with the nitric oxide synthase inhibitor N(G)-nitro-L-arginine methyl ester at 0.1 mμM followed by treatment with CI-1018 diminished Fas mRNA levels in HPASMC in co-culture with HMVEC-L. Fas expression in HMVEC-L was not changed by treatment with CI-1018. These data suggest an important paracrine role for endothelial nitric oxide in PDE IV inhibitor-induced Fas expression in PASMC with important implications in the etiology of vascular smooth muscle cell apoptosis induced by PDE IV inhibition *in vivo*.

229 PYROLYTIC PRODUCTS OF METHAMPHETAMINE HYDROCHLORIDE AS POTENTIAL MARKERS FOR SMOKED METHAMPHETAMINE.

M. Sanga, B. J. Schuler, S. S. Wolfe, R. Carrier, P. S. Callery, T. Bland and T. S. Tracy. *Basic Pharmaceutical Sciences, West Virginia University, Morgantown, WV.*
Sponsor: M. Davis.

Methamphetamine hydrochloride and other smoked drugs of abuse pyrolyze during volatilization to produce breakdown products with potential lung toxicity. Although pyrolysis products of cocaine and phencyclidine have been identified in urine and used as markers for the detection of smoked drugs of abuse, there are currently no markers identified for methamphetamine abuse by smoking. Smoking of methamphetamine HCl laced tobacco yields several volatile products. In order to identify pyrolytic products of methamphetamine in the absence of potentially reactive substances found in tobacco, differential scanning calorimetry (DSC) was used as a pyrolysis chamber to generate thermal breakdown products of methamphetamine hydrochloride. Sample sizes of 0.6-1.0 mg of methamphetamine hydrochloride were pyrolyzed using a Perkin Elmer Differential Scanning Calorimeter 7. Samples were crimped in air-tight and then the sample was placed in the sample holder with a reference pan. Heating rates of 20 and 40 °C/min were evaluated in the temperature range of 275 to 450 °C. Samples were eluted with ethanol and 15 microL portions of the eluant were injected onto a C-18 reverse phase HPLC column with 70:30 MeOH:H_2O mobile phase at a flow rate of 1 mL/min. Samples were also analyzed by gas chromatography-mass spectrometry on a DB5 capillary column with oven temperature 50 °C held for 1 min then programmed at 15 °C/min to 280 °C and by direct injection electrospray ionization ion trap mass spectrometry. Methamphetamine hydrochloride degraded when heated in the DSC instrument above its melting point. At least five decomposition products were observed by HPLC and mass spectral analysis. Beta-methylstyrene (1-propenylbenzene) was one of the major degradation products identified and is a good candidate for use as an indicator of methamphetamine hydrochloride abuse by smoking.

230 CJC-1131, A LONG-ACTING GLP-1 ANALOGUE, EXHIBITS SAFETY AND TOLERABILITY IN DOGS.

S. Wen[1], S. Wilson[2], D. Trebec[1], K. Pham[1], J. Castaigne[1] and B. Lawrence[1]. *[1]ConjuChem, Inc., Montreal, QC, Canada and [2]Milestone Biomedical Associates, Frederick, MD.*

CJC-1131 is an anti-diabetic compound being developed for the control of Type 2 diabetes. By applying the Drug Affinity Complex (DAC) technology to glucagon-like peptide-1 (GLP-1), the hormone selectively and covalently binds to plasma proteins, primarily albumin, after parenteral administration. Pharmacokinetic data demonstrated a long half-life of ~75 hrs following subcutaneous (SC) administration of CJC-1131 in dogs. The acute toxicity of CJC-1131 was evaluated in Beagle dogs following single SC doses of 2, 4 and 8 mg/kg. No treatment-related effects on survival, physical examinations, blood pressure, organ weights, clinical pathology and gross necropsy were observed. Clinical signs included decreased fecal output at doses of ≥4 mg/kg, and emesis at 8 mg/kg. Transient decreased food consumption was noted at all doses in both sexes, as was decreased water consumption in the males at all doses. Both effects were related to the pharmacological action of GLP-1. A sub-chronic study in dogs was also conducted with SC administration every other day (q2d) at doses of 0.25, 1 and 4 mg/kg for 14 days. All dogs survived to termination and no treatment-related effects were noted during physical, ophthalmic and ECG examinations, or on hematology, urinalysis and gross necropsy. Slight dose-dependent weight loss (<6%) was noted at all doses, which correlated with the transient decreases in food (↓6-66%) and water (↓3-41%) consumptions when compared to control animals. Decreases in food and water consumptions were more pronounced on dosing days and were of a lesser magnitude during week 2. Cholesterol values were lower (↓18-31%) in dogs treated at 4 mg/kg. Mild reversible inflammation, noted microscopically in SC tissue at the injection site in all dose groups, including controls, was attributed to administered dose volume and repeated injections in the same site. In conclusion, CJC-1131 up to 4 mg/kg was generally well tolerated in Beagle dogs after SC administration q2d for 14 days.

231 CALCIFICATION OF MUCOSA IN GLANDULAR STOMACH OBSERVED DURING WITHDRAWAL PERIOD AFTER SEVELAMER HYDROCHLORIDE TREATMENT IN RAT.

R. Takai, K. Adachi, T. Koizumi, K. Otabe, Y. Misawa, E. Fujii, K. Watanabe, T. Sugimoto and S. Chiba. *Chugai Pharmaceutical Co., LTD, Gotenba-shi, Japan.*
Sponsor: S. Tsuda.

Calcification of glandular part of gastric mucosa was observed after 4-week withdrawal in 1-month toxicity study in rats with RenaGel®(Sevelamer Hydrochloride), which is used for hyperphosphatamia of hemodialysis patients. This study is to investigate the time course change of calcification in glandular stomach during withdrawal period. Normal diet or 10 g/kg/day of RenaGel was administered by diet mixture for 4 weeks to 25 male rats (Slc:SD, 6-week-old), respectively. Then, at the end of administration (day 0 of withdrawal), and on days 3, 7, 14 and 28 of withdrawal, histopathological examination and clinical pathology were carried out. 5 animals/group were assigned for each time point. On day 0 of withdrawal, serum inorganic phosphorus (IP) and calcium (Ca) x IP product (Ca x IP product) decreased, and chloride (Cl) increased, although histopathology revealed no lesions in glandular stomach. On days 3 and 7 of withdrawal, serum IP and Ca x IP product increased, and then those resumed to control level by day 14 of withdrawal. Serum Cl decreased on days 3 and 7 of withdrawal, and then recovered to control level by day 14 of withdrawal. Serum Calcium was maintained control level during withdrawal. In histopathological examination, mucosal calcification in glandular stomach had been most remarkable on days 3 and 7 of withdrawal, afterward, its frequency and severity declined. Furthermore, hypertrophy of parietal cell was observed on day 3 of withdrawal, suggesting hypersecretion of gastric acid after early period of the withdrawal. Susceptibility of mucosal calcification in glandular stomach during withdrawal period after RenaGel treatment was increased by: (i) immediate increase of blood Ca x IP product after the start of the withdrawal, and (ii) elevated pH in the interstium of glandular stomach by hypersecretion of gastric acid immediately after withdrawal (which may be compensating the disappearance of RenaGel derived Cl from the stomach cavity).

232 FLOW CYTOMETRY METHOD TO EVALUATE BONE MARROW TOXICITY IN THE RAT.

S. Zhao, J. E. Heward, G. L. Cockerell, B. W. Mattes and C. W. Johnson. *Investigative Toxicology, Pharmacia, Kalamazoo, MI.*

The use of flow cytometry has led to significant advances in the understanding of toxicity of some drugs in the bone marrow. We have previously reported several methods to assess toxicity by flow cytometry in the bone marrow such as using cell sorting on Forward and Side Scatter properties; using CD45R and CD71 staining; using Rh123 and nonyl acridine for mitochondria membrane potential evaluation, and a special combination of paraformaldehyde and digitonin fixation with propidium iodide (PI) staining for cell cycle analysis. The present study describes new flow cytometry methods for our investigations on the bone marrow toxicity. CD71 and CD45 have proved to be particularly useful in evaluating the effects of drugs on bone marrow. Two-color analysis using CD45 and CD71 staining provides a means where erythroid precursors, myeloid precursors, lymphocytes and granulocytes can be visualized on one histogram. Other specific stains, such as CD45R or CD11b can be used to evaluate specific cell types on an as-needed basis. Combination of CD45 or CD71 with MitoFluor Green and LDS-751 staining allowed assessment of the mitochondria function for specific cell lineages. Apoptosis has been evaluated in human bone marrow cells using Annexin V in conjunction with PI. However in rats, Annexin V cross-reacts with immature B-cells in the marrow making identification of apoptotic bone marrow cells difficult. Therefore, staining with an activated fluorescent marker of apoptosis, Caspase 3, was evaluated. Combining Caspase 3 with 7AAD as the nuclear stain has allowed the addition of a third marker, such as CD45R or CD71. Thus using 3-color analysis is possible to evaluate cell death and apoptosis in a specific cell lineage. Cells can also be specifically stained for the presence of a drug receptor to determine whether toxicity is due to pharmacology. Flow cytometry methods in cell sorting, apoptosis, cell cycle and immunophenotyping techniques not only provide a rapid bone marrow cells evaluation, but also offer a reliable and fully understanding for the mechanism of toxicity.

233 MEDIATORS OF INFLAMMATION IN PHOSPHODIESTERASE INHIBITOR-INDUCED MESENTERIC VASCULOPATHY IN RATS.

L. A. Dethloff, R. Slim and M. Albassam . *Drug Safety Evaluation, Pfizer Global Research and Development, Ann Arbor, MI.*

Mesenteric vasculitis induced in rats by the phosphodiesterase (PDE) subtype IV inhibitor CI-1018 is characterized by infiltration of mixed inflammatory cells and is associated with increases in peripheral blood neutrophils. We sought to detail the time course of appearance of inflammatory cytokines and chemokines as potential contributors to inflammatory cell activation, differentiation, and recruitment to affected tissues. Eight groups of four female Wistar rats each were given daily oral doses of vehicle or CI-1018 at 750 mg/kg for 3 days. Animals were euthanized 2, 4, 8, 16, 24, 48, and 72 hours after the first dose. Vascular lesions were evident at 48 hours with exacerbation at 72 hours. Serum levels of interleukin-6 (IL-6), interleukin-10 (IL-10), interleukin-1β (IL-1β), tumor necrosis factor alpha (TNF-α), interferon gamma (IFN-γ), and granulocyte macrophage colony stimulating factor (GM-CSF) were determined by enzyme immunoassay. TNF-α and IL-10 were transiently elevated 2 hours after administration of CI-1018. IL-6 was increased at

48 hours and sustained through 72 hours. No changes in serum IL-1β, GM-CSF, or IFN-γ were noted. In concordance with serum data, semiquantitative RT-PCR analysis of mesenteric vessels revealed elevated mRNA levels of IL-6 and TNF-α. Similarly, mRNA levels encoding for chemoattractant factor interferon-inducible protein-10 (IP-10) were increased. The rapid increases in serum TNF-α, IL-10, IL-6 and tissue IP-10 mRNA suggest their involvement in the early pathogenic events leading to frank vasculitis. In particular, the qualitative correlation between the incidence of vasculitis and the magnitude of changes in serum IL-6 support its consideration as a principle component in any proposed battery of biomarkers for vasculitis.

234 CJC-1131, A LONG-ACTING GLP-1 ANALOGUE, IS WELL TOLERATED IN RATS UP TO 14 DAYS.

B. Lawrence[1], S. Wen[1], D. Dunn[2], V. Iordanova[1] and J. Castaigne[1]. *[1]ConjuChem, Inc., Montreal, QC, Canada and [2]Milestone Biomedical Associates, Frederick, MD.*
Sponsor: S. Wilson.

CJC-1131 is a novel agent being developed as an anti-diabetic compound for the control of Type 2 diabetes. It is a synthetic modification of the hormone glucagon like peptide-1 (GLP-1) that allows the compound to selectively and covalently bind to albumin, following parenteral administration. In this way, CJC-1131 retains the activity of the GLP-1 pharmacophore while adopting the pharmacokinetic profile of albumin. Pharmacokinetic data in rats has shown that CJC-1131 exhibits a long plasma elimination half-life of approximately 21-28 hours, following a single subcutaneous (SC) administration. The acute toxicity of CJC-1131 was evaluated in CD rats following single SC doses of 0.75, 1.5, 3 and 6 mg/kg. CJC-1131 was generally well tolerated with decreased fecal output, and decreased food and water consumption at all dose levels. Transient decreased activity was noted at doses ≥1.5 mg/kg with recovery noted within 1-2 hours postdose. In a sub-chronic study, the toxicity of CJC-1131 was investigated in CD rats, following every other day SC injections for 14 days at 0.12, 0.6 and 3 mg/kg. Similar clinical observations were noted, including decreased fecal output, reduced food intake (↓7-87%), reduced water consumption (↓16-66%) at 3 mg/kg only, and dose-dependent decreases in the body weight gain (↓19-70%) when compared to the control animals. Food and water consumption effects were less pronounced on non-dosing days. There was no effect on survival, ophthalmology, hematology, urinalysis, clinical chemistry, organ weights, macroscopic and microscopic pathology that was clearly attributed to treatment. Microscopically, minimal depletion of vacuoles in the cytoplasm of hepatocytes was found in female rats at 0.6 and 3 mg/kg and considered related to the decreased body weight gain rather than evidence of hepatotoxicity. In conclusion, CJC-1131 was well tolerated in rats, following single and repeat SC administration at dose levels up to 3 mg/kg.

235 REPEATED DOSE SUBCUTANEOUS TOXICITY AND TOXICOKINETICS STUDY OF NAHBED IN BEAGLE DOGS.

C. E. Frantz, D. G. Fairchild, C. E. Green, P. Catz, S. Phillips, E. Payson and C. Tyson. *Toxicology, SRI International, Menlo Park, CA.*

The objective of this work was to evaluate potential toxic effects and determine plasma drug concentrations in male and female beagle dogs following repeated daily subcutaneous administration of the monosodium salt of N, N-di(2-hydroxybenzyl)ethylenediamine-N, N-diacetic acid (NaHBED). NaHBED is an iron-specific chelating agent that has been shown to be effective in producing net iron excretion in the iron-loaded Cebus monkey model and has been selected as a candidate therapeutic agent for treating patients with transfusional iron overload. In this study dogs were administered 14 consecutive daily doses of NaHBED in aqueous solution at 32.13 (15% or 20% w/v), 96.39 (20% w/v), or 192.78 mg/kg/day (20% w/v) by slow bolus injection. Administration of 192.78 mg/kg/day caused mortality. Some minimal injection site irritation was observed in all groups with the incidence and severity being lower in controls than in treated animals but comparable among all the NaHBED-exposed groups. High dose animals also exhibited increased emesis, hypoactivity, hunched posture, body weight loss (~19-24%), elevated ALT levels, hepatic biliary leukocyte infiltration, pigmented Kupffer cells, and renal tubular vacuolation. The liver lesions were also present in dogs administered 20% formulations of NaHBED at 32.13 and 96.39 mg/kg/day. Serum iron was notably elevated in all dose groups that received NaHBED relative to controls. Iron-to-total iron-binding capacity was also elevated. NaHBED was readily absorbed as shown by a Tmax of approximately 0.5 hr on Day 1. The Cmax and AUC values increased with dose in both sexes. Based on mortality and moribundity seen the maximum tolerated dose is considered to be at least 96.39 mg/kg/day but less than 192.78 mg/kg/day in dogs administered NaHBED in this dosing regimen. The liver and kidney were identified as target organs. Based on the biliary effects, the no-observed-adverse-effect-level is considered to be 32.13 mg NaHBED/kg/day when administered as a 15% (w/v) formulation.
This work was supported by NIDDK Contract No. N01-DK-3-2201.

236 RAT SPECIFIC MECHANISM OF SRA88O-INDUCED RHABDOMYOLYSIS.

M. Dominguez Estevez, U. Schramm and A. Wolf. *Integrative Compound and Product Profiling, Novartis Pharmacology AG, Basel, Switzerland, Switzerland.*

The ergoline and somatostatin receptor antagonist (sst1) SRA880 was found to decrease serum creatine kinase (CK) activity (> 90 %) and to induce myonecrosis (rhabdomyolysis) after histopathological examination in a 2 week rat study. The underlying mechanism and the relevance of this finding to man was investigated *in vitro* in rat skeletal muscle cells (rSkMC) with and without metabolic activation in a rSkMC-hepatocyte coculture. The results indicate that the SRA880 parent compound was neither toxic in rSkMC, nor did it cause CK inhibition when given to rat or human serum. However, after preincubation with rat hepatocytes SRA880 was toxic to rSkMCs and caused CK inhibition in rSkMCs and rat serum. SRA880 did not cause any effects when it was preincubated with human hepatocytes. While the O-demethylated metabolite 227-450, which is the main SRA880 metabolite in human, was not toxic in rSkMCs, 227-809, the main metabolite in the rat was toxic. Indicators of toxicity were decreased CK activity and ATP content as well as an increased intracellular lactate/pyruvate ratio. The present result suggests that SRA880 can cause rhabdomyolysis in rats but not in man by the formation of metabolite 227-809. By inhibition of the cellular energy supply 227-809 is causing increased anaerobic glycolysis with acidification and damage of the skeletal muscle fibres.

237 ABSENCE OF TOXICITY IN A 13-WEEK INTRAVENOUS INFUSION STUDY WITH INTERCEPT PLASMA IN SPRAGUE-DAWLEY RATS.

T. Sullivan[1], V. Ciaravino[1], T. McCullough[1] and V. A. Sharper[2]. *[1]Cerus Corporation, Concord, CA and [2]Argus Research, A Division of Charles River Laboratories, Horsham, PA.*

The INTERCEPT Blood System for Plasma has been shown to inactivate a broad range of viruses, bacteria, parasites and leukocytes using the psoralen derivative, amotosalen HCl (formerly S-59), in an *ex vivo* treatment process. After addition to plasma, amotosalen reversibly intercalates into nucleic acids. Upon exposure to UVA light, amotosalen reacts to form covalent DNA and RNA cross-links. After the treatment process, the levels of free photoproducts and residual amotosalen are reduced by exposure to a Compound Adsorption Device (CAD). The study was designed to determine any potential adverse effects of treated rat plasma with and without CAD exposure when administered *via* 2-hour daily intravenous infusion at 40 mL/kg to three groups of 15 rats/sex for 13 weeks (91 days), followed by a four-week observation period for five rats/sex/group. The vehicle control was rat plasma. The mean doses of amotosalen given to the rats were ~14.6 and ~993 µg/kg/day for rats receiving treated plasma, with and without CAD exposure, respectively. The high dose was ~250 fold the anticipated human dose, based on a 1L plasma transfusion. Rats were observed for evidence of mortality, moribundity and clinical signs. Body weights and feed consumption were measured. Ophthalmological examinations were performed twice. Hematology, clinical chemistry, and urinalysis evaluations were performed. All rats were evaluated macroscopically on necropsy, organ weights recorded, and tissues processed for histopathologic evaluation. On the first day and during the last week of dose administration, blood samples were taken for evaluation of toxicokinetic parameters. On Day 1 of dosing, the amotosalen C_{max} values were 9.73 and 37.4 ng/mL in rats administered ~14.6 and ~993 µg/kg, respectively. The AUC_{last} values after dosing were 47.5 and 109 ng·hr/mL and the $t_{1/2}$ values were 6.7 and 6.0 hours. There was no observed accumulation of amotosalen in plasma after 91 days of dosage. There was no amotosalen related toxicity in this study.

238 TOXIC EFFECTS OF HMG-COA REDUCTASE INHIBITIORS IN THE HUMAN SKELETAL MUSCLE PRIMARY CELL CULTURE.

A. Wolf[1], L. Ndountse-Tchapda[1], W. E. Trommer[2] and U. Schramm[1]. *[1]Integrative Compound and Product Profiling, Novartis Pharmacology AG, Basel, Switzerland, Switzerland and [2]Department of Chemistry, University of Kaiserslautern, Kaiserslautern, Germany.*

Hydroxymethylglutaryl-coenzyme A (HMG-CoA) reductase inhibitors are well established as pharmacologic agents to improve the lipid profile of dyslipidemic patients as well as decrease cardiovascular-related morbidity and mortality. Rhabdomyolysis is a rare but clinically relevant side effect of statin mono and combination therapy in man, with a higher prevalence for simva- and lovastatin as compared to other statins. The mechanisms leading to HMG-CoA reductase inhibitor mediated myonecrosis are not yet understood. In the present study we compared simva- lova-, atorva-, prava- and fluvastatin in human skeletal muscle cell primary culture (hSkMC) concerning their effects on energy status, caspase-3 activation and cytoplasmic membrane damage (LDH-release). After 2 hours of incubation 50 µM simavastatin and 100 µM lovastatin induced almost similarly, sig-

nificant increases in caspase-3 activity and in parallel increased ATP levels. After 20 hours of incubation with simva- and lovastatin the ATP pools were significantly decreased in comparison to controls and cells started to become leaky for LDH. At the same concentrations, none of the other investigated statins, fluva-, atorva- and pravastatin showed effects comparable to the findings seen with simva- and lovastatin. Effects were seen only at concentrations of 400 µM. These results suggest that induction of capase-3 activity might be an important early event in the development of the statin-induced rhabdomyolysis. Since the caspase-3 activity is depending upon the intracellular ATP levels, the results further suggest that the intracellular energy state might serve as a checkpoint, which could drive cells into necrosis.

239 SAFETY AND ABSORPTION OF PULMONARY DELIVERED HUMAN INTERFERON BETA-1A IN THE NON-HUMAN PRIMATE.

D. R. Demady[1], D. L. Hutto[1], J. L. Lane[1], S. Vaidyanathan[1], P. L. Martin[1], D. Baker[1], N. Shepherd[2] and J. D. Green[1]. *[1]Pharmacotoxicology, Biogen Inc., Cambridge, MA and [2]Covance Laboratories, Harrogate, United Kingdom.*

Safety and absorption of pulmonary-delivered human interferon beta-1a (IFN beta-1a) were evaluated in the rhesus macaque to assess an alternate delivery route. IFN beta-1a was administered *via* inhalation with a dose range of 0-4500 micrograms per week. Serum interferon beta and neopterin, an interferon-induced biological response marker, were measured throughout the study. Safety assessments were performed following one, three, and six months of treatment, the latter followed by a 4-week recovery period prior to sacrifice. Inhaled IFN beta-1a was not associated with any significant changes in safety parameters. In the lung, histomorphologic changes consisted of minimal to mild subchronic alveolitis, which increased slightly with dose but did not progress over six months. Resolution of pulmonary lesions was seen in all recovery animals. Approximately 70% of the blisterpack content was available to the monkeys for inhalation over the exposure period. There was a dose-dependent increase in IFN beta serum concentration levels in treated compared to control animals at doses up to 900 micrograms per week and in the biological response marker, neopterin. Neutralizing titers of anti-IFN beta antibodies (NAbs) were evident in the repeat dose groups beginning at the third week of dosing, which correlated with decreased serum IFN beta and neopterin levels in those animals testing positive for NAbs. However, the lungs were exposed to active IFN beta throughout the entire six-month dosing period as evidenced by analysis of bronchioalveolar lavage fluid. In conclusion, these studies show that chronic pulmonary administration of human IFN beta-1a is generally safe and that sufficient systemic absorption occurs to induce biologic responses in the macaques. These studies suggest that the pulmonary route of administration is a viable alternate route for the systemic delivery of IFN beta-1a.

240 EVALUATION OF SOMATROPIN INHALATION POWDER IN A SINGLE DOSE AND 4-WEEK MONKEY INHALATION TOXICOLOGY STUDY.

M. A. Carfagna[1], D. O. Clarke[1], M. E. Shaw[2], H. W. Smith[1], M. Stiff-Torvik[1] and R. K. Wolff[1]. *[1]Eli Lilly and Company, Greenfield, IN and [2]Battelle, Columbus, OH.*

The toxicity of Somatropin Inhalation Powder (SIP), a dry powder formulation consisting of large porous particles of recombinant human growth hormone and 1, 2-dipalmitoyl-sn-glycero-3-phosphocholine, was investigated in single dose and 4-week inhalation toxicology studies in young rhesus monkeys. Standard toxicology study parameters plus respiratory function (respiratory rate, tidal volume, minute volume), bronchial alveolar lavage parameters and serum levels of immunoreactive growth hormone (GH) and GH-specific antibodies were monitored in each study. Body weights, urinalysis parameters and cardiovascular function were also monitored during the 4-week study. Necropsies were conducted 1 day after the 4-week exposure and after a re-challenge dose following an approximate 2-week recovery period. Organ weights were analyzed and gross and histopathological examinations, including lung tissue stained with proliferating cell nuclear antigen (PCNA) to evaluate a potential mitogenic response, were conducted for all animals. In the single dose study, systemic bioavailability of human growth hormone (hGH) was approximately 10% relative to subcutaneous (sc) injection. Serum pharmacokinetic profiles were similar between pulmonary and sc administration. A moderate immunogenic response was observed in monkeys exposed for 4 weeks. There was no evidence of neutralizing antibodies and there was no anaphylactic response upon single-dose re-challenge after the 4-week exposure. There were no histopathological or other toxicological effects attributable to SIP in any of the parameters evaluated following single doses, during the 4-week exposure period, or following re-challenge. In conclusion, no adverse effects were noted in young rhesus monkeys exposed to single inhaled doses up to 4.0 mg hGH/kg bw or exposed daily to inhaled doses up to 5.5 mg hGH/kg bw for 4 weeks. In sc-administered equivalents, these data in monkeys provide margins of safety well above the recommended clinical doses of hGH.

241 LACK OF GENOTOXICITY WITH THE NOVEL ANTI-INFECTIVE PRODRUG DB289 AND ITS ACTIVE METABOLITE DB75, A 2, 4-DIPHENYL FURAN DIAMIDINE WITH DNA MINOR GROOVE BINDING ACTIVITIES.

P. M. Bak[1], J. L. Allen[1], G. L. Erexson[3], M. M. Mecchi[3], H. Murli[3], R. R. Tidwell[2] and D. W. Boykin[4]. *[1]Immtech International, Inc., Vernon Hills, IL, [2]Covance Laboratories, Inc., Vienna, VA, [3]University of North Carolina, Chapel Hill, NC and [4]Georgia State University, Atlanta, GA.*

The antimicrobial activities of DNA minor groove binding agents have been well-established. DB289 (2, 5-Bis-[4-(N-methoxyamidino)phenyl]furan) is the dimethoxime prodrug of DB75 (2, 5-Bis[4-amidinophenyl]furan), a potent anti-infective that binds to the minor groove of DNA. To support initiation of clinical trials with DB289, the genotoxicity of DB289 and its active metabolite DB75 were evaluated. The potentials for DB289 and DB75 to induce reverse mutations in an Ames assay were assessed at concentrations up to 5000 (DB289) or 333 (DB75) mg/plate using various Salmonella typhimurium strains and 5000 mg/plate using E. coli strain WP2uvrA, with and without metabolic activation. The potentials for DB289 and DB75 to induce structural and numeric chromosomal aberrations in CHO cells at concentrations up to 120 (DB289) and 75 mg/ml (DB75) were assessed, with and without metabolic activation. Finally, potential *in vivo* clastogenicity of DB289 was assessed in a rat micronucleus assay. In duplicate trials of the Ames assay, DB289 and DB75 did not significantly increase the mean number of revertants beyond vehicle control levels in all strains tested. In duplicate trials of the CHO cell chromosomal aberration assay, DB289 and DB75 did not significantly increase either the number or type of chromosomal aberrations beyond vehicle control levels. In the rat micronucleus assay, no significant increase in micronucleated polychromatic erythrocytes was detected in rats treated with DB289 up to 1000 mg/kg. Similarly, DB75 was not clastogenic in this assay since it was present as a major metabolite. Thus, DB289 and DB75 are not mutagenic or clastogenic, and binding of DB75 to the minor groove of DNA is not associated with genotoxicity in these assays.

242 SIMULTANEOUS DETERMINATION OF ACETYLSALICYLIC ACID NON-ENZYME MEDIATED OXIDATIVE PRODUCTS.

L. Zang. *HELD/EAB, NIOSH, Morgantown, WV.* Sponsor: V. Castranova.

Aspirin (ASP) is a commonly used analgesic and anti-inflammatory agent. After ingestion, it is hydrolyzed to salicylic acid (SA) by esterase in the gastrointestinal tract and in liver. We found that ASP can be oxidized to SA without enzyme. On the other hand, SA can react with hydroxyl radical to form its derivatives, 2, 3-dihydroxybenzoate and 2, 5-dihydroxybenzoate. The reaction system consisted of hydrogen peroxide (H2O2), ferrous iron (Fe2+) and ASP or SA. The hydroxyl radical production in the Fenton reaction was confirmed by electron spin resonance (ESR) in combination with spin trapping technique. The assay of ASP oxidative products was performed on high-performance liquid chromatography (HPLC) equipped with UV-visible diode array detector and an XTerra Phenyl column (3.5 um, 2.1 mm x 150 mm). The mobile phase consisted of 0.3% formic acid and acetonitrile at the gradient ratios from 85:15 for 3 min to 80:20 for 6 min and kept for 1 min, then back to 85:15 for 1 min at a constant flow rate of 0.3 mL/min. The compounds were monitored at 230 nm and a reference wavelength 360 nm with 100 nm widths. Benzoic acid was used as the internal standard for quantification. A detection limit of less than 5 ng per injection for these products could be achieved. The reproducibility was found to be better than 10%. The method also could be used to evaluate the *in vivo* and *in vitro* oxidative stress induced by toxicant dermal exposure.

243 OTOTOXICITY OF NORVANCOMYCIN: AN EXPERIMENTAL STUDY IN GUINEA PIGS.

W. Gao[1] and S. Zhang[2]. *[1]Physiology, The Second Military Medical University, Shanghai, China and [2]Antibiotics, North China Pharmaceutic Company, Shijiazhuang, China.* Sponsor: B. Qian.

Norvancomycin (NV), a structural analogue of vancomycin, is used to treat methicillin-resistant staphylococcus infections. The aim of this study was to investigate the ototoxic effects of norvancomycin on the inner ear. Guinea pigs with positive Preyer's reflex were given fourteen consecutive daily doses intravenously of norvancomycin at either 56, 108 or 216 mg/kg. Control animals received equivalent volumes of saline. For a comparison, other animals received daily vancomysin (V) at either 56, 108 or 216 mg/kg for 14 days. The duration of post-rotatory nystagmus and threshold of auditory brainstem response stimulated by click and pop tone were recorded before and after the treatment. The cochleas were dissected for hiar cell counting by the surface preparation, and examined by transmission and scan-

ning electron microscopy. The results showed that there was no changes in duration of post-rotatory nystagmus after treatment in all groups.There was no significant difference in hearing loss between the saline controls and the animals treated with 56 and 108 mg/kg NV . The threshold shifts after administration with NV 216 mg/kg were about 5dB. There was no significant difference in threshold shifts between the groups treated with NV and V at all doses. No inner hair cells were missing and about 2% loss of the outer hair cells of the basal turn were observed in the animals treated with NV and V of 216 mg/kg. Scanning electron microscopy showed a normal appearance of stereocilia and cuticular plateof hair cells in all groups. There is also a normal intracellular ultrastructure of hair cells in the coahleas with NV and V at all doses. Conclusion: There is no clear evidence for the existence of ototoxicity of norvancomycin.

244 PRE-CLINICAL EVALUATION OF ITRACONAZOLE NANOSUSPENSION FOR INTRAVENOUS INJECTION.

R. D. White[1], J. Wong[2], J. Kipp[2], T. Barber[1], J. Glosson[1], J. Kerzee[1], N. Goud[1], J. N. Cammack[1] and B. Rabinow[2]. *[1]Technology Resources, Baxter Healthcare Corporation, Round Lake, IL and [2]Pharmaceutical R&D/Scientific Affairs, Baxter Healthcare Corporation, Round Lake, IL.*

The commercially available Itraconazole, a broad-spectrum antifungal agent, contains Cyclodextrin, a potentially toxic excipient. Therefore, a new Itraconazole nanosuspension was prepared without Cyclodextrin, but using a proprietary microprecipitation and homogenization process. This preparation was found to be stable both at room temperature and at 5°C for more than 1 year without any changes in potency, particle size or agglomeration. Regarding acute toxicity, intravenous injection of nanosupension to Sprague-Dawley rats resulted in no lethality with up to 8 times the dose of the commercially available solution. The NOEL for the nanosuspension was 80 mg/kg in contrast to 20 mg/kg for the commercial solution. The nanosuspension appeared more bioavailable as indicated by the pharmacokinetic parameters. For example, the plasma half-life of the nanosuspension was 14 h, in contrast to 5 h for the commercial Itraconazole solution at an equivalent dose (20 mg/kg). Similarly, the mean resident time for the nanosuspension was 13 h in contrast to 5h for the commercial Itraconazole suspension. Higher PK values were also observed for the metabolite, hydroxy-itraconazole, using the nanosuspension. In efficacy studies, the nanosuspension appeared more efficacious than the commercial solution in eliminating *Candida albicans* from the body, in that alternate day dosing of nanosupension was more effective than every day dosing of the commercial solution. Furthermore, a dose of 80 mg/kg of nanosuspension completely eliminated the Candida colonies from the kidney of rats, whereas dosing with the commercial solution was limited by toxicity. After a high dose (320 mg/kg) intravenous injection of nanosuspension, histopathological studies revealed the appearance of nanoparticles in rat splenic macrophages. In summary, Itraconazole nanosuspension is less toxic and appears to be a more effective antifungal agent than the commercially available solution we evaluated.

245 POLYISOTYPIC ANTIBODY AND MIXED CYTOKINE RESPONSES TO THE MAJOR PEANUT ALLERGENS IN AN ORAL MOUSE FOOD ALLERGY MODEL.

F. van Wijk[1], S. Hartgring[1], L. M. Knippels[2] and R. Pieters[1]. *[1]Immunotoxicology, IRAS, Utrecht, Netherlands and [2]Immunotoxicology, TNO, Zeist, Netherlands.*
Sponsor: M. van den Berg.

Peanut is responsible for the majority of fatal food-induced allergic reactions and peanut-allergy is known for its persistence for life. The mechanism of sensitization is largely unknown. To investigate this, we used a mouse food allergy model. The animals were orally or intra-peritoneally exposed to a peanut protein-extract (PE) together with cholera toxin in order to investigate cytokine production and both Th2 and Th1 antibody responses to the extract and purified peanut allergens Ara h1, Ara h2 and Ara h3. B-cell responses to PE, Ara h1, Ara h2 and Ara h3 were characterized by serum Elisa's and Elispot. After one week, PE-specific IgG1 antibodies could be detected in 2 out of 8 animals orally exposed to PE. Only T-cells of IgG1 positive animals showed IL-4 and IL-5 production upon restimulation with PE. Remarkably, IFN-γ levels were also clearly elevated in cultures of these animals compared to IgG1-negative and control animals. After 3 weeks, peanut specific antibody levels IgE, IgG1 as well as IgG2a were increased in the serum of orally and i.p. peanut-exposed mice. A few animals from the orally dosed groups did not respond and showed no antibody production at all. PE-specific IgA levels were significantly higher in orally dosed animals compared to i.p. treated mice. Strong mixed antibody responses (both IgG1 and IgG2a) were also observed to the purified allergens Ara h1 and Ara h3, whereas the response to Ara h2 was more skewed to Th2. In the animals with serum antibody responses to PE, the PE -induced antibody secreting cells were located in the bone marrow. These results indicate that cytokine production in an early stage may serve as a mechanistic tool to study the onset of sensitization and also as a predictive factor for the development of food allergy. Furthermore, data imply that immune responses to the strong allergen peanut, are not restricted to Th2 induced phenomena but involve Th1/Th2 cytokine production and polyisotypic antibody responses.

246 EVALUATION OF RESPIRATORY SENSITIZATION POTENTIAL OF PHTHALATE ESTERS.

J. H. Butala[1], R. M. David[2], G. Gans[3], R. H. McKee[4] and K. L. White[5]. *[1]Toxicology Consultants Inc., Gibsonia, PA, [2]Consultant to Eastman Chemical Co, Kingsport, TN, [3]BASF, Washington, DC, [4]ExxonMobil Biomedical Sciences, Annandale, NJ and [5]ImmunoTox, Richmond, VA.*

Bronchial asthma is mediated, in part, by the immunoregulatory cytokines IL-4 and IL-13. These cytokines stimulate IgE synthesis which is associated with airway hyperresponsiveness, a hallmark of asthma. Compounds that stimulate IgE synthesis and elicit bronchial reactivity are generally considered to be respiratory sensitizers. A recent publication (Tox Sciences Late-Breaking Absts Suppl, Vol 66, No 1-S, p. 22, 2002) showed that DEHP did not stimulate IgE in mice, and, therefore is unlikely to produce respiratory sensitization. To extend these observations, the potential for three other commercial phthalate ester plasticizers, DINP, DIHP and BBP, to induce respiratory sensitization was assessed. Testing followed the method of Dearman et al. (1992): topical application (and challenge) of the phthalate esters to mice followed by measurement of serum IgE. In addition, auricular lymph nodes were harvested for measurement of IL-4 and IL-13 proteins as well as IL-4 and IL-13 mRNAs. Because skin absorption of higher molecular weight phthalate esters is limited, liver weight increase, a measure of peroxisome proliferation, was monitored for DEHP and DINP. Liver weights were significantly increased indicating that these phthalates achieved systemic distribution. ELISA and RNAse protection assays showed that levels of IgE, IL-4 protein, IL-13 protein, IL-4 mRNA and IL-13 mRNA in phthalate ester treated animals were similar to control values. The positive control, a respiratory sensitizer, trimellitic anhydride, produced large and statistically-significant increases in all parameters, demonstrating responsiveness of the assay. As expected, dinitrochlorobenzene, a contact sensitizer, produced small but significant increases in IgE and in mRNA for IL-4 and IL-13 but not in the levels of these cytokines. In summary, DEHP, DINP, DIHP and BBP were without activity in the mouse IgE test suggesting that they would not induce respiratory sensitization.

247 INDUCTION OF IgE ANTIBODY FOLLOWING SYSTEMIC EXPOSURE OF MICE TO RESPIRATORY SENSITIZING PROTEINS.

I. Kimber[1], D. A. Basketter[2], K. Sarlo[3] and R. J. Dearman[1]. *[1]Syngenta CTL, Macclesfield, Cheshire, United Kingdom, [2]SEAC Unilever Colworth Laboratory, Sharnbrook, United Kingdom and [3]Procter & Gamble Miami Valley Laboratories, Cincinnati, OH.*

With the advent of genetically modified crop plants there is an increased interest in the development of methods for the identification of novel proteins as potential allergens. We have demonstrated previously that food proteins display a differential capacity to stimulate IgE antibody following systemic (intraperitoneal; ip) exposure of BALB/c mice which is consistent with their apparent differing allergenic potential (in man). An additional concern is that inhalation exposure to the novel allergens *via* plant pollens may lead to sensitization. We have therefore investigated the induction of IgE antibody following systemic (ip) exposure of mice to the detergent enzymes Lipolase® and Termamyl®, proteins for which the primary route of sensitization is *via* inhalation. BALB/c strain mice received an ip injection of protein (1%) on days 0 and 7. Control animals were exposed to ovalbumin (OVA), a relatively common food allergen which can also cause occupational asthma. Seven days later, serum samples were analyzed for specific IgE antibody by homologous passive cutaneous anaphylaxis assay and for IgG antibody by enzyme-linked immunosorbant assay. Administration of OVA and Lipolase each induced high titer IgG antibody responses (ranging from 1in 1600 to 1 in 3200 and 1in 512 to 1 in 1024, respectively). Both proteins provoked vigorous IgE antibody production, with all animals testing positive for IgE and titers of 1 in 16 and 1 in 256 recorded for OVA and Lipolase, respectively. Despite the fact that the IgG antibody response was considerably less vigorous (titers ranging from 1 in 32 to 1 in 64), all Termamyl-treated mice were IgE responders and an IgE titer of 1 in 2 was recorded. These data show that those proteins which have respiratory sensitizing capacity may also be characterized by their ability to stimulate IgE responses following systemic treatment of BALB/c strain mice.

248 THE PESTICIDE METARHIZIUM ANISOPLIAE HAS AN ADJUVANT EFFECT ON THE ALLERGIC RESPONSE TO OVALBUMIN IN MICE.

C. Instanes[1], M. D. Ward[2], E. Groeng[1] and G. Hetland[1]. *[1]Environmental Immunology, Norwegian Institute of Public Health, Oslo,, Norway and [2]NHEERL, USEPA, Triangle Park, NC.*

Metarhizium anisopliae is a parasitic fungus employed as a biological control agent against vermin and used in the US for indoor control of cockroaches. Sensitization to cockroach allergens is associated with development of asthma. This pesticide is

non-pathogenic for humans and is therefore an alternative to more toxic chemicals. However, in previous studies M. anisopliae has been shown to cause allergic and asthma-like responses in mice. We examined the adjuvant activity of M. anisopliae crude antigen (MACA), consisting of different parts of the fungus including mycelium, and mycelium alone, on the response to the model allergen ovalbumin (OVA) in the poplietal lymph node assay (PLNA). Groups of 8 mice were injected with MACA + OVA, mycelium + OVA, MACA, mycelium or OVA alone in the right hind footpad. On day 21 the animals were boosted with OVA and then exsanguinated and the PLN removed on day 26. The levels of OVA-specific serum IgE and IgG1 (Th2 immune response), and IgG2a (Th1 immune response) were determined by ELISAs. There was a statistically significant increase in the levels of anti-OVA IgE and IgG1, but not anti-OVA IgG2a in the group given mycelium + OVA compared with OVA alone. In the group given MACA (1/5 of concentration for mycelium) + OVA the levels of anti-OVA IgG1 increased in one out of two experiments. Moreover, both MACA and mycelium + OVA compared with OVA alone induced increased weight and cell number of the excised PLN. Our study shows that exposure to M. anisopliae together with OVA results in an increased local inflammatory response and Th2-dependent immune response to a model allergen in mice. This indicates that M. anisopliae has the ability to increase an allergic response to allergens in the environment. In particular, use of this pesticide for cockroach control in homes, may result in an enhanced allergic reactions in individuals who are sensitized to cockroach allergens. (This abstract does not reflect EPA policy.)

249 PYROGALLOL INDUCES WEAK CONTACT SENSITIZATION BUT STRONG IRRITATION IN FEMALE BALB/C MICE.

T. L. Guo[1], L. X. Zhang[1], R. D. Brown[1], D. R. Germolec[2] and K. L. White, Jr.[1]. *[1]Virginia Commonwealth University, Richmond, VA and [2]NIEHS, Research Triangle Park, NC.*

The reducing agent pyrogallol (PYR) was used as topical therapy for chronic plaque psoriasis, and has found extensive use as an antioxidant in industrial and commercial processes. The objective of this study was to determine the potential for PYR to elicit an allergic response when applied dermally to female BALB/c mice. Measurement of the contact hypersensitivity response was initially accomplished using the local lymph node assay (LLNA). Because PYR was soluble at a concentration of 75% (w/v) in the AOO (Acetone:olive oil at 4:1) vehicle, the exposure level selected was 2.5%, 5%, 10%, 25% and 50% in the first LLNA. Since PYR at all the concentrations produced a significant increase in the proliferation of lymph node cells, two additional LLNAs were performed. The concentrations of PYR used in the second study were at 0.5%, 1% and 2.5%, and the third at 0.25%, 0.5%, 1.0%, 5% and 10%. Significant increases in the proliferation of lymph node cells were observed at the concentrations of 0.5% and higher. Based on the results of the LLNA, a Primary Irritancy Assay (PIA) study was conducted using exposure levels at 0.125%, 0.25%, 0.5%, 1%, 5% and 10%. The results suggest that PYR is an irritant at concentration as low as 0.125%. To further determine if PYR is primarily an irritant, two Mouse Ear Swelling Tests were performed. In the first MEST, mice were sensitized with PYR at concentrations of 0.25%, 1%, and 5%, and challenged with 0.25% of PYR. There was no significant difference when the naïve, vehicle, and three dose groups were compared to background control at either 24- or 48-hr time point. In the second MEST, mice were sensitized with PYR at concentrations of 1% and 5%, and challenged with 1% of PYR. Significant increase in mouse ear thickness was observed at 66 hr after challenge in mice that were sensitized with 5% PYR. Taken together, these results demonstrate that PYR is a weak sensitizer but a strong irritant in female BALB/c mice. (Supported by the NIEHS Contract ES 05454).

250 GENE EXPRESSION CHANGES IN AN ANTIGEN-SPECIFIC SECONDARY RESPONSE USING A DENDRITIC CELL / T CELL CO-CULTURE.

F. Gerberick[1], C. Ryan[1], B. Hulette[1], R. Dearman[2] and I. Kimber[2]. *[1]Procter & Gamble Company, Cincinnati, OH and [2]Syngenta CTL, Macclesfield, Cheshire, United Kingdom.*

The defining event of skin sensitization is the stimulation of T cell activation and proliferation by antigen presenting dendritic cells (DC). Therefore a reasonable approach for the development of an *in vitro* test is to examine at the cellular and molecular levels the interactions between these cells, utilizing a culture system comprising both DC as antigen presenting cells and responding T cells. Therefore, to increase our understanding of the changes in gene expression that are induced by antigen-specific T cell/DC interactions in humans we examined changes in gene expression that occur in a secondary antigen-specific response using cells from a sensitized donor. T cells isolated from a dinitrochlorobenze (DNCB) sensitized subject were cultured with untreated autologous DC or with DC treated with dinitrobenzene sulfonic acid (DNBS), the water soluble analog of DNCB. Total RNA was obtained after 6hrs incubation and changes in gene expression were analyzed using Affymetrix U95Av2 Genechips®. Comparison of mean signal values from triplicate cultures found 29 genes that were significantly different ($p \leq 0.001$) between T cells cultured with untreated versus hapten-treated DC. 25 genes were up-regulated with fold increases of +1.5 to +10.6. Some of the up-regulated genes of interest include interferon regulatory factor 1, interferon-γ, interleukin-2, STAT1 and guanylate binding protein 2. Four genes were down-regulated with fold decreases of -1.1 to -3.7 and only one of the four could be associated with T cells. It is our aim to utilize these data to develop endpoint measures which might form the basis of an *in vitro* approach for the identification of skin sensitizing chemicals.

251 COMPARISON OF UREA-TYPE REACTION PRODUCTS OF METHYLENE DIPHENYL DIISOCYANATE (MDI) AND THE BIS-THIOCARBAMATE METHYLENE DIPHENYL DIISOCYANATE CYSTEINE METHYL ESTER (MDI-CME).

S. J. Stetson[2,1], G. J. Depree[1] and P. D. Siegel[1]. *[1]ASB/HELD, NIOSH, Morgantown, WV and [2]Kettering University, Flint, MI.*

Diisocyanates (dNCOs) are a class of chemicals used worldwide in polyurethane products such as foams, spray paints and wood products. Diisocyanates have been associated with respiratory irritation, asthma, hypersensitivity pneumonitis, bronchitis, irritant and allergic dermatitis, and conjunctival irritation. They are the most commonly reported cause of chemically induced occupational asthma, but the antigenic component is unknown. Reaction of dNCO with free thiol gives rise to bis-thiocarbamate formation. It has been established that the bis-thiocarbamates can form rapidly, and although reversible, are more stable in biological systems than the parent dNCO. The urea-type reaction products obtained from the reactions of both methylamine and HSA with MDI and MDI-CME, were compared. Reactions were carried out under aqueous conditions and analyzed using HPLC, measurement of primary amine content, and 1 and 2-dimensional (D) gel electrophoresis. It was found that at least some of the reaction products of MDI and its bis-thiocarbamate were different. MDI was able to cross link HSA causing loss of primary amine and altered migration in 1D gels. Two methylamine reaction products were evident with the less polar product predominant. The MDI-CME caused no apparent loss of primary amine or 1D gel shift. HSA conjugation was noted by both 2D gel shifts and HPLC-UV analysis. The more polar methylamine MDI-CME product was predominant. This data, along with our previously reported MDI-CME (consecutive) hydrolysis kinetics, suggest potentially different antigenic products may be formed from reaction of MDI vs MDI-thiocarbamates to endogenous proteins.

252 CHARACTERIZATION OF LAMOTRIGINE-SPECIFIC T-CELLS FROM HYPERSENSITIVE PATIENTS.

D. J. Naisbitt[1], J. Farrell[1], J. E. Hopkins[1], G. Wong[1], W. J. Pichler[2], M. Pirmohamed[1] and K. Park[1]. *[1]Pharmacology, The University of Liverpool, Liverpool, Merseyside, United Kingdom and [2]Immunology and Allergology, University of Bern, Bern, Switzerland.* Sponsor: I. Kimber.

Lamotrigine causes severe hypersensitivity reactions. It has been suggested that these reactions have an immune aetiology, and T-cell involvement has been postulated. However, there is little evidence for this. The aim of this study was to characterize the role of T-cells in lamotrigine hypersensitivity. Lymphocytes from hypersensitive patients proliferated when exposed to lamotrigine. T-cell clones were generated by serial dilution and characterized in terms of their phenotype, functionality and mechanisms of antigen presentation (including structure-activity relationships and processing pathways) and cytotoxicity. Forty-four drug-specific T-cell clones were generated; most were CD4+ with occasional CD8+ cells. All clones expressed the αβ T-cell receptor with use of a single Vβ chain, and the skin-homing receptor CLA. Although the Vβ repertoire was heterogeneous, several Vβ 5.1(+) or 9(+) T-cell clones were generated. Lamotrigine-stimulated T-cells were cytotoxic and secreted perforin, IFN-γ, IL-5 and MIP-1α, MIP-1β and I-309. RANTES was expressed constitutively. Lamotrigine was presented on MHC class II (both DR and DQ) by HLA matched antigen presenting cells, in the absence of overt drug metabolism and antigen processing. The T-cell receptor of certain clones could accommodate structural analogues of lamotrigine but no cross reactivity was seen with other anticonvulsants. The data show that Th1 secreting T-cells mediate lamotrigine hypersensitivity. Demonstration of IL-5 secretion, expression of the skin homing receptors CLA and perforin-mediated killing are consistent with clinical features of hypersensitivity including eosinophilia and the observed tissue damage in skin.

253 PATHOLOGIC AND IMMUNOLOGIC RESPONSES IN THE RESPIRATORY TRACT OF A/J MICE AFTER INTRANASAL SENSITIZATION AND CHALLENGE WITH TRIMELLITIC ANHYDRIDE.

A. K. Farraj[1], J. R. Harkema[2] and N. E. Kaminski[1]. *[1]Pharmacology and Toxicology, Michigan State University, East Lansing, MI and [2]Pathobiology and Diagnostic Investigation, Michigan State university, East Lansing, MI.*

Sensitization of the respiratory tract to low molecular weight chemicals (LMWC) including trimellitic anhydride (TMA) is a leading cause of occupational asthma and allergic rhinitis in industrial settings. Mucus hypersecretion and airway inflammation consisting of lymphocytes and eosinophils are pathologic features of such allergic airway diseases (AAD). Many experimental models have linked LMWC-induced AAD to Th2 cytokine expression. Most murine models, however, use systemic administration (e.g., topical) to sensitize mice. The present study tests the hypothesis that intranasal sensitization and challenge with TMA will induce the immunologic and pathologic responses characteristic of LMWC-induced AAD in the nasal and pulmonary airways. A/J mice were intranasally sensitized and then intranasally challenged twice with TMA or 1:4 ethyl acetate/olive oil vehicle. Nasal and pulmonary airways were processed for light microscopic examination. Right lung lobes were analyzed for Th2 cytokine mRNA expression using real-time PCR and total serum IgE was measured using an ELISA. Only mice that were intranasally sensitized and challenged with TMA had a marked allergic rhinitis characterized by an influx of eosinophils, lymphocytes and plasma cells, 24 h after the final challenge. By 96 h, the nasal airway epithelium exhibited increases in stored mucus and a regenerative hyperplasia. Only TMA-sensitized and challenged mice exhibited an increase in lung-derived IL-5 mRNA and elevated total serum IgE that was 4-fold the control level by 24 h after exposure and persisted at that level by 96 h. However, no pulmonary lesions were found in any group. This study is the first to demonstrate that intranasal administration of an LMWC is an effective method of sensitization resulting in the hallmark features of allergic rhinitis and the up-regulation of critical mediators of AAD, IL-5, within the lung after challenge, and total serum IgE (Supported in part by American Chemistry Council Grant #0051).

254 AN *IN VITRO* SENSITIZATION TEST USING HUMAN CELL LINE, THP-1, FOR THE EVALUATION OF WATER INSOLUBLE CHEMICALS.

Y. Yoshida, Y. Ito, H. Sakaguchi, M. Okuda and H. Suzuki. *Kao Corporation, Tochigi, Japan.* Sponsor: J. Avalos.

In our previous study, we found that the expression of CD54 and/or CD86 on human monocytic leukemia cell line, THP-1, were enhanced after a 24-hour exposure of allergens but not non-allergens. These results suggested that measuring CD54 and CD86 expression on THP-1 cells could be used as an *in vitro* sensitization method. However, water insoluble chemicals add a degree of complexity to a cell culture system (i.e., lack of homogeneity). The aim of this study was to identify suitable conditions to evaluate the insoluble chemicals in our *in vitro* system. Under normal conditions, the insoluble chemicals are first solubilized in vehicle (DMSO) at a high concentration and added to the culture medium to make the final concentration of DMSO 0.1%. However, when the insoluble sensitizers, α-hexylcinnamaldehyde (HCA) and benzocaine, were evaluated, the expression of CD54 and CD86 was not enhanced. We first studied a way to evaluate the insoluble chemicals using DNCB as a positive control. When the vehicle concentration was increased to 2% DMSO and exposure time was shortened to 4 hours, the CD54 and CD86 expression was not enhanced. Interestingly, when the cells were cultured in the medium for an additional 20 hours following a 4-hour exposure, the expression of CD54 and CD86 was augmented. We then evaluated HCA and benzocaine using this procedure; namely, the cells were exposed to HCA and benzocaine in 1% DMSO vehicle for 4 or 8 hours and then cultured in the medium to make the total culture time 24 hours. Under these conditions, the insoluble sensitizers enhanced CD54 and/or CD86 expression. It was postulated that the antigens could stimulate the cells during the 4-hr time period and that the surface markers would be expressed on the cell surface later. The results suggest that insoluble chemicals can be evaluated in an *in vitro* culture system by modifying the test conditions. With these modifications, our skin sensitization assay using THP-1 cells can evaluate a larger variety of chemicals.

255 CYTOKINE EXPRESSION IN A ASTHMATIC MURINE MODEL INDUCED BY TOLUENE DIISOCYANATE.

K. Zheng[1] and M. Ariizumi[1]. *[1]Preventive Medicine, University of the Ryukyus, Okinawa, Okinawa, Japan and [2]Preventive Medicine, University of the Ryukyus, Nishihara, Okinawa, Okinawa, Japan.* Sponsor: W. Dong.

This study was aimed at investigated the cytokine status and their gene expressions in airways of asthmatic mouse caused by toluene diisocyanate (TDI). After the mice were exposed to TDI vapor for 5 consecutive days, bronchoaveloar lavage (BAL) was carried out and the cells in the BAL fluid were counted. Lung histological examine was coducted to analyse the inflammatory status in the airways. Total serum IgE and IL-4 and IL-5 concentrations in the BAL fluid were determined with ELISA kits. RT-PCR was applied to investigate IL-4 and IL-5 mRNA from BAL cells. The airway cell count and histological analysis showed that TDI exposure resulted in airway inflammatory responses characterized by marked infiltration of eosinophils in the central and peripheral airways. Total serum IgE was significantly increased in the TDI-exposed mice. IL-4 and IL-5 productions in the BAL fluid were significantly enhanced in the mice exposed to TDI, but in BAL cells IL-4 and IL-5 mRNA were slighlty enhanced without any significant difference compared to the control mice. These results further support the hypothesis that Th2 cytokines are predominantly produced in TDI-induced airway hypersensitivity. However, our data was not able to indicate the exact source of these cytokines and we could not determine whether the change of cytokines in the airways was controlled by gene transcription level.

256 OXIDATIVE STRESS AND PROSTAGLANDIN E2 RELEASE FROM AIR PARTICULATE PM1648 TREATED MACROPHAGES.

J. C. Schneider, A. Archer, G. Card and A. Holian. *Center for Environmental Health Sciences, University of Montana, Missoula, MT.*

Epidemiological studies reveal associations between air pollution and the occurrence of respiratory symptoms characteristic of asthma, but the mechanisms of this effect are not yet clear. The prevalence of asthma has been increasing since the 1970's. Asthmatics are particularly sensitive to attacks brought on by air pollution. Air pollution particulate matter is cleared from the lung by the alveolar macrophage, and the effects of the particulates seem to be mediated by macrophage derived cytokines and lipid mediators. PM1648, a characterized urban particulate, and air particulates in general cause an increased asthmatic, Th2-driven response. Because eicosanoids may play a role in the asthmatic response, this study was based on the hypothesis that PM1648 would affect eicosanoid release from macrophages, possibly through an oxidative stress response. RAW 264.7 cells were treated with PM1648, and oxidative stress was measured as increased dichlorofluorescein oxidation and subsequent increases in intracellular glutathione observed at 6 and 12 hours following treatment with PM1648. Prostaglandin E2 (PGE2) measured by EIA in culture supernatants was also significantly elevated 6 hours after treatment. This increase in PGE2 could be blocked with addition of cell permeable glutathione monoethylester. We have shown that instillation of PM1648 *in vivo* exacerbates bronchial hyperresponsiveness in a mouse model of asthma. These results together suggest that PM1648-induced oxidative stress may lead to changes in eicosanoid metabolism that may affect hyperresponsiveness in the lung. This work was supported by the NIH Grant ES11120 and the Stella Duncan Memorial Research Foundation.

257 TRIMELLITIC ANHYDRIDE (TMA)-INDUCED CELL INFILTRATION IN A MOUSE MODEL OF OCCUPATIONAL ASTHMA IS NOT COMPLEMENT DEPENDENT.

J. F. Regal and M. E. Mohrman. *Pharmacology, University of Minnesota, Duluth, MN.*

Trimellitic anhydride (TMA) is a small molecular weight chemical known to cause occupational asthma. Recent studies in ovalbumin-induced asthma in guinea pig and murine models suggest that the complement system plays a role in mediating symptoms of asthma, particularly airway hyperresponsiveness. Also, in a guinea pig model of TMA-induced asthma, complement depletion reduced eosinophil infiltration into the airspace. In the present study, to determine if an intact complement system is essential in TMA-induced asthma in the mouse, animals were depleted of complement with cobra venom factor (CVF) and the effect on TMA-induced cell infiltration into the lung determined. BALB/c mice were sensitized as follows: days 1 and 3 intradermally with TMA in corn oil vehicle, and day 12 intratracheally with TMA conjugated to mouse serum albumin (TMA-MSA). To elicit the allergic response, mice were challenged intratracheally on day 19 with 400 ug TMA-MSA or control MSA. To deplete complement, animals were treated with CVF or its vehicle (Veh) for 4 days, beginning 24 hours before challenge. Eosinophil and neutrophil infiltration and concentrations of complement component 3 (C3) in the bronchoalveolar lavage (BAL) were assessed 72 hr after challenge in 4 to 8 animals per group. Challenge of sensitized animals with 400 ug of TMA-MSA resulted in significant eosinophil infiltration into the lung compared to MSA challenge. Veh treatment itself reduced TMA-induced eosinophilia in BAL. However, CVF treatment did not significantly reduce TMA-induced eosinophil infiltration into the BAL or lung when compared to Veh treatment. Measurements of C3 in the BAL confirmed that CVF treatment significantly depleted complement compared to controls. These data demonstrate that complement depletion with CVF does not

inhibit TMA-induced eosinophilia in the mouse and that the presence of an intact complement system is not essential for TMA-induced occupational asthma in this model. (Supported by Graduate School and Academic Health Center of University of Minnesota).

258 PARTIAL CHARACTERIZATION OF ALLERGENS IN EXTRACTS OF *STACHYBOTRYS CHARTARUM*.

M. E. Viana[1], M. K. Selgrade[2] and M. D. Ward[2]. [1]*MBS CVM, NCSU, Raleigh, NC and* [2]*ORD NHEERL, USEPA, Research Triangle Park, NC.*

Exposure to *Stachybotrys chartarum* has been associated with the development of serious health problems in humans, including asthma. Previous studies in this laboratory demonstrated respiratory exposure to an extract of a pool of 5 *S. chartarum* isolates caused inflammatory and allergic biochemical, immunological, and physiological responses similar to those observed in human allergic asthma. The goal of the present study was to characterize the major allergens responsible for the observed immune responses. Five isolates of *S. chartarum* obtained from wallboards in water-damaged houses were grown and combined in approximately equal weight amounts, extracted using Hanks' Balanced Salt Solution (HBSS) + Tween-80, and filter sterilized to form a crude antigen preparation (SCE-1). A hyperimmune serum was generated by injecting female BALB/C mice with a 25 µg dose of SCE-1 in alhydrogel adjuvant, followed by additional 15 µg doses of SCE-1 in HBSS at 21 and 35 days. Five days after the 3rd dose, the mice were exsanguinated by cardiac puncture. The resulting serum was used to probe western blots of individual *S. chartarum* isolates, loaded at equal total protein amounts and using an anti-IgE secondary antibody to visualize the major IgE-positive antigens. IgE-positive protein bands were observed in all the extracts; however, the positive bands varied in intensity, suggesting that the isolates differ in their overall antigen profile. (Supported by NCSU/EPA Cooperative Training Agreement CT826512010.) (This abstract does not reflect EPA policy.)

259 STRUCTURE ACTIVITY RELATIONSHIPS OF EPOTHILONE B AND ANALOGUES IN THE MURINE LLNA.

P. Ulrich, J. Streich, N. Runser, R. Schaffner, L. Mueller, M. Wartmann, K. Altmann and A. Floersheimer. *Novartis Pharmacology AG, Basel, Basel, Switzerland.*

Epothilone B (EPO906) is a non-taxane microtubule-stabilizing agent intended for the therapy of cancer. EPO906 and related structures (CGP085720 and CGP085217) were tested in the murine local lymph node assay (LLNA) to identify a putative skin sensitising potential. Test items were applied to female, 7 to 9 weeks old BALB/c mice on the dorsum of both ears on 3 consecutive days. 24 hours after the last application mice were sacrificed and ear biopsies as well as ear-draining lymph nodes (LN) were taken in order to assess skin irritation and LN hyperplasia. A concentration range of EPO906 from 20% to 0.0001% (w/v) was applied in order to identify the concentration, which would lead to a 1.05-fold increase in ear weight (circular biopsy of 0.5qcm), and a 1.3-fold in LN cell count, when compared with the vehicle-treated control group. These increases had been shown by analysis of historical data to serve as a threshold at which usually statistically significant ear skin irritation and LN hyperplasia had been observed. Testing of EPO906 in the LLNA resulted in a bell-shaped concentration response curve with a maximum increase at 0.1% for ear weight, LN weight as well as LN cell count. Minima were identified at 20% and 0.0001% for all parameters. Since body weight was significantly reduced at concentrations above 0.1%, and were not changed at the lower concentrations, it is assumed that general toxicity at higher concentrations is responsible for the sub-maximal ear skin and LN parameters. The threshold concentrations for the ear skin and the LN cell count were calculated as 0.0152% and 0.0032%, respectively. CGP085720 is a structural analogue of EPO906 lacking the macrocycle epoxy-group potentially responsible for the postive effects of EPO906. With CGP085720 similar threshold concentrations as with EPO906 were obtained in the LLNA. CGP085217, an EPO906 analogue containing the respective epoxy group but lacking the macrocycle lactone moiety, produced threshold concentrations above 0.1%, indicating that the lactone group may be involved in the positive LLNA reaction.

260 DETECTION OF ANTI- R-SP-C ANTIBODIES IN SERA OF DOGS AND MONKEYS USING A SPECIFIC ELISA SYSTEM.

M. Mueller[1], W. Ise[2], M. Hecht[1], A. Braun[1], A. Emmendoerffer[1] and J. Kemkowski[2]. [1]*Immunology / Allergology, Fraunhofer Institute of Toxicology and Aerosol Research, Hannover, Germany and* [2]*Institute for Pathology and Toxicology, Altana Pharmacology AG, Hamburg, Germany.* Sponsor: H. Muhle.

Rationale: Recombinant surfactant protein C (r-SP-C) represents an important option for the reconstitution of the alveolar surfactant system in patients undergoing intensive medical care. In studies investigating the biological activities of the recombinant protein, the induction of r-SP-C-specific antibodies in r-SP-C-surfactant treated monkeys and dogs has to be considered. The appareance of those antibodies during the treatment phase indicates the development of a specific immune reaction of the animals against the protein. Therefore an ELISA was established, detecting the r-SP-C-specifc IgG, IgA and IgM-antibodies. Methods: The sera of r-SP-C-surfactant treated monkeys or dogs were prediluted 1:100 and then titrated 1:2 over 8 wells in plates coated with the antigen. After a washing step the bound antibodies of the sera were detected using polyclonal antibodies against IgG, IgM or IgA of dogs or monkeys. The coating of the antigen was investigated using an antibody directed against r-SP-C to ensure a positive signal. To evaluate the data of the treated animals, a negative group of at least 71 untreated animals were investigated to determine the range of the response of a normal group. Results: Three concentrations of r-SP-C-surfactant were investigated in the studies. Only in single animals slightly increased titers of r-SP-C-specific antibodies could be detected. The appearance of the antibodies did not correlate with the treatment or the dose given to the animals. Conclusion: The treatment with r-SP-C-surfactant used in the approach did not indicate a specific immunogeneic risk of the protein in monkeys and dogs. The ELISA assay developed for this specific surfactant protein represented an useful tool for the investigation of the induction of antigen-specific antibodies of several subclasses in these species.

261 THE RELATIONSHIP BETWEEN CELLULAR DISPOSITION AND CYTOKINE POLARIZATION FOR SIMPLE HAPTENS.

J. E. Hopkins[1], D. J. Naisbitt[1], R. J. Dearman[2], I. Kimber[2] and K. Park[1]. [1]*Pharmacology, The University of Liverpool, Liverpool, Merseyside, United Kingdom and* [2]*Syngenta Central Toxicology Laboratory, Macclesfield, United Kingdom.*

2, 4-Dinitrochlorobenzene (DNCB) and trimellitic anhydride (TMA) are haptens that induce a polarized cellular immune responses. Cutaneous exposure of BALB/c strain mice to DNCB results in vigorous production of type 1 cytokines such as IFN-g and IL-12 by lymph node cells (LNC) draining at the site of exposure. The opposite is true for TMA; with the production of low levels of type 1 cytokines and higher levels of the type 2 cytokines IL-4, IL-5 and IL-10 by activated LNC. In an attempt to study whether such qualitatively divergent immune responses are associated with differential disposition we have applied a Western Blot method. Briefly, DNCB and TMA (50-500mM in 1% dimethylsulfoxide) were incubated with the human macrophage-like cell line U937 in the presence or absence of 10% fetal calf serum. At one hour cells and serum were separated and assayed. The proteins were separated by SDS-PAGE, and hapten binding was analyzed using anti-DNCB and anti-TMA antibodies. DNCB was found to bind selectively to cells when the chemical, serum and cells were incubated together. In contrast, TMA bound selectively to serum. However, both chemicals were found to bind covalently to cells and to serum when incubated with either cells or serum alone. In conclusion, we show that TMA and DNCB interact differentially with cellular and extracellular proteins, and propose that this may be an important factor in the development of polarized cellular immune responses to chemical allergens.

262 RELATIONSHIP OF CD86 SURFACE MARKER EXPRESSION AND CYTOTOXICITY ON DENDRITIC CELLS EXPOSED TO CHEMICAL ALLERGEN.

B. Hulette[1], N. Gilmour[2], C. Ryan[1], D. Basketter[2] and F. Gerberick[1]. [1]*Procter & Gamble, Cincinnati, OH and* [2]*SEAC, Unilever Colworth Laboratory, Sharnbrook, United Kingdom.*

Human peripheral blood derived dendritic cells (PBMC-DC) respond to a variety of chemical allergens by upregulating expression of the co-stimulatory molecule CD86. We recently reported that PBMC-DC, treated with the highest non-cytotoxic concentrations of chemical allergen, marginally upregulated CD86 expression and concluded this measure did not provide the dynamic range for assessing a chemical's sensitization potential. For the work presented here, DC were derived from either human monocytes in GM-CSF and IL-4 or from CD1c+ leukocytes cultured in the presence of GM-CSF, IL-4 and TGFb. DC were treated with various concentrations of the chemical allergens dinitrochlorobenzene (DNCB) or dinitrochlorobenzene sulfonic acid (DNBS) for 48 hrs in the presence of GM-CSF and IL-4. Mean fluorescence intensity of CD86 expression, measured by flow cytometry, was upregulated in 5/5 preparations (150%-340% control) on PBMC-DC treated with concentrations of DNBS which induced 10-15% cytotoxicity. In one case, CD86 was upregulated with a non-cytotoxic concentration of DNBS (182% control). CD86 expression was upregulated in 2/2 experiments (130% and 420% control) with CD1c-derived DC treated with DNCB at a concentration which induced slight cytotoxicity. The irritant sodium dodecyl sulfate did not induce upregulation of CD86 expression when tested at concentrations which induced similar cytotoxicity. Our results illustrate that concentrations of chemical al-

lergen which induce slight to moderate cytotoxicity are capable of inducing upregulation of CD86 expression. We did not observe differences in the ability of DC to respond to chemical allergens based on the way in which the DC were isolated and cultured. An association between CD86 expression and cytotoxicity appears evident, but the mechanisms underlying this phenomenon are unknown and should be understood if assessment of changes in CD86 expression is to be used as a predictive tool for skin sensitization.

263 THE CCR7 RECEPTOR IS UP-REGULATED BY HAPTENS ON HUMAN DENDRITIC CELLS.

F. Boisleve and M. Pallardy. *Faculté de Pharmacie, INSERM U461, Chatenay-Malabry, France.*

The frequency of allergic diseases in industrial countries is still increasing. Chemical haptens are responsible for a large part of those immune pathogenesis. These chemicals penetrate into the organism and are taken up by immature dendritic cells (DC) and then presented to naive T-lymphocytes thus eliciting hypersensitivity reactions. Activation of DC by haptens in cooperation with cytokines produced by DC themselves or by keratinocytes induces the maturation of DC. During this process, DC leaves peripheral tissues and migrates to lymph nodes to activate naive T-lymphocytes. Migration of DC involves many factors including the expression of the chemokine receptor CCR7. In this study, we tested the effects of two well-known chemical haptens, dinitrochlorobenzene (DNCB) and nickel sulfate (NiSO4), on the expression of CCR7 on immature DC. These cells were differenciated from cord blood CD34+ hematopoietic progenitor cells in the presence of GM-CSF, TNF-alpha and Flt-3 ligand for 7 days. Treatment of immature DC by DNCB (25 microM) or NiSO4 (500 microM) during 24 hrs induced the maturation of these cells as assessed by the expression of CD83 and CD86. CCR7 mRNA was not detected by RT-PCR on unstimulated DC. However, DC incubated for 4 hrs with DNCB or NiSO4 express the CCR7 mRNA and this expression increases with time. As measured by cytofluorometry DC stimulated 24 hrs by DNCB or NiSO4 express the protein CCR7 on cell membrane respectively. Using microchambers Transwell we showed that DC stimulated by these two haptens were able to migrate in response to CCL19, a ligand of CCR7. Up-regulation of CCR7 was independant of IL-1beta as shown using an antagonist of IL-1 Receptor (IL-1Ra). However, inhibition of TNF-alpha could partially reverse the effect of haptens on CCR7 expression. Taking together, these results suggest that DNCB and NiSO4 are able to provoke the migration of human DC through the expression of CCR7 independently of IL-1beta secretion.

264 PRION PATHOGENESIS: A JOURNEY THROUGH GUT, SPLEEN, & NERVES.

A. Aguzzi. *Department of Pathology, University Hospital Zurich, Schmelzbergstrasse 12, SWITZERLAND, Switzerland.* Sponsor: M. Ehrich.

Prion neuroinvasion consists of an ordered sequence of events resulting in infection of the central nervous system. Successful oral challenge requires transepithelial migration of prions, which may be accomplished by M-cells. Depletion of lymphocytes from the intestinal mucosa by ablation of $\alpha_4\beta_7$ integrins does not prevent pathogenesis, yet mice exhibiting reduced number of Peyer's patches are virtually uninfectible orally. After gaining access to the body from peripheral sites, prions colonize lymphoid organs of mice, humans, and sheep: the failure of peripherally administered prions to elicit disease in immune deficient mice indicates that this is crucial for pathogenesis. B-lymphocytes are required for neuroinvasion upon intraperitoneal administration, probably (but not necessarily only) because they provide lymphotoxins to secondary lymphoid organs, thereby maintaining follicular dendritic cells: genetic or pharmacological interference with lymphotoxin signaling effectively impairs patho-genesis. We have recently generated mice expressing lymphotoxins in lymphoid organs despite the absence of B lymphocytes: this should help determining the precise contribution of B lymphocytes to pathogenesis. The sympathetic nervous system appears to be involved in prion transfer to brain, since sympathectomy delays or prevents pathogenesis, whereas sympathetic hyperinnervation accelerates it. Topographic relationships between follicular dendritic cells and sympathetic endings in lymphoid organs control efficiency of pathogenesis: CXCR5 deficient mice, whose follicular dendritic cells are juxtaposed to sympathetic endings, effect neuroinvasion more efficiently than wild-type mice. Various components of the complement system are modifiers of neuroinvasion efficiency, and their pharmacological or genetic ablation interferes with neuroinvasion. Although isogenic prions are immunologically inert, expression of anti-PrP^C antibodies in transgenic mice has uncovered that (1) autoreactivity to PrP^C does not necessarily tolerize B-cells, and (2) sustained anti-PrP^C IgM titers can prevent peripheral prion pathogenesis.

265 FREE RADICALS IN THE TOXICOLOGY OF ALCOHOLS.

R. P. Mason[1] and J. J. Lemasters[2]. *[1]Laboratory of Pharmacology and Chemistry, NIEHS, Research Triangle Park, NC and [2]Department of Cell Biology and Anatomy, University of North Carolina at Chapel Hill, Chapel Hill, NC.*

Evidence exists supporting the postulate that alpha-hydroxylethyl free radical is involved in the toxicity of alcohols. This free radical has been detected in animal and human models by ESR and immunological techniques. Nonetheless, the metabolic origin of the oxygen free radical species responsible for this free radical formation remains obscure with evidence suppporting the role of both hepatocytes and Kupffer cells. The purpose of this symposium is to bring together leading experts representing different viewpoints in this important area. Several investigators have combined detection of free radicals with ESR with knockout mice to provide new insights. Another investigator is transfecting cell lines with specific radical-generating enzymes. Another investigator is the world leader in antibodies to the alpha-hydroxyl ethyl radical in humans and rodent models. This syposium will address controversial issues in the area of free radicals and alcohol-induced hepatotoxicity.

266 PRONOUNCED HEPATIC FREE RADICAL FORMATION PRECEDES PATHOLOGICAL LIVER INJURY IN ETHANOL-FED RATS.

L. A. Reinke[1] and A. A. Nanji[2]. *[1]Pharmaceutical Sciences, University of Oklahoma Health Sciences Center, Oklahoma City, OK and [2]Pathology, University of Hong Kong, Hong Kong, Hong Kong.* Sponsor: J. Lemasters.

Ethanol is metabolized to a free radical intermediate, the 1-hydroxyethyl radical, after acute and chronic administration to both rats and mice. Furthermore, large acute doses of alcohol, as well as chronic alcohol administration in liquid diets, stimulate radical formation from endogenous compounds that are assumed to be lipids. In order to explore the role of radicals in development of liver injury, we used spin trapping and EPR spectroscopy with rats that had received intragastric alcohol feeding in diets that contained either saturated fat or fish oil. When alcohol is fed in combination with saturated fats, livers develop steatosis, but no further evidence of injury. In this dietary model, biliary concentrations of lipid radical adducts were similar in alcohol-fed and control rats after two weeks of feeding. In contrast, when identical experiments were conducted with diets containing fish oil, alcohol-fed rats formed lipid radical adducts at rates that were 5 to 6 times those of controls. Furthermore, enhanced rates of lipid radical formation continued even after blood alcohol concentrations had returned to zero. Rats given alcohol and fish oil develop hepatic inflammation, fibrosis and necrosis after about four weeks of feeding. Thus, liver pathology develops subsequent to pronounced radical formation in rats fed fish oil and alcohol. In contrast, feeding alcohol with saturated fats does not enhance radical formation or produce liver injury.

267 CYP2E1-DEPENDENT TOXICITY AND OXIDATIVE STRESS IN HEPG2 CELLS.

A. I. Cederbaum. *Pharmacology and Biological Chemistry, Mount Sinai School of Medicine, New York, NY.* Sponsor: R. Mason.

CYP2E1 metabolizes toxicologically important substrates including ethanol. Oxidative stress is a mechanism by which ethanol is hepatotoxic. Induction of CYP2E1 is one pathway by which ethanol generates oxidative stress. We established HepG2 cell lines, which express CYP2E1 by retroviral infection (E9 cells) or by plasmid transfection methods (E47 cells). Ethanol, iron or polyunsaturated fatty acids was more toxic to E9 cells than control cells. Toxicity was associated with elevated lipid peroxidation and prevented by antioxidants. Mitochondrial membrane potential was lowered in E47 cells. Mitochondria appear to be an important target for CYP2E1-dependent toxicity. Toxicity of ethanol, iron, or arachidonic acid was enhanced when GSH was depleted. The E47 cells had an increased GSH content due to transcriptional activation of the gGCS gene. Levels of catalase, alpha-, and microsomal-glutathione transferases were also increased in the E47 cells. Up-regulation of these antioxidant genes may reflect an adaptive mechanism to remove CYP2E1-derived oxidants. Hepatic stellate cells (HSC) are central to the fibrotic response to liver injury and ROS can activate HSC. A possible interaction between CYP2E1, and CYP2E1-derived diffusable mediators, with HSC was evaluated developing a co-culture model. There was an increase in collagen levels in HSC co-incubated with E47 cells compared to C34 cells. Catalase and vitamin E completely blocked the increase. This suggests that the E47 cells are releasing ROS such as H2O2 and lipid peroxidation-derived products that contribute to the elevation in collagen protein. HepG2 cells expressing CYP2E1 appear to be a valuable model to characterize biochemical and toxicological properties of CYP2E1. While several mechanisms contribute to alcohol-induced liver injury, the linkage between

CYP2E1-dependent oxidative stress, mitochondrial injury and GSH homeostasis and elevation of collagen levels of HSC by CYP2E1-derived ROS may contribute to the toxic action of ethanol on the liver.

268 HYDROXYETHYL FREE RADICALS AS A TRIGGER FOR ALCOHOL-INDUCED IMMUNO-TOXIC REACTIONS.

E. Albano. *Medical Sciences, University of East Piedmont, Novara, Italy.* Sponsor: M. Ronald.

Hydroxyethyl free radicals (HER) originate as side products of ethanol oxidation by cytochrome P450 2E1 (CYP2E1). HER are reactive intermediates capable of interacting with a variety of molecules including nucleic acids and proteins. HER-protein adducts are stable enough to be recognised by the immune system and lead to the production of antibodies against HER-derived epitopes (anti-HER ab). These antibodies are detectable in alcohol-fed rats as well as in 50-60% of alcoholic patients. The formation of anti-HER antibodies in both experimental animals and humans strictly depends on CYP2E1 activity and alcoholics with low-inducible CYP2E1 phenotype do not show appreciable immunization by HER-derived epitopes. Although, HER alkylate several hepatic proteins, the binding to CYP2E1 is particularly interesting from the toxicological point of view. We have observed that HER-alkylated CYP2E1 is present on the outer surface of the plasma membranes of isolated hepatocytes exposed to ethanol where it is recognized by human anti-HER antibodies. Furthermore, the reaction of anti-HER IgG with plasma membrane epitopes triggers antibody-dependent cell mediated cytotoxicity when ethanol-treated rat hepatocytes are incubated with normal human periferal blood mono-nucleated cells. Furthermore, the analysis of patients with advanced alcoholic liver disease has revealed that subjects immunized against HER-derived antigens have a 4 fold higher risk of developing auto-immune reactions against CYP2E1 than those non-immunized. Such a risk is further increased up to 22 fold in patients caring a functional mutation in immune regulatory molecule CTLA-4 that reduce inhibitory signals regulating lymphocyte proliferation. This indicates that HER might participate to the development of alcohol liver damage by triggering immuno-toxic reactions as well as by favouring the breaking of immune tolerance towards CYP2E1 that can in turn further contribute to cause immune-mediated hepatic injury.

269 AN *IN VIVO* ESR SPIN-TRAPPING STUDY: FREE RADICAL GENERATION IN RATS FROM METHANOL AND FORMATE INTOXICATION— ROLE OF THE FENTON REACTION.

R. P. Mason. *NIEHS, Research Triangle Park, NC.*

Electron spin resonance spectroscopy (ESR) has been used to study free radical generation in rats with acute sodium formate poisoning. The *in vivo* spin-trapping technique was utilized with alpha-(4-pyridyl-1-oxide)-*N*-t-butylnitrone (POBN), which reacts with free radical metabolites to form radical adducts. The radical adducts were detected in the bile and urine samples from Fischer rats. The use of [13C]-sodium formate and computer simulations of the spectra identified the twelve-line spectrum as arising from the POBN/carbon dioxide anion radical adduct. The identification of POBN-carbon dioxide anion radical adduct provides for the first time direct ESR evidence for the formation of carbon dioxide anion radicals during acute intoxication by sodium formate, suggesting a new metabolic pathway. To study the mechanism of free radical generation by formate, we tested several known inhibitors. Both allopurinol, an inhibitor of xanthine oxidase, and amino-benzo-triazole, a cytochrome P450 inhibitor, decreased free radical formation from formate, which may imply a dependence on hydrogen peroxide. In accord with this hypothesis, the catalase inhibitor 3-aminotriazole caused a significant increase in free radical formation. The iron chelator Desferal decreased the formation of free radicals up to twofold. Presumably, iron plays a role in the mechanism of free radical generation by formate *via* the Fenton reaction. The detection of formate free radical metabolites generated *in vivo* and the key role of the Fenton reaction in this process may be important for understanding the pathogenesis of both formate and methanol intoxication. The mechanism of oxidation of methanol to the alpha-hydroxymethyl radical is also being investigated.

270 INFLAMMATORY CELL-DERIVED OXIDANTS IN ALCOHOLIC LIVER DISEASE: STUDIES *IN VIVO.*

G. E. Arteel. *Pharmacology and Toxicology, University of Louisville, Louisville, KY.*

The evidence that alcohol causes oxidative stress is extensive. Both *in vitro* and *in vivo* data support the hypothesis that alpha-hydroxyethyl free radical is critical adduct formed during alcohol exposure. Furthermore, we have shown that delivery of the antioxidant Cu/Zn-superoxide dismutase (SOD) *via* adenovirus (Ad) also prevented alcohol-induced liver injury and alpha-hydroxyethyl radical formation. While gene delivery of SOD with Ad clearly demonstrates a role for superoxide ($O_2^{\cdot-}$) in alcohol-induced liver injury, there are many superoxide-producing enzymes *in vivo*. Potential sources of $O_2^{\cdot-}$ *in vivo* include xanthine oxidase, NADPH oxidase on macrophages or neutrophils, or CYP2E1 and mitochondria, which are located predominantly in hepatocytes. In addition, $O_2^{\cdot-}$ is not itself a potent oxidant; for example, it cannot attack ethanol to form the alpha-hydroxyethyl radical. These data suggest that $O_2^{\cdot-}$ reacts with other biological molecules to create a more reactive oxidizing species. There are multiple pathways involving $O_2^{\cdot-}$ that can lead to the formation of potent oxidants. Applying knockout technology to the mouse enteral model of alcohol-induced liver injury now makes it possible to determine the specific role of oxidants during alcohol exposure. For example, injury and free radical production is completely blocked in mice deficient in the superoxide-producing enzyme NADPH oxidase (p^{47phox} knockout), suggesting a key role of $O_2^{\cdot-}$ production from this enzyme in alcohol-induced liver injury. Further, we recently showed that mice deficient in inducible nitric oxide synthase (iNOS knockout mice) were completely protected against alcohol-induced liver injury and radical formation, analogous to studies with NADPH oxidase deficient mice. These results support the hypothesis that the potent oxidant formed during alcohol-induced liver injury is dependent on both $O_2^{\cdot-}$ and $NO^{\cdot}$, such as $ONOO^{-}$, an oxidant that is indeed potent enough to form the alpha-hydroxyethyl radical.

271 GENE-ENVIRONMENT INTERACTIONS *IN UTERO*: THE FETAL BASIS OF ADULT DISEASE.

J. Heindel[1] and K. Shiverick[2]. [1]*Division of Extramural Research and Training, NIEHS, Research Triangle Park, NC and* [2]*Pharmacology and Therapeutics, University of Florida, Gainsville, FL.*

The purpose of this symposium is to address an important and emerging area of developmental toxicology: the effect of *in utero* exposures that cause functional changes that are not overtly teratogenic but that result in increased susceptibility to disease/dysfunction later in life. It is becoming apparent that there is an environmental component to every disease. In some cases the environmental trigger is exposure to the adult. However, it is now clear that in many cases the fetus is more sensitive to the same environmental insults and that the effect of exposures during development may have a more detrimental effect on the etiopathology of the disease. Indeed, there is overwhelming epidemiological and clinical evidence that intrauterine conditions alter development of tissues and organs that lead to increased susceptibility to diseases. During development fetuses respond to adverse conditions by favoring the metabolic demands of the growing brain and heart at the expense of other tissues . The long-term consequences of this response are that the individual is protected from death but is more prone to diseases later in life. While epidemiology studies have identified the phenomenon of metabolic programming, little is known about mechanisms by which fetal insults lead to altered programming and to disease later in life. In addition, emphasis thus far has been on alterations in nutrition during development with virtually no focus on the role that exposures to environmental agents either alone or in combination with alterations in nutrition might have on this phenomenon. This symposium will focus not only on the role of altered nutrition in fetal programming but will also show evidence that some environmental agents, especially those with endocrine agonist or antagonist activity, may alter developmental programming *via* alteration in gene expression or gene imprinting and that these changes will also result in increased susceptibility to disease later in life.

272 PRENATAL PROGRAMMING OF ADULT CARDIOVASCULAR DISEASE.

K. Thornburg, M. Morton, G. Girard, A. Barbera, J. Maylie, S. Jonker, N. Sundgren, P. Ahmed, J. Shultz and L. Davis. *Heart Research Center, Oregon Health & Science University, Portland, OR.* Sponsor: J. Heindel.

Known risk factors for coronary disease are based upon statistical associations with high plasma cholesterol, smoking, hypertension and physical inactivity. However, all of the known risk factors combined are believed to account for only about 1/2 of the known cases of coronary disease within the USA. The theories regarding the etiology of coronary artery disease include oxidized lipid damage to endothelium, infectious agents, low production of endothelial dilators and direct oxidative damage. Since the report by Barker et al. (1989), there have been numerous studies showing an inverse relationship between adult onset ischemic heart disease/diabetes and term birth weight in men and women. At present there are no proven underlying mechanisms relating coronary disease to fetal undergrowth. Several hypotheses have been proposed: 1) Increased fetal plasma glucocorticoids. 2) Intrauterine hypox-

emia. 3) High placental vascular resistance. 4) Maternal under-nutrition. We studied the fetal sheep model to test the hypotheses that intrauterine pressure load and anemia re-program the developing myocardium for life. We occluded the main pulmonary artery (PA) of the near term fetal sheep for 10 days to increase PA pressure by a mean of 10 mmHg. Loading dramatically reduced the pool of cardiac cells able to divide. In fetuses made anemic for 6 days, coronary conductance doubled. When these same sheep were studied as full-grown adults with normal hemaotcrits since birth, their coronary conductance was still 2X that of their undisturbed twin. We conclude that prenatal loading and anemic stress alter heart development in ways that predict pathological changes later in life.

273 MATERNAL-FETAL PROGRAMMING *IN UTERO*: ADULT METABOLIC DISEASE AND DIABETES.

K. Shiverick and T. Medrano. *Department of Pharmacology, University of Florida, Gainsville, FL.*

Epidemiological studies in humans have shown that poor growth *in utero* predisposes to later development of type-2 non-insulin-dependent diabetes and hypertension in adulthood. Animal studies have similarly found that pregnant rats fed low protein diets have alterations in glucose metabolism and blood pressure in their offspring. Dietary protein deficiency during pregnancy has long-term effects on the structure and function of the developing endocrine pancreas. In pregnant rats fed isocaloric low protein diets, the fetal pancreas has been shown to have reduced b-cell proliferation, islet size and vascularization, as well as well as impaired insulin secretion *in vitro*. Exposure to a low protein diet *in utero* and through lactation has been associated in young animals with increased pancreatic β-cell apoptosis, decreased proliferation and altered growth factor expression. The livers of low protein offspring also show morphological changes in zonation and alterations in enzymes involved in glucose metabolism and insulin sensitivity. Study of fetal hepatic function, however, is complicated because the fetal liver is a major hematopoietic organ that is primarily comprised of nonhepatic hematopoietic stem cells until the time of birth. Our studies have found that the low fetal liver content of hepatocytes significantly impacts on the evaluation of the effect of environmental exposures on hepatic function. This developmental shift in the cellular composition of the fetal liver is an important factor that must be considered in studies designed to compare fetal hepatic function and gene expression with patterns found in postnatal and adult liver. In summary, multiple mechanisms influence the nutrient and endocrine milieu which can alter the expression of the fetal genome and the adult functioning of the pancreas and liver.

274 ENVIRONMENTAL EFFECTS ON PERINATAL RESPIRATORY/NEURAL DEVELOPMENT: LASTING CONSEQUENCES OF EARLY EXPOSURE.

K. Pinkerton[1], J. Joad[1], F. Seidler[2] and T. Slotkin[2]. [1]*University of California, Davis, CA and* [2]*Duke University, Durham, NC.*

The respiratory and nervous systems are complex organs composed of multiple cell types involved in a variety of functions. Exposure to a wide range of environmental toxicants during perinatal life has the potential to significantly affect the growth, maturation, and function of both respiratory and neural processes. we examined the effects of perinatal exposure to environmental tobacco smoke (ETS) on lung and neural development in rats and monkeys. Exposure to ambient levels of ETS (1 mg/m3 of total suspended particles) was for 6 h/day, 5 d/week from early gestation to late postnatal age (pre-puberty). We assumed that such exposures could likely affect critical molecular signals expressed during distinct stages of development. We also factored in the tenet that respiratory/ neural development is a multi-step process. Therefore, some studies involved only *in utero* exposure, others only postnatal exposure and others both *in utero* and postnatal exposure. We found differential effects in both the lungs and the brain following ETS exposure. Some respiratory effects (airway hyper-reactivity and neuroendocrine cell hypertrophy) were not evident with only *in utero* or only postnatal exposure, but demonstrated significant effects with combined exposure; these effects persisted weeks after exposure to ETS had ended. Neural consequences displayed a wider window of vulnerability. In both rats and monkeys, we measured significant effects of either prenatal or postnatal ETS that could lead to lasting adverse consequences of asthma, cardiovascular compromise and neurological deficits. Many of these changes were consonant with abnormalities associated with sudden infant death syndrome (SIDS), immune imbalance and lingering respiratory hyper-reactivity. We conclude that critical windows of exposure to ETS during perinatal life can alter the growth and development of neural and respiratory systems. Perinatal exposure to common environmental pollutants may thus have adverse consequences that emerge later in life.

275 EFFECTS OF ENVIRONMENTAL ANTIANDROGENS DURING FETAL REPRODUCTIVE DEVELOPMENT: CONSEQUENCES FOR THE ADULT.

P. Foster[1], K. Turner[2], M. Sar[2] and N. Barlow[2]. [1]*Environmental Toxicology Program, NIEHS, Research Triangle Park, NC and* [2]*CIIT Centers for Health Research, Research Triangle Park, NC.*

There has been significant concern that environmental agents are contributing to increased human male reproductive disorders (decreases in sperm counts, increases in reproductive tract malformations, cryptorchidism and testicular cancer). Experimental evidence in rats indicates that a number of environmental antiandrogens can produce a range of reproductive effects identical to those for which there is human concern. Two agents, di-n-butyl phthalate (DBP) and linuron (L), produce major malformations, predominantly of the epididymis, in the absence of toxicity to the dam when administered during critical windows of *in utero* development (GD 12-21). The epididymal malformations are observable postnatally, with resulting testicular effects occurring at adulthood. However, DBP and L operate *via* different mechanisms that affect fetal androgen signaling. An analysis of gene expression changes in fetal and neonatal testes and epididymides by cDNA microarrays with confirmation by RT-PCR has indicated significant down regulation of genes in a number of critical pathways. DBP in fetal testes (GD 19 and 21) produced a down regulation of several genes in the steroidogenic pathway producing testosterone (T), consistent with lowered fetal testicular T levels, while changes in c-kit expression are consistent with aberrant gonocyte development. Interestingly, while mRNA levels for the androgen receptor (AR) were not changed in the fetal epididymis, the distribution of AR protein between epithelial and mesenchymal cells was altered. In the case of L, fetal (GD 21) and neonatal (PND 7) epididymides had decreases in gene expression in the Bone Morphogenic Protein, EGF and IGF signaling pathways, all consistent with a failure of normal Wolffian duct development and altered interaction between epithelial and mesenchymal cells. The range of gene changes noted following *in utero* exposure to DBP and L could be directly related to morphological disturbances in perinatal animals and ensuing injury noted in later life.

276 DIETHYLSTILBESTROL(DES) EXPOSURE DURING DEVELOPMENT ALTERS UTERINE GENE EXPRESSION: INFLUENCE ON CANCER LATER IN LIFE.

R. Newbold. *Environmental Toxicology Program, NIEHS, Research Triangle Park, NC.* Sponsor: J. Heindel.

Estrogenic substances like DES alter development of reproductive tract tissues leading to structural, functional, and long term abnormalities including neoplasia later in life. Since the developing organism is uniquely sensitive to perturbation by chemicals with hormone-like activity, the present study addresses whether exposure to these chemicals during critical stages of differentiation will permanently alter normal gene expression during uterine development, so that the uterus responds atypically to further estrogen stimuli later in life. Outbred CD-1 mice were treated by subcutaneous injections with DES (0.0001 - 1, 000 mg/kg) dissolved in corn oil, or corn oil alone (control), on days 1-5 of neonatal life. Mice were weaned at 17 days prior to puberty and challenged with 3 daily doses of 17b-estradiol (500 mg/kg) or DES (10 mg/kg). On the 4th day, uterine wt./body wt. ratios were determined and uterine tissues evaluated for both cellular and molecular changes. Neonatal DES exposure resulted in altered uterine gene expression and response to estrogen at puberty. The response varied depending on the dose of neonatal exposure; neonatal exposure to the low dose of DES (0.01 mg/kg) caused an enhanced response to estrogen at puberty as compared to controls, whereas higher neonatal doses of DES caused reduced uterine response. To determine if these altered uterine responses were permanent, an additional group of mice was neonatally treated with DES (0.001-10 mg/kg) and housed until 4-5 months of age. Following ovariectomy, these adult mice challenged with estrogen showed similar altered gene expression and uterine response as the immature mice. DES-associated transgenerational events involving an increased susceptibility for tumors were also studied to determine if altered gene expression was playing a role in uterine neoplasia observed in second generation DES exposed mice.

277 HEALTH RISK ASSESSMENT OF HEXAVALENT CHROMIUM IN DRINKING WATER: CARCINOGENICITY, RESEARCH, AND REGULATION.

D. M. Proctor[1] and E. V. Ohanian[2]. [1]*Exponent, Irvine, CA and* [2]*Office of Water, USEPA, Washington, DC.*

It has been well established that hexavalent chromium [Cr(VI)] can cause lung and nasal cancer among workers exposed to high airborne concentrations in certain industries. However, the potential oral carcinogenicity of Cr(VI) has been a matter of

controversy and conjecture in recent years. It is known that Cr(VI) is detoxified by reduction to Cr(III) in the acidic and reducing environment of the stomach. USEPA cited the gastric reductive capacity in support of their decision to raise the chromium maximum contaminant level (MCL) from 50 ppb to 100 pbb. USEPA and other agencies have also determined that there is insufficient evidence at this juncture to indicate that Cr(VI) poses an oral cancer risk. However, some uncertainties remain with respect to the quality of the available data, and as a result, the National Toxicology Program recently initiated a subchronic and chronic drinking water toxicity research project. The purpose of this study is to supplement the available animal pharmacokinetic and toxicity information. The potential hazards posed by Cr(VI) in drinking water, and the practical implications for assessing risk and setting health-based standards, depends on the weight of evidence from many scientific disciplines, including mechanistic and whole-animal toxicology, epidemiology, and kinetics. Significant new research in these fields has been conducted and will be discussed in this symposium. The use of new data for assessing the health risk from drinking water exposures, and the basis for setting health-based standards, will be presented with a case study of a recent risk assessment for Cr(VI) drinking water exposure in San Fernando Valley, California.

278 MECHANISM OF HEXAVALENT CHROMIUM [(CR(VI)] TOXICITY AND CARCINOGENICITY.

J. W. Hamilton. *Department of Pharmacology & Toxicology, Dartmouth Medical School and Center for Environmental Health Sciences, Dartmouth College, Hanover, NH.*

Long term occupational inhalation exposure to chromium(VI)-containing dusts has been associated with an increased risk of respiratory cancers whereas other routes of exposure (dermal, ingestion) have not been associated with significant adverse health effects. Conversely, chromium(III) is an essential trace element in humans and animals and is essentially non-toxic. The basis for the differences in the biological effects of these two chromium valence states, and for the selective toxic effects of chromium(VI) which are restricted by chemical and physical form, route of exposure, and target tissue toxicity, are explained by the unique biology and chemistry of chromium and have been summarized in the cellular uptake-reduction model of Wetterhahn and the *in vivo* reduction model of De Flora. Chromium(III) is taken up very poorly by the gut and also does not easily cross cell membranes. An organic complex containing chromium(III) interacts with cell surface receptors to elicit effects on cell signaling that underlie its essential trace element role in glucose homeostasis. Chromium(VI) has the potential to cross cellular membranes through the anionic transport system but does not normally reach internal cellular targets due to the high reductive capacity of the body, especially the GI system and the skin, except under very high dose conditions which can overwhelm this capacity. However, under historical occupational conditions in which workers were exposed to very high concentrations of chromium(VI) dusts daily over several decades, the reductive capacity of the respiratory system was likely overwhelmed leading to increased risk of cancer, perforating ulcers and fibrosis. The available data, in conjunction with these models, is consistent with the prediction that there is no significant health risk associated with most environmental exposures to chromium(VI) including exposure *via* drinking water.

279 CHROME EXPOSURE AND LUNG CANCER, STOMACH CANCER AND OTHER CAUSES OF DEATH: AN EPIDEMIOLOGIC META-ANALYSIS.

P. Cole[1] and B. Rodu[2]. [1]*Department of Epidemiology, School of Public Health, University of Alabama, Birmingham, AL and* [2]*Department of Pathology, School of Medicine, University of Alabama, Birmingham, AL.* Sponsor: D. Proctor.

We reviewed the entire epidemiologic literature on chromium exposure and cancer published since 1950. This included more than 100 papers, 72 of which contained useful information on cancer risks. Eight epidemiologic design features of each study were evaluated and scored independently by the authors. The studies were then divided into two groups of higher and lower scoring studies. Findings were then compiled for All Causes of Death Combined, All Cancer Combined, Cancer of the Lung, Cancer of the Stomach and for each of six additional forms of cancer. This was done separately for the higher and lower-scoring studies. Nearly all of the studies related to occupational, not to drinking-water, exposures. However, 20% to 40% of inspired chromium particulates eventually reach the stomach. Among persons exposed to Cr(VI), there was a slight but significant deficit of All Causes of Death. There was a minimal, but significant, excess of deaths from All Cancer; this was due almost entirely to an excess of lung cancer. For lung cancer, the overall meta-standardized mortality ratio (mSMR) was 148 (95% CI=140-155) but among studies that controlled for cigarette smoking the mSMR was 120(113-128). There was a slight (mSMR=106) and non-significant excess of stomach cancer. However, among studies that controlled for the economic status of their subjects, the mSMR was actually depressed to 79 (67-93). Discrepancies between the higher and lower-scoring studies will be discussed. This comprehensive evaluation indicates that there probably is a causal relationship between exposure to Cr(VI) and lung cancer. However, this relationship previously has been over-estimated because early studies did not adjust for the heavy smoking of their subjects. The findings also suggest that there is no association, much less a causal relationship, between exposure to Cr(VI) and stomach cancer. The implications of the findings for other forms of cancer will be discussed.

280 REFINING THE PBPK MODEL FOR CHROMIUM(VI) IN HUMANS.

S. M. Hays[2], D. M. Proctor[1] and D. J. Paustenbach[2]. [1]*Exponent, Irvine, CA and* [2]*Exponent, Menlo Park, CA.*

A physiologically based pharmacokinetic (PBPK) model for trivalent and hexavalent chromium [Cr(VI)] in humans was recently published (OFlaherty et al., 2000). A critical parameter within the model is the rate at which Cr(VI) is reduced to Cr(III) in the gastrointestinal tract (GI). Two limitations of the current model are: 1) that it relies on limited data regarding the gastric reduction capacity of humans, and 2) the GI tract is described as a single combined stomach and small intestine (SI) compartment. This latter limitation requires that absorption and reduction processes be described as simultaneous competing reactions, whereas physiologically, reduction of Cr(VI) occurs primarily in the stomach followed by absorption in the SI. This work describes refinements to the current PBPK model. Specifically, we used new *in vitro* reduction rate data, simulating a variety of conditions (e.g., fasted, fed, antacids, diluted stomach fluid), to better quantify the rate of Cr(VI) reduction in the stomach, focusing on the rate within the first few minutes before transfer of stomach contents to the SI occurs while fasting. Based on these new data, first-order reduction rate constants and gastric half-lives were calculated to range from 10 to 0.7 minutes, with an average of 2.7 minutes. These rates are up to 14 times faster than that used in the current PBPK model. We also modified the current model, separating the stomach compartment (where reduction occurs) from the SI compartment (where reduction continues, but at a slower rate, and absorption occurs). The revised model provides vastly different estimates of the amount of Cr(VI) that might be absorbed systemically by humans following ingestion of Cr(VI), as compared to the first model. These results are valuable for understanding the potential risks associated with Cr(VI) in drinking water and the potential threshold for absorbing Cr(VI) following ingestion.

281 NATIONAL TOXICOLOGY PROGRAM STUDIES OF HEXAVALENT CHROMIUM.

J. R. Bucher and K. Abdo. *NIEHS, Research Triangle Park, NC.*

Hexavalent chromium (CrVI) is a known human carcinogen through occupational exposures, but there is inadequate information to characterize its carcinogenic hazard when consumed in drinking water. Consequently, private individuals, the State of California and members of the California Congressional delegation nominated CrVI to the NTP. In preliminary studies, CrVI (as sodium dichromate dihydrate in all studies) was administered in drinking water (1 to 300 mg Cr/L) for 3 weeks to rats, mice and guinea pigs. Significant differences were not apparent in the shapes of the dose response curves for total Cr accumulation (measured once following a two-day wash out) in blood and kidney in the three species, although absolute levels differed. In subsequent studies, rats and mice received 62.5 to 1000 mg sodium dichromate dihydrate/L (24 to 384 mg CrVI/L) in drinking water for 13 weeks. Significant toxic effects were limited to metaplasic (mice) and inflammatory and/or erosive lesions (rats) of the glandular stomach at 1000 mg/L, a microcytic, hypochromic, responsive anemia in all dosed groups of rats, and effects secondary to decreased water consumption primarily in the 1000 and 500 mg/L dose groups. Based on these results, a 2-year drinking water study in F344 rats and B6C3F1 mice is under design. Additional 13-week studies are examining the comparative toxicity of CrVI in BALB/c and C57BL/6 mice, and *in vivo* mutagenicity in the am3-C57BL/6 mouse. Immunotoxicity studies will be performed in female B6C3FI mice. Protocols can be accessed at http://ntp-server.niehs.nih.gov/htdocs/Studies/HexChromium/hexchromiumpg.html

282 RISK ASSESSMENT FOR HEXAVALENT CHROMIUM IN DRINKING WATER.

R. Sedman and R. A. Howd. *Office of Environmental Health Hazard Assessment, California EPA, Oakland, CA.*

Hexavalent chromium has been detected in the drinking water of a number of communities in California. An evaluation of risk associated with chemicals in the drinking water supply should consider all relevant routes of exposure, such as inges-

tion and the inhalation of water generated during showering. The assessment of exposure to hexavalent chromium in drinking water is complicated by the classification of hexavalent chromium as carcinogenic by inhalation, while there are no high quality cancer studies in animals and humans by the oral route. Mechanistic and genotoxic studies suggest a reason for concern about increased levels of hexavalent chromium (and perhaps trivalent chromium) within cells. Differences in the pharmacokinetics of orally administered hexavalent chromium and trivalent chromium compounds have been observed in both humans and animals. Compared to trivalent chromium, a higher fraction of orally administered hexavalent chromium is absorbed, higher levels of chromium are detected in the blood and tissues, and more chromium is recovered in the urine. A prolonged urinary half-life of chromium following the administration of hexavalent chromium in humans also suggests orally administered hexavalent chromium is taken up into tissues and then slowly released. Limited carcinogenicity data and uncertainties regarding interpretation of the pharmacokinetics, mechanism of action, and genotoxicity prompted OEHHA to nominate hexavalent chromium for NTP cancer bioassays. A risk assessment for hexavalent chromium based on the presently available data considers non-cancer effects by the oral route, and the potential for inhalation of respirable droplets in showering, to arrive at predicted health-protective levels in drinking water.

283 WORLD TRADE CENTER AFTERMATH: LOOKING BACK TOWARDS THE FUTURE.

H. Zenick and S. H. Gavett. *USEPA NHEERL, Research Triangle Park, NC.*

The World Trade Center (WTC) disaster of September 11, 2001 galvanized the public health community to respond rapidly with environmental pollutant monitoring, exposure assessments, toxicological research, and health risk assessments. This symposium draws upon the WTC experience to better understand the major challenges that were presented, and the key response, research, and data needs that emerged. An effective public health response to environmental health emergencies requires a unified infrastructure of institutions with a coordinated communications strategy, preparedness response plans, and capacities in medical care, environmental monitoring, and surveillance. Exposure assessments of the general population and workers involved in recovery and cleanup utilize newly developed analysis and computational tools, monitoring databases, and personal exposure monitoring. The destruction of the WTC and associated fires caused the release of pollutants which are possibly unique in composition and toxicity. Toxicological assessment of particulate matter (PM) from the WTC relative to previously characterized emission and ambient air PM samples contributed to the health risk assessment of WTC-derived airborne pollutants. The human health risk assessment approach integrates information from compositional analysis, toxicological assessments, ambient air monitoring, modeling of the plume movement, and comparisons against historical pollutant levels and benchmark health values. As the WTC recovery effort moves into the indoor residential environment where cleaning efforts are ongoing, the long-term health risks to local residents are being addressed by establishing clearance criteria of contaminants of potential concern. This symposium provides an integrated view of the role of research in helping the Nation to better anticipate, prepare, detect and respond to environmental health threats in the future. [This abstract does not necessarily reflect USEPA policy.]

284 ON-THE-GROUND PUBLIC HEALTH RESPONSE TO THE WTC COLLAPSE: LESSONS LEARNED.

P. Meehan. *National Center for Environmental Health, CDC, Atlanta, GA.* Sponsor: H. Zenick.

Public health is a critical part of the response system for disasters, terrorism and other domestic and international emergencies. The role of federal health agencies, as defined in the various federal response plans, is described in this presentation. The requirements of a prepared public health system include an incident command and support structure, preparedness response plans, effective communications, epidemiology and surveillance capacity, chemical and biological laboratory capabilities, medical care surge capacity, and capacity in occupational and environmental health. The events in New York City since Sept. 11, 2001, vividly demonstrate the importance of these capacities and provide lessons that are useful in improving the public health response system. On Sept. 11, staff from the Centers for Disease Control and Prevention (CDC) were on the ground to assist the New York City Department of Health (NYCDOH) in its response to this disaster. Immediate issues were the need to institute effective emergency response coordination, the need for surveillance for possible biological or chemical terrorism, and response to a request to provide materiel from the National Pharmaceutical Stockpile. Over the next several weeks, CDC assisted the NYCDOH in response to worker health and safety issues and environmental contamination and toxicology. As a major part of the federal health response system, the Centers for Disease Control and Prevention has developed a comprehensive approach to terrorism and emergency public health that includes the development of internal capacities, support for the development of state and local capacity building and the development of a national stockpile of medical supplies and pharmaceuticals.

285 PLUME RECONSTRUCTION AND MICROENVIRONMENTAL MODELING FOR ASSESSING EXPOSURES TO CONTAMINANTS ASSOCIATED WITH THE WTC FIRE AND COLLAPSE.

P. G. Georgopoulos. *EOHSI (Environmental and Occupational Health Sciences Institute), UMDNJ - R. W. Johnson Medical School and Rutgers University, Piscataway, NJ.* Sponsor: H. Zenick.

This project has been focusing on the development and implementation of an integrated computer-based Exposure Information System (EXIS) intended to support assessments of population exposures and doses for contaminants released from and following the World Trade Center (WTC) fire and collapse on 9/11/2001. This system, WTC-EXIS, includes both observational databases and prognostic/diagnostic computational modules, jointly used to characterize the spatial and temporal attributes of the contaminant plume and deposition over multiple scales, and the air quality of affected local microenvironments (street canyons, residences, offices, stores, etc.). Distributions of microenvironmental parameters and of human activities are being developed at resolutions that depend on distance from the WTC site (the highest being for the census blocks of the 84 census tracts within 2.5 km distance from the WTC site). Components of WTC-EXIS include: (a) multiscale atmospheric transport and fate analysis tools, utilizing University. Colorado's prognostic mesoscale Regional Atmospheric Modeling System (RAMS), coupled with EOHSI's Computational Chemodynamic Laboratory's (CCL) dynamic fate modules and with local computational fluid dynamics (CFD) modules; (b) computational tools of the MENTOR/SHEDS (Modeling Environment for Total Risk with Stochastic Human Exposure and Dose Simulation) system, developed jointly by CCL and USEPA's National Exposure Research Laboratory (NERL); (c) relational databases and geodatabases, of contaminant-related observations (from both local monitoring efforts and remote sensing stations), meteorological, land-use, microenvironmental, and demographic information; and (d) a Geographical Information System (GIS) interface (implemented in ArcInfo/ArcGis), to facilitate usage of information by researches involved in related health impact studies.

286 EXPOSURE ASSESSMENT OF WORKERS INVOLVED IN CLEANUP OPERATIONS AT THE WORLD TRADE CENTER DISASTER SITE.

A. S. Geyh[1], S. Chillrud[2], D. Williams[1], J. Herbstman[1], J. Symons[1], M. Watson[3] and P. Breysse[1]. *[1]Environmental Health Sciences, Johns Hopkins Bloomberg School of Public Health, Baltimore, MD, [2]Lamont Doherty Earth Observatory, Columbia University, Palisades, NY and [3]International Brotherhood of Teamsters, Washington, DC.* Sponsor: H. Zenick.

The destruction of the World Trade Center (WTC)on September 11, 2001 created a large amount of airborne contamination including crushed concrete, metals, asbestos, plastics, foams, solvents, insulations, glass, and asphalt. Fires, which burned for several weeks, generated potentially high concentrations of toxic volatile organic compounds (VOCs). The purpose of this study was to assess the personal exposures of cleanup workers to airborne contaminants at the WTC disaster site. The study was conducted in October 2001 with a follow up assessment in April 2002. Truck drivers hauling rubble away from the debris pile were recruited to wear personal monitors during their 12-hr work shifts. Personal monitoring was conducted every day of the week in both day and night shifts. Area monitoring was conducted at street intersections in the immediate vicinity of the disaster site, and also directly in the debris pile in October and in the pit in April. Thirty-two percent of drivers reported being at the site during the first week after the disaster. During any work shift 52% reported spending at least half the shift outside their truck walking around the site. In October personal exposures to Total Suspended Particles ranged from 65.8 to 765.8 $\mu g/m^3$. Personal and area concentrations of VOCs were low; the highest area concentration was measured for benzene (17.8 ppb), with the highest personal exposure found for m, p-xylene (13.7 ppb). Overall area concentrations and personal exposures to asbestos were low. Area monitoring and personal exposure assessment to airborne contaminants at the disaster site was necessary to understand exposure in the context of the potentially wide range of resulting possible health outcomes. Preparation for future environmental disasters must include a comprehensive and coordinated air monitoring and exposure assessment plan.

287 RESPIRATORY TOXICOLOGICAL EFFECTS OF WORLD TRADE CENTER FINE PARTICULATE MATTER IN MICE.

S. H. Gavett[1], N. Haykal-Coates[1], L. Chen[2], M. D. Cohen[2] and D. L. Costa[1]. *[1]NHEERL USEPA, Research Triangle Park, NC and [2]NYU Medical Center, Tuxedo, NY.*

The destruction of the World Trade Center (WTC) caused the release of high levels of airborne pollutants which were reported to cause adverse respiratory responses in rescue workers and nearby residents. We examined whether WTC-derived fine particulate matter ($PM_{2.5}$) has detrimental respiratory effects in mice. Samples of

WTC $PM_{2.5}$ were derived from settled dust collected at several locations around Ground Zero on September 12 and 13. Chemical analysis showed high levels of calcium sulfate and calcium carbonate. Aspirated samples of WTC $PM_{2.5}$ induced mild to moderate degrees of pulmonary inflammation one day after exposure, but only at a relatively high dose (100 micrograms). This response was not as great as that caused by 100 μg $PM_{2.5}$ derived from residual oil fly ash (ROFA) or Washington DC ambient air PM (NIST 1649a). However, this same dose of WTC $PM_{2.5}$ caused airway hyperresponsiveness to methacholine aerosol comparable to NIST 1649a and to a greater degree than ROFA. Mice exposed to lower doses by aspiration or inhalation exposure did not develop significant inflammation or hyperresponsiveness. These results show that a high dose of WTC $PM_{2.5}$ can promote mechanisms of airflow obstruction in mice. Airborne concentrations of WTC $PM_{2.5}$ which would cause comparable doses in people are high but conceivable in the immediate aftermath of the collapse of the towers. We conclude that a high-level exposure to WTC $PM_{2.5}$ could cause pulmonary inflammation and airway hyperresponsiveness in people. The effects of chronic exposures to lower levels of WTC $PM_{2.5}$, the persistence of any respiratory effects, and the effects of coarser WTC PM are unknown and were not components of these studies. Degree of exposure and respiratory protection, individual differences in sensitivity to WTC $PM_{2.5}$, and species differences in responses are important elements in the health risk assessment of WTC $PM_{2.5}$. [This abstract does not necessarily reflect USEPA policy.]

288 APPROACHES TO EVALUATION OF POTENTIAL HUMAN EXPOSURES AND HEALTH IMPACTS ASSOCIATED WITH AIRBORNE CONTAMINANTS FROM WORLD TRADE CENTER COLLAPSE/FIRES.

L. D. Grant[1], J. P. Pinto[1] and A. Galizia[2]. *[1]NCEA/Research Triangle Park, USEPA, Research Triangle Park, NC and [2]Region 2, USEPA, New York, NY.* Sponsor: H. Zenick.

The 9/11/01 World Trade Center (WTC) attack resulted in dispersal of numerous potentially toxic materials in the dust/smoke cloud that enveloped lower Manhattan and extended over other New York City (NYC) areas. The US Environmental Protection Agency (U.S. EPA) worked quickly with numerous other Federal, State, and local government agencies to mobilize emergency response efforts. This included cooperative actions to expand rapidly monitoring capabilities by which to measure environmental contamination derived from the 9/11 attack, the collapse of WTC buildings, the ensuing WTC Ground Zero fires, and WTC rescue/recovery operations. Environmental sampling was also carried out by others, e.g., academic investigators sponsored by various government agencies. This paper will mainly illustrate approaches employed, under challenging circumstances and time constraints, to evaluate potential human exposures to WTC-derived airborne pollutants and possible associated human health impacts, based on integrating information derived from: (a) analyses of composition of dust deposited from collapse of WTC buildings and associated toxicity testing of such dust; (b) data from ambient air monitoring at WTC Ground Zero, its immediate perimeter, and at sites in lower Manhattan and elsewhere in NYC metropolitan area; (c) preliminary results of meteorologically-based modeling of WTC plume movement/dispersal; (d) comparison of monitored or estimated concentrations against historical pollutant levels in NYC or other US urban areas; and (e), for those substances discernibly elevated above typical background levels, comparison against health benchmark values judged to be indicative of low risk for adverse health effects due to acute and/or prolonged exposures. [This abstract does not necessarily reflect USEPA policy.]

289 INDOOR AIR ASSESSMENT FOR THE WORLD TRADE CENTER SITE: SELECTING CONTAMINANTS OF POTENTIAL CONCERN AND SETTING HEALTH-BASED BENCHMARKS.

M. A. Maddaloni. *USEPA, Region II, New York, NY.*

As the clean-up and ambient air monitoring of the World Trade Center site comes to an end, health and environmental agencies are directing resources to evaluate the indoor environment for the presence of pollutants that might pose long-term health risks to local residents. Based on historical knowledge of building collapses/fires and review of both outdoor and limited indoor sampling data, six contaminants of potential concern (COPCs) were identified: lead, dioxin, PAHs, asbestos, fibrous glass and crystalline silica. Health-based benchmarks for indoor air and settled dust for each of these COPCs were developed to serve as clearance criteria. Existing environmental standards were utilized where appropriate. The Housing and Urban Development (HUD) standard for lead in settled dust (40 $\mu g/ft^2$) and the National Ambient Air Quality Standard (1.5 $\mu g/m^3$) were employed in this manner. In the absence of existing standards, risk-based clearance levels were developed employing IRIS verified toxicity factors and a residential exposure scenario (30 year duration). Health-based benchmarks for asbestos, dioxin and PAHs were developed in this way. Finally, for substances lacking a widely recognized environmental toxicity assessment, occupational standards with added safety factors were employed. Clearance criteria for fibrous glass and crystalline silica were derived by adding a safety factor of 100X to existing occupational standards.

290 DERMAL EXPOSURE LEADING TO RESPIRATORY TRACT SENSITIZATION AND DISEASE: A TRIVIAL OR CRITICAL LINK?

A. Munson and M. Luster. *NIOSH, Morgantown, WV.*

Exposure to allergens resulting in respiratory tract sensitization has classically been considered to occur by inhalation. Increasing evidence from epidemiological and clinical studies and data from animal models support the hypothesis that dermal exposure may lead to respiratory sensitization and resultant alterations in pulmonary function. Permeation studies have demonstrated the potential for proteins as well as low molecular weight chemicals to penetrate the skin and mechanistic studies have demonstrated the skin to be a permissive site for the induction of Th2 responses. Animal models have been used to demonstrate specific and non-specific increases in airway hyper-reactivity following dermal exposure to allergens. Using latex allergy, chronic beryllium disease and allergy to low molecular weight chemicals as examples, these presentations will lay the ground-work for a discussion of the relevant clinical and experimental data and the mechanistic basis for the role of skin contact in the development of respiratory sensitization. Only by understanding the mechanisms of sensitization can effective intervention strategies be implemented to protect against respiratory allergens.

291 INFLUENCE OF DERMAL EXPOSURE ON THE DEVELOPMENT OF SENSITIZATION OF THE RESPIRATORY TRACT TO CHEMICAL ALLERGENS.

I. Kimber and R. J. Dearman. *Syngenta Central Toxicology Laboratory, Macclesfield, CHESHIRE, United Kingdom.*

Many chemicals are able to cause skin sensitization and allergic contact dermatitis. Fewer in number have been shown to cause allergic sensitization of the respiratory tract; among these being certain diisocyanates, acid anhydrides, reactive dyes and platinum salts. It is often assumed that sensitization of the respiratory tract to chemical allergens is induced exclusively following inhalation exposure. However, an argument can be made on the basis of theoretical considerations, experimental data and anecdotal clinical evidence that this is not necessarily the case. Allergy, by definition, requires the stimulation of a specific immune response and there is reason to suppose that the responses which result in allergic sensitization will normally be systemic in nature. In theory, therefore, dermal exposure to a chemical respiratory allergen may provoke the vigor and quality of immune responses necessary for effective sensitization of the respiratory tract. The results of experimental studies support this argument since it has been shown for instance that topical or intradermal exposure of guinea pigs to a known chemical respiratory allergen is able to sensitize animals such that subsequent inhalation challenge with an aerosol of the same chemical will provoke a respiratory hypersensitivity reaction. Taken together, the available evidence suggests that in certain circumstances respiratory sensitization to chemical allergens may be achieved by dermal exposure.

292 DERMAL EXPOSURE TO TRIMELLITIC ANHYDRIDE (TMA) POWDER INDUCES AIRWAY SENSITIZATION IN AN ANIMAL MODEL.

X. Zhang, J. Fedan, L. Millecchia, D. Lewis and P. Siegel. *NIOSH, Cincinnati, OH.*

TMA is a low-molecular-weight chemical used as a dry, fine powder by industry. Specific IgE and subsequent occupational asthma have been reported in exposed workers. The respiratory tract is considered to be a major route of TMA exposure, but dermal exposure is also possible. The role of exposure route in the development of TMA asthma is not known. The present study investigated the potential role of dermal exposure to dry TMA powder in both immunological sensitization and subsequent pulmonary responses to TMA inhalation challenge using the Brown Norway rat. Various doses of TMA were applied to the back (hair clipped carefully with scissors) on day 0, 7, 14 and 21, occluded with surgical tape and washed away after overnight, or after 5 hours of non-occluded exposure. Sera were collected on day 0, 7, 14, 21, 28 and 35 for specific IgE test. Exposed skin was also taken for morphologic study. TMA aerosol challenge was performed on day 35 and respiratory parameters including enhanced pause (Penh) recorded overnight.

Bronchoalveolar lavage was performed and pulmonary eosinophils assessed. The application area appeared normal, without any sign of inflammation examined grossly or microscopically. Immunohistochemical study (with one exposure only) found TMA-adduct staining in the stratum corneum and hair follicle. Specific IgE was noted by day 14 and levels were TMA dose-dependent. Eosinophilic inflammation and both early (EAR) and late airway response (LAR), were observed after airway challenge. EAR subsided within 30 min following challenge. LAR typically began 2 or more hours following challenge and persisted longer than 8 hours. TMA specific IgE and airway responses occurred in both occluded and non-occluded dermally exposed rats. Dermal exposure to dry TMA powder can induce specific-IgE and subsequent asthmatic-like EAR and LAR following TMA aerosol challenge. This model may be useful for mechanism study of dermal exposure and asthma from low-molecular-weight chemicals.

293 THE ROLE OF DERMAL EXPOSURE IN THE DEVELOPMENT OF LATEX ALLERGY.

J. Meade[1], B. Hayes[2], M. Howell[1] and M. Woolhiser[3]. *[1]NIOSH, Morgantown, WV, [2]School of Medicine, Boston University, Boston, MA and [3]Immunotoxicology, Dow Chemical Company, Midland, MI.*

Latex allergy remains a serious risk for health care workers with past prevalence rates reported to range from 2.7-12%. Exposure may occur through inhalation as latex proteins bind to glove powders and are aerosolized during donning and removing gloves or through dermal exposure. Although hand dermatitis has been accepted as a risk factor, little is known of the relative contribution of the two routes of exposure to the development of sensitization. Animal models (BALB/c mice and hairless guinea pigs) have been used to evaluate the role of dermal exposure in the development of latex sensitization and to compare the potential for sensitization by the two routes. *In vitro* penetration studies using human surgical specimens and hairless guinea pig skin have demonstrated the importance of skin condition in the penetration of latex proteins with less than 1% of the applied dose of non-ammoniated latex (NAL) penetrating intact skin while as much as 30% penetrated through abraded skin. Exposure of BALB/c mice to 25µg NAL every 5th day by the dermal or intratracheal (i.t.) routes resulted in similar levels of latex specific IgE as measured by ELISA. A robust latex specific IgA response was seen in animals exposed by the i.t. route as compared to the dermal route. Upon respiratory challenge with methacholine, non-specific airway hyper-reactivity was dose-responsively increased and positively correlated with total IgE levels in animals exposed to latex proteins by either the i.t. or dermal routes. Immunoblot analysis revealed a different spectrum of sero-recognition of individual latex protein when exposure was *via* the i.t. versus the dermal route. Intervention strategies have been aimed at reducing the powder and latex protein content of gloves. Although these efforts have been observed to reduce the prevalence of symptoms in sensitized individuals, these data raise concerns regarding dermal exposure resulting from the continued use of low protein latex gloves. This work was supported in part by NIEHS interagency agreement #Y1-ES-0049-03.

294 INCLUSION OF SKIN EXPOSURE REDUCTION IN A TOTAL HYGIENE PROGRAM TO REDUCE EXPOSURE TO BERYLLIUM: BACKGROUND AND RESULTS.

D. Deubner. *Brush Wellman, Inc., Elmore, OH.* Sponsor: A. Munson.

Recent epidemiological studies show no or very weak association between the mass concentration of beryllium in air, the traditional metric of exposure, and the prevalence of sensitization to beryllium or chronic beryllium disease. In general in the USA beryllium workplaces have permitted unlimited skin contact with beryllium solutions or particulate. In 1998 the possibility that sensitization to beryllium might occur *via* the skin was raised. Since then measures have been introduced to reduce skin exposure to beryllium solutions and particulate. Also taken were measures to reduce lung exposure to beryllium as well as dispersion of beryllium by various pathways within the workplace. Early data suggests these measures together reduce sensitization to beryllium.

295 GENOMIC MARKERS OF NEPHROTOXICITY IN FEMALE CYNOMOLGUS MONKEYS.

J. W. Davis, F. M. Goodsaid, C. M. Bral, G. Mandakas, L. A. Obert, C. E. Garner, R. J. Smith and I. Y. Rosenblum. *Schering-Plough Research Institute, Lafayette, NJ.*

The emergence of genomic technologies has led to a focused effort to identify early predictive markers of target organ toxicity. We define gene expression changes that correlate with the onset of histopathlogical lesions as genomic indicators of toxicity. For a genomic target to be considered an early predictive marker its expression pattern must quantitatively change before the development of the lesion, and the magnitude of change should intensify with the detection of histopathology. We have studied quantitative gene expression changes in the kidneys of female cynomolgus monkeys dosed with gentamicin (10 mg/kg) and/or everninomicin (30 or 60 mg/kg), an experimental oligosaccharide antibiotic, for seven days. Both drugs have been demonstrated to cause renal tubular necrosis and degeneration in rodents and non-human primates. Monkeys receiving both drugs showed renal lesions as early as day 1, consistent with a potentiation mechanism of gentamicin on everninomicin toxicity. By day 7 monkeys dosed with 60 mg/kg everninomicin alone also developed renal lesions, while the group exposed to both compounds had more extensive renal damage. The modulation of several genes previously identified to be associated with nephrotoxicity in rodent models was confirmed using quantitative real-time PCR. Among these, c-myc, c-jun, and MMP-9 exhibited changes consistent with the definition of a genomic marker of toxicity. Logistic regression modeling demonstrated a high degree of correlation between changes in gene expression and the development of histopathology. In addition, we identified a candidate early marker of toxicity. The expression of clusterin, a protein previously associated with renal necrosis, was significantly different from control levels (≥2-fold change) on day 1, and its level of expression was greater on day 7. These results provide the first data confirming gene expression changes associated with rodent nephrotoxicity in a non-human primate model, and are the first step in the validation of clusterin as an early marker for nephrotoxicity.

296 EXPRESSION OF GENES ASSOCIATED WITH DRUG-INDUCED BILIARY HYPERPLASIA AND CELL PROLIFERATION IN CYNOMOLGUS MONKEYS.

C. M. Bral, F. M. Goodsaid, F. Poulet, L. Li, W. Choy, G. Mandakas, H. Zairov and I. Y. Rosenblum. *Genetic and Molecular Toxicology, Schering-Plough Research Institute, Lafayette, NJ.*

Bile duct hyperplasia (BDH) can develop following administration of certain drugs. It is an important health concern because there are no predictive biomarkers for BDH that would allow adequate patient monitoring in the early stages. BDH arises as a consequence of cell proliferation within the hepatobiliary tree. We have investigated gene expression changes associated with BDH and cell proliferation in Cynomolgus monkeys treated with an experimental S-P compound. Histopathological evaluation of the livers and determination of a BrdU labeling index (BrdU-LI) for the biliary epithelium were used to separate the treated monkeys into good responders (BDH and high BrdU-LI), poor responders (BDH and low BrdU-LI) and non-responders (no BDH and no change in BrdU-LI). RNA isolated from the livers of these monkeys was hybridized on the Affymetrix U133 human genome chip. Analysis of this data with the GeneLogic Gene Express software revealed gene expression changes associated exclusively with monkeys in each of the good-, poor- and non-responder groups. There was limited overlap between the histopathological results for individual monkeys in each of these groups and between gene sets in these groups. Some of the genes that overlap include cyclins and other genes associated with cell proliferation. We identified 13 gene expression changes that discriminate between good- and non-responders, 63 for discrimination between good- and poor responders, and 23 for discrimination between poor- and non-responders. We also identified 5 gene expression changes that would discriminate between groups of monkeys with hyperplasia and those with no hyperplasia, 7 for high BrdU and low BrdU, and 2 for both of these effects. The predictive value of these changes will be evaluated further with quantitative PCR.

297 GENE EXPRESSION PROFILING OF NORMAL MAMMARY TISSUES FROM RAT STRAINS SENSITIVE AND RESISTANT TO MAMMARY CARCINOGENESIS.

A. S. Kim[1,2], H. Xie[1], A. M. Mikheev[1], R. C. Sullivan[1] and H. Zarbl[1,2]. *[1]Human Biology, Fred Hutchinson Cancer Research Center, Seattle, WA and [2]Center for Ecogenetics and Environmental Health, University of Washington/ NIEHS, Seattle, WA.* Sponsor: T. Kavanaugh.

While human genetic linkage analyses have identified tumor suppressors that are responsible for familial breast cancer, many susceptibility genes are likely to be partially penetrant, due to the modifying effects of diverse genetic backgrounds and gene-environmental interactions. The advantage of using animal models to study inherited cancer susceptibility genes is the ability to use carefully controlled carcinogen exposure in highly inbred strains of animals. Consequently, breast cancer suppressor mutations that would have low penetrance in the human population may present as highly penetrant phenotypes in experimental tumor models. To gain insight into gene-environmental interactions in mammary carcinogenesis, we compared gene expression profiles in normal mammary glands from the sensitive Fisher 344 and resistant Copenhagen rat strains. Gene expression profiles were compared

at the onset of puberty (50 to 55 days of age), when rats are most sensitive to mammary carcinogenesis. Expression levels of ~8, 000 known genes and ESTs were compared among five individual animals from each strain using Affymetrix Rat Genome GeneChips. We identified ~1, 000 genes whose expression levels are significantly different ($P < 0.001$) between the two rat strains. The altered patterns of gene expression implicated several biochemical pathways in the differential sensitivity to mammary carcinogenesis, including a diminished anti-oxidant response. Studies are in progress to compare expression profiles in additional strains before and after exposure to carcinogenic doses of nitrosomethyl urea and dimethylbenz[a]anthracene. Comparisons of expression profiles among differentially sensitive rat strains are expected to identify biochemical mechanisms affected by loss of the rat mammary tumor suppressor(s). This study was supported by PHS Grants U19-ES-011387 & P30 ES-07033 from the NIEHS.

298 USE OF AN EMPIRICAL BAYES SCREENING APPROACH AND GENE ONTOLOGY ANNOTATIONS TO FILTER AND INTERPRET MICROARRAY DATA FROM THE UTERI OF ESTROGEN-TREATED MICE.

K. Fertuck[1], J. E. Eckel[2], C. Gennings[2] and T. R. Zacharewski[1]. *[1]Biochemistry & Molecular Biology, National Food Safety & Toxicology Center, and Institute for Environmental Toxicology, Michigan State University., East Lansing, MI and [2]Biostatistics, Virginia Commonwealth University., Richmond, VA.*

While microarrays can useful in screening compounds *in vivo* for (anti)estrogenic activity, important basic information is still lacking in several key areas. In particular, transcriptional responses to estrogen itself must be better understood, and methods for distinguishing significant responses from baseline or irreproducible signals must be refined. Mu11KSubA GeneChip data (6523 probe sets) was examined from uterine tissue of duplicate immature, ovariectomized C57BL/6 mice treated orally with 0.1 mg/kg ethynyl estradiol or vehicle for 2, 8, 12, 24 hr, or 3x24 hr. A nonparametric empirical Bayes approach identified responses with a treatment and/or time effect (881 probe sets), and a subsequent ANOVA model distinguished treatment effects and treatment by time interactions (392 probe sets) from time-only effects. These 392 responses were clustered into 8 generalized temporal patterns by k-means, and annotated with Gene Ontology (GO) descriptions where available (193 probe sets). GO terms appearing at high frequency in specific k-means clusters, and therefore associated with specific temporal expression patterns, were found to be valuable in interpreting the cellular and tissue responses occurring over time in response to estrogen, both confirming published findings and suggesting novel estrogen-induced responses. Knowledge of the specific processes that are activated by estrogen in the uterus, and the corresponding temporal distribution of these responses, will be very helpful in the design and interpretation of assays aimed at identifying and characterizing xenoestrogens. Furthermore, the filtering, clustering, and annotation strategy described here addresses common microarray study issues of analysis and interpretation. Supported by ES 011271.

299 IDENTIFICATION OF NRF2-DEPENDENT ARE-DRIVEN GENES CONFERRING PROTECTION AGAINST OXIDATIVE STRESS IN PRIMARY CORTICAL ASTROCYTES AND NEURONS: CELL TYPE SPECIFIC NRF2-DEPENDENT ARE-DRIVEN GENE EXPRESSION.

J. Lee[1,2], K. Chan[3], Y. Kan[3] and J. Johnson[1,2]. *[1]School of Pharmacy, UW-Madison, Madison, WI, [2]Molecular and Environmental Toxicology Center, UW-Madison, Madison, WI and [3]Cardiovascular Research Institute, UCSF, San Fransisco, CA.*

The antioxidant responsive element (ARE) mediates transcriptional regulation of many phase II enzymes and antioxidant proteins such as NAD(P)H:quinone oxidoreductase (NQO1), glutathione S-transferases, and glutamate-cysteine ligase. Several lines of evidence demonstrated that Nrf2 binds to the ARE sequence leading to transcriptional activation of ARE-driven genes. Also, many studies demonstrated that Nrf2 plays an important role in protecting cells from oxidative stress induced cellular damage. In this study, we report that b-Zip transcription factor Nrf2 is critical for both NQO1 gene expression and cellular defense in primary mouse cortical astrocytes and neurons. We identified astrocyte- and neuron-specific Nrf2-dependent ARE-driven genes by oligonucleotide microarray analysis. First, primary cortical astrocytes and neurons derived from Nrf2-/- mice have decreased levels of basal NQO1 activity than those derived from Nrf2+/+ cells. Furthermore, tert-butylhydroquinone increased NQO1 activity only in Nrf2+/+ astrocytes and neurons. Second, Nrf2-/- astrocytes were more sensitive to H2O2-induced cytotoxicity compared to Nrf2+/+ astrocytes. Similarly, Nrf2-/- neurons were more vulnerable to rotenone-induced apoptosis suggesting Nrf2 is important for cellular defense against oxidative stress in both astrocytes and neurons. Finally, in support of these observations, microarray analysis revealed that Nrf2-/- astrocytes and neurons have decreased levels of antioxidant and detoxification gene expression compared to Nrf2+/+ astrocytes and neurons, respectively. Taken together, these findings imply that Nrf2 plays a central role in ARE-driven antioxidant/detoxification gene expression contributing to cellular defense against oxidative damage in primary cortical astrocytes and neurons. (Funded by ES08089, ES10042, ES09090).

300 TRANSCRIPTIONAL PROGRAM OF NRF2 IN LUNG CONFERS PROTECTION AGAINST ENVIRONMENTAL TOXICANTS.

T. Rangasamy, R. K. Thimmulappa, K. Mai and S. S. Biswal. *Environmental Health Sciences, Bloomberg School of Public Health, Johns Hopkins University, Baltimore, MD.*

Nrf2 is a bzip transcription factor which is activated in response to various toxicants. Nrf2 plays a pivotal role in the transcriptional induction of various phase 2 enzymes and antioxidant proteins by binding to antioxidant response element (ARE) in their promoters. In order to investigate the role of Nrf2 in lungs, Nrf2 +/+ and Nrf2 -/-mice were exposed to a complex mixture of toxicants, the environmental tobacco smoke (ETS). Nrf2 -/- mice was more sensitive to ETS and tobacco carcinogen, benzo[a]pyrene.In response to ETS, there was an increased infiltration of macrophages and intense staining for 8 Oxo-dG in the lungs of Nrf2 -/- mice. DNA postlabeling method revealed higher amounts of DNA adducts in the lungs of B[a]P treated Nrf2 -/- mice than Nrf2 +/+ mice. EMSA showed the increased binding of nuclear Nrf2 (Nrf2 +/+ mice) to ARE sequence, after exposure to ETS.To elucidate the protective role of Nrf2, the transcriptional profile of lungs from Nrf2 +/+ and Nrf2 -/- mice were compared with and without exposure to ETS (using Affymetrix Murine Genome U74A genechip).Oligonucleotide microarray analysis revealed the induction of sixty genes in the lungs of Nrf2 +/+ mice compared to Nrf2-/- mice. The target genes include various antioxidant and xenobiotic metabolizing enzymes that can counteract a wide spectrum of exogenous as well as endogenous free radicals and toxicants.Screening with GCG Find Patterns Software Program revealed the presence of ARE (s) in most of the genes, suggesting the involvement of Nrf2 in the transcriptional regulation of these genes. The microarray data was validated by northern blot analysis and enzyme assay of selected genes. This study concludes that transcriptional program of Nrf2 in lungs plays an important role in protection against environmental toxicants. (This work was supported by NIEHS center grant P30 ES03819).

301 DIFFERENTIAL GENE EXPRESSION INDUCED BY PEROXISOME PROLIFERATOR, CI-924, IN RATS AND MICE.

A. H. Hofstra[2], P. H. Koza-Taylor[1] and M. Lawton[1]. *[1]Drug Safety Evaluation, Pfizer Global Research, Groton, CT and [2]Drug Safety Evaluation, Pfizer Global Research, Sheridan Park, ON, Canada.*

The lipid lowering agent 5, 5{[1, 1-biphenyl]-2, 5-diylbis(oxy)}bis[2, 2-dimethylpentanoic acid] (CI-924) induces peroxisome proliferation to a greater extent in rats than in mice. However, an increase in the incidence of hepatic tumors in mice only, not in rats, was observed following treatment with CI-924 for 2 years. CI-924 is, therefore, an interesting tool for exploring the mechanism of tumor induction by peroxisome proliferators. Previous studies looking at differences between rats and mice in peroxisome proliferation, hepatic enzyme induction, serum biochemistry, cell proliferation and rates of apoptosis did not reveal any clear predictors of subsequent tumor incidence. The current study explored the difference in gene expression between rats and mice. CI-924 was administered to Wistar rats and B6C3F1 mice for 1, 7 and 28 days at 25 and 75 mg/kg. Total RNA was isolated and hybridized to Affymetrix Rat Genome U34A and Mouse GenomeU74A GeneChips respectively. Different expression profiles were observed between rats and mice and the differential regulation was much greater in rats than mice. The expression of genes linked to CYP4A and peroxisomal enzyme genes were induced to the largest extent in the mice. Little impact was observed on genes associated with cell cycle. In the rats, enzymes involved in acyl CoA metabolism, followed by CYP4A, then peroxisomal enzyme genes were induced to the greatest extent. Further biometric analysis to explore the differential tumor response between rats and mice revealed areas of substantial similarity and difference in the gene expression profiles of rats and mice.

302 COMPARISON OF CELL PROLIFERATION ASSOCIATED GENE EXPRESSION BETWEEN REVERSIBLE AND IRREVERSIBLE LIVER PATHOLOGIES IN MALE WISTAR RATS TREATED WITH A SERIES OF HEPATOTOXIC COMPOUNDS AND DRUGS.

K. M. Hershman[1], H. E. Olsen[1], M. F. DeCristofaro[1], D. A. McCabe[1], O. R. Crasta[1], R. W. Gerwien[1], B. Wahle[2], B. Stuart[2], T. A. Mansfield[1] and M. McKenna[1]. *[1]Pharmacogenomics Department, CuraGen Corporation, New Haven, CT and [2]Toxicology Department, Bayer Corporation, Stilwell, KS.*

The liver is unique among the major organs in its capacity to regenerate after injury. Proliferation of specific cell populations within the liver is a critical event in the normal repair and regeneration of damaged tissue. Perturbation of this process can

serve as the pathogenesis for irreversible pathologies including fulminate liver failure, cirrhosis, and cancer. There is limited information relating various types of liver histopathology with a comprehensive survey of changes in transcript expression for genes involved in cell proliferation. The GeneCalling® open architecture platform was selected to identify changes in expression of hepatic gene transcripts important in cell proliferation. Male Wistar rats received either a high or low dose of over 100 different hepatotoxic compounds daily over a two-week period. Groups of 5 animals were sacrificed at 1, 3, 7 and 14 days and tissues recovered for gene expression studies and histopathological evaluation. High doses were adjusted to produce one or more liver histopathologies. Low doses were 1/10 of the high dose and in general produced minimal or no histopathological changes. Negative controls included both vehicle treated and untreated animals. Gene expression was altered in a number of biological pathways important to cell proliferation including cell cycle control and cellular communication. Changes in gene expression could be associated with specific cell populations within the liver. Comparisons between gene expression and reversible and irreversible pathological changes were made. Results point to the importance of coupling traditional methods of toxicity assessment (histopathology) with toxicogenomics to provide a more detailed understanding of liver injury and regeneration after toxic insult.

303 TOWARDS ESTABLISHING A TOXIC SIGNATURE FOR VARIOUS ASBESTOS FORMS-MICROARRAY ANALYSIS OF 900 TOXIC RESPONSE GENES.

M. Pershouse, C. Schwanke, K. Wallis and E. A. Putnam. *Center for Environmental Health Sciences, University of Montana, Missoula, MT.* Sponsor: A. Holian.

In the post-genomics era, the biological questions we ask hopefully take advantage of the new wealth of genomic information available. The generation of a toxic signature for various types of asbestos particles by microarray analysis of gene expression is an example of one such globally directed investigation. Rather than look for changes in gene expression one gene or protein at a time following asbestos exposure in a mouse model, we are assessing expression changes in 900 toxic response genes simultaneously. The set of genes examined represented a conversion of the NIEHS Human ToxChip V1.0 to a mouse version, creating a Mouse ToxChip V1.0. Balb/c mice were exposed *via* intratracheal installation of winchite, tremolite, crocidolite, or chrysotile forms of asbestos, as well as silicate, wollastinite and saline controls. Following a three month long exposure, mice were sacrificed, and RNA was isolated from lungs of mice from each treatment group. Microarray analysis of each exposure set was compared to a mouse reference standard (Stratagene) so that all exposures could be compared. Lungs from each treatment group were preserved for histological observation. Evidence of widespread fibrosis was found in all asbestos or silica exposed mice, but not in wollastinite or saline control mice. Genes found to be reproducibly activated or repressed in each exposure were clustered using Spotfire Decision Suite k-means clustering algorithms, and will be further analyzed at the protein level for their role in the fibrotic process. In this constantly expanding set of toxic-response related genes, many pathways, functional cohorts, and classes of genes are represented, refining our knowledge of cellular response to asbestos. This work was supported by NIH/EPSCoR EPS-0091995.

304 OZONE TOXICITY UPREGULATES EXPRESSION OF THE P44/42 MAP KINASE IN ALVEOLAR MACROPHAGES.

L. Fakhrzadeh[1], T. DeSimone[1], J. D. Laskin[2] and D. L. Laskin[1]. *[1]Pharmacology & Toxicology, Rutgers University, Piscataway, NJ and [2]Environmental & Comm. Med., UMDNJ-Robert W Johnson Med. Sch, Piscataway, NJ.*

Inhalation of ozone (O_3) causes lung injury and inflammation in humans and experimental animals. We have previously demonstrated that macrophages recruited to the lung following exposure to this oxidant contribute to the pathogenesis of tissue injury. In the present studies we analyzed mechanisms regulating alveolar macrophage (AM) activation after O_3 inhalation that cause production of inflammatory mediators. We found that exposure of mice to O_3 (0.8 ppm, 3 h) resulted in increased AM expression of inducible nitric oxide synthase (NOSII) and production of nitric oxide, as well as cyclooxygenase-2 (COX-2) and prostaglandin E2. These mediators have been directly implicated in ozone-induced toxicity. The MAP kinases p44/42 (ERK1/2) and p38 kinase are known to be important in regulating expression of NOSII and COX-2. We found that AM constitutively express low levels of ERK1/2 and the p38 MAP kinase. O_3 inhalation caused a marked increase in AM expression of ERK1/2 without altering expression of the p38 kinase. This was evident immediately following exposure of mice to O_3 and was maximal within 6 hr. O_3 inhalation also induced phosphorylation of ERK1/2 in AM. Activation of ERK1/2 is known to downregulate caveolin-1, a negative regulator of the p85 subunit of phosphatidylinositol 3'-kinase (PI3K). We found that caveolin-1 was markedly down-regulated in AM after O_3 inhalation. This was directly associated with activation of PI3K and its downstream target, protein kinase B (PKB), in the cells. We have previously demonstrated that PI3K and PKB regulate NF-κB, a transcription factor important in controlling expression of NOSII and COX-2. Taken together, these data demonstrate that, in AM, O_3 is an effective activator of the MAP kinase ERK1/2, an early upstream component of the signaling that leads to reactive-intermediate producing enzymes. This may be an important pathway by which irritants induce lung injury. Support: NIH ES04738 and ES06897

305 LOSS OF CYCLIN D1 DOES NOT INHIBIT THE PROLIFERATIVE RESPONSE OF MOUSE LIVER TO MITOGENIC STIMULI.

A. Columbano, M. Pibiri, C. Cossu, D. Concas, M. Tripodi and G. Ledda-Columbano. *Toxicology, University, Cagliari, Sardinia, Italy.*

Cyclin D1 is considered to play a critical role in the progression from G1 to S phase of cell cycle, and its overexpression is seen in many human tumors including the majority of human mammary carcinomas. However, previous studies in cell lines have shown that cyclin D1 is not sufficient to trigger cell replication. To directly test the role of cyclin D1 in the progression of cell cycle, we have examined the proliferative response of hepatocytes to the powerful hepatomitogen 1, 4-bis[2-(3, 5-dichloropyridyloxy)]benzene (TCPOBOP), in mice with homozygous disruption of the cyclin D1 gene. We found that 24 hours after a single treatment with TCPOBOP the number of bromodeoxyuridine-positive hepatocytes was significantly reduced in cyclin D1-/- when compared to cyclin D1+/- mice (LI was 1.9% in knockout mice vs 9.7 % of heterozigous mice); however, no difference in the number of proliferating hepatocytes could be found at 36 or 72 hours after treatment (LI was 16% and 43% in cyclin D1-/- mice vs 20% and 41% of heterozygous mice), thus, indicating that lack of cyclin D1 may transiently delay the entry into S phase, but is not sufficient to inhibit the response of hepatocytes to mitogenic stimuli. Results also showed that while there was no difference in hepatic protein levels of cyclin D2 and D3 between untreated cyclin D1-/- and cyclin D1+/- mice, mRNA and protein levels of cyclin E were much higher in the former. In conclusion, our results showed that cyclin D1 is not essential for liver development and hepatocyte proliferation induced by mitogenic stimuli and suggested that cyclin E overexpression may compensate for the lack of cyclin D1.

306 FUNCTIONAL GENOMIC ANALYSIS OF STRESS-ACTIVATED PROTEIN KINASE SIGNALLING PATHWAYS.

J. G. Moggs[1], A. Hollis[2], C. A. Hazzalin[2], S. Thomson[2], L. C. Mahadevan[2], I. Kimber[1] and G. Orphanides[1]. *[1]HAES Research, Syngenta CTL, Macclesfield, Cheshire, United Kingdom and [2]Department of Biochemistry, Oxford University, Oxford, Oxfordshire, United Kingdom.*

Mammalian cells respond to a wide variety of external stimuli including growth factors, cytokines, pharmaceutical agents and toxicants *via* protein kinase signalling pathways. We have used transcript profiling to identify novel molecular targets and mechanisms of toxicity associated with stress-activated and mitogen-activated protein (MAP) kinase signalling pathways. Anisomycin, a potent activator of stress-activated and MAP kinase cascades in mammalian cells, induced more than 15 genes in mouse fibroblasts, including several immediate early genes (C-FOS; CYR61; MKP-1) and an EST encoding a novel protein. We have combined transcript profiling with the use of small molecule protein kinase inhibitors to reveal the contribution of specific signalling pathways in mediating the transcriptional response to chemically induced stress. Most of the anisomycin-induced genes we examined were sensitive to the p38 MAP kinase inhibitor SB203580 and thus are regulated *via* p38 MAP kinase activation. In contrast, one anisomycin-induced EST was relatively insensitive to this inhibitor, implying that it may be regulated by a distinct signalling pathway. The mechanisms by which these stress response genes integrate information from complex intracellular signalling cascades are being elucidated using a combination of genomic and biochemical approaches. Data mining of recently completed mammalian genome sequences allows the analysis and identification of target gene regulatory sequences. This genomic information has been used to design chromatin immunoprecipitation assays that measure the recruitment and modification of gene regulatory proteins targeted to stress response genes. Furthermore, we have identified a novel stress response protein kinase activity using a functional biochemical screen. Together, these functional genomic experiments provide insights into the mechanisms governing transcriptional responses to toxic agents.

307 ENHANCED LIVER TISSUE REPAIR IN DIET RESTRICTED RATS UPON TOXIC CHALLENGE: A BATTLE WON BY COOPERATION OF SIGNALING PATHWAYS.

U. M. Apte[1], P. B. Limaye[1], S. Devi[1], F. A. Witzmann[2] and H. M. Mehendale[1]. [1]*Department of Toxicology, The University of Louisiana at Monroe, Monroe, LA and* [2]*Department of Cellular & Integrative Physiology, Indiana University School of Medicine, Indianapolis, IN.*

We have reported that moderate diet restriction (DR, 35% for 21 days) protects from lethal dose of thioacetamide [TA, 70% survival in DR vs 10% in ad libitum (AL)] due to early onset of robust liver tissue repair response. Mechanisms of the augmented tissue repair in DR were investigated over a time course after TA challenge. Our results indicate that the enhanced tissue repair is a result of prompt upregulation of a number of pro-mitogenic signaling pathways. The higher plasma and liver IL-6 in TA challenged DR rats and 2-fold induction of iNOS by DR may explain earlier cell division. MAPK signaling pathway (TGF-α, EGFR, and p38 MAPK) was upregulated in DR rats after TA treatment. Liver levels of TGF-α and EGFR were upregulated along with p38 MAPK in DR rats. The sustained robust DNA synthesis and cell division in DR rats was also consistent with higher levels of HGF and its receptor (c-met) in the liver. Proteomic analysis using 2-DE combined with MALDI-MS revealed additional players in the enhanced liver tissue repair in DR rats. DR rats had higher levels of calmodulin, a Ca^{2+} binding protein known to be involved in cell division. Glucose regulated mediator of cell division, grp78 was induced in TA challenged DR rats. Stimulation of cell division by grp78 is known to be mediated by MAPK, which was upregulated in TA treated DR rats. Apart from higher tissue repair, DR rats also exhibited higher apoptosis after TA administration, a mechanism conducive for efficient tissue repair by ridding damaged and weak cells. These data indicate that the enhanced tissue repair in DR rats is stimulated by a combination of signaling pathways related to stress induced by TA challenge and highlights the augmented ability of diet restricted rats to handle toxicant-induced stress (Supported by ES-9870).

308 SYNERGISTIC ACTIVATION OF ESTROGEN RECEPTOR TARGET GENES BY HORMONAL SIGNALS AND CHEMICAL STRESS.

D. G. Deavall, D. N. Hickinson, J. G. Moggs, J. W. Edmunds, I. Kimber and G. Orphanides. *HAES Research, Syngenta CTL, Macclesfield, Cheshire, United Kingdom.*

Mammalian cells are capable of integrating responses to a wide spectrum of external stimuli including cellular stress, hormonal signals, growth factors and toxicants. In the physiological milieu, such stimulation simultaneously activates a range of signalling mechanisms. Thus, the effects of endocrine-disrupting estrogen receptor ligands can potentially be modulated by other signalling pathways, perhaps amplifying the biological effects of these compounds. We are using genomic and biochemical techniques to investigate the responses to combinations of such signals. We have focused on transcriptional induction of an endogenous classical estrogen-responsive gene, pS2 (TFF1), in a model system, the ERα-expressing MCF-7 breast cancer cell line, in response to estradiol (E2) and 12-O-tetradecanoylphorbol-13-acetate (TPA). TPA is a well-characterised cellular stressor and protein kinase C agonist capable of activating mitogen-activated protein kinase cascades and inducing activator protein 1 (AP1)-mediated transcription. Northern blot analysis has revealed that E2 and TPA (10^{-7}M) are both capable of increasing pS2 mRNA abundance independently, and that a combination of the two stimuli induces transcription in a synergistic manner across a range of E2 doses from 10^{-7} to 10^{-11}M, such that TPA is capable of potentiating E2 responsiveness to a level above that achievable with E2 alone. We are now using large-scale genomic analysis to identify other E2-responsive genes regulated in a similar synergistic fashion. In addition to transcript profiling, we are using biochemical approaches including the chromatin immunoprecipitation (X-ChIP) assay to investigate differences in promoter occupancy by transcription factors and components of the transcriptional machinery in response to E2 and TPA alone and in concert. Comparison of the recruitment profiles observed with E2, TPA and the combined stimulus will further our understanding of the molecular mechanisms underlying the observed synergy between estrogen receptor ligands and signals that induce stress.

309 CHARACTERIZATION OF THE SPECIES-SPECIFICITY OF PEROXISOME PROLIFERATORS IN RAT AND HUMAN CELL LINES.

S. O. Mueller, M. Ammerschlaeger, M. Kling and P. Kramer. *Institute of Toxicology, Merck KGaA, Darmstadt, Hessen, Germany.*

Peroxisome proliferation is a well-defined effect that leads to liver tumors in rodents. Since peroxisome proliferation is much less pronounced in humans than in rodents and, so far, no increased liver tumor incidences have been reported in humans who are exposed to peroxisome proliferators like fibrates, this effect is considered to be a species-specific phenomenon. The peroxisome proliferation activated receptor (PPAR) α has been identified as the key regulator in peroxisome proliferation. PPARα mediates effects of peroxisome proliferation by inducing gene expression and subsequently enzyme activity. Our aim was therefore to define the species-specificity and potency of peroxisome proliferators by analyzing enzyme activity, PPARα-mediated transactivation and PPAR regulated target gene expression in human and rodent cell lines as well as in primary hepatocytes. The human HepG2 cell line showed weak induction of peroxisomal enzyme activity by fibrates, whereas in the rat FAO and MH1C1 cells, fibrates strongly induced acyl-CoA oxidase activity and highest enzyme activities were induced in primary rat hepatocytes. A similar ranking of sensitivity towards fibrates could also be shown in transient transactivation assays using rat or human PPARα on a rat consensus PPAR response element (rPPRE). We then analyzed whether a rPPRE is more sensitive for peroxisome proliferators than a consensus human PPRE (hPPRE). Indeed, in transient transfection experiments, clofibrate and Wy 14, 643 were more active on the rPPRE than on the hPPRE, indicating that the higher susceptibility of rodents vs. man may be due to species specific PPREs. In on-going studies we are analyzing expression of PPAR target genes acyl-CoA oxidase, catalase and PCNA in rat and human cells with defined expression of either rat or human PPARα by TaqMan PCR. This comprehensive analysis in human and rat hepatic cell lines should help in further deepen our understanding of the species-specific effects of peroxisome proliferators.

310 THE COORDINATE ACTIVATION OF ERK AND P38 MAPK IS REQUIRED FOR HISTONE H3 PHOSPHORYLATION IN RESPONSE TO ROS-INDUCED DNA DAMAGE.

J. Dong, S. Ramachandiran, K. Tikoo, S. S. Lau and T. J. Monks. *Center for Molecular and Cellular Toxicology, University of Texas at Austin, Austin, TX.*

2, 3, 5-Tris-(Glutathion-S-yl)hydroquinone (TGHQ) is a reactive metabolite of the nephrotoxicant hydroquinone. TGHQ catalyzes the rapid formation of DNA single strand breaks in renal proximal tubular epithelial cells (LLC-PK_1), in a reactive oxygen species (ROS)-dependent manner, resulting in oncotic/necrotic cell death. TGHQ induced mitogen activated protein kinase (MAPK) activation and histone H3 phosphorylation precede cell death. Both cell death and histone H3 phosphorylation were attenuated by inhibition of extracellular signal-regulated kinase (ERK) (PD98059). Inhibition of p38 MAPK (SB202190) also protected cells from death, whereas inhibition of c-Jun N-terminal kinase (JNK) had no effect on cell death. Because epidermal growth factor (EGF) mediated ERK activation does not induce histone H3 phosphorylation in LLC-PK_1 cells, we attempted to define whether TGHQ induced EGF receptor (EGFR) activation is coupled to histone H3 phosphorylation. We compared the relative ability of TGHQ, H_2O_2 and EGF to activate EGFR and MAPKs. TGHQ and EGF induced rapid EGFR phosphorylation at both Y992 and Y1068, either of which could lead to ERK activation. In contrast, H_2O_2 did not induce EGFR phosphorylation at either of these two sites. EGF-mediated EGFR phosphorylation was more rapid than with TGHQ and subsequent ERK activation was also more rapid and more sustained with EGF. H_2O_2 induced ERK activation was also more intense and sustained than with TGHQ, but was not as rapid as EGF. Although AG1478, an inhibitor of EGFR, blocked ERK activation induced by TGHQ, EGF and H_2O_2, it failed to block either TGHQ or H_2O_2-mediated JNK or p38 MAPK activation, neither of which was induced by EGF. The data suggest that the coordinate activation of the ERK and p38 MAPK pathways is required for effective histone H3 phosphorylation in response to ROS-mediated DNA damage in LLC-PK_1 cells. (ESO7784, ES07247, DK59491)

311 DIFFERENTIAL MODULATION OF STRESS AND UBIQUITINATION SIGNALING PATHWAYS BY CADMIUM, H_2O_2, AND SERUM WITHDRAWAL IN CULTURED MOUSE FIBROBLASTS.

M. R. Garry[1,2], J. S. Sidhu[1], T. J. Kavanagh[1] and E. M. Faustman[1]. [1]*Environmental Health, University of Washington, Seattle, WA and* [2]*Exponent, Bellevue, WA.*

Cadmium causes oxidative stress in cells by inducing lipid peroxidation, binding to protein thiols, and altering intracellular glutathione status. Oxidative stress can lead to structural changes in proteins, ubiquitination of the damaged proteins, and subsequent proteolysis of the ubiquitin-tagged proteins. Cadmium has been shown to affect the ubiquitin/proteosome proteolytic pathway, causing an accumulation of ubiquitinated proteins in mouse neuronal cells and in yeast. Cadmium induces apoptosis, but very little is known of the molecular signaling mechanisms involved. In this study cultured mouse fibroblasts were exposed to cadmium chloride ($CdCl_2$), hydrogen peroxide (H_2O_2), and serum deprivation for 1-24 hours. Proteins from whole cell extracts were separated by SDS-PAGE, and analyzed for

stress (p38, SAPK/JNK, and the cell survival regulator Akt) and ubiquitin signaling pathway responses using the indicated polyclonal antibodies. Fifty and 100μM $CdCl_2$ induced p38 and SAPK/JNK phosphorylation, and accumulation of poly-ubiquitinated proteins in a time-dependent manner, but very little increase in caspase-3 cleavage. $CdCl_2$ also activated Akt by 1 hour, with a diminishing response over time. Serum deprivation also resulted in p38 and SAPK/JNK phosphorylation, but less accumulation of poly-ubiquitinated proteins relative to $CdCl_2$, and marked caspase-3 cleavage or Akt activation. 200μM H_2O_2, despite clear morphological evidence of cytotoxicity by 4 hours, did not cause p38 phosphorylation, accumulation of ubiquitinated proteins, or caspase-3 cleavage. These results show the involvement of the ubiquitin/proteosome proteolytic pathway in cadmium-induced cytotoxicity. Efforts are currently underway to identify specific targets of cadmium-induced ubiquitination. Supported by NIH Grants P30 ES07033, T32 ES07032, R01 ES09601 and R01 ES10613-01, and EPA Grant R826886.

312 REGULATION OF CYP1A1 TRANSCRIPTION ELONGATION BY AH RECEPTOR THROUGH INTERACTION WITH P-TEF B.

Y. Tian[1], S. Ke[1], M. Chen[1], A. B. Rabson[3], M. A. Gallo[2] and T. Sheng[1]. *[1]Vet. Physiology and Pharmacology, Texas A&M University, College Station, TX, [2]EOHSI, UMDNJ-Robert Wood Johnson Medical School, Piscataway, NJ and [3]Center for Advanced Biotechnology and Medicine, UMDNJ-Robert Wood Johnson Medical School, Piscataway, NJ.*

The aryl hydrocarbon receptor (AhR) is a ligand-dependent transcription factor that regulates most of the dioxin-induced toxic responses. Dioxin, as a classic ligand for the AhR, causes the AhR to translocate from its cytoplasmic residence into the nucleus where it binds to the xenobiotic response elements (XREs), which are the cis-acting element for the regulation of gene expression. We now report that AhR may directly control transcriptional elongation by interacting with the positive transcription elongation factor b (p-TEFb). We found that AhR directly associated with the cyclin T1 subunit of p-TEFb. P-TEFb regulates the transcription elongation by phosphorylating the C-terminal peptapeptide repeats (YSPTSPS) of RNA polymerase II (Pol II-CTD). Furthermore, expression of cyclin T1 by transient transfection in Hepa 1c1c7 cells caused marked enhancement of AhR-driven luciferase reporter gene, suggesting that elongation control by p-TEF-b is a rate-limiting step in AhR-regulated transcription. Intriguingly, we observed that dioxin treatment induced time-dependent differential phosphorylation of the serine 2 and serine 5 of Pol II C-terminal domain on the promoter region of cyp1a1, suggesting involvement of different kinases at different stage of transcription elongation. These results demonstrate that AhR exerts an elaborate control of transcription through regulating transcription elongation as well as formation of preinitation complex. Supported in part by NIEHS Grant ES09859.

313 INVOLVEMENT OF CASPASE-2 UPSTREAM OF MITOCHONDRIA DURING ETOPOSIDE-INDUCED APOPTOSIS.

J. D. Robertson, M. Enoksson, B. Zhivotovsky and S. Orrenius. *Toxicology, Karolinska Institutet, Stockholm, Sweden.*

DNA damage induced by the cancer chemotherapeutic drug etoposide triggers the onset of a series of intracellular events characteristic of apoptosis. Among the early changes observed is the release of cytochrome *c* from mitochondria, although the mechanism responsible for this effect is unclear. In the present study, we demonstrate a role for caspase-2 in etoposide-induced cytochrome *c* release. Jurkat T-lymphocytes treated with an irreversible caspase-2 inhibitor, benzyloxycarbonyl-Val-Asp-Val-Ala-Asp-fluoromethyl ketone (z-VDVAD-fmk), or stably transfected with pro-caspase-2 antisense (*Casp-2/AS*) are refractory to cytochrome *c* release stimulated by etoposide. Experiments performed using a reconstituted cell-free system indicate that etoposide-induced cytochrome *c* release by way of caspase-2 occurs independently of cytosolic factors, suggesting that the nuclear pool of pro-caspase-2 is critical to this process. Apart from inhibiting cytochrome *c* release, undermining caspase-2 activity results in an attenuation of downstream events, such as pro-caspase-9 and -3 activation, phosphatidylserine (PS) exposure on the plasma membrane, and DNA fragmentation. Taken together, our data indicate that caspase-2 provides an important link between etoposide-induced DNA damage and the engagement of the mitochondrial apoptotic pathway.

314 DIFFERENTIAL SENSITIVITY OF LUNG AND BRAIN CELL LINES TO TETRAHYDROCANNABINOL-INDUCED MITOCHONDRIAL INJURY.

T. A. Sarafian[1], P. L. Carter[2], A. C. Howlett[2], K. Badal[1], D. Lin[1], D. P. Tashkin[1] and M. D. Roth[1]. *[1]Medicine, UCLA, Los Angeles, CA and [2]Neuroscience/Drug Abuse Research Program, North Carolina Central University, Durham, NC.*

Marijuana smoking produces numerous neuropsychologic and neuromotor effects without extensive brain cell injury or cell death. However, in the lungs marijuana smoking is associated with chronic bronchitis, inflammation, immunosuppression and loss of ciliated epithelial cells. We reported previously that exposure of pulmonary A549 cells to marijuana smoke or to 9-tetrahydrocannabinol (THC) suppressed apoptotic cell death and increased necrotic death (Sarafian et al., 2001, Toxicol. Appl. Pharmacology 174:264-272). THC exposure was found to be associated with a decrease in cellular ATP levels. Studies with the fluorescent probe, JC-1, revealed that THC caused a dose-dependent decrease in red fluorescence suggesting disruption of the mitochondrial membrane potential. Disruption of cell energetics could be responsible for the observed suppression of apoptotic death in A549 cells since cellular energetics must be maintained above critical permissive level for apoptosis to occur. To investigate this possibility, we have compared three different cell lines for sensitivity to THC. Unlike A549 cells, neuroblastoma N18TG2 cells are relatively resistant to THC-induced cell killing, while U87 glioma cells are killed by an apoptotic mechanism. JC-1 fluorescence studies revealed that 24 hr exposure to 6 microg/ml THC had a greater impact on mitochondrial membrane potential in A549 cells (61% decrease in red fluorescence) than in U87 (25 % decrease) or N18TG2 (4 % decrease)cells. Loss of cellular ATP was also enhanced in A549 cells. These changes showed a relationship to patterns of apoptotic and necrotic cell death which may, in part, explain the differing pathologies observed in tissues of marijuana smokers. (Supported by NIH R37DA030)

315 MECHANISM OF CANNABINOID-INDUCED APOPTOSIS IN CELLS OF IMMUNE ORIGIN.

C. A. Lombard[1], M. Nagarkatti[1] and P. S. Nagarkatti[2]. *[1]Microbiology and Immunology, MCV Campus, Virginia Commonwealth University, Richmond, VA and [2]Pharmacology and Toxicology, MCV Campus, Virginia Commonwealth University, Richmond, VA.*

Previous studies from our laboratories have shown that ligation of cannabinoid receptor by delta 9 -tetrahydrocannabinol (THC) leads to the induction of apoptosis in normal and transformed immune cells. These data suggested that immunosuppression mediated by cannabinoids may result from induction of apoptosis and that cannabinoids can be used as novel anti-cancer agents. Here we show that JWH015, a CB2 specific agonist, exerts a similar effect on splenocytes and thymocytes *in vitro*. Splenocytes treated with JWH015 showed a decreased ability to proliferate in response to mitogenic stimuli. In addition treatment of both splenocytes and thymocytes with JWH015 led to the induction of apoptosis *in vitro*. Studies to determine the mechanism of action of JWH015 showed a decrease in mitochondrial membrane potential of thymocytes and splenocytes, suggesting the involvement of the mitochondrial pathway. Further mechanistic studies conducted in the human lymphoma cell line Jurkat showed that caspase 8-deficient and FADD-deficient cells were sensitive to decrease in the mitochondrial membrane potential thereby suggesting that the mitochondrial pathway was independent of death-receptor signaling. However, the caspase 8 deficient cells were partially sensitive to apoptosis thereby suggesting that death-receptor pathway may play a role in THC-induced apoptosis. Moreover, Western blot analysis of protein extracted from wild-type Jurkat cells treated with THC showed cleavage of both caspase 8 and caspase 9, thereby confirming the involvement of these two pathways. Together this study shows that cannabinoids induce apoptosis in cells of immune origin and that both the death receptor and the mitochondrial pathways are involved. (Supported by NIH grants ES09098, DA014885 and HL058641).

316 ARSENIC-INDUCED APOPTOSIS AND NECROSIS IN RAMOS B CELLS ARE DEPENDENT ON INTRACELLULAR CA2+ FLUXES.

D. J. McConkey, L. K. Nutt, J. C. Pahler and B. Mirnikjoo. *Cancer Biology, University.T. M.D. Anderson Cancer Center, Houston, TX.*

Arsenicals have significant anti-tumor activity in hematopoietic malignancies, but their mechanisms of action remain elusive. Our recent work indicated that efflux of Ca2+ from the endoplasmic reticulum and subsequent mitochondrial Ca2+ uptake in apoptosis induced by staurosporine and the cancer chemotherapeutic agent doxorubicin in human prostate cancer cells. In this study we characterized the effects of arsenic trioxide on apoptosis in the human Ramos B cell lymphoma. At clinically achievable concentrations (1-10 uM) arsenic trioxide induced delayed, caspase-independent depletion of the endoplasmic reticular Ca2+ pool, resulting in mitochondrial Ca2+uptake, cytochrome c release, and apoptotic cell death. However, higher concentrations caused immediate increases in cytosolic and mitochondrial Ca2+, cytochrome c release, and necrotic cell death. Importantly, a selective inhibitor of the mitochondrial Ca2+ uniporter (RU-360) inhibited mitochondrial Ca2+ uptake, cytochrome c release, and death in cells exposed to either high or low doses of arsenic, indicating that mitochondrial Ca2+ uptake functioned as a final common pathway for cell death under all conditions. Together, our data demonstrate that intracellular Ca2+ fluxes leading to increases in mitochondrial Ca2+ are centrally involved in arsenic trioxide-induced cytochrome c release and cell death.

317 ARSENITE INDUCED MITOTIC ARREST IS P53 DEPENDENT.

J. States[1], S. C. McNeely[1], B. D. Beauerle[1] and M. J. McCabe[2]. [1]*Pharmacology & Toxicology, University of Louisville, Louisville, KY and* [2]*Environmental Medicine, University of Rochester, Rochester, NY.*

SV40 transformed human fibroblasts are sensitive to arsenite induced cytotoxicity. Exposure of SV40 transformed human fibroblasts to low concentrations of arsenite induces mitotic arrest followed by apoptosis. In contrast, only a mitotic delay is induced by arsenite in normal diploid fibroblasts. One effect of SV40 T-antigen is to abrogate p53 function. Therefore, we investigated the potential for p53 to modulate the response to arsenite exposure using TR9-7 human fibroblasts in which p53 is under exogenous control (tet-off). Effects of high (p53hi), low (p53lo) and no (p53-) p53 expression on arsenite induced cytotoxicity and mitotic arrest were examined. TR9-7 p53hi cells grew very little and were relatively resistant to arsenite induced toxicity. In asynchronous populations of TR9-7 p53- cells, 5 μM arsenite caused an accumulation of cells arrested in mitosis indicated by an 3-fold increase in mitotic index and induced apoptosis as indicated by morphological criteria. Arsenite did not cause asynchronous TR9-7 p53lo cells to accumulate in mitosis. Arsenite exposure caused a delay of entry into mitosis in TR9-7 cells released from G2 synchronization regardless of p53 expression. However, TR9-7 p53lo cells exited from mitosis whereas TR9-7 p53- cells remain arrested long after p53lo cells had exited. These results suggest that p53 plays an essential role in preventing arsenite induced mitotic arrest but does not affect delayed exit from G2 and entry into M phase. (Supported by ES06460 and Kentucky Research Challenge Trust Fund)

318 COORDINATE REGULATION OF BLEOMYCIN-INDUCED APOPTOSIS BY P53 TARGET GENES IN THE MURINE LUNG.

D. W. Davis[1], A. B. Santamaria[2], J. Lawler[3], H. Ananthaswamy[2] and D. J. McConkey[1]. [1]*Cancer Biology, University.T. M.D. Anderson Cancer Center, Houston, TX,* [2]*Immunology, University.T. M.D. Anderson Cancer Center, Houston, TX and* [3]*Pathology, Beth Israel Deaconnes Medical Center and Harvard Medical School, Houston, TX.*

Chronic inflammation leading to pulmonary fibrosis is the unfortunate consequence of exposure to a variety of cancer chemotherapeutic agents and environmental pollutants. We recently demonsrated that the DNA damaging agent bleomycin, induced higher levels of apoptosis in $p53^{-/-}$ mice compared to wild-type controls. Here we used C57BL/6 mice deficient in p53 target genes to define the regulators of apoptosis *in vivo*. Intratracheal bleomycin instillation stimulated p53-dependent increases in Fas and Fas ligand (FasL) in $p53^{+/+}$ but not $p53^{-/-}$ lungs. Levels of bleomycin-induced apoptosis were significantly reduced (by 80%) in the lungs of FasL-deficient (*gld*) mice, confirming that Fas-FasL interactions accounted for almost all of the cell death observed on a $p53^{+/+}$ background. However, bleomycin only induced significant increases in Bax expression in $p53^{-/-}$ lungs. We speculate that DNA damage-induced Bax induction occurs in $p53^{-/-}$ mice to compensate for the loss of the Fas/FasL pathway. Thrombospondin-1 (TSP-1) is another p53 target gene that functions as an immunomodulator *via* its effects on TGF-β activation and the clearance of apoptotic cell debris. Bleomycin stimulated significant increases in TSP-1 expression in wild-type but not in $p53^{-/-}$ lungs, and TSP-$1^{-/-}$ mice displayed higher rates of apoptosis compared to controls. Furthermore, TSP-1-deficient macrophages failed to ingest apoptotic cells *in vitro*. Together, our results establish a novel role for p53-dependent increases in TSP-1 in the requirement for ingestion of apoptotic cell debris. Our data are also the first to establish that p53 can inhibit stress-induced increases in Bax expression.

319 TCDD-INDUCED LOSS OF MITOCHONDRIAL MEMBRANE POTENTIAL IN SPERMATOZOA IS INDEPENDENT OF FAS AND FASL.

M. Fisher[1], P. S. Nagarkatti[1] and M. Nagarkatti[2]. [1]*Pharmacology and Toxicology, Virginia Commonwealth University, MVC Campus, Richmond, VA and* [2]*Microbiology and Immunology, Virginia Commonwealth University, MVC Campus, Richmond, VA.*

2, 3, 7, 8-tetrachlorodibenzo-p-dioxin (TCDD) is known to have toxic effects on the male reproductive system. These include reduced fertility, reduced reproductive organ weight, reduction in sperm counts, and an increase in abnormal spermatozoa. However, the mechanism(s) through which TCDD exerts toxic effects on the testes are not fully understood. Recently, it has been shown that the Fas death receptor system is involved in TCDD-induced atrophy of the thymus. In addition, the Fas system is active in the testes, although the expression pattern of Fas and FasL remain controversial. As it has been shown that TCDD treatment does not result in a loss of either germ cells or Sertoli cells, we examined the effects of TCDD on spermatozoa. Male C57BL/6 mice were injected i.p. with TCDD suspended in corn oil. The expression of Fas was upregulated in the testes following a 24hr exposure to 50 μg/kg TCDD compared to vehicle controls. In addition, histological examination of the epididymus showed a reduction in spermatozoa in TCDD treated mice. Sperm quality was assessed by measuring loss of mitochondrial membrane potential ($\Delta\Phi_m$) using $DiOC_6(3)$ staining. Doses as low as 0.1 μg/kg TCDD resulted in a reduction in $\Delta\Phi_m$ in 17.5% of spermatozoa after a 24hr exposure. 42% ± 16.3% of spermatozoa from mice treated with 50 μg/kg for 24hr showed loss of $\Delta\Phi_m$. To determine if Fas/FasL interactions were involved in the effect of TCDD on spermatozoa, the $\Delta\Phi_m$ of FasL defective *gld* and Fas-deficient *lpr* mice was assessed after exposure to 50 μg/kg TCDD. 50.3% ± 17.1% of spermatozoa from *gld* mice and 61.5% ± 13.6% of spermatozoa from *lpr* mice showed loss of $\Delta\Phi_m$, suggesting that Fas and FasL are not involved in TCDD-induced loss of mitochondrial membrane potential in spermatozoa (Supported by NIH grants R01ES09098, F32ES011732, R21DA014885 and R01HL058641).

320 IDENTIFICATION OF CASPASE-INDEPENDENT APOPTOSIS IN EPITHELIAL AND CANCER CELLS.

G. R. Kinsey, B. S. Cummings and R. G. Schnellmann. *Pharmaceutical Sciences, Medical University of South Carolina, Charleston, SC.*

We recently reported that 50% of cisplatin-induced apoptosis in primary cultures of rabbit renal proximal tubule cells (RPTC) proceeded *via* caspase-independent mechanisms. The goals of this study were to determine if caspase-independent apoptosis was induced by toxicants other than cisplatin and in cell models other than RPTC. Cisplatin (50 μM), staurosporine (2 μM), vincristine (2 μM), and A23187 (10 μM) induced RPTC apoptosis after 24 hr as determined by 2-2.5-fold increases in annexin V staining in the absence of propidium iodide staining (a marker for oncosis). All toxicants induced 8-50-fold increases in caspase 3 activity, and caspase 3 activities were completely inhibited by the pan caspase inhibitor ZVAD-fmk (50 μM). However, ZVAD-fmk only decreased toxicant-induced RPTC annexin V staining 30-50%. Cisplatin and staurosporine also induced annexin V staining in the human epithelial cancer cell lines Caki-1 (kidney carcinoma), A549 (lung carcinoma), A172 (glioblastoma) and murine L1210 cells (lymphocytic leukemia). Cisplatin increased annexin V staining to 20 ± 1%, 24 ± 1%, 26 ± 1%, and 28 ± 2% in Caki-1, A549, A172 and L1210 cells, respectively (vs. 12 ± 1% in controls). Pretreatment with ZVAD-fmk did not reduce cisplatin-induced annexin V staining in L1210 cells, but reduced annexin V staining to 17 ± 2% in A549 cells, 10 ± 1% in A172 cells, and 13 ± 1% in Caki-1 cells. Staurosporine increased annexin V staining to 41 ± 1%, 58 ± 2%, 36 ± 2%, and 46 ± 3% in Caki-1, A549, A172 and L1210 cells, respectively. Pretreatment with ZVAD-fmk did not decrease annexin V staining in Caki-1, A549, and L1210 cells, but decreased annexin V staining in A172 cells to 31 ± 2%. Cisplatin- and staurosporine-induced caspase 3 activation was totally inhibited by ZVAD-fmk in all cell lines. These results suggest that a significant fraction of apoptosis induced by diverse toxicants in renal epithelial cells and in four different cancer cell lines is caspase-independent.

321 THE COMBINATION OF THE PROTEASOME INHIBITOR, PS-341, AND DOCETAXEL INHIBITS ANGIOGENESIS AND OVERCOMES CELL-CYCLE MEDIATED RESISTANCE IN PANCREATIC CANCER.

S. T. Nawrocki, B. Sweeney-Gotsch, R. Takamori and D. J. McConkey. *Cancer Biology, UT M.D. Anderson Cancer Center, Houston, TX.*

Pancreatic carcinoma is the fourth most common cause of cancer-related death in the United States. Chemotherapy and irradiation are largely ineffective, and metastatic disease frequently develops even after potentially curative surgery. Therefore, more effective therapies are clearly needed for treatment of this disease. PS-341, a boronic acid dipeptide derivative, is a selective and potent inhibitor of the proteasome. Our previous studies demonstrated that PS-341 treatment results in an accumulation of cells in the G2-M phase of the cell cycle. Considering this phenomenon, we hypothesized that the combination of PS-341 with docetaxel may have synergistic anti-tumor activity. Two pancreatic cell lines, MiaPaCa2 and L3.6pl, were selected to test this hypothesis *in vitro* and *in vivo*. This drug combination was antagonistic in MiaPaCa2 cells and showed no difference from single treatment in L3.6pl cells *in vitro*. The antagonism resulted from a decreased percentage of mitotic cells due to stabilization of the cyclin dependent kinase inhibitors, p21 and p27, and cdc2 inhibition. Combination studies were also conducted *in vivo* using an orthotopic, nude mouse model. Surprisingly, tumor weight and volume were significantly reduced in both cell line models despite the cell-cycle mediated resistance observed *in vitro*. Further characterization of the tumors revealed a significant decrease in tumor endothelial cells and a reduction in vascular endothelial growth factor (VEGF) expression. The anti-angiogenic effect is cell-cycle independent and may provide an explanation for the reduction in tumor size. Our studies demonstrate that while the combination of PS-341 and docetaxel ex-

hibits cell-cycle related effects that render it ineffective *in vitro*, the anti-angiogenic effects of this drug combination appear to overcome this mechanism of resistance *in vivo*. Thus, PS-341 is a candidate for use in combination chemotherapy in the treatment of pancreatic cancer and warrants further investigation.

322 EVALUATION OF CELL CYCLE KINETICS IN P53 MOUSE EMBRYONAL FIBROBLASTS: EFFECTS OF METHYL MERCURY.

E. J. Gribble, A. Mendoza, S. Hong, J. Sidhu and E. M. Faustman. *Environmental Health, University of Washington, Seattle, WA.*

Methyl mercury, a ubiquitous environmental contaminant, is a known potent teratogen selectively affecting the developing central nervous system. While a definitive mechanism for methyl mercury (MeHg) induced developmental neurotoxicity remains elusive, rats exposed *in utero* to low levels of MeHg appear to have reduced numbers of cerebellar cells without cell death. This suggests earlier toxicant interference with critical molecular signaling events controlling cell behavior i.e. proliferation. We have previously observed an accumulation of cells in G2/M following MeHg treatment (0, 2, 4, and 6μM) in asynchronous transgenic mouse embryonal fibroblasts (MEFs) independent of p21 or p53 genotype. The degree of inhibition is differential by genotype and dose indicating partial involvement of p21 and p53 but not a singular mechanism. Specifically, after 24h treatment with 2 μM MeHg, a statistically significant increase in the proportion of cells in G2/M was observed in (+/-) and (-/-) and the difference became significant in all genotypes at 4μM. We employed bivariate flow analysis and observed cyclin B1 downregulation in treated p53 (+/+) cells and induction in (-/-) cells in the 4N population. Taken together, this data suggests MeHg acts through a p53-dependent pathway in these cells but also causes G2/M accumulation through other as of yet undetermined mechanisms. To examine the role that cell cycle stage plays in MeHg toxicity, we synchronized p53 transgenic MEFs through 24h serum starvation and are following their progression through the cell cycle by BrdU-Hoechst flow cytometric analysis. Our data have shed light on the potential role that cell cycle signaling pathways play in mediating MeHg toxicity. This should greatly enhance our understanding of temporal and regiospecific MeHg neurodevelopmental susceptibility. Supported by NIH grants ES10613-01, ES07033, ES0-7032.

323 METHYL MERCURY INDUCES DIFFERENTIAL UBIQUITIN-CONJUGATED PROTEIN LEVELS IN P53 VARIANT MOUSE EMBRYONAL FIBROBLASTS.

J. S. Sidhu, S. Hong, A. Erickson, A. Baker, J. Robinson, P. Vliet and E. M. Faustman. *Env Health, University of Washington, Seattle, WA.*

The ubiquitin-proteasome pathway is critical for the targeting and rapid intracellular degradation of many proteins associated with regulation of cell cycle progression, differentiation, and development. The accumulation of ubiquitinated proteins is usually attributable to a malfunction, inhibition, or overload of this pathway. Recent studies have suggested that various chemical stressors can disrupt critical cell cycle checkpoints, e.g. p53, *via* increased ubiquitination resulting in cytotoxicity. We examined such a potential mechanism for the environmental contaminant, methylmercury (MeHg), which causes neurological disorders and disruption of fetal neurodevelopment. Cultures of p53 transgenic mouse embryonal fibroblasts (MEFs) were treated for 0.5, 1, 2, 4, 8 and 24h with MeHg (0, 0.5, 2.5 μM) and compared to similar treatments with lactacystin, a potent proteosomal inhibitor. Cell extracts were prepared and ubiquitinated protein levels were visualized by western blot analysis using a polyclonal antibody to ubiquitin. Lactacystin induced the accumulation of ubiquitinated proteins in a time-dependent manner irrespective of p53 genotype. In contrast, MeHg treatment (2.5 μM) resulted in a saturated accumulation between 4-24h in the p53 (+/+) cells. In the (+/-) cells, an equivalent accumulation peaked at 4h and then declined while the (-/-) cells showed a minor response at early timepoints. MeHg-induced accumulation of ubiquitinated proteins suggests an inhibition of the proteasome by this agent which is qualitatively comparable to that observed with lactacystin. However, the significant disparity in the level of ubiquitinated proteins observed between both agents in the (-/-) suggests a p53-dependent mechanism for MeHg-induced disruption of proteosomal degradation. The toxicant-induced inhibition of this critical cellular function may help explain the aberrant effects associated with MeHg-induced cytotoxicity in neuronal populations of the developing fetal brain. Supported by NIH Grants ES10613-01, ES09601-02, ES07033.

324 TOXICITY OF METHYLMERCURY IN CO-CULTURES OF ASTROCYTES AND NEURONS.

T. Syversen, T. S. Morken, B. Urfjell, H. Qu and U. Sonnewald. *Department of Clinical Neuroscience, Norwegian University of Science and Technology, Trondheim, Norway.*

Methylmercury (MeHg) causes damage in selective areas of the brain. The mechanism of toxicity is not known although the selective loss of e.g. cerebellar granule cells has been known for a long time. It has been suggested that the loss of neurons might be the result of primary effects on astrocytes. We have incubated cerebellar granule neurons and astrocytes separately and in co-culture and used changes in MTT-reduction and LDH leakage as indicators of methylmercury toxicity. The primary cerebellar cultures were prepared from seven-day-old mice. Cortical astrocytes were prepared from one-day-old mice. The results obtained from these experiments are compared to those from cell lines (C6 glioma and IMR-32 neuroblastoma), using EC50 (concentration where 50% change occurs). The neuroblastoma cells were slightly more sensitive than the glioma cells (3 versus 5 μM). These numbers agree well with literature values. The cerebellar neurons demonstrated sensitivity similar to the C-6 glioma cells and were far more sensitive than astrocytes which proved to be considerably more resistant. Cortical astrocytes were slightly more sensitive than cerebellar astrocytes. When cerebellar astrocytes and neurons where incubated in separable co-culture using inserts the astrocytes became more sensitive to MeHg while neurons could tolerate a three-fold increase in MeHg concentration. Thus, astrocytes appear to reduce the sensitivity of neurons considerably indicating a possible protective role for astrocytes in methylmercury neurtoxicity.

325 EXPRESSION OF CALBINDIN D-28K CORRELATES WITH DECREASED METHYLMERCURY (MEHG) CYTOTOXICITY IN MYENTERIC PLEXUS NEURONS.

J. R. Edwards and W. D. Atchison. *Department Pharmacology/Tox, Mich State University, East Lansing, MI.*

MeHg causes selective neurotoxicity, particularly in cerebellar granule neurons. The exact mechanisms of MeHg-induced cytotoxicity are unknown, but MeHg elevates intracellular divalent cations including Ca^{2+}. Granule cells don't express the Ca^{2+} binding protein, calbindinD-28k -in contrast to adjacent Purkinje cells which express calbindinD-28k and are more resistant to MeHg cytotoxicity. Calbindin is thought to prevent neuronal death and buffer against elevations of $[Ca^{2+}]_i$. Neurons containing calbindin are more resistant to cell death associated with neurodegenerative diseases and neuronal cell lines transfected with calbindin are more resistant to glutamate excitotoxicity. We hypothesized that other neurons containing calbindinD-28k would also be resistant to MeHg cytotoxicity. To test this, guinea pig myenteric plexus neurons, some of which express D-28k, were exposed in culture to 2, 5 and 7 μM MeHg for 1 h. Viability was assayed 24 h later. Little or no cell death occurred in control or 2 μM MeHg groups. However, ~ 60% of cells died in the 5 and 7 μM MeHg groups. Two cell types remained at both 5 and 7 μM MeHg treatment groups, fibroblast type cells and cells immuno-reactive for calbindinD-28k. To explore the role of calbidinD-28k in buffering $[Ca^{2+}]_i$, cells were loaded with fura-2 and exposed to 2 μM MeHg. In prior studies, cells with greater resistance to MeHg-induced cytotoxcity have longer time-to-onset increases in fura-2 fluorescence. Myenteric plexus neurons exhibiting the distinct morphology of calbindinD-28k positive neurons had a biphasic increase in fura-2 fluorescence. The 1st increase occurred at 14.1 ±1.8 min, and the 2nd at 22.8 ±5.4 min. Similar times-to-onset of fura-2 fluorescence were seen previously in cerebellar Purkinje neurons, in response to MeHg. These data support the hypothesis that expression of calbindinD-28k provides enhanced resistance to the cation elevating and subsequent cytotoxic effects of MeHg. Supported by NIEHS grant ES03299.

326 EFFECTS OF PRE- AND POSTNATAL METHYLMERCURY EXPOSURE ON EXPRESSION OF EPHS AND EPHRINS IN THE MOUSE.

D. T. Wilson[1], K. R. Reuhl[1] and R. Zhou[2]. *[1]Toxicology, Rutgers University, Piscataway, NJ and [2]Chem. Biol., Rutgers University, Piscataway, NJ.*

Repulsive interactions mediated by the EPH tyrosine kinase receptors and their ephrin ligands guide several morphogenetic processes, including the establishment of proper topographical mapping of CNS pathways. Methylmercury (MeHg), a potent environmental neurotoxicant, induces morphological changes during brain development suggestive of neuronal guidance errors. The effects of maternal MeHg exposure on EPH and ephrin mRNA expression in brains of exposed offspring were examined in the C57 mouse. Pregnant mice were administered 2.5 mg/kg MeHg *via* gavage every other day from gestational day 14 until sacrifice of their pups on postnatal day 1, 5, 10, or 15. On days 1 and 5, whole brains were removed; on days 10 and 15, brains were dissected into cerebellum, hippocampus, and rest of brain (ROB). Samples were analyzed for EPH and ephrin mRNA expression using an RNase protection assay. In day 1 whole brains, EPHA3, A4 and ephrin-B3, B2, B1, A3 were decreased while on day 5, receptors A3, A4, A5, A6, A7, A8 and ligands B3, B2, A3 showed increased expression. Ephrin-A5 was significantly elevated in day 10 hippocampus while the other ligands and receptors were less sensitive to MeHg. Day 10 cerebellum samples showed a trend for decreased ligand expression. EPHA4 was most significantly decreased in day 15 cerebellum while the other receptors were decreased to a lesser extent. These data suggest that even slight perturbation of repulsive guidance molecules may play a role in the brain dysmorphogenesis caused by MeHg. (Supported by ES 05022, ES 07148, and ES 11256).

327 ALTERED APOPTOTIC GENE EXPRESSION IN WHOLE CEREBELLA OF MICE EXPOSED TO METHYLMERCURY *IN VIVO*: A cDNA MICROARRAY ANALYSIS.

K. A. Thuett and L. C. Abbott. *Veterinary Anatomy and Public Health, Texas A&M University / College of Veterinary Medicine, College Station, TX.* Sponsor: E. Castiglioni.

Human and animal exposure to methylmercury within the environment occurs mainly due to the consumption of fish. Methylmercury has been known since the mid-1900s to be a neurotoxicant and the resulting symptoms are well known; however, the molecular mechanisms of its toxicity have yet to be elucidated. Neurodegeneration of the cerebellum by means of apoptosis produces similar symptoms to those observed in methylmercury exposed individuals and therefore apoptosis is suspected of playing a role in methylmercury toxicity. In this study, the Panorama Mouse Apoptosis Gene Array (Sigma Genosys) containing 243 apoptosis-related genes was used to analyze gene expression in cerebella of 21 day old C57BL/6J, male and female mice that were exposed to a total of 5 mg/kg methylmercury over a 7 day period. Array results indicate an upregulation in several apoptosis-related factor genes such as TDAG8 and DAXX. In addition, upregulation was observed in caspase-11, caspase-14, and IL-1 RI. Decreased gene expression was observed in TRADD and DR-6. These data indicate that cells within the cerebellum of methylmercury exposed mice undergo apoptotic cell death and provide a basis for further investigation into the mechanism of methylmercury neurotoxicity. Supported by CERH Pilot Project funds to L.C.A. (NIEHS grant P30-EF09106).

328 REACTIVE OXYGEN SPECIES MEDIATE METHYLMERCURY-INDUCED NEUROTOXICITY IN ASTROCYTES: PROTECTIVE EFFECT OF ANTIOXIDANTS.

G. Shanker, L. A. Mutkus, K. M. Erikson and M. Aschner. *Physiology and Pharmacology, Wake Forest University School of Medicine, Winston-Salem, NC.*

Excessive reactive oxygen species (ROS) generation has been implicated as a causal factor in various neurodegenerative diseases. The present work examined the effect of methylmercury (MeHg) on ROS formation by monitoring 2', 7'- dichlorodihydro-fluorescein diacetate (H2DCF-DA) fluorescence in primary astrocytic cultures from neonatal rat cerebral cortex. MeHg, at 10 and 20 uM concentrations, induced a significant increase in ROS formation (10 uM, $p<0.01$; 20 uM, $p<0.001$). Additional studies demonstrated that both superoxide dismutase (SOD), an antioxidant enzyme and n-propyl gallate (PG), a free radical scavenger, were able to significantly attenuate the MeHg-stimulated ROS generation. A significant decrease in MeHg-induced ROS generation was also observed when the astrocytes were preincubated (3 hours) with arachidonyl trifluoromethyl ketone (AACOCF3, 20 uM, $p<0.05$), a specific inhibitor of cytosolic phospholipase A2 (cPLA2). In additional studies, preincubation (24 hours) of astrocytes with 100uM buthionine-L-sulfoxamine (BSO, a glutathione synthesis inhibitor), was found to significantly increase ($p<0.05$) ROS formation in MeHg treated astrocytes, compared to controls. In summary, the present study invokes ROS as potent mediators of MeHg cytotoxicity and support the theory that excessive ROS generation, at least in part, contribute to MeHg-induced neurotoxicity. (This work was supported by PHS grant NIEHS 07331).

329 CALCIUM HOMEOSTATIS AND REDOX STATUS ALTERATIONS IN SY5Y NEUROBLASTOMA CELLS EXPOSED TO INORGANIC MERCURY.

E. Tiffany-Castiglioni and K. A. Thuett. *Veterinary Anatomy and Public Health, Texas A&M University / College of Veterinary Medicine, College Station, TX.*

Heavy metals found in contaminated environmental sites pose serious risks to human and animal health. Mercury toxicity, for example, produces moderate to severe central nervous system disorders. CNS toxicity associated with mercury involves organic forms of mercury that cross the blood-brain barrier; however, once internalized within the brain, specific toxicity is perpetuated by the disassociated inorganic form. It is suspected that inorganic mercury within the brain perturbs intracellular signaling pathways and interferes with normal cellular function. Studies suggest that calcium homeostasis and redox status may play a role in mercury toxicity and in the subsequent induction of genes responsible for cytoprotection. In this study, mercuric chloride was administered *in vitro* to SY5Y cells cultured in 96-well plates. Mercury exposure occurred for a period of 24 and 36 hours at concentrations of 0, 0.1, 1.0 and 10 μM $HgCl_2$. Subsequent analysis of intracellular calcium (Ca), glutathione (GSH), mitochondrial membrane potential (MMP), and reactive oxygen species (ROS) was performed with the fluorescent dyes Fluo-4 AM, monochlorobimane (mBCl), tetramethylrhodamine (TMRE), and 5-6-chloromethyl-2', 7'-dichlorodihydrofluorescein diacetate (CM-H2DCFDA), respectively. Fluorescence was detected with a microplate reader. Data indicate a significant dose dependent increase in Ca, GSH, MMP and ROS levels after 24 hours of exposure to $HgCl_2$, followed by recovery to control levels at 36 hours. It appears as though mercury initially caused changes in calcium homeostatasis and redox potential, but that other mechanisms within the cells provided a cytoprotective effect. These results provided a basis for further investigations involving the secondary effects associated with alterations in calcium and redox homeostasis.

330 BLOCKAGE OF IL-6 SECRETION IN GLIA BY LEAD AND MERCURY.

N. M. Pourrajabi[1], Y. Qian[1], R. Tjalkens[1], K. Ramos[2] and E. Tiffany-Castiglioni[1]. [1]*Veterinary Anatomy & Public Health, Texas A&M University, College Station, TX and* [2]*Veterinary Physiology & Pharmacology, Texas A&M University, College Station, TX.*

Mercury (Hg) and lead (Pb) are among known neurotoxicants to the development and function of the central nervous system (CNS). IL-6 produced by astroglia protects neurons from damage in many progressive degenerative disorders. It was reported that IL-6 secretion was chaperoned by a 78 kD glucose-regulated protein (Grp78), which is an ER-chaperone protein and involved in protein folding, assembly and trafficking, and Pb can target Grp78 in astroglia. We hypothesize that Pb and Hg could target Grp78 and block IL-6 secretion from astroglia. In this report, we constructed an IL-6/EGFP chimera and transiently transfected rat C6 glioma cells and rat primary astroglia. IL-6/EGFP signal in transfected cultures exposed to Pb, Hg or anti-oligos against Grp78 was detected with a fluorescence microscope. Data of bioimage analysis showed that the retention of IL-6/EGFP in both astroglia and C6 cells transfected with IL-6/EGFP was at an undetectable level. However, the IL-6/EGFP signal in these cultures, while exposed to Pb or Hg (0-10 μM) for 24 hrs, apparently increased, suggesting that Pb and Hg could block IL-6 secretion from astroglia. Furthermore, when these transfected cultures were exposed to anti-oligos against Grp78, as expected, the retention of IL-6/EGFP inside cultures obviously increased. In order to identify the increase of IL-6/EGFP retention, we used ELISA to detect IL-6 level in the medium of non-transfected astroglia exposed to Pb (0-100 μM). Data showed that IL-6 level decreased with increased Pb concentration, suggesting that the increased retention results in part from a decrease of IL-6 secretion. These data, together with our previous studies, suggest that Pb and Hg probably impaired IL-6 metabolism by targeting Grp78 for their neurotoxicity.

331 NICOTINE REVERSES SPATIAL LEARNING DEFICITS IN PERINATALLY LEAD-EXPOSED RATS.

M. Zhou and J. B. Suszkiw. *Mol&Cell Physiology, University.Cincinnati, Cincinnati, OH.*

The effect of nicotine on spatial learning performance in Morris Water Maze was investigated in perinatally lead-exposed rats. Rats were exposed to lead *via* maternal administration of 0.2% lead acetate in drinking water from gestational day 16 through weaning on postnatal day 21 (P21). Lead-exposed and age-matched controls were tested on reference and working memory from P28 through P40. Half the littermates in each group received intraperitoneal injections of nicotine hydrogen tartrate salt at dose of 1 mg/ml/kg once per day, 20 min prior to the start of behavioral session. The perinatal lead-exposure resulted in a 20% reduction of hippocampal ChAT activity, and a significant spatial learning and memory deficits, including an increased latency to find the hidden platform in reference memory (133%) and working memory (166%) trials, and a reduction of the swimming time (72%) and swimming distance (81%) in reference memory probe test. In the lead-exposed littermates that were given nicotine prior to behavioral session, the latencies to find the hidden platform in reference memory (108%) and working memory (106%) trials, and swimming time (89%) and swimming distance (96%) on probe tests, were not significantly different from those in control animals. Administration of nicotine to control animals by itself had no effect on any of the behavioral parameters. These results indicate that nicotine reverses the learning and memory deficits induced by lead-exposure without affecting spatial learning performance in normal animals. Reversal by nicotine of spatial learning deficits in lead-exposed rats supports the hypothesis of a causal link between cognitive impairments and lead-induced cholinergic deficit in the hippocampus. Supported by grant # ES06365 from NIEHS

332 ACUTE LEAD EXPOSURE INCREASES THE RESPONSE TO N-METHYL-D- ASPARTATE IN MIDBRAIN DOPAMINE NEURONS OF THE RAT.

M. W. Lewis and D. K. Pitts. *Pharmaceutical Sciences, Wayne State University, Detroit, MI.* Sponsor: G. Corcoran.

Previous *in vivo* studies have shown that, at clinically relevant blood levels, inorganic lead (Pb) caused a decrease in the number of spontaneously active dopamine (DA) neurons without causing a decrease in immunohistologically stained TH (+)

cell count. The direct effects of Pb on the electrophysiological properties of DA neurons is unknown. Using the whole cell patch clamp recording technique we studied the effect of acute Pb exposure on the NMDA-induced inward current of young dopamine (DA) neurons in the rat brain slice. Pb (10 uM) was applied *via* addition to a standard Krebs based perfusion solution. Following acute Pb exposure(5 minutes) the response to NMDA (30uM) increased by 59+/-23% in Krebs + lead acetate (n=6; $p<0.05$) and 57+/-10% in Krebs + lead atomic absorption standard solution (n=7; $p<0.005$). In 2 out of 15 neurons, Pb did not alter the NMDA (30uM)-induced inward current. These results indicate that acute 10uM Pb exposure has significant effects on excitatory glutamatergic neurotransmission within the substantia nigra.

333 DIFFERENTIAL MODULATION OF DOPAMINE AND GLUTAMATE RECEPTOR AGONISTS ON LEAD-INDUCED CHANGES IN NEUROTRANSMITTER RELEASE IN CULTURED CORTICAL AND HIPPOCAMPAL NEURONS.

Y. Gedeon and A. L. Jadhav. *College of Pharmacy & Health Sciences, Texas Southern University, Houston, TX.*

Low level lead (Pb) exposure has been repeatedly demonstrated to disrupt reinforcement-related behavior in the mesocorticolimbic system of the brain. Interaction between the dopaminergic and glutamatergic release mechanisms of the mesocorticolimbic system plays a major role in reinforcement-based behavior. In order to investigate the role of D_1/D_2 dopamine receptors, N-methyl D-aspartate (NMDA) and metabotropic glutamate (mGLU) receptors on the effects of Pb on dopaminergic and glutamatergic release mechanisms, primary cultures of cortical (FC) and hippocampal (HIP) neurons were used to test the hypothesis that Pb alters glutamate receptor-mediated dopamine release. This study used the relatively novel sequential high-performance liquid chromatography analysis of monoamines and amino acids to examine the modulatory effects of quinpirole (a D_2-like receptor agonist), SKF-38393 (a D_1-like receptor agonist), NMDA (an NMDA receptor agonist) and trans-ACPD (a mGLU receptor agonist) on dopamine (DA) and glutamate (GLU) release in Pb-exposed primary cultures of FC and HIP neurons. Exposure to 1 to 1000 nM Pb for periods from 1 hour to 24 hours produced time-dependent and neuron-specific effects on DA and GLU release. Cortical neurons exposed to 100 nM Pb released increased levels of DA in response to 20 mM K^+, 100 μM SKF-38393 and 50 μM trans-ACPD but released decreased levels in response to 100 μM NMDA compared to control. However, similarly exposed hippocampal neurons released lower levels of DA in response to 20 mM K^+, 1000 nM quinpirole, 100 μM NMDA, and higher levels of DA in response to 50 μM trans-ACPD. These findings suggest that Pb may change DA release by modulating ionotropic GLU receptors in FC neurons and metabotropic GLU receptors in HIP neurons. Supported by ATSDR Cooperative Agreement # U50/ATU 398948.

334 LOW LEVEL LEAD ENHANCES GLUTAMATE TRANSPORT BY ASTROCYTES.

M. M. Tsang and F. A. Schanne. *Pharmaceutical Sciences, St. John's University, Jamaica, NY.*

Low-level lead (Pb) exposure in children is associated with disturbances in learning, memory and behavior. Glutamate, an excitatory amino acid neurotransmitter, is responsible for initiating long-term changes in the strength of synaptic connections, such as long-term potentiation (LTP) and long-term depression (LTD). LTP and LTD are understood to form the basis of memory processing. The concentration of glutamate in the synaptic cleft, available for triggering EPSPs and initiating changes in synaptic communication, is determined by the amount of presynaptic release, the rate of presynaptic reuptake and the magnitude of astroglial glutamate uptake. The purpose of this study was to examine the effects of Pb on Na^+-dependent glutamate uptake by astrocytes. Astrocytes were grown and maintained in DMEM in 24 well plates. Astrocyte cultures were washed and treated in Krebs HEPES buffer solution for 30 min with the protein kinase c (PKC) activator phorbol myristate acetate (PMA) (10 nM) or with Pb^{2+} (10^{-9} to 10^{-6} M maintained with 5F-BAPTA as the divalent cation buffer). Astrocyte glutamate uptake was measure by addition of ^{3}H-glutamate to the treatment solutions. Uptake was stopped and cultures were washed and cellular content of ^{3}H-glutamate was measured and normalized to protein content of cells. Glutamate uptake in the absence of Na^+ (choline Krebs) was subtracted from total uptake in normal Na^+-containing Krebs to determine Na^+-dependent uptake. PMA treatment resulted in a 60% increase in Na^+ dependent glutamate uptake while Pb^{2+} treatment resulted in a University-shape dose response with a maximal 60% increase in glutamate uptake at 10^{-8} M. These data indicate that the activity of the glutamate transporter in astrocytes in regulated by PKC and that Pb^{2+} at very low concentrations and most likely by acting on PKC can also increase glutamate transport in astrocytes. Increased glutamate uptake by astrocytes may alter the dynamic glutamate concentration present in synapses and necessary for the induction of changes in synaptic strength and thus alter the ability of lead-exposed individuals to learn.

335 LOW LEVEL LEAD DISRUPTS PKC-MEDIATED REGULATION OF EVOKED GLUTAMATE RELEASE FROM HIPPOCAPAL PRESYNAPTIC NERVE TERMINALS.

J. A. Trejos and F. A. Schanne. *Pharmaceutical Sciences, St John's University, Jamaica, NY.*

Low-level lead (Pb) exposure is associated with learning and memory deficits in children and laboratory animals. Glutamate, an excitatory neurotransmitter, plays a central role in the production long-term changes in the strength of synaptic connections, such as long-term potentiation (LTP) and long-term depression (LTD). LTP and LTD are thought to form the electro-physiological basis of memory processing. Control of presynaptic glutamate release is essential to the expression of both LTP and LTD. The purpose of this study was to examine the effects of Pb on the evoke release of glutamate from presynaptic nerve terminals. Presynaptic nerve terminals (synaptosomes) were isolated from young rat hippocampi using a Percoll gradient method. Synaptosomes were loaded with ^{3}H-glutamate and superfused with oxygenated Krebs HEPES buffer. Synpatosomes were treated for 30 min with or without Pb^{2+} buffered with 5F-BAPTA to set the free Pb^{2+} concentrations in the superfusion solutions. Superfusate was collected to measure the fractional release of ^{3}H-glutamate from synaptosomes. Evoked release was initiated by depolarization in 25 mM K^+. Potentiation of glutamate release from nerve terminals was induced with the PKC activator, phorbol myristate acetate (PMA)(10 nM), added to the superfusion buffer for the 6 min preceding K^+ depolarization. PMA treatment potentiated the evoked release of glutamate to twice that of control. Pb treatment at 10^{-8} M enhanced the evoked release of glutamate by nearly 40% but inhibited the PMA-induced potentiation of glutamate release by 50%. These results indicate that Pb, at very low concentrations, can disrupt the regulation of depolarization-evoked glutamate release from hippocampal presynaptic nerve terminals. Pb-induced disruption of the regulation of presynaptic glutamate release could contribute to the reduction in LTP and LTD induction described in Pb exposed rats and the learning deficits found in low level Pb intoxicated children.

336 THE APP PROMOTER RESPONDS TO PB EXPOSURE IN TRANSFECTED PC12 CELLS.

N. H. Zawia and W. Wei. *Biomedical Sciences, University of Rhode Island, Kingston, RI.*

The predominantly sporadic nature of Alzheimer's disease (AD) and the occurrence of neurodegenerative processe in the aging brain suggest that the environment may play a role in the development of AD. AD is characterized by excessive deposits of aggregated beta-amyloid peptides (Aβ), which are snippets of a larger protein, the β-amyloid precursor protein (APP). Therefore, any agent, which results in the overproduction of APP, would also elevate the formation of Aβ, eventually leading to the neuropathological changes of AD. The regulatory region of the APP gene contains elements recognized by the transcription factor Sp1, which is essential for the activation of the APP gene. Exposure to lead (Pb) has been previously shown by us to induce Sp1 activity. To test the hypothesis that Pb may induce APP gene expression, we transfected PC12 cells with the human APP promoter linked to a reporter gene (luciferase). The responsiveness of the promoter was tested over time in the presence of nerve growth factor (NGF) and low levels of Pb. We found that the presence of Pb stimulated APP promoter activity in a time and dose-dependent manner suggesting that Pb exposure may be a potential risk factor for the promotion of amyloidgenesis.

337 ZINC-INDUCED CHANGES IN HSP70 DISTRIBUTION AND ACTIN CYTOSKELETON IN CULTURED CULTURED CHOROID PLEXUS.

K. M. Kransler and A. R. Villalobos. *Department of Environmental Medicine, University of Rochester, Rochester, NY.*

Previously, our laboratory showed latent stimulation and thermoprotection of choline transport by Zn preconditioning in cultured choroid plexus epithelium. Our present objective is to investigate MAP kinase (MAPK) regulation of the concomitant thermoprotection of actin networks and altered HSP70 distribution by Zn preconditioning. Cultured choroidal epithelial cells were incubated with 10 μM $ZnCl_2$ for 1.5h (37C) and recovered 0-6h in Zn-free medium/5% NuSerum before severe heat shock (SHS, 45C, 1h). After fixation, cells were probed for actin with

TRITC-labeled phalloidin and immunostained for HSP70 using FITC-labeled secondary antibody. Epifluorescence imaging of control cells showed modest peri-nuclear HSP70 accumulation and colocalization of HSP with microfilaments. SHS markedly reduced microfilaments but greatly intensified perinuclear accumulation of HSP70. Inhibition of p38 MAPK by SB203580 during SHS resulted in complete disappearance of microfilaments; an ERK pathway inhibitor, PD98059 had no effect. Zn exposure modestly increased peri-nuclear HSP70 accumulation and microfilament formation, but also induced migration of filaments to the cell cortex. During recovery, bundling of microfilaments and peri-nuclear HSP70 staining progressively increased; colocalization of HSP70 with microfilaments was more pronounced. Immunoblot analysis indicated increased and sustained phosphorylation of ERK-1/2 with Zn exposure and subsequent Zn-free recovery that was attenuated by PD98059. Zn preconditioning enhanced thermotolerance of the actin cytoskeleton against SHS; complete protection was observed at 3-6 h recovery. Neither MAPK inhibitor modified Zn-induced changes in actin networks or HSP distribution; however, PD98059 attenuated thermotolerance. These data suggest 1) responses to SHS are mediated in part by p38 MAPK, 2) HSP70 may colocalize with actin filaments, and 3) ERK-1/2 may regulate thermoprotection of actin networks and HSP70 redistribution induced by Zn preconditioning. 338 EFFECT OF Zn ON THE ENERGY STATUS OF THE C6 GLIOMA AND THE HEPG2 CELLS.

M. S. Yang[1] and R. C. Gupta[2]. [1]*Department of Biology, Hong Kong Baptist University, Kowloon, Hong Kong, China and* [2]*Toxicology Department, Murray State University, Hopkinsville, KY.*

Zn has been implicated in mediating a number of neurological injuries and disorders including global ischemia, epilepsy, Parkinson's and Alzheimer's diseases. In other tissues, the level of Zn could change in respond to physiological or toxicological status. The mechanism of action of Zn is not well understood. In the nervous system, studies have shown that the toxic action of Zn may be related to its ability to interfere with energy metabolism. The present study was designed to examine the action of Zn on cellular energy metabolism in the C6 glioma and the HepG2 cells. In the C6 glioma cells, toxicity of Zn (0, 0.6, 0.9 and 1.2 mM) was measured by its effect on decreasing mitochondrial activity following a 3-hr exposure. The LC_{50} of Zn was 0.8 mM. Morphological observation showed that as the level of Zn increased, an increasing amount of cytosolic Zn containing granules (zincosomes) were visualized by TSQ staining. At [Zn]=1.2 mM, cells appeared apoptotic with a birefringent nucleus. Only a very small amount of Zn can be visualized near the nucleus. Cellular ATP, ADP, and AMP were measured by isocratic RP-HPLC. Results revealed that Zn caused a decreased in total cellular adenylate nucleotides (ATP+ADP+AMP). The ratio of ATP:ADP:AMP also varied from 0.82:0.07:0.11 at control to 0.88:0.07:0.05 after exposure to 1.2 mM Zn. The marked decrease in AMP resulted in a significant increase in cellular energy charge potential (ECP) from 0.85±0.007 to 0.92± 0.008. The cellular lactate level remained unchanged. This is consistent with an energy state that could inhibit glycolysis. On the other hand, the HepG2 cells respond to Zn differently. While increasing the level of Zn caused a decrease in total adenylate nucleotide level and cell viability in this cell line, cellular ECP calculated from the levels of ATP:ADP:AMP decreased from 0.77 to 0.67. These findings indicated that the nervous system and the hepatic system respond differently to the action of a high concentration of Zn.

339 STRUCTURE-ACTIVITY RELATIONSHIP AMONG ORGANOTINS IN A MODEL OF NEURONAL DIFFERENTIATION AND PROGRAMMED CELL DEATH.

S. M. Jenkins[1,2], L. D. White[1] and S. Barone[1]. [1]*Neurotox. Division, USEPA, Research Triangle Park, NC and* [2]*Curriculum in Toxicology, UNC Chapel Hill, Chapel Hill, NC.*

The organotins are used as heat stabilizers in PVC pipes and as marine biocides. Human exposure to monomethyltin (MMT) and dimethyltin (DMT) can occur in the water supply as a result of leaching from PVC pipes. Here we compared the effects of MMT, DMT, and TMT on neurite outgrowth and cell viability, endpoints relevant for developmental neurotoxicity, using PC12 cells. The dose-response curve for the effects of TMT on neurite outgrowth was steep with 2 μM TMT having no significant effect while 4.0 μM TMT inhibited NGF-induced neurite outgrowth by approximately 80%. Higher concentrations of TMT further inhibited neurite outgrowth. DMT also inhibited neurite outgrowth at low micromolar concentrations although not as dramatically. NGF-stimulated neurite outgrowth was inhibited by approximately 6% in the presence of 2.0 μM DMT. Higher concentrations of DMT resulted in progressively greater inhibition of neurite outgrowth. MMT did not have any significant effects on NGF-stimulated neurite outgrowth. Cell viability following organotin treatment was measured by trypan blue exclusion. Treatment with 6.0 μM TMT increased the percentage of non-viable cells from 7% to 16%. Treatment with 10 μM DMT increased the percentage of non-viable cells to approximately 18%. Higher concentrations of DMT caused a further increase in the percentage of non-viable cells. MMT had no significant effect on cell viability at any concentration tested. The cell death induced by TMT was apoptotic as indicated by increased DNA fragmentation while that induced by DMT was not. Our results will be correlated with neurotoxic effects observed following organotin administration *in vivo* to determine whether this type of *in vitro* assay can be used as a predictor of *in vivo* toxicity when evaluating a family of compounds. Because human exposure to MMT and DMT occurs as a mixture, we will also evaluate the effect of MMT and DMT mixtures on neurite outgrowth and cell viability. This abstract does not reflect EPA policy.

340 THE NEUROTOXICANT TRIMETHYLTIN STIMULATES APOPTOSIS VIA OXIDATIVE STRESS, CASPASE ACTIVATION AND P38 PROTEIN KINASE.

L. D. White[1], S. M. Jenkins[1,2] and S. Barone[1]. [1]*Neurotox. Division, USEPA, Research Triangle Park, NC and* [2]*Curriculum in Toxicology, UNC Chapel Hill, Chapel Hill, NC.*

Acute exposure to the tri-substituted organotin trimethyltin (TMT) causes neuronal degeneration in the hippocampus, amygdala, pyriform cortex, and neocortex. Developmental exposure to TMT impairs later learning and memory. Despite extensive efforts elucidating neuropathological changes and behavioral deficits following TMT exposure, little work has examined the molecular signaling mechanisms that lead to these changes. The present study demonstrates that TMT impairs neurite outgrowth and cell viability in an *in vitro* model of neuronal differentiation utilizing NGF-primed PC12 cells. Similar doses of TMT were required for both of these effects suggesting that inhibition of neurite outgrowth might be a secondary consequence of decreased cell viability. The increase in cell death is paralleled by a decrease in cell body size, an increase in DNA fragmentation, activation of caspase-9, and cleavage of the caspase substrate poly-ADP ribose polymerase (PARP) suggesting that TMT induces apoptosis. Pharmacological inhibition of caspase activity, p38 stress-responsive protein kinase activity, or oxidative stress prevented TMT-induced cell death. Inhibition of JNK, another stress-responsive protein kinase, or PARP, a DNA repair enzyme thought to be involved in some forms of necrosis, did not prevent TMT-induced cell death. This work provides the first evidence for a TMT-initiated apoptotic pathway involving oxidative stress, caspase activation, and p38 activation. This abstract does not reflect EPA policy.

341 BEHAVIORAL IMPAIRMENTS FOLLOWING TRIMETHYLTIN-EXPOSURE ARE LINKED TO ALTERATIONS IN PSA-NCAM EXPRESSION.

A. K. Halladay[1], G. C. Wagner[2] and K. R. Reuhl[1]. [1]*Neurotoxicology Labs, Rutgers University, Piscataway, NJ and* [2]*Psychology, Rutgers University, Piscataway, NJ.*

Trimethyltin (TMT) has been shown previously to produce temporal changes in polysialated neural cell adhesion molecule (PSA-NCAM) expression in the mouse hippocampus, with maximal reduction occurring 24hrs and partial recovery observed 7d after treatment. The current studies sought to link these alterations in PSA-NCAM expression with established TMT-induced impairments in learning. Male BALB/c mice, 6-9 weeks old, were treated with 2.25 mg/kg TMT or saline i.p. and observed 24, 96, and 168hrs after injection for motor activity and trained on both the visible and hidden version of a water maze. PSA-NCAM levels, as determined by Western Blot, were maximally reduced at 24hrs post-treatment, a time point which revealed impairments on the hidden, but not visible platform version of the maze. At 96hrs post-treatment, TMT exposed mice showed a persistent alteration in cortical and hippocampal PSA-NCAM expression, and significant impairment in water maze acquisition. However, when TMT was administered after maze navigation was acquired, increased escape latencies were observed only the first few trials, indicating the post-translational modification of NCAM protein is necessary for acquisition and consolidation, but not maintenance and storage of a learned task. Finally, by 168hrs post-TMT, both PSA-NCAM expression and acquisition of the water maze had returned to control levels. In addition, the 5HT1a agonist buspirone was administered to TMT and saline-treated animals 96hrs post injection, and animals were tested for changes in motor activity and time spent in the lighted side of a light/dark chamber. Buspirone differentially reversed deficits in motor activity and produced an anxiolytic effect in TMT-treated mice. These results demonstrate a transient and reversible TMT-induced reduction in PSA-

NCAM levels which is linked to learning and plasticity in the mouse; and furthermore links these effects to alterations in 5HT1a sensitivity. (Supported by NIH/EPA ES11256, NJ Governor's Council on Autism and F32ES11729-01)

342 EFFECTS OF 7-NITROINDAZOLE ON KAINATE-INDUCED SEIZURES, NO AND ENERGY METABOLITES IN RAT BRAIN REGIONS.

R. C. Gupta[1] and W. Dettbarn[1]. [1]*Toxicology, Murray State University, Hopkinsville, KY and* [2]*Pharmacology, Vanderbilt University, Nashville, TN.*

This investigation was undertaken to determine whether the nNOS inhibitor 7-nitroindazole (7-NI) prevents kainate (KA, 15 mg/kg, sc)-induced seizures and related changes in NO and high-energy phosphates (HEP) in rat brain regions (cortex, amygdala, and hippocampus). After a single injection of KA, the onset of seizures appeared within 30-45 min, progressed to full seizure activity within 60 min, and lasted more than 2 hr. Rats were sacrificed using head-focused microwave irradiation and brain regions were analyzed for citrulline (determinant of NO) and HEP. Time course studies revealed significant increases in NO, preceding the seizures and depletion of HEP (ATP and PCr) and their metabolites. The maximum changes by KA in NO and HEP occurred 2 hr post-injection. A single dose of 7-NI (50 mg/kg, ip) 30 min prior to KA delayed the onset of seizures by 15-20 min and significantly prevented an increase in NO and a decrease in HEP in all three brain regions. 7-NI given 30 min before and 30 min after KA injection further delayed the onset of seizures and prevented induced changes in NO and HEP. These results suggest that NO (derived from NOS) is involved in depletion of HEP in brain caused by KA-induced seizures.

343 ELEVATED BLOOD BETA-CARBOLINE ALKALOID CONCENTRATION IN ESSENTIAL TREMOR PATIENTS: A CASE-CONTROL STUDY.

E. D. Louis[1], U. P. Andersson[2] and W. Zheng[2,3]. [1]*Neurology, Columbia University, New York, NY,* [2]*School of Public Health, Columbia University, New York, NY and* [3]*Pharmacology, Columbia University, New York, NY.*

The etiology and pathogenesis of essential tremor (ET) are not well understood. Although beta-carboline alkaloids are normal body constituents, they are potent tremor-producing chemicals that are naturally present in the food chain. The objective of this study was to explore the hypothesis that high concentrations of beta-carboline alkaloids are associated with ET. One hundred cases and 100 controls were frequency matched on age, gender, and ethnicity. Harmane and harmine in whole blood were extracted and their concentrations were quantified by high performance liquid chromatography, blinded to clinical information. The mean log blood concentration of harmane was higher in cases than controls (0.72 +/- 0.53 g^{-10}/ml vs. 0.51 +/- 0.64 g^{-10}/ml, means +/- SEM, p = 0.01). A non-parametric test on non-transformed data (median harmane = 5.21 g^{-10}/ml in cases and 2.28 g^{-10}/ml in controls) confirmed this difference (p = 0.005). The mean log blood concentration of harmine was 0.20 +/- 0.48 g^{-10}/ml in cases and 0.10 +/- 0.65 g^{-10}/ml in controls (p = 0.20). Log harmane concentrations were stratified based on the median value; 62% of cases vs. 39% of controls had a high log harmane concentration (p = 0.001). Mean log harmane concentration was similar in the cases with (0.74 +/- 0.58 g^{-10}/ml) and without (0.71+/- 0.50 g^{-10}/ml) an affected relative (p = 0.83). These data indicate that blood concentrations of harmane were elevated in cases with and without a family history of ET, further suggesting a possible role of environmental risks in the etiology of ET. (Support in part by NIH RO1 NS39422, P30 ES09089 and RO1 ES08146)

344 LEARNING IMPAIRMENT CAUSED BY INFUSION OF A TOXIN PRODUCED BY *PFIESTERIA PISCICIDA* INTO THE HIPPOCAMPUS OF RATS.

E. D. Levin[1], W. P. Blackwelder[1], H. B. Glasgow[2], J. M. Burkholder[2], P. R. Moeller[3] and J. S. Ramsdell[3]. [1]*Department of Psychiatry and Behavioral Sciences, Duke University Med. Ctr, Durham, NC,* [2]*Center for Applied Aquatic Ecology, Department of Botany, North Carolina State University, Raleigh, NC and* [3]*Marine Biotoxins Program, NOAA-National Ocean Service, Charleston, SC.*

Pfiesteria piscicida, an estuarine dinoflagellate, which has been shown to kill fish, has also been associated with neurocognitive deficits in humans. With a rat model, we have demonstrated the cause-and-effect relationship between Pfiesteria exposure and learning impairment. In several studies, we have replicated the finding in Sprague-Dawley rats that exposure to fixed acute doses of Pfiesteria caused radial-arm maze learning impairment. In the current study, hydrophilic toxin (Pftx) isolated from cultures of P. piscicida zoospores recloned from cultures toxic to fish was administered by bilateral infusion into the ventral hippocampus of Sprague-Dawley rats (N=9) caused persisting learning impairment relative to vehicle infused controls (N=7) on a repeated acquisition procedure in which new learning is assessed each session over weeks. Both control and Pftx-treated groups showed learning, however, the Pftx-treated group learned more slowly. There was a significant Pfiesteria x trial interaction ($p<0.01$). The Pftx-treated rats had significant deficits during the early phase of learning. Tests of the simple main effects of Pftx on performance at each trial showed significant impairments on Trial 1 ($p<0.05$) and Trial 2 ($p<0.01$). The Pftx-treated rats were not incapable of learning and the Pftx-induced impairment was overcome during the later part of the session with no differences detected for Trials 3-5. The Pftx-induced deficit showed no sign of diminishing over the 6 weeks after a single infusion. Pftx treatment did not have a significant effect on response latency. This model has demonstrated the cause-and-effect relationship between Pfiesteria toxin exposure and learning impairment and specifically that the ventral hippocampus was critically involved. (Supported by NOAA and Duke University)

345 *IN VIVO* BASAL AND AMPHETAMINE-STIMULATED STRIATAL DOPAMINE (DA) RELEASE IS SIMILAR IN ADULT SPONTANEOUSLY HYPERTENSIVE (SHR), WISTAR-KYOTO (WKY), AND SPRAGUE-DAWLEY (SD) MALE RATS.

S. A. Ferguson and B. J. Gough. *Neurotoxicology, NCTR/FDA, Jefferson, AR.*

Nigrostriatal alterations are proposed to partially underlie the hypertension and hyperactivity exhibited by the SHR relative to the WKY. Certainly, *in vitro* studies of striatal DA release provide substantial support for this hypothesis. Few studies, however, examine *in vivo* release and fewer still compare these two strains (SHR and WKY) to other common rodent strains. Linthorst et al. (1991) described decreased *in vivo* basal DA levels in the SHR but Inada et al. (1992) reported no strain differences. Here, *in vivo* microdialysis measured basal and d-amphetamine (AMPH)-stimulated striatal DA, homovanillic acid (HVA), and 3, 4-dihydroxyphenylacetic acid (DOPAC) in unanesthetized 19-week-old male SHR, WKY, and SD rats. Basal levels were measured for 60 minutes after which time, each rat was injected ip with 2 mg/kg AMPH and samples collected for the subsequent 200 minutes. There were no significant differences in basal levels although DOPAC was slightly decreased in the WKY relative to the SD. AMPH treatment altered DA, DOPAC, and HVA to a similar extent in all strains; thus, there were no strain differences. Similarly, area under the curve for DA release did not differ between strains. Previous testing of these subjects indicated mildly elevated blood pressure and only moderate hyperactivity in the SHR (see Ferguson & Cada, in press). Thus, the current results do not support hypotheses of nigrostriatal alterations in the SHR, at least as measured by *in vivo* microdialysis. Further, although there was a substantial body weight difference (≅ 100 g) between the SD and the other two strains, basal and AMPH-stimulated DA release was quite similar.

346 TESTOSTERONE REVERSES THE EFFECTS OF ETHANOL ON NITRIC OXIDE SYNTHASE IN THE CORTEX OF CASTRATED RATS.

R. H. Khalil[1], M. A. King[1] and M. R. Soliman[2]. [1]*Department of Neuroscience, College of Medicine & Brain Institute, University of Florida, Gainesville, FL and* [2]*College of Pharmacy, Florida A&M University, Tallahassee, FL.*

Previous results obtained in our lab have indicated that testosterone reverses ethanol-induced spatial memory deficit in castrated rats. The present study was conducted to investigate the effects of ethanol and testosterone on the activity of nitric oxide synthase (NOS) in specific brain regions of castrated rats. Male Sprague-Dawley rats (150-200g) were used in this study. Animals were castrated under halothane anesthesia and allowed to recover for a period of 15 days. Animals were randomly assigned to 4 groups. The animals were administered either ethanol (3 g/Kg as a 22.5% w/v solution orally), testosterone (2 mg/Kg, S.C.), a combination of ethanol (3g/Kg) and testosterone (2 mg/Kg), or saline (control). The animals were dosed daily at 9:00 AM for 7 consecutive days. One hour after the last injection, the animals were sacrificed by decapitation, and their brains were immediately flash frozen in liquid nitrogen and kept at -70 C until analysis. NOS activity was measured in the cortex, hippocampus, hypothalamus and midbrain using C14 Arginine and NOS detect assay kits (Stratagene, Ca). Ethanol administration resulted in a significant increase in NOS activity in the cortex of castrated rats

(38.3% increase). Testosterone did not significantly alter cortical NOS activity in the cortex. However, when testosterone was concurrently administered with ethanol, it completely reversed ethanol-induced increase in NOS. Ethanol did not produce any significant alteration of NOS activity in other brain regions tested. The present findings may in part explain the reversal of ethanol-induced memory deficit by testosterone as well as the sex difference in ethanol effects. (Supported by NIAA grant T31 AA 07561 and by NIH grant RR30320)

347 12 WEEK EXPOSURE TO CARBONYL SULFIDE PRODUCES BRAIN LESIONS AND CHANGES IN BRAINSTEM AUDITORY (BAER) AND SOMATOSENSORY (SEP) EVOKED POTENTIALS IN FISCHER 344N RATS.

D. W. Herr[1], J. E. Graff[1], P. B. Little[2], N. George[3], D. L. Morgan[3] and R. C. Sills[3]. *[1]Neurotoxicology, USEPA, Durham, NC, [2]Pathology Associates, Research Triangle Park, NC and [3]NIEHS, Research Triangle Park, NC.*

Carbonyl sulfide (COS) is a chemical intermediate in the production of pesticides and herbicides, is a metabolite of carbon disulfide, is produced by the combustion of organic material, and is found occurring in nature. COS was included in a Toxic Substances Control Act request for data, and has been listed as a Clean Air Act hazardous air pollutant. To examine possible neurotoxicity of COS, male and female Fischer 344N rats were exposed by inhalation to 0, 200, 300, or 400 ppm COS for 6 h/day, 5 days/week, for 12 weeks. After the final exposure, the animals were allowed to recover for about 42 days. Subjects were surgically implanted with screw electrodes over the forelimb/facial and hindlimb/tail somatosensory cortex and the cerebellum, and allowed to recover for one week. Unanesthetized animals were placed in a restrainer and presented with electrical stimuli (1, 2, 3 mA biphasic square wave presented at 0.9 Hz) to the ventral caudal tail nerve to record somatosensory potentials (SEPs). Auditory stimuli consisted of rarefaction clicks and pure tone pips (4, 16, 64 kHz presented at 5.6 Hz) using three intensities (50, 65, 80 dB SPL; 65, 70, 80 dB SPL for 64 kHz). Exposure to COS produced a lesion in the lateral frontal/parietal cortex in a subset of the 400 ppm group. In the animals with the lesion there was an increase in SEP amplitude recorded from the forelimb/facial (but not the hindlimb/tail) somatosensory cortex. Exposure to COS decreased BAER amplitudes (peak P_3 and P_4 region), and histopathology confirmed the presence of brainstem lesions in the superior olivary complex and inferior colliculus. Thus, exposure of rats to COS resulted in changes in auditory and somatosensory physiology and produced brain lesions in regions associated with the neural generators of these physiological measures. *This is an abstract of a proposed presentation and does not necessarily reflect EPA policy.*

348 THROMBIN PRECONDITIONING PROVIDES NEUROBEHAVIORAL PROTECTION AGAINST A UNILATERAL 6-HYDROXYDOPAMINE LESION.

J. R. Cannon, G. Xi, T. Schallert, Y. Hua and R. F. Keep. *The University of Michigan, Ann Arbor, MI.*

Pretreatment with thrombin has been shown to protect against both ischemic and hemorrhagic stroke models. Here, thrombin preconditioning (TPC) was evaluated for protection against neurobehavioral deficits elicited by 6-hydroxydopamine (6-OHDA). In a blinded study, three groups of male Sprague-Dawley rats (250-300g) were administered either 6-OHDA (n=6), saline+6-OHDA (n=5), or thrombin (1 unit/50mL saline)+6-OHDA (n=5). Animals were anesthetized with pentobarbital (50mg/kg, ip.), followed by pargyline and desipramine (50 and 25mg/kg, ip.). After 30 min, the animals were given a stereotaxic injection of 10µg of 6-OHDA (2.5µg/µL at 0.5µL/min), containing 0.02% ascorbic acid, onto the medial forebrain bundle. Three days prior to administration, the preconditioning groups received 50mL of saline or thrombin, 1mm dorsal to 6-OHDA site. Behavioral deficits were assessed at intervals before 6-OHDA injection and for 3 weeks after. Vibrissae-elicited placing was measured for both sides and the percentage of unsuccessful placings determined. A forelimb asymmetry score was calculated by observing the use of the left, right or both forelimbs, during rearing. The animals turn preference on escaping a corner was also determined. TPC or saline injection alone did not induce a behavioral deficit. After 6-OHDA injection, deficits in the saline group were not significantly lower than in rats given 6-OHDA alone. The TPC group exhibited a significantly ($p<0.05$) lower placing deficit on days 3 (12±15% vs. 63±14%; mean±SE) and 21 (11±11% vs. 55±12%) than the 6-OHDA group. The asymmetry score for TPC was significantly ($p<0.05$) lower than the 6-OHDA group on days 3 (30±8% vs. 80±4%), 7 (25±10% vs. 46±7%) and 21 (6±5% vs. 44±15%). The corner test deficit was less ($p<0.05$) in the TPC group than either of the 6-OHDA and saline+6-OHDA groups at 7, 16, and 21 days. The results indicate that TPC provides protection from 6-OHDA induced behavioral deficits. Mechanistic analysis of TPC-induced protection may identify novel protective mechanisms for Parkinson's disease.

349 PROSTAGLANDIN H SYNTHASE (PHS)-DEPENDENT OXIDATIVE STRESS AND DNA DAMAGE IN LONG-TERM AMPHETAMINE-INITIATED NEURODEGENERATION AND FUNCTIONAL DEFICITS.

A. Ramkissoon[1], W. Jeng[1] and P. G. Wells[1,2]. *[1]Pharmacy, University of Toronto, Toronto, ON, Canada and [2]Pharmacology, University of Toronto, Toronto, ON, Canada.*

Reactive oxygen species (ROS) are implicated in amphetamine-initiated neurodegeneration, but the mechanism is unclear. Here, we show that 3, 4-methylenedioxyamphetamine (MDA) and methamphetamine (METH) cause immediate PHS-dependent CNS oxidative DNA damage, with related long-term structural and functional changes. CD-1 female mice were treated with low and high doses of MDA (10 or 20mg/kg), METH (5 or 10mg/kg) or their saline vehicle. The brains were isolated 1, 3 or 6 hr following drug administration, microdissected and analyzed for oxidized DNA, determined by 8-oxoguanine formation. Within 1 hr, compared to saline controls, both low and high doses of MDA caused a 2- to 3-fold elevation in DNA oxidation in the striatum ($p<0.001$), substantia nigra ($p<0.001$) and brainstem ($p<0.007$), with delayed elevations in the hippocampus at 3 hr ($p<0.001$) and in the cortex at 6 hr ($p<0.04$). A similar pattern of increased DNA oxidation was seen for METH. Increased DNA oxidation was not apparent in the cerebellum. MDA and METH dose- and time-dependent DNA oxidation in multiple brain areas was dependent upon the level of PHS-1 expression, and pretreatment with the PHS inhibitor acetylsalicylic acid (ASA) reduced MDA-initiated DNA oxidation in all affected regions ($p<0.05$). Degeneration of dopaminergic neurons occurred in the striatum within 18 hr of MDA and METH administration, with increased neurodegeneration after 1 wk, and motor coordination impairment, assessed by the rotarod test, was evident 2 and 3 wk after MDA ($p<0.04$) and METH ($p<0.001$) administration respectively, consistent with a 2-fold greater enhancement of striatal DNA oxidation by MDA ($p<0.009$). This is the first direct evidence for temporal and spatial differences in PHS-catalyzed amphetamine bioactivation and CNS oxidative DNA damage related to structural and functional consequences, which may provide mechanistic insights into amphetamine-related neurodegeneration and neurodegenerative diseases (Support: CIHR).

350 NEUROPROTECTION AGAINST STEREOSELECTIVE 3, 4-METHYLENEDIOXYMETHAMPHETAMINE (MDMA, ECSTASY)-INITIATED OXIDATIVE STRESS AND DNA DAMAGE IN PROSTAGLANDIN H SYNTHASE-1 (PHS-1) KNOCKOUT MICE.

W. Jeng[1] and P. G. Wells[1,2]. *[1]Pharmacy, University of Toronto, Toronto, ON, Canada and [2]Pharmacology, University of Toronto, Toronto, ON, Canada.*

MDMA generates reactive oxygen species (ROS), which can oxidatively damage cellular macromolecules, causing altered CNS cell function or death. We previously showed that MDMA and related amphetamines are substrates for PHS-catalyzed bioactivation to free radical intermediates that lead to DNA oxidation *in vitro* (Tox. Sciences. abstr. No. 1752, 2001). Here, we used PHS-1 knockout mice to determine *in vivo* neurodegenerative contribution of PHS-catalyzed bioactivation of MDMA. Wild-type [+/+] PHS-1 normal, and heterozygous [+/-] and homozygous [-/-] PHS-deficient, knockout female and male mice were treated with racemic MDMA (rac-MDMA), (+)-MDMA, (-)-MDMA isomer (4x10 mg/kg) or their saline vehicle. Brains were isolated 1 hr following the last drug administration, microdissected and analyzed for oxidized DNA, determined by 8-oxoguanine formation. Within 1 hr, rac-MDMA ($p<0.04$) and (+)-MDMA ($p<0.002$) caused respective 2.8- and 2.4-fold elevations in DNA oxidation in the striatum of +/+ PHS-normal mice, whereas the nontoxic (-)-MDMA isomer was comparable to saline. In contrast, rac- and (+)-MDMA-initiated DNA oxidation seen in the +/+ mice was reduced 45% and 33% in +/- PHS-deficient mice ($p=0.057$, $p=0.06$) and 57% and 46% in -/- PHS-deficient mice ($p<0.05$, $p<0.01$), respectively. A similar gene dose-dependent pattern was seen in the brainstem and substantia nigra, except that the latter was sensitive to (+)-MDMA for all genotypes, suggesting increased susceptibility ($p<0.05$). DNA oxidation was not enhanced in the cerebellum, cortex or hippocampus, although the latter two regions may experience delayed damage (Proc. Soc. Neurosci. Abstr. No. 809.3, 2002). The stereoselective nature of oxidative DNA damage and PHS-1 gene dose-dependence provide the first direct *in vivo* evidence for PHS-catalyzed bioactivation of MDMA to a free radical intermediate that initiates DNA oxidation, which may contribute to the mechanism of MDMA neurotoxicity. (Support: CIHR)

351 PERIPHERAL BENZODIAZEPINE RECEPTOR RESPONSE TO DEMYELINATION IN THE MOUSE BRAIN: ASSOCIATION WITH GLIAL CELL TYPES.

M. Chen and T. R. Guilarte. *Environmental Health Sciences, Johns Hopkins University Bloomberg School of Public Health, Baltimore, MD.*

The peripheral benzodiazepine receptor (PBR) has been used as a sensitive marker of gliosis and inflammation associated with chemical-induced neurotoxicity. We have previously shown using a model of cuprizone-induced demyelination that PBR expression is increased in a region, dose, and time-dependent manner consistent with the degree of demyelination (Chen & Guilarte, Toxicology. Sciences. 66(1-S); 211, 2002). In the present study, we report the association of the PBR response to cuprizone-induced demyelination with specific glial cell types, i.e. microglia and astrocytes. Adult male C57BL/6J mice were continuously fed a 0.2% (w/w) cuprizone-mixed powder diet and sacrificed at 2, 3 and 4 weeks of treatment. [3H]-(R)-PK11195 autoradiography was performed to quantitatively measure PBR levels in selected brain regions. Glial fibrillary acidic protein (GFAP) and CD 11b (Mac-1) immunohistochemistry were used as specific markers of activated astrocytes and microglia, respectively. Increased PBR levels in the cerebellum deep nuclei, hippocampus, frontal, temporal, and entorhinal cortex in cuprizone treated mice appeared to be associated with activation of both microglia and astrocytes. However, increased PBR expression in the corpus callosum, striatum, thalamic regions, and intermediate white layer superior colliculus was mostly due to activation of microglia. In general, microglia were anatomically more closely associated with increased PBR expression in demyelinated brain regions, with astrocytes providing a background contribution. This study supports the notion that in some brain regions microglia are primarily responsible for the increased PBR signal in this model of demyelination but astrocytes also contribute to the overall PBR response. [Supported by grant # ES07062 to TRG]

352 MORPHOMETRIC ANALYSIS OF γ-DIKETONE AXONOPATHY IN RAT SPINAL CORD.

J. F. Ross[2] and R. M. LoPachin[1]. *[1]Anesthesiology, Albert Einstein College of Medicine, Bronx, NY and [2]The Health & Environmental Safety Alliance, Cincinnati, OH.*

Quantitative morphometric analysis of peripheral nerves from 2, 5-hexanedione (HD) intoxicated rats showed that axon atrophy was the primary neuropathological feature, whereas neurofilamentous swellings were a minor component related to lower daily dose-rates (Tox Appl Pharmacol 165: 127-140, 2000). In this study we used analytical morphometrics to measure axonal changes in nerve roots and white matter tracts of lumbar spinal cord from rats intoxicated at either 400 mg/kg/d (x8, 13, 18 or 22 days) or 175 mg/kg/d (x42, 70, 85 or 99 days). Results show that at the higher HD dose-rate extensive axon atrophy occurred in both ascending (gracile, cuneate, spinocerebellar) and descending (corticospinal, rubrospinal) tracts. As an early (day 8) consequence of HD intoxication, axon area decreased significantly (30-40%) and was accompanied by reductions in myelin. Axon and myelin perimeters were also reduced, although to a lesser extent (20-25%). Neither g-ratio nor the index of circularity were affected. Analyses of ventral and dorsal roots revealed similar initial quantitated atrophic changes in axons and myelin. As exposure to the 400 mg/kg rate continued (days 13-22), the magnitude of this initial atrophy response did not change in any area examined. Regardless of region or experimental time-point, no axon swellings were observed. At the lower dose-rate (175 mg/kg/d), atrophy was the earliest(42 and 70 days) and most prominent axon alteration noted in the spinal cord tracts and nerve roots examined. As intoxication continued (85 and 99 days), both atrophy and giant axonal swellings were frequently noted. Our combined results now suggest that axon atrophy is the hallmark feature in PNS and CNS, and that corresponding functional consequences might be a pathophysiologically relevant effect involved in diketone neurotoxicity. Supported by NIEHS grant ESO7912-06.

353 ACUTE NEUROTOXIC EFFECTS OF INHALED PERCHLOROETHYLENE ON PATTERN VISUAL EVOKED POTENTIALS AS A FUNCTION OF EXPOSURE AND ESTIMATED BLOOD AND BRAIN CONCENTRATION.

M. Bercegeay, E. M. Kenyon and W. K. Boyes. *NHEERL, USEPA, Research Triangle Park, NC.*

Previous experiments have shown the effects of acute inhalation exposure to trichloroethylene (TCE) and toluene are related to the target tissue concentration at the time of testing. The current studies examined exposure to another volatile organic compound, perchloroethylene (PERC), for comparison to the other solvents. A physiologically- based pharmacokinetic (PBPK) model was developed for ad-lib fed (350-450 g) adult male Long-Evans rats. Rats were exposed by inhalation to 0, 1, 000, 2, 000, 3, 000 or 4, 000 ppm PERC and tested at exposure durations (including 0.5, 1, 1.5 or 2 hr) yielding C x t products up to 4000 ppm-hr. Exposure conditions yielding C x t products greater than 4000 ppm-hr were not tested. Steady-state pattern-elicited visual evoked potentials were recorded during exposure sessions. The pattern stimulus was a 0.16 cpd vertical sinusoidal grating with a contrast of either 60% or 0% ("noise" evaluation), that was modulated in an appearance / disappearance mode at 5 Hz. Exposure to PERC reduced the amplitude of the frequency-double spectral component (F2) at all air concentrations tested, including those projected to produce concentrations as low as 17.7 mg/l in blood and 97.1 mg/l in brain (1000 ppm for 0.5 hr). The actions of PERC were qualitatively similar to those measured previously for toluene and TCE. (This abstract does not necessarily reflect EPA policy).

354 DURATION ADJUSTMENT OF ACUTE EXPOSURE GUIDELINE LEVEL (AEGL) VALUES FOR TRICHLOROETHYLENE (TCE) USING A PHYSIOLOGICALLY- BASED PHARMACOKINETIC (PBPK) MODEL.

W. K. Boyes[1], C. R. Eklund[1], P. Janssen[2] and J. E. Simmons[1]. *[1]EPA, Research Triangle Park, NC and [2]Centre of Substances and Risk Assessment, National Institute Public Health and the Environment, Bilthoven, Netherlands.*

AEGL recommendations are developed for 10 min, 30 min, 1 hr, 4 hr, and 8 hr exposure durations that are designated as concentrations above which acute exposures may cause notice- able discomfort including irritation (AEGL-1), irreversible health effects or impaired ability to escape (AEGL-2), and life threatening health effects or death (AEGL-3). Standard procedure for setting AEGL values across durations when applicable data are unavailable involves empirical modeling. We employed an alternative approach in which adverse outcomes appropriate for AEGL-1, 2, or 3 level effects were selected from the literature, then a PBPK model was used to predict the arterial blood concentrations (Ca) associated with those outcomes. Finally, the model was used in a boot- strap approach to estimate the atmospheric concentration sufficient to produce the same Ca levels at each exposure duration. This approach yielded Ca values of 3.93-4.78 mg/l for AEGL-1 (depending on which of two outcome studies was used), or 18.3 mg/l for AEGL- 2. AEGL-3 analyses are currently in progress. This approach has several advantages including that exposure duration adjustments are based on production of the same target tissue dose, and should therefore be more likely to provide similar degrees of toxicity, or toxicity protection, than are models based on external dose factors. In addition, the parameters of the PBPK model can be adjusted based on known or measurable physiological parameters, to predict toxicity in a variety of situations such as across species, ages, levels of physical exertion, or other factors. (This abstract does not reflect EPA policy).

355 SENSITIVE HISTOLOGICAL INDICATORS OF DAMAGE REVEAL TREATMENT WITH SUPRAPHYSIOLOGICAL LEVELS OF CORTICOSTERONE AND HIGH DOSAGES OF KAINIC ACID PRODUCE LIMITED HIPPOCAMPAL DAMAGE IN A STRAIN OF MICE RESISTANT TO KAINATE NEUROTOXICITY.

S. A. Benkovic and D. B. Miller. *Toxicology and Molecular Biology, CDC-NIOSH, Morgantown, WV.*

The high levels of glucocorticoids that accompany stress are believed to increase the sensitivity of the hippocampus to excitotoxic injury but this issue has received little examination utilizing mouse strains reported to be resistant to this type of neurotoxicity. We have previously utilized standard histological methods and GFAP ELISA to examine the interaction of supraphysiological levels of corticosterone and high doses of kainic acid on the integrity of the hippocampus in "kainate-resistant" C57BL/6J mice. No overt cell loss was evident in KA-treated mice but GFAP elevation indicated damage was present. Cort alone produced no damage, and was unable to exacerbate the injury produced by KA. Here, we used histological stains sensitive to damage (cupric-silver and Fluoro-Jade) to further characterize the interactions between supraphysiological levels of Cort and KA. C57BL/6J mice were implanted with 35 or 100 mg corticosterone pellets (68 mg/kg/d and 192 mg/kg/d respectively). After seven days, mice were injected with 35 mg/kg kainic acid and were allowed to recover for an additional seven days. These stains revealed moderate damage to hippocampal neurons caused by KA. In mice treated with Cort+KA, significant neuronal damage was observed in cortex and cerebellum; however, limited damage was seen in hippocampus. No damage profiles were observed in mice treated with Cort alone. These data suggest high physiological levels of corticosterone may attenuate hippocampal damage caused by certain neurotoxicants in mice.

356 METAL AND PESTICIDE INTERACTION: EFFECTS OF ALUMINIUM CHLORIDE AND ACEPHATE EXPOSURE FOR SHORT TERM AND SUB CHRONIC DURATION ON RAT BRAIN SEROTONINERGIC SYSTEM.

K. Sripathirathan. *Department of Pharmacology and Environmental Toxicology, P.G. Institute of Basic Medical Sciences, University of Madras, Madras, TN, India.*

Metals and pesticides are suspected etiological agents in neurodegenerative disorders such as Parkinson's disease. The present investigation aims to study changes in the serotoninergic system of rat brain following exposure to aluminium chloride and the organophosphorous pesticide acephate individually and in combination and to study 1] short term and sub chronic duration specific changes and 2] brain region specific changes following toxicant exposure. Male Wistar albino rats were divided into four groups and each group of animals were orally dosed individually water, sub-chronic doses of aluminium chloride (320 mg/kg), acephate (178 mg/kg) and a 1:1 combination (145 mg/kg and 178 mg/kg) respectively for 0, 4, 14 and 60 days. Significantly increased 5-HT level observed in the brain regions following aluminium exposure suggests aluminium deactivating 5-HT system by decreased release and subsequent breakdown of 5-HT. Decreased 5-HT level was observed in cerebral cortex, hippocampus (60 days) and in cerebellum after 4 and 60 days of exposure suggest inhibitory effect of aluminium on 5-HT system due to withdrawal of cholinergic input. 5-HIAA level changes correlate with 5-HT level changes. Acephate exposure decreased 5-HT level in brain regions at the different durations studied. A short-term increase in 5-HIAA levels was observed in olfactory lobe and midbrain after 14 days of treatment. Acephate exposure produced activation of the serotoninergic system, resulting in decrease of the monoamine levels and its metabolite. Exposure to combination of the compounds for 60 days results in decreased serotonin level and its metabolite 5-HIAA, but produced no change in serotonin level in olfactory lobe, striatum, hypothalamus and pons brain regions. The results reveal that the vulnerability of the brain regions following exposure to the combination of compounds are brain region specific and are able to recover from the toxic effect of the combination of toxicants.

357 DEMONSTRATION OF MURINE NEUROTOXIC RESPONSES TO 1, 2-DIACETYLBENZENE PREPARATORY TO TOXICOGENOMIC CHARACTERIZATION.

D. D. Tshala-Katumbay, V. S. Palmer, R. J. Kayton, M. I. Sabri and P. S. Spencer. *CROET, Oregon Health & Science University, Portland, OR.*

The aromatic gamma-diketone 1, 2-diacetylbenzene (1, 2-DAB), but not 1, 3-diacetylbenzene, forms blue-colored polymeric protein adducts and induces proximal, neurofilamentous axonal swellings in motor and, to a lesser extent, sensory nerve cells of Sprague-Dawley rats (Kim et al., Toxicol. Appl. Pharmacology 177: 121-131, 2001). Toxicogenomic responses in rat spinal cord are reported at this meeting (Kim et al.). We assessed whether these chromogenic and neurotoxic responses are also seen in C57BL/6N mice, the animal of choice for toxicogenomic studies. Male 10-week-old mice (~25g) were treated i.p. daily or every other day with 30 (low), 50 or 70 (high) mg 1, 2-DAB/kg body weight (n=4/dose) for up to 3 weeks. Animals lost body weight and developed limb muscle spasms and abnormal gait in proportion to total 1, 2-DAB dose. Tissues, including brain, spinal cord, and peripheral nerves, were stained blue after two high-dose injections. Light microscope examination revealed grossly swollen axons most prominently in lumbar anterior horn and proximal ventral roots after one week of treatment with higher doses of 1, 2-DAB. Spinal tracts showed beginning pathological changes after 3 weeks of 50 mg/kg every other day. Ventral root nerve fibers with swollen axons sometimes showed edema between ruptured layers of myelin. Ultrastructural examination of swollen axons revealed clumps of maloriented 10 nm neurofilaments and excessive numbers of mitochondria and other organelles. These findings demonstrate qualitative similarities between the chromogenic and neurotoxic responses of mice and rats treated with 1, 2-DAB, although the former appears to be less susceptible to this agent. Mice treated with single doses of 50-70 mg/kg 1, 2-DAB and equivalent doses of its non-neurotoxic isomer are suitable to define genomic and proteomic signatures that precede induction of aromatic gamma-diketone axonopathy. Supported by NIEHS grants ES10338 & ES11384, and Oregon's Worker Benefit Fund.

358 SUB-ACUTE SARIN EXPOSURE LEADS TO NEUROPATHOLOGICAL AND NEUROCHEMICAL CHANGES IN THE RAT BRAIN: DOSE-RESPONSE RELATIONSHIPS.

A. A. Abdel-Rahman, A. K. Shetty and M. B. Abou-Donia. *Pharmacology and Cancer Biology, Duke University Medical Center, Durham, NC.*

We previously reported that acute exposure to an LD50 dose of sarin induces early neuropathlogical changes in the adult rat brain. In the present study, we investigated the effects of a single exposure to sarin on the adult rat forebrain after 7 days. Adult male rats were exposed to sarin by a single intramuscular injection at doses of 1, 0.5, 0.1, and 0.01x LD50. Seven days after the treatment, both sarin-treated and vehicle-treated (controls) animals were analyzed for: (i) plasma butyrylcholinesterase (BChE) activity; (ii) brain acetyl cholinesterase (AChE) activity, (iii) m2 muscarinic acetylcholine receptor (m2 mAChR) ligand binding; (iv) histopathological changes in the brain using H & E staining, TUNAL and ssDNA immunostining and microtubule-associated protein (MAP-2) and glial fibrillary acidic protein (GFAP) immunoassaying, . Animals treated with 1x LD50 sarin, exhibited a significant decrease in forebrain and brainstem AChE and m2 mAChR ligand binding. Whereas, animals treated with 0.5X LD50 exhibited a significant decrease in forebrain and brainstem m2 mAChR ligand binding; a diffuse neuronal cell death; a significant reduction of healthy (or surviving) neurons; a typical apoptotic (TUNAL-positive) cell, detection of ssDNA; a reduced MAP-2 immunoreactivity, and increased GFAP expression. Further, degenerating neurons were infrequent in animals treated with 1X LD50 compared to animals treated with 0.5X LD50. In contrast, neither the 0.1X or 0.01X LD50 treatment exhibited significant changes in the above brain regions. Collectively, the above results indicate that, sarin causes neuronal degeneration in many regions of the brain which is clearly dose-dependent, and exacerbated with time.(Supported in part by a grant from the US Army Medical Research and Materiel Command under DAMD 17-98-8027).

359 COMPARATIVE EFFECTS OF WEEKLY EXPOSURES TO ANATOXIN-A AND NICOTINE ON THE OPERANT PERFORMANCE OF RATS.

K. A. Jarema and R. C. MacPhail. *NHEERL, USEPA, Research Triangle Park, NC.*

Anatoxin-a is a nicotinic-receptor agonist produced by several genera of cyanobacteria. We have previously shown (Jarema et al., 2002) tolerance to the effects of nicotine on discrete-trial operant behavior (repeated acquisition) when the drug was administered at weekly intervals. The current experiment was undertaken to extend this finding to free-operant performance and to directly compare the effects of weekly nicotine and anatoxin-a exposures. Adult male Long Evans rats were maintained at 350 g body weight and trained to perform under a multiple variable-ratio 30-response variable-interval 30-sec schedule of food reinforcement. Once performances had stabilized, rats were divided into groups of eight that received saline vehicle or a dose of nicotine (0.125 - 1.8 mg/kg) or anatoxin-a (50 - 250 mcg/kg). Treatments were administered s.c. (1 ml/kg) 5-min prior to 45-min sessions. When initially administered, both compounds decreased response rates and reinforcement rates in both components of the multiple schedule. Substantial tolerance developed to the disruptive effects of both compounds with subsequent weekly administrations. These results indicate substantial similarity in the behavioral effects of anatoxin-a and nicotine with both acute and weekly administration. This abstract does not necessarily reflect USEPA policy.

360 TEA EPIGALLOCATECHIN 3-GALLATE PREVENTS MPTP-INDUCED PARKINSON'S DISEASE THROUGH THE INHIBITION OF NEURONAL NITRIC OXIDE SYNTHASE EXPRESSION IN MICE.

J. Choi, W. Chung, S. Ryu and C. Park. *Pharmacology, Inha Univeristy, Inchon, South Korea.*

The toxicity of 1-methyl-4-phenyl-1, 2, 3, 6-tetrahydropyridine (MPTP) is mediated by oxidative stress, especially by nitric oxide (NO) in animal models of Parkinson's disease (PD). Inhibition of excessive NO production in the brain produces a neuroprotective effect against PD induced by MPTP. Green tea containing high levels of (-)-epigallocatechin 3-gallate (EGCG), which has been known to inhibit inducible NO synthase (NOS), was administered to test whether EGCG attenuates MPTP-induced PD in mice through the reduction in the expression of NOSs. Both tea and the oral administration of EGCG prevented the loss of tyrosine hydroxylase (TH)-positive cells in the substantia nigra and of TH activity in the striatum. These treatments also preserved striatal levels of dopamine and its metabolites, 3, 4-dihydroxyphenylacetic acid and homovanillic acid. Both tea and EGCG decreased expressions of nNOS in the substantia nigra. Also tea pus MPTP and EGCG puls MPTP treatments decreased expressions of nNOS at the similar levels of EGCG treatment group. Unexpectedly, the expression of iNOS was not detectable in substantia nigra. Therefore, the preventive effects of tea and EGCG on the MPTP-mediated PD can be explained by the inhibition of nNOS in the substantia nigra.

361 FERTILITY & GENERAL REPRODUCTION TOXICITY STUDY OF A SURROGATE MURINE ANTI-CD11A ANTIBODY IN MICE.

J. Clarke, J. Beyer, S. Ortega, B. Wu, A. Hoberman, A. Brechbill and B. Mounho. *Argus Research, Division of Charles River, Horsham, PA.*

CD11a is a subunit of lymphocyte function antigen-1, a β2 integrin expressed on leukocytes involved in intercellular interactions necessary for immunologic responses and inflammation. Raptiva™ is a humanized anti-human CD11a mono-

clonal antibody in development for psoriasis. Due to the binding specificity of Raptiva to human and chimpanzee CD11a, a surrogate antibody, muM17 (a chimeric rat/mouse anti-mouse CD11a antibody), was developed for nonclinical safety assessment studies. In a fertility and general reproduction toxicity study, CD-1 male and female mice were administered vehicle or muM17 (3, 10, or 30 mg/kg) subcutaneously once a week. Previous studies evaluating the suitability of muM17 as a surrogate antibody for Raptiva determined the 3 mg/kg/wk muM17 dose as approximately equivalent to the clinical dose of Raptiva. Male mice received a total of 8 doses beginning 28 days prior to cohabitation and finishing 1 week after the end of cohabitation. Female mice received a total of 4 doses beginning 15 days prior to cohabitation until 1 week after confirmed mating. Male mice were euthanized after completion of the cohabitation period, and cesarean sections were performed on females on Day 11 of gestation. Toxicokinetic analysis confirmed exposure to muM17 in treated animals, and no antibodies to muM17 were detected. There were no muM17 treatment-related mortalities or effects on clinical observations or body weight. No treatment-related effects on mating, fertility, sperm motility or sperm density were noted in any males. In females, treatment with muM17 did not affect weight gain or estrous cycling, and the average numbers of corpora lutea, implantations, and viable/nonviable embryos did not differ among the groups. In summary, the fertility and general reproductive no observable effect level (NOEL) for muM17 was greater than 30 mg/kg/wk, and inhibition of the interaction between CD11a and ICAM-1 did not appear to adversely effect fertility or reproduction.

362 *IN UTERO* THROUGH LACTATIONAL EXPOSURE TO ETHINYL ESTRADIOL CAUSES ANOMALY OF THE FEMALE EXTERNAL GENITALIA AND LOSS OF REPRODUCTIVE CYCLICITY OF SD IGS RAT.

M. Sawaki[1], S. Noda[1], T. Muroi[1], H. Mitoma[1], S. Takakura[1], S. Sakamoto[1], K. Yamasaki[1] and N. Ito[2]. *[1]Chemicals Evaluation and Research Institute, Hita, Oita, Japan and [2]Nagoya City University Medical School, Nagoya, Japan.*

Endocrine-active chemicals may affect fetuses and neonates more seriously than adults. To evaluate the efficacy of an "*in utero* through lactational exposure" protocol and to estimate the optimal endpoints, 0, 0.5, 5, and 50 μg/kg/day of ethinyl estradiol (EE) was administered by gavage to pregnant Crj: CD (SD) IGS BR rats from gestational day 7 to day 18 after delivery. Clinical signs, body weight and physical development of the offspring were recorded. In addition, reproductive performance of the offspring at 14-20 weeks old was evaluated by checking their copulation indices and examinations at the caesarian section. Furthermore, at least 7 females / group were maintained until 6 months old and their cyclicity was examined followed by necropsy and histopathological examination of the genital tract. As a result, the dams showed no abnormalities. As to the offspring, cleft phallus was observed in the female at 50 μg/kg. Although the retardation of body weight gain of both sexes at 50 μg/kg was observed, it did not cause any secondary deleterious effects. Sex cycle prior to mating and reproductive performance of the EE-exposed offspring did not differ to those of the control rats. However, at 6 months old, abnormal cyclicity, mostly persistent estrus, was observed in 6/8 of the female at 50 μg/kg whereas 8/8, 6/7 and 9/9 at 0, 0.5 and 5 μg/kg respectively, showed normal cyclicity. Histopathologicaliy, the rats with persistent estrus showed absence of corpora lutea and follicular cysts in the ovary. These findings are similar to those in aged rats. In conclusion, cleft phallus was observed in the female at 50 μg/kg, the dose which did not induce major adverse effects. Furthermore, although their fertility was confirmed, later examination disclosed their loss of reproductive cyclicity. These suggest the study protocol we employed is effective and observation of the cyclicity at 6 months old or later may be useful.

363 *IN UTERO* AND LACTATIONAL EXPOSURE TO 1R4F CIGARETTE SMOKE: EFFECTS ON NEONATAL DEVELOPMENT, GROWTH AND NEUROBEHAVIOR IN THE OFFSPRING RATS.

C. L. Gaworski[1], A. S. Faqi[2], N. Rajendran[2] and E. L. Carmines[1]. *[1]Philip Morris USA, Richond, VA and [2]IIT Research Institute, Chicago, IL.*

Potential pre-and postnatal effects of 1R4F cigarette smoke were examined using male and female Sprague-Dawley rats exposed 2 hrs/day 7 days/wk by nose-only inhalation at total particulate matter (TPM) concentrations of 150, 300, or 600 mg/m3 (males: 4-wks prior to and during mating, females: 2-wks prior to mating, during mating, and through lactation day 20). Sham controls received filtered air to simulate exposure conditions, while shelf controls were untreated. During lactation and until weaning (post natal day: PND 61), the offspring rats were weighed, examined for gross signs of toxicity and evaluated for neurobehavioral effects. Biomarker analysis indicated smoke concentration related increases in blood COHb, nicotine and cotinine in exposed parental animals. Nicotine and cotinine were found in the pup blood during the lactation period. Characteristic cigarette smoke-related rodent respiratory tract histopathological changes were noted in all exposed parental groups. During gestation, maternal toxicity was indicated at smoke concentrations of 300 and 600 mg TPM/m3, where total maternal body weight gain was significantly ($p \leq 0.05$) decreased compared to sham controls. Smoke-related effects in the offspring rats were noted at 600 mg TPM/m3, where pup body weights were significantly decreased at birth (~17%), at weaning (~18%) and at PND 61 (~12%). At 300 mg TPM/m3, significantly reduced pup weights were noted at birth but were consistent with sham controls thereafter. No adverse effects on developmental landmarks, age at vaginal patency or preputial separation, motor activity, acoustic startle response or learning and memory were observed in the offspring rats. This study indicates that maternal exposure to toxic levels of cigarette smoke during gestation, reduces birth weight, and retards growth in the rat. Cigarette smoke does not appear to produce developmental or neurobehavioral effects under the conditions of this test.

364 DEVELOPMENTAL EFFECTS OF ZINC CHLORIDE IN RATS.

F. Johnson[1], L. Ogden[1], T. Graham[2], T. Thomas[1], E. Gilbreath[1], M. Hammersley[1], L. Wilson[1], Q. Knight[1] and B. DeJan[1]. *[1]Biomedical Sciences, Tuskegee University, Tuskegee Institute, AL and [2]Pathobiology, Tuskegee University, Tuskegee Institute, AL.* Sponsor: R. Dalvi.

Zinc is frequently found in the environment and at hazardous waste sites in several National Priority List (NPL) sites. The primary objective of our study was to evaluate the effects of zinc chloride in neonatal and maternal mammalian models. Rats were randomly assigned to one of four treatment groups (25/group/sex) to receive either 0.00; 7.5, 15.0 and 30 mg/kg by oral gavage. Rats were dosed during precohabitation (11 weeks), cohabitation (3 weeks); gestation (3 weeks); lactation (3 weeks) periods. Selected tissues from the reproductive tract (testes, seminal vesicles, ovaries, uterus) liver, brain, kidney, bone, spleen, and pituitary were evaluated histopathologically and for zinc analysis. Daily clinical observations and feed consumption and body weights were recorded. The F_1 pups (2 males and 2 females/litter) were randomly selected for neonatal evaluations including body weights, land mark developments, surface rightening reflex, and negative geotaxis. There was a significant difference (SD) in body weight of male and female pups versus their respective controls. Males exposed to the high dose showed a trend toward earlier incisor eruption. Zinc hastened incisor eruption in females which was SD when control was compared to the high dose group. Eye opening in both male and female pups was significantly shortened in all zinc treated groups (SD between high dose and control). There was no difference in testicular decent. Zinc chloride caused a significant increase in anogenital distance in male pups. There was a trend toward hastening vaginal opening, but there were no SD between the zinc treated groups. There were no differences in the pup rightening reflex on postnatal days 2-5. Male rats appear to be more affected by zinc exposure at the mid and high dose levels than their female siblings. Based on these data zinc can affect neonatal development of rats.

365 MULTIGENERATIONAL EFFECTS OF ZINC CHLORIDE ON THE REPRODUCTIVE PERFORMANCE OF CD-1 MICE.

L. Ogden[1], T. Graham[2], A. Atkinson[2], F. Johnson[1], M. Mahommed[1] and H. Michael[1]. *[1]Biomedical Sciences, Tuskegee University, Tuskegee Institute, AL and [2]Pathobiology, Tuskegee University, Tuskegee Institute, AL.* Sponsor: R. Dalvi.

Zinc chloride ($ZnCl_2$) has been found in significant levels at many hazardous waste (NPL) sites.The major objective was to determine the effects of low doses of $ZnCl_2$ on reproductive performance in a mammalian species. Mice were exposed during puberty, cohabitation, gestation, and lactation. Mice (25/group/sex) were exposed to either 0.00, 0.78, 1.56, or 3.125 mg/kg $ZnCl_2$ daily by oral gavage until terminated. Males were sacrificed after cohabitation and females after lactation. The F_1 parents were randomly selected from the F_1 pups and the reproductive cycle was repeated. The F_1 generation was exposed to $ZnCl_2$throughout their prenatal and postnatal life. Reproductive parameters evaluated were mean litter size, pup viability index, pup litter weight, live births, clinical signs, fertility index, post partum dam body weights, food consumption and parental body weights. There were no significant differences (SD) in the F_0 male and female body weight gain or food consumption. There were trends toward a decrease in MCV and MCH in both F_0 and F_1 mice suggestive of early phases of anemia associated with zinc exposure. Control groups in both generations had the highest number of total pups and live pups per liter, whereas, the highest and the mid dose groups had the fewest number of total pups. The fertility index was higher in the F_0 generation compared to the F_1 generation in all $ZnCl_2$ treated groups. Abnormal nursing and nesting behaviors were observed in the mid and high dose groups in both generations, but were more prominent in the F_1 generation. The latter maternal behavior was characterized by hyperactivity, irritability, absence of nest building, failure to allow pups to nurse

and killing of pups. Parental mortalities occurred in all $ZnCl_2$ treated groups in both generations. These data suggest that $ZnCl_2$ adversely affects some reproductive parameters when mice were exposed to oral doses of either 0.78, 1.5, and 3.125 mg/kg/day. (Supported by MHPF/ATSDR Cooperative Agreement # U50/ATU3922660032).

366 REPRODUCTIVE EFFECTS OF ZINC CHLORIDE IN SPRAGUE-DAWLEY RATS.

T. Graham[2], L. Ogden[1], A. Atkinson[2], F. Johnson[1], M. Hammersley[1], L. Wilson[1], B. DeJan[1] and Q. Knight[1]. *[1]Biomedical Sciences, Tuskegee University, Tuskegee Institute, AL and [2]Pathobiology, Tuskegee University, Tuskegee Institute, AL.* Sponsor: R. Dalvi.

Zinc is commonly encountered in the environment and is a frequent contaminant at over 700 National Priority List (NPL) sites. The major objective of our study was to evaluate the effects of zinc chloride in a mammalian model. Selected doses were derived from earlier studies that established maximum tolerated dose (MTD). Rats were randomly assigned to one of four treatment groups (25 /group/sex) to receive either 0.00; 7.5, 15.0 and 30 mg/kg/day by oral gavage. Rats were dosed during precohabitation (77 days), cohabitation (21 days), gestation (21 days), and lactation (21 days) periods. Males were removed after cohabitation, weighed, and terminated for pathologic evaluation. The testes, seminal vesicles, ovaries, uterus, liver, brain, kidney, bone, spleen, and pituitary were evaluated for histopathological and zinc analysis. Clinical observations were made throughout the day, weekly feed consumption, weekly and biweekly body weights (gestation period) were maintained throughout the study. There were no significant differences (SD) in the hematological and clinical chemistry values, or organ-body weight ratios. The control group had the highest implantation efficiency, which was SD from the low dose group. There were no SD in the length of gestation, the total number of pups born, the mean number of live births and the pup litter weights at days 0, 4, 7, 14, and 21. There were dose related trends toward decreased numbers of implantation sites and decreases in survival indices on postnatal days 0, 4, 7, 14, and 21. Similar trends toward decreased live birth index and weaning index were also noted in zinc treated groups. Based on these data, although mild, zinc chloride decreased the reproductive performance in rats when they were exposed to doses as low as 7.5 mg/kg/day.

367 CROSS-FOSTERING STUDY WITH ATOSIBAN IN CD RATS TO ELUCIDATE THE ROLE OF MATERNAL EFFECTS.

L. M. Burns[1] and P. McAnulty[2]. *[1]Reproduction Toxicology, Sequani Limited, Ledbury, United Kingdom and [2]Ferring Pharmaceuticals A/S, Copenhagen, Denmark.*

Atosiban, an oxytocin antagonist, has been demonstrated safe for the treatment of imminent preterm labour. In a peri- and post-natal study in rats there was an effect on neonatal survival at a high dosage of 300 mg/kg/day. Whilst considered attributable to a transient effect on milk production, this was not demonstrated unequivocally. This cross-fostering study was designed to investigate the aetiology of this effect. Atosiban was administered subcutaneously to 40 rats from Day 15 to 20 of gestation at a dosage of 300 mg/kg/day. Controls received the vehicle. Gestation length, duration of parturition, number of pups born and live birth index were unaffected. Within one hour of completion of parturition, litters were standardised to five per sex and cross-fostered either between or within groups. At birth, and within 2 hours of cross-fostering, the percentage of lactating treated females was markedly reduced. Prior to cross-fostering, litters from atosiban-treated females had the highest incidence of litters not being fed. Atosiban-treated litters cross-fostered to control females showed a marked increase in the percentage of pups fed; this was not the case for treated litters fostered to treated females. Control litters cross-fostered to atosiban-treated females showed a marked decrease in the percentage of pups fed. Offspring viability was reduced in both control and treated litters fostered to atosiban-treated females. Offspring bodyweight on Day 0 showed no effect of maternal treatment, but following cross-fostering weight gain to Day 7 was lower for litters fostered to atosiban-treated females. Bodyweight gains for treated litters fostered to control females were marginally greater than those recorded for control litters fostered to control litters. It was concluded that there was a clear effect on milk letdown in the atosiban-treated dams, leading to an indirect effect on neonatal survival; offspring were not directly affected.

368 A FIVE GENERATION REPRODUCTIVE TOXICITY ASSESSMENT OF THE SOY ISOFLAVONE GENISTEIN IN CD SPRAGUE-DAWLEY RATS.

K. B. Delclos[1], C. C. Weis[1], G. Olson[2], T. J. Bucci[2] and R. R. Newbold[3]. *[1]NCTR, Jefferson, AR, [2]Pathology Associates International, Jefferson, AR and [3]NIEHS, Research Triangle Park, NC.*

Genistein, the major isoflavone found in soy products, interacts with estrogen receptors (ER), with preference for ER-β, and with multiple other biochemical targets, depending on dose. An assessment of the toxicology of genistein is important in light of high levels of human exposure from the intake of soy infant formula and dietary supplements. The toxicity of dietary genistein (0, 5, 100, and 500 ppm) has been evaluated in a unique multigeneration design using NCTR CD rats. Serum levels of genistein achieved by these doses were previously shown to span the range expected from human consumption of soy products. The parental generation was exposed to genistein in a soy- and alfalfa-free diet (Purina 5K96) from 28 days prior to mating until necropsy at PND 140, the age at which all generations were terminated. The F_1 and F_2 generations were exposed continuously from conception, F_3 from conception until wean, and F_4 was not exposed to genistein. In the continuously exposed generations, body weight gain in females was depressed ≥ 10% at 500 ppm. A linear trend toward decreasing litter size was observed in the F_1-F_3 generations and mean litter size was lower than the control in F_2 (by 13% at 100 ppm and 33% at 500 ppm) and F_3 (by 17% at 500 ppm). Time and/or body weight at vaginal opening were accelerated at 500 ppm in F_1-F_3 and also at 100 ppm in F_1. There were significant small (5-7%) decreases in female anogenital distance at 100 and 500 ppm, with results dependent on the method of adjustment for body weight. Microscopic evaluation revealed treatment effects only in the male mammary gland (alveolar and/or ductal hyperplasia) and kidney (mineralization). These effects were most evident in the F_1 and F_2 generations, suggesting the importance of exposure during early development and the apparent reversibility of the effects. Thus, for data analyzed to this point, possible adverse reproductive effects of genistein under these exposure conditions were generally modest.

369 MULTI-GENERATION REPRODUCTION STUDY OF AMMONIUM PERFLUOROOCTANOATE IN RATS.

J. L. Butenhoff[1], G. L. Kennedy[2], J. C. O'Connor[2] and R. G. York[3]. *[1]3M, Saint Paul, MN, [2]Dupont, Newark, DE and [3]Argus Research, A Division of Charles River Laboratories, Horsham, PA.*

Ammonium perfluorooctanoate (APFO) is a surfactant used primarily as an aid in processing various fluoropolymers, and perfluorooctanoate has been identified in human sera from the US at very low concentrations (mean 6 ppb). The potential reproductive toxicity of APFO was studied using current EPA OPPTS 870.3800 guidelines. Male and female Sprague-Dawley rats were dosed orally with 0, 1, 3, 10, or 30 mg/kg/day APFO. P rats (~ 6 weeks old) were dosed at least 70 days prior to mating and until sacrificed (after mating for males; after weaning for females). F1 rats were dosed similarly, beginning at weaning. The F2 pups were maintained through 22 days of lactation. Reproductive parameters evaluated in P and F1 rats included estrous cycling, sperm number and quality, mating, fertility, natural delivery, and litter viability and growth. Day of sexual maturation (F1) and anogenital distance (F2) were also determined. Feed consumption, body weight gain, selected organ weight, gross pathology and appropriate histopathology were collected. No effects on mating or fertility were discovered. P and F1 males experienced significant toxicity (decreased body weight and organ weight changes) even at the lowest dose tested. P females had reduced body weights and organ weight changes at 30 mg/kg/day, and F1 females had reduced body weight gains at 30 mg/kg/day and reduced pituitary weights at 3 mg/kg/day and higher. The 30 mg/kg/day F1 pups had decreased birth weight and viability; however, F2 pups at 30 mg/kg/day did not show a loss in viability. Sexual maturation was delayed in F1 (both sexes). Estrous periods per 21 days were increased in F1 females; however, this is likely an artifact of the evaluation method, as an evaluation of raw estrous cycling data did not indicate significant abnormalities. At the doses tested, APFO did not cause specific effects on reproductive capacity, but did produce toxicity and delayed sexual maturation. The NOAEL for reproduction was > 30 mg/kg (P and F1) based on lack of effect on mating, fertility, and natural delivery.

370 A COMBINED REPEATED DOSE TOXICITY STUDY AND REPRODUCTION/DEVELOPMENTAL SCREENING STUDY IN SPRAGUE-DAWLEY RATS WITH ACETOPHENONE (OECD GUIDELINE NO. 422).

R. W. Kapp[1], B. A. Thorsrud[2], W. J. Moffatt[3] and L. Lawton[4]. *[1]BioTox, Richmond, VA, [2]Springborn Laboratories, Inc., Spencerville, OH, [3]JLM Chemicals, Inc., Blue Island, IL and [4]Aceto Corporation, Lake Success, NY.*

This study consisted of a repeated dose toxicity test combined with a reproduction/developmental screening test conducted following OECD Guideline No. 422. The purpose was to: 1.) provide initial information on the repeated dose systemic toxicity of acetophenone - including potential neurological effects, and 2.) serve as a screening study for potential reproductive and developmental effects in male and female rats. Upon completion of a range finding study, acetophenone was administered for a minimum of 28 days *via* oral gavage once daily to 4 groups of 10 male and female rats per group at 0, 75, 225 and 750 mg/kg/day for the toxicity phase and once daily for a minimum of 14 days through day 3 of lactation *via* oral gavage to 4 groups of 10 female rats per group at 0, 75, 225, and 750 mg/kg/day for the reproduction/developmental phase. The male rats from the toxicity phase were used

to breed the reproduction phase females. There was no mortality in the toxicity study. Mean forelimb grip strength and motor activity were decreased in the high dose males. Predose and postdose salivation was noted in both the 225 and 750 mg/kg/day groups. Body weights and food consumptions were lower in the high dose group. Hematology and coagulation parameters were unremarkable; however, the cholesterol levels were increased in the high dose animals. The 75 mg/kg/day dose level was determined to be the NOAEL for systemic toxicity while the 225 mg/kg/day dose level was determined to be the NOAEL for neurological effects. There were no parental deaths in the reproduction study; however, the live birth index, pup survival during the lactation phase and mean pup body weights were decreased in the high dose group. Hence, the 225 mg/kg/day dose level was considered a NOAEL for reproductive effects. However, the mating and fertility indices and mean gestation length appeared unaffected at dosage levels up to 750 mg/kg/day.

371 DOSE ADDITIVITY OF ATRAZINE AND BROMODICHLOROMETHANE IN CAUSING PREGNANCY LOSS IN F344 RATS.

M. G. Narotsky[1], D. S. Best[1], S. R. Bielmeier[2] and R. L. Cooper[1]. [1]*Reproductive Toxicology Division, USEPA, ORD, NHEERL, Research Triangle Park, NC and* [2]*Curriculum in Toxicology, University of North Carolina, Chapel Hill, NC.* Sponsor: J. Andrews.

Atrazine (ATRZ), a widely used herbicide, and bromodichloromethane (BDCM), a disinfection by-product found in drinking water, have both been shown to cause pregnancy loss, i.e., full-litter resorption (FLR), in F344 rats. Although chemically quite different, both ATRZ and BDCM have similar modes of action; ATRZ- and BDCM-induced pregnancy loss are associated with reduced levels of luteinizing hormone (LH) and progesterone during the LH-dependent period of gestation. ATRZ and BDCM co-exist in drinking water; thus, we sought to evaluate their cumulative effect on pregnancy maintenance using a dose-additivity model. Each agent was administered alone at near-threshold doses and in combination at one-half of the near-threshold doses. If synergistic, the two sub-threshold doses would combine to cause a greater-than-threshold response. Both agents were administered by gavage (BDCM in 10% alkamuls EL-620, then ATRZ in 1% methylcellulose) on gestation days 6-10. Each agent was administered alone at 40 mg/kg/d (LOEL=50 mg/kg); whereas the two were administered together at 20 mg/kg/d each. Dams were allowed to deliver and litters were examined on postnatal days 1 and 6. Uteri of nonparous females were stained with 10% ammonium sulfide to detect FLR. Alone or in combination, the agents were maternally toxic, causing weight loss after the first dose. As expected, 40 mg/kg of each chemical was a near-threshold dose for causing FLR; low rates (5-6%; 1 affected of 18-19 dams) were seen for each chemical alone. In combination, no FLR was seen (n=19). Thus, in this study, ATRZ and BDCM clearly lacked synergy in their ability to cause pregnancy loss in F344 rats. Although we did not assess the possibility of antagonism, these results are consistent with the default risk-assessment assumption of dose additivity for agents with the same mechanism. [This is an abstract of a proposed presentation and does not necessarily reflect EPA policy.]

372 EXPOSURE PARAMETERS FOR DELAYED PUBERTY AND MAMMARY GLAND DEVELOPMENT IN LONG-EVANS RATS EXPOSED *IN UTERO* TO ATRAZINE.

J. L. Rayner[1] and S. E. Fenton[2]. [1]*DESE, UNC-Chapel Hill, Chapel Hill, NC and* [2]*RTD, NHEERL, ORD, USEPA, Research Triangle Park, NC.*

Prenatal exposure to the herbicide atrazine (ATR) was found to delay vaginal opening (VO) in the offspring of Long-Evans (LE) rats. Our preliminary studies suggested that ATR exposure also delayed mammary development in LE female offspring. To evaluate ATR exposure parameters for pubertal and mammary gland development delays, we asked whether ATR-induced delays were strictly dam-mediated (via milk) or a direct effect (transplacental) on the pups. Timed-pregnant LE rats (N=20/group) were gavaged gestational days 15-19 with 100 mg ATR/kg body weight (BW) or vehicle (controls, C). On PND1, half of all litters were cross-fostered, creating 4 treatment groups; C-C, ATR-C, C-ATR, and ATR-ATR (birth-milk source, respectively). BW was compared on PND4, PND22, day of VO, and PND60. Pup BW was significantly reduced on PND4 for all groups exposed to ATR vs. C-C, but was no longer different among the dose groups at weaning. On PND40 and 60 serum luteinizing and prolactin levels did not vary between groups. Serum thyroid stimulating hormone was slightly elevated in the ATR-ATR group on PND60, but not PND40 ($p<0.05$). A significant delay in VO and increase in VO BW was seen only in the litters receiving milk from ATR-treated dams (MeanVO±SE, N>8 litters/group); C-C 33.3±0.6d, ATR-C 33.8±1.1d, C-ATR 35.1±0.9d, and ATR-ATR 37.0±0.7d. Following developmental scoring, mammary glands of female offspring (2/dam) in groups ATR-C, C-ATR, and ATR-ATR displayed significant delays in epithelial development on PNDs4, 33, and 40. However, at all ages examined, ATR-ATR offspring exhibited the least developed glands. Our data suggests that the delay in VO of *in utero* ATR-exposed offspring is mediated *via* the dam [milk], and does not appear to be influenced by offspring BW or direct exposure to ATR *in utero*. However, delays in mammary gland development appear to be the result of direct and/or suckling exposure parameters. (This is an abstract of a proposed presentation and does not necessarily reflect EPA policy; Supported by NHEERL-DESE, USEPA CT826513, and NSF, No. HRD-9978874)

373 EFFECTS OF PERINATAL EXPOSURE OF FIVE PUTATIVE ENDOCRINE DISRUPTING CHEMICALS (EDCS), METHOXYCHLOR, GENISTEIN, DIISONONYLPHTHALATE 4-NONYLPHENOL AND BISPHENOL A, ON ENDOCRINE/REPRODUCTIVE SYSTEMS IN RATS.

H. Takagi[1,2], M. Shibutani[1], N. Masutomi[1], C. Uneyama[1], K. Mitsumori[3] and M. Hirose[1]. [1]*Division Pathol., National Inst. Health Sciences., Tokyo, Japan,* [2]*United Graduate School of Veterinary Sciences, Gifu, Japan and* [3]*Lab. of Veterinary Pathology, Tokyo University of Agriculture and Technology, Tokyo, Japan.* Sponsor: S. TOMOYUKI.

Methoxychlor (MXC, 24, 240, 1200 ppm), genistein (GEN, 20, 200, 1000 ppm), diisononylphthalate (DINP, 400, 4000, 20000 ppm), 4-nonylphenol (NP, 60, 600, 3000 ppm) or bisphenol A (BA, 60, 600, 3000 ppm) were given to maternal rats from gestational day 15 to postnatal day (PND) 10 to assess their perinatal exposure effects on offsprings. Soybean-free diet was used as a basal diet. Organ weights at PND 21, onset of puberty, estrous cyclicity, gonadotrophin-immunopositive index (IPI) in pituitary at PND 21 and 77, and histological changes at PND77 were assessed as well as the size of sexually dimorphic nucleus of preoptic area (SDN-POA). In terms of MXC, DINP and GEN studies, expression of GABA transporter-1 (GAT-1), an estrogen responsive gene, was analyzed in medial preoptic area (MPOA) at PND10 using microdissection and real-time RT-PCR techniques. Females exposed to 1200 ppm MXC showed accelerated onset of puberty, irregular estrous cyclicity, histological changes such as multifollicular ovaries, hyperplasia in endometrium, vaginal mucosa and anterior pituitary at PND77, and decrease in LH-IPI at PND21 and increase in FSH- and PRL-IPIs at PND77. Females of 240 ppm MXC also showed increased PRL-IPI at PND77. Males of 1200 ppm MXC showed delayed onset of puberty and decreased LH-, FSH- and PRL-IPIs at PND21. DINP at 20000 ppm caused very slight degeneration of spermatocytes and Sertoli cells at PND77. The sizes of SDN-POA did not alter at any doses of chemicals examined. GAT-1 levels in male MPOAs decreased with DINP at 20000 ppm, and also showed a dose-related decreasing tendency with MXC. GEN, BA and NP did not affect any endocrine parameter examined. Results suggest that maternal exposure to MXC and DINP affects reproductive system of offsprings by disrupting brain sexual differentiation.

374 THE INDUCTION OF OXIDATIVE STRESS IN VARIOUS BRAIN REGIONS OF RATS FOLLOWING SUBCHRONIC EXPOSURE TO TCDD.

E. A. Hassoun, M. Al-Ghafri and A. Abushaban. *Pharmacology, The University of Toledo, Toledo, OH.*

In this study, TCDD was administered to various groups of female Sprague-Dawley rats, p.o, at doses of 0, 10, 22 and 46 ng/kg/day for 90 day. The animals were then sacrificed and their brains were removed and dissected into various regions including, cerebral cortex (Cc), hippocampus (H), mid brain (MB) and cerebellum (C). Production of superoxide anion (SA) and lipid peroxidation (LP), as well as the activities of various antioxidant enzymes, including superoxide dismutase (SOD), catalase and glutathione peroxidase (GSH-Px) were determined in those regions. The results of the studies indicate that TCDD caused dose dependent increases in the production of SA and LP in the H and Cc with no significant changes in these biomarkers observed in the MB and the C. While dose dependent elevations in SOD activities were observed in C and MB, dose dependent suppressions in the activities of this enzyme were observed in the Cc and H. Catalase activities on the other hand underwent dose dependent elevations in the C and were significantly elevated in the H and Cc of rats treated with the lowest dose of TCDD. However, Catalase activities were suppressed in a dose dependent manner in H and Cc of rats treated with doses higher than 10 ng of TCDD/kg/day and were not significantly changed in MB of rats treated with any of the doses of the compound. While patterns similar to those of catalase were observed in GSH-Px activities in C, Cc and H of the treated rats, GSH-Px activities in MB underwent dose-dependent elevations. The results suggest that oxidative tissue damage is significantly induced in the Cc and H but not in the MB and C of brains after exposure to subchronic doses of

TCDD. Also, modulation of activities of various antioxidant enzymes in those regions by various doses of TCDD may contribute to the production of, or protection against tissue damage observed in those regions. (Supported by NIH/NIEHS grant ES11048).

375 FCCP-INDUCED TOXICITY AND OXIDATIVE STRESS IN RHABDOMYOSARCOMA CELLS.

C. Hu[1], L. M. Storck[1], S. K. Kuruvilla[2], M. A. Tirmenstein[1], P. K. Narayanan[1], H. C. Thomas[1] and L. W. Schwartz[1]. *[1]Safety Assessment, GlaxoSmithKline, King of Prussia, PA and [2]Toxicogenomic Mechanisms, GlaxoSmithKline, Research Triangle Park, NC.*

Carbonyl cyanide *p*-trifluoromethoxyphenylhydrazone (FCCP) is a mitochondrial respiratory chain uncoupler which depletes cellular ATP. The objective of this investigation was to assess FCCP potential to induce cytotoxicity, oxidative stress (OS) and OS relevant gene expression. FCCP at concentrations up to 150 μM produced minimal toxicity in rhabdomyosarcoma derived human cell line (RD) (≤ 20% cell death) after 10 h incubation. As expected, FCCP dramatically depleted cellular ATP in RD in a concentration-dependent manner. Flow cytometric analysis indicated FCCP induced apoptosis after 4 h. Biochemical markers of OS were affected by FCCP. Intracellular superoxide production was elevated by FCCP at concentrations ≥ 10 μM after 1 h. FCCP induced a concentration-dependent increase in lipid peroxidation in RD after 1 and 4 h. FCCP (50 μM — 150 μM) markedly decreased cellular reduced glutathione (GSH) and increased oxidized glutathione (GSSG) after 10 h. A panel of OS related genes were examined by RT-PCR in RD after FCCP exposure. Genes examined included: CYP1A1, heme oxygenase–1, DNA topoisomerase 2A, p21, γ-glutamyl-cysteinyl ligase regulatory subunit, thioredoxin reductase and glutathione reductase. FCCP significantly altered expression of these genes. As an example, heme oxygenase–1 expression was induced 30 fold by 150 μM FCCP. Our study suggests that high concentrations of the mitochondrial uncoupler, FCCP, in addition to depleting cellular ATP induces apoptosis and oxidative stress in RD.

376 ROLE OF OXIDATIVE STRESS IN THE MODIFICATION ON RAT UTERINE CONTRACTION BY 2, 2'-DICHLOROBIPHENYL.

D. Chung and R. Loch Caruso. *Environmental Health Sciences, University of Michigan, Ann Arbor, MI.*

Previously, we showed that polychlorinated biphenyl (PCB) mixtures and several lightly chlorinated ortho-substituted PCB congeners modify contractions of uterine strips *in vitro*. The present study characterizes the *in vitro* effects of 2, 2'-dichlorobiphenyl (2, 2'-DCB) on spontaneous oscillatory uterine contractions and examines the role of oxidative stress in 2, 2'-DCB-induced modification of uterine contraction. Uterine strips from gestation day 10 pregnant rats were suspended in isometric muscle baths and exposed to 30, 60 or 100 mM 2, 2'-DCB. Over 150 min of exposure, 2, 2'-DCB increased the frequency of oscillation, decreased the average peak amplitude per contraction, and decreased the syncronization of contractions as measured by the percent of contractions that returned to baseline (completed contractions). These 2, 2'-DCB-induced changes reversed spontaneously and the time to recovery was directly related to 2, 2'-DCB concentration. The most dramatic effect was an increase of contraction frequency to 1288.5% at 110 min, a decrease in the amplitude to 10.5% at 140 min, and a decrease in the completed contractions to 10.9% at 140 min after 100 mM 2, 2'-DCB exposure. Pre- and co-treatment with the antioxidants 100 mM ascorbic acid or 100 mM glutathione ethyl ester did not alter the uterine response to 2, 2'-DCB. In response to pre- and co-treatment with a-tocopherol, 100 mM a-tocopherol had no effect whereas 200 or 400 mM a-tocopherol delayed the onset of 2, 2'-DCB-induced modification of uterine contraction. When uterine strips were treated with 100 mM a-tocopherol or 50 mM deferoxamine mesylate after a 1-h exposure to 100 mM 2, 2'-DCB, the 2, 2'-DCB-induced modifications were reversed within 1 h. In contrast, treatment with 100 mM ascorbic acid or 100 mM glutathione ethyl ester after a 1-h exposure to 100 mM 2, 2'-DCB did not alter the response to 2, 2'-DCB. This study suggests that 2, 2'-DCB modifies uterine contraction by a mechanism that is at least partially dependent on oxidative stress.

377 NITROTYROSINE AND SPLENIC TOXICITY OF ANILINE.

M. F. Khan, X. Wu, P. J. Boor and G. S. Ansari. *University of Texas, Galveston, TX.*

Splenic toxicity of aniline is characterized by vascular congestion, hyperplasia, fibrosis and development of a variety of sarcomas in rats. However, the mechanisms of this selective splenic toxicity are not well understood. Previously we observed that aniline exposure causes oxidative damage to spleen. To further explore the oxidative mechanism of aniline toxicity, we evaluated the role of nitric oxide. Nitric oxide reacts with superoxide anion to form peroxynitrite, a powerful oxidant which converts the tyrosine residues of proteins to nitrotyrosine (NT). Therefore, aim of this study was to establish the role of nitric oxide through the formation and localization of NT in the spleen of rats exposed to aniline. Male SD rats were given 1 mmol/kg/day aniline hydrochloride in water by gavage for 7 days, while the controls received water only. Immunohistochemical analysis for NT showed an intense staining in the red pulp areas of spleen from aniline-treated rats, localized in macrophages and sinusoidal cells. Occasionally mild NT immunostaining was also evident in the white pulp areas. To further characterize the nitrated proteins, Western blot analyses of the post-nuclear fraction of the spleens showed major nitrated proteins with molecular weights of 18 kD, 30 kD and 49 kD. Immunohistochemical analysis of inducible nitric oxide synthase (iNOS) also showed increased expression in the red pulp of the spleens from aniline-treated rats; the cellular localization was similar to nitrated proteins. These studies suggest that oxidative stress in aniline toxicity also includes aberration in nitric oxide production leading to nitration of proteins. Functional consequences of such nitration will further elucidate the contribution of nitric oxide to the splenic toxicity of aniline.

378 NITRIC OXIDE MEDIATES INCREASED SUSCEPTIBILITY TO DOPAMINERGIC DAMAGE IN NURR1 DEFICIENT MICE.

A. D. Disch[1], S. Z. Imam[1], J. Jankovic[2], J. T. Skinner[1], W. Xie[2], O. M. Conneely[2], W. Le[2] and S. Ali[1]. *[1]Neurotoxicology, USFDA/NCTR, Jefferson, AR and [2]Department Neurology, Baylor College of Medicine, Houston, TX.*

Mutation in Nurr1 gene, a member of the nuclear receptor superfamily, causes selective agenesis of dopaminergic neurons in the midbrain. Reduced expression of Nurr1 increases the vulnerability of mesencephalic dopamine neurons to dopaminergic toxins. We evaluated the role of nitric oxide as a possible mechanism for this increased susceptibility. Increased expression of neuronal nitric oxide synthase and increased 3-nitrotyrosine were observed in the striatum of Nurr1 deficient mice as compared to the wild type. Increased cytochrome C activation and the consecutive release of Smac/DIABLO were also observed in Nurr1 deficient mice. Furthermore, an induction of active Caspase-3 and p53, cleavage of poly-ADP(ribonuclease) polymerase and reduced expression of bcl-2 were observed in Nurr1 deficient mice. Methamphetamine significantly potentiated the increase of these markers in Nurr1 deficient mice as compared to the wild type. The present data, therefore, suggest that nitric oxide plays a role as a modulating factor for the increased susceptibility of the dopaminergic system in Nurr1 deficient mice. We also report that this increased neuronal nitric oxide synthase expression and increased nitration in Nurr1 deficient mice led to the activation of apoptotic cascade *via* differential alterations in the DNA-binding activity of transcription factors responsible for the propagation of growth arrest as well as apoptosis.

379 COCAINE INDUCES A DOSE DEPENDENT ALTERATION IN GENE EXPRESSION OF APOPTOTIC CASCADE IN PC12 CELLS.

H. M. Duhart, S. Z. Imam, J. T. Skinner, W. Slikker, Jr and S. Ali. *Neurotoxicology, USFDA/NCTR, Jefferson, AR.*

Cocaine is a widely used drug of abuse and psychostimulant which acts on the central nervous system by blocking the dopamine re-uptake sites. PC12 cells, a rat pheochromocytoma clonal line, which in the presence of nerve growth factor (NGF), multiply and differentiate into competent neurons that can synthesize, store and secrete the neurotransmitter dopamine (DA). In the present study, we evaluated the effect of increasing doses of cocaine on the expression of immediate early genes (IEGs), c-fos and SP-1 and a closely related nuclear factor, NF- 24 h after exposure to cocaine (50, 100, 250, 500, 1000, 2500 M) in NGF-differentiated PC12 cells. Cocaine (50-500 M) resulted in significant induction of the expression of c-fos, SP-1 and NF-. However, higher concentrations of cocaine (1000 & 2500 M) resulted in the down-regulation of these expressions after 24 h. To further understand the role of dose-dependent changes in the mechanisms of cell death, we evaluated the protein expression of apoptotic markers. A dose-dependent increase in the expression of caspase 9 and 3 was observed upto 500 uM of cocaine. However, the higher dose did not show any expression. We also evaluated the effect of increasing doses of cocaine on dopamine concentration and the expression of dopamine transporter. A significant dose-dependent decrease in the concentration of dopamine as well as the expression of dopamine transporter was observed 24 h after the exposure of PC12 cells to cocaine. Therefore in the present study, we report that cocaine has both upstream and downstream regulatory actions on some IEGs and nuclear factors, which can regulate the mechanism of cell death and these effects on gene expression, are independent of its action on the dopaminergic system.

380 REPERFUSION DERIVED OXYGEN RADICAL DAMAGE IN ATLANTIC MENHADEN, *BREVORTIA TYRANNUS.*

D. W. Lehmann[1] and J. M. Law[2]. *[1]Environmental and Molecular Toxicology, North Carolina State University, Raleigh, NC and [2]FAHRM, College of Veterinary Medicine, North Carolina State University, Raleigh, NC.*

Atlantic Menhaden, *Brevortia tyrannus*, serve a role as primary consumer in the estuaries of the mid-Eastern Atlantic coast in the US. These fish serve as a basic component of food webs for game fish as well as an economic resource (as a source of polyunsaturated oils). Hundreds of thousands of these fish die in kills unassociated with any specific etiology in the New, Neuse, and Tar-Pamlico River systems on the coast of North Carolina each year. Epizootic ulcerative syndrome (EUS), frequently associated with these kills (5-95‰), is seen during seasonal outbreaks, but has a complex pathogenesis and uncertain primary etiology. Due to the fact that menhaden are often trapped in estuarine hypoxic zones, this experiment was designed to test the hypothesis that reperfusion derived oxyradicals, driven by hypoxia, causes skin and/or muscle injury which may lead to EUS. A system has been designed which sparges oxygen from tank water *via* a foam fractionator and nitrogen source. Hypoxic treatments (1.4 +/- 0.091 mg/L) for 48 hours were followed by rapid resumption of normoxic conditions. Sampling occurred at 0, 24, 48, and 60 hours. Lipid peroxidation, 8-hydroxy-2'-deoxyguanisine formation, low molecular weight antioxidant status, total oxyradical scavenging capacity (TOSC), and histology were selected as endpoints to assess oxygen radical damage. Histology and lipid peroxidation showed no significant increases in cellular damage beyond background post-treatment. These data suggest that Atlantic Menhaden are highly resistant to reperfusion derived oxyradical damage.

381 DFP-INDUCED OXIDATIVE STRESS IN SKELETAL MUSCLES OF RATS.

D. Milatovic[1], R. C. Gupta[2], T. J. Montine[1] and W. D. Dettbarn[3]. *[1]Pathology, University of Washington, Seattle, WA, [2]Murray State University, Hopkinsville, KY and [3]Pharmacology, Vanderbilt University, Nashville, TN.*

This study was undertaken to determine the role of oxidative stress as determined by effects on energy metabolism and lipid peroxidation in the skeletal muscles of rats acutely intoxicated with diisopropylphosphorofluoridate (DFP, 1.5 mg/kg, sc). F2-isoprostanes (F2-IsoPs), specific markers of reactive oxygen species (ROS)-induced lipid peroxidation, and citrulline (determinant of nitric oxide, NO and nitric oxide synthase, NOS), markers of reactive nitrogen species (RNS), were determined in skeletal muscle. Control values for F2-IsoPs varied from 0.963 to 1.270 ng/g, for citrulline 331.2 to 451.2 nmol/g, for ATP 3.42 to 4.91 mmol/g, and for phosphocreatine (PCr) 6.18 to 9.63 mmol/g. Treated rats developed onset of toxicity signs (tremors) within 5-10 min, which progressed to maximal severity (convulsions and fasciculations) within 60 min. At this time point, acetylcholinesterase activity was reduced by 90-96%, Severe fasciculations induced by DFP caused significant increases in F2-IsoPs (156%), increases in citrulline (272-288%), and declines in high-energy phosphates (ATP and PCr) (30-43%). Findings revealed that the increase in NO and NOS was greater than the decrease of ATP and PCr. The data suggest that the DFP-induced muscle hyperactivity produces oxidative stress by excess generation of ROS and RNS, causing depletion of energy metabolites and increased lipid peroxidation, leading to muscle fiber damage/death (Supported by NIH grant ES04597-W-D Dettbarn and KSTC 2002-RCG).

382 LOW DOSE OXIDATIVE INSULT PROMOTES APOPTOSIS IN DOPAMINERGIC CELLS VIA CASPASE-3 DEPENDENT PROTEOLYTIC ACTIVATION OF PKCδ: RELEVANCE TO ENVIRONMENTAL FACTORS AND PARKINSON'S DISEASE.

S. Kaul, V. Anantharam and A. Kanthasamy. *Biomedical Sciences, Iowa State University, Ames, IA.*

Oxidative stress has been recognized as an important cell death mechanism in many degenerative conditions including Parkinson's disease. Recently, we demonstrated that dopaminergic toxins, including 1-methyl-4-phenylpyridinium (MPP^+) (Kaul *et al.*, 2001), dieldrin (Kitazawa *et al.*, 2001), and MMT (Anantharam *et al.*, 2002) initiate oxidative stress and subsequently promote caspase-3 dependent proteolytic activation of pro-apoptotic protein kinase Cδ in mesencephalic dopaminergic neuronal (N27) cells. This study was designed to examine the effects of a low dose oxidative insult on apoptotic signaling in N27 dopaminergic neuronal cells. Significant cell death was observed in dopaminergic cells within 4 hrs of exposure to 100 μM H_2O_2, as demonstrated by a live-dead cell fluorescence assay. Caspase-3 activity increased two-fold within 30 min of H_2O_2 exposure and continued to increase time-dependently over the next 4 hrs. H_2O_2 induced a dose-dependent proteolytic cleavage of PKCδ (72-74 kDa) into a 41-kDa catalytic and a 38-kDa regulatory subunit; the cleavage was completely attenuated by caspase-3 inhibitor Z-DEVD-FMK (50 μM), indicating that it was mediated by caspase-3. Quantification of DNA fragmentation by ELISA revealed that low dose H_2O_2 also induces cellular apoptosis in a time dependent manner over a 4 hr period. Furthermore, pretreatment with MnTBAP (a SOD mimetic-5 μM), rottlerin (a PKCδ specific inhibitor-2 μM) and Z-DEVD-FMK (caspase-3 specific inhibitor-50 μM) significantly attenuated H_2O_2-induced apoptosis in dopaminergic cells. Together, we demonstrate for the first time the rapid induction of an apoptotic pathway involving caspase-3 mediated PKCδ proteolytic cleavage in dopaminergic cells by low dose oxidative insult.*(Supported by NIH grant ES 10586)*

383 OXIDATION OF 4-HYDROXY-2-NONENAL BY SUCCINIC SEMIALDEHYDE DEHYDROGENASE (ALDH5A).

M. J. Picklo[1], K. Gibson[2] and T. C. Murphy[1]. *[1]Pharmacology and Physiology, University of North Dakota School of Medicine, Gramd Forks, ND and [2]Molecular and Medical Genetics, Oregon Health Sciences University, Portland, OR.*

4-Hydroxy-trans-2-nonenal (HNE) is a cytotoxic aldehyde product of lipid peroxidation that is implicated in the progression of several neurodegenerative disorders such as Alzheimer disease and Parkinson disease. Previous studies have implicated the mitochondrial detoxification of aldehydes in the development of AD. Numerous studies have demonstrated the oxidation of HNE in liver and kidney mitochondria but have not identified the aldehyde dehydrogenases (ALDH) responsible for this oxidation. Two potential ALDH enzymes, ALDH2 and succinic semialdehyde dehydrogenase (ALDH5A) are found in mitochondria. In this study, we examined the oxidation of HNE to 4-hydroxy-2-nonenoic acid (HNEAcid) in isolated rat brain mitochondria in order to determine if HNEAcid formation occurs and the enzymes responsible. HNEAcid was generated from HNE in lysed mitochondria with an apparent Km of 20 μM HNE and a Vmax of 4 nmol/min/mg protein. Dose response curves were then established to compare HNEAcid formation, ALDH2 activity, and SSADH activity using the fungicide, benomyl, a potent ALDH2 inhibitor. Benomyl (3 μM) completely inhibited ALDH2 activity. However, HNEAcid formation and SSADH activity were inhibited only 30%, suggesting that SSADH may be responsible for oxidizing HNE. To test this hypothesis, recombinant rat SSADH (rrSSADH) was expressed as a poly-histidine tagged fusion protein in E.coli. Following purification by nickle-agarose chromatography, a protein of approximately 55 kDa with a Km of 3.3 μM for succinic semialdehyde with a Vmax of 20 μmol/min/mg was obtained, similar to native enzyme. rrSSADH oxidized HNE with a Vmax of 1.2 μmol/min/mg and a Km of 50 μM. Other alkenals such as 2-nonenal, 2-hexenal, and 4-hydroxyhexenal had lower rates of oxidation. These data demonstrate that the oxidation of HNE in rat brain mitochondria, in part, is due to SSADH activity.

384 MOTOR NEURONS FAIL TO UPREGULATE METALLOTHIONEIN DURING OXIDATIVE STRESS: A SOURCE OF VULNERABILITY TO DISEASE?

D. Taylor and H. D. Durham. *Montreal Neurological Institute, McGill University, Montreal, QC, Canada.*

Amyotrophic lateral sclerosis (ALS) is a disease characterized by selective degeneration of motor neurons leading to paralysis and death. Excitotoxicity and oxidative stress contribute to the preferential vulnerability of motor neurons relative to spared neuronal populations. Approximately 1-2% of ALS cases can be attributed to dominantly inherited mutations in the gene encoding Cu/Zn-superoxide dismutase (SOD1). Although disease does not result from loss of dismutase activity, but from a toxic gain of function, evidence from transgenic mouse and human studies indicates oxidative stress is a contributing factor. Metallothioneins are a group of non-enzymatic, low molecular weight, metal-binding proteins that are cytoprotective through sequestration of reactive oxygen species and metal ions. Transgenic mice expressing a disease-associated mutant form of human SOD1 on a MT-I/II null background died significantly earlier than those expressing MT at normal levels (Nagano et al. 2001), suggesting a protective role for MT in motor neuron diseases. We have examined the constitutive expression of MT isoforms MT-I/MT-II and MT-III in motor neurons of dissociated murine spinal cord cultures and induction by oxidative stress, excitotoxicity or expression of mutant SOD1. MT-I and MT-II were not detected in motor neurons by immunocytochemistry (DAKO:E9), either under basal conditions or following treatment with paraquat (LD50 = 10mM for 48 hrs), glutamate (LD50 = 20mM for 48 hrs) or zinc chloride (LD50 = 30mM for 48 hrs). MT-I/II expression also remained below detection in motor neurons microinjected with G93A mutant human SOD 1 expression vector. However, MT was expressed in glial cells and increased levels were measured by Western blot following zinc chloride treatment. MT-III was expressed in motor neurons, but also failed to upregulate with treatment. It is concluded that the failure to upregulate MT isoforms during oxidative stress, coupled with low levels of reduced glutathione, may contribute to the vulnerability of motor neurons in disease. supported by CIHR.

385 THE USE OF PROTEOMIC ANALYSIS TO ASSESS OXIDATIVE INSULT, AND PROTECTION BY DEHYDROEPIANDROSTERONE, USING CELL MODEL SYSTEMS.

S. Aldred and H. R. Griffiths. *Life and Health Sciences, Aston University, Birmingham, West Midlands, United Kingdom.*

Oxidative stress has been implicated in a number of chronic disease states including cardiovascular disease, rheumatoid arthritis, vascular dementia, and Alzheimer's disease. Uptake of oxidised low density lipoprotein (LDL) by monocytes leads to the formation of foam cells, which initiates the formation of atherosclerotic plaques and vascular dementia. Oxidative insult upon neuronal cells has also been linked to plaque formation in Alzheimer's disease. Dehydroepiandrosterone (DHEA) is the most abundant steroid in human circulation, with levels naturally decreasing with age to less than 20% of those found in young adults. It has been shown to protect against free radical insult in the brain and can protect against LDL oxidation. In order to increase knowledge of the effects of oxidative insult on cellular adaptation and survival, and to evaluate the effects of DHEA in this process, the protective properties of DHEA against oxidative insult were assessed in two cell model systems. Human neuroblastoma SH-SY5Y were exposed to hydrogen peroxide (50, 100μM) after pre-treatment with DHEA (3, 10, 30μM). DHEA reduced oxidative insult and returned cell viability to control levels. Protein expression, assessed by colloidal gold staining on 2D-electroblotted samples, was seen to increase after insult. This was seen to decrease upon DHEA pre-treatment. LDL, prepared from human plasma, was exposed to oxidative insult (2, 2'-azobis(amidinopropane)dihydrochloride [AAPH] 50mM) in the presence or absence of DHEA (3μM). Uptake by U937 monocytes of oxidised LDL was increased significantly compared to uptake of native LDL, but was reduced to control levels by co-incubation with DHEA. Following uptake of oxidised LDL U937 moncytes showed an increase in protein expression, both quantitatively and qualitatively, which returned to control levels when DHEA was used as a protective agent. Proteomic analysis demonstrates the complexity of the adaptive response to oxidative stress and the nature of protective effects of DHEA.

386 DETECTION OF CARBONYLATION AND 3-NITROTYROSINE AS PROTEIN OXIDATION BIOMARKERS.

M. Grant and H. Griffiths. *Life and Health Sciences, Aston University, Birmingham, West Midlands, United Kingdom.* Sponsor: E. Lock.

Reactive oxygen species (ROS) lead to protein oxidation, where ROS can arise from endogenous processes, e.g. glycoxidation and lipid peroxidation, or from xenobiotic metabolism or radiation. Furthermore, in the absence of ROS specific scavenging, nitric oxide can combine with the superoxide anion to form the potent reactive nitrogen species (RNS), peroxynitrite, which can further cause post-synthetic protein modification through nitration. The resultant formation of carbonyl groups and 3-nitrotyrosine on proteins represent stable changes that can be utilized as biomarkers of oxidative stress. The antioxidant hypothesis suggests that dietary supplementation with antioxidants may decrease disease progression. We have reported previously, that dietary vitamin C protects against immunoglobulin oxidation, over 10 weeks *in vivo* ($P<0.01$). However, the nature of protection afforded by dietary vitamin C against other plasma proteins has not previously been investigated. Therefore, the purpose of this work was to assess the use of 2D electrophoresis and Western blotting as a sensitive and reproducible method for the investigation of protein oxidation and nitration. Carbonyls were detected following derivatisation on the electroblot using 2, 4-dinitrophenylhydrazine. Analysis of plasma from subjects receiving vitamin C (400mg/day for 10 weeks) showed a differential pattern of nitration and carbonylation pre- and post-supplementation. Immunoglobulins showed significant oxidation that can be ameliorated by vitamin C supplementation and intensity of immunoglobulin staining for carbonyl groups correlated with ELISA determination of immunoglobulin carbonyl groups. Concurrent cellular experiments, in the neuroblastoma SH-SY5Y cell line, using vitamin C (100μM) to prevent oxidant (100μM H_2O_2) induced apoptosis, have also been examined for nitrotyrosine and protein carbonyl groups. Colloidial gold staining of Western blots showed differences in protein expression when insulted cells were protected with vitamin C.

387 METABOLISM OF 4-OXONONENAL BY HUMAN CLASS 2 ALDEHYDE DEHYDROGENASE.

J. A. Doorn[1], T. D. Hurley[2] and D. R. Petersen[1]. *[1]Pharmaceutical Sciences, University of Colorado Health Sciences Center, Denver, CO and [2]Biochemistry, Indiana University, Indianapolis, IN.*

Class 2 aldehyde dehydrogenase (ALDH2) catalyzes the oxidation of the lipid peroxidation product 4-hydroxynonenal (4-HNE) to 4-hydroxynonenoic acid, resulting in inactivation of 4-HNE as an electrophile (i.e. Michael acceptor). Structurally analogous to 4-HNE is 4-oxononenal (4-ONE), a recently discovered product of lipid peroxidation, which is more reactive than 4-HNE towards protein nucleophiles. The goal of this work was to determine whether 4-ONE is a substrate or inhibitor of human ALDH2 (hALDH2). Kinetic analyses were performed using hALDH incubated with NAD and various concentrations of 4-ONE. At low concentrations of 4-ONE (≤ 10 mM), hALDH2 catalyzed the oxidation of 4-ONE to 4-oxononenoic acid (4-ONA) with a yield of 20 mol 4-ONA produced per mol of enzyme. However, subsequent analysis of hALDH2 activity using propionaldehyde as a substrate revealed that both 4-ONE and the oxidation product, 4-ONA, inhibited hALDH2 activity. The reactivity of 4-ONA toward glutathione was measured and found to be comparable to that of 4-HNE, indicating that the 4-ONA oxidation product is a reactive electrophile. Matrix-assisted laser desportion/ionization time of flight mass spectrometery analysis of tryptic peptides revealed covalent modification of hALDH2 by 4-ONE and 4-ONA that was NAD-dependent. These data indicate that hALDH2 catalyzes the oxidation of 4-ONE to 4-ONA; however, 4-ONA is also a reactive electrophile that like 4-ONE is capable of covalently modifying and inhibiting hALDH2. (Supported by grants NIH/NIAAA R01AA09300 and NIH/NIEHS R01ES09410 (DRP); and PHS 5T32AA07464 and NIH/NIEHS F32ES011937 (JAD)).

388 PROTEIN AND PEPTIDE CROSS-LINKING BY 4-OXONONENAL.

D. R. Petersen, J. A. Doorn and D. J. Claffey. *Pharmaceutical Sciences, University of Colorado Health Sciences Center, Denver, CO.*

Previous work demonstrated that the lipid peroxidation product 4-oxononenal (4ONE) covalently modifies peptides and proteins. Reaction of proteins/peptides with 4ONE *via* Michael addition results in an adduct with two carbonyls that can react with amines to yield protein cross-links. The purpose of this study was to determine whether 4ONE cross?links proteins and to identify residues involved in cross-linking. Ovalbumin (OVA) was reacted with various concentrations of 4ONE ranging from 10 μM to 1 mM under reducing and non-reducing conditions. The products were analyzed using SDS-PAGE. In a separate experiment, OVA was treated with concentrations of the 4ONE-glutathione conjugate ranging from 20 μM to 1 mM under reducing conditions and analyzed *via* SDS-PAGE. Combinations of peptides containing one or more nucleophilic residues (i.e. Arg, Cys, His, and Lys) were reacted with 4ONE under reducing and non-reducing conditions, and the products analyzed by mass spectrometry. Cross-linking of OVA was apparent for protein treated with ≥50 μM 4ONE under non?reducing conditions. Protein cross?linking was observed for OVA modified by ≥10 μM 4ONE when treated with a reducing agent. Furthermore, cross-linking of OVA occurred for protein treated with ≥100 μM of the 4ONE-glutathione conjugate. Reaction of 4ONE with peptides resulted in new products with masses corresponding to a peptide dimer plus one molecule of 4ONE. The peptide dimers consisted of one peptide with a Cys residue cross?linked to a peptide with a Lys residue. These data indicate that low concentrations of 4ONE (i.e. 10 μM) can induce protein cross-linking and that the reaction occurs *via* Michael addition of 4ONE with Cys followed by reaction of the adduct with a primary amine (i.e. Lys), yielding a Schiff base. Furthermore, results of this study indicate that glutathione conjugation of 4ONE does not result in an inactive product. (Supported by grants NIH/NIAAA R01AA09300 and NIH/NIEHS R01ES09410 (DRP); and PHS 5T32AA07464 and NIH/NIEHS F32ES011937 (JAD)).

389 REGULATION OF C-FOS PHOSPHORYLATION AND AP-1 ACTIVATION BY OXIDANTS IN CARDIOMYOCYTES.

J. Coronella-Wood, H. Sun and Q. Chen. *Pharmacology, University of Arizona, Tucson, AZ.*

Cardiomyocytes develop hypertrophy during the process of heart failure. We have found that oxidants cause cardiomyocytes to enlarge within 4-5 days. Within 30 minutes of oxidant exposure, a number of signaling molecules are activated including phosphoinositide 3-kinase (PI3K), p70 S6 kinase and three branches of MAPKs (ERKs, p38 and JNKs). Oxidative stress also results in AP-1 transcription factor activation after 2 hrs in cardiomyocytes. A known component of AP-1 that responds to oxidative stress is c-fos protein. Measurement of c-fos protein by Western blots showed an increase in the protein level at 1-2 hrs after 100 mM H2O2 treatment. Interestingly, c-fos protein showed posttranslational modification as shown by slower migrating bands on Western blots. Using the type 2 serine/threonine phosphatase (PP2A), we are able to shift the intensity of the upper band to the lower band of c-fos in the nuclear extract, suggesting that c-fos is phosphorylated in cardiomyocytes by H2O2 treatment. The cytosolic extracts show 3 bands of c-fos protein which were abolished following incubation with PP2A. With immunoprecipitated c-fos protein from the cytosol, dephosphorylation with PP2A did not cause a loss of the c-fos protein, suggesting the possibility that phosphorylation of c-fos

protein protects it from being degraded. Using pharmacological inhibitors, we found that JNKs but not PI3K, p70S6K, ERKs or p38 are likely the upstream regulators of c-fos phosphorylation. In conclusion, we show a novel mechanism of AP-1 regulation by c-fos phosphorylation.

390 GENERATION OF OXYGEN FREE RADICALS BY PEROXISOMICINE A1.

M. Zanatta-Calderon, L. Garza-Ocañas, O. Torres-Alanis and A. Piñeyro-Lopez. *Pharmacology and Toxicology, University.A.N.L., Monterrey, Nuevo Leon, Mexico.*

Dimeric anthracenones have been isolated from toxic plants of the genus Karwinskia. T-514 (Peroxisomicine A1) is one of these anthracenonic compounds which has been demonstrated that exhibit selective toxicity *in vitro* on tumor cells. At present, Peroxisomicine A1 is being assessed like anticancer drug in patients. A redox cycling mechanism has been suggested for anticancer activity and cytotoxicity of a number of drugs used in tumor therapy. Some of these drugs (anthracyclines) are structurally related to Peroxisomicine A1. In general these compounds induced oxygen free radicals formation. Activation of these compounds to reactive intermediates provided a rational explanation for their cytotoxic properties. The present study was undertaken to assess the production of oxygen free radicals by Peroxisomicine A1 *in vitro*. In addition the oxygen free radicals inhibition by antioxidant enzymes was also evaluated. The results showed that Peroxisomicine A1 readily form oxygen free radicals which were inhibited in presence of Superoxide dismutase and Catalase.

391 ROS-INDUCED HISTONE H3 PHOSPHORYLATION DOES NOT INVOLVE SITES NORMALLY ASSOCIATED WITH MITOTIC CHROMOSOMAL CONDENSATION.

A. H. Palmer, K. A. Cox, K. Tikoo, S. S. Lau, K. N. Dalby and T. J. Monks. *Center for Molecular and Cellular Toxicology , The University of Texas at Austin, Austin, TX.*

Treatment of renal proximal tubular epithelial (LLC-PK1) cells with the reactive oxygen species (ROS)-generating toxicant, 2, 3, 5-*tris*-(glutathion-S-yl)hydroquinone (TGHQ) causes extensive DNA damage and increases the phosphorylation of histone H3. This increase is concurrent with premature chromatin condensation, which may contribute to cell death. Phosphorylation of histone H3 at serines 10 and 28 contributes to the appropriate condensation of chromosomes during mitosis. These same residues can be phosphorylated by mitogen- and stress-activated kinase (MSK1) in response to treatments with UV-B and 12-*O*-tetradecanoylphorbol-13-acetate. To identify the role of MSK1 in the cellular events following TGHQ treatment, LLC-PK1 cells were transfected with wild-type or dominant-negative MSK1. [^{32}P] ortho-phosphoric acid labeled cells expressing wild-type or dominant-negative MSK1 showed no change in histone H3 phosphorylation after TGHQ treatment compared with empty-vector transfected cells. Accordingly, neutral red analysis showed no change in cytotoxicity between wild-type MSK1, dominant-negative MSK1, and empty-vector transfected cells. To determine if S10/S28 were involved in the increase in histone H3 phosphorylation after TGHQ treatment, Western analysis was performed using commercial antibodies for histone H3 phosphorylated at S10 or for histone H3 phosphorylated at S28. When LLC-PK1 cells were treated with TGHQ, both antibodies showed a decrease in the phosphorylation of histone H3 at S10/S28 compared to untreated cells. We conclude that the increase in histone H3 phosphorylation observed in cells undergoing ROS-induced cell death is not due to phosphorylation of S10 or S28, but perhaps a novel site responsive to ROS-induced DNA damage. (ES07784, ES07247, DK59491)

392 BIOLUMINESENT MEASUREMENT OF OXIDATIVE STRESS.

D. Jekic McMullen, S. E. Malstrom, D. West and L. Sambucetti. *LPTA, Xenogen Corporation, Alameda, CA.*

Transgenic mice expressing the luciferase gene under the control of the Heme oxygenase (HO-1) promoter (HO-1-luc) were used to measure oxidative stress. HO-1, also known as heat shock protein HSP32, is exquisitely sensitive to a very diverse set of stimuli and agents that cause oxidative stress and cellular toxicity. We previously reported HO-1-luc activity measured *in vivo* by the Xenogen IVISTM, low light imaging system, in response to compounds known to produce oxidative stress. Here we examined correlations between HO-1-luc expression, HO-1 protein levels and chemical toxicity. Effects of cadmium chloride (CdCl2)(3.7 mg/kg), doxorubicin (15 mg/kg) and thioacetimide (300 mg/kg) were studied from 6-48 hours in male and female mice. The greatest increase in HO-1-luc was observed in response to CdCl2 and lower responses were observed for doxorubicin and thioacetimide. To assess other markers of toxicity, selected tissues were harvested and examined. Histopathological changes indicated mild to severe tissue damage in response to all treatments. HSP70 protein levels, catalase activity and circulating enzyme levels of alkaline phosphatase (ALP), alanine aminotransferase (ALT), aspartate aminotransferase (AST) and creatine kinase (CK) were measured and found to reflect expected toxicity profiles. Western blot analysis demonstrated that the increase in endogenous HO-1 protein levels agreed temporally with HO-1-luc activity. These results suggest that the HO-1-luc transgenic mouse can be used as a model for *in vivo* screening of new and unknown compounds for their potential toxic effects.

393 CIGARETTE SMOKE AND ARSENIC SYNERGISTICALLY INCREASE DNA OXIDATION IN THE LUNG.

A. M. Hays and R. Lantz. *Cell Biology & Anatomy, University of Arizona, Tucson, AZ.*

Epidemiological evidence has indicated that cigarette smoking and arsenic exposure act synergistically to increase the incidence of lung cancer. Oxidative damage of DNA has been linked to cancer. Our hypothesis is that aerosolized arsenic and cigarette smoke work synergistically to decrease both reduced and total glutathione and increase DNA oxidation in the lung. To test this hypothesis male Syrian golden hamsters were exposed to room air (control), aerosolized arsenic trioxide (3 mg/m^3 for 30 minutes), cigarette smoke (5 mg/m^3 for 30 minutes), or both smoke and arsenic. Exposures were for 5 days/week for 5 and 28 days. Animals were sacrificed one day after the last exposure. In the 28 day group, glutathione was determined from the lungs of animals exposed to arsenic and/or cigarette smoke using HPLC. Results are reported as nmoles/mg lung tissue. In this same group, DNA oxidation (8-oxo-2'-deoxyguanosine (8-oxo-dG)) was quantified from genomic DNA extracted from lungs of animals exposed to arsenic and/or cigarette smoke using HPLC. In the 5 day group, the lungs were processed for immunohistochemistry. An antibody against 8-oxo-dG was used to analyze DNA oxidation in the lung using confocal microscopy. Our results show that in the 28 day group there was a significant increase in DNA oxidation, and a significant decrease in both the reduced and total glutathione levels in the combined arsenic/smoke group when compared with arsenic or smoke alone. In the 5 day group, while glutathione levels were decreased in the combined exposure group, total lung 8-oxo-dG was not significantly increased. However, in the five day exposures, we found that the combined arsenic/smoke-exposure group showed an increase in nuclear staining of the 8-oxo-dG over that of controls. This effect was seen mostly in the small airways. (Supported in part by NIEHS Grant P30 ES06694).

394 FEMALE MICE TRANSGENIC FOR MITOCHONDRIAL-DIRECTED CATALASE HAVE ALTERED GLUTATHIONE REDOX CYCLE ENZYME ACTIVITIES COINCIDENT WITH TISSUE SPECIFIC CATALASE EXPRESSION.

S. Shi[1], M. B. Hendsch[1], C. E. Ogburn[2], P. S. Rabinovitch[2], G. M. Martin[2] and T. Kavanagh[1]. [1]*Environmental Health, University of Washington, Seattle, WA and* [2]*Pathology, University of Washington, Seattle, WA.*

Oxidative stress is thought to contribute to many diseases associated with aging including cancer, atherosclerosis, diabetes mellitus, and chronic neurological disorders such as Parkinson's and Alzheimer's diseases. In lower organisms, it has been shown that overexpression of antioxidant enzymes leads to increased scavenging of reactive oxygen species and a prolongation of life. We wished to determine if this also applied to mammals. Accordingly, we have created transgenic mice which overexpress human catalase in mitochondria (mCAT mice), with exceptionally strong overexpression in heart and skeletal muscles. Two independently derived mCAT founder lines were found to have increased expression of catalase in cardiac and skeletal muscle, and cells cultured from these animals displayed increased resistance to oxidative insult. We wished to determine what effect overexpression of catalase in mitochondria has on the activity of another system used by cells for scavenging hydrogen peroxide, namely, enzymes of the glutathione redox cycle. Brains, spleens, liver, heart, skeletal muscle, kidney and lungs from male and female mCAT transgenic mice and non-transgenic litter mates of different ages were assayed for glutathione peroxidase, glutathione reductase, and glucose-6-phosphate dehydrogenase activities. GPx and GRx enzyme activities were increased in skeletal muscle of female mCAT mice, but no significant differences from controls were noted in other organs examined from both sexes. In addition, no significant age-related changes in activity were noted in the activity of any of these enzymes. These changes suggest co-regulation of these two hydrogen peroxide scavenging systems. Supported by NIH grants P42ES04696, P30AG01571, and P30ES07033.

395 LIPID PEROXIDATION IN FATHEAD MINNOW GILLS.

E. G. Spokas[1], J. M. Levine[1], B. W. Spur[1], H. Smith[1], J. D. Bogden[2], F. W. Kemp[2], W. Li[2] and G. M. Cohen[3]. *[1]Cell Biology, UMDNJ-School of Osteopathic Medicine, Stratford, NJ, [2]Preventive Medicine and Community Health, UMDNJ-New Jersey Medical School, Newark, NJ and [3]Biological and Environmental Sciences, Troy State University, Troy, AL.*

This study was carried out to evaluate whether in vitro exposure of isolated whole gills to the heavy metal lead (Pb) results in lipid peroxidation injury. Isoprostanes (iPs) were used as a marker in this study; viz., immunoreactive 8-iso-PGF2α (iPF2α-III). Isolated gills of *Pimephales promelas* (fathead minnow) were incubated in 10 ml of oxygenated modified Cortland's saline medium. Two experimental designs were used to determine the time course of the release of iPs from control gills (no Pb present): 1) sampling small aliquots (200 µl) of medium at 20 min intervals without medium replacement, and 2) complete replacement of the medium at successive 20 min intervals by rapidly decanting and adding fresh oxygenated Cortland's saline. These two experimental designs yielded dramatically different results. For example, when small aliquots were removed at 20 min intervals, virtually all of the iP release occurred during the initial 20 min, whereas when all of the medium was replaced every 20 min, the cumulative release of immunoreactive 8-iso-PGF2α increased almost linearly over the 100 min observation period. The ability of Pb to cause oxidative stress was examined in similar experiments wherein medium was collected at only one time point (after 60 min of incubation). Gills incubated with Pb(NO3)2; either 12, 60 or 120 µM, for 60 min exhibited a dose-dependent reduction in the ratio of reduced to oxidized glutathione (GSH/GSSG). At the highest levels of iP release, tissue levels of total glutathione (GSH + GSSG) tended to correlate negatively with iP release. The results indicate that exposure of isolated whole gills to Pb results in direct oxidative damage to gill membranes. In addition, we conclude that teleost gills are exquisitely sensitive to lipid peroxidation injury as determined by measurement of iP release. SUPPORTED BY NIEHS GRANT 1R15ES09434 01A1

396 FREE RADICAL FORMATION IN THE RAT KIDNEY INDUCED BY CYCLOSPORIN A: PREVENTION BY DIETARY GLYCINE, RENAL DENERVATION, AND GREEN TEA POLYPHENOLS.

Z. Zhong[1], H. D. Connor[2], R. P. Mason[2], N. Moss[3], J. J. Lemasters[1] and R. G. Thurman[4]. *[1]Cell and Developmental Biology, University of North Carolina, Chapel Hill, NC, [2]NIEHS, Research Triangle Park, NC, [3]Physiology, University of North Carolina, Chapel Hill, NC and [4]Pharmacology, University of North Carolina, Chapel Hill, NC.*

BACKGROUND: Cyclosporin A (CsA) causes vasoconstriction and nephrotoxicity. Here, we investigated the role of hypoxia and free radical production in renal injury caused by CsA. **METHODS:** Rats were treated daily with CsA (25 mg/kg, i.g.) for 5-21 days. Pimonidazole, a hypoxia marker, was injected 2 h after CsA. POBN (α-(4-pyridyl 1-oxide)-*N*-tert-butylnitrone) was injected 3 h after CsA to trap free radicals. **RESULTS:** CsA doubled serum creatinine and decreased glomerular filtration rates (GFR) by 65%. Pimonidazole adduct binding in the kidney was increased 3-fold by CsA, providing physical evidence for tissue hypoxia. Dietary supplementation of glycine (5%), an inhibitory neurotransmitter, blunted hypoxia caused by CsA. Moreover, CsA increased POBN/radical adducts 4-fold in the urine but did not alter levels in the serum. Administration of CsA with ^{12}C-DMSO produced two radical species in urine, one with hyperfine coupling constants similar to the 4-POBN/methyl radical adduct, a product of hydroxyl radical attack. CsA given with ^{13}C-DMSO produced a 12-line spectrum, confirming the formation of hydroxyl radicals. Increases in free radical production and decreases in GFR were attenuated by glycine, renal denervation and dietary green tea polyphenols (0.1%) which are potent free radical scavengers. CsA infusion for 30 min increased efferent renal nerve activity 2-fold. Dietary glycine totally blocked this phenomenon. **CONCLUSION:** Taken together, these data support the hypothesis that CsA causes renal injury, at least in part, by increasing renal nerve activity resulting in hypoxia-reoxygenation. Moreover, CsA nephrotoxicity can be prevented effectively by dietary glycine which causes vasodilatation thus minimizing hypoxia/reperfuion and by free radical scavenging green tea polyphenols.

397 EFFECTS OF ORAL EXPOSURE TO METHYL *TERTIARY*-BUTYL ETHER ON REACTIVE OXYGEN SPECIES IN SPECIFIC RAT BRAIN REGIONS.

L. Forrester, E. Oriaku and M. R. Soliman. *College of Pharmacy, Florida A&M University, Tallahassee, FL.*

Methyl tertiary-butyl ether (MTBE) is added to gasoline to boost octane and enhance combustion, thereby reducing carbon monoxide and hydrocarbon emissions. However, it has become a contaminant of surface water and groundwater due to its high solubility in water. MTBE is neurotoxic and has been shown to affect motor activity in laboratory animals. The mechanism by which MTBE exerts this toxicity is still unclear. Oxidative stress has been shown to play a major role in the neuronal cell death associated with neurodegenerative diseases such as Parkinsons disease, which is clinically manifested as motor impairment. The present study was conducted to evaluate the effects of sub-acute oral exposure to MTBE on the levels of Reactive Oxygen Species (ROS) and the activity of Catalase (CAT), Superoxide Dismutase (SOD), Glutathione Peroxidase (GPx), Glutathione Reductase (GR) as well as Glutathione (GSH) levels. Male Sprague-Dawley rats (n=8/group) were used in this study and were orally exposed to MTBE in drinking water (0, 150, 300, 900, 1200, 2400, and 3600 ppm for 14 days). At the end of the 14 days, animals were sacrificed by decapitation, their brains removed and the levels of ROS and antioxidant activities were measured in the prefrontal cortex and hippocampus. There were no significant differences among groups in body weight gain and absolute brain weights MTBE exposure resulted in a significant ($p < 0.01$) increase of ROS in the cortex at all dose levels except the 150 ppm, but caused an increase of ROS levels in the hippocampus only at the 1, 200 and 3, 600 ppm dose levels ($p < 0.01$ and $p < 0.05$, respectively). MTBE also augmented SOD, CAT, GR, GPx, and GSH activity in the cortex and hippocampus, the regions associated with motor activity and behavior. These results clearly show that MTBE not only increases ROS levels but also induces an impairment of antioxidant enzymes which indicates oxidative stress. These findings suggest that MTBE-induced oxidative stress may in part explain its effects on locomotor activity. (Supported by NIH Grant RR03020).

398 DOXORUBICIN INHIBITS FERRYLMYOGLOBIN-DEPENDENT LIPID PEROXIDATION.

G. Minotti, P. Menna, E. Salvatorelli and R. Giampietro. *Department of Drug Sciences, University of Chieti School of Medicine, Chieti, Italy.* Sponsor: S. Aust.

Doxorubicin (DOX) and other anticancer anthracyclines can cause cardiomyopathy attributed to oxyradical- and iron- dependent lipid peroxidation. However, we have shown that DOX can both facilitate formation and diminish reactivity of non heme iron-centered lipid oxidants; moreover, chain-breaking antioxidants seem to prevent anthracycline-induced cardiomyopathy in laboratory animals but not in patients. Little is known on the effects of DOX on heme iron-derived lipid oxidants. Myoglobin (Mb) is the most abundant source of heme iron in the heart. Hydrogen peroxide (H_2O_2), generated through the redox cycling of DOX, oxidizes Mb to an oxoferryl species (Mb^{IV}) that promotes lipid peroxidation; therefore, we evaluated whether DOX diminished the reactivity of Mb^{IV} the same way it diminished that of non heme-iron derived oxidants. Mb^{IV} was formed *in vitro* by reacting H_2O_2 with metmyoglobin (Mb^{III}). Optical spectroscopy showed that DOX reduced Mb^{IV} to Mb^{III} with an apparent second order rate constant of 1.3×10^3 M^{-1} s^{-1}. Comparisons between DOX and other approved or investigational anthracyclines showed that DOX reduced Mb^{IV} through a hydroquinone moiety in its tetracyclic ring. DOX did not promote complete reduction of Mb^{IV} to $Mb^{II}O_2$, but limited reduction of Mb^{IV} to Mb^{III} was sufficient to prevent peroxidation of arachidonic acid to thiobarbituric acid-reactive substances. DOX inhibited lipid peroxidation also when Mb^{IV} was formed in cytosolic fractions derived from human myocardial biopsies, a model developed to predict the biochemical mode of action of anthracyclines in clinical settings. These results argue against an involvement of lipid peroxidation in anthracycline-induced cardiotoxicity, as they confirm that DOX can inactivate lipid oxidants possibly formed in the heart during the course of chemotherapy. Pharmacologic measures to prevent anthracycline-induced cardiomyopathy should therefore be reappraised and targeted to biochemical events other than lipid peroxidation.

399 OXYGEN TOXICITY: A METABOLIC DISEASE.

J. Li[1], X. S. Gao[2], M. W. Qian[2] and J. W. Eaton[2]. *[1]Department of Pharmacology and Toxicology, University of Louisville, Louisville, KY and [2]Department of Medicine, University of Louisville, Louisville, KY.* Sponsor: D. Hein.

Prolonged exposure of mammals to increased partial pressures of oxygen (hyperoxia) causes progressive damage to the lung. It has been suggested that hyperoxic damage may derive from enhanced formation of reactive oxygen species (ROS) and mitochondria are probably the major source of this reactive oxygen. We hypothesized that if mithochondrial metabolism were responsible for enhanced ROS production under hyperoxia, then cells with impaired mitochondrial respiration might be relatively resistant to increased oxygen tensions. To test this general idea, we produced rho0 HeLa cells which lack mitochondrial DNA, mitochondrial membrane potential and respiration by long term exposure to ethidium bromide (EB). Under both normoxia and hyperoxia (80% O2), these cells exhibited greatly decreased ROS production as assessed by (1) dichlorofluorescein (DCFH) oxidation, (2) dihydroethidium oxidation, (3) ROS-mediated suppression of aconitase activity and (4) cell survival under hyperoxia. The ROS generation is largely mitochondrial because the protonophoric uncoupler, carbonyl cyanide m-chloro phenylhydrazone (CCCP) reduced ROS production under both normoxia and hyperoxia by >80%.

As a control for ancillary EB DNA damage, we also re-introduced normal mitochondria to these rho0 cells *via* platelet fusion and found that ROS production and cell survival once again resembled that of the wild type Hela cells. Finally, we grew HeLa cells in the presence of chloramphenicol (which disrupts the synthesis of mitochondrial inner membrane proteins and suppresses both respiration and mitochondrial ROS production). Under 80% O2, these cells were quite resistant to hyperoxic damage and death. Overall, these results support the concept that interactions between respiring mitochondria and O2 are primarily responsible for hyperoxic cell damage. These observations further suggest that hyperoxic damage might be averted through the use of pharmacological agents which preferentially diminish mitochondrial respiration.

400 COMPARISON OF COMPOUND CLASSIFICATIONS DETERMINED FROM STRUCTURAL ALERTS FOR RODENT CARCINOGENICITY EXTRACTED FROM DIFFERENT DATABASES.

M. A. Cheeseman[2], N. Collazo-Braier[2], M. L. Twaroski[2], J. Mayer[2], C. Yang[1], G. J. Myatt[1] and P. E. Blower[1]. *[1]LeadScope, Inc., Columbus, OH and [2]CFSAN, USFDA, Washington D.C., DC.*

Toxicity endpoints reported in various sources vary widely. A major challenge in data analysis, especially with regard to developing predictive models, is dealing with disparate forms of data, ranging from continuous numerical values to categorical responses. For example, although the compound set having rodent carcinogenicity data in the NTP database is a complete subset of the CPDB database, the latter uses TD50 as a measure of carcinogenicity potency of a compound, whereas NTP reports nominal degrees of evidence. Structure alerts are extracted from the CPDB dataset using TD50 values as the response variable. Certain compound classes that correlate strongly with TD50 were identified for descriptive usage: therapeutic categories, fungicide, pesticide, etc. The same analysis was performed using the nominal 0/1 NTP response data. The structure alerts mined from these two data sources were compared for rodent models. Structural alerts were applied to then build prediction models.

401 DEVELOPMENT OF A DATABASE FOR QUANTITATIVE MODELING OF AGE-RELATED CARCINOGENICITY STUDIES.

M. K. MacGregor, T. A. McDonald, R. Schlag, R. Tomar, S. Yaghoubie, C. D. Sherman, M. S. Sandy and L. Zeise. *Office of Environmental Health Hazard Assessment, Cal/EPA, Oakland, CA.*

In support of the California Childrens Environmental Health Initiative (AB 2872), we have developed a relational database consisting of data extracted from published animal cancer bioassays that utilized exposures early-in-life. To date, we have identified over 1200 cancer bioassays with early-in-life exposure data on over 40 different compounds or substances representing different mechanisms of action that range from direct-acting genotoxic carcinogens to endocrine disruptors. These substances include alkylating agents, polycyclic aromatic hydrocarbons, hormones and hydrazines. Based on available developmental information on several species including rats, mice, hamsters, gerbils and non-human primates, the following four exposure windows were defined for each species: prenatal, postnatal, juvenile and adult. Strict selection criteria have been developed for inclusion in the database. The publication must contain data on approximate age at dosing, age at death/sacrifice, and tumor incidence data. The study must be on a single chemical or mixture, contain a concurrent control group, have a study length greater than 40 weeks and report a survival rate greater than 60% (except for early death due to neoplasms). Results of the literature review will be presented along with the methods of literature identification, rationale for including experiments and conventions adopted in summarizing and standardizing the extracted data. In addition, a complete description of the database structure and function will be demonstrated. This database is being used to support quantitative analysis of differential responses to cancer induction by age at exposure and to identify trends in tumor response related to specific chemicals, classes of compounds, and common modes of action. Such analyses may help to determine if an early-life susceptibility is anticipated in the absence of specific compound data.

402 DIET OPTIMIZATION AND BODY WEIGHT GROWTH RATE IN RATS - EFFECTS ON SURVIVAL, TUMOR INCIDENCE AND HISTOPATHOLOGY.

C. Auletta, H. F. Bolte and S. J. Gosselin. *Huntingdon Life Sciences, Huntingdon, United Kingdom.*

Appropriate study designs to assure adequate survival of rats in chronic studies have been the topic of much discussion in the toxicology community. One way to enhance survival is to moderately restrict feed and, therefore, growth (diet optimization). A possible alternative is the use of rats which are smaller and slower-growing and should, therefore, have enhanced survival. This poster presents data on survival, tumor incidence and histopathology for rats using these two alternatives and compares these data to data from rats using the traditional (ad libitum feeding) protocol. 200 Charles River Sprague-Dawley rats (IGS) were divided into 2 groups of 100 (50/sex). One group received food ad libitum (AL) and one group (Optimization - Opt) received mild to moderate diet restriction (75 to 90% of ad libitum group). Data were compared for these 2 groups and for a group of 240 (120/sex) ad libitum fed Harlan Spargue-Dawley rats, which are smaller and grow more slowly than the Charles River rats. Survival was similar for the Harlan and AL rats (24-28% for males and 46-53% for females) and clearly higher for the Opt group (84% for males and 80% for females). Dietary optimization decreased the incidence of pituitary tumors (adenomas of the pars distalis) in both sexes and of mammary gland tumors (adenocarcinomas) in females when compared to ad libitum fed IGS rats. Incidence of these neoplasms in Harlan rats was similar to that seen in Opt rats. [Pituitary Tumors: Males: Opt: 10%, Harlan: 13%, AL: 36%; Females: Opt: 48%, Harlan: 34%, AL: 82%] [Mammary Gland Tumors (Females): Opt: 24%, Harlan: 18%, AL: 34%]. Dietary optimization also reduced the incidence and severity of microscopic lesions in the liver and kidney, when compared to ad libitum fed IGS rats.

403 TOXICITY EVALUATION OF A LIPOSOME-BASED FORMULATION OF SN38 IN MICE.

A. Sarkar, N. Kamath, D. Carbonaro, S. Sheikh, A. Zhang, S. Ali and I. Ahmad. *NeoPharm Inc., Waukegan, IL.* Sponsor: S. Khan.

SN38 is an active metabolite of CPT-11, an anti-neoplastic agent, prescribed for the treatment of colorectal cancer. SN38 contributes to the anti-tumor activity and toxicity of CPT-11. SN38 is 100-1000 fold more potent than CPT-11 *in vitro*. Due to unavailability of a suitable solubilizing agent, SN38 has not been exploited for therapeutic use as an anti-cancer agent. In general, the liposome encapsulation of anti-cancer drugs reduces the toxicity and thus enhancing the therapeutic efficacy. A liposome-based formulation of SN38 (LE-SN38) was developed at NeoPharm using proprietary NeoLipidTM Technology to overcome some of the problems associated with SN38. Significant increased *in vitro* cytotoxicity and therapeutic efficacy of LE-SN38 vs. CPT-11 against various tumor models, prompted us to evaluate the toxicity of LE-SN38 in CD2F1 mice. The acute dose toxicity data suggested a maximum tolerated dose of 37 and 46 mg/kg in males and females respectively. The multiple dose toxicity (i.v.x5 daily) study suggested a tolerated dose of 5 and 7.5 mg/kg in males and females respectively. The hematology and clinical chemistry results showed reversible toxicity. At higher doses the lesions were observed in small intestine, liver, lung and spleen. However, the liver was predominantly affected organ in the male animals. These lesions were greatly reduced or absent on day 20. Phase I clinical trials of LE-SN38 are planned.

404 THE LACK OF CARCINOGENICITY IN A 26-WEEK INTRAVENOUS STUDY WITH S-303-TREATED MOUSE RED BLOOD CELLS IN C57BL/6TAC-TRP53TML HETEROZYGOTE MICE.

V. Ciaravino[1], T. McCullough[1], T. Sullivan[1] and J. Ivett[2]. *[1]Cerus Corporation, Concord, CA and [2]Covance Laboratories, Inc., Vienna, VA.*

The INTERCEPT Blood System for Red Blood Cells has been shown to inactivate a broad range of viruses, bacteria, and leukocytes in red blood cells (RBC) using the compound S-303 in an *ex vivo* process. S-303 was designed to react rapidly with nucleic acid and then decompose by an independent hydrolytic step. After addition to RBC, S-303 intercalates into nucleic acids, forms covalent DNA and RNA cross-links, and hydrolyzes to a negatively charged unreactive decomposition product, S-300. An indwelling Compound Adsorption Device (CAD) integral to a 35-day RBC storage container is used to reduce levels of residual S-300 by ~10-fold. The study evaluated the potential oncogenicity of S-303-treated mouse blood components (RBC and plasma) with and without CAD exposure when administered IV at 20 mL/kg, to groups of 20 mice/sex for 26 weeks. The treatment regimens ranged from 1 mM S-303-treated RBC with CAD exposure once weekly (~10 times the clinical dose) to 1 mM S-303-treated RBC without CAD exposure once per week + 1 mM S-303-treated mouse plasma without CAD treatment twice per week (~100-fold the clinical dose). Chronic transfusions for sickle cell or thalassemia patients occur at an approximate frequency of once monthly. Therefore, the doses used in the study were 40-to 1200-fold the clinical exposure based on dose and frequency. A positive control group received p-cresidine by daily oral gavage at 400 mg/kg. Mice were observed for evidence of mortality and moribundity. Body weight and food consumption were measured during the study. After 26 weeks of treatment, mice were bled for hematologic evaluations, euthanized, and evaluated macroscopically. Tissues from all mice were processed for histopathologic evaluation. The positive control caused urinary bladder transitional cell hyperplasia and transitional/squamous cell carcinoma, findings consistent with previous 2-year mouse bioassay data for this compound. No S-303-related toxicities or evidence of S-303-induced carcinogenicity were observed.

405 THE FAILURE OF CHLOROFORM ADMINISTERED IN THE DRINKING WATER TO INDUCE RENAL CELL CANCER IN THE F344/N RAT.

A. B. DeAngelo, M. H. George, S. Kilburn and D. R. Geter. *NHEERL, USEPA, Research Triangle Park, NC.*

Chloroform (TCM) has been demonstrated to be a renal carcinogen in the male Osborne-Mendel rat when administered either by corn oil gavage or in drinking water. We examined the ability of TCM in the drinking water to enhance renal tubular cell (RTC) cancer in the Male F344/N rat. Animals (78/group) were exposed to concentrations of 803 ± 5 or 1592± 21 mg/L TCM in the drinking water for 100 weeks. Distilled water served as the vehicle control; lead acetate, 2000 mg/L, was the positive control. A complete necropsy was done at 100 weeks. Water consumption did not differ among the groups. Mean daily doses of 53, 126, and 132 mg/kg were calculated for the low and high dose TCM and lead acetate respectively. Mean body weight was significantly depressed by TCM treatments. No RTC tumors were found in the control or in the TCM groups. Lead acetate increased ($p<0.05$) the incidence of RTC carcinoma (12.8%), adenoma (10.3%) and hyperplasia (100%) compared to 7.7% for hyperplasia in the control. No RTC hyperplasia was seen in the THM groups. The high TCM dose increased the prevalence (% of animals with a lesion) of hepatocellular neoplasia (carcinoma and adenoma) 17.5% vs 5.1% ($p<0.05$) and marginally enhanced the prevalence of combined preneoplastic and neoplastic tumors (20.5% vs 7.7%, $0.05<p<0.1$). The numbers of combined neoplasms (0.18 vs 0.05). Combined preneoplastic and neoplastic lesions (0.23 vs 0.05) were also increased ($p<0.05$). RTC proliferation at 100 weeks was depressed by 132 mg/kg/day TCM. TCM and lead acetate significantly depressed the severity of RTC hyaline droplets. These results are similar to those recently described (George, MH et al. 2002, Internat. J. Toxicol., 21, 219-230) in which bromodichloromethane (BDCM) in the drinking water of male F344/N rats failed to induce RTC and colon cancer which had been reported in a corn oil gavage. BDCM did, however, increase hepatocellular neoplasia. (This is an abstract of a proposed presentation and does not reflect the views of the EPA)

406 EFFECTS OF BISPHENOL A, AN ENDOCRINE DISRUPTOR, ON HEPATOCARCINOGENESIS AND REPRODUCTIVE SYSTEM PARAMETERS IN A MEDIUM-TERM LIVER BIOASSAY.

T. Ichihara[1,2], N. Imai[1], S. Tamano[1], K. Imaida[3] and T. Shirai[2]. *[1]Daiyu-Kai Institute of Medical Science, Ichinomiya, Japan, [2]Department of Exp. Pathol. and Tumor Biol., Nagoya City University, Nagoya, Japan and [3]Department of Onco-Pathol., Kagawa Med. University, Kita, Japan.*

Bisphenol A (4, 4-isopropylidene-2-diphenol, BPA) is a high-production volume chemical used in manufacture of polycarbonate plastics. It is of great concern as an example of an estrogenic xenobiotic and the present study was performed to investigate its potential influence on rat hepatocarcinogenesis in a medium-term liver bioassay system. In addition, its influence on male accessory organs and spermatogenesis was examined. A total of 78 rats were divided into 6 groups. The rats in groups 1 to 4 were given a single i.p. injection of DEN (200 mg/kg body weight) dissolved in saline to initiate hepatocarcinogenesis. Groups 5 and 6 received a saline injection instead of DEN. After 2 weeks, the rats in groups 1 and 5 were maintained on basal diet without BPA. Animals in groups 2-4 and 6 received diet containing 25, 250, 2000 and 2000 ppm BPA, respectively, for the remaining experimental duration of 6 weeks. All rats were subjected to two-thirds partial hepatectomy at week 3 and survivors were sacrificed under ether anesthesia at week 8 for examination of livers immunohistochemically for glutathione S-transferase placental form (GST-P)-positive foci. Significant retardation of body weight gain was observed in rats treated with 2000ppm BPA. No modifying potential was evident in terms of numbers or areas of GST-P-positive foci. Furthermore spermatogenesis was not affected in any of the treated groups. These results demonstrate that BPA lacks initiating or modifying potential for liver carcinogenesis in our medium-term bioassay system.

407 INACTIVITY OF 2-HYDROXYESTRADIOL, 4-HYDROXYESTRADIOL, ESTRIOL, AND 4-HYDROXYESTRONE AS MAMMARY CARCINOGENS IN THE ACI RAT.

V. K. Turan[1], A. H. Conney[1,2], J. J. Li[4], S. A. Li[4], K. R. Reuhl[1,3] and P. E. Thomas[1,2]. *[1]Joint Grad Prog in Toxicology, Ernest Mario School of Pharmacy, Rutgers University, Piscataway, NJ, [2]Lab. for Cancer Res, Ernest Mario School of Pharmacy, Rutgers University, Piscataway, NJ, [3]Pharmacol and Toxicology, Ernest Mario School of Pharmacy, Rutgers University, Piscataway, NJ and [4]Kansas Cancer Inst, University of Kansas Medical Center, Kansas City, KS.*

The ACI rat, an inbred cross between August and Copenhagen Irish strains, is a valuable model in the study of factors modulating susceptibility to mammary carcinogenesis. ACI rats are highly susceptible to mammary carcinogenesis when estrogen levels are continuously elevated. This study investigated whether metabolites of estradiol were more or less effective than estradiol as complete carcinogens in this animal model. Adult female, ovary-intact ACI rats were implanted subcutaneously with pellets composed of either cholesterol vehicle or cholesterol (18 mg) and 2 mg estradiol, 2-hydroxyestradiol, 4-hydroxyestradiol, estriol, or 4-hydroxyestrone. The rats were monitored for mammary tumor incidence, markers of estrogen action, and general health. Rats treated with estriol had significantly reduced body weight compared to all treatment groups with the exception of estradiol. The food consumed per body weight of rat did not differ between the estriol and vehicle treated rats, demonstrating that this effect is not due to appetite suppression. The study was ended after 36 weeks of treatment. Rats treated with estradiol had 73% incidence of palpable mammary tumors, but none of the animals treated with the vehicle or estradiol metabolites had palpable mammary tumors. In some experimental models where estrogen shows toxicity, the proposed mechanism of toxicity has involved primary metabolites of estradiol. However, in this ACI rat model in which estradiol induces mammary tumors, the metabolites prove to be ineffective at mammary tumorigenesis. (Supported by ES05022, ES07148)

408 THE ARYL HYDROCARBON RECEPTOR (AHR) REGULATES PROSTATE TUMOR PROGRESSION IN THE TRAMP MOUSE.

W. A. Fritz, T. Lin, R. W. Moore and R. E. Peterson. *School of Pharmacy, University of Wisconsin, Madison, WI.*

The AhR is a signal transduction protein that binds chlorinated dioxins, other xenobiotics, and putative endogenous ligands and mediates their effects on gene expression in various organs including prostate. We previously demonstrated that the AhR is necessary for normal prostate development. We have now interbred AhR null mutant mice with transgenic adenocarcinoma of the mouse prostate (TRAMP) mice to test the hypothesis that the AhR signaling pathway can affect prostate cancer development. TRAMP mice express SV40 T antigen under control of a rat probasin promoter to develop prostate cancer. TRAMP mice of each *Ahr* genotype were necropsied at 105, 140, 175 and 210 days of age to determine the incidence of macroscopic poorly differentiated prostate tumors (CaP). Mice died from CaP as early as 105 days and with much greater frequency at 175 days of age and older. The incidence of CaP in $Ahr^{+/+}$ TRAMP mice was 0/1, 1/15, 3/15 and 1/23 at 105, 140, 175 and 210 days of age, respectively. In TRAMP mice lacking one *Ahr* allele ($Ahr^{+/-}$), the incidence of CaP was much higher (3/20, 14/45, 16/37 and 8/31, respectively) than when both alleles were present. An even higher CaP incidence was observed in $Ahr^{-/-}$ TRAMP mice, which lack both *Ahr* alleles (1/4, 9/17, 8/10 and 3/4, respectively). These differences do not appear to be due to *Ahr*-dependent differences in TRAMP transgene expression because (1) large T antigen was comparably detectable, by immunohistochemistry, in prostatic epithelial cells of mice of each *Ahr* genotype, and (2) mice of each *Ahr* genotype exhibited comparable incidences and degrees of prostatic intraepithelial neoplasia. These results demonstrate that the AhR signaling pathway regulates the progression phase of prostate cancer development, and suggest that *Ahr* may be a tumor suppressor gene. (Supported by NIH grant ES 01332).

409 TIME TO FATAL TUMOR IN P53 KNOCKOUT MICE.

A. O. Chiu[1], C. Chen[1], N. Chiu[2], D. Singh[1], J. Beaubier[3] and L. Donehower[4]. *[1]NCEA, ORD, USEPA, Washington, DC, [2]OST, ODW, USEPA, Washington DC, DC, [3]OPPT, USEPA, Washington DC, DC and [4]Depts Mol Virol & Microb Mol Cell Biol, Baylor Coll Med., Houston, TX.*

P53 knockout mice were generated by gene targeting strain129 mice at Baylor University. Heterozygous P53 +/- F1 mice were crossbred to generate homozygous P53 -/- and P53 +/+ mice. More than 400 animals were bred and divided into 3 groups. We analyzed time to death and tumor type data with parametric and non-parametric statistical models. Only a limited number of critical events ($1 < n <= 10$) are possible in the chain affecting the cell-cycle in these animals. Malignant lymphoma, soft tissue sarcoma and various carcinomas cluster at different time intervals of their life spans. The homozygous P53- /- died mostly from a thymic lymphoma in less than nine months versus one year typical of heterozygotes. About half of this lymphoma resulted from a loss-of-heterozygosity. Soft tissue sarcoma time-to-death was similiarly affected by P53 genetic status. Osteogenic sarcoma was lower among homozygous recessives versus heterozygotes. Carcinoma frequency was low in both homozygous and heterozygous P53 knockout mice.

410 26-WEEK VALIDATION STUDY OF THE Tg.rasH2 MOUSE TEST SYSTEM USING THREE CARCINOGENS.

D. Jacobson-Kram[1], D. Gulezian[2], M. L. Wenk[1], L. L. Lanning[3] and G. B. Smith[1]. *[1]Mammalian Toxicology, BioReliance Corporation, Rockville, MD, [2]Transgenic Models and Services, Taconic, Germantown, NY and [3]Subcontracted Pathologist, Middletown, MD.*

The Tg.rasH2 mouse carries multiple copies of the human protooncogene c-Ha-ras linked to its endogenous promoter/enhacer and is recommended for genotoxic and non-genotoxic carcinogen identification. Short term carcinogenicity assays con-

ducted using this model are acceptable alternatives to traditional carcinogenicity testing as described in the ICH S2B document. With this in mind and anticipated increases in the use of the Tg.rasH2 model in the US, we performed a 26-week validation study in which the effects of three carcinogens were examined. Two groups of ten animals per sex and one group of nine animals per sex were administered N-methyl-N-nitrosourea (MNU) (single i.p. dose, 75 mg/Kg), urethane (three i.p. doses at two day intervals, 1000 mg/Kg), and p-cresidine (i.g. daily for 26-weeks, 400 mg/Kg), respectively. One other group of ten animals per sex was administered corn oil for 26 weeks by daily oral gavage. Preliminary results indicate MNU-mediated toxicity presented as decreased bodyweights and the presence of a palpable axillary mass in one animal. One early death was recorded due to bladder distention likely resulting from blockage of the urethral canal in a female animal treated with urethane. Interestingly, papilloma formation was observed at the site of tail tattoo in five male animals and 4 female animals treated with MNU, and in one female animal treated with urethane. The presence of papillomas at the site of tail tattoo in treatment groups implicates a possible synergy between sytemic carcinogen administration and the tissue repair and proliferation following damage from tattooing. These results, although preliminary, indicate the necessity for validation studies and the creation of an historical database demonstrating the responses of this test system to various classes of carcinogens. Further investigation of the interaction between carcinogens and skin wounding or other pseudo-promotional events may prove valuable.

411 EVALUATION OF ALTERNATE DOSE METRICS FOR BENZO[A]PYRENE INHALATION CANCER POTENCY USING A NASAL-PBPK HAMSTER MODEL.

A. G. Salmon, J. P. Brown, J. F. Collins and M. A. Marty. *Office of Environmental Health Hazard Assessment, Cal/EPA, Oakland, CA.*

The current OEHHA inhalation cancer potency of 1.1E-3 $(\mu g/m^3)^{-1}$ is based on an applied dose metric and upper respiratory tract (URT) tumors in hamsters (Thyssen et al. 1981). A 13 compartment nasal-physiologically-based pharmacokinetic model was used to evaluate the ability of various dose metrics and dose averaging to provide an improved fit by the observed URT tumor incidence (Frederick et al., 1998). The model employed physiological and biochemical parameters scaled from a 380g rat to a 120 g hamster. Nasal biochemical values were estimated from dog tracheal epithelium (Gerde et al., 1997). Rates of hydrolysis and conjugation of the BAP oxidative metabolite were estimated from mean rodent values for butadiene monoxide (Kohn and Melnick, 1993). Two model forms were used: 1) a single species BaP model with metabolized dose (AMET) metrics in liver, lung and nasal tissue; and 2) a twin species BaP/BaP metabolite model with concentration based metrics for the BaP metabolite in the nasopharynx compartment. In both models daily exposures in mg/m3 were regressed against the best fitting model-derived internal metrics to estimate external equivalents. For the single species model the best fitting metric for URT tumors was liver AMET with daily average dose (χ^2 = 2.02; P = 0.36; quantal probit regression). This metric gave a human scaled potency of 2.5E-3 $(\mu g/m^3)^{-1}$. For the twin species model the best metric was the lifetime time weighted average (LTWA) area under the tissue concentration x time curve (NP-AUC) for the BaP metabolite in the nasopharynx compartment (χ^2 = 2.28; P = 0.32; quantal probit regression) with a human potency estimate of 1.8E-3 $(\mu g/m^3)^{-1}$. In both cases potency estimates were based on 0.1/ LED10 values (Benchmark Dose Software v.1.3.1) and provided superior fits by the URT data when compared to the applied dose LTWA metric (χ^2 = 7.3; P = 0.063). Further improvements in this dose response assessment will require additional chemical-specific and hamster-specific data.

412 TOXIC AND CARCINOGENIC EFFECTS IN THE LUNGS OF RATS AND MICE EXPOSED TO VANADIUM PENTOXIDE BY WHOLE-BODY INHALATION.

N. B. Ress[1], J. H. Roycroft[1], J. R. Hailey[1], J. K. Haseman[1], B. J. Chou[2], R. A. Renne[2], J. A. Dill[2], R. A. Miller[2] and J. R. Bucher[1]. *[1]NTP, NIEHS, Research Triangle Park, NC and [2]Battelle Toxicology Northwest, Richland, WA.*

Vanadium pentoxide (V_2O_5), commercially the most important vanadium compound, presents a hazard during the cleaning of oil-fired boilers and furnaces, the handling of catalysts, and during the refining, processing, or burning of vanadium-rich mineral ores or fossil fuels. The toxicity and carcinogenicity of V_2O_5 in male and female F344/N rats and B6C3F$_1$ mice was determined in a series of whole-body inhalation studies (NTP, 2001). In the 90-day study, rats and mice were exposed to particulate aerosols of V_2O_5 at concentrations of 0, 1, 2, 4, 8, or 16 mg/m^3. As expected, the lung was the primary site of toxicity in both species. This was indicated by concentration-related increases in absolute and relative lung weights, and increased incidences of inflammation and alveolar and bronchiolar epithelium hyperplasia/metaplasia. Fibrosis was only observed in rats. Based on the results from the 90-day study, exposure concentrations of 0, 0.5, 1, and 2 mg/m^3(rats) and 0, 1, 2, and 4 mg/m^3 (mice) were selected. In the 2-year study, significant concentration-related increases in inflammation, fibrosis, alveolar and bronchiolar epithelium hyperplasia/metaplasia, and squamous metaplasia were observed in male and female rats. Although not significant, chemical-related increases in alveolar/bronchiolar neoplasms occurred in male rats exposed to 0.5 and 2 mg/m^3, with the incidences in some groups exceeding the NTP historical control ranges. A marginal increase in alveolar/bronchiolar neoplasms was observed in female rats exposed to 0.5 mg/m^3. In mice, inflammation and alveolar and bronchiolar epithelium hyperplasia were observed in almost every exposed animal, while fibrosis also was observed, the incidences were less than that in rats. Alveolar/bronchiolar neoplasms were significantly increased in all exposed mice, providing clear evidence of carcinogenicity of V_2O_5 in mice.

413 EXPRESSION OF MUTANT HUMAN KI-ras INDUCES LUNG TUMORS IN BITRANSGENIC MICE.

H. S. Floyd[1], J. W. Tichelaar[2], S. T. Dance[1], J. Everitt[4], J. A. Whitsett[3] and M. S. Miller[1]. *[1]Wake Forest University, Winston-Salem, NC, [2]University of Cincinnati, Cincinnati, OH, [3]Children's Hospital Research Foundation, Cincinnati, OH and [4]CIIT, Research Triange Park, NC.*

Ki-*ras* mutations have been implicated as an early event in the development of human and mouse lung adenocarcinomas. We developed a bitransgenic mouse model to regulate mutant human Ki-*ras* in a lung-specific and DOX-inducible manner. Monotransgenic mice containing the mutant Ki-*ras*CYS^{12} transgene linked to a tetracycline-inducible promoter are crossed to monotransgenic mice that constitutively express the reverse tetracycline transactivator from either the lung-specific SP-C or CCSP promoters. Induction of the Ki-*ras* transgene was detected by RT-PCR in bitransgenic mice following 1 week of DOX exposure. Bitransgenic mice exhibited hyperplastic lung foci after only 12 days of DOX treatment. By 3 months of treatment, extensive epithelial hyperplasia of the alveolar region of the lung tissue could be seen, as well as multiple macroscopic tumors, the majority of which were less than 1 mm in size. The tumor incidences following 3 months of DOX treatment were 80% and 100% for SP-C/Ki-*ras* and CCSP/Ki-*ras* mice, with tumor multiplicities of 2.0±2.0 and 7.2±5.8 (n=5), respectively. Histopathology analysis of one of these lesions identified it as a well differentiated adenoma, as the lesion contained normal sized nuclei and was encapsulated with no signs of invasion into surrounding tissue. These analyses are continuing on other tissue samples. Lung morphology of untreated bitransgenic mice and DOX-treated single transgenic mice was normal. These results indicate that induction of mutant Ki-*ras* in the lung is sufficient to induce the formation of lung tumors, providing strong evidence that mutation of Ki-*ras* is a critical, early event in lung tumor pathogenesis. This mouse model is being utilized to further define the role of mutant Ki-*ras* in lung tumorigenesis and should be an important new model for the testing and development of chemopreventive and chemotherapeutic agents for lung cancer. (Supported by NCI grant CA91909)

414 TUMORIGENICITY IN A/J AND RASH2 MICE FOLLOWING MAINSTREAM TOBACCO SMOKE INHALATION.

G. M. Curtin, M. A. Higuchi, P. H. Ayres, J. E. Swauger and A. T. Mosberg. *Regulatory Toxicology, R.J. Reynolds Tobacco Company, Winston-Salem, NC.*

Towards developing a rodent inhalation model for evaluating lung tumorigenicity, A/J strain and rasH2 transgenic mice were provided mainstream tobacco smoke (MTS) from Kentucky 1R4F reference cigarettes according to whole-body and nose-only exposure regimens. The whole-body regimen included a 5-month dosing period, with animals exposed to humidified air or 0.2 mg WTPM/L for 6 hrs/d (5 d/wk), and a 4-month recovery period. The nose-only regimen included 7-month dosing, with animals exposed to 0.4, 0.125 or 0.04 mg WTPM/L for 3 hrs/d (5 d/wk), and a similar recovery period. Gross examination of lungs was used to evaluate tumorigenic responses. Following whole-body exposure of A/J mice to MTS, both tumor incidence and multiplicity were decreased relative to sham. Inclusion of the recovery period led to increases for both indices, though no statistical differences were evident. Whole-body exposed rasH2 mice demonstrated increased tumor incidence and multiplicity in response to MTS dosing. Increases were enhanced during recovery, with MTS-exposed mice exhibiting a statistical increase in tumor incidence. Both strains demonstrated minimal body weight reductions during whole-body exposure relative to sham. Nose-only exposure of A/J mice to MTS resulted in reductions for tumor incidence and multiplicity relative to sham. These indices were increased during recovery, providing an apparent dose-related trend for MTS exposure concentration; statistical increases were limited to tumor multiplicity at 0.4 mg WTPM/L. Nose-only exposed rasH2 mice provided a markedly different response, with tumor incidence and multiplicity increased to the greatest extent at 0.04 mg WTPM/L; similar results were observed following recovery. The dissimilar responses exhibited by the two strains are possibly explained by their divergent profiles of body weight reduction during nose-only MTS exposure. A/J mice exhibited significant reductions (up to 20%) in an exposure-dependent manner, while body weight loss for rasH2 mice was unaffected by MTS concentration.

415 A 30-WEEK DERMAL TUMOR PROMOTION ASSAY USING SENCAR MICE FOR THE COMPARATIVE EVALUATION OF CIGARETTE SMOKE CONDENSATES.

D. R. Meckley, J. R. Hayes, A. T. Mosberg and J. E. Swauger. *Regulatory Toxicology, RJ Reynolds Tobacco Company, Winston-Salem, NC.*

Mouse dermal initiation/promotion assays have been used for several decades to evaluate the potential carcinogenicity of cigarette smoke condensates (CSC). However, these studies have used highly variable methodoligies that differ in methods of CSC collection, duration of treatment, mouse strain, number of mice and endpoints measured. R.J. Reynolds uses a standardized protocol which utilzes female, SENCAR mice (40/group), which were treated with a single dose (75 ug) of dimethylbenz(a)anthracene (DMBA) as an initiator, followed one week later by treatment (three times/week) with 10, 20 or 40 mg "tar"/application of CSC for 29 weeks. End-points include survival, body weights, clinical observations, organ weights, dermal tumor development data and histopathology. As part of product stewardship efforts, CSC from Kentucky 1R4F reference cigarettes was included in four dermal tumor promotion studies conducted between 1994 and 2000. The combined results for the 1R4F cigarettes from the four studies are reported. The number of mice developing masses and the total number of masses produced were highly dose-dependent and reproducible. The average numbers of tumor bearing mice were 3.5, 15.5 and 32 and the average total numbers of tumors were 5.3, 79 and 208 for the low, mid and high dose groups, respectively. The combined results of these studies demostrate this comparative 30-week dermal tumor promotion assay provides a highly reproducible and quanitiative study design that can be used to assess the promotional activity of CSC.

416 COMPARATIVE 30-WEEK DERMAL TUMOR PROMOTION STUDY USING SENCAR MICE: COMPARISON OF CIGARETTE SMOKE CONDENSATE FROM A REFERENCE CIGARETTE CONTAINING DIRECT-FIRE FLUE-CURED TOBACCO AND A TEST CIGARETTE CONTAINING HEAT-EXCHANGE FLUE-CURED TOBACCO.

J. R. Hayes[1], M. S. Stavanja[1], D. R. Meckley[1], K. R. Van Kampen[2], P. R. Nelson[1], P. H. Ayres[1], A. T. Mosberg[1] and J. E. Swauger[1]. *[1]R.J. Reynolds Tobacco Company, Winston-Salem, NC and [2]The Van Kampen Group, Inc., Hoover, AL.*

A 30-Week dermal tumor promotion study was conducted to evaluate the relative tumor-promoting potential of cigarette smoke condensate (CSC) collected from a test cigarette containing flue-cured tobacco cured by heat-exchange to that of a reference cigarette containing flue-cured tobacco cured by direct-firing. Heat-exchange tobacco contains significantly lower concentrations of tobacco-specific nitrosamines compared to direct-fire cured tobacco. Mainstream CSCs were collected by cold trap from smoke generators using the Federal Trade Commission puffing regimen. Female SENCAR mice were "initiated" with a single 75-ug application of DMBA to the shaved dorsal skin. The CSCs were then applied to the skin three times per week for 29 weeks. Each CSC was administered at 9, 18, or 36 mg 'tar'/application to groups of 40 or 50 mice. In addition to the appropriate sentinel and vehicle controls, non-initiated mice received high-dose treatments of CSC from the reference and test cigarettes to demonstrate the main effect of CSC is promotion. End-points included body weights, clinical observations, organ weights, dermal tumor development data and histopathology. The number of dermal tumors and the number of tumor-bearing animals for both the reference and test CSCs were greater than the "DMBA-initiated" control group and increased with increasing dose. When corresponding doses of reference and test CSC were compared, there were no statistically significant differences noted with the exception of the mid-dose test CSC where the total number of microscopically-confirmed tumors was less than the reference CSC. Evaluation of these data in total indicates no toxicologically significant differences between the heat-exchange tobacco CSC and the direct-fire tobacco CSC.

417 TOXICOLOGICAL EVALUATION OF HONEY AS AN INGREDIENT ADDED TO CIGARETTE TOBACCO.

M. S. Stavanja, P. H. Ayres, D. R. Meckley, B. R. Bombick, M. F. Borgerding, M. J. Morton, A. T. Mosberg and J. E. Swauger. *R.J. Reynolds Tobacco Company, Winston-Salem, NC.*

A tiered testing strategy has been developed to evaluate the potential for new ingredients, tobacco processes, and technological developments to increase or reduce the biological activity that results from burning tobacco. The foundation of this evaluation strategy is comparative testing, typically including chemical and biological components. In the manufacture of cigarettes, honey is used as a casing ingredient to impart both aroma and taste. As part of ongoing stewardship efforts, cigarettes produced with honey (5% wet weight) as an alternative to invert sugar in tobacco casing material were subjected to extensive evaluation. Principal components of this evaluation included a determination of selected mainstream smoke constituent yields, Ames assay, sister chromatid exchange assay in Chinese hamster ovary cells, a 30-Week dermal tumor promotion evaluation of mainstream cigarette smoke condensate in SENCAR mice, and a 13-Week inhalation study of mainstream cigarette smoke in Sprague-Dawley rats. Comparative analytical evaluations demonstrated that the substitution of honey for invert sugar as a casing material in cigarettes had no significant impact on mainstream smoke chemistry. In addition, *in vitro* and *in vivo* studies demonstrated that cigarettes containing tobacco cased with honey had comparable biological activity as cigarettes that contained invert sugar. Collectively, these data demonstrate that the use of honey as an alternative casing material in the manufacture of cigarettes is acceptable.

418 DETERMINATION OF THE SKIN CANCER POTENTIAL OF BENZO(*A*)PYRENE (BaP) AND A PETROLEUM REFINERY STREAM IN K6/ODC MICE.

M. A. Amoruso[2], R. C. Forgash[2], S. K. Gilmour[1] and J. J. Freeman[2]. *[1]Toxicology and Environmental Sciences Division, ExxonMobil Biomedical Sciences, Inc., Annandale, NJ and [2]Lankenau Medical Center, Wynnewood, PA.*

ExxonMobil and the petroleum industry have historically utilized the mouse dermal carcinogenesis bioassay to assess the carcinogenicity of petroleum-derived materials. This assay, albeit an accurate predictor of carcinogenic potential, is expensive and takes two years to complete. Scientists have been searching for a faster, less costly but effective means to identify carcinogenic compounds. The K6/ODC transgenic mouse shows promise as a replacement for the conventional two-year rodent dermal bioassay. The skin of these mice is genetically tumor promoted probably as a result of the constitutive overexpression of ornithine decarboxylase (ODC).All that is needed for skin tumor development in this model is an initiating event which can be accomplished by low, even single doses of genotoxic carcinogens. In this study, six groups of K6/ODC mice (15 mice/group) were treated as follows: Groups 1, 2 and 3 received 25, 100 or 400 micrograms (µg) BaP in acetone, respectively, as a single dose applied topically to the dorsal area of the back; Group 4 received 750 µg of catalytically cracked clarified oil (CCO; a high-boiling carcinogenic petroleum material) in acetone as a single topical dose; Group 5 received 25 µg BaP in acetone applied topically once a week for the duration of the study (6- months).Groups 6 and 7 received 37.5 microliters acetone as a single dose or once a week for the duration of the study, respectively. Development of skin tumors was monitored weekly. After 20 weeks, 9/15 animals in Group 1, 15/15 animals in Groups 2 and 3 and 5/15 animals in Group 4 had developed papillomas and/or carcinomas. Of note, in Group 5 (25 µg BaP, 1 x week) 11/15 animals had developed tumors by week 14. Thus, repeated application of low dose BaP significantly decreased tumor latency. Tumors were not observed in either control group. These results clearly demonstrate that the K6/ODC mouse is very sensitive to the topical application of genotoxic carcinogens.

419 EVALUATION OF 2, 4–D PHOTOCARCINOGENIC ACTIVITY IN K6/ODC TRANSGENIC MICE.

Y. Chen, J. Bastien and T. G. O'Brien. *ODC Mouse Group, Drexel Hill, PA.*

As a result of overexpression of the enzyme ornithine decarboxylase (ODC) in skin, the K6/ODC transgenic mouse appears to be extremely sensitive to tumor induction with both genotoxic chemicals and UV radiation. 2, 4–dichlorophenoxyacetic acid (2, 4–D), a phenoxy acetic acid herbicide has been used world-wide in agriculture and pest management with the accompanying potential for both incidental and accidental human exposure. It has been found to induce proliferation of peroxisomes in the liver of rodents and is a possible carcinogen. In this study, the carcinogenic effect of 2, 4–D on UV irradiation-induced skin tumors was evaluated by using K6/ODC mice. 2, 4–D (one of 2 doses) was applied topically 2 times per week on days when no UV radiation was given for a period of 22 weeks. Lomefloxacin was used as a positive control for enhancement of UV carcinogenesis, and unirradiated, chemical treated and irradiated and unirradiated vehicle controls were also used. No signs of phototoxicity were seen. Skin tumors were observed in all the irradiated groups. Tumor incidence was significantly increased in lomefloxacin plus UV irradiation, but not in 2, 4–D plus UV compared to vehicle plus UV exposed animals. There were no tumors in unirradiated control groups. The results suggest that 2, 4–D is not a carcinogen or enhancer of UV induced photocarcinogenesis in this model. Because of the positive result of lomefloxacin in this study, the K6/ODC mouse may provide a highly sensitive test system for detecting enhancers of photocarcinogenesis.

420 DERMAL EXPOSURE OF MALE AND FEMALE HEMIZYGOUS Tg.AC AND FVB/N MICE FOR 52 WEEKS TO N-NITROSODIETHYLAMINE (DEN).

G. Moser[1], A. Elmore[1], J. Spalding[2], M. Streicker[1], T. Goldsworthy[1] and R. Cannon[2]. *[1]Integrated Laboratory Systems, Research Triangle Park, NC and [2]NIEHS, Research Triangle Park, NC.*

The Tg.AC (v-Ha-ras) transgenic mouse model has been proposed as a short term *in vivo* alternative or adjunct to the chronic bioassay to identify and characterize the mechanisms of action of carcinogens. To test the ability of Tg.AC mice to detect a

multi-organ genotoxic carcinogen and suspected human carcinogen, groups of 15-25 male and female hemizygous Tg.AC and FVB/N mice, the background strain, were exposed to 0, 50, 100, or 200 μg DEN/200 μl acetone topically twice weekly for up to 52 weeks. As a positive control, TPA (2.50 μg) was applied to the shaved dorsal surface of mice two times a week for up to 38 weeks in male and female Tg.AC and 52 weeks in male and female FVB/N mice. Although not dose-dependent, there was an increase in mortality of Tg.AC male mice exposed to DEN as compared to controls. Group mean body weight gain of DEN-exposed mice was decreased in comparison to the solvent control mice, for both strains (Tg.AC and FVB/N) and sexes. At necropsy, there was a very low incidence of papillomas in the Tg.AC male and female mice exposed to DEN. Papillomas were not induced by DEN in a dose-response manner, and only in one case was more than a single papilloma observed at the test site. In TPA-exposed male and female Tg.AC and FVB/N mice, the incidence of skin papillomas was 100%, 100%, 0%, and 0%, respectively. There was a high occurrence of lung masses in DEN-exposed Tg.AC and FVB/N male and female mice and an increased incidence of stomach tumors in DEN-exposed male and female Tg.AC and female FVB/N mice. Collectively, it can be concluded that dermal administration of DEN for up to 52 weeks of exposure did not induce a significant skin papilloma response in the Tg.AC model or the background FVB/N strain. DEN exposure, irrespective of genotype, induced lung tumors in male and female exposed mice. This work was sponsored by NIEHS (N01-ES-95442).

421 COMPARISON OF THE Tg.AC AND SENCAR DERMAL CARCINOGENESIS TEST SYSTEMS IN RESPONSE TO TPA PROMOTION FOLLOWING DMBA INITIATION OR VEHICLE TREATMENT.

M. L. Wenk, D. Jacobson-Kram and G. B. Smith. *Mammalian Toxicology, BioReliance Corporation, Rockville, MD.*

The Tg.AC mouse carries an activated v-Ha-ras oncogene linked to the promoter of the zeta-globin gene. These transgenic mice do not require chemical initiation and respond in a dose responsive manner to dermal applications of various tumor promoters including TPA, with development of squamous cell papillomas. The SENCAR mouse is a selectively bred animal for "sensitivity to carcinogenesis". SENCAR mice respond with similar paillomas to TPA promotion following a prerequisite chemical initiator treatment. The purpose of this study was to compare the Tg.AC and SENCAR test system responses to TPA so as to determine the more effective and responsive model for use in dermal carcinogenicity testing. Two groups of Tg.AC animals received a single dermal initiation treatment with either DMBA (50 μg) or vehicle. This was followed by 12 weeks of dermal TPA treatments (1.25 μg per dose per three times per week) beginning one week after initiator treatment. One group of female SENCAR animals received a single dermal initiation treatment with DMBA (50 μg), followed by 11 weeks of dermal TPA treatments (1.0 μg per dose per three times per week) beginning one week after initiatior treatment. Tumor incidence was recorded weekly and followed ILSI guidelines. At study termination, tumor multiplicity was highest in SENCAR animals followed by initiated male Tg.AC animals, non-initiated male Tg.AC animals, initiated female Tg.AC animals, and non-initiated Tg.AC females in descending order. Interestingly, latency of tumor formation based on the incidence of animals with papillomas was found to be shortest in SENCAR animals. Initiated Tg.AC animals (both sexes) also demonstrated decreased latency compared to the non-initiated animals. These results indicate that the SENCAR test system is the more effective and more responsive model at a lower cumulative dose of promoter. Additionally, in Tg.AC animals, development of skin papillomas resulting from TPA promotion is potentiated by a single pre-treatment with a mutagenic carcinogen.

422 VEHICULAR EFFECTS OF DIMETHYL SULFOXIDE (DMSO) ON DERMAL CARCINOGENESIS IN TETRADECONYL PHORBOL ACETATE (TPA)-TREATED HEMIZYGOUS Tg.AC TRANSGENIC MICE.

G. B. Smith[1], C. M. Keenan[2], M. L. Wenk[1] and D. Jacobson-Kram[1]. *[1]Mammalian Toxicology, BioReliance Corporation, Rockville, MD and [2]Adolor Corporation, Malvern, PA.*

Hydrophobic test material must often be solubilized in DMSO to facilitate administration, particularly at high concentrations approaching typical maximum tolerable doses. The purpose of this study was to examine the vehicular effects of DMSO on dermal carcinogenesis in TPA-treated Tg.AC transgenic mice. The Tg.AC mouse carries an activated v-Ha-ras oncogene linked to the promoter of the zeta-globin gene. These mice respond in a dose responsive manner to dermal applications of various tumor promoters including TPA, with development of squamous cell papillomas. Four groups of five animals per sex were treated three times per week for 12 weeks with incremental doses of TPA delivered in DMSO (2.5, 5.0, 10 and 20 μg TPA respectively for each 100 μl dose). Two additional groups of 5 animals per sex, a negative or vehicle control (DMSO alone) and a positive control (TPA 1.25 μg per dose delivered in acetone), were also included in the study. Tumor incidence was recorded weekly and followed ILSI guidelines. At study termination, statistical analyses revealed significant increases in tumor incidence in male animals treated with 5.0, 10, and 20 μg TPA per dose and female animals treated with 10 and 20 μg TPA per dose compared to vehicle control animals. A positive linear trend was observed in animals carrying site-of-application skin tumors, indicating a definitive dose response. However, when compared to the positive control group it was determined that treatments in the range of 10 to 20 μg TPA per dose in DMSO would be required to obtain similar incidences and tumor multiplicity as groups treated with 1.25 μg TPA in acetone. In conclusion, at low doses of TPA (< 10 μg per dose) the vehicular effects of DMSO result in decreased incidences and multiplicities, and increased latency periods for the appearance of papillomas. At present the mechanism of these effects are unclear, however they can be overcome at high doses of promoter.

423 THE MULTIDRUG RESISTANCE-ASSOCIATED PROTEIN 1 (MRP1/ABCC1) PROTECTS THE TESTICULAR TUBULES AGAINST METHOXYCHLOR DAMAGE.

L. Bain[1], R. H. Bruner[2] and T. E. Tribull[3]. *[1]Biological Sciences, University of Texas at El Paso, El Paso, TX, [2]Biotechnics, Inc., Cincinnati, OH and [3]Environmental Toxicology, Clemson University, Pendleton, SC.*

The multidrug resistance-associated protein-1 (MRP1/ABCC1) is a 190kDa membrane-bound glycoprotein that mediates cellular efflux of a variety of xenobiotics, typically as glucuronide, sulfate, or glutathione conjugates. We examined the ability of MRP1 to transport methoxychlor, a commonly used pesticide with estrogenic and antiandrogenic metabolites, which can also be conjugated with glutathione. NIH 3T3 cells stably expressing MRP1 were 2.5-fold more resistant to the toxicity of methoxychlor, and eliminated methoxychlor twice as rapidly than the mock-transfected counterparts. We then examined whether mrp1 expression could alter the toxicity of methoxychlor *in vivo* using male FVB/mrp1 knockout mice (FVB/mrp1-/-) over the length of a spermatogenic cycle. Methoxychlor treatment reduced CYP-mediated testicular testosterone metabolism in both the FVB and the FVB/mrp1-/- mice, although it did not significantly affect testicular morphology in the FVB mice. However, methoxychlor treatment greatly reduced the number of developing spermatocytes and reduced the integrity of the germinal epithelium in the FVB/mrp1-/- mice. These results suggest that the elimination of methoxychlor by MRP1 is important in protecting the testicular tubules from damage.

424 CHILDREN'S EXPOSURE TO DEET AND OTHER TOPICALLY-APPLIED INSECTICIDES.

A. E. Brown and K. S. Menon. *University of Maryland, College Park, MD.*

Use of topical repellents on children to control mosquitoes, ticks, and biting flies is common and, for achieving good control of these nuisance and disease-carrying arthropods, sometimes necessary. Anecdotal reports suggest that repellents may be applied more frequently and for a longer duration than recommended, but no studies characterizing the actual usage patterns and exposure of children have been reported. In summer 2002, a cross-sectional survey on the use patterns of repellents and possible associated effects was conducted at Maryland campgrounds. Information requested included products used, number of applications, duration of exposure, areas of the body treated, postapplication practices, and acute signs or symptoms. Information on parents' decision-making process was also compiled. The study yielded 301 respondents using repellents on their children. Deet was the most commonly used active ingredient (83.4%); aerosols were the most common formulation (42.5%). Most parents (65.4%) applied the repellent to their child only once within a day. Over a third of respondents (38.8%) treated their children's clothing as well as their skin. Forty one (13.6%) treated their child's hands, and about a third (34.9%) treated the child's face. Of these, 11.4% sprayed the product directly onto the child's face. Over half of the children did not remove the repellent by washing, swimming or other means before going to bed. More than a third of parents failed to read or follow label directions. Differences in patterns of use between mother's application and father's application were noted. Relatively few respondents reported increasing (or planning to increase) use of repellents due to concerns about West Nile Virus or Lyme disease. Only two cases of adverse reactions were reported. Minimization of children's exposure to pesticides is always desirable. While this study does not support a finding of acute adverse health effects from practices in common use, it does provide documentation of practices leading to undesirable exposure. Educational outreach to change parents' usage patterns is called for.

425 HUMAN EXPOSURE TO FIPRONIL FROM DOGS TREATED WITH FRONTLINE.

R. J. Keller[1], B. H. Atieh[1], K. A. Jennings[2], T. D. Canerdy[2], R. B. Doss[3] and R. C. Gupta[3]. The objective of this investigation was to determine fipronil residues in gloves worn while handling dogs after Frontline application. Veterinarians and animal care technicians handle large numbers of dogs every day, and there are currently no reports regarding the exposure to Frontline that may occur in these professionals. Frontline contains the active insecticidal ingredient fipronil (9.8%), which is known to provide fast, effective and convenient treatment and control of fleas and ticks in dogs for at least 30 days. Fipronil exerts its toxicity, including convulsions and seizures, through a well-established mechanism, i.e., non-competitive inhibition of GABA receptors. Frontline (1.34 ml) was applied topically on adult household dogs and gloves worn for 5 min during handling were collected (at the intervals of 24 hr, and 1, 2, 3, 4, and 5 weeks post-Frontline application) as the source samples for fipronil residues determination. At no time did the dogs show any clinical signs of fipronil toxicity. Glove extracts were analyzed for quantitation and confirmation of transferable residues of fipronil using GC/MS. The highest concentration of fipronil (589.33 + 205.70 ppm) was detected after 24 hr of Frontline application. Transferable residue of fipronil was of slightly lesser magnitude after one week, and followed a further descending trend during the 2nd, 3rd, and 4th weeks. Fipronil residue was undetectable in the gloves collected at the 5-week interval. Glove extracts from the control dogs did not reveal any residue of fipronil. These results suggest that in spite of the sequestration of fipronil in the lipids of skin and hair follicles, gloves were contaminated with a significant residue. Thus, repeated exposure to such contamination may result in potential health risks to veterinary personnel.

426 DEVELOPMENT AND APPLICATION OF A MULTI-COMPARTMENT KINETIC MODEL FOR PREDICTING THE FATE OF PARATHION AND ITS METABOLITES IN HUMANS.

M. Bouchard[1], N. H. Gosselin[1], R. C. Brunet[2], M. Dumoulin[1] and G. Carrier[1]. [1]*Environmental and Occupational Health, Université de Montréal, Montreal, QC, Canada and* [2]*Département de mathématiques et de statistique, Université de Montréal, Montreal, QC, Canada.*

A multi-compartment kinetic model was developed to predict the time evolution of parathion and its metabolites, p-nitrophenol and alkylphosphates, in the human body and excreta, under a variety of exposure routes and scenarios. The biological determinants of the kinetics were established from published data on the *in vivo* time profiles of parathion and its metabolites in blood and urine of human volunteers exposed by intravenous, oral and dermal routes. In the model, body and excreta compartments were used to represent the amounts of each of the following: parathion, p-nitrophenol and alkylphosphates. The dynamics of inter-compartment exchanges was described mathematically by a differential equation system that ensures conservation of mass, in moles, at all times. The model parameters were determined by adjusting statistically the explicit solution of the differential equations to the experimental human data. Extensive use was made of the different time scales involved in the biological processes to simplify the differential equations and enable no more than two model parameters to be estimated per fit. Simulations provided a close approximation to kinetic data available in the published literature. When simulating a dermal exposure to parathion, the main route-of-entry for workers, the absorption half-life was set to 8 hr. The model predicted an overall urinary elimination half-life of parathion as p-nitrophenol of 19 hr and as alkylphosphates of 31 hr. The fraction of absorbed dose accumulated in urine as p-nitrophenol and alkylphosphates were determined experimentally to be 37% and 46% respectively. With this, the model can estimate the absorbed dose of parathion from measurements of amounts of metabolites accumulated in urine over a given period of time. In particular, the model was used to determine the absorbed dose of parathion from measurements of p-nitrophenol in urine of workers exposed to the pesticide in fruit orchards.

427 A TOXICOKINETIC MODEL FOR THE RISK ASSESSMENT OF WORKER EXPOSURE TO TRICLOPYR THROUGH MEASUREMENTS IN URINE SAMPLES.

N. H. Gosselin[1], A. Dosso[1], M. Bouchard[1], R. C. Brunet[2] and G. Carrier[1]. [1]*Environmental and Occupational Health, Université de Montréal, Montreal, QC, Canada and* [2]*Département de mathématiques et de statistique, Université de Montréal, Montreal, QC, Canada.*

A toxicokinetic model was developed to establish links between the absorbed dose, the time varying body burdens and the excretion levels of trichlopyr in humans. The biological determinants of the kinetics were established from published data on the *in vivo* time profiles of trichlopyr in the blood and urine of human volunteers. In the model, compartments represent the amounts of trichlopyr in the body and in excreta. The dynamic of inter-compartment exchanges was described mathematically by a differential equation system that ensures conservation of mass at all times. Through back calculations, the model was used to evaluate the absorbed dose of trichlopyr in eight workers starting from measurements of the amounts of trichlopyr accumulated in urine over a 20-hr period following the onset of an 8-hr work shift. The workers exhibited excretion values of trichlopyr in their 20-hr urine samples ranging from 4 to 50 μmol. This corresponds, according to model predictions, to an absorbed dose between 0.8 to 10.5 times the reference dose (RfD) established by the US Environmental Protection Agency (EPA). The workers, who were exposed no more than a few consecutive months to trichlopyr, did not however show any apparent adverse effects, as documented by questionnaires. This raises questions concerning the adequacy of using the EPA RfD to estimate the health risk from short-term exposure to trichlopyr in workers. The EPA RfD is very conservative; it is based on the results of an animal study and an uncertainty factor of 100 was applied to account for inter-individual and species variations in toxic response.

428 CHARACTERIZATION OF ATRAZINE METABOLISM BY HUMAN GLUTATHIONE S-TRANSFERASES (GSTs).

E. L. Abel[1], S. M. Opp[1], C. L. Verlinde[2], T. K. Bammler[1] and D. L. Eaton[1]. [1]*Env Health, University of Washington, Seattle, WA and* [2]*Biochemistry, University of Washington, Seattle, WA.*

Atrazine is one of the most widely used herbicides in the United States, and has been detected occasionally at low levels in drinking water sources. Although atrazine exhibits relatively low toxicity to mammals, it has tested positive in some genotoxicity assays and has been implicated as a potent endocrine disrupter in frogs. The metabolism of atrazine in humans has not been fully characterized. Rodent studies suggest Phase I-dominated metabolism with minor Phase II-mediated metabolism likely effected by pi class GST. However, in human urine, mercapturates of atrazine are major metabolites, yet the specific GST form(s) responsible for GSH conjugation have not been identified. Using recombinant alpha, mu, pi and theta class human GSTs, we have demonstrated that only hGSTP1-1 displayed significant activity toward atrazine, with a specific activity of 7.1 nmol/min/mg protein. We have also confirmed that mouse GST pi protein is likely responsible for the glutathione-dependent metabolism of atrazine in mouse liver; the recombinant mGSTP1-1 had a specific activity of 7.3 nmol/min/mg protein. As expected, human liver- which expresses very little hGST pi protein- displayed little activity toward atrazine. Whether genetic variants of GSTP1 exhibit important catalytic differences in GST-mediated conjugation of atrazine has not been determined. However, from the crystal structure it is clear that the Ile105Val amino acid change in the hGSTP1*B genetic variant lies in the hydrophobic substrate pocket whereas the hGSTP1*D variation (Ala114Val) lies outside that area. Molecular docking studies suggest that both the wild type and the hGSTP1*B variant can accommodate atrazine in the pocket. Homology modeling and substrate docking of the atrazine-GST conjugate in the binding site are consistent with a thiolate nucleophilic attack and stabilization for the Cl- leaving group, and suggest that the hGSTP1B variant may have altered catalytic activity toward atrazine, relative to the common form. (Supported by P30ES07033).

429 COMPELLING EVIDENCE THAT FOMESAFEN CAUSES MOUSE LIVER TUMORS BY A MECHANISM OF PPARα ACTIVATION THAT IS NOT RELEVANT TO HUMANS.

R. C. Peffer[1], G. J. Moffat[2], S. C. Lloyd[2] and R. A. Roberts[3]. [1]*Syngenta Crop Protection, Inc., Greensboro, NC,* [2]*Syngenta Ltd.,, Macclesfield, United Kingdom and* [3]*Aventis Pharmaceuticals, Paris, France.*

Recent advances in the understanding of how peroxisome proliferator-activated receptor α (PPARα) ligands cause rodent liver tumors have led to growing consensus on key data elements in the mode of action (ILSI, 1998). Fomesafen is a diphenylether herbicide that has produced liver tumors in mice, but not rats, at dietary levels of 100 and 1000 ppm. In shorter term studies, treatment of mice with fomesafen at 100 and 1000 ppm produced changes classically associated with PPARα activation in rodents: increased liver weight and hepatic peroxisomal volume. In addition, concordant histopathological changes (centrilobular hypertrophy and eosinophilia) and decreased plasma triglyceride levels were observed. Assessment of hepatocyte replication by BrdU labelling indicated increased cell replication at 100 ppm and 1000 ppm within 7 days, and this trend continued after 28 and 56 days. Peroxisomal β-oxidation (as measured by palmitoyl-CoA oxidation) in males and females was increased after 7 days at 100 ppm (4-5 fold) and 1000 ppm (6-8 fold). After 28 days, palmitoyl-CoA oxidation was increased at 10 ppm (3-4 fold) as well as at 100 ppm (4-9 fold) and 1000 ppm (8-9 fold). Finally, hepatocytes isolated from control mice, PPARα null mice, and humans were used

for *in vitro* investigations of the response to PPs. In wild type mouse hepatocytes, fomesafen (250mM) increased the rate of peroxisomal β-oxidation, increased DNA synthesis and decreased apoptosis. In contrast, PPARα null mice hepatocytes and human hepatocytes were refractory to the effects of fomesafen. These data demonstrate that activation of PPARα in the mouse mediates the multiple hepatic effects of fomesafen, but human hepatocytes are not responsive to the key events mediated by PPARα in mice. The combined evidence indicates that fomesafen belongs to the PP class of rodent specific hepatocarcinogens that induce tumors in mice *via* a mode of action that is not relevant to man.

430 EFFECTS OF CHLORPYRIFOS AND METHYL PARATHION ON HEPATIC CYTOCHROME P450 IN NEONATAL RATS.

R. E. Kramer, K. E. Schneider and R. C. Baker. *Pharmacology and Toxicology, University Mississippi Medical Center, Jackson, MS.* Sponsor: I. Ho.

The adult pattern of hepatic cytochrome P450 is imprinted neonatally. Organophosphorus compounds might affect expression of cytochrome P450 in liver directly, or indirectly by changing cholinergic activity or hormone secretion. Also, their desulfuration can result in inactivation of cytochrome P450. These actions might cause changes in the levels and pattern of cytochrome P450 isozymes in neonates that could persist into adulthood. Studies were performed to examine the effects of chlorpyrifos (2 or 5 mg/kg) and methyl parathion (5 mg/kg) on hepatic P450s of neonatal rats. Pups of each sex were treated dermally once daily from postnatal day 3 to postnatal day 15. The rate* of NADPH-dependent conversion of methyl parathion to methyl paraoxon (*nmol/min/mg prot) in microsomes from livers of control pups decreased over 20 minutes from 0.91±0.07 to 0.34±0.22; an effect consistent with desulfuration-dependent inactivation of P450. Neither rate was affected by methyl parathion treatment (0.74±0.06, 0.46±0.16). In contrast, chlorpyrifos treatment inhibited the initial rate at which methyl parathion was converted to methyl paraoxon by 45% (0.51±0.04) and the final rate by 90% (0.05±0.03); the latter effect suggesting that chlorpyrifos is a more efficient suicide substrate than is methyl parathion. In general, rates of p-nitrophenol production from methyl parathion paralleled those of methyl paraoxon production. Both chlorpyrifos (0.14±0.01 versus 0.09±0.01 nmol/mg prot) and methyl parathion (0.12±0.01) increased total hepatic microsomal cytochrome P450 content. The level of CYP2E1 was also increased in liver microsomes of treated pups. In contrast, the level of CYP2C11 (an isozyme implicated in oxidative desulfuration) was reduced by treatment with chlorpyrifos, but increased by treatment with methyl parathion. These data indicate that the effects of organophosphorus compounds on hepatic P450s reflects a combination of inhibition and induction. The mechanisms and specific isozymes involved remain to be fully identified. (Grant R06/CCR419466 from the CDC).

431 EXPOSURE TO A COMMERCIAL HERBICIDE MIXTURE CAUSES A DECREASE IN LITTER SIZE IN MICE.

F. Cavieres[1], W. P. Porter[2] and J. Jaeger[2]. *[1]Faculty of Pharmacy, University of Valparaíso, Valparaíso, Chile and [2]Zoology, University of Wisconsin-Madison, Madison, WI.*

We investigated the developmental toxicity in mice of a commercial formulation of herbicide containing a mixture of 2, 4-dichlorophenoxyacetic acid, mecoprop, dicamba and inert ingredients. Pregnant mice were exposed to one of four different doses of the herbicide mixture diluted in their drinking water, either during preimplantation and organogenesis or only during organogenesis. Litter size, birth weight and crown-rump length were determined at birth. Dams were sacrificed by carbon dioxide asfixiation and the number of implantation sites was determined by staining with ammonium sulfide. The data, although apparently influenced by season, showed an inverted or u-shaped dose response pattern for reduced litter size, with the lowest dose - which corresponds to the reference dose for 2, 4-D - producing the greatest decrease in the number of embryos implanted and number of pups being born. Fetotoxicity, as evidenced by a decrease in weight and crown-rump length of the newborn pups was not significantly different in herbicide-treated litters.

432 EFFECT OF PYRETHRINS ON RAT HEPATIC XENOBIOTIC METABOLISING ENZYME ACTIVITIES.

B. G. Lake[1], A. B. Renwick[1], R. J. Price[1], K. L. Gabriel[2], J. M. Finch[3] and T. G. Osimitz[4]. *[1]TNO BIBRA International Ltd.,, Carshalton, Surrey, United Kingdom, [2]Con Toxicology Ltd, Fort Washington, PA, [3]Inveresk Research, Tranent, Scotland, United Kingdom and [4]Infoscience Inc., Charlottesville, VA.*

High doses of Pyrethrins (PY) have been shown to produce liver and thyroid tumors in rats. The aim of this study was to examine the effect of PY on some markers of hepatic xenobiotic metabolism and to compare PY with the well known rat liver and thyroid tumor promoter sodium Phenobarbital (NaPB). Female Sprague-Dawley rats were fed diets containing 0 (control), 100, 3000 and 8000 ppm PY for 7, 14 and 42 days and for 42 days followed by 42 days of reversal. In addition, male rats were fed 0 and 8000 ppm PY diets for the same time periods and male and female rats were also fed diets containing 1200-1558 ppm NaPB for 7 and 14 days. Liver microsomes were prepared and assayed for protein and total cytochrome P450 (CYP) content, CYP-dependent enzymes and thyroxine UDPglucuronosyltransferase (UDPGT). The treatment of male and female rats with NaPB for 7 and 14 days and 8000 ppm PY for 7, 14 and 42 days produced significant increases in microsomal CYP content and a marked induction of CYP2B-dependent 7-pentoxyresorufin O-depentylase and testosterone 16beta-hydroxylase activities. Significant increases were also observed in CYP3A-dependent testosterone 6beta-hydroxylase and thyroxine UDPGT activities. Overall, the effects of PY were qualitatively similar to those of NaPB. However, on a mmol/kg/day intake basis, NaPB was a significantly more potent inducer of CYP2B and CYP3A forms, being 9.1 and 3.4 times more potent than PY in male and female rats, respectively. In female rats PY exhibited a threshold of 3000 ppm, where similar but less marked effects to those seen at 8000 ppm were observed . In both sexes the hepatic effects of PY were reversible on cessation of treatment. These results suggest that PY induces hepatic CYP-dependent enzymes and thyroxine UDPGT in the rat, much like other non-genotoxic agents that produce liver and thyroid tumors in this species *via* a threshold-based mechanism. (Supported by the Pyrethrin Joint Venture).

433 MECHANISTIC TOXICITY STUDY IN RATS WITH PYRETHRINS: PATHOLOGIC EFFECTS.

J. M. Finch[1], T. G. Osimitz[2], K. L. Gabriel[3], W. H. Butler[4] and W. Henderson[1]. *[1]Inveresk Research, Tranent, Scotland, United Kingdom, [2]Infoscientific Inc., Charlottesville, VA, [3]ConTox Ltd, Fort Washington, PA and [4]Consultant, Bletchingley, Surrey, United Kingdom.*

The purpose of this study was to investigate how Pyrethrins (PY) produced liver and thyroid gland tumours in rats. Rats were given 100, 3000 or 8000 p.p.m. PY in the diet for 7, 14 or 42 Days. A recovery group was included. Phenobarbital treated groups were included for comparison. Animals were given bromodeoxyuridine (BrdU) prior to necropsy. After completion of treatment animals were killed. Blood samples were analysed for thyroid hormone levels (reported separately). Liver and thyroid glands were weighed and examined histologically and the BrdU labelling index was assessed. Frozen liver samples were subjected to microsomal enzyme analysis (reported separately). There were no effects seen in animals receiving 100 p.p.m. PY. However, in groups receiving 3000 or 8000 p.p.m. PY histological examination revealed liver cell hypertrophy in 60-100% of animals at each time point. This correlated with increased liver weights of approximately 30-60% above control values. In the animals killed after 7 or 14 days there were BrdU labelling indices of 3-10 fold the control values. Histological examination of thyroid glands showed follicular cell hypertrophy in 40-100% of animals at each time point, correlating with approximately 20-50% increases in organ weight. BrdU labellng indices were 3-6 fold greater than controls in animals killed after 14 days. Phenobarbital treated animals gave similar results. These results are consistent with the induction of liver mixed function oxidases with increased catabolism of thyroid hormones causing a secondary stimulation of thyroid follicular cells. Results of serum hormone and liver enzyme analyses confirmed this. In conclusion, Pyrethrins, like Phenobarbital, act through a dose related proliferative response in the liver and a secondary proliferative stimulation of thyroid follicular cells which is specific to rats. These effects are reversible and only appear above a dose threshold.

434 MECHANISTIC TOXICITY STUDY IN RATS WITH PYRETHRINS: EFFECTS ON THYROID HORMONES.

T. G. Osimitz[2], K. L. Gabriel[3], C. C. Capen[4], J. M. Finch[1] and T. Martin[1]. *[1]Inveresk Research, Tranent, Scotland, United Kingdom, [2]Infoscientific Inc., Charlottesville, VA, [3]ConTox Ltd.,, Fort Washington, PA and [4]Ohio State University, Columbus, OH.*

The purpose of this study was to investigate how Pyrethrins (PY) produced liver and thyroid gland tumours in rats. Rats were given 100, 3000 or 8000 p.p.m. PY in the diet for 7, 14 or 42 Days. A recovery group was included. Phenobarbital treated groups were included for comparison. Other details of the experimental method are reported separately. After completion of treatment animals were killed and blood samples were taken and analysed for thyroid hormone levels (tri-iodothyronine (T3), thyroxine, reverse tri-iodothyronine (rT3) and thyroid stimulating hormone (TSH)). In male animals receiving 8000 p.p.m. PY there were statistically significant reductions in serum thyroxine levels from 3.69 to 2.55 at Day 7, 2.91 to 2.24 at Day 14 and 3.96 to 3.11 at Day 42 (ng/ml). T3 levels were reduced at Days 7

and 14. In the same groups TSH levels were significantly elevated from 4.46 to 7.69 at Day 14 and 2.68 to 6.95 at Day 42 (ng/ml). In females, there were significant increases in serum TSH which appeared earlier than in males. In females receiving 8000 p.p.m. PY there were increases in TSH from 1.87 to 4.77 at Day 7, 1.97 to 7.88 at Day 14 and 2.07 to 7.82 at Day 42 (ng/ml). Animals treated at 3000 p.p.m. had smaller increases. There were no effects seen in animals receiving 100 p.p.m. Phenobarbital treated animals gave similar results. These results are consistent with increased catabolism of thyroid hormones in liver causing a secondary stimulation of thyroid follicular cells *via* the pituitary gland. Liver enzyme analyses (reported separately) confirmed this. In conclusion, Pyrethrins, like Phenobarbital, act through a dose related metabolic response in the liver which is specific to rats and a secondary proliferative stimulation of thyroid follicular cells. These effects are reversible and only appear above a dose threshold.

435 EFFECTS OF PYRETHROID COMPOUNDS ON ALKALINE PHOSPHATASE ACTIVITY IN ESTROGEN RECEPTOR POSITIVE HUMAN BREAST CANCER CELLS.

I. Kim[1]. [1]*Endocrine Toxicology Division, National Institute of Toxicological Reseach, Korea FDA, Seoul, South Korea and* [2]*National Institute of Toxicological Research, Korea FDA, Seoul, South Korea.* Sponsor: I. Yu.

Pyrethroids are one of the most commonly used insecticides in worldwide, but it remains unclear whether pyrethroid compounds possess endocrine disrupting activity or not. T47D cells, an estrogen receptor positive human breast cancer cell line, is known to induce alkaline phosphatase (AlkP) only in response to progestins. Because the action of estrogen may be changed by the action of progestins, it is important to examine the potential to produce progestin-mediated effects for determining endocrine disrupting activity of chemicals. In this study we investigated the progestagenic/ antiprogestagenic effects of pyrethroid compounds using AlkP activity assay and expression of progesterone receptor in T47D cells. After a 48 hr exposure period, progesterone significantly increased AlkP activity in a dose-dependent manner, and maximum activity was observed at the level of 10-8M. However pyrethroid compounds (bioallethrin, cypermethrin, deltamethrin, fenvalerate, permethrin, sumithrin, and tetramethrin) showed no increase in AlkP activity at any concentration. Among seven pyrethroid compounds fenvalerate and permethrin significantly decreased the progesterone-induced AlkP activity, but only at a relatively high concentration (10-5M). The present study suggests that some pyrethroid compounds (fenvalerate and permethrin) may have weak endocrine disrupting effects *via* progesterone related mechanism. Supproted by NITR/Korea FDA Grant ED2001-19

436 IDENTIFYING TRIAZINE HERBICIDES ON EPA DRINKING WATER CONTAMINANT CANDIDATE LIST (CCL) FOR COMMON MECHANISM OF TOXICITY AND CUMULATIVE RISK ASSESSMENT.

F. Adeshina[1], T. Mast[2], N. Moore[2], A. Mahfouz[1], A. Protzel[1] and H. Choudhury[1]. [1]*USEPA, Washington, DC and* [2]*Battelle-Pacific, Richland, WA.*

The USEPA's Office of Research and Development (ORD) and Office of Water (OW) have identified a subset of triazine herbicides that may be considered for a potential common mechanism of toxicity, based on a weight-of-evidence approach developed by the EPA. Chlorotriazine compounds selected exclusively from the CCL included: atrazine, simazine, propazine and cyanazine. Also, triazine degradants in drinking water — desethylatrazine (DEA), desisopropylatrazine (DIA) and diaminochlorotriazine (DACT) — were included. Animal studies indicate that these compounds induce mammary gland tumors in female rats, and cause a disruption of hormonal homeostasis (i.e., alteration of the estrus cycle, attenuation of the LH and PRL surge, delayed puberty in both males and females, etc). Available data indicate that these compounds interfere with control of the hypothalamic-pituitary axis (HPA), possibly by interacting within the hypothalamus. The association with LH surge is indicative of a common mechanism of toxicity. Hence, the incidence of mammary tumors is postulated to be related with the HPA. Evidence to-date indicates that no specific molecular entity has been identified as either the proximate toxicant or its receptor, although it strongly suggests that all four parent chlorotriazines act *via* the same mechanism. The proposed grouping for cumulative risk assessment, based on a common mode of action (disruption of the HPA axis), includes atrazine, simazine, propazine, cyanazine, DEA, DIA, and DACT. However, in performing cumulative risk assessment, it is important to consider the occurrence, use, and existing regulations of each of the parent compounds. ** The views expressed in this paper are those of the authors, and do not necessarily reflect the views and policies of the USEPA.

437 EFFECT OF CHLORPYRIFOS ON THE EXPRESSION AND FUNCTION OF AN EFFLUX MEMBRANE TRANSPORTER IN INTESTINAL CELLS.

S. Agarwala, W. Chen and T. J. Cook. *Department of Pharmaceutics, Rutgers, The State University of New Jersey, Piscataway, NJ.* Sponsor: E. Weyand.

Chlorpyrifos (CPF) and its metabolite, chlorpyrifos-oxon (CPO), have been reported to affect the expression of P-glycoprotein (P-gp) in rat intestine. Changes to the expression of P-gp, a membrane efflux transporter, may result in changes to the oral bioavailability of xenobiotics such as pesticides and drugs. To determine the effect of CPF on the expression of *mdr1* (the gene coding for P-gp), Caco-2 cells were treated with CPF (30 μM) over a 24 h period. RNA from the cells was isolated at 0, 4, 8 and 24 h and reverse transcribed. The cDNA was subjected to a competitive PCR (compPCR) reaction to quantify the *mdr1* copy number in treated and control cells. The competitor fragment for the compPCR assay was designed with a sequence that annealed with the same primers as the target *mdr1* sequence but resulted in a smaller size product (350 bp vs 507 bp). The gene copy number for a particular treatment was determined by running several compPCR reactions with a range of competitor concentrations. CPF treated cells exhibited a significant increase in *mdr1* copy number with a maximum effect at 8 h (100% increase) compared to control cells (copy numbers: CPF_{8h} = 122, 446±13; $Control_{8h}$ = 61, 374±352). CPO treated cells did not exhibit a significant change in *mdr1* expression. Based on the expression results, functional studies were performed with Caco-2 cells treated with CPF for 8 h. The efflux ratio (ER) of verapamil was calculated from the efflux (basolateral to apical) and influx (apical to basolateral) permeabilities ($ER=P_{efflux}/P_{influx}$). Cells treated with CPF for 8 h exhibited an increase in ER, 27% and 13%, at the two verapamil concentrations tested, 0.01 μM and 100 μM, respectively. The effect of CPF on *mdr1* expression and efflux transporter function suggests that exposure to CPF may modulate the oral bioavailability of xenobiotics, particularly those administered with a concurrent exposure to CPF. This effect could potentially lead to pesticide-drug interactions that result in drug toxicity.

438 EFFECT OF CYP SUBSTRATES ON THE METABOLISM OF CHLORPYRIFOS IN HUMAN LIVER MICROSOMES.

T. Mullarkey, P. Shah and T. J. Cook. *Department of Pharmaceutics, Rutgers, The State University of New Jersey, Piscataway, NJ.* Sponsor: E. Weyand.

Metabolism of chlorpyrifos (CPF) to its active and inactive metabolites occurs through the catalytic activity of the cytochrome P450 (CYP) enzyme superfamily. Several CYP isoforms may be responsible for CPF metabolism including CYP3A4, the predominant CYP isoform in the human liver. Concurrent exposure to CYP substrates or inhibitors could affect the balance between CPF activation and detoxification. More importantly, CPF exposure may dramatically affect the disposition of drugs that are also substrates for CYP3A4 and potentially other CYP isoforms. The aim of this study was to examine the inhibitory effect of CYP substrates on the metabolism of CPF in human liver microsomes. Ketoconazole and doxycycline, two common antibiotics that are known CYP substrates with a demonstrated high affinity for CYP3A4, were investigated. Human liver microsomes were incubated with radiolabeled CPF and either ketoconazole or doxycycline at varying concentrations for 5 minutes at 37°C to determine K_i. The formation of chlorpyrifos-oxon (CPO), the active metabolite, was determined by HPLC utilizing radioactivity detection. Based on the enzyme kinetics of the inhibition studies, the formation of CPO was suppressed in the presence of ketoconazole and doxycycline with a decrease in Vmax of 43% and 20%, respectively, and calculated K_i values of 0.094 μM and 0.173 μM for ketoconazole and doxycycline, respectively. The pattern of inhibition suggests a mixed competitive-noncompetitive mechanism is occurring in the metabolism of CPF in the presence of either inhibitory substrate. The results suggest that concurrent exposure to CPF and other CYP substrates may decrease the formation of CPO, the toxic metabolite of CPF. Results from these studies also establish that ketoconazole and doxycycline inhibit CPF metabolism and infer that CPF may also interfere with metabolism of other CYP substrates. Therefore, these studies provide a framework for ongoing studies in our lab on pesticide-drug interactions and their potential for toxicity.

439 ESTROGENIC ACTIVITIES OF PYRETHROID COMPOUNDS IN MCF-7 BUS CELLS.

S. Han. *Endocrine Toxicology Division, National Institute of Toxicological Reseach, Korea FDA, Seoul, South Korea.* Sponsor: I. Yu.

Pyrethroids are extensively used as insecticide in agriculture and home. Several studies have reported that pyrethroids are relatively safe to humans and wildlife. However, some studies have suggested that pyrethroids possess estrogen-like activity. Thus, the purpose of this study was to investigate the effects of pyrethroid compounds on cell proliferation, and expression of ERs and pS2 using estrogen receptor positive human breast cancer cell line (MCF-7 BUS cells). Seven pyrethroids

(bioallethrin, cypermethrin, deltamethrin, fenvalerate, permethrin, sumithrin, and tetramethrin) were tested with 17b-estradiol as a positive control. Among the pyrethroid compounds tested, only sumithrin increased the MCF-7 BUS cell proliferation in a dose-dependent manner, maximum induction of cell proliferation was observed at dose of 10-5M. In ER expression, 17b-estradiol (10-10M) decreased the level of cytosolic ERa and ERb protein expression compared with the vehicle control, and sumithrin significantly decreased the expression of ERa and ERb protein at high concentrations, 10-7 ~ 10-5M, in a dose-dependent manner. Similarly to 17b-estradiol, sumithrin dose-dependently increased pS2 mRNA expression. The other six test compounds used in the present study did not show any estrogenic effect at all concentrations (from 10-11 to 10-5M). These findings suggest that sumithrin could be considered to induce weak estrogenic activity *via* ER related pathways. Supported by NITR/Korea FDA Grant ED 2001-19.

440 INTESTINAL METABOLISM OF ORGANOPHOSPHATE INSECTICIDES: POTENTIAL FIRST-PASS METABOLISM.

H. Wu, C. Timchalk, A. Kousba and T. S. Poet. *Molecular Biosciences, Pacific Northwest National Laboratory, Richland, WA.*

Chlorpyrifos (CPF) and diazinon (DZN) are organophosphate (OP) insecticides, and their toxicity is mediated through CYP450 metabolism to CPF-oxon and DZN-oxon, respectively. Detoxification of CPF and DZN is also mediated by CYP450 and A-esterase (A-EST) metabolism of CPF- and DZN-oxon, resulting in the formation of trichloropyridinol (TCP) and 2-isopropyl-4-methyl-6-hydroxypyrimidine (IMHP), respectively. This study evaluated the potential role that intestinal metabolism (CYP450 and A-EST) may play in the first-pass clearance of OPs. Microsomes prepared from whole liver or isolated intestinal enterocytes demonstrated similar CYP450 and A-EST metabolic profiles. CYP450 content, as measured by reduced CO spectra, was ~10-fold lower in enterocyte than hepatocyte microsomes. For enterocyte CYP450 metabolism, the overall metabolic efficiency for the conversion to their active oxon metabolites was ~5-fold greater for CPF than DZN. When metabolism was compared per nmol P450 (nmol/min/nmol P450), the Vmax was ~3 and ~2 times higher in enterocytes than liver microsomes for CPF-oxon and TCP, respectively. The affinity (Km) for the metabolism of CPF to CPF-oxon was the same in liver and enterocyte microsomes, however the Km for TCP production was lower in enterocytes. Due to the smaller volume of intestine, the lower amount of CYP450, and the higher Km for TCP in the enterocyte microsomes, the catalytic efficiency was lower in intestine than liver for CPF-oxon, DZN-oxon and TCP. Enterocytes also demonstrated A-EST metabolism of CPF- and DZN-oxon. Although the Km for the substrates were comparable in hepatic and enterocyte microsomes, the Vmax was significantly faster, 69- to 255-fold in liver. These results suggest that intestinal metabolism may impact first-pass metabolism of OPs following low-dose oral exposures that would be expected from residues on foods. (Sponsored by CDC/NIOSH Grant R01 OH03629-01A2 and EPA grant R828608).

441 HPLC ANALYSIS OF VINCLOZOLIN AND ITS METABOLITES IN SERUM.

A. Sierra-Santoyo[1,2], H. A. Barton[1] and M. F. Hughes[1]. *[1]ETD, NHEERL, ORD, USEPA, Research Triangle Park, NC and [2]Toxicology Section, CINVESTAV-IPN, Mexico, D.F, Mexico.*

The fungicide vinclozolin (V) is used predominantly for treatment of grains, fruits, ornamental plants and turfgrass. V administered to rats is hydrolyzed to 2-[[(3,5-dichlorophenyl)-carbamoyl]oxy]-2-methyl-3-butenoic acid (M1), 3'5'-dichloro-2-hydroxy-2-methylbut-3-enanilide (M2), and 3,5-dichloroaniline (M3). V, M1 and M2 have antiandrogenic properties both in vivo and in vitro by interacting with the androgen receptor. However, data on V and its metabolites in biological samples is limited. The aims of this study were to optimize a method for the analysis of V and its metabolites by HPLC and to evaluate the stability of V in rat serum. A gradient program with a mobile phase consisting of 60-75% methanol:acetonitrile (70:30) and 0.05 M phosphate buffer (PB) pH 3.3 at 1 ml/min, C-18 column and wavelength of 212 nm were used. The method was validated using spiked serum samples (pH 1.0) in a concentration range of 2-10 µg/ml. All analytes were extracted with acetonitrile (pH 2.5) from 100 µl aliquots. Retention times for M3, M1, M2 and V were 10.3, 12.8, 15.4 and 18.2 min, respectively. Detection limits for analytes ranged from 8.3 to 36.2 ng/ml. The recoveries were from 60 to 105% and the coefficient of variation was lower than 10% for all analytes. The relative concentration of V in PB pH 7.4 and serum (37°C) decreased over 4 h. V was more stable in PB than in serum. M3, M2 and M1 were observed in both media and at 48 h M3 had the highest relative concentration (50-60%). High serum levels of V, M1 and M3 in rats orally exposed to V (100 mg/kg) during 24 h after dosing were observed. These results suggest that the metabolism of V is both enzymatic and non-enzymatic. A better understanding of the biotransformation and pharmacokinetics of V will clarify the relationship between toxicity and tissue dose of V and its metabolites. (Funded in part by cooperative agreement CR 828790 with the NRC. This abstract does not represent USEPA policy).

442 CHLOROPYRIFOS OXON AND CARBARYL INHIBITION OF TRANS-PERMETHRIN HYDROLYSIS IN HUMAN LIVER FRACTIONS.

J. Choi, R. Rose and E. Hodgson. *Environmental and Molecular Toxicology, North Carolina State University, Raleigh, NC.*

Permethrin is a pyrethroid insecticide used in the Gulf War with other deployment related chemicals such as chlorpyrifos, pyridostigmine bromide and N, N-diethyl-m-toluamide. The hydrolysis of permethrin by esterases is a major detoxification process. Chemical interactions among deployment related chemicals have been suggested as a potential cause of Gulf War Related Illnesses. In this study the inhibitory effects of chlorpyrifos on trans-permethrin hydrolysis in humans is investigated using human liver fractions. Chlorpyrifos is an organophosphorus insectide and chlorpyrifos oxon (CFO), an active metabolite, is a potent inhibitor of t-PMT hydrolysis. The parent chlorpyrifos must be metabolically activated to the oxon by cytochrome P450 (CYP) to exert inhibitory effects. Pyridostigmine bromide and N, N-diethyl-m-toluamide did not inhibit trans-permethrin hydrolysis. Complete inhibition by CFO indicated that the esterases involved in trans-permethrin hydrolysis are B-esterases, which are inhibited by organophosphorus pesticides. Ki values for CFO inhibition of trans-permethrin hydrolysis are 20 nM in the cytosolic fraction and 100 nM in the microsomal fraction. The pattern of inhibition kinetics was non-competitive irreversible reflecting the known mechanism of organophosphorus pesticides, covalent modification of the active site of esterases. Carbaryl, another anticholinesterase agent with a similar inhibition mechanism, also showed the same inhibition kinetics but with higher Ki values, which was expected from the fact that carbaryl is reversible and a less persistent esterase inhibitor compared to organophosphorus compounds. Different from CFO, carbaryl does not completely inhibit trans-permethrin hydrolysis even at high concentrations. This indicates that two or more esterases are involved in trans-permethrin hydrolysis in human liver fractions, all sensitive to organophosphate but variably sensitive to carbaryl.

443 DEFINING MULTIGENE DOSE-RESPONSE RELATIONSHIPS BY MICROARRAY ANALYSIS.

K. M. Towndrow, T. K. Baker, D. J. Cummins, M. W. Farmen, C. E. Thomas and J. L. Stevens. *Lilly Research Laboratories, Eli Lilly and Company, Greenfield, IN.*

Microarray studies often focus on increasing replicates to maximize statistical power. As a result, conducting complete dose response microarray studies can be cost prohibitive. However, in drug safety assessment, margin of safety (MOS) calculations are based on the difference between efficacy and toxicity. If genes are to serve as biomarkers to refine MOS calculations, then understanding their dose response relationships is critical. The purpose of this investigation was to develop methods to generate ED50 and maximum response (Rmax) values from microarray data. Peroxisome proliferator-activated receptor (PPAR) agonists are ideal for this type of investigation since their effects are transcriptionally-regulated. We determined PPAR-induced global liver gene expression profiles in rats exposed to either Fenofibrate (Feno), a weak, but specific PPARα agonist, or another potent PPAR agonist (PPARag). Eight doses were chosen spanning the ED50s for efficacy parameters (lowered triglyceride and/or glucose) with gene expression data collected on pooled liver RNA samples from control and treated rats. Overall, Feno induced more gene changes than PPARag. Both agonists induced fatty acid (FA) and drug metabolism-related gene expression. Comparing ED50 values for FA genes affected by Feno and PPARag yielded gene-based potency information. Consistent with the affinities for PPARα, Feno ED50s were right-shifted compared to PPARag. However, ED50 values for genes induced by either Feno or PPARag vary between genes suggesting gene selective responses. FA gene changes and gene-based potencies correlate with induction of *in vitro* and *in vivo* liver peroxisomal β-oxidation by Feno and PPARag. Feno, while less potent, produced higher Rmax values for FA gene expression compared to PPARag. Based on these studies, a dose response-based microarray data analysis design is proposed that is both cost effective and maximizes the value of microarrays by yielding ED50 and Rmax values that allow for compound comparisons.

444 GENOMIC AND PROTEOMIC PROFILING IN A PARKINSONIAN MODEL OF NEURODEGENERATION.

K. Sriram and J. P. O'Callaghan. *Centers for Disease Control & Prevention (CDC)-NIOSH, Morgantown, WV.*

The pathogenic mechanisms underlying Parkinson's disease (PD) remain enigmatic. In an effort to identify early molecular events associated with PD, we profiled genomic and proteomic changes in the MPTP mouse model of PD. cDNA and antibody microarray analysis revealed time-dependent (1h-48h) changes in striatal gene expression following dopaminergic neurotoxicity and associated reactive gliosis. A medley of genes exhibiting altered expression is tabulated. Other genes expressed included cytokines & chemokines, growth factors, transcription factors, protein kinases and genes related to stress, cell cycle and apoptosis. Further,

by proteomic profiling using ProteinChip®-SELDI-TOF® we identified smaller peptides & proteins associated with MPTP-neurotoxicity. These included neuropeptides (substance P, neurokinin A, brain natriuretic peptide), neuronal protein 15.6, PEA-15, MRF-1, cytokines & chemokines (IL-9, IL-17, MCP-1, MCP-5, MIP-2, MIP-3), growth factors (BMP, CT-1, LIF), transcription factors (ATF-3, BTF-3, CREB-bp, IEF-3, NTF-2) and stress proteins (MT-1C, MT-1H, MT-3). These findings helped identify early effectors/mediators and have provided a foundation for (1) further characterization of candidate genes involved in the neurodegenerative process and (2) identifying potential targets for therapeutic intervention.

445 DIFFERENTIAL TRANSCRIPTION FACTOR ACTIVATION AND GENE EXPRESSION PROFILES IN HUMAN VASCULAR ENDOTHELIAL CELLS ON EXPOSURE TO RESIDUAL OIL FLY ASH (ROFA) AND VANADIUM.

S. S. Nadadur and D. L. Costa. *Pulmonary Toxicology, USEPA, Research Triangle Park, NC.*

Endothelial cells, that line the vascular tree, serve as a selective thrombogenic barrier between blood components and tissues. Dysfunction of vascular permeability contributes to the pathogenesis of a wide range of diseases. Whether the vascular endothelial cells play any role in the observed cardiovascular effects of PM and/or its constituents is unclear. Acute injury to a cell on exposure to a toxicant can initiate a complex series of biological responses, which in turn link to transcriptional regulation of genes. Assessing the temporal and functional relationship of transcription factor activation and differential expression of genes could reveal novel interactions in the initiation and progression of acute injury. In this study primary cultures of human umbilical vein endothelial cells were exposed to saline, ROFA (1mg/ml) or vanadium (V) (1mM) for 20 minutes to investigate the immediate injury and or stress response. Differential activation of an array of 54 transcription factors was analyzed in the nuclear extracts of cells using Transcription Factor array (Panomics, Inc., Redwood City, CA) and the gene expression using human plastic microarray (Clontech, Palo Alto, CA). Analysis of Transcription factor regulation indicated exposure specific activation of AP-1, AP-2, EGR, E2F and p53 in ROFA and V exposed compared to saline exposed cells. Similarly the gene expression data revealed exposure-specific differential expression in ~1200 genes. Around 700 genes were induced 5-20 fold and ~500 genes were suppressed (5-10 fold) due to ROFA or V exposure. Hierarchical clustering analysis on the gene expression data generated three unique gene clusters representing exposure specific alteration in gene expression. Differential activation of transcription factors and regulation of down stream gene expression observed in this study suggests ROFA specific effects on endothelial cells in mediating PM toxicity. 446 COMPARATIVE STUDY OF DNA MICROARRAY DATA ANALYSIS: PRINCIPAL COMPONENT ANALYSIS VERSES FISHER LINEAR DISCRIMINANT ANALYSIS.

M. D. Stevenson[1], V. Chan[2], S. Gustafson[4], N. Kelley-Loughnane[3], B. Harker[1], D. Rudnicki[1], S. Hussain[2,4], C. Wang[2] and J. Frazier[1]. *[1]Operational Toxicology Branch, US Air Force, Wright-Patterson AFB, OH, [2]ManTech Environmental Technology, Inc., US Air Force, Wright-Patterson AFB, OH, [3]Geo-Centers, Inc., US Air Force, Wright-Patterson AFB, OH and [4]Air Force Institute of Technology, US Air Force, Wright-Patterson AFB, OH.*

DNA microarray technology has been extensively used in toxicology studies in recent years. Among many potential applications of this approach, it is DNA microarray technology has been extensively used in toxicology studies in recent years. Among many potential applications of this approach, it is expected that monitoring gene expression changes induced directly or indirectly by different classes of toxicants should ultimately allow molecular- and mechanistic-based classification of chemicals. To test the feasibility of classifying chemicals based on their effects on genes expression, DNA microarray data derived from exposure of primary cultures of rat hepatocytes to two model chemicals, namely cadmium and hydrazine, were analyzed using different statistical techniques. In an attempt to develop an algorithm that requires minimal data pre-processing, changes in expression levels of all 984 genes on the microarray were included in the analysis. Principal Component Analysis (PCA) was initially used to classify chemical and dose effects. It however failed to separate experimental groups (27.4% accuracy) with respect to chemical treatment or dosage due to the effects of animal variability and adaptation to *in vitro* culture environment on overall gene expression. In contrast, using Fisher Linear Discriminant Analysis (FLDA) we could successfully separate experimental groups on the basis of time, chemical and dosage with a high degree of accuracy (75%) using data from two cadmium experiments and 2 hydrazine experiments as training data and data from one experiment of either treatment as the test data. Our results demonstrated FLDA is a useful technique for DNA microarray data analysis. It requires no data filtering and thus minimizes biases that might be generated by subjective criteria during this process.

447 A DYNAMIC GENETIC NETWORK MEDIATES DOSE-DEPENDENT OXIDATIVE STRESS RESPONSES.

C. N. Giroux, A. Weiss, J. DelProposto and S. Stapels. *Center for Molecular Medicine and Genetics, Wayne State University, Detroit, MI.*

Comparison of the yeast and human genomes confirms that the genetic pathways mediating the cellular responses to toxicant stress are remarkably conserved. We have exploited this conservation to develop a yeast functional genomics model for the cellular response to oxidative stress. Yeast cells exhibit a highly reproducible graded pattern of dose dependent cellular responses to oxidant exposure, similar to those reported for mammalian cells: adaptation, cell cycle checkpoint arrest, apoptosis, and necrosis. In microarray gene expression profiling of hydrogen peroxide stressed cells, we observe distinct transcriptional patterns that distinguish chronic from acute exposures. Using OmniViz data mining software, we have constructed a genetic network model for these data which is dynamic over time. Cells that survive acute oxidative stress have incurred extensive genetic damage to both their mitochondrial and nuclear genomes. We are using two functional profiling approaches to determine the cellular pathway and target dependencies of this genotoxicity. First, by selecting the subset of nuclear genes that are essential for mitochondrial function, we have applied a "target-based gene filter" to visualize aspects of our genetic network model that are specific to the mitochondrial target. Second, we have constructed a "phenotype macroarray" of yeast gene knockout strains and have used it to identify susceptibility genes for oxidative stress. We find that functional profiling identifies genes that are important for defense against oxidative stress but which are not identified by gene expression profiling. In addition, functional profiling with our phenotype macroarray distinguishes among oxidative stressors that act by similar mechanisms of toxicity but which may have different cellular targets (such as hydrogen peroxide, menadione, and tert-butylhydroperoxide). We conclude that our transcriptional and functional profiling methods provide overlapping but complementary approaches to whole genome analysis of the mechanisms of cellular toxicity.

448 EXAMINATION OF THE POTENTIAL AH RECEPTOR AGONISM OF PHA-X673 AND PHA-X680 USING DNA MICROARRAYS.

M. E. Elrick[1], K. L. Kolaja[1], J. A. Kramer[3], P. Worboys[2], W. Solis[4] and E. G. Blomme[1]. *[1]Toxicology, Pharmacia, Skokie, IL, [2]Drug Metabolism, Pharmacia, Skokie, IL, [3]Toxicology, Pharmacia, St. Louis, MO and [4]Toxicology, Sugen, S. San Francisco, CA.*

Profound induction of hepatic cytochrome P450 in rodents can be predictive of rodent liver carcinogenicity and can identify potential drug-drug interactions. In particular, induction of cytochrome P450 1A1 (CYP 1A1) can be indicative of an interaction with the aryl hydrocarbon or dioxin receptor signaling cascade. Short-term toxicology studies are ideally positioned in the drug development testing funnel to identify potential development limiting toxicities, such as profound P450 induction. Presented herein are results from a 7-day rat toxicology study with two compounds, PHA-X673 and PHA-X680, two compounds known to induce CYP 1A1 *in vivo* similar to the known Ah-agonist, TCDD. Male Han Wistar rats were dosed with either PHA-X673 (100 or 600 mg/kg/day, BID, po) or PHA-X680 (600 mg/kg/day BID, sq). Two control groups for the different dose administration routes (po and sq) were included. Due to excessive toxicity, animals in the PHA-X680 group and the respective dosage route control group were sacrificed early on Day 4. All animals treated with PHA-X673 survived to necropsy on Day 8.

PHA-X673 at the highest dose induced CYP 1A1 mRNA levels over 10, 000 fold as determined by Taqman analysis and increased specific activity over 2, 000 fold. PHA-X680 also increased CYP 1A1 mRNA levels and activity (~200 fold for each). Microarray analysis (Affymetrix Rat ToxChip) of mRNA from livers from animals treated with PHA-X673 and PHA-X680 revealed several Ah-inducible genes were upregulated, including a 145 fold and 10 fold increase in CYP 1A1, respectively. Further, PHA-X673 and PHA-X680 both increased hepatocyte proliferation, yet had no apparent effect on apoptosis, as measured by PCNA and caspase-3 immunohistochemistry, respectively. These data indicate that PHA-X673 and PHA-X680 profoundly activate the Ah receptor and may represent novel tools for understanding Ah receptor mediated toxicity.

449 FROM "OMICS" TO INSIGHT: THE USE OF A NOVEL COMPUTATIONAL APPROACH TO STUDY GENE-GENE INTERACTIONS.

C. D. Johnson[1], Y. Balagurunathan[1], M. Tadesse[2], M. H. Falahatpisheh[1], E. R. Dougherty[1], M. K. Walker[3] and K. S. Ramos[1]. *[1]Center for Environmental and Rural Health, Texas A&M Unversity, College Station, TX, [2]Statistics, Texas A&M Unversity, College Station, TX and [3]Toxicology, University of New Mexico, Albuquerque, NM.*

The linear approaches used historically in toxicology to unravel gene networks underlying the toxic response can be overly simplistic. In the present studies, a novel computational method was used to identify gene sets that predict a specific target gene. Transcript levels were categorized into ternary expressions and randomly divided into training and test sets. The conditional probability that a target gene takes on one of three transcriptional states was estimated for all possible predictor gene set patterns. The goodness of the predictor sets was verified by cross validation against the test data set and averaged over all iterations. The predictability of the gene set for each target was quantified by the coefficient of determination ((T=target) average ($|T_{obs}-T_{mean}|$) - average ($|T_{obs-Tpred}|$)]/average ($|T_{obs}-T_{mean}|$). This measure, along with cross-validated errors, provided a good criterion for identification of the optimal predictor sets. To maximize possible gene combinations, 40 Affymetrix mouse arrays of murine embryonic kidney, fetal heart, and vascular smooth muscle subjected to different chemical treatments were used to form predictor/training data sets. Biologically relevant gene predictor sets were calculated for the specified target genes, including Ahr and Cyp1b1. For Ahr, the best gene predictor set included angiotensin II receptor type 2, meprin 1-alpha, alpha-internexin, Mac-2 antigen and pigment epithelial derived factor. For Cyp1b1 the best predictor set included glutathione-S-transferase pi2, cytochrome P450 3a16, platelet derived growth factor inducible protein, runt-related transcription factor, and HMG1-c. With this information in hand, unique clues of biological interrelationships are being identified. (Supported by NIH grants ES04849, ES09106, CA90301, ES07273, and ESO9804).

450 DIFFERENTIAL EXPRESSION OF BRAIN PROTEINS IN THE DEVELOPING MICE EXPOSED TO METHYLMERCURY AND PCB CONGENERS THROUGH PERINATAL TRANSFER: A PROTEOMICS APPROACH.

S. Lee[1], J. T. Belisle[2] and R. Yang[1]. *[1]Environmental and Radiological Health Sciences, Colorado State University, Fort Collins, CO and [2]Microbiology, Immunology, and Pathology, Colorado State University, Fort Collins, CO.*

To explore the effects of methylmercury (MeHg) and PCB congeners either alone or in combination on neurodevelopment, the expression patterns of proteins were analyzed in cerebellums of mice exposed to neurotoxicants *via* perinatal transfer. From gestational day (GD) 7 until postnatal day (PND) 21, each group of pregnant C57BL/6 mice were exposed to control, MeHg alone (40 ug/kg), PCB 153 alone (5 mg/kg), PCB 126 alone (5 ug/kg), the mixture of PCB 153 (5 mg/kg) + PCB 126 (5 ug/kg), the mixture of PCB 153 (5 mg/kg) + MeHg (40 ug/kg), and the mixture of all three chemicals. At PND 9, and PND 30, cerebellums of neonatal mice were collected and total proteins were extracted. Two-dimensional electrophoreses were performed and protein expression patterns were compared between control and chemical-treated groups. At PND 9, forty nine protein spots were differentially expressed in the groups exposed to single chemical and thirty two protein spots were differentially expressed in the groups exposed to chemical mixtures. At PND 30, forty five protein spots were differentially expressed in the groups exposed to single chemical and thirty four protein spots were differentially expressed in the groups exposed to chemical mixtures. Individual protein spots are being identified by liquid chromatography-tandem mass spectrometry. The elucidation and quantitation of expression changes of critical proteins during the neurodevelopmental process will be important in the understanding of the toxicologic interactions of MeHg and PCB congeners. (Supported by NIEHS R03 ES 10116 and ATSDR Cooperative Agreement U61/ATU 881475)

451 MICROARRAY ANALYSIS TO EXAMINE CHANGES IN EXPRESSION LEVEL OF GENES AS A FUNCTION OF TIME OF DAY IN FISCHER 344 RAT LIVER.

V. G. Desai[1,2], C. L. Moland[1,2], W. S. Branham[1,2], P. H. Duffy[2], R. R. Delongchamp[3], H. Fang[4], C. A. Peterson[5], M. L. Beggs[5] and J. C. Fuscoe[1,2]. *[1]Center for Functional Genomics, NCTR, Jefferson, AR, [2]DGRT, NCTR, Jefferson, AR, [3]Division of Biometry, NCTR, Jefferson, AR, [4]ROW, NCTR, Jefferson, AR and [5]University of Arkansas for Medical Sciences, Little Rock, AR.* Sponsor: M. Moore.

Circadian rhythm appears to regulate various biological processes, including hormonal activity and various aspects of metabolism. This fundamental element of life seems essential to consider in toxicology studies since circadian variation may influence the endpoints measured. To determine the influence of circadian rhythm on gene expression, we used microarray analysis, a powerful tool that measures on a massive scale relative expression level of the biological relevant genes that are expressed at any condition. Oligonucleotide microarrays used consisted of 3959 genes (Clontech, Palo Alto, CA). Sixteen *ad libitum* fed 12-months-old male Fischer-344 rats were sacrificed at four different time of day (0600, 1100, 1700, and 2300 hr, n=4 at each time point, 12 hr light (0200-1400)/ dark cycle). Liver tissues were stored in RNALater at -20°C until processed for RNA isolation. Total RNA isolated using TRI reagent was reverse transcribed to cDNA for indirect labeling with fluorescent cyanine dyes, Cy3 or Cy5. Each individual test sample was compared to a reference sample that was prepared by pooling equal amounts of total RNA extracted from livers of all 16 animals. Differentially labeled test and reference cDNAs were hybridized on a microarray. Reverse labeling was also performed to reduce dye-specific biases in signal intensity. Hybridized arrays were scanned using GenePix 4000B scanner and analyzed by GenePix Pro 3.0 software. Preliminary results indicated that of 3959 genes evaluated, 1369 (~35%) were expressed. Among the expressed genes, 37 genes had rhythmic circadian expression showing evidence of significant effect ($p<0.05$) of time of day. Most of 37 genes were associated with signal transduction pathways, immune function, and lipid metabolism.

452 VARIATION IN GENE EXPRESSION PROFILES FOR 17-α ETHINYL ESTRADIOL IN THE FATHEAD MINNOW, *PIMEPHALES PROMELAS.*

A. Miracle[1], D. Lattier[1], B. Aronow[2], C. Tomlinson[3] and G. Toth[1]. *[1]Molecular Ecology Research Branch, USEPA - NERL, Cincinnati, OH, [2]Division of Developmental Biology and Pediatric Informati, Children's Hospital Research Foundation and University of Cincinnati, Cincinnati, OH and [3]Genomics and Microarray Laboratory, Department of Environmental Health, University of Cincinnati, Cincinnati, OH.* Sponsor: G. Reddy.

The fathead minnow is an excellent freshwater fish model for biological indicator development for the following reasons: 1) the species widespread distribution in North America and 2) a lengthy history of use in acute and chronic testing of contaminants, effluents and receiving waters by North American and European ecotoxicologists. The inherent, dynamic patterns of gene expression that are present in an individual animal, within a specific tissue, will vary not only within the individual fish at other time points, but also among different individuals within the same population, between life stages, exposure duration and concentration of stressor. We have developed a low-density cDNA microarray representative of differentially regulated genes in response to a 24 hour exposure of 5 ng/L 17-α ethinyl estradiol for male fathead minnow (*Pimephales promelas*) liver. To examine the differences in individual variation, life stage, and dose concentration, we screened the array with samples derived from the exposure of individuals to different combinations of these 3 variables. Our data suggest that gene expression profiling will provide a sensitive measure of environmental estrogen response in the presence of age and other inter-individual variations.

453 IDENTIFICATION OF TRANSCRIPTOME FINGERPRINTS FOR THE DNA DAMAGING AGENTS BLEOMYCIN AND HYDROGEN PEROXIDE IN L5178Y MOUSE LYMPHOMA CELLS.

S. D. Seidel, H. L. Kan, W. T. Stott, M. R. Schisler and B. B. Gollapudi. *The Dow Chemical Co., Midland, MI.*

Genomic technologies offer the prospect of defining the cellular pathways leading to chemically induced toxicity including genotoxicity. It is generally believed that some aspects of genotoxicity is associated with changes in the transcription levels of certain genes, especially those involved in DNA repair and cell cycle control. Additionally, it is hypothesized that chemicals that share a common mode of genotoxic action should display similarities in gene expression changes. We have evaluated these hypotheses by analyzing the transcriptome profiles of mouse lymphoma (L518Y/TK+/-) cells treated with bleomycin and hydrogen peroxide, two mutagens that induce genotoxicity through the generation of reactive free radicals. The cells

were treated for 4 hours and mRNA was isolated at the end of the treatment or after a 20 hour recovery. Transcriptome analyses were performed using Clonetech Mouse 1.2K cDNA microarray (1176 genes) and hybridizing with 32-P labeled cDNA synthesized from the mRNA of the treated cells. In addition, the mutant frequencies induced by each chemical in the treated cells were also determined to confirm the adequacy of the experimental conditions to induce genotoxicity. Of the 1176 genes examined, each of the two mutagens altered the expression (1.5-fold or greater) of only 2 genes at the end of the 4 hour treatment. In cells allowed to recover for 20 h, bleomycin and hydrogen peroxide affected the expression of 8 and 5 genes respectively. Many of the affected genes were upregulated and are associated with apoptosis. Of these genes, 3 were in common between chemicals, granzyme A, integrin beta 7 and 45kDa calcium-binding protein precursor. The expression of none of the DNA repair genes present on the array was affected. These results show that bleomycin and hydrogen peroxide have both unique and commonly regulated genes that may serve as useful biomarkers of exposure to agents causing DNA damage by free radical mechanisms.

454 GENE ARRAY ANALYSIS OF THE VENTRAL PROSTATE IN RATS EXPOSED TO EITHER VINCLOZOLIN OR PROCYMIDONE.

M. B. Rosen, V. S. Wilson, J. E. Schmid and L. E. Gray Jr. *ORD/NHEERL/RTD, USEPA, Research Triangle Park, NC.*

Vinclozolin (Vi) and procymidone (Pr) are antiandrogenic fungicides. While changes in gene expression have been described in the ventral prostate (VP) following vinclozolin exposure, similar studies have not been conducted with procymidone, a compound proposed to share a common mechanism of action (see VS Wilson et al., SOT 2003). Here we examine the gene expression profiles of animals exposed to both compounds. 100 day old male SD rats were surgically castrated and administered silastic implants either with or without testosterone. A subset of testosterone treated animals were then orally dosed using 200 mg/kg of either vinclozolin or procymidone in corn oil. Four treatment groups with six animals per group were utilized: castrated (C), testosterone (T), testosterone+Vi (V), and testosterone+Pr (P). Tissue from the VP was collected from 3 animals per group at 20 hrs and 4 days after the start of treatment for isolation of total RNA followed by analysis using Clontech Atlas 1.2 Toxicology arrays. In support of the hypothesis that Pr shares a common mechanism or mode of action with Vi, similar changes in gene expression were observed in the C, P and V groups at both the 20 hr and 4 day time points. While only 36 genes were affected at 20 hrs, 156 genes were altered 4 days after the start of treatment. This may in part reflect regression of the VP at the later time point. Of note was an up-regulation of the androgen receptor after 20 hrs of treatment along with an up-regulation of clusterin after 4 days. Both changes were predicted in the C, P and T groups prior to the conduct of the study. Of interest for future studies is the kallikrein family of serine proteases which appeared to be a more robust marker of androgenic activity than clusterin. The effects of Vi after 4 days of treatment were, in a number of cases, greater than those of procymidone, suggesting that vinclozolin may be a more potent antiandrogen than Pr. A replicate of this study is currently being conducted. This abstract does not necessarily reflect EPA policy.

455 TOXICOGENOMIC EFFECTS OF LOW-LEVEL AS (III) EXPOSURE TO HUMAN KIDNEY CELLS.

X. Zheng[1], G. S. Watts[2], S. E. Vaught[2] and A. Gandolfi[1].
[1]Pharmacology/Toxicology, University of Arizona, Tucson, AZ and [2]Arizona Cancer Center, The University of Arizona Health Sciences Center, Tucson, AZ.

In order to answer the question of whether exposure of human kidney cells to low-level arsenic would affect gene expression. HEK293 cells were incubated with 1, 10, and 25 μM arsenite [As (III)] for 6 or 24 hr. Total RNA from treated and control cells was isolated, reverse transcribed, and labeled with Cy3 or Cy5, and hybridized to a high-density gene array system representing 5K non-redundant human cDNA clones. Hybridizations were performed at least three times using independent total RNA preparations to ensure reproducibility. In this study, 17 genes were up-regulated, and 14 genes were down-regulated, based on a 2-fold increases/decreases and consistent occurrence. Because the microarray we used contain a relatively small fraction (one seventh) of the expressed genes in HEK293 cells, by extrapolation As (III) could affect as many as 200 genes in the whole genome of HEK293 cells. The expression of affected genes showing a dose-dependent (1 - 25 μM) trend which was apparently not time-dependent (6 hr versus 24 hr). The affected genes indicate that even this realistic, low-level arsenite exposure was recognized by the HEK 293 cells (e.g., metallothionein genes) and produced an oxidative stress (e.g., heme oxygenase gene). These affected genes were characterized as stress response genes, proto-oncogene, hormone, transcription factors, chemokine receptors, proteolytic enzymes, EST and unknown genes. These findings imply that arsenite induces complex cellular injury and the cellular adaptation to As (III) is associated with alterations in the expression of many genes (NIEHS 04940).

456 HYDRAZINE AFFETCS EXPRESSION OF LIPID TRANSPORT AND METABOLISM GENES IN C57BL/6J MOUSE LIVER.

V. E. Richards, B. Chau and C. A. McQueen. *Department of Pharmacology and Toxicology, The University of Arizona, Tucson, AZ.*

The antituberculosis drug isoniazid (INH) can cause hepatic necrosis or steatosis. Neither the pathogenesis of the hepatotoxicity nor the damaging products are well understood. Both acetylisoniazid and hydrazine (HD) have been implicated as hepatoxic metabolites of INH. A study was initiated to test the hypothesis that alterations in lipid transport and metabolism are initiated prior to hepatic cell death. Gene expression profiles were determined after oral or intraperitoneal (ip) administration of the putative hepatoxic metabolite HD. Adult male C57Bl/6J mice received 100 mg/kg orally or by ip injection while control mice were given saline. Twenty-four hours later livers and blood samples were obtained from some animals for evaluation of hepatic cytotoxicity. Livers were harvested from the remaining animals, RNA isolated and used to synthesize cDNAs labeled with Cy3 or Cy5. Labeled cDNAs from control and treated animals were hybridized to a 5300-gene chip then scanned to detect fluorescence intensities. The expression ratios for all 3 animals from each group were subjected to a limit-fold change restriction. Both routes of administration of HD resulted in changes in gene expression; however, the expression of a greater number of genes was changed following the oral dose (270 genes and ESTs) compared to the ip dose (92 genes and ESTs). These included genes involved in lipid metabolism/transport (Apoa4, Apoa5, Aplp1) and energy balance (Atp2a1, Abcg1, and Ckmm). There were no significant increases in serum ALT levels or in hepatic activity of caspase 3 and caspase 8. These markers indicate that HD induced alterations in hepatic gene expression at a dose that did not result in hepatic necrosis or in capspase-mediated apoptosis. This suggests that the effects on lipid metabolism and transport do not arise as a secondary response to cell and tissue death but are associated with HD initiated patterns of gene expression. (Supported by R01 ES10047 and P30 ES06694).

457 PROTEOMICS CHARACTERIZATION OF THE EFFECTS OF A KINASE INHIBITOR ON PROTEIN EXPRESSION IN RAT LIVER.

J. Leonard[1], E. Boitier[1], M. Courcol[1], R. A. Roberts[1], Z. Jayyosi[2], P. Rao[2], M. Duchesne[3], F. Parker[3] and J. Gautier[1]. *[1]Drug Safety Evaluation, Aventis Pharmacology, Vitry-sur-Seine, France, [2]Drug Safety Evaluation, Aventis Pharmacology, Bridgewater, NJ and [3]Functional Genomics, Aventis Pharmacology, Vitry-sur-Seine, France.*

Protein kinases are key regulatory enzymes of signal transduction pathways and form a target family of great relevance in finding new drugs for treatment of numerous diseases. Compound X is a kinase inhibitor that has been developed for the treatment of asthma. In a 14-day oral toxicity study in rats, compound X produced an increase in liver weight and a marginal increase in liver enzymes (≤3-fold) at the high dose of 200 mg/kg but not at a pharmacological dose of 10 mg/kg. A proteomics study was initiated to identify molecular mechanisms which could be indicative of potential toxicity in the liver. After protein extraction, 2D gel electrophoresis was performed using differential gel electrophoresis technology. Protein identification of the up- and down-regulated spots was performed by mass spectrometry. Results showed that compound X, at the low dose of 10 mg/kg, induced over-expression of 40 proteins whereas at 200 mg/kg it gave an up-regulation of 69 proteins and a down-regulation of 20 proteins. Data bio-analysis showed that a number of biochemical pathways were modulated such as lipid and fatty acid metabolism, amino acid and protein metabolism and citric acid cycle. Proteins involved in anti-oxidant defence and xenobiotic metabolism were found to be strongly affected by treatment, suggesting that toxicity might be linked to induction of oxidative stress by a reactive metabolite in liver. In addition, mass spectrometry results showed that a few proteins such as carboxylesterase 4, fumarylacetoacetase and 3-oxo-5 beta steroid 4-dehydrogenase were detected as several spots corresponding to different isoelectric points. Opposite effects of compound X on the expression ratios of these different protein forms were observed at the highest dose, suggesting that drug-induced post-translational modifications could be used as a toxicity-specific signature of compound X in the liver.

458 GENOMIC ANALYSIS OF ALACHLOR-INDUCED ONCOGENESIS IN RAT OLFACTORY MUCOSA.

M. Genter[2], D. M. Burman[2], S. Vijaykumar[3], C. L. Ebert[1] and B. J. Aronow[1].
[1]Environmental Health, University of Cincinnati, Cincinnati, OH, [2]Medicine, Columbia University, New York, NY and [3]Pediatrics/Developmental Biology, Children's Hospital, Cincinnati, OH.

The herbicide alachlor induces olfactory mucosal tumorogenesis in a highly ordered temporal process in specific regions of the rat nasal cavity. We used GeneChip analysis to test the hypothesis that histological progression and oncogenic transfor-

mation are accompanied by gene expression changes that might yield clues as to the molecular pathogenic mechanisms for the formation of these tumors. Acute alachlor exposure was associated with up-regulation of matrix metalloproteinases (MMP-) 2 and 9, as well as tissue inhibitor of metalloproteinase-1, carboxypeptidase Z, and many other genes related to extracellular matrix homeostasis and collagen regulation. Heme oxygenase, an indicator of oxidative stress, was upregulated early and maintained elevated expression. Post-acutely, expression of ebnerin, related to the putative human tumor suppressor gene DMBT1 and the polarity reversal protein hensin, progressively increased in alachlor-treated olfactory mucosa. The induction of ebnerin was confined to the epithelial cells undergoing progressive morphological changes that preceded tumor formation. Neoplastic progression from adenomas to adenocarcinoma was highly correlated with upregulation of genes that play key roles in the wnt signaling pathway. Activated wnt signaling within the adenocarcinomas was confirmed by immunohistochemical localization of beta-catenin to adenocarcinoma cell nuclei, but not in earlier adenomas or foci of respiratory metaplasia. These observations suggest that alachlor-induced initiation and progression of olfactory mucosal carcinogenesis is based on early alterations in extracellular matrix components, induction of oxidative stress, upregulated ebnerin expression, and final transformation to the malignant state accompanied by wnt pathway activation.

459 GENOMIC AND IMMUNOFLUORESCENCE ANALYSIS OF INTERACTIVE GENE NETWORKS IN OXIDANT-INDUCED ATHEROGENESIS.

C. R. Partridge[1], E. S. Williams[1], K. P. Lu[1], S. Chao[2], C. D. Johnson[1], R. Barhoumi[1], G. A. Meininger[2], E. Wilson[2,1] and K. S. Ramos[2,1]. [1]*Center for Environmental and Rural Health, Texas A&M University, College Station, TX and* [2]*Medical Physiology, Texas A&M University System Health Science Center, College Station, TX.*

Oxidative injury to cells within the vascular wall is a critical event in the pathogenesis of atherosclerosis. To study the cellular and molecular basis of this complex interaction, this laboratory has adopted an *in vivo* model of repeated cycles of oxidative injury by allylamine (AAM), a cardiovascular-specific toxicant that induces vascular lesions reminiscent of those seen in human atherosclerosis. AAM is metabolized within the vascular wall by a vascular specific enzyme, known as semicarbazide sensitive amine oxidase, to acrolein and hydrogen peroxide. These metabolites compromise redox homeostasis in vascular smooth muscle cells leading to oxidative stress, activation/ repression of redox-regulated genes, peroxidative injury, and cell death. To study these interactions, six week-old (175-180g) male Sprague-Dawley rats were gavaged daily with 35 or 70 mg/kg/day AAM or water as control (1ml/kg/day) for twenty days. The occurrence of aortic vascular lesions was documented by light microscopy. mRNA from thoracic aortas was isolated and hybridized against the rat genome Affymetrix microarray. Frozen sections of the same vessels were also processed for immunofluorescence analysis of selected proteins at sites of vascular injury. Tissues were visualized using a Bio-Rad RTS200MP confocal microscope equipped with 4, 6-diamidino-2-phenylindole, dihydrochloride (DAPI) long-pass (LP) and fluorescein-5-isothiocyanate (FITC) filter sets. Multiple gene and protein expression patterns were altered by AAM-induced oxidative injury. Key interactive gene networks involved in diverse cellular activities such as adhesion, extracellular matrix composition, cytoskeletal arrangement, growth, and signal transduction were altered by repeated cycles of chemical injury. (Supported by NIH grants HL 22863, HL 62539 and ES09106).

460 DETERMINATION OF E3 PROTEIN INTERACTIONS: CLUES TO CLAM TUMORIGENESIS?

K. E. Harring[1], M. L. Kelley[2] and R. J. Van Beneden[1]. [1]*University of Maine, Orono, ME and* [2]*University of Texas, Austin, TX.*

Gonadal tumors of the softshell clam (Mya arenaria) have been found in several eastern Maine populations. While the etiology of these germinomas is unknown, one hypothesis is that environmental contaminants are contributing to their formation. Sites with a high prevalence of gonadal cancer have been polluted by herbicides historically contaminated with dioxin. Using a differential display polymerase chain reaction, an E3 ubiquitin-protein ligase was initially identified in gill tissue from clams exposed to dioxin in the laboratory. Ubiquitin-protein ligases are responsible for ubiquitinating a target protein, thereby specifying it for degradation. Clam E3 function as a ubiquitin-protein ligase was confirmed by an *in vitro* ubiquitination assay. Clam E3 also has significant sequence similarity to E6-AP, a well-characterized ubiquitin-protein ligase that plays a role in the abnormal degradation of the tumor suppressor p53 in human cervical cancer. Increased clam E3 protein levels have been observed in female tumor-bearing gonads compared to normal gonadal tissue, suggesting a role of E3 in these tumors. Clam E3 also contains the key regions for p53 binding and degradation. The interaction of clam E3 with clam p53 was tested with GST pull-down assays. Results indicate that clam E3 interacts with clam p53, although the specificity of this interaction has not yet been confirmed. A yeast two-hybrid system is being employed to identify proteins that interact with clam E3, which may potentially include p53. Yeast vectors encoding N-terminal and C-terminal LexA-E3 bait fusion proteins have been constructed for screening clam gill and gonad cDNA libraries for potential interactors. Additionally, clam p53 will be constructed as a target protein for clam E3 in yeast to specifically determine if these two proteins interact. By discovering potential targets and interacting proteins of clam E3, we hope to further understand the mechanism of gonadal tumor formation in the softshell clam.

461 IDENTIFICATION OF RAT LIVER CYTOSOL PROTEIN TARGETS OF ACRYLONITRILE *IN VIVO* USING TWO-DIMENSIONAL GEL ELECTROPHORESIS AND MASS SPECTROMETRY.

C. Campian, F. W. Benz, D. E. Nerland and J. Cai. *Pharmacology and Toxicology, University of Louisville, Louisville, KY.*

Acrylonitrile (AN) is an organic compound produced in large quantities by the chemical industry. It is used as a monomer in the production of various polymers. Acrylonitrile is an acute toxin. The long-term goal of this research is to identify the mechanism responsible for the acute lethality of AN. Several mechanisms have been proposed to explain the toxicity of AN: Glutathione depletion with subsequent oxidative tissue damage, metabolism by P450 followed by release of cyanide (CN) and covalent binding to tissue proteins. Glutathione depletion doesn't seem to be the major factor involved in lethality because diethylmaleate, which is a potent glutathione depletor, is not particularly toxic. Cyanide, although toxic by itself, is not the only mechanism involved in the acute toxicity of AN, because preventing CN formation by P450 inhibitors does not prevent AN induced lethality. Covalent binding to tissue proteins could alter the function of vital proteins and might prove to be a major component in AN-induced toxicity. This study addresses this last mechanism. Rats were treated with 115 mg/kg (LD90) of C14 labeled AN. Liver cytosolic proteins were separated by two-dimensional polyacrylamide gel electrophoresis using immobilized gradients of pH 3-10. Radiolabeled spots were in-gel digested and identified by peptide mass fingerprinting using matrix-assisted laser desorbtion/ionization mass spectrometry. More than 10 radioactively labeled proteins have been identified to date and efforts are continuing to complete a database of rat liver protein targets of AN. This database will be a valuable resource for investigation of the biochemical basis of AN acute toxicity. Understanding the mechanism of toxicity of AN will help design better treatments for AN intoxication, as well as for compounds with a similar mechanism of toxicity. (The project described was supported by grant number ES06141 from the National Institute of Environmental Health Sciences, NIH).

462 IN SILICO IDENTIFICATION OF ESTROGEN RESPONSE ELEMENTS IN HUMAN AND MOUSE SEQUENCES.

Y. Sun[1,2,3], K. C. Fertuck[1,2,3] and T. R. Zacharewski[1,2,3]. [1]*Biochemistry and Molecular Biology, Michigan State University, East Lansing, MI,* [2]*, National Food Safety and Toxicology Center, Michigan State University, East Lansing, MI and* [3]*Institute for Environmental Toxicology, Michigan State University, East Lansing, MI.*

The biological actions of estrogen are mediated by estrogen receptor (ER) alpha and beta. Both ERs specifically bind to estrogen response elements (EREs) with high affinity. EREs are detected in the promoter and transcribed regions of many estrogen responsive genes. The perfect ERE (pERE) is a 13 bp (basepair) palindrome with two 5 bp arms and 3 bp spacer in between (GGTCAnnnTGACC). Direct binding of ER to the ERE can activate gene expression in response to estrogen. Half ERE sites can respond to ER signal through transcriptional modulators such as AP1 or Sp1. The purpose of this study is to identify EREs and other estrogen responsive regulons in silico within mouse and human genomic sequence data. Approximately 8, 000 mouse and 15, 000 human gene promoter sequences were extracted from the UCSC genome browser (http://genome.ucsc.edu), indexed by RefSeq ID. A JAVA program to search for pERE and one bp mismatch EREs in the dataset has been developed and has initially identified 341 mouse and 569 human genes that contain pEREs within their promoter or transcribed region. Twenty-five of these ERE-regulated genes were conserved between human and mouse, and published reports confirm estrogen regulation for at least 15 of the in silico identified genes. In a refined search of the 5000 bp upstream from the transcription start site, 59 mouse genes and 70 human genes were identified. Of these, 51 mouse genes and 47 human genes have products with known function including 9 genes related to JAK/STAT signal transduction pathway, 7 genes related to transcriptional regulation, 7 gene products located in nucleus and 12 gene products associated with the membrane, all of which are consistent with known anchors of estrogen. Many of the remaining genes currently do not have well defined functions, but their role in estrogen-induced responses is suggested. This work was supported by National Institute of Health Grant ES 011271.

463 RECIPROCAL REGULATION OF CYTOCHROME P450 3A1 AND P-GLYCOPROTEIN IN RAT LIVERS BY CARBON TETRACHLORIDE AND CHLOROFORM.

T. D. Nolan and A. P. Li. *PHASE-1 Molecular Toxicology, Inc., Santa Fe, NM.*

P-Glycoprotein (MDR1) is expressed on the bile cannalicular membrane in the liver, where it plays a critical role in the biliary excretion of a wide array of cytotoxic xenobiotics. Cytochrome P450 3A (CYP3A) enzymes are the most abundant P450 enzymes in the liver, and they transform a wide array of xenobiotics including many substrates of MDR1. A number of studies have described similar regulation (e.g. coinduction) of MDR1 and members of the CYP3A family, suggesting a cooperative relationship between these key detoxification proteins. Here, we describe a reciprocal regulation of MDR1 and CYP3A1 in the rat liver in response to treatment with carbon tetrachloride (CCl4) and chloroform (CHCl3). Livers from Sprague-Dawley rats injected intraperitoneally with CCl4 (0.25 ml/kg and 1 ml/kg) and CHCl3 (0.25 ml/kg and 0.50 ml/kg) were sacrificed at 6h, 24h, and 72h after administration for microarray gene expression measurement. Statistically significant ($p < .01$) induction of MDR1 was observed at 6, 24, and 72 hours after administration of both doses of CCl4, with maximum induction observed at 24 hours for both the 0.25 ml/kg (1.9-fold) and 1 ml/kg (3.5-fold) doses. Statistically significant ($p < .05$) suppression of CYP3A1 was observed at 6 and 24 hours after administration of CCl4, with maximum suppression observed at 24 hours for both the 0.25 ml/kg (-2.3-fold) and 1 ml/kg (-5.4-fold) doses. Statistically significant, maximum induction of MDR1 and maximum suppression of CYP3A1 were also observed after administration of 0.5 ml/kg CHCl3 at 24 hours. There was a negative correlation between the expression of MDR1 and CYP3A1 in CCl4- (-0.667) and CHCl3-treated (-0.374) liver samples, but not in samples treated with dexamethasone, a known CYP3A1 and MDR1 inducer (0.267). In summary, our results show a similar reciprocal modulation of MDR1 and CYP3A1 by CCl4 and CHCl3.

464 CHEMICAL DISRUPTION OF GLOBAL GENE EXPRESSION DURING NEPHROGENESIS: ROLE OF ARYL HYDROCARBON RECEPTOR.

M. H. Falahatpisheh[1], C. D. Johnson[1], M. G. Tadesse[2] and K. S. Ramos[1]. *[1]Center for Environmental and Rural Health, Texas A&M University, College Station, TX and [2]Statistics, Texas A&M University, College Station, TX.*

This laboratory has recently shown that unregulated activation of aryl hydrocarbon receptor (Ahr), a member of the large basic helix-loop-helix (bHLH) and PAS homology domain family of transcription factors, participates in the regulation of mesenchymal-to-epithelial transition during nephrogenesis. This response involves modulation of alternative splicing and post-transcriptional control of the Wilms' tumor suppressor (wt1) gene. The present studies were conducted to test the hypothesis that Ahr mediates disruption of nephrogenesis by BaP. In these experiments, organ cultures of E11.5 metanephric blastema from Ahr wild type, heterozygous and null C57BL/6J mice were treated daily with 3 μM BaP for 4 days. Microarray analysis identified eight discrete gene classes altered by hydrocarbon challenge. These genes are involved in cellular differentiation, cell proliferation, apoptosis, cell cycle progression, stress response, transformation, extracellular remodeling and transcriptional control. While many of the genes identified are known to participate in nephrogenesis (GDNF, frizzled receptor, IGFR, syndecan, and laminin), others such as Sry, oncostatin M, pinin, GATA-3, CCAAT/enhancer-binding protein, Sox-18, Nrf-2, FBG-MuSV, GRO1 oncogene, cyclin G and fibulin were novel targets for developmental dysregulation. Genes of the Ahr gene battery, such as cytochrome P450s, diaphorase, and glutathione S-transferase were affected in an Ahr dependent manner. A significant degree of reciprocity in terms of Ahr dependence, was observed in the regulation of several novel target genes, most notably kidney androgen regulated protein and hnRNP-associated with lethal yellow. These data implicate unregulated Ahr signaling, either through P450-catalyzed bioactivation or transcriptional and post-transcriptional interference, in genomic alterations during disruption of nephrogenesis by BaP. (Supported by NIH grants ES04917, ES09106 and CA90301).

465 DIFFERENTIAL MODULATION OF HEPATIC CASPASE GENE EXPRESSION BY TAMOXIFEN AND ESTRADIOL IN SPRAGUE-DAWLEY RATS.

U. Sankar and A. P. Li. *PHASE-1 Molecular Toxicology Inc., Santa Fe, NM.*

As part of our program in the application of toxicogenomics to evaluate drug-induced hepatoxicity, we report here our results on the effects of two agents, the hormone estradiol and its hepatotoxic analog, the antibrest cancer drug tamoxifen. Sprague-Dawley rats were treated with each compound intraperitoneally (i.p.) for 24, 48 and 72 hours. The animals were sacrificed at 72 hours post-treatment, and the livers were harvested for total RNA extraction and for histopathology evaluation. We hybridized the total RNA from the livers to our Rat Comprehensive Toxicology (RCT) microarrays and measured the gene expression as relative to control. Gene expression results were analyzed using MatrixExpress(tm) software. We found that the caspase genes were modulated in response to the treatments with estradiol and tamoxifen. Estradiol administration apparently led to the suppresion of the expression of caspase 1, caspase 3 and caspase 7 genes, while tamoxifen administration led to the induction of the expression of caspase 3 gene, with no apparent effect on caspase 1 and 7 genes. Neither compounds had significant effects on caspase 6 gene expression. We will continue our research to evaluate the relationship between the differential effects of estradiol and tamoxifen on caspase gene expression and their hepatotoxic potential. Our results suggest that toxicogenomics may be used as a tool to identify the differences in biological effects the effects of structurally-similar drugs and thereby guide the selection of most appropriate drug candidates for further development.

466 USE OF A TOXICOGENOMIC APPROACH AS A POTENTIAL MEANS TO INVESTIGATE IDIOSYNCRATIC HEPATOTOXICITY OF QUINOLONES AND THIAZOLIDINEDIONE COMPOUNDS.

M. J. Liguori[1], M. Heindel[1], R. Ciurlionis[1], C. Caccamo[1], B. Spear[1], S. Bukofzer[1], C. Nduaka[1], J. Retief[2] and J. F. Waring[1]. *[1]Molecular Toxicology, Abbott Laboratories, Abbott Park, IL and [2]Affymetrix, Santa Clara, CA.*

Idiosyncratic drug toxicity, defined as toxicity that is dose-independent, host-dependent, and usually cannot be predicted during preclinical or early phases of clinical trials, is a particularly confounding complication of drug development. This type of toxicity is not limited to any one class of drugs, but has been seen in a wide spectrum of compound classes including quinolones and thiazolidinediones (TZDs). Clearly, an understanding of the mechanisms that lead to idiosyncratic hepatotoxicity would be extremely beneficial for the development of new compounds. The application of microarrays towards toxicology, termed toxicogenomics, has been used to identify toxic mechanisms. Several recent publications have utilized microarray analysis to identify discrete gene changes. In addition, research has shown that compounds associated with a particular mechanism of toxicity yield similar gene expression profiles. We are examining two classes of compounds: quinolone antibacterials and TZDs for diabetes. MTT studies were conducted to identify cytotoxic dosage range. Subsequently, several quinolone compounds were supplemented into human hepatocyte incubation medium. Due to known low aqueous solubility of quinolones, HPLC analysis was completed to verify compound concentration and to be cognizant of compound degradation. The total cellular RNA was harvested and subjected to microarray analysis using a human genome chip. Preliminary results reveal that clinafloxacin has a distinct global gene expression pattern from the other quinolones investigated. Furthermore, Mitoscan assay results suggested that troglitazone is a more potent mitochondrial damaging agent than the other TZDs studied. These experiments will provide more information regarding the use of human hepatocytes in toxicogenomics studies. Ultimately, we hope to identify marker genes that can be used to screen compounds for potential idiosyncratic toxicity.

467 MICROARRAY ANALYSIS OF ADIPOGENESIS: USING TCDD AS A TOOL TO DETERMINE GENE CHANGES CRITICAL FOR DIFFERENTIATION.

P. Hanlon[2] and C. R. Jefcoate[2]. *[1]University of Wisconsin, Madison, WI and [2]Molecular and Environmental Toxicology Center, University of Wisconsin, Madison, WI.*

The multipotential C3H10T1/2 cell line can be differentiated into adipocytes using a hormonal mixture (IDM/BRL) consisting of insulin, dexamethasone, isomethylbutylxanthine and a ligand for PPARγ. In the first 24 hours of differentiation, IDM/BRL generates an essential change in cell morphology and an increase in gene expression related to the commitment to adipogenesis. Between 24 and 48 hours of differentiation, several endpoints associated with cell cycle regulation are downregulated, including several cyclins and the phosphorylation of RB. Microarray analysis has been carried out on the IDM/BRL-induced changes present at the interface of these two phases, 24 hours after treatment. The analysis was carried out under conditions in which IDM/BRL was added to depleted media (unrenewed serum protocol), and not in the presence of fresh serum. The use of the unrenewed serum protocol has the benefit of eliminating multiple inessential gene changes caused by serum addition. In the initial analysis, 304 genes were identified that changed significantly in three independent experiments. Of these genes, 130 decreased in expression and 174 increased in expression. Typical markers of the commitment phase of adipogenesis were identified, including C/EBPβ, C/EBPδ, SREBP1 and SCD1. Interestingly, 10 genes associated with the cytoskeleton were downregulated by IDM/BRL treatment. Other genes involved in cell signaling, extra cellular matrix and cellular redox status were also identified. The environmental contaminant TCDD has previously been shown to inhibit adipocyte differenti-

ation through a mechanism that is dependent upon active ERK. TCDD therefore has additionally been used as a tool to inhibit gene changes required for adipocyte differentiation. Gene changes associated with IDM/BRL that are reversed by the combination of TCDD and ERK identifies mechanisms that are critical for differentiation.

468 INVESTIGATION OF DNA REPAIR AND CELL CYCLE ARREST FOLLOWING AFLATOXIN B_1 TREATMENT IN YEAST EXPRESSING HUMAN CYTOCHROME P450 1A2.

Y. Guo[1,2], L. Jing[2], H. Xie[2], J. Sidorova[2], L. L. Breeden[2,1], H. Zarbl[2,1] and D. L. Eaton[1,2]. *[1]Env Health, University of Washington, Seattle, WA and [2]Fred Hutchinson Cancer Research Center, Seattle, WA.*

Aflatoxin B_1 (AFB) is a human hepatotoxin and hepatocarcinogen produced by the mold *Aspergillus flavus.* In humans, AFB is bioactivated by hepatic cytochromes P450 (CYP) 1A2 and 3A4 to a genotoxic epoxide that forms N^7-guanine DNA adducts. Relatively little is known about the cellular response to these bulky DNA adducts. Characterization of global gene expression patterns will lend insights into the molecular responses to DNA damage that may result in gene alterations that either protect cells from further damage and mutagenesis, or result in necrosis or apoptosis. Previously, we characterized transcriptional responses to AFB genotoxicity using yeast cDNA microarrays, using dose and time points that are minimally cytotoxic but substantially genotoxic, in a human CYP 1A2-expressing diploid strain of yeast. In the current study, flow cytometric analysis demonstrated a dose and time-dependent S phase delay under these same treatment conditions. Additional microarray studies were analyzed by cluster analysis. It was found that *RAD51* and ribonucleotide reductase genes (*RNR1*, *RNR2*, *RNR3*, *RNR4*) were co-upregulated in a dose and time-dependent manner, as well as *RAD53* and several other DNA repair genes. Haploid mutants defective in DNA repair genes and cell cycle checkpoint were transformed with human CYP 1A2 to investigate the role of recombinational repair and *MEC1* pathway after AFB treatment using a colony forming assay and flow cytometry. Both *rad51* and *mec1* exhibited decreased cell survival rates after AFB treatment, relative to their wild type. The S phase delay induced by AFB was abolished in *mec1-1* and *mec1-1/rad53* strains, but not in *rad51*. These results indicate that, in a yeast model, *RAD51* recombinational repair plays an important role in repair of AFB-induced DNA damage, and *MEC1* is involved in mediating AFB-induced S phase delay. (Supported by grants R01ES05780, P30ES07033 and U19ES011387).

469 IMPACT OF THE PEROXISOME PROLIFERATOR CLOFIBRIC ACID ON CELLULAR STRUCTURE AND TRANSCRIPT PROFILE IN MOUSE LIVER UPON 1-WEEK IN FEED TREATMENT.

F. Staedtler[1], E. Persohn[1], M. Court[1], L. Meister[1], J. D. Retief[2], D. Finkelstein[2], P. Grass[1] and S. Chibout[1]. *[1]Preclinical Safety, Novartis Pharmacology AG, Basel, Switzerland, Switzerland and [2]Affymetrix, Inc., Santa Clara, CA.* Sponsor: V. Nogues.

The new field of toxicogenomics, with the aid of genome-wide arrays, promises to deliver a complete view of all the molecular processes in the cell. Such a complete view should enable us to simultaneously monitor the on-target effect of a drug as well as its toxicological side effects and other perturbations of the biological system. To deliver on this promise we need a robust experimental design capable of detecting small, but statistically significant, changes in the gene expression level combined with functional annotations to a level where the biological interpretations can easily be made. In this regard gene ontologies are emerging as a useful tool to unify and simplify biological interpretation. In the present study we investigated the treatment-related effects of Clofibric acid (CLO), a well-studied peroxisome proliferator and non-gentoxic liver carcinogen in rodents. CLO was mixed into the diet and administered to groups of five mice at doses of 0.25 or 0.5% for one week. The equally sized control group received only the diet. In the liver traditional toxicological end points such as organ weight, histomorphology and cellular ultrastructure were investigated in conjunction with a genome wide transcript profiling using DNA micro arrays. The results indicate that all known morphological and molecular changes in the cell such as peroxisome proliferation, oxidative stress, inflammatory response, changes in lipid and glucose metabolism, and apoptosis could be detected in a single micro-array experiment.

470 CARCINOGENICITY PREDICTION BY PROTEOME ANALYSIS: 2D-DIGE-BASED EXPRESSION MONITORING.

H. Yamanaka, Y. Onuki, R. F. Whittier, T. Ohira, K. Watanabe and Y. Shinohara. *R&D, Amersham Biosciences, Tokyo, Japan.* Sponsor: H. Yamanaka.

Proteomics aims to chart the ebb and flow of tens of thousands of proteins at once to produce snapshots of cell status. These protein expression patterns potentially represent signatures of organ responses to specific chemicals and may offer insights into the processes accompanying tumorigenesis. We ran proteomic analyses on liver homogenates of control and treated animals using the quantitative fluorescent 2D-DIGE method (Amersham Biosciences, UK Limited). The 10 chemical compounds tested included genotoxic and non-genotoxic carcinogens as well as non-carcinogens. Each gel contained differentially labeled homogenates from treated and control animals. For example, 2D-DIGE of one carcinogen treated liver (250mg/kg/day, 28days) indicated significant ($p<0.001$) quantitative changes in 108 liver proteins compared to controls. To enable comparison among different chemical treatments, all gel images (>300 gel images) were matched to one master gel using Decyder software. Based upon such matching, we were able to apply data mining with bioinformatics tools such as cluster analysis of the various protein expression profiles. All four tested non-carcinogens were successfully grouped into the same cluster. This study is part of an on-going systematic large scale project supported by METI (Ministry of Economy, Trade and Industry, Japan) utilizing emerging technologies such as toxicogenomics and toxicoproteomics to developing quick and reliable alternatives to traditional long-term rodent protocols for carcinogen risk assessment.

471 THE EFFECTS OF POOLING RNA SAMPLES IN A DNA MICRO ARRAY TOXICOGENOMICS STUDY WITH CLOFIBRIC ACID IN MICE.

D. Finkelstein[1], J. D. Retief[1], P. Grass[2] and F. Staedtler[2]. *[1]Affymetrix, Inc., Santa Clara, CA and [2]Preclinical Safety, Novartis Pharmacology AG, Basel, Switzerland, Switzerland.* Sponsor: V. Nogues.

It is a common practice to pool RNA samples for DNA micro array analysis with the obvious benefit of reducing the size, cost and complexity of an experiment and also simplifying the data analysis. However, it is important to understand what information is lost in the pooling process so that the best balance between pooling and not pooling in an experimental design can be achieved. In this experiment Clofibric acid was mixed into the diet and administered to groups of five mice at doses of 0.25 or 0.5% for one week. The equally sized control group received only the diet. Liver RNA from individual animals was analyzed on MGU74A GeneChip expression probe arrays. In parallel we pooled equivalent amounts of RNA from all livers of each experimental group and analyzed them along with the replicate samples to answer the following question: what information is lost during pooling and can we still reach the same biological conclusions? A key observation made from this data set was that, while pooled and replicate data may appear to agree on the array wide scale, they do not yield the same results as robust statistical methods of gene selection cannot be applied to unreplicated pools. This is due to the loss of our ability to measure the consistency and reliability of gene expression changes in the pooled data. A second observation was that global measures of similarity might not be sensitive enough to detect outliers, such as small subsets of transcripts that are affected by a technical cause. In both cases, replicate data was more informative that pooled data without replication. Pooling samples for analysis on micro arrays may have a benefit by reducing variance in large studies, but the pool must be replicated to provide robust results. That is given a large number of replicate biological samples, creating several pools of equal size is better than creating a single pool. In this way we get the benefits of reduced variance from pooling without loosing the ability to measure variance.

472 BACKGROUND AND CHEMICALLY INDUCED VARIATION IN CDNA MICROARRAY PROFILES: EVALUATION OF THE INFLUENCE OF RAT STRAIN AND DIET.

L. Kan[1], B. R. Sparrow[2], L. Gued[1], B. B. Gollapudi[1] and W. T. Stott[1]. *[1]TERC, Dow Chemical Company, Midland, MI and [2]Battelle, Columbus, OH.*

DNA microarray technology is being employed in a number of screening, hazard identification and mechanistic studies. Several potential sources of variation in transcriptome levels of test animals were investigated using membrane-based, 1176 gene cDNA microarrays. The influence of rat strain (male CD vs CDF), and diet (ad libitum, diet restriction, and phytoestrogen-free) on background and benzo(a)pyrene (B[a]P)-induced gene expression profile in liver was examined. Results were compared to functional assays of several Phase I and II enzymes. In untreated controls of both strains, the numbers of expressed genes were significantly higher in the restricted and phytoestrogen-free groups than ad libitum groups. In CD rats, B[a]P-treatment resulted in a higher numbers of up- and down- regulated genes in estrogen free group rats relative to either other diet group. In particular, relatively few genes were down-regulated in the ad libitum group. In CDF rats, B[a]P treatment resulted in more up-regulated genes in restricted and ad libitum groups than phytoestrogen-free group rats and little difference between diets for down-regulated genes. CYP1A1 and CYP1A2 were up-regulated by B[a]P treatment in both strains while the metallothionein gene was up-regulated only in CD rats under all dietary conditions. Gene expression was reflected in induction of

specific Phase I enzymes in liver of rats treated with B[a]P. Results demonstrate the need to take strain and diet into consideration when interpreting cDNA microarray data.

473 SIMULTANEOUS MULTIPLEXED TOXICOGENOMIC AND TOXICOPROTEOMIC PROFILING.

S. Singh, D. Tabor, T. Tian, L. Chen, L. Cao, S. Williams, T. Matray, A. Chenna and Y. Tan. *ACLARA BioSciences, Mountain View, CA.*

Toxicogenomic and toxicoproteomic biomarkers are becoming critical to efficient lead development, since multi-analyte assay panels revealing patterns of gene and protein expression can predict toxic effects. In addition, researchers require multiplex analyte assays that analyze hundreds of mRNAs or proteins from thousands of samples. Traditional methods such as microarrays, quantitative PCR and ELISA assays do not meet these demands. Here we describe the eTagTM Assay System as an ideal method for the investigation of both gene and protein expression profiles used for the characterization and classification of chemical toxicants. The eTag Assay System is ideal for high throughput sample analysis using completely solution-phase assays that are easy to automate and that work with limited biological samples. This - solution phase system does simultaneous quantitative detection of specific mRNAs and proteins direct from cell lysate in a homogeneous and isothermal manner. In both the eTag gene expression and protein assays, eTag reporters are released from target recognition complexes in direct proportion to the amount of specific mRNAs or proteins in the sample. These released eTag reporters are then separated and quantified using capillary electrophoresis. eTag reporters are low molecular weight fluorescent labels with unique and well-defined electrophoretic mobilities and can be clearly resolved using standard capillary electrophoresis instruments. The eTag Assay System provides the multiplexed analyte results that have low background, high precision, small bio-sample requirements, wide dynamic range, and complete separation of signals generated for each individual mRNA and protein. Custom configured analyte panels can be easily assembled from existing core multiplex panels in a modular fashion. In addition to assay validation, analysis of genes and proteins involved in toxicological profiling will be presented. This new system meets the unique demands of toxicogenomic and pharmacogenomic screening in lead discovery.

474 DATA INTEGRATION IN THE NEW ERA OF TOXICOGENOMICS.

B. Lu and M. P. Lawton. *Molecular and Investigative Toxicology, Pfizer, Inc., Groton, CT.*

The application of new technologies such as genomics, proteomics and metabonomics to toxicity research has created the need to store, integrate, mine, and visualize enormous amounts of data. “Panomic” analysis of tissues and fluids from even a single investigative study can easily generate over a million data points. Integration of these data is a challenge because the data are generally stored in separate databases and are of distinct formats. To bring these disparate data into a common resource, we developed an Oracle-based information management system capable of capturing the data derived from different technical platforms and the tools and an interface to make that data easily accessible to investigators. We have used this system to integrate the genomic, proteomic, and metabonomic data from an individual animal with conventional clinic chemistry, hematology, and histopathology data from the same animal. We believe such a data integration approach greatly increases the value of toxicogenomic studies by enabling us to use statistical approaches to identify previously unknown relationships among diverse data types.

475 THE ACUTE EFFECT OF ETHANOL ON CNS AND ITS DEPENDENCE ON ALDH2 POLYMORPHISM MEASURED BY THE SIMPLE LIGHT REACTION TIME USING ELECTROMYOGRAM.

Y. Ogawa and R. Yoshida. *Work Stress Control, National Institute of Industrial Health, Kawasaki, Kanagawa, Japan.*

The acute effect of ethanol on CNS was measured by the simple light reaction time using electromyogram (LRT-EMG) and its interaction with ALDH2 polymorphism was analyzed. Our institutional ethical committee approved this study project. The subjects were 10 healthy males. Six of them were randomly allocated to exposure group and remaining was allocated to control group. Each subject of exposure group took ethanol (0.4/kg) orally and each subject of control group took water orally. LRT-EMG tests were performed after -0, 20, 60, 90, 120, and 180 min, and blood was corrected after -0, 15, 60, 120, and 180 min. The LRT-EMG measurement includes pressing a switch when red LED flashes and keeps it pressing until the time S1 when the trigger shoots and blue LED flashes. Subjects are noticed to release the button as quickly as possible when they recognized the appearance of blue LED light. At that occasion the EMG of muscle extensor indices of the dominant hand side and the voltage level that show on and off level of the switch were monitored. Reaction time was defined by the time difference between the button release and S1. Conduction time was defined by the time difference between the appearance of EMG and S1. Movement time was defined by the difference between Conduction time and Reaction time. We also measured ethanol and acetaldehyde concentrations of blood and ALDH2 gene type. The concentrations of ethanol and acetaldehyde in blood steeply increased at 15 min after the intake and atypical ALDH2 cases did not return to the control level even after 180 min. Among the atypical ALDH2 exposure group movement time decreased at 60 minutes after the intake but there were no change among the typical ALDH2 group. Acetaldehyde might enhance the speed of finger movement. Conduction time elongated among control group, whereas Conduction time did not change among exposure group. This elongation might due to the decline of the concentration induced by tiredness and boring occurred among control group and not among exposure group.

476 HEPATOTOXICITY BY ACUTE ETHANOL INTAKE IN *ALDH2* GENE TARGETING MOUSE.

A. Matsumoto[1], K. Kitagawa[2], T. Isse[1], N. Kunugita[3], T. Oyama[1], K. Tomokuni[4] and T. Kawamoto[1]. *[1]Environmental Health, University of Occupational and Environmental Health, Kitakyusyu, Fukuoka, Japan, [2]1st Department of Biochemistry, Hamamatsu University School of Medicine, Hamamatsu, Shizuoka, Japan, [3]School of Health Science, University of Occupational and Environmental Health, Kitakyusyu, Fukuoka, Japan and [4]Department of Environmental Medicine, Saga Medical School, Saga, Japan.*

The genetic polymorphism of aldehyde dehydregenase-2 (ALDH2), which is the important enzyme in ethanol metabolism, has been characterized as *ALDH2*2* in contrast to the wild type, *ALDH2*1*. To investigate the *in vivo* significance of *ALDH2* polymorphism, mice lacking *Aldh2* were created for the use of gene targeting in embryonic stem cells (K. Kitagawa et al. 2000). The ethanol-induced cytochrome -CYP2E1- generates reactive oxygen species, activates many toxicologically important substrates, and may be the important pathway by which ethanol causes oxidative stress. There is concurrently modification of glutathione, which is the major redox buffer and which may be modulated by TNF-alpha secretion in the liver receiving ethanol. In this study, mRNA in the liver tissue of the *Aldh2* gene targeting mouse, which received 5 g/kg body weight ethanol p.o., was extracted for real time PCR assay for Cyp2e1 and cytokines. The amount of total glutathione in the liver tissue was measured at the same time. There turned out to be a significant difference in the Cyp2e1 mRNA expression by *Aldh2* genotypes.

477 INFLUENCE OF METABOLIC GENOTYPES ON CHROMOSOME ABERRATIONS IN BUTADIENE EXPOSED WORKERS.

M. Warholm[1], A. Rannug[1], S. Fustinoni[2], P. Begemann[3], L. Soleo[4], R. Barale[5], H. Järventaus[6] and H. Norppa[6]. *[1]Institute of Environmental Medicine, Karolinska Institutet, Stockholm, Stockholm, Sweden, [2]Instituti Clinici di Perfezionamento, Milano, Italy, [3]University of North Carolina, Chapel Hill, NC, [4]University of Bari, Bari, Italy, [5]University of Pisa, Pisa, Italy and [6]Finnish Institute of Occupational Health, Helsinki, Finland.* Sponsor: G. Johanson.

1, 3- Butadiene (BD) is believed to exert its genotoxic effects after metabolic activation to epoxides. Inherited variations in the activity of BD activating and detoxifying enzymes may be responsible for individual differences in susceptibility to BD exposure. In the present study the influence of metabolic genotypes on chromosomal aberrations (CA) in lymphocytes of 10 clerks (controls) and 30 workers exposed to low levels of BD (4-201 μ g/m3) was investigated. The study was approved by the Italian local health authority and informed consent was obtained from all participants. The total number of CA, gaps excluded, was nonsignificantly (p=0.15) higher in the workers (mean % aberrant cells =1.4) compared with controls (0.9%). The urinary BD metabolite N-acetyl-S-(3, 4-hydroxybutyl)-L-cysteine (0.48-4.55 mg/g creatinine) and hemoglobin N-(2, 3, 4-trihydroxybutyl)-valine adducts (17.7-61.3 pmol/g globin) were significantly correlated to CA in workers (r=0.46 and r=0.39, respectively) as well as in the total group (r=0.38 and r=0.35, respectively). Stratification according to the glutathione transferase (GST) M1 genotype showed that the correlations were only evident in the subgroup lacking GSTM1 (r=0.61 vs – 0.14 for the urinary metabolite and r=0.51 vs 0.02 for the hemoglobin adduct). Individuals lacking GSTT1 had significantly higher CA compared to those possessing this gene. Furthermore, polymorphisms in GSTP1 and alcohol dehydrogenase 1C also affected the CA frequency. In conclusion, genetic polymorphisms in genes relevant for the metabolism of BD appear to influence the frequencies of CA in human lymphocytes.

478 EXPLORATION OF ALTERNATIVE SPLICING OF MONOAMINE OXIDASE-B TRANSCRIPTS BY THE INTRON 13 POLYMORPHISM.

S. Kelada, P. Costa-Mallen, H. Checkoway and L. G. Costa. *University of Washington, Seattle, WA.*

The role of monoamine oxidase B (MAO-B) in Parkinson's disease (PD) has been an area of interest for many years due to its role in dopamine catabolism and bioactivation of MPTP. A common polymorphism in intron 13 of the MAOB gene, an A->G substitution located 36 bases upstream of exon 14, was discovered and subsequently shown to be associated with PD, with a relative risk of ~2 for carriers of the G allele. No direct phenotypic effect of the polymorphism has yet been elucidated. The goal of the current project is to investigate whether the intron 13 polymorphism is associated with alternative splicing of MAOB transcripts. cDNA from astrocytes of intron 13 genotype A (normal human astrocytes) and genotype G (human astrocytoma cell line 132 1N1) was obtained by reverse transcription of total RNA using gene-specific primers. cDNA fragments from the 3' region of exon 13 to the 5' region of exon 14 were then amplified by PCR and cloned. Sequences of 20 clones obtained from each genotype were identical to the sequence of the predicted normal transcript. We conclude that MAO-B intron 13 genotype does not directly affect splicing and thus a genetic explanation for the observed difference in Parkinson's disease risk due to intron 13 genotype remains to be discovered. This research was supported in part by National Institute for Environmental Health Sciences Grants ES-04696, 10750, 07032, 07033.

479 GENETIC SUSCEPTIBILITY TO ASBESTOS-RELATED DISEASES.

E. A. Putnam[1], A. Groves[1], K. Wallis[1], J. Caruso[2] and M. A. Pershouse[1]. *[1]Pharmaceutical Sciences, University of Montana, Missoula, MT and [2]Psychology, University of Montana, Missoula, MT.* Sponsor: A. Holian.

The relationship between genetic susceptibility and environmental exposure in the development of disease has been hypothesized for many years. It has also been hypothesized that inherited differences in DNA sequence contribute to phenotypic variation, influencing an individual's risk of disease and response to the environment. A promising approach to dissect this association is to systematically explore the common gene variants that may be associated with disease. Although asbestos-related diseases (ARD) are among the most well studied occupational diseases, relatively little is known about the host factors that may affect individual susceptibility. Candidate genes implicated in susceptibility or resistance to ARD include those involved in inflammation and subsequent fibrosis. We are interested in the role of single nucleotide polymorphisms (SNPs) in these genes in the association between asbestos exposure and the development of ARD. Since 93% of genes contain a SNP, and 98% of genes are within 5 kilobases of a SNP, this approach provides a powerful tool for genetic analysis. DNA was isolated from blood samples donated by Libby MT and Missoula MT residents (as exposed and control populations, respectively). PCR was used to determine the distribution of the constitutional deletion of glutathione S-transferase M1 gene (GSTM1). PCR followed by restriction enzyme digestion (PCR-RE) was used for SNP analysis of the GSTP1 gene. Constitutional deletion of GSTM1 resulted in an odds ratio of 1.58 (95% CI 0.676-3.144), but without enough power to achieve significance. SNPs in the GSTP1 gene did not appear to contribute to the development of ARD, with the caveat that more samples are needed for conclusive analysis. PCR-RE was used to examine a SNP in the interleukin 1 beta (IL1B) gene, and was demonstrated to contribute to ARD susceptibility ($p<0.05$). Further studies will be needed as asbestos-response genes are identified in other ongoing investigations. This work was supported by R21 ES11676-01 (EAP).

480 GLUTAMATE CYSTEINE LIGASE CATALYTIC SUBUNIT TRINUCLEOTIDE REPEAT POLYMORPHISM AND TYPE I DIABETES.

L. M. Bekris, C. Shephard, M. Zarghami, F. Farin, W. Griffith, T. Kavanagh and A. Lernmark. *Environmental Health, University of Washington, Seattle, WA.*

Glutathione (GSH) protects against reactive oxygen species (ROS)-mediated cell injury. Glutamate cysteine ligase (GCL), the rate limiting enzyme in the synthesis of GSH consists of catalytic (GCLC) and modifier (GCLM) subunits. T1DM is an autoimmune disease involving auto-reactive T-cells and ROS which cause pancreatic beta-cell destruction. We hypothesized, that individuals with low endogenous levels of antioxidant enzymes, such as GCLC, may be susceptible to T1DM. A polymorphic GAG trinucleotide repeat (TNR) exists in the 5' region of the GCLC gene. The specific aim was to determine the frequency of this polymorphism and associations with age-at-onset and islet autoantibodies in a group of 100 new onset 0 - 14 year old T1DM and in 100 healthy controls from Sweden. A fluorescent dNTP microsatellite analysis was performed whereby the GCLC TNR region was amplified by 2-step PCR utilizing genomic DNA. Statistical analysis was performed utilizing PRIZM. 3.0. Results show American Caucasians and the Swedish population have similar GCLC TNR allele frequencies, no significant difference in GCLC TNR allele frequency between T1DM and controls, a younger age-at-onset among females positive for the GCLC TNR 7 ($p = 0.027$). Autoantibodies against glutamic acid decarboxylase (GAD65 Ab), but not against IA-2 or insulin, showed higher levels among females positive for either the GCLC TNR 7 or TNR 9 allele ($p = 0.0014$). Since GCLC TNR 7 has been reported to be associated with lower GSH levels, we speculate that the GCLC TNR polymorphisms may contribute to gender associated differences in T1DM risk.

481 MUTATION SCANNING OF THE COMPLETE FLAVIN-CONTAINING MONOOXYGENASE GENE FAMILY IN AFRICAN-AMERICANS.

B. Furnes[1], S. Sommer[2], J. Feng[2] and D. Schlenk[1]. *[1]Department of Environmental Sciences, University of California, Riverside, Riverside, CA and [2]Department of Molecular Genetics, City of Hope National Medical Center, Duarte, CA.*

The flavin-containing monooxygenases (FMO) catalyze the monooxygenation of numerous important N-, P- and S-containing drugs, pesticides and environmental toxicants. Most of the xenobiotics are transformed into more soluble compounds readily excreted or further metabolized by phase II enzymes, but in some cases FMOs can also catalyze the formation of reactive metabolites. Six FMO genes (FMO1-6) have been identified so far, but the major alleles of FMO2 and FMO6 encode non-functional proteins due to a nonsense mutation and splice-site abnormalities, respectively. Except for FMO3, little is known about the degree of variability found in human FMOs. The complete FMO family was scanned in 50 individuals of African-American descent using Detection of Virtually All Mutations-SSCP (DOVAM-S). In brief, the coding regions and splice sections were amplified using PCR and pooled using a PE Biosystems robotic device. The pooled products were run under 5 different nondenaturing electrophoretic conditions. A total of 49 sequence variants were identified, of which 29 were Variants Affecting Protein Structure or Expression (VAPSE), some of which are expected to be detrimental for the activity of the protein. The rest were either silent or located in intronic regions not expected to affect splicing of the mRNA. In FMO6 a nonsense substitution, Q105X was found in 66% of the alleles. A deletion, 337G, was found in 27% of the FMO2 alleles. Substitutions of highly conserved amino acid residues were also found in the remaining FMOs: FMO1 I303T and R502X, FMO4 E339Q and FMO5 P457L. In summary, this study demonstrates a high degree of sequence variability in the FMO family and it also suggests that only 3-4 of the FMOs are functional in most individuals. Some of the substitutions identified in this study might be useful markers in future association studies looking at sensitivity to toxicants and common disease

482 HIGH ACETALDEHYDE LEVELS AFTER ETHANOL GAVAGES IN ALDEHYDE DEHYDROGENASE 2 (*ALDH2*) GENE TARGETING MICE.

T. Isse[1], K. Kitagawa[2], K. Matsuno[3], A. Matsumoto[1], T. Oyama[1], A. Yoshida[4] and T. Kawamoto[1]. *[1]Environmental Health, University of Occupational and Environmental Health, Kitakyushu, Fukuoka, Japan, [2]First Department of Biochemistry, School of Medicine, Hamamatsu Medical University and Environmental Health, Shizuoka, Japan, [3]Research Center for Common Use, University of Occupational and Environmental Health, Kitakyushu, Fukuoka, Japan and [4]Beckman Research Institute of the City of Hope, Duarte, CA.*

Acetaldehyde, an intermediate metabolite of ethanol, is detoxicated by mainly aldehyde dehydrogenase 2 (ALDH2). A diminished enzyme activity of the mutant ALDH2 allele (*ALDH2*2*) due to single nucleotide mutation is associated with high sensitivity and a low tolerance to ethanol in humans. *ALDH2*2* is more commonly found in Japanese than in Caucasoid. We genearated Aldh2 gene tageting C57BL/6 (*Aldh2* -/-) mice. Their activity of acetaldehyde dehydroxylation was null in the mitchondrial fraction of the liver (K Kitagawa et al. FEBS Lett 2000).
After single oral administration of 5.0 g/Kg BW ethanol, we measured ethanol and acetaldehyde consentrations in the blood, brain and liver. Ethanol levels in blood, brain and liver of the *Aldh2* -/- were almost same as those of the *Aldh2* +/+ mice. The *Aldh2* -/- mice showed about ten times higher acetaldehyde levels in blood, brain and liver than wild-type C57BL/6 (*Aldh2* +/+) mice. On the other hand, in a free-choice ethanol and water drinking test, acetaldehyde concentrations in brain and liver of *Aldh2* -/- mice were almost equal to those of wild-type (*Aldh2*+/+) mice although the *Aldh2* -/- mice drank one third less ethanol than the *Aldh2* +/+ mice (T Isse et al. Pharmacogenetics *in press*). The primary genetic factor controlling the alcohol preference of the mouse C57BL/6 must be the *Aldh2* gene as it has been observed in the ethnic difference of alcohol sensitivity in humans. The *Aldh2* -/- mouse may be used for identification of genetic factor(s) involved in individual and ethnic difference of other toxicology, drug sensitivity, and pathophysiology studies.

483 DIFFERENTIAL RESPONSE OF HUMAN CELL LINES TO ARSENIC: EVALUATION OF CANDIDATE GENES.

Y. He, H. R. Craven, D. K. Barnes and D. A. Bell. *National Institute of Envirnonmental Health Sciences, Research Triangle Park, NC.* Sponsor: C. Portier.

The epidemic-like public health problem caused by arsenic exposure in certain areas worldwide has made the understanding of arsenic toxicity and susceptibility a high priority. This project seeks to identify genes that modify arsenic toxicity *in vitro*, and to evaluate if genetic variation or gene expression profiles associate with arsenic susceptibility. A set of 24 lymphoblastoid cell lines was tested (4-6 times in duplicate) for acute toxicity and inducible tolerance to sodium arsenite. Following acute exposure to 1-50 mM sodium arsenite, cell lines were evaluated for survival using the MTS assay. There was little evidence of differential acute toxicity among these cell lines; the average EC50 for all cell lines was 13 mM (range 9.2-15.1 mM). To evaluate inducible tolerance to arsenic, cells were exposed to a nontoxic dose (1 mM) of arsenic for 72 hrs and subjected to a subsequent acute treatment with toxic doses of arsenic. Cell lines with and without adaptive tolerance to arsenic were identified. Growth rate was not associated with tolerance. Genes involved in arsenic transport or metabolism were evaluated for a role in arsenic tolerance. GSTO1 and Cyt19 are involved in arsenic reduction and methylation respectively. DNA sequencing of ~10 kb in 24 cell lines identified 2 SNPs in coding regions, 2 in promoters and 8 in noncoding intron sequence. SNP genotypes for ASNA1, an energy-dependent arsenic efflux pump, and GSTP1, involved in arsenic efflux and metabolism, were obtained from existing data sources (dbSNP). Preliminary analysis suggests that polymorphisms in ASNA1 and GSTP1 are not associated with differences in arsenic toxicity. Further analysis of the relationship between arsenic sensitivity, SNPs, and gene expression profiles (microarrays) is ongoing. Identification of human cell lines with reproducible adaptive tolerance to sodium arsenite provides a model system for discovery of arsenic susceptibility genes. Analysis of sequence variation and expression profiles may reveal molecular determinants of arsenic susceptibility.

484 GENOTYPING WITH TAQMAMA.

B. Li, I. Kadura and D. E. Watson. *Eli Lilly and Company, Greenfield, IN.* Sponsor: C. Thomas.

TaqMAMA combines strengths of the fluorogenic 5-nuclease assay (TaqMan) with allelic discrimination of the mismatch amplification mutation assay (MAMA). Here we employ TaqMAMA to screen for known human genetic polymorphisms in two sets of experiments. First, we developed TaqMAMA genotyping assays for 11 human genetic polymorphisms. Genotypes were assigned correctly for all individuals at each of the 11 polymorphic sites. The signal/noise ratios for discrimination between alleles was ~10-fold to ~1, 000, 000-fold. In all cases data interpretation was rapid and could be automated. In addition, we show that SybrGreen can be used in place of more expensive fluorescent probes that are commonly used in TaqMan. Our second set of experiments was plasmid-based. The goal of these experiments was to explore the relationship between MAMA primer design and strength of allelic discrimination. Plasmids were created that contained all 16 possible nucleotide combinations in a two-nucleotide location. The amplification efficiency was then determined for each of 16 MAMA primers acting on these 16 plasmids to determine the TaqMan efficiency of perfect match and every possible mismatch. The data demonstrate that all types of genetic polymorphisms can be detected using TaqMAMA, and provide a guide for both MAMA primer design and DNA strand selection for the design of future genotyping assays using TaqMAMA. Collectively, the experiments show that TaqMAMA genotyping assays can be developed and deployed rapidly, with high probability of success, and be conducted at a cost and throughput for screening assays in toxicogenetics.

485 NEW POLYMORPHISMS IN THE HUMAN PARAOXONASE (PON1) GENE.

C. E. Furlong[1,2], M. J. Rieder[2], C. S. Carlson[2], D. A. Nickerson[2], R. L. Jampsa[1,2], L. G. Costa[3] and G. P. Jarvik[1]. *[1]Medicine/Medical Genetics, University of Washington, Seattle, WA, [2]Genome Sciences, University of Washington, Seattle, WA and [3]Environmental Health, University of Washington, Seattle, WA.*

Paraoxonase (PON1) is a high density lipoprotein (HDL)-associated enzyme involved in the metabolism of organophosphorus (OP) insecticides, nerve agents and oxidized lipids. Single nucleotide polymorphisms (SNPs) have been described in the 5' regulatory region (5), the coding region (L55M; Q192R) and in the 3' UTR (4), as well as a microsatellite in an intron [(CA)n]. The Q192R polymorphism significantly affects the catalytic efficiency for metabolism of some substrates while the 5' C-108T polymorphism affects levels of PON1. Analysis of the known 5' regulatory region and coding SNPs shows significant levels of recombination between PON1 regions. Resequencing the complete PON1 genomic region (~30 kb) in 47 individuals identified 192 SNPs in the region, including 1 novel cSNP, 8 new 5' and 12 new 3' UTR SNPs. Analysis of the linkage disequilibrium (LD) patterns between common variants demonstrates that a significant fraction of Caucasian haplotypes represent recombinants between Q192R and the promoter region. Thus, PON1 activity in a given individual likely represents a combination of intrinsic enzyme activity and differential expression resulting from cis acting regulatory elements, in addition to genetic background contributions. A rare nonsense SNP was identified at codon 194. Analysis of samples with discordant assignment by 2-D enzyme determination of PON1 status and genotyping revealed an individual whose functional PON1 status was explained by this SNP. (ES09883, ES07033l, ES09601/EPA-R826886, HL67406, HL66682)

486 CONTRIBUTION OF PARAOXONASE (PON1) LEVELS AND Q192R GENOTYPE TO ORGANOPHOSPHATE DETOXICATION: EVIDENCE FROM HUMANS AND "HUMANIZED" TRANSGENIC MICE.

T. B. Cole[1,2], B. J. Walter[1], L. G. Costa[1], R. J. Richter[2,3], C. Pettan-Brewer[2], D. M. Shih[4], A. Tward[4], A. J. Lusis[4] and C. E. Furlong[2,3]. *[1]Environmental Health, University of Washington, Seattle, WA, [2]Medicine/Medical Genetics, University of Washington, Seattle, WA, [3]Genome Sciences, University of Washington, Seattle, WA and [4]Microbiology/Molecular Genetics, UCLA, Los Angeles, CA.*

Biological monitoring studies demonstrate widespread exposure of the population to organophosphorous (OP) pesticides. Differences in detoxication efficacy of specific OPs among individuals are influenced by differences in catalytic efficiency or abundance of the HDL-associated enzyme, paraoxonase (PON1). PON1 hydrolyzes the highly toxic oxon derivatives of chlorpyrifos and diazinon. PON1 activity is determined in part by a coding region polymorphism (Q192R) that affects its catalytic efficiency, and in part by differences in plasma PON1 abundance. Infants represent a particularly susceptible population for OP exposure due to low abundance of PON1. Developmental onset of PON1 expression is variable, and PON1 abundance varies widely (> 13-fold) among adults. We describe a transgenic mouse model for investigating the PON1Q192R polymorphism. Mice were produced that expressed human transgenes encoding either the hPON1192Q or hPON1192R isoforms in place of mouse PON1, using human flanking sequences to drive expression faithfully in the liver. Mice expressing hPON1192R had similar PON1 levels as mice expressing hPON1192Q, but were significantly more resistant to dermal toxicity of chlorpyrifos oxon, and to a lesser extent chlorpyrifos, consistent with a higher catalytic efficiency of chlorpyrifos oxon hydrolysis for the hPON1192R isoform. This mouse model is providing critical information on the relative importance of the two isoforms for protecting against OP-related toxicity. Since the presence of the hPON1192Q allele is widespread in Northern Europeans, and to varying extents in other ethnic groups, these findings have importance for sensitivity to specific OP compounds in the general population. (ES09883, ES07033, ES09601/EPA-R826886, HL3300568, AHA 11133-GI1, T32 AG00057).

487 THE MODIFICATION OF CYSTIC FIBROSIS LUNG DISEASE BY A POLYMORPHISM IN A GLUTAMATE CYSTEINE LIGASE GENE.

J. Shao[1], E. F. Mckone[2], C. L. Keener[1], C. A. Shephard[1], F. M. Farin[1], M. L. Aitken[2] and T. J. Kavanagh[1]. *[1]Environmental Health, University of Washington, Seattle, WA and [2]Division of Pulmonary and Critical Care Medicine, University of Washington, Seattle, WA.*

GSH modifies the clinical course of several pulmonary diseases. A polymorphism in a gene that regulates GSH synthesis might influence cystic fibrosis (CF) lung disease. We tested for an association between severe CF lung disease and a GAG repeat polymorphism in the glutamate cysteine ligase catalytic subunit gene (GCLC). In a cross sectional study, subjects were recruited from the CF clinic at the University of Washington. Relevant data were collected on each subject. Linear regression was used to test the relationship between CF lung disease and GCLC genotype. Gene-gene interaction between the GCLC polymorphism and CFTR genotype was measured using multiplicative interaction terms. Mechanistic studies were done to test the rate of GSH repletion after depletion, GCLC mRNA stability and rate of protein synthesis in cells with different GCLC polymorphism. 101 CF subjects participated in the study (51% male, mean (SD) age=26±8 yrs, mean FEV1=59±25% predicted). There was no association between GCLC genotypes and CF lung disease after adjusting for age, sex, P.aeruginosa infection and CFTR genotype (Coefficient (SEM) = 1.38 (1.86), p=0.46). However, after adjusting for gene-gene interaction between the GCLC polymorphism and the presence of a severe CFTR mutation, there was a significant association between GCLC genotypes and CF lung function (Coefficient (SEM) = 11.7 (4.5), p=0.01). There was a significant gene-gene interaction between GCLC and CFTR genotypes (Coefficient (SEM) = -8.4 (4.0), p=0.04). Also, the 9 GAG repeat was associated with faster GSH repletion, more stable mRNA and higher rate of protein synthesis in cultured lung fibroblasts. There is an association between the GCLC polymorphism and CF

lung disease and this association is significantly influenced by CFTR genotype. Mechanistic studies implicate a potential role for this GCLC polymorphism in regulating GCLC gene expression and protein synthesis. Supported by NIH grants P42ES04696, P30ES07033 and T32HL07287.

488 CLASSIFICATION OF SKIN SENSITISATION POTENCY USING THE LOCAL LYMPH NODE ASSAY.

D. A. Basketter[1], N. Gilmour[1], R. J. Dearman[2], I. Kimber[2], C. A. Ryan[3] and F. Gerberick[3]. *[1]SEAC, Unilever, Sharnbrook, Bedfordshire, United Kingdom, [2]Syngenta CTL, Alderley Park, Macclesfield, Cheshire, United Kingdom and [3]Human and Environmental Safety Division, Procter & Gamble, Cincinnati, OH.*

It has long been appreciated that chemicals that possess the potential to cause skin sensitization (allergic contact dermatitis) vary widely in their relative potency. However, until recently predictive test methods have not been well suited to measurement of this parameter. The local lymph node assay (LLNA) has been shown to provide a clinically relevant indication of the relative potency of skin sensitizers *via* the estimated concentration required to produce a 3-fold stimulation of proliferation in draining lymph nodes (EC3: the threshold for identification of a chemical as a sensitizer). In the present investigations we have examined the utility of a simple grading scheme for skin sensitizers based on order of magnitude differences in EC3 value. 50 chemicals have been classified as extreme (EC3 < 0.1%), strong (EC3 < 1.0%), moderate (EC3 < 10%), weak (EC3 ≤ 100%) or non-sensitizing (ie threshold for classification as a skin sensitizer not reached). It is suggested that this simple grading scheme provides a useful foundation on which to develop regulatory risk assessment/management strategies.

489 CURRENT REGULATORY STATUS OF THE LOCAL LYMPH NODE ASSAY.

N. Gilmour[1], D. A. Basketter[1], C. Ryan[2], F. Gerberick[2], R. Dearman[3] and I. Kimber[3]. *[1]SEAC, Unilever, Sharnbrook, Bedfordshire, United Kingdom, [2]Human and Environmental Safety Division, Procter & Gamble, Cincinnati, OH and [3]Central Toxicology Laboratory, Syngenta, Macclesfield, Cheshire, United Kingdom.*

Although the ideal alternative to the guinea pig as a model for the predictive identification of skin sensitization potential would be an *in vitro* method, such is not yet available. Where complete replacement is not yet possible, refined and reduced alternatives represent the best option, particularly where they also provide a superior quality of information compared with the earlier protocols. This is the situation with regard to the murine local lymph node assay (LLNA), a method based on the fact that skin sensitizers stimulate T cell division in lymph nodes draining the site of application on the skin. The LLNA has been formally validated in the USA *via* the Interagency Coordinating Committee on the Validation of Alternative Methods, as well as *via* the European Centre for the Validation of Alternative Methods. The hazard identification protocol for the LLNA has now (April 2002) been accepted by the Organization for Economic Cooperation and Development as OECD Guideline 429. Given the OECD agreements concerning mutual acceptance of data, this means that the reduction and refinement opportunities offered by the LLNA can be fully realised. For these reasons, the UK competent authority, the Health and Safety Executive, has taken the step of identifying the LLNA as the preferred method for hazard identification. This regulatory acceptance of an objective, quantitative method for the identification and classification of skin sensitizers opens up the prospect of further categorisation of sensitizers according to potency, so permitting improvements to risk assessment and risk management to be made.

490 THE MOUSE LOCAL LYMPH NODE ASSAY: COMPARISON OF CELLULAR PROLIFERATION RESPONSE (CPR) USING VARIOUS VEHICLES.

E. L. Blanchard, L. A. Waterson and A. D. Bull. *Huntingdon Life Sciences, Huntingdon, Cambridgeshire, United Kingdom.*

The mouse local lymph node assay (LLNA) is a refined *in vivo* alternative to traditional guinea pig tests for assessment of potential to cause skin sensitisation. A new OECD guideline (OECD 429) has recently been finalised which recognises the LLNA to be of equal merit to the traditional tests. The OECD 429 test guideline provides a list of vehicles ranked in order of preference; acetone:olive oil (4:1)(AOO), Dimethylformamide (DMF), propylene glycol (PPG) and Dimethyl sulfoxide (DMSO). Historically the aqueous vehicles acetone (AC) and absolute alcohol (AA) have also been common choices for such studies. The objective of this review was to determine whether the choice of vehicle affects the quantified background cellular proliferation response (CPR). In addition, as AOO is the preferred vehicle, assessment was made as to the consistency of the quantified CPR over a 7-year period. The protocols followed a standard design using pooled lymph node values. All studies used 6 to 8 week old female CBA/Ca strain mice obtained from Harlan UK Ltd., The 173 studies were performed between 1996 and 2002. The vehicles investigated were AOO, DMF, PPG, DMSO, AC and AA. The CPR was quantitatively measured as disintegrations per minute (DPM) after incorporation of ^{3}H-methyl thymidine. Comparison of the various vehicles revealed the mean CPR values for DMSO were generally higher (approximately 50%) than those of the other vehicles, whilst for the remaining vehicles CPR values were generally similar. Data for AOO treated animals over time indicated that between 1996 and 2000 the background CPR generally remained constant. However, data for 2001 were consistently lower than previous years. This is considered to be due to housing the studies in a full barrier maintained facility. In conclusion, the analyses show that the OECD test guideline preferred vehicles AOO, DMF and PPG produce similar background CPR. In addition, the responses in AOO are generally consistent over time but in the last year there has been a decline in the background CPR.

491 AN EUROPEAN INTER-LABORATORY VALIDATION OF ALTERNATIVE ENDPOINTS OF THE MURINE LLNA.

J. Huesler[9], H. Vohr[2], T. Maurer[10], P. Ulrich[1], G. Ehling[3], M. Hecht[4], C. Wiemann[5], B. Griffon[6], H. van Loveren[8], L. Ullmann[7] and A. Heusener[11]. *[1]Novartis Pharmacology AG, Basel, Basel, Switzerland, [2]Bayer AG, Wuppertal, Germany, [3]Aventis Pharmacology AG, Frankfurt, Germany, [4]ITA Fraunhofer Institute, Hannover, Germany, [5]BASF AG, Ludwigshafen, Germany, [6]CIT, Evreux, [7]RIVM, Utrecht, Netherlands, [8]University of Bern, Bern, Switzerland, [9]RCC, Fullingsdorf, Switzerland, [10]Swiss Agency for Therapeutic Products, Bern and [11]Merck, Darmstadt, Germany.*

The new OECD guideline 429 (Skin Sensitisation: Local Lymph Node Assay) is based upon a protocol, which utilises the incorporation of radioactivity into DNA as a measure for cell proliferation *in vivo*. The guideline also enables the use of alternative endpoints in order to assess draining LN cell proliferation. Here we describe the 1st round of an inter-laboratory validation of alternative endpoints in the LLNA conducted in 4 industrial laboratories, 3 CRO labs and 1 governmental agency laboratory. The validation study was managed and supervised by the Swiss drug agency SwissMedic. Statistical analysis was performed at the university of Bern, Department of Statistics. Ear-draining lymph node (LN) weight and cell count were used to assess proliferation instead of radioactive labelling of lymph node cells. In addition, the acute inflammatory skin reaction was measured by ear swelling and weight of circular biopsies of the ears to identify skin irritating properties of the test items. Hexyl cinnamic aldehyde and 3 blinded test items were applied to female, 8 to 10 weeks old NMRI and BALB/c mice. Results were sent to the independent study manager for statistically evaluation. The results of this first round showed that the alternative endpoints of the LLNA are sensitive and robust parameters. The use of ear weights added an important parameter assessing the skin irritation potential, which supports the differentiation of pure irritative from contact allergenic potential. The results highlighted that many parameter do have an impact on the strength of the responses. Therefore, such parameters have to be taken into consideration for the categorisation of compounds due to there relative sensitising potencies.

492 INTEGRATION OF PRIMARY IRRITATION WITH THE LLNA.

P. K. Anderson, M. R. Woolhiser, J. M. Rase and M. P. Holsapple. *Toxicology & Environmental Research and Consulting, The Dow Chemical Company, Midland, MI.*

The LLNA is a stand alone model to assess contact sensitization potential of chemicals, and is preferred by many governmental agencies unless technical difficulties with a test material requires the use of a guinea pig test. Historically, non-specific proliferation due to irritation has confounded LLNA interpretation. We have begun to test the hypothesis that chemicals which elicit a 10% increase in ear thickness (minimal irritating concentration-MIC_{10}) will produce a LLNA stimulation index near 3.0 due to the physiology surrounding primary irritation. Initial studies evaluated three concentrations of the isocyanates, MDI and IPDI, the anhydrides, TMA and PA, or DNCB applied to ears of mice for two days. Ear thickness was determined 24 hr later and following a third application, a LLNA was completed. MDI demonstrated a higher sensitization potential (EC_3=0.09%) than irritancy potential (MIC_{10}=0.28%). Conversely, 0.03% IPDI elicited a 3-fold proliferation but a 10% increase in ear thickness below 0.02% IPDI. In the case of TMA and PA, both demonstrated proliferation at chemical concentrations (EC_3=0.87% and 0.45%, respectively) below those required for primary irritation (MIC_{10}=4.6% and 0.95%, respectively). Likewise, 0.3%DNCB elicited 10% ear swelling while only 0.06%DNCB (EC_3) was needed to stimulate a 3-fold increase in LN proliferation. It appears that a specific irritating concentration and EC_3 values do not correlate to the same testing concentration for any given chemical and for 4/5 chemical tested, EC_3<MIC_{10}. As such, it does appear useful to minimize false positive proliferation

by testing chemicals at concentrations below which excessive irritation is elicited. An irritation screen over a range of soluble test material concentrations also serves to reduce unwarranted pain to laboratory animals. These studies suggest that simultaneous integration of ear swelling with lymph node proliferation can be beneficial when interpreting LLNA results. Additional studies evaluating chemical irritants (e.g., SLS) should be tested to confirm this testing scheme.

493 DEVELOPMENT OF THE LOCAL LYMPH NODE ASSAY IN NON-HUMAN PRIMATES.

M. G. Wing, D. F. Lanham, E. L. Hunter, J. M. Bidgood and D. Spencer-Briggs. *Huntingdon Life Sciences, Huntingdon, Cambridgeshire, United Kingdom.* Sponsor: C. Atterwill.

The selection of an appropriate non-rodent species for toxicology studies should be based on scientific considerations, which in the case of biopharmaceuticals should be to reproduce similar pharmacology to man. The local lymph node assay (LLNA) may be used as a model to monitor the pharmacology of immunomodulatory drugs, and because of the above need to evaluate biopharmaceuticals in non-rodent species, we have developed this model in the marmoset and cynomolgus monkey. Animals were given 3 daily topical applications of oxazalone to the dorsal surface of the ear and the draining lymph nodes dissected at necropsy on day 5. In some experiments, 7 oral administrations of cyclosporin A were given daily, commencing 2 days before the first dose of oxazolone. At necropsy the draining lymph nodes were removed and a single cell suspension of the lymph node was made using a cell strainer, then the cells were either resuspended in tissue culture medium for overnight culture with tritiated thymidine or processed for flow cytometry. *Ex vivo* proliferation of the draining lymph nodes demonstrated a dose-dependent increase in the number of proliferating cells in the marmoset, with stimulation indexes of 3, 7 and 12 being observed following the application of 1, 2.5 and 5% w/v oxazalone. Analysis of the cellular composition of the lymph nodes revealed that there was a dose dependent increase in the total number of lymph node cells, and in particular an increase in the proportion of B lymphocytes accompanied sensitization with oxazolone. In the cynomolgus monkey, the application of oxazolone was again associated with increased draining lymph node cellularity, B lymphocyte numbers and *ex vivo* proliferation, which could be inhibited in a dose dependent manor by cyclosporin A. In conclusion, these preliminary results demonstrate the potential of the LLNA to monitor immunomodulatory drugs intended to suppress the cellular immune response or influence cell migration in the non-human primate.

494 INTER-RELATIONSHIPS BETWEEN DIFFERENT CLASSES OF CHEMICAL ALLERGENS.

R. W. Crevel[2], R. J. Dearman[1], D. A. Basketter[2] and I. Kimber[2]. *[1]SEAC Unilever Colworth Laboratory, Sharnbrook, United Kingdom and [2]Syngenta CTL, Macclesfield, Cheshire, United Kingdom.*

Although sensitization of the respiratory tract induced by chemical allergens is not as common as skin sensitization and allergic contact dermatitis, it is nevertheless an important occupational health issue. Occupational asthma is associated with considerable morbidity and can be fatal. Several experimental approaches have been proposed for the identification and characterization of chemical respiratory allergens, but despite considerable progress none of these has yet been validated formally. In the absence of a widely accepted method for toxicological assessment of respiratory allergens it is appropriate to explore their relationship with skin sensitizing chemicals. In an analysis of a series of known chemical respiratory sensitizers we have found that without exception they elicit positive responses in one or more tests used for the prospective identification of skin sensitizing potential (guinea pig maximization test, the occluded patch test of Buehler and/or the local lymph node assay). We suggest that this observation could form the basis of an alternative paradigm for the initial characterization of sensitizing potential. Specifically, the proposal is that chemicals that fail to elicit positive responses in accepted methods for the identification of contact allergens are also regarded as lacking the potential to induce sensitization of the respiratory tract.

495 A HAZARD IDENTIFICATION MODEL FOR PROTEIN ALLERGENICITY: A MOUSE STRAIN COMPARISON.

M. R. Woolhiser, J. M. Rase, P. K. Anderson and M. P. Holsapple. *Toxicology & Environmental Research and Consulting, The Dow Chemical Company, Midland, MI.*

With the advent of biotechnology, the need for an animal model to identify allergic potential of proteins has increased. This laboratory's approach has involved i.p. administration of proteins to mice followed by evaluation of specific IgE (mouse Passive Cutaneous Anaphylaxis), total IgE, and specific IgG_1 and IgG_{2a} (ELISA $titer_{OD\ 0.5}$). BALB/c, CBA, B6C3F1, A/J and BDF1 mice were injected i.p. with 1 mg/ml ovalbumin (OVA) on days 1, 8, 15, 22, and 29. Tail bleeds were performed on day 21 followed by a terminal bleed on day 35. By day 21 (3 i.p. injections), A/J mice demonstrated increases in total IgE (10-fold) and OVA IgG_1 (titer=10, 993). Specific IgG_1 was not detected in any naive mice at dilutions of 1:10. While BDF1, B6C3F1, BALB/c and CBA mice exhibited little to no elevation in total IgE, B6C3F1 and BDF1 mice had appreciable increases in specific IgG_1 (titer=12, 150 and 35, 067). CBA mice had only 2/10 exhibit positive PCA reactions by day 21; sera from all other strains had at a least a 90% response rate at dilutions of 1:2. By day 35, A/J mice still had the only appreciable increase in total IgE. A/J mice also developed the highest OVA IgG_1 titer (>3x106), followed by BDF1 (>1.3x106) and B6C3F1 (920, 825). A/J mice had the largest IgG_{2a} titer (>59, 000) with CBA next at 6, 126. All strains demonstrated a 100% PCA response rate at 1:2 sera dilutions following 5 i.p. OVA injections with the following order of sensitivity: A/J>BDF1=B6C3F1>BALB/c>CBA. OVA specific IgG_1 demonstrated a better correlation with PCA reactions than did any other endpoint, including total IgE. A/J, BDF1 and B6C3F1 mice appeared most responsive to OVA exposures suggesting that evaluations of IgG_1 and PCA response by day 21, following only 3 i.p. injections, should be sufficient to evaluate allergenicity potential of proteins. Subsequent studies will investigate additional proteins including weak- and non-allergens to ensure that our model does not provide false positive results.

496 IMMUNOHISTOCHEMICAL ANALYSIS OF LOCAL LYMPH NODE ASSAY IN BALB/C MICE USING BROMDEOXYURIDINE.

J. Lee[1], J. Park[1], H. Kim[1], S. Chung[1], J. Eom[1], S. Park[1], Y. Heo[2] and H. Oh[1]. *[1]Division of Immunotoxicology, National Institute of Toxicological Research, KFDA, Seoul, South Korea and [2]College of Natural Sciences, Daegu Catholic University, Daegu, South Korea.*

A murine local lymph node assay (LLNA) has been developed as an alternative test to guinea pig maximization test. The disadvantage of LLNA is the need for the use of radioactive material. In this study, we aimed to investigate immunohistochemical analysis of local lymph node assay in Balb/c mice using Bromodeoxyuridine (BrdU). Female Balb/c mice were treated by the topical application on the dorsum of both ears with strong allergens, 2, 4-dinitrochlorobenzene (DNCB), Toluene diisocyanate (TDI) and strong irritant, Sodium lauryl sulfate (SLS), once daily for three consecutives, respectively. The proliferation of cells in auricular lymph node, and ear were analyzed by labelling index (LI) of BrdU incorporation into cells. The cell number and weight of lymph node in the mice treated with allergens, DNCB and TDI were increased compared to vehicle control. There was an increase in the percentage of B220+ cell of mice treated with DNCB and TDI compared to vehicle control, but was not with SLS. Because we observed B cell increase in allergen-treated group, we measured stimulation index (SI) in cortex and medulla (C+M) of lymph node. The SI of C+M in lymph node of mice treated with DNCB and TDI were over three-fold increase compared to that of the control. However, the SI of C+M in lymph node of mice exposed to SLS was not significantly increased compared to vehicle control, although the lymph node weight of SLS was significantly increased. These results suggest that the measurement of SI in cortex and medulla with immunohistochemical profile of lymph node using BrdU could be one of the useful methods for screening for irritant and allergen.

497 DEVELOPMENT OF A NOVEL ANAPHYLAXIS MODEL IN MICE BY INTERMITTENT INTRAVENOUS INJECTIONS OF OVALBUMIN WITHOUT USE OF ADJUVANT.

H. Hattori, M. Miyamoto, T. Aoki, M. Kato and K. Furuhama. *Drug Safety Research Laboratory, Daiichi Pharmaceutical Co., Ltd.,, Tokyo, Japan.*

Several types of mouse anaphylaxis models have been used to investigate the immediate type hypersensitivity to foods, respiratory allergens or pharmaceuticals. In these models, mice were needed to be sensitized for a long period with the allergens *via* several routes, such as oral, intraperitoneal, subcutaneous and topical application, in combination with aluminum hydroxide gel or Freund's complete adjuvant. To the best of our knowledge, there has been no report in which the intravenous injection of an antigen without the adjuvant was used for sensitization. To develop a novel anaphylaxis model, 10-week female ICR (CD-1) mice were given by intermittent intravenous injections (3 times at 4-day intervals) of 0.5, 5, 15 or 50 mg/kg of ovalbumin (OA) alone. In addition, strain difference was examined using 10-week female BALB/c and C57BL/6. In ICR mice, anaphylactic signs were observed immediately after the third injection of OA at 0.5 mg/kg or higher. Elevations in serum histamine level and permeability of the subcutaneous vasculature were associated with the onset of the signs. Anti-OA IgE and IgG antibodies were detected by the passive cutaneous anaphylaxis reactions in sera collected from mice 4 days after the second injection. The anaphylactic reactions due to OA were also observed in BALB/c and C57BL/6 mice at 15 mg/kg or higher, but not 5 mg/kg, indicating less susceptibility in these two strains than in ICR. Bovine serum albumin (BSA) also induced anaphylactic reactions in ICR mice by the same procedures. However,

higher doses (5 and 50 mg/kg) were needed to induce the reactions, and neither anti-BSA IgG nor IgE antibodies were detected even in mice receiving 50 mg/kg. In conclusion, anaphylaxis reactions were shown to be induced in mice by 3 intermittent intravenous injections of OA and BSA, and especially the OA-induced anaphylaxis was characterized by the production of specific IgE antibody despite of the short sensitization period without the adjuvant.

498 A 4-WEEK IMMUNOTOXICITY STUDY IN RATS TO VALIDATE IMMUNOLOGICAL ENDPOINTS.

G. Paul, D. Roman, E. Perentes, N. Runser, J. Streich, R. Schaffner and P. Ulrich. *Novartis Pharmacology AG, Basel, Basel, Switzerland.*

Assessment of the immune system's capability to respond to antigens with the generation of specific antibodies, whilst under the influence of a test article, is required in toxicity tests according to the European guideline for repeated dose toxicity testing of medicinal products. The purpose of this study in rats was to validate methodology for the determination of Keyhole Limpet Haemocyanin (KLH)-specific antibodies under the influence of an immunologically active compound. Prograf, a commercially available immunosuppressant, was administered orally (gavage) to 5 rats/sex/group at dosages of 0.5 or 3 mg/kg/day, once daily for a period of 4 weeks. On days 14 and 22, KLH was administered subcutaneously, with an adjuvant (AluGel), to the two treated groups and a control (i.e. without Prograf treatment) approximately 1 hour following administration of Prograf. Terminal investigations included haematology parameters, titration of KLH-specific antibodies in serum (ELISA), macroscopic pathology, spleen and thymus weights, immunophenotyping of splenocytes (FACS analysis) and limited histopathology. At 3 mg/kg/day a minimal reduction of subcutaneous KLH-induced granuloma formation and a moderate to marked reduction of germinal centre development (axillary lymph node and spleen) were observed. Reduced CD4+ (T-cell) counts were found in the spleen of males, consistent with a suppressed production of KLH specific antibodies (IgG in both sexes, IgM in males only) and a higher incidence of atrophy in the periarteriolar lymphoid sheaths of males. Slight to moderate lymphopenia was present in both sexes at 3 mg/kg/day. These findings are consistent with the known pharmacological activity of Prograf. In conclusion, determination of antibody titres following immunisation of rats with KLH, with concurrent exposure to a test item, appears to be a valid method in the context of the immunotoxicity evaluation required by European regulation.

499 IMMUNOTOXICOLOGICAL ASSAYS: MEASURING AND REDUCING THE VARIABILITY.

G. F. Healey, R. J. Brammer and M. G. Wing. *Huntingdon Life Sciences, Huntingdon, Cambridgeshire, United Kingdom.* Sponsor: C. Atterwill.

Immunotoxicity testing is being increasingly requested as part of the development of pharmaceuticals, pesticides, industrial chemicals and food additives. However, many of the functional assays are recognised as having high between- and within-study variability. For example, using historical data, the within-group coefficient of variation of the widely-used natural killer (NK) cell activity assay and the specific antibody formation in a plaque forming cell (PFC) assay, was found to be around 60%. Whilst between-animal variation is usually found to be the dominant source of variability in such assays, the multiple sample processing steps are also likely to contribute. Since little precise information is available on this, we therefore carried out a data-analysis investigation into the NK, PFC and other assays to formally separate out and measure the degree of variability from the various sources. Historical data were used and new validation studies were performed. It was found possible to improve the efficiency of certain of the assays by reducing the number of replicates or plates and by using randomized block designs to eliminate biases. In conclusion, the main method of reducing between-animal variability in non-invasive assays (blood rather than spleen samples) was shown to be the adjustment of data by pre-treatment values. Additional variability between studies and between sampling occasions was also found and is being looked at further.

500 COMPARATIVE STUDY OF THE IMMUNOTOXIC ACTIONS OF CYCLOSPORIN A, DEXAMETHASONE AND FUROSEMIDE IN THE RAT.

R. Forster, C. Mimouni, B. Griffon, J. Pavard and M. Attia. *CIT, Evreux, France.*

In this study Sprague-Dawley rats were treated with cyclosporin A (at 10, 15 and 20 mg/kg), dexamethasone (15 mg/kg) and furosemide (70 mg/kg) by oral gavage for 28 days. Hematological investigations were performed on blood samples taken at terminal sacrifice. The antibody response to the T-cell dependent antigen Keyhole Limpet Hemocyanin (KLH) was evaluated by subcutaneous administration of KLH on Day 22, followed by ELISA determination of IgM levels on blood samples taken at terminal sacrifice. Lymphocyte subsets in peripheral blood were quantified by flow cytometry on samples taken at the end of the study. Organ weight analysis and histopathological examinations were performed on lymphoid organs. The methods used correspond to those proposed for the evaluation of the potential toxicity to the immune system in recent European testing guidelines for new drugs. The test materials were all well tolerated clinically, and treatments with all three resulted in reductions in bodyweight gain, thus providing evidence that the selected dose-levels resulted in some general toxicity. Treatment with cyclosporin A provoked a dose-related decrease in the IgM antibody response to KLH, but treatment with dexamethasone or furosemide did not affect this parameter. Treatment with cyclosporin A resulted in a reduction in the proportion of CD4 and CD8 T-cells in rats of both sexes. Treatment with dexamethasone or furosemide did not influence T-cell populations. None of the treatments adversely affected B-cell populations. The test methods clearly permitted identification of the immunosuppressive actions of cyclosporin A. The immunosuppressive action of dexamethasone was not detected by the KLH response or lymphocyte subset analysis at the dose-level selected for this study. The results with furosemide were consistent with the view that this drug does not have immunotoxic properties.

501 EVALUATION OF PRIMARY ANTIBODY RESPONSE TO KEYHOLE LIMPET HEMOCYANIN IN SPRAGUE-DAWLEY RATS.

J. R. Piccotti[1], J. D. Alvey[1], C. Y. Malinczak[1], L. A. Belisle[1], T. T. Kawabata[2] and M. R. Bleavins[1]. *[1]Drug Safety Evaluation, Pfizer Global Research & Development, Ann Arbor, MI and [2]Drug Safety Evaluation, Pfizer Global Research & Development, Groton, CT.*

The Committee for Proprietary Medicinal Products (CPMP) and the Food and Drug Administration (FDA) recommend evaluating a primary T-dependent antibody response when assessing the immunotoxicity potential of new drug candidates. Although the immune response to sheep red blood cells (sRBC) in rodents is well documented, responses to other T-dependent antigens such as keyhole limpet hemocyanin (KLH) have not been fully characterized. The current study evaluated the primary IgM response to KLH in male and female Sprague-Dawley rats. Animals were given a single intravenous injection of KLH at 30, 100 or 300 μg per animal. Serum samples were collected prior to immunization, and on Days 3, 5, 7, 10, 14 and 21 post-immunization. IgM specific for KLH was measured by ELISA, using a detection antibody with high reactivity with rat IgM and no cross-reactivity with rat IgG. Anti-KLH IgM was undetectable in sera collected from animals prior to immunization. In contrast, robust dose-dependent antibody responses were seen in rats immunized with KLH. The peak IgM response in both male and female rats occurred between 5 and 7 days post-immunization. The timing of the IgM response to KLH in this study was consistent with reported responses to sRBC. However, the use of KLH as an antigen may provide a better standardized model compared to sRBC. Experiments evaluating the effects of known immunosuppressive agents such as cyclosporin A and cyclophosphamide on the primary antibody response to KLH are ongoing.

502 DEVELOPMENT AND VALIDATION OF AN ASSAY TO EVALUATE THE CANINE T-DEPENDENT ANTIBODY RESPONSE.

D. Finco-Kent and T. T. Kawabata. *DSE/MIT, Pfizer, Groton, CT.*

New immunotoxicity testing guidelines have been adopted by the CPMP and are forthcoming from the FDA. The primary T-dependent antibody response (TDAR) is an assay recommended by both agencies. Immunotoxicity assays have been validated for mice and rats, however methods for the dog have not been reported. Our lab has developed a dog model for the assessment of a primary TDAR to keyhole limpet hemocyanin (KLH). Dogs were immunized with KLH using 3, 10 or 30 mg/dog by intramuscular injection. Serum samples were collected prior to immunization and on days 3, 5, 7, 10, 14 and 21 post-immunization. Serum samples were tested in a dog anti-KLH IgM ELISA developed in our lab. Immunization with KLH resulted in a robust antibody response at all doses of antigen. Peak IgM response occurred on day 7 post-KLH injection. The 10mg/dog dose elicited the highest response. After the peak response, the anti-KLH response flattened out or decreased slightly through the end of the study. The ELISA assay showed high specificity for IgM with little to no cross-reactivity with IgG. Intra-assay and inter-assay precision of endpoint titers (log 2) is less than 10%. Additional validation studies are planned to determine the sensitivity of the dog TDAR to a known immunosuppressive agent.

503 VALIDATION OF AN ELISA PROCEDURE WITH NITROPHENYL-CHICKEN GAMMA GLOBULIN (NP-CγG) AND KEYHOLE LIMPET HEMOCYANIN (KLH) AS ANTIGENS FOR TESTING HUMORAL IMMUNOTOXICITY.

H. W. Smith, C. J. Winstead, B. W. Halstead and D. Wierda. *Investigational Toxicology, Eli Lilly and Company, Greenfield, IN.*

Limitations of the standard sheep red blood cell plaque assay for evaluating preclinical immunotoxicity have led to an interest in the feasibility of using alternative antigens, together with an ELISA format, for assessing humoral immunotoxicity.

The purpose of this study was to evaluate the predictive value of NP-CγG and KLH antigen challenge in determining the immunotoxicity of orally administred azathioprine (AZA), cyclophosphamide (CY), or cyclosporin A (CsA) at doses of 17, 10, or 25 mg/kg per day, respectively, for 30 days in F344 female rats. The effect of treatment on the immune response was assessed in a humoral model that consisted of the administration of nitrophenyl-chicken gamma globulin (NP-CγG) and keyhole limpet hemocyanin (KLH) antigens during immunosuppressive treatment and the measurement of resulting rat antigen-specific IgG and IgM, as well as total IgG, levels. Cellular assessment parameters included organ weights and cellularity, hematology, lymphocyte phenotype characteristics, spleen cell mitogen stimulation (T and B cell dependent), splenic natural killer (NK) cell cytotoxicity, and bone marrow cellularity and lymphocyte phenotype differential. Although decreases in several of the cellular assay parameters were induced by all three immunosuppressive agents, the only functional assays to demonstrate a statistically significant immunosuppressive effect were the antigen-specific serum IgG levels. The primary (Day 10; 15 days post immunization) and secondary (Day 25; 5 days post rechallenge) NP responses were significantly suppressed by >60%. The use of NP hapten provided consistent responses when analyzed with a sensitive, well developed, ELISA methodology. Absolute lymphocyte phenotyping and lymphocyte hematology were also predictive of T cell immunosuppression for all 3 compounds. The data suggest that these two parameters, NP-IgG humoral response and lymphocyte phenotyping, are sufficient for identifying immunosuppressive compounds.

504 CHARACTERIZATION OF KEYHOLE LIMPET HEMOCYANIN (KLH) AS AN ALTERNATIVE T-DEPENDENT ANTIGEN FOR ELISA IMMUNOTOXICOLOGICAL EVALUATIONS IN MICE.

J. A. Shea, V. L. Peachee and K. L. White. *Medical College of Virginia, Richmond, VA.*

Previous studies by the NTP/NIEHS identified the spleen plaque forming cell response to T-dependent antigen sRBC as one of the most sensitive functional assays for detecting immunomodulating compounds. Various regulatory agencies currently accept the sRBC ELISA for immunological evaluation. Problems with the sRBC ELISA is that depending on the sRBCs and animals, low affinity antibody can be produced following a single injection. Furthermore, lot to lot preparations of sRBC membranes can vary significantly. Since no standard antibody is available ELISA results are usually expressed as serum titers. The objective of this study was to optimize the KLH ELISA as an alternative T-dependent antigen and to evaluate how it compared to the plaque assay. Commercial KLH (Pierce) produced a uniform solution unlike preparations from other vendors. Mice were injected with 100 ug/animal iv and evaluated on days 3 - 7. Antibody response to KLH reached a plateau on days 4, 5, and 6, with day 5 having the least variability. The 100 ug/animal concentration was selected after dose response studies ranging from 30 ug/animal to 500 ug/animal demonstrated a plateau effect. The optimal ELISA conditions utilized Immunlon II plates coated with 0.5 ug/well of KLH in PBS incubated overnight. Purified mouse IgM mAB against KLH (PharMingen) was used as a standard. Daily treatment with cyclophosphamide ip, at doses from 5 mg/kg to 60 mg/kg resulted in dose dependent suppression on day 5. Animals treated daily with dexamethasone ip at 0.1 mg/kg to 5 mg/kg did not differ significantly from the vehicle controls. A similar lack of effect of dexamethasone was observed in the plaque assay when data were expressed as PFC/10^6 spleen cells. KLH as the T-dependent antigen in ELISA studies has several advantages over sRBC including; being commercially available, prepared under quality control conditions, produces a robust response with a single injection, and a KLH standard is available for quantitating serum antibody levels in mice. (Supported in part by NIEHS Contract ES55387).

505 VALIDATION METHOD FOR THE DETECTION OF ANTI KEYHOLE LIMPET HEMOCYANIN ANTIBODIES IN SPRAGUE-DAWLEY RAT SERUM BY ELISA.

N. Rouleau, J. Jean-Baptiste, G. Desilets, R. Riffon and L. LeSauteur. *Immunology Laboratories, CTBR, Senneville, QC, Canada.* Sponsor: D. Jones.

Immunotoxicity testing guidance have recommended the T-cell dependent antibody response assay; keyhole limpet hemocyanin used as an antigen and ELISA monitoring for antibody formation provides advantages over traditional methodology. Validation of a qualitative ELISA for the detection of KLH specific antibodies in sprague-dawley rat serum was performed. The ELISA method consisted of plates coated with KLH, adding the test serum, then the antibodies were detected using a peroxidase conjugated secondary antibody; a colorimetric substrate was used for color development. Parameters validated for the ELISA method included specificity, cut-off determination, intra- and inter-assay precision, and stability. High, medium, low and species (rat immunoglobulin) positive controls were included. Specificity, intra- and inter-assay precision met the acceptance criteria of mean A450 values above the cut-off value and the coefficient of variation ≦20%. A cut-off value was determined. Stability of samples at room temperature for approximately 6 hours, at 4°C for approximately 24 hours, and after 4 freeze-thaw cycles at −70°C, long-term storage stability of samples at approximately −70°C are ongoing. A similar method has been developed for monitoring IgM and both methodologies can be used for monitoring the T-cell dependent antibody response in a toxicology study.

506 VALIDATION METHOD FOR THE DETECTION OF ANTI-KEYHOLE LIMPET HEMOCYANIN ANTIBODIES IN CYNOMOLGUS MONKEY SERUM BY ENZYME LINKED IMMUNOSORBENT ASSAY (ELISA).

G. Desilets, N. Rouleau, J. Jean-Baptiste, R. Riffon and L. LeSauteur. *Immunology Laboratories, CTBR, Senneville, QC, Canada.* Sponsor: D. Jones.

Immunotoxicity testing guidelines have recommended the T-cell dependent antibody response assay; keyhole limpet hemocyanin used as an antigen and enzyme linked immunosorbent assay (ELISA) monitoring for antibody formation provides advantages over more traditional methodologies. The ELISA method consisted of coating plates with KLH, and subsequently adding the test serum; the antibodies were then detected using a peroxidase conjugated secondary antibody, with a colorimetric substrate for color development. Validation of this qualitative ELISA for the detection of KLH specific antibodies in Cynomolgus monkey serum was performed. Parameters validated included specificity, cut-off determination, intra- and inter-assay precision, and stability. High, medium, low and species (monkey immunoglobulin) positive controls were used for the validation. Specificity, intra- and inter-assays previously met the acceptance criteria of mean A450 values over the determined cut-off value, coefficients of variation (CVs) < 20%. Stability of samples at room temperature for approximately 6 hours, at 4°C for approximately 24 hours, and after 4 freeze-thaw cycles at approximately −70°C met the acceptance criteria, long-term storage stability at approximately −70°C is ongoing. A similar method has been developed for monitoring IgM and both methodologies can be used for monitoring the T-cell dependent antibody response in support and toxicology studies

507 INTERLABORATORY STUDY OF THE PRIMARY ANTIBODY RESPONSE TO SHEEP RED BLOOD CELLS IN OUTBRED RODENTS FOLLOWING EXPOSURE TO DEXAMETHASONE.

S. E. Loveless[1], G. S. Ladics[1], C. Smith[1], M. P. Holsapple[2], M. R. Woolhiser[2], P. K. Anderson[2], K. L. White[3], D. L. Musgrove[3], R. J. Smialowicz[4] and W. C. Williams[4]. *[1]DuPont Haskell Lab., Newark, DE, [2]Dow Chemical Co, Midland, MI, [3]Virginia Commonwealth University, Richmond, VA and [4]USEPA, ORD, NHEERL, Research Triangle Park, NC.*

EPA guidelines provide a choice in evaluating immune system function in rats and mice using sheep red blood cells (sRBC), namely, an antibody-forming cell (AFC) assay or a sRBC-specific serum IgM ELISA. All four laboratories used the same source of sRBC to determine which of the two methods was more sensitive in detecting suppression of the antibody response by dexamethasone (DEX). CD rats and CD1 mice were injected iv with sRBC followed by ip injections of 0, 0.1, 0.3, 1, 3 or 5 mg/kg/day DEX. In rats, statistically significant reductions in antibody response as measured by AFC/106 splenocytes were first detected at 0.1 mg/kg/day (47% suppression) by one lab and at 1 mg/kg in 3 labs. In contrast, suppression measured by ELISA was first detected at 5 mg/kg (20-33% suppression). In mice, statistically significant reductions in the antibody response were detected at 1 mg/kg (52% suppression - AFC assay) by 1 lab and 3 mg/kg (55% suppression) by another lab. Suppression using the ELISA was detected at 3 mg/kg (7% inhibition). In conclusion, the PFC assay detected significant suppression at lower concentrations compared to the ELISA in both rats and mice. At concentrations of DEX where both assays showed significant suppression, greater suppression was observed using the PFC assay. These results in the mouse mirror those observed in an earlier collaboration using cyclophosphamide (CY), but differ from those in rats in which the rat ELISA detected significant suppression with CY at the same (2 labs) or lower (1 lab) concentration compared to the PFC assay. Additional compounds will need to be evaluated before concluding that one method is superior to the other in detecting suppression of the antibody response. (This abstract does not reflect EPA policy).

508 QUANTITATION OF ANTI-SHEEP RED BLOOD CELL (SRBC) MEMBRANE-SPECIFIC IGM: A NOVEL METHOD USING ABSORPTION OF SPECIFIC ANTIBODY.

D. B. Walker, T. E. Morey and J. R. Sibley. *Clinical Pathology, Wyeth Research, Chazy, NY.* Sponsor: S. Marina.

The primary humoral immune response against SRBC has been recommended in regulatory guidance documents to evaluate potential unexpected immunosuppression by pharmaceutical compounds or chemicals. Currently, specific IgM to SRBC

membrane antigens is most commonly assessed as a relative value based on the density of specific IgM-producing splenocytes in the hemolytic plaque assay, or serum titers. Both of these methods are labor-intensive andand present significant challenges for achieving and maintaining GLP compliance. The objectives of this study were to develop and validate a time- and cost- efficient ELISA to quantitate specific IgM against SRBC membrane antigens in rat serum that could be readily implemented as a GLP-compliant procedure. Serum was collected from rats immediately prior to, and 6 days following immunization with SRBC; total IgM was quantitated in these samples using a standard curve established with polyclonal goat IgG against rat IgM. In samples collected following immunization, total IgM was measured before and after absorption to fixed SRBC to determine the quantity of IgM specifically directed against SRBC membrane epitopes. To validate this assay, male rats were given cyclophosphamide at 0, 10 or 30 mg/kg/day beginning one day prior to immunization. An additional group of rats was immunized with 1 mg keyhole limpet hemocyanin (KLH) subcutaneously as a negative control group to assess non-specific binding of IgM to fixed SRBC. Results of this novel ELISA and those of the traditional titer method for determination of SRBC-specific IgM were compared. Additional parameters evaluated in these rats included routine hematology and histology of lymphoid tissues, and by flow cytometry, distribution of major lymphocyte subtypes in peripheral blood, spleen, thymus and mesenteric lymph nodes. Results demonstrated excellent correlation between the quantitative ELISA developed in this study and traditional titer method, and between histology and results of lymphocyte subtype distribution in peripheral lymphoid tissues.

509 AUTOMATED MEASUREMENT OF LEUKOCYTE MIGRATION IN NORMAL AND OXIDATIVE ENVIRONMENTS.

N. Hadjout, X. Yin, D. A. Knecht and M. A. Lynes. *Molecular and Cell Biology, University of Connecticut, Storrs, CT.*

We have developed a novel method (ECIS/taxis) for automated real time monitoring of leukocyte cell movement in response to chemotactic factors. In this report, we describe the migration of several primary and immortalized leukocytes in response to several chemoattractants. In the ECIS/taxis system, cells migrate in an under-agarose environment, and their positions are monitored using the electric cell substrate impedance sensor technology to measure the impedance change at a target electrode that is lithographed onto the substrate. Cell arrival is indicated by significant increase in the impedance at the target electrode. The intensity of migration of cells, in response to increasing doses of chemoattractant, was proportional to the increase in the absolute value of resistance measured by the target electrode. Modifications to the design of the target electrode have been shown to increase the sensitivity of the assay. The multiwell assay configuration allowed the detection of antagonistic effects of pharmaceutical drugs as well as the detection of the damaging effects of reactive oxygen species on the migrating cells. Finally, we have further used the system to evaluate the role of metallothionein as an antioxidant in the preservation of inflammatory phagocyte function following exposure to exogenous and endogenous oxidants. Higher levels of endogenous metallothionein correlated with a greater resistance to the effects of oxidant on the chemotactic response. These results suggest that ECIS/taxis measurements will expand the experimental and diagnostic capacity to evaluate normal and dysfunctional chemotactic cell movement, and that metallothionein induced as a consequence of toxicant exposure can have significant impact on the motility of cells in inflammatory environment. This work was supported in part by NIH Grants: EB00208 and ES07408

510 COMPARISON OF THE PHAGOCYTIC ACTIVITY IN RATS AND MONKEYS USING TWO COMMERCIAL KITS.

C. Cretinon[1], F. Condevaux[1], F. Horand[1] and J. G. Descotes[2]. *[1]MDS Pharmacology Services, l'Arbresle, France and [2]Poison Center, E.Herriot Hospital, Lyon, France.*

Phagocytosis is an essential arm of non-specific defences against infections and is therefore an important part of immunotoxicity evaluation. In this study, phagocytosis was studied by flow cytometry in rats and in Cynomolgus and Rhesus monkeys, using 2 commercial human kits: the Phagotest© and the Bursttest© (Orpegen). The Phagotest© measures the percentage of phagocytes which have ingested bacteria and the number of bacteria in each cell, while the Bursttest© measures the percentage of phagocytes which have produced reactive oxygen radicals and the enzymatic activity per cell (oxydative burst). Overall, results in monkeys were similar to those obtained in man. Various interspecies differences were identified in this study. In the Phagotest©, the proportion of phagocytic cells was approximately 80% in monkeys, but only 60% in rats. Two stimuli are used in the Bursttest©, namely opsonized E. coli and phorbol myristate acetate (PMA). In monkeys, as in humans, PMA was more potent than E. coli, with 90% and 70% of positive phagocytic cells, respectively. In rats, only 60% of phagocytes were positive with either stimuli. In addition, these two kits can be used to calculate mean fluorescence intensity, which depends on the number of bacteria or enzymatic activity per cell. Results were not homogeneous due to the influences of sampling, number of bacteria and the technique. Although the Phagotest© and Bursttest© were both found to be suitable to evaluate phagocytosis in rats and monkeys, this study suggested that monkeys are preferable to rats for this investigation. This confirms our previous results using chemiluminescence.

511 INTERLABORATORY STANDARDIZATION OF FLOW CYTOMETRY DATA ACQUISITION PRACTICES.

W. J. Komocsar, A. R. Cohen, J. E. Heward, C. W. Johnson, K. L. Kowalkowski, M. Mameli, D. Moneta, S. Zhao and S. M. Furst. *Global Toxicology, Pharmacia, Skokie, IL.*

In today's global work environment, it is common for a research facility to have laboratories exist in multiple geographic locations. To harmonize flow cytometry practices in the toxicology groups across 3 major Pharmacia sites located in Skokie, IL, Kalamazoo, MI and Nerviano, Italy, a cross-site standardization study was conducted. The goals were to standardize instrument set-up and data acquisition protocols across sites to assure optimal alignment for light scattering and fluorescence resolution as well as appropriate compensation when using multiple fluorochromes. This standardization also harmonized quality control practices across sites using different model flow cytometers. Uniformly sized fluorospheres (Flow-Check™) were used to monitor photomultiplier tube (PMT) and system fluidic performance. Fluorescently labeled microparticles (CaliBRITE beads) were used to target fluorescence for each PMT to a specific channel and then set-up appropriate compensation. This protocol was followed each time sample data was acquired. To assess the adequacy of the harmonized set-up, CD-Chex®Plus, a commercially available normal human peripheral blood control preparation were immunophenotyped. All sites used the same labeling protocols and reagent lots. Both BD instruments (FACSCalibur, FACScan) showed very similar high voltage trends for the CaliBRITE beads as did the Coulter XLs. Compensation settings day to day for each instrument showed very little variability. In analyzing CD-Chex®Plus data, all three labs were within 5% of group mean values in quantitation of CD3+/CD45+, CD3+/CD4+, CD3+/CD8+ and CD45+/CD19+ cells. The values obtained for CD45+/CD16, CD56+ showed a little more variability, but were still considered acceptable. These acceptable immunophenotyping results confirm the success of the standardization protocol and demonstrate the ability to harmonize data collection across multiple geographic sites using five different flow cytometers and furthermore suggests that a common reference range may be developed across laboratories.

512 SEX DIFFERENCE IN THE RESPONSE OF MOUSE LIVER TO CAR-MEDIATED INDUCTION OF CYP2B10 AND HEPATOCYTE PROLIFERATION.

G. M. Ledda-Columbano, M. Pibiri, F. Molotzu, D. Concas, G. Simbula, C. Cossu and A. Columbano. *Toxicology, University, Cagliari, Sardinia, Italy.*

The nuclear receptor Constitutive Androstane Receptor (CAR) binds DNA as a heterodimer with the retinoic-X receptor and activates gene transcription in a constitutive manner. Previously, *in vitro* studies have shown that the testosterone metabolites, androstanol, and androstenol, inhibit the constitutive transcriptional activity of CAR, suggesting that differences might exist in the response to CAR-mediated gene activation between different sexes. In this study, we have analyzed the response of female and male mice hepatocytes to two processes induced by the CAR ligand and non-genotoxic mouse liver carcinogen TCPOBOP, namely induction of CYP2B10 transcription and stimulation of hepatocyte proliferation. Results showed that levels of CYP2B10 mRNA were more abundant in the liver from female mice treated with TCPOBOP than those of males. Similarly, labeling index of female hepatocytes at 24, 30 and 36 hours after treatment was much higher than that found in males. The higher proliferative activity of female hepatocytes was associated with increased hepatic levels of cyclin D1, cyclin A, E2F and enhanced phosphorylation of p107. Administration of androstanol to males caused a decrease of labelling index and CyP2B10 mRNA levels. In conclusion, the results show that, at least two biological responses elicited by the CAR ligand TCPOBOP, namely, induction of microsomal detoxification and hepatocyte proliferation occur at higher levels in female than male mice, suggesting that CAR transactivating activity in males is partially counteracted by physiological higher levels of testosterone metabolites such as androstanol and androstenol.

513 ALTERATIONS IN AIRWAY INTRACELLULAR SIGNALING PATHWAYS FOLLOWING AIR POLLUTION PARTICLE (PM) EXPOSURE USING LASER CAPTURE MICRODISSECTION AND PROTEIN ARRAY TECHNOLOGIES.

E. S. Roberts[1], L. Charboneau[2], L. Liotta[2], E. Petricoin[3] and K. L. Dreher[4]. *[1]College of Veterinary Medicine NC State University, Raleigh, NC, [2]National Institutes of Health, Bethesda, MD, [3]CBER, US Food and Drug Administration, Rockville, MD and [4]NHEERL, US Environmental Protection Agency, Research Triangle Park, NC.*

Understanding the mechanisms by which PM and associated constituents mediate adverse health effects would provide biological plausibility to epidemiological findings indicating an association between PM and increased rates of morbidity and mortality. Whole lung extracts have provided insight into mechanisms that mediate ambient air and PM-induced pulmonary injury. This approach, however, makes it difficult to elucidate detailed cellular and molecular pathology associated with PM-induced injury. Therefore, the majority of information regarding the means by which PM generates lung injury has been derived from *in vitro* studies where it is unclear to what extent these mechanisms can be extrapolated to the *in vivo* situation. Recent technological advances have allowed the direct study of susceptible cells or cell populations *in vivo*. In the present study we applied laser capture microdissection (LCM) and protein array technologies to examine the effect residual oil fly ash (ROFA) exposure had on airway intracellular signaling pathways associated with cell growth and differentiation. Sprague-Dawley rats were intratracheally instilled with 0.5 mg/rat ROFA in saline or saline alone. LCM was used to recover airway epithelial cells from the lungs of control and exposed rats. Protein array analysis examined alterations in cellular signaling pathways from protein extracted from LCM captured tissue. ROFA increased p-ERK:ERK at 6h and 24h ($P < 0.001$) post exposure when compared to saline or cage control animals. This study shows the utility of LCM and protein arrays in addressing environmental health issues and demonstrates *in vivo*, that lung injury due to PM exposure is associated with airway epithelial cell MAPK activation. *(This abstract does not reflect EPA policy.)*

514 INSULIN-LIKE GROWTH FACTOR 1 - ESTROGEN RECEPTOR α CROSSTALK IN MCF 7 BREAST CANCER CELLS.

S. Zhang and S. Safe. *Veterinary Physiology & Pharmacology, Texas A&M University, College Station, TX.*

Polypeptide growth factors such as insulin-like growth factor I (IGF-I) induce proliferation of breast cancer cells through activation of growth factor signaling pathways and ligand-independent activation of estrogen receptor α (ERα). Treatment of MCF-7 cells with 10 nM IGF-I for 9 days resulted in a > 5-fold increase in cell number, whereas solvent (DMSO)-treated cells increased by approximately 2.5-fold. In contrast, MCF-7 cell proliferation was inhibited after treatment with 1 μM ICI 182, 780 (an antiestrogen), 15 or 5 μM PD98059 or LY294002 which inhibit mitogen-activated protein kinase kinase (MAPKK) and phosphatidyl inositol-3-kinase (PI3-K), respectively. Inhibition by these agents was cytostatic and did not induce cytotoxic responses at the concentrations used in this study. Cotreatment of cells with 10 nM IGF-I plus PD980059, LY294002 or ICI 182, 780 significantly decreased growth factor-induced cell proliferation only with the latter two inhibitors, whereas PD980059 was inactive as an inhibitor. PD980059 and LY294002 inhibited IGF-I-induced MAPK and Akt phosphorylation, respectively, whereas ICI 182, 780 did not inhibit MAPK or Akt phosphorylation. IGF-I also induced constructs containing the serum response element from the c-*fos* protooncogene promoter or multiple copies of the serum response factor element; however, in cotreatment studies, ICI 182, 780 did not inhibit these IGF-I-induced responses. These results suggest that both ERα and PI3-K are critical factors for mediating IGF-I-induced proliferation of MCF-7 cells and induction of c-*fos* is not critical for cell growth. Current studies are determining between PI3K-ERα interactions. (Supported by NIH ES09106 and ES09253)

515 ROLE OF DIOXIN-INDUCED MAP KINASE SIGNALING IN ARYL HYDROCARBON RECEPTOR PHOSPHORYLATION.

Z. Tan, A. Puga and Y. Xia. *Center for Environmental Genetics and Department of Environmental Health, University of Cincinnati Medical Center, Cincinnati, OH.*

Recent evidence has shown that treatment of mouse hepatoma Hepa-1 cells with 2, 3, 7, 8-tetrachlorodibenzo-*p*-dioxin (TCDD) induces intracellular mitogen-activated protein (MAP) kinases that are required for maximal activation of the aryl hydrocarbon receptor (AHR). In this study, we investigated the role of TCDD in activation of signaling pathways leading to MAP kinase induction and AHR phosphorylation. In AHR-negative CV-1 cells, AHR-dependent reporter gene expression was potentiated by co-expression of AHR/ARNT with the upstream regulators of the MAP kinase pathways, MEKK1 and Raf1. This effect on AHR activity was suppressed by specific inhibitors of the ERK (extracellular signal regulated kinase) and the JNK (Jun N-terminal kinase), but not the p38 MAP kinase. ERK activation was completely abolished in a PLC-γ null cell line, while PLC-γ reconstitution of these cells restored ERK responsiveness to TCDD. These results suggest a role for PLC-γ, MEKK1 and Raf1 in TCDD-dependent activation of MAP kinases. *In vivo* ^{32}P-orthophosphate labeling of mouse hepatoma Hepa-1 cells showed that TCDD exposure led to rapid ERK activation followed by the transient induction of AHR phosphorylation. *In vitro*, ERK directly phosphorylated AHR isolated from untreated Hepa-1 cells. Hence, MAP kinases may act as central effectors of different pathways in TCDD signaling and their role on AHR activity is likely to be mediated through direct receptor phosphorylation. *(Supported by NIH ES06273, NIH ES10807, NIH P30-ES06096 and a grant from the Philip Morris External Research Program).*

516 REGULATION OF HIF TRANSACTIVATION AND CAP43 EXPRESSION BY NICKEL COMPOUNDS THROUGH PI-3K/AKT-DEPENDENT, P70S6K-INDEPENDENT PATHWAY.

G. Davidson, J. Li, Y. Huang, M. Costa and C. Huang. *Environmental Medicine, New York University School of Medicine, Tuxedo Park, NY.*

Nickel compounds induce a marked induction of hypoxia inducible factor 1 (HIF-1), and this is considered to be important in nickel-induced tumor promotion and progression. As yet, however, the signal transduction pathways leading to the induction of HIF-1 are not fully understood. We demonstrate in this study that exposing mouse epidermal C141 cells to either $NiCl_2$ or Ni_3S_2 results in the activation of the phosphatidylinositol 3-kinase (PI-3K) pathway, including PI-3K, Akt and p70 S6 kinase ($p70^{S6k}$). In addition, exposure to $NiCl_2$ and Ni_3S_2 leads to transactivation of HIF-1. HIF-1 transactivation in response to $NiCl_2$ and Ni_3S_2 can be inhibited by pre-treatment of the C141 cells with the PI-3K inhibitors wortmannin and LY294002, which also attenuates the activation of PI-3K, Akt and $p70^{S6k}$. Overexpression of a dominant negative mutant of PI-3K, Δp85, also led to inhibition of PI-3K, Akt, and $p70^{S6k}$, and impaired nickel-induced HIF-1 transactivation. In addition, overexpression of an Akt dominant negative mutant, Akt-T308A/S473A, was shown to block nickel-induced Akt phosphorylation and HIF-1 transactivation. In contrast, pre-treatment of cells with rapamycin, a $p70^{S6k}$ specific inhibitor, did not result in HIF-1 transactivation, but did attenuate $p70^{S6k}$ activity. HIF-1 activation has previously been shown to induce Cap43 gene expression and, consistent with this observation, we demonstrate here that inhibition of the PI-3K pathway using either wortmannin or LY294002, or by overexpression of Δp85 or Akt-T308A/S473A leads to a significant inhibition of nickel-induced Cap43 protein expression. Rapamycin, in contrast, did not inhibit Cap43 expression in a similar manner. In summary, our results demonstrate that nickel compounds induce both HIF-1 activation and Cap43 protein expression through a PI-3K/Akt dependent and $p70^{S6k}$-independent pathway. These results may help us understand the signal transduction pathways related to the carcinogenic effects of nickel,

517 INTERFERENCE OF POLYCHLORINATED BIPHENYLS WITH G-PROTEIN-COUPLED ATP-RECEPTOR SIGNAL TRANSDUCTION IN HUMAN MACROPHAGES.

H. Wiegand. *Med.Inst.Environm.Hygiene, Duesseldorf, NRW, Germany.*

ATP stimulates different types of purine receptors to increase intracellular calcium concentrations ([Ca++]i) in monocyte derived human macrophages, the ion channel type P2X as well as the effector chain type P2Y receptors. Up to now it is poorly understood which type of receptors mediate the peak-like increase of [Ca++]i induced by ATP which is enhanced by the polychlorinated biphenyl congener PCB47 (Dehnhardt et al., 2000). The present investigation tries to characterize the contribution of P2Y receptors to this phenomenon. Human monocyte derived macrophage cultures treated with PCB47 were stimulated using the ATP as agonist to monitor single cell [Ca++]i using FURA-2 as fluorescence probe in an imaging system. cAMP levels were determined in macrophage cultures to monitor the adenylyl cyclase dependent branch of intracellular signal transduction. We also used the selective phospholipase C (PLC) inhibitor U73122 to block the PLC dependent branch of the P2Y receptor chain. Treatment of macrophage cultures using PCB47 in a concentration range between 10nmol and 100 μmol significantly reduced intracellular cAMP levels. Application of forskolin reduced this effect. In macrophages pretreated with U73122 (100 nmol to 10 μmol for 10 min) to inhibit PLC the peaklike intracellular [Ca++]i increase was drastically reduced in PCB 47 exposed as well as in unexposed controls. The benzoyl-ATP (bATP) stimulated [Ca++]i increase which is known to be induced only by P2X type of ATP receptors

was lower as compared to the [Ca++]i increase induced by ATP known to target both ion channel type and effector chain type of ATP receptors. These experiments show that beside P2X receptors P2Y receptors are targets for PCB47 interference in human macrophages. (partly supported by DFG, Germany)

518 DOWN REGULATION OF EGFR/MAPK SIGNALING IN THIOACETAMIDE TREATED DIABETIC RATS.

S. S. Devi, M. C. Korrapati and H. M. Mehendale. *Toxicology, The University of Louisiana at Monroe, Monroe, LA.*

Previously we have shown that hepatotoxicity of thioacetamide (TA) (300 mg/kg) was markedly potentiated in streptozotocin-induced diabetic (DB) rats [90% mortality in DB group vs 0% mortality in non-diabetic (NDB) group] due to combined effects of enhanced CYP2E1-mediated injury and compromised compensatory tissue repair. Diallyl sulfide, a specific inhibitor of CYP2E1, did not rescue diabetic rats from TA-induced mortality, underscoring the determining role of suppressed tissue repair in lack of survival. Even at the doses (30 in DB rats vs 300 mg/kg in NDB rats) that caused equal liver injury, tissue repair was compromised in diabetic rats, indicating that failing tissue repair is a function of diabetes. The objective of present study was to test our hypothesis that cellular mitogenic signaling is down regulated in diabetic rats. Our results indicate that TNF-aα and IL-6 mediated pro-mitogenic signaling in TA-treated DB rats is higher than TA-treated NDB rats over the time course of 0 to 48 h, indicating that the problem is not at the level of cytokine signaling. Western blot analysis of epidermal growth factor receptor (EGFR) revealed that EGFR is significantly down regulated in the DB rats and is further down regulated after TA treatment (300 mg/kg). Down stream events occurring through mitogen activated protein kinases (MAPKs), such as ERK1, ERK2 and p38 were also down regulated in the DB rats. After TA treatment (300 mg/kg), ERK1, ERK2 and p38 were further down regulated in DB rats. In contrast, in the DB rats treated with equitoxic dose of TA (30 mg/kg), EGFR, ERK1 and ERK2 were significantly up regulated as early as 6 h after TA treatment and either sustained or elevated thereafter as compared to the DB rats treated with 300 mg/kg of TA. These data indicate that down regulation of MAPK signal transduction pathway *via* EGFR may explain failed tissue repair in the unfavorable toxic outcome of TA treatment in DB rats. (Supported by Kitty DeGree Endowed Chair and LBRSF)

519 LACTOFERRIN MODULATES IMMUNE RESPONSE THROUGH THE ACTIVATION OF MITOGEN-ACTIVATED PROTEIN KINASE IN RAW 264.7 CELLS.

Y. Na[1], S. Han[2], J. Kang[1], H. Kim[2] and K. Yang[1]. *[1]Biological Sciences, KAIST, Daejeon, South Korea and [2]KRIBB, Daejeon, South Korea.*

Lactoferrin, an iron binding glycoprotein produced by epithelial cells and neutrophils, is found in most biological fluids. To date, lactoferrin has been shown to have various biological functions: antitumor, anti-inflammatory, antifungal, antibacterial, protease, transcription factor, procoagulating, and immunomodulating activities. This protein may directly regulate the inflammatory responses. However, some of the proposed functions still remain unclear and controversial. In the present study, we investigated the mechanism of action of lactoferrin on macrophages. We treated bovine lactoferrin to RAW 264.7 cells, a murine macrophage cell line. Lactoferrin increased the production of inflammatory cytokines such as IL-1β, IL-6, and TNF-α, and effector molecules such as nitric oxide in a dose dependentmanner. As an upstream effectors in the inflammatory cytokine production, lactoferrin markedly induced activation of a transcription factor NF-κB and mitogen-activated protein kinases (MAPKs) such as p38, JNK, and ERK1/2. Taken together, we demonstrated here that lactoferrin directly activated macrophages by mediating NF-κB and MAPK signalings, resulting in increase of inflammatory cytokine production.

520 THE ROLE OF PHOSPHATIDYLCHOLINE PLC IN THE INHIBITION OF GAP JUNCTION COMMUNICATION, ACTIVATION OF MAPK, AND THE RELEASE OF ARACHIDONIC ACID BY SPECIFIC ISOMERS OF METHYLATED ANTHRACENES.

B. L. Upham[1], P. K. Tithof[2] and J. E. Trosko[1]. *[1]Pediatrics &Human Development, Michigan State University, East Lansing, MI and [2]Department of Animal Science, University of Tennessee, Knoxville, TN.*

The mitogenic activity of tumor promoters requires the removal of an initiated cell from growth suppression by inhibiting gap junctional intercellular communication (GJIC) and the activation of intracellular mitogenic pathways. We determined the structure activity relationship of two isomers of 1- and 2-methylanthracene (1-MeA and 2-MeA) on the temporal activation of mitogen activated protein kinase (MAPK), the release of arachidonic acid (AA) from the plasma membrane, and the inhibition of GJIC in F344 rat liver epithelial cells. Noncytotoxic doses of 1-MeA, which contains a bay-like region, reversibly inhibited GJIC, induced the release of AA, and strongly activated ERK 1 & 2 and P38 but only weakly activated SAPK/JNK. In contrast, the linear-planar isomer 2-MeA had no effect on GJIC, AA release, and MAPK activation. MAPK was activated 10-20 min after the down-regulation of GJIC and release of AA, which indicates that MAPK is not involved in the initial regulation of GJIC and that AA may play an upstream role in activating all MAPKs. Inhibition of phosphatidylcholine specific phospholipase C (PLC), but not phosphatidylinositol specific PLC, prevented the inhibition of GJIC by 1-MeA. Apparently: the choline-specific PLC is a key upstream regulator of GJIC. In summary: our results are consistent with the hypothesis that mitogenesis requires the removal of growth suppression by inhibition of GJIC and then the activation of mitogenic pathways. This research was supported by the NIEHS Superfund grant #P42 ES04911-07.

521 HORMONAL REGULATION OF LACTATE DEHYDROGENASE-A IN BREAST CANCER CELLS IS DEPENDENT ON ACTIVATION OF PROTEIN KINASE C.

X. Li and S. Safe. *Veterinary Physiology & Pharmacology, Texas A&M University, College Station, TX.*

Lactate dehydrogenase (LDH) catalyzes the conversion of pyruvate to lactate during anaerobic glycolysis and LDH forms are upregulated in many types of tumors and cancer cell lines. LDH-A is increased in mammary gland carcinogenesis and in breast cancer cells, and treatment of estrogen receptor (ER)-positive MCF-7 cells with 17β-estradiol (E2) induces LDH activity. In this study, we show that E2 induces LDH-A gene expression in MCF-7 cells and the molecular mechanisms of this response have been further investigated using constructs containing the 1173 to +25 region of the LDH-A rat gene promoter (pLDH-A) which is highly homologous to the human and mouse gene promoters. Analysis studies of the LDH-A promoter showed that a series of promoter deletion constructs, pLDH-1 (-332 to +9), pLDH-2 (-249 to +9), pLDH-3 (192 to +9), pLDH-4 (-110 to +9), and pLDH-5 (-92 to +9), were E2-responsive, whereas pLDH-6 (37 to +9) was not inducible by E2. Subsequent mutation analysis of pLDH-7 (-58 to +9) demonstrated that a cAMP response element (CRE) was required and electrophoretic mobility shift assays indicated interactions of CREB and ATF-1 at this site. Although cAMP/protein kinase A activate constructs containing the CRE motif, hormonal activation of pLDH-7 is not blocked by PKA inhibitors. Subsequent studies with multiple inhibitors and a chimeric protein containing the yeast GAL4 DNA-binding domain fused to CREB demonstrated that hormonal activation of LDH-A was dependent on activation of protein kinase C through non-genomic pathways. (Supported by NIH ES09106 and E209253)

522 A POSSIBLE ROLE FOR ARSENIC AS A MEDIATOR FOR CARDIAC HYPERTROPHY.

Z. E. Derbyshire, U. M. Halfter and R. R. Vaillancourt. *Pharmacology and Toxicology, University of Arizona, Tucson, AZ.*

Previous reports have indicated that the MAP/ERK kinase, MEKK4, functions upstream of the p38 MAP kinase and that dominant-negative MEKK4 will disrupt arsenite-induced activation of the JNK MAP kinase. However, no agonists or upstream kinases have previously been reported that modulate its activity. The objective of this study was to identify and characterize proteins that regulate MEKK4 signal transduction, to determine a physiological role for MEKK4 and to see how arsenic could affect that system. Previous experiments indicated the calcium-regulated protein, annexin II, associates with MEKK4, indicating that calcium might regulate MEKK4 activity. Early experiments also indicated that MEKK4 could be phosphorylated on tyrosine, suggesting that a tyrosine kinase might regulate MEKK4 activity. A likely candidate for the upstream kinase is the calcium-regulated tyrosine kinase Pyk2. To investigate this, Pyk2 was immunoprecipitated from aortic smooth muscle cells treated with angiotensin II followed by an *in vitro* kinase assay to evaluate the kinase activity of Pyk2 on MEKK4. The ability of Pyk2 to phosphorylate MEKK4 on tyrosine was confirmed, but only in response to the angiotensin II treatment. As both angiotensin II and p38 have been reported to modulate COX II, we tested whether MEKK4 was involved in this pathway. HEK cells stably expressing the angiotensin receptor were transiently transfected with dominant-negative MEKK4 and a COX II-luciferase reporter construct. Dominant negative MEKK4 greatly reduced the luciferase activity, indicating MEKK4 modulates COX II production. Similarly we confirmed that arsenic could activate the COX II reporter and that dominant negative MEKK4 also inhibited

the effect. We hypothesize that Pyk2 phosphorylates MEKK4 on tyrosine in response to angiotensin II, subsequently regulating COX II production and that arsenic exposure is able to activate this signaling cascade. Ongoing studies are aimed at investigating the site of arsenic activity in this pathway and its possible role in cardiac hypertrophy. (NIH ES 12007 and ES 04940)

523 MECHANISMS FOR SELECTIVE ACTIVATION OF SRC FAMILY KINASES AND JNK BY LOW LEVELS OF CHROMIUM(VI).

K. A. O'Hara, L. R. Klei and A. Barchowsky. *Pharmacology and Toxicology, Dartmouth Medical School, Hanover, NH.*

Inhaled hexavalent chromium (Cr(VI)) promotes pulmonary disease and lung cancer through poorly defined mechanisms. These mechanisms were studied in A549 lung epithelial cells to investigate the hypothesis that non-toxic Cr(VI) exposures selectively activate cell signaling that shifts the balance of gene transcription. These studies demonstrated that non-toxic doses of Cr(VI) increased reactive oxygen species and selectively activated JNK, relative to ERK or p38 MAP kinase. In contrast, only toxic, non-selective levels of exogenous oxidants stimulated JNK. However, JNK activation in response to chromium and exogenous H_2O_2 shared requirements for intracellular thiol oxidation, activation of Src family kinases, and $p130^{cas}$ (Cas). Cr(VI) did not mimic H_2O_2-mediated stimulation of JNK in cells containing only Src and did not activate Src or Yes in A549 cells. Instead, Fyn and Lck were activated in A549 cells indicating cell specific activation of Src family kinases in response to Cr(VI). Finally, Cr(VI) was demonstrated to directly activate purified Fyn *in vitro* and that the majority of this activation did not require oxidant generation. These data suggest that non-toxic levels of Cr(VI), which can shift patterns of gene transcription, are selective in their activation of cell signaling and that Cr(VI) can directly activate Src family kinases. *Supported by NIEHS grant ES10638.*

524 ROLE OF THE SERINE/THREONINE KINASE MEKK4 IN CYCLOOXYGENASE II REGULATION IN HUMAN KERATINOCYTES.

U. M. Halfter, Z. E. Derbyshire and R. R. Vaillancourt. *Pharmacology and Toxicology, University of Arizona, Tucson, AZ.*

We are interested in cellular arsenate and arsenite stress response mechanisms. The mitogen-activated protein kinase/extracellular signal-regulated kinase kinase 4 (MEKK4) signaling pathway is implicated to respond to arsenate and arsenite stress. Using immortalized human keratinocytes, HaCaT cells, as a model system we are investigating the regulation of the serine/threonine protein kinase MEKK4. We show that extracellular calcium is essential for MEKK4 phosphorylation. We have evidence that ATP binding to a purinergic receptor leads *via* a G protein-coupled response to Ca2+ influx and to a localized rise of cytoplasmic Ca2+ concentration. Annexin II is a calcium-binding protein and preliminary evidence suggests that annexin II interacts with components of the MEKK4 pathway. Blocking the influx of extracellular Ca2+ results in lesser or basal state of MEKK4 activation. Stimulation of HaCaT cells with ATP, a purinergic receptor agonist, results in tyrosine phosphorylation of MEKK4. We have evidence that the MEKK4 pathway regulates cyclooxygenase II expression levels. To corroborate data obtained with immortalized keratinocytes we, in addition, employ normal human epidermal keratinocytes (NHEK). The inflammatory mediator interferon gamma has been reported to activate cyclooxygenase II expression. Indeed, we demonstrate an interferon gamma dependent tyrosine phosphorylation of MEKK4. Furthermore, the tyrosine kinase Pyk2 co-immunoprecipitates with MEKK4, suggesting that this tyrosine kinase may mediate the phosphorylation of MEKK4. Also present in this complex is the calcium-binding protein annexin II as identified by co-immunoprecipitation. This may indicate a calcium dependent regulation of tyrosine phosphorylation of the serine/threonine kinase MEKK4. Ongoing studies investigate the role of MEKK4 in arsenic signal transduction in keratinocytes.

525 *IN VIVO* DETECTIONS OF MULTIPLEX PHOSPHOPROTEINS AND CYTOKINES WITH BIO-PLEX PROTEIN ARRAY SYSTEM.

A. Zhang, K. Simonyi, Q. Gao, C. Suen, M. Malit and I. Huang. *Life Science Group, Bio-Rad Laboratories, Hercules, CA.*

Phosphoproteins and cytokines play pivotal roles in cell signaling events, mediating a wide range of physiological responses. These proteins are well defined targets for toxicology study. Bio-Plex Protein Array System based on Luminex technology has been proven a novel system to detect these protein markers in a multiplex format. We have presented *in vitro* data in last SOT meeting. At current study, we treated mice with synthesize substance A at concentrations of 1, 3, 10 and 30mg/dose and sacrificed the mice after 0, 0.5 and 17 hours. We collected the livers from those treated mice and prepared the tissue lysate samples. The samples were run with Bio-Plex multiplex phosphoproteins reagents and Bio-Plex Protein Array System. Five phosphoproteins were detected simultaneously from the liver tissue samples, including JNK, p38, Erk, IkBa and Akt. The results showed that phosphorylations of these kinases induced by the substance were dose-dependent and time dependent. The MAP kinase p38 was the most sensitive target and the phosphorylation was observed significantly at 3mg/dose of the compound. There was no significant phosphorylation detected within half an hour after dosing. However, after 17 hours, all the targets had more than 5-folds of phosphorylation observed compared with controls. The results clearly demonstrate that Bio-Plex Protein Array System and Phosphoprotein reagents are very reliable and efficient tools to detect phosphoproteins from tissues in multiplex format. We also have collected 9-plex cytokine data from rat tissue and 18-plex cytokine data from mouse tissues. These studies strongly support that Bio-Plex Protein Array System and multiplex assay reagents are very powerful tools for *in vivo* toxicology study, which can detect several phosphoproteins and many cytokine targets simultaneously from one tissue sample.

526 AH RECEPTOR-MEDIATED TRANSCRIPTIONAL SUPPRESSION OF INTERLEUKIN-6.

M. Chen, S. Ke, T. Sheng and Y. Tian. *Vet. Physiology and Pharmacology, Texas A&M University, College Station, TX.* Sponsor: M. Gallo.

The Ah receptor (AhR) mediates most of the toxic responses induced by 2, 3, 7, 8-tetrachlorodibenzo-p-dioxin (TCDD). TCDD exposure causes marked immune suppressive responses. The mechanism for the immune suppression by TCDD remains to be investigated. In an earlier study, we found mutually suppressive interactions between the AhR and a pleiotropic transcription factor nuclear factor kappa B (NF-kB). NF-kB is known to regulate a large group of immune and inflammatory responsive genes, including the interleukin 6 (IL-6). The IL-6 gene is known to be regulated directly by NF-kB and its promoter regions has been well characterized, making it a good system to analyze the effects of AhR/NF-kB interaction. In the present study, we found IL-6 mRNA transcripts can be induced in Hep1c1c7 (mouse hepatoma cell line) by either TNF-alpha (2.5 ng/ml, 30 min) or lipopolysaccharide (LPS, 1 ug/ml, 4 hrs) as determined by RT-PCR quantitation. TCDD treatment (10 nM) blocked the TNF and LPS-induced IL-6 gene expression. The suppressive effects of TCDD on the IL-6 gene expression are clearly dependent on the intact AhR complex, since TCDD treatment had no effect on the mutant cell lines Bpr or Tao, which either lack the AhR nuclear translocator (Bpr) or the AhR, respectively. Supported in part by NIEHS Grant ES 09859.

527 EFFECTS OF ESTROUS CYCLE AND SOY ON CYTOCHROME P450 1B1 (CYP1B1) PROTEIN EXPRESSION IN FEMALE RAT ADRENAL GLANDS.

X. Fu[1], B. Blaydes[1], D. W. Roberts[1], C. Weis[1], J. R. Latendresse[2], L. Muskhelishvili[2], T. R. Sutter[3] and B. Delclos[1]. *[1]Biochemical toxicology, National Center for Toxicological Research, Jefferson, AR, [2]Pathology Associates International, Jefferson, AR and [3]University of Memphis, Memphis, TN.*

Previous work in our laboratory found that female NCTR Sprague-Dawley (SD) rats fed a soy- and alfalfa-free diet were more sensitive to 7, 12-dimethylbenz(a)anthracene (DMBA)-induced adrenal toxicity than expected based on extensive literature. Because CYP1B1 has been shown to be important in the bioactivation of DMBA to an adrenal toxin in rats, we are investigating the effects of diet and genetic background on CYP1B1 expression in rat adrenal glands. In this experiment, female SD rats were placed on standard NIH31 rat chow or soy- and alfalfa-free 5K96 diet from postnatal day (PND) 21 until sacrifice at PND50 ± 5. Stage of estrous cycle at sacrifice was predicted by daily vaginal cytology and confirmed by histological examination of the vagina. Serum was collected at necropsy and estradiol and progesterone levels measured. Immunohistochemical analysis confirmed that CYP1B1 was exclusively expressed in the zona fasciculata and zona reticularis in adrenal cortex, which are the regions vulnerable to DMBA-induced adrenal necrosis. Western blot analysis showed significantly higher CYP1B1 expression in diestrus than in proestrus in the adrenal microsomes of rats fed 5K96 but not in rats fed NIH-31. In both estrus and diestrus, CYP1B1 expression was higher, though not significantly so, in rats fed with 5K96 diet than rats fed with NIH-31 diet. *In vitro* adrenal microsome reactions showed that 4-OH estradiol formation from estradiol, a reaction associated with human CYP1B1, was slightly, but not significantly, higher in diestrus than in proestrus for both diet groups (diestrus: 0.037 ± 0.010 and 0.037 ± 0.003 pmole/μg/min (mean ± SD); proestrus: 0.029 ± 0.001 and 0.030 ± 0.013 pmole/μg/min for NIH31 and 5K96, respectively). DMBA metabolism is being investigated. Adrenal CYP1B1 appears to be regulated by modulation of hormones during the estrous cycle and soy may affect this regulation.

528 ORGAN SPECIFIC INDUCTION OF CYP1A1 AND 1B1 BY CARCINOGENIC POLYCYCLIC AROMATIC HYDROCARBONS IN ENGINEERED C57BL/6J MICE OF ARYLHYDROCARBON RECEPTOR GENE.

T. Shimada, T. Nakajima, E. Azuma, M. Hashimoto and K. Inoue. *Pharmacology, Osaka Prefectural Institute of Public Health, Osaka, Japan.* Sponsor: F. Guengerich.

Organ-specific induction of mRNAs of CYP1A1 and 1B1 by polycyclic aromatic hydrocarbons (PAHs) was investigated in wild and arylhydrocarbon receptor (AhR)-deficient C57BL/6J mice. CYP1A1 mRNA was detected in control mice at very low levels in liver, lung, heart, kidney, intestine, thymus, testis, uterus, ovary, and brain and was highly inducecd in these organs by benzo[a]pyrene in AhR(+/+) mice. In AhR(+/+) and AhR(-/-) mice, CYP1B1 mRNA was found to be constitutively expressed at significant levels in heart (the ratio of mRNAs of CYP1B1 to actin was about 0.7), kidney (about 0.7), intestine (about 0.3), testis (about 1.0), thymus (about 0.4), uterus (about 0.2), ovary (about 1.5), and brain (about 0.4), whereas it was low in liver and lung (<0.2 in these cases). CYP1B1 in the latter two organs was highly induced by PAHs in AhR(+/+) mice. The induction of CYP1B1 by PAHs was more extensive in organs where the constitutive expression of CYP1B1 was low. These results suggest that CYP1A1 and CYP1B1 are differentially regulated in their expression in extrahepatic organs of mice and could be induced by PAHs with different extents depending on the inducers used and the organs in AhR(+/+) mice. The findings of significant levels of constitutive expression of CYP1B1 in AhR(-/-) mice as well as AhR(+/+) mice in several organs including heart, kidney, thymus, testis, ovary, and brain in AhR(-/-) mice as well as AhR(+/+) mice are of importance in understanding the basis of toxicity and carcinogenesis by chemicals that are metabolized by CYP1B1. (Supported in part by Grants from the Ministry of Education, Science, and Culture of Japan and the Petroleum Energy Center.)

529 DEVELOPMENT OF AN *IN VITRO* MODEL SYSTEM TO EVALUATE SWITCH-LIKE BEHAVIORS OF HEPATOCYTES IN RESPONSE TO ENZYME INDUCERS.

C. T. French, L. S. Chubb, R. E. Billings, W. H. Hanneman and M. E. Andersen. *CIIT, Research Triangle Park, NC.*

Receptor-mediated enzyme induction in the liver has been reported to demonstrate switch-like behaviors. As dose increases, more cells become fully induced rather than observing a proportionate induction in all hepatocytes. The inducing chemicals act *via* different receptor pathways, indicating that the switch-like response is a generic property of induction within these cells. We developed an *in vitro* model system using primary rat hepatocytes and a prototypical enzyme inducer to study this phenomenon. The induction of cytochrome P450 1A1 protein and mRNA was examined by treatment with PCB 126, an aryl hydrocarbon receptor agonist. Primary rat hepatocytes were exposed to concentrations of PCB 126 ranging from 10-5 to 10-11 M for various time points. Dose response curves in hepatocyte populations were established using western blots for total protein induction and real-time RT-PCR for mRNA. To analyze the switching response at the level of individual cells, the techniques of immunocytochemistry and in situ hybridization were used. The integrated responses of populations of hepatocytes were compared with responses of individual cells by visualization and quantification of single cell induction. Induction of individual cells and the dose response for increasing numbers of cells with increasing dose was qualitatively evident for both the protein and mRNA. Single cell quantification with a Bioquant imaging system permitted comparison of induction level on a cell-by-cell basis. Interpretations of distributions are based on methodologies evaluating a switch response in oocytes (Ferrell and Machleder, Science, 280, 895, 1998). Distributions of induced cells were compared with those generated from similar *in vivo* studies. Our *in vitro* model provides a system with which to characterize the switching response and to investigate the underlying molecular mechanisms (American Chemistry Council contract RSK0005).

530 REGIONAL INDUCTION OF CYP1A1 PROTEIN AND MESSAGE IN RAT LIVER DURING TREATMENT WITH MIXTURES OF PCB126 AND PCB153.

L. Chubb[1], S. A. Benjamin[1], J. T. Painter[1], C. E. Dean, Jr[1], C. T. French[1] and M. E. Andersen[2]. *[1]College of Veterinary Medicine and Biomedical Sciences, Colorado State University, Fort Collins, CO and [2]CIIT, Research Triangle Park, NC.*

Liver enzyme induction by various inducers is regional and has all-or-none, switch-like characteristics *in vivo* and *in vitro*. This has been studied in an *in vitro* switching model (CT French et al., this meeting). We have studied this switch *in vivo* by evaluating enzyme induction and liver tumor promotion due to a mixture of the co-planar PCB126 and the non co-planar PCB153 in Fisher rats using a modified Ito medium term initiation-promotion study. Two weeks after DEN initiation, rats were gavaged 3 times per week with PCBs at varying concentrations of the PCBs alone and as mixtures. In a second study, enzyme activities for CYP1A1 were estimated in liver microsomes from Sprague-Dawley rats treated with PCBs for 13 and 30 weeks. At moderate doses, there was a greater than additive increase in CYP1A1 activity in the 13/30 week dosing study and increased liver concentration of PCB153 in mixture treated rats in the Ito study. At moderate to high doses in the Ito study, there were less than additive increases in number and area of GST-P foci. Also in the Ito study, exposure to PCB126 caused regional induction of CYP1A1, starting in the centrilobular region at 0.1μg/kg/day and progressing outward until the entire liver was induced at 10μg/kg/day, then shifting to only the periportal region in rats treated with the highest dose mixture (10μg/kg/day PCB126; 10, 000μg/kg/day PCB153). The pattern of induction was the same for CYP1A1 mRNA as assessed qualitatively by in-situ hybridization and immunohistochemistry on sequential liver sections. Quantitatively, induction was assessed by measuring mRNA levels in individual cells. The unexpected regional interaction may correlate with the inhibitory interactions for GST-P positive foci and the increased concentration of PCB153 in liver of the high dose mixture-treated rats. (American Chemistry Council contract #1467, NIEHS grants SBRP ES05949, KO8 ES00314 and KO8 ES00380.)

531 ANALYSIS OF TCDD-MEDIATED INDUCTION OF *CYP1A1* IN IKKβ$^{+/+}$ AND IKKβ$^{+/-}$ MICE.

D. E. Machemer[1], A. Galijatovic[1], D. J. Beaton[1], Z. Li[1], M. Karin[1] and R. H. Tukey[1,2]. *[1]Department of Pharmacology, University of California San Diego, La Jolla, CA and [2]Department of Chemistry & Biochemistry, University of California San Diego, La Jolla, CA.*

Cytochrome P450 1A1 (CYP1A1) catalyzes the hydroxylation of a variety of xenobiotic compounds and is strongly induced by halogenated and polycyclic aromatic hydrocarbons through activation of the aryl hydrocarbon receptor (AhR). Several lines of evidence indicate a linkage between activation of the AhR / *Cyp1a1* signal transduction pathway and NF-κB activation, in both function and regulation. To further characterize this linkage, TCDD-mediated induction of *Cyp1a1* was investigated in IKKβ$^{+/+}$ and IKKβ$^{+/-}$ C57Bl/6 mice. IKK is a kinase composed of 2 catalytic subunits (α and β) and 1 regulatory subunit (γ). IKK phosphorylates IκB, which causes dissociation of IκB from the IκB - NF-κB complex and triggers degradation of IκB. Free NF-κB then translocates to the nucleus, binds to κB binding sites on DNA, and stimulates transcription of target genes. Embryonic fibroblasts from IKKβ$^{+/-}$ C57Bl/6 mice exhibit a 50% reduction in IKK activity and a 90% reduction in NF-κB DNA binding activity. IKKβ$^{+/+}$ and IKKβ$^{+/-}$ mice were treated for 18 hours with different doses of TCDD, ranging from 0.32 μg/kg to 125 μg/kg. Liver Cyp1a1 RNA and protein levels were quantitated. In IKKβ$^{+/+}$ mice, Cyp1a1 RNA and protein were detectable after treatment with 0.32 μg/kg TCDD. Cyp1a1 RNA and protein reached maximum levels after treatment with 1.6 μg/kg TCDD. At TCDD doses of 16 μg/kg, 45 μg/kg, and 125 μg/kg, Cyp1a1 RNA and protein levels observed were similar to those of mice treated with 1.6 μg/kg TCDD. At all TCDD doses, Cyp1a1 RNA and protein levels were not significantly different in IKKβ$^{+/-}$ mice when compared to IKKβ$^{+/+}$ mice. This suggests that TCDD-mediated induction of *Cyp1a1* is not affected by a significant loss of NF-κB activity *in vivo*. (Supported by USPHS grant ES10337.)

532 DEVELOPMENT OF A HUMAN *CYP1A1*-LUCIFERASE TRANSGENIC MOUSE MODEL.

A. Galijatovic[1], D. Beaton[1], R. Johnson[2] and R. H. Tukey[1,3]. *[1]Department of Pharmacology, University of California, San Diego, La Jolla, CA, [2]Department of Biology, University of California, San Diego, La Jolla, CA and [3]Department of Chemistry & Biochemistry, University of California, San Diego, La Jolla, CA.*

Regulation and expression of *CYP1A1* is mediated in part through activation of the Ah-receptor by environmental toxicants such as polycyclic and heterocyclic aromatic hydrocarbons, in addition to dietary compounds such as flavonoids. The human *CYP1A1* gene contains three Ah receptor enhancer sequences (XRE) that associate with the ligand activated Ah receptor resulting in enhanced transcription. Previously, the human *CYP1A1* promoter and 1600 bases of 5′-flanking sequence was subcloned upstream of the fire-fly luciferase reporter gene and stably transfected into HepG2 cells. This cell line, called TV101, has been used to identify Ah receptor ligands and to study the regulatory patterns of the *CYP1A1* gene. In these studies, the human *CYP1A1*-luciferase chimeric was microinjected into the pronucleus of fertilized mouse eggs and then transferred to pseudopregnant C57Bl/6 mice. From 53 offspring, the incorporation of the *CYP1A1*-luciferase gene was identified in four founders. Each founder was bred and transmission of the gene into the F1 population was examined for inducibility in each of the four litters. Upon treatment with a single dose of dioxin or 3-methylcholanthrene, induction of

hepatic fire-fly luciferase activity was observed in siblings from two of the breedings. Treatment of *CYP1A1*-luciferase transgenic mice with differing doses of TCDD ranging from 8 to 32 μg/kg demonstrated a concordance of liver induced luciferase activity with the accumulation of microsomal cyp1a proteins. Thus, these studies demonstrate the potential usefulness of a transgenic mouse model for examining the regulatory properties of the human *CYP1A1* gene. (Supported by Superfund Grant ES10337)

533 SMOKING INCREASES HUMAN NASAL EPITHELIAL CYTOCHROME P450 1A1 GENE TRANSCRIPTION.

R. Brundage[1], T. Rossignol[2], R. Hanshaw[1], M. Lucas[2], D. Fekedulegn[1], G. Opheim[2], M. Kashon[1], V. Castranova[1] and D. Weissman[1]. *[1]ASB/HELD, NIOSH, Morgantown, WV and [2]Madigan Army Medical Center, Ft. Lewis, WA.*

Respiratory tract carcinogenesis, mediated by polycyclic aromatic hydrocarbons (PAH) such as those associated with cigarette smoke, is in part due to induction of cytochrome P450 1A1 (CYP1A1) mRNA and protein expression with subsequent carcinogenic activation of PAH by CYP1A1. Respiratory epithelium is a key target tissue for these events. We therefore hypothesized that CYP1A1 mRNA expression level could be noninvasively monitored in human nasal epithelium, the most easily sampled respiratory epithelium, as a potentially pre-carcinogenic health effect of exposures to inhalants such as cigarette smoke. Subjects were healthy office and garage workers. Demographic, smoking, and occupational histories were obtained by questionnaire. Nasal epithelium was collected using Rhinoprobes(Tm) to obtain scrapings from subjects inferior turbinates. Tissue samples were stabilized using RNLater(Tm) to inhibit RNAses. RNA was extracted using Trizol(Tm). Isolated RNA was reverse transcribed, and abundance of mRNA encoding CYP1A1, IL-8, and G3PDH was evaluated by real time TaqMan(Tm)PCR. Cycle threshold (CT) was used as a measure of the mRNA level in each sample, standardized between samples by using the CT for G3PDH, and the following equation used to calculate a delta CT: CT (CYP1A1 or IL-8) minus CT (G3PDH) = delta CT. Data demonstrated a significant increase ($p < 0.001$) of CYP1A1 expression in current smokers (n=16) as compared to non-smokers (n=17) or former smokers (n=23) in our study group. No significant differences were seen in IL-8 expression levels between these groups nor were any associations apparent between occupational exposures and expression levels of CYP1A1 or IL-8. We conclude that CYP1A1 gene expression can be monitored noninvasively in human nasal epithelium, and that expression level can be modulated by exposures to agents such as cigarette smoke.

534 ROLES OF THE AH RECEPTOR IN OXYGEN-MEDIATED INDUCTION OF PULMONARY AND HEPATIC CYTOCHROME P4501A ENZYMES AND IN THE ATTENUATION OF HYPEROXIC LUNG INJURY.

B. Moorthy[1], S. E. Welty[2], X. I. Couroucli[1], R. Barios[3], S. R. Kondraganti[1] and W. Jiang[1]. *[1]Pediatrics, Baylor College of Medicine, Houston, TX, [2]Pediatrics, The Ohio State University, Columbus, OH and [3]Pathology, Baylor College of Medicine, Houston, TX.*

Administration of supplemental oxygen is frequently encountered in infants suffering from pulmonary insufficiency. However, hyperoxia causes lung damage in experimental animals, and may do so in humans. The mechanisms of oxygen-mediated lung injury are not completely understood. In the present investigation, we tested the hypotheses that: (i) hyperoxia would modulate pulmonary and hepatic cytochrome P450 (CYP)1A1/1A2 expression by Ah receptor (AHR)-dependent mechanisms; and (ii) AHR (-/-) mice would be more susceptible to hyperoxic lung injury than wild type (C57BL/6J) [(AHR (+/+)] mice. Two month-old adult male AHR (+/+) and AHR (-/-) mice were maintained in room air or exposed to hyperoxia (greater than 95% oxygen) for 24-72 h, and pulmonary and hepatic CYP1A1/1A2 expression was studied. Extent of lung injury was determined by measuring lung weight/body weight ratios and by histology. Hyperoxia caused significant increases in pulmonary and hepatic ethoxyresorufin O-deethylase (EROD) (CYP1A1) activities and pulmonary CYP1A1 mRNA levels in AHR (+/+), but not AHR (-/-) mice, suggesting that AHR-dependent mechanisms contributed to CYP1A1 induction. On the other hand, hyperoxia augmented hepatic CYP1A2 expression in AHR (+/+) as well as AHR (-/-) animals, suggesting that AHR-independent mechanisms contributed to this phenomenon. AHR (-/-) mice exposed to hyperoxia were more susceptible to hyperoxic lung injury, as indicated by significantly higher lung weight/body ratios, increased pulmonary edema, and enhanced neutrophil recruitment into the lungs than similarly exposed wild type animals. Taken together, our results support the hypothesis that there is a mechanistic link between the AHR, induction of CYP1A enzymes, and development of hyperoxic lung injury. (Supported in part by NIH grant ES09132 and by the American Lung Association.)

535 ALLEVIATION OF HYPEROXIC LUNG INJURY IN THE NEWBORN RAT BY RETINOIC ACID.

X. I. Couroucli[1], W. Jiang[1], H. W. Strobel[2] and B. Moorthy[1]. *[1]Pediatrics, Baylor College of Medicine, Houston, TX and [2]Biochemistry, The University of Texas-Houston Medical School, Houston, TX.*

Supplemental oxygen is frequently used in infants having pulmonary insufficiency, but prolonged hyperoxia contributes to the development of chronic lung disease in these infants. Hyperoxic exposure during the newborn period leads to acute lung injury and abnormal lung maturation in rats. Cytochrome P450 (CYP) enzymes have been implicated in lung injury induced by hyperoxia. In this investigation, we tested the hypothesis that neonatal exposure of rats to a combination of retinoic acid (RA) and hyperoxia would lead to decreased susceptibility of these animals to lung injury and improved lung maturation in adulthood, compared to those exposed to hyperoxia only, and that modulation of cytochrome P450 (CYP)1A and/or CYP4F4 expression contributes to the beneficial effects of RA. Newborn Fisher rats were maintained in room air or exposed to hyperoxia (≥95% O_2) for 7 days. Some animals were treated i.p. with RA (0.5 mg/kg) or vehicle (saline), once daily for 5 days. Animals were sacrificed 1 or 30 days after termination of hyperoxia, and lung injury was assessed by measuring lung weight/body weight (LW/BW) ratios and by histology. Pulmonary CYP1A1 and CYP4F4 expression was studied by RT-PCR. Exposure of animals to hyperoxia alone for 7 days showed higher LW/BW ratios at 1 day compared to those exposed to RA + hyperoxia. Hyperoxia significantly suppressed CYP1A1 mRNA expression at 1 day, and this effect was potentiated by RA treatment. On the other hand, while hyperoxia dramatically attenuated CYP4F4 expression, this effect was counteracted by pretreatment with RA. At the 30 day time point, the oxygen-exposed animals showed retarded alveolarization. In contrast, RA + hyperoxia-exposed animals showed improved alveolarization. The differential regulation of CYP1A and CYP4F4 expression by hyperoxia and hyperoxia + RA suggests that these enzymes may contribute to the beneficial effects of RA in alleviating lung damage induced by hyperoxia. (Supported in part by NIH grant KO8 HL04333 to XC)

536 EFFECTS OF LIGHT AND DARK BEERS ON HEPATIC CYTOCHROME P450 EXPRESSION IN MALE RATS RECEIVING ALCOHOLIC BEVERAGES AS PART OF TOTAL ENTERAL NUTRITION.

J. Badeaux[3], H. Hardy[3], N. Floyd[3], T. Fletcher[3], M. Ferguson[3], K. Hale[3], T. Dallari[3], M. J. Ronis[1,3] and T. M. Badger[2,3]. *[1]Pediatrics, University of Arkansas for Medical Sciences, Little Rock, AR, [2]Physiology, University of Arkansas for Medical Sciences, Little Rock, AR and [3]Arkansas Children's Nutrition Center, Little Rock, AR.*

Alcoholic beverages contain many congeners in addition to ethanol. Therefore, consumption of alcoholic beverages may have considerably different effects on expression of hepatic microsomal monooxygenases than the relatively selective induction of CYP2E1 observed following ethanol consumption. In the current study we compared the effects of two beers: larger (a light roasted beer) and stout (a dark roasted beer) infused intragastrically into groups of N = 10-13, 300 g male Sprague-Dawley rats for 21 d using a system of total enteral nutrition (TEN) with a group of rats infused an equivalent amount of ethanol isocalorically. At the end of the infusion period, rats were sacrificed and liver microsomes prepared. Cytochrome P450s CYP1A1/2, CYP2B1, CYP2E1, CYP3A and CYP4A expression was assessed by Western immunoblot analysis. In addition monooxygenase activities were assayed for the following substrates: ethoxy-, methoxy-, pentoxy- and benzyloxyresorufin, tesosterone, midazolam, erythromycin and p-nitrophenol. No effects of larger or stout were observed on relative expression of CYP2E1or CYP2B1 or activity towards p-nitrophenol or pentoxyresorufin. However, higher expression of CYP1A2, CYP3A and CYP4A were observed in stout-infused relative to larger and ethanol-infused rats ($p \leq 0.05$). In addition, although no differences were observed in alkoxyresorufin, midazolam or testosterone metabolism between groups, stout-infused rat had greater erythromycin N-demethylase activity (a CYP3A substrate) and higher lauric acid 12-hydroxylase activity (a CYP4A substrate) than other groups ($p \leq 0.05$). Therefore stout contains congeners which are inducers of cytochrome P450s other than CYP2E1. Supported in part by R01 AA08645 (TMB).

537 EFFECTS OF CHRONIC ETHANOL ON HEPATIC CYP2C11 IN MALE RATS: INTERACTIONS WITH THE JAK2-STAT5B PATHWAY.

T. M. Badger[2,3], M. J. Ronis[1,3], Y. Chen[3] and L. He[3]. *[1]Pediatrics, University of Arkansas for Medical Sciences, Little Rock, AR, [2]Physiology, University of Arkansas for Medical Sciences, Little Rock, AR and [3]Arkansas Children's Nutrition Center, Little Rock, AR.*

Chronic alcohol consumption results in altered expression of many genes. These effects are often secondary to alterations in hormonal actions. GH is secreted from the pituitary gland in a sexually dimorphic pulsatile pattern and this secretory pat-

tern is known to be important in the regulation of gene expression involving the JAK-STAT signal transduction pathway. Chronic alcohol treatment in male rats results in: 1) demasculinization of the GH pulse pattern; and 2) decreased expression of the male-predominant hepatic CYP2C11. Using the total enteral nutrition (TEN) model, Western and Northern analysis and electrophoretic mobility shift assays, we have evaluated the involvement of the JAK-STAT pathway in male rats (8-10/group) chronically infused intragastric diets with or without ethanol for 45 days. We have found that hepatic levels of CYP2C11 mRNA and protein, STAT 5b and phospho-STAT 5b levels were reduced ($P \leq 0.05$) in ethanol-infused rats as compared to rats not infused with ethanol. However, the levels of JAK2 were elevated ($P \leq 0.05$) in ethanol-treated rats. These results suggest that: 1) the JAK2 suppression in the classic GHR-JAK-STAT-CYP2C11 pathway is masked by ethanol-induced increases in other JAK2-dependent pathways; or 2) ethanol does not reduce CYP2C11 through the classical GH-GHR-JAK2-STAT 5b pathway. Supported by NIAAA08645 (TMB).

538 A CELL-BASED ASSAY FOR SCREENING INDUCERS OF CYTOCHROME P450 3A4 AND ANALYZING TRANSCRIPTIONAL REGULATION BY PREGANE X RECEPTOR (PXR).

T. Sheng[1], W. Xie[2], M. Chen[1], P. E. Thomas[4], M. A. Gallo[3], S. Ke[1] and Y. Tian[1]. *[1]Vet. Physiology and Pharmacology, Texas A&M University, College Station, TX, [2]College of Pharmacy, University of Pittsburg, Pittsburg, PA, [3]EOHSI, UMDNJ-Robert Wood Johnson Medical School, Piscataway, NJ and [4]College of Pharmacy, Rutgers University, Piscataway, NJ.*

Cytochrome 3A4 (CYP3A4) is a major enzyme in hepato-intestinal detoxification and is estimated to metabolize over 50% of clinical drugs in use. Expression of CYP3A4 is transcriptionally regulated by the pregnane X receptor (PXR). PXR is activated by a wide range of endogenous and exogenous compounds, which induce CYP3A4. Regulations of CYP3A4 expression are of great interests to drug development and application. Here, we report the development of a human PXR-based luciferase reporter assay for screening compounds that activate hPXR and induce CYP 3A4 gene expression. Cell lines have been developed by stable transfection of human PXR and luciferase reporter gene into the HepG2 cells. The luciferase reporter gene was constructed using a combination of enhancer (-7836 to -7208) /promoter (-362 to +53) modules from CYP3A4 gene. The assay system is highly responsive to known CYP3A4 inducers such as rifampicin, clotrimezole, extracts of St. John's wort, but not to rodent CYP3A inducers such as pregnenolone-16a-carbonitrile and dexamethasone. Interestingly, utilizing the cell-based assay, we found synergistic activation of the luciferase reporter gene when the cells were co-treatd with the inducers of CYP3A4 and CYP1A1. For example, TCDD, benzo-(a)-pyrene markedly enhances rifampicin-induced luciferase reporter gene activity. These results reveal, for the first time, a potential interaction between the Ah receptor-regulated pathways and PXR-regulated pathways. In summary, the above bioassay offers a sensitive and cost-effective means for screening potential CYP3A4 inducers, while avoiding variability of human primary hepatocytes. In addition, this PXR-based bioassay has also been proven useful in analyzing the mechanism of transcriptional regulation by PXR. Supported in part by NIEHS Grant ES09859.

539 HEPATIC EFFECTS OF OCTAMETHYLCYCLOTETRASILOXANE (D4) IN FEMALE FISCHER 344 RATS AND FEMALE HARTLEY GUINEA PIGS FOLLOWING A 14-DAY ORAL ADMINISTRATION.

P. A. Jean[1], K. M. Carroll[2], R. G. Meeks[1] and K. P. Plotzke[1]. *[1]Dow Corning Corporation, Midland, MI and [2]XenoTech, LLC, Lenexa, KS.*

This study was conducted to compare hepatic responses in the rat to that in the guinea pig following oral administration of octamethylcyclotetrasiloxane (D4). Female Fischer 344 rats and female Hartley guinea pigs were dosed with D4 (300 mg/kg/day, po), phenobarbital (positive control; 80 mg/kg/day, po), or vehicle (corn oil, po) for 14 consecutive days. On day 15 the animals were euthanized, organ weights were determined and tissues collected. In rats, D4 administration resulted in increased liver weight (59% increase in absolute and relative liver weight), induction of CYP2B (20 to 27-fold increase in enzyme activity and a marked increase in protein) and only minor changes in CYP1A (enzyme activity and protein), CYP3A (protein), CYP4A (protein), NADPH cytochrome c reductase activity, and epoxide hydrolase (protein). In contrast, liver weight was not significantly changed by D4 administration to the guinea pig. Only minor changes in CYP2B (enzyme activity and protein), CYP1A (enzyme activity and protein), NADPH cytochrome c reductase activity, and epoxide hydrolase (protein) were observed. Analysis of liver D4 content demonstrated a marked difference between species. Rat liver D4 content (0.86 ± 0.13 μg/g liver) was markedly lower than that for guinea pig (7.93 ± 7.44 μg/g liver). Overall, this study has confirmed that repeated administration of D4 to female Hartley guinea pigs, at a dose that causes increased liver weight and cytochrome P450 induction in female Fischer 344 rats, does not cause liver weight increases or significant induction of liver microsomal CYP2B, CYP1A and epoxide hydrolase in the guinea pig.

540 EPIGALLOCATECHIN GALLATE ELICITS SEX-DEPENDENT MODULATION OF CYP450 ISOFORMS IN THE SWISS WEBSTER MOUSE.

M. G. Goodin and R. J. Rosengren. *Department of Pharmacology and Toxicology, University of Otago, Dunedin, New Zealand.*

Epigallocatechin gallate (EGCG) is a potent cancer-preventative agent. The cytochrome P450 (CYP450) family plays a crucial role in bioactivation of carcinogens and EGCG is a potent *in vitro* inhibitor of CYP450 isoforms. However, EGCG's effect on CYP450 isoforms has not yet been investigated *in vivo*. Therefore, the aim of the present study was to characterize the modulatory effect of EGCG on CYP450 isoforms in male and female mice. Swiss Webster mice were dosed with EGCG (25 or 50 mg/kg, ip) for 7 days and hepatic microsomes were prepared on day 8. EGCG at 25 mg/kg was well tolerated by both females and males, as indicated by normal levels of liver transaminases and body weight gain. However, doses of 50 mg/kg caused 75% mortality in females compared to 30% in males. Following EGCG (25 mg/kg), CYP1A2 remained unchanged in females, while both CYP3A and CYP2E1 were increased. Specifically, CYP3A catalytic activity and polypeptide levels were increased 32 and 17% above vehicle control, respectively ($p<0.001$). Similarly, CYP2E1 catalytic activity was induced compared to vehicle control (*p*-nitrophenol hydroxylation values of: 2.03 ± 0.11 vs 1.54 ± 0.07 nmol/mg/min, $p<0.001$), while polypeptide levels were increased 24% above vehicle control ($p<0.001$). In males, EGCG (25 mg/kg) did not alter CYP1A2, 3A or 2E1. However, EGCG (50 mg/kg) inhibited CYP1A2 catalytic activity and polypeptide levels by 41 and 50%, respectively, compared to vehicle control ($p<0.005$). In conclusion, high doses of EGCG are hepatotoxic to the Swiss Webster mouse, and females are more susceptible than males. The mechanism of this toxicity is unknown. The toxic response may be species-specific as EGCG has been administered to rats without any reported mortality or toxicity. In males, EGCG inhibits CYP1A2 as demonstrated *in vitro*. However, EGCG is an inducer of CYP450 isoforms in female mice and suggests that EGCG could cause an increased activation of xenobiotics. Therefore, the anticarcinogenic action of EGCG is more likely to result from it's antioxidant properties.

541 MULTIGENERATIONAL POSTMORTEM FINDINGS IDENTIFY TARGET ORGANS OF RATS EXPOSED TO LOW LEVELS OF CHLORDANE.

V. V. St. Omer, B. C. Datiri, M. M. Mansour, L. H. Billups, E. O. Abdullah, S. Lettsome, R. R. Dalvi, H. Goyal, P. S. Dalvi and K. Ali. *Biomedical Sciences, Tuskegee University, Tuskegee, AL.*

Technical chlordane (TC), a complex organochlorine mixture banned in 1988, is in the food chain, all environmental media & biota and in humans. It poses a risk to humans. Human target organs for chronic oral exposures at environmental levels are unknown. Our previous generational rat studies identified reproductive, developmental & CNS in-life effects. Sprague-Dawley rats were used in this oral two-generation study to identify target organs of TC toxicity at postmortem. F0, F1, F2 rats were exposed daily to TC at 0.00, 0.125, 0.25 and 1 mg/kg b.w. /day. Endpoints were terminal body weight (TBW) and weights & histopathology of brain, pituitary, liver, spleen, thymus, kidney, adrenals, uterus, testes, seminal vesicles, prostate, and epididymus; vaginal cytology for 21 days inclusive of day of sacrifice, sperm motility, velocity, morphology and concentration, blood parameters (testosterone, estrogen, chemistry and hematology) and liver cytochrome P450 (CYP1A1, 2B1, 2E1) enzymes. Gross pathology was unremarkable. Data different ($p<0.05$) from controls are reported. Absolute and relative (organ/brain & organ/TBW) liver weights increased in F0 females and F2 males at 1.0 mg/kg levels. Relative pituitary weights decreased in F1 females at 0.25 and 1.0 mg/kg and increased in F2 males at 1.0 mg/kg levels. At 0.25 mg/kg level, brain weight increased in F1 females & decreased relative to TBW in F0, males. TBW increased in F1 & F2 males. Relative adrenal weights decreased in F1 & F2 males at 0.25 &1.0 mg/kg. TC increased plasma estrogen & estrogen/testosterone ratio in Fo males. In F0, F1 & F2. TC induction of CYP1A1, 2B1& 2E1 was sex and dose-dependent. Histopathologically, TC increased seminiferous tubular & luminal diameters and epithelial heights of F1 & F2 and caused liver centrilobular hypertrophy in F1 males. Reproductive organs, liver, CNS & adrenals are targets of chronic TC exposures. (Supported by MHPF/ATSDR U50/ATU398948)

542 DEXAMETHASONE TREATMENT DECREASES HEPATIC ARACHIDONIC ACID EPOXYGENASE ACTIVITIES IN RATS AS A RESULT OF DECREASED CYP2C23 EXPRESSION.

H. Kim[1,3], Y. Yuan[1], S. Wei[2], K. J. Woodcroft[3], D. A. Putt[1], B. M. Barren[1], J. Chun[1], E. Diviney[1], R. F. Novak[3], J. H. Capdevila[2] and X. Ding[4]. *[1]Detroit R&D, Inc., Detroit, MI, [2]Institute of Environmental Health Sciences, Wayne State University, Detroit, MI, [3]Department of Medicine, Vanderbilt University, Nashville, TN and [4]Wadsworth Center, New York State Department of Health, Albany, NY.*

A sensitive and specific ELISA for 14, 15-dihydroxyeicosatrienoic acid (DHET) has been developed to facilitate investigation of the physiological and pathophysiological roles of epoxyeicosatrienoic acids (EETs) and DHETs, metabolites of arachidonic acid (AA) epoxygenase and soluble epoxide hydrolase (sEH), respectively. Male Sprague-Dawley rats were treated with corn oil or dexamethasone (DEX) (10 mg/kg for 4 days, i.p.) and hepatic microsomal AA epoxygenase activity was measured by ELISA after chemical hydration of 14, 15-EET to 14, 15-DHET. DEX treatment dramatically decreased hepatic microsomal AA epoxygenase activity. This result was confirmed by measurement of [14-C]EET formation activity of microsomal AA epoxygenase after incubation of microsomes with [14-C]AA and NADPH. The [14-C]EET was separated from other metabolites by HPLC. In rats, AA can be biotransformed to EET by the activities of several cytochromes P450, including CYP2C11, CYP2C23, CYP2J3 and CYP2J4. However, Western blot analyses revealed that, among these CYPs, only CYP2C23 levels were dramatically decreased by DEX treatment. These results suggest that decreased AA epoxygenase activities in liver obtained from rats after treatment with DEX was a result of decreased CYP2C23 expression. Contrary to decreased EET formation activities, free + esterified EET levels did not decrease after 4 days of DEX treatment. This result suggests that a long-term DEX treatment is necessary to affect the large EET pool in liver. Supported by NIEHS SBIR Phase II contract ES05459 (H.K. and J.H.C.), NIEHS grant ES07462 (X.D.) and NIEHS Center grant P30 ES06639.

543 EFFECTS OF BYSTANDER CELLS: IMPLICATIONS FOR LOW-DOSE EXTRAPOLATION OF CHEMICAL AND RADIATION-INDUCED CANCER RISK.

R. J. Bull[1] and R. O. McClellan[2]. *[1]Environmental Sciences, Washington State University, Richland, WA and [2]CIIT retired, Albuquerque, NM.*

Estimation of cancer risk at low doses of carcinogens has been dominated by the conceptualization of single cells as the target. Research has shown that some of the effects of ionizing radiation (including mutation) are seen not only in the cell that was hit by radiation, but in the neighboring cells (referred to as bystander effects). The fate of both hit and non-hit cells are diverse, ranging from cell death, cell cycle arrest and reproductive failure, mutation, or the development of an unstable genome. This symposium will focus on how bystander effects and other indirect effects contribute to two phenomena related to cancer, the adaptive response and genomic instability. The first presentation will provide an overview of bystander phenomena that have been observed in radiation biology and provide some insight into how they may be mediated. This will be followed by a demonstration of one mechanism by which selection pressures can give rise to an unstable genotype (via signals generated from mismatch repair). The subsequent talk will discuss the indirect mechanisms implicated in arsenic carcinogenesis and their implications for risk of cancer at low doses. The nature of dose-response curves that are plausibly generated through interactions between direct and indirect mechanisms of damage and adaptation will be discussed in the fourth presentation. The final presentation will discuss a general theory of carcinogenesis that includes genetic and epigenetic contributions to carcinogenesis in the context of the overall structure of the tissue. The symposium will provide a forum in which the necessity of addressing these phenomena in risk assessment and the difficulties in doing so can be discussed. The symposium should be of considerable interest to researchers interested in how basic biological responses observed at low doses should influence estimates of carcinogenic risk.

544 BYSTANDERS, ADAPTIVE RESPONSES AND GENOMIC INSTABILITY - POTENTIAL MODIFIERS OF LOW-DOSE CANCER RESPONSES.

R. J. Preston. *Environmental Carcinogenesis Division, University.S Environmental Protection Agency, Research Triangle Park, NC.* Sponsor: R. bull.

There has been a concerted effort in the field of radiation biology to better understand cellular responses that could have an impact on the estimation of cancer risk (and possibly other health risks) at low dose levels.It is unclear which of these responses are produced from chemical exposures. Bystander effects are a response in cells that are known not to have been traversed by a particle track.Low LET responses have been described.Such responses include induction of gene expression, mutagenic responses and cell transformation.Thus, the concept of effects only in "hit" cells does not hold and cells at risk per unit dose takes on a new definition. The bystander effects are the result of different cellular processes; cell-cell communication and diffusion mediated effects. Adaptive responses for a variety of cellular endpoints have been described for radiation and chemical exposures.The response is lower when a small adaptive dose is given prior to a much larger challenge dose than when the challenge dose alone is given.Thus, there is reduction of response per unit dose under adaptive conditions.However, adaptive responses are not universal and there is considerable interindividual variation. A number of studies have shown that genomic instability can occur at times quite far removed from a radiation exposure.This process also calls into question the concept of response per unit dose.Genomic instability is a hallmark of most tumor types.It remains to be established if it is induced or selected by exposure to radiation or chemicals. Adaptive responses and genomic instability can be induced in bystander cells. This further complicates the considerations of dose and response.There is the potential for all these cellular responses to modify the dose response for cancer at low exposure levels.The need is to further study the underlying mechanisms for these responses for radiation and to establish if similar effects can be operative for chemical exposures.(This is an abstract of a proposed presentation and does not necessarily reflect EPA policy.)

545 THE SELECTION OF MISMATCH REPAIR DEFECTS: THINKING ABOUT EXPOSURE AND RISK ASSESSMENT.

R. fishel. *Kimmel Cancer Institute, Philadelphia, PA.* Sponsor: R. Bull.

Defects in human homologs of the bacterial DNA Mismatch Repair (MMR) proteins MutS and MutL have been found to be causative of Hereditary Non-Polyposis Colorectal Cancer (HNPCC). However, of the 9 known human MutS homologs (MSH) and MutL homologs (MLH), the majority of HNPCC mutations are confined to 2 genes, hMSH2 and hMLH1; in spite of the fact that hMSH2 and hMLH1 function as heterodimers with other MMR MSH and MLH partners. We have found that the primary human mismatch/lesion MSH recognition complex (hMSH2-hMSH6) functions as an adenosine nucleotide molecular switch. Mismatch/lesions provoke ADP→ATP exchange by MSH proteins that results in a large conformational transition and the formation of a hydrolysis-independent sliding clamp on the DNA. Our results suggest that stochastic loading of multiple ATP-bound MSH "signaling" sliding clamps, leads to "threshold" activation of the repair machinery. These studies support a new model for MRR in which MSH molecular switches signals the timing of downstream events in a manner that is similar to cellular signal transduction by G proteins. Recent studies on the mechanism of MMR signal transduction will be presented The recognition that MSH and MLH proteins constitute signaling molecules suggested the possibility of signaling interfaces and downstream effectors that are outside of the fundamental MMR process. It has always been assumed that elevated mutation rates, associated with an MMR defect, are the root cause of HNPCC (known as the "Mutator Hypothesis"). Identification of a role for the MMR machinery in signaling damage-induced apoptosis introduced the possibility that defects in the MMR process may not the cause of HNPCC. These and other data have led us to propose that there is a selection for MMR-defects that involves cellular survival following overwhelming DNA damage. Our results are consistent with an additional role for MMR in sensing and signaling cellular DNA damage. These studies have broad implications when considering the risk assessment following toxic exposures of populations containing variable levels MMR damage recognition machinery.

546 PROPOSED MECHANISMS FOR ARSENIC CARCINOGENECITY: IMPLICATIONS FOR THE SHAPE OF THE DOSE-RESPONSE CURVE.

M. Luster. *Toxicology & Molecular Biology Branch, NIOSH, Morgantown, WV.*

Epidemiological studies have established that inorganic arsenic is a significant human carcinogen that causes tumors predominantly in the skin and bladder following oral exposure and in the lung following inhalation. Despite numerous experimental studies and proposed hypotheses, there is no consensus on arsenic's mechanism of action. It does not behave as most classical chemical carcinogens, including other metals such as cadmium or chromium. In this respect, it does not induce bacterial or mammalian cell mutations at relevant concentrations nor does it produce tumors in standard one- or two-stage animal bioassays. Recent advances have allowed development of atypical rat or mouse models for arsenic carcinogenesis. These, in conjunction with *in vitro* studies, have suggested that arsenic may be inducing carcinogenesis by one or more mechanisms including it's ability to cause global hypomethylation leading to heritable changes in gene expression, act as a 'comutagen' by inhibiting DNA repair, to induce chronic growth signaling through

persistent activation of the MAPKinase pathway and induce oxidative damage through formation of dimethylarsenic radicals. Such mechanisms suggest the likelihood that the dose-response for arsenic may be non-linear in the low dose region and evoke the possibility that such events as genomic instability and by-stander effects may be involved.

547 BIOLOGICAL IMPLICATIONS OF ADAPTIVE RESPONSES AND BYSTANDER EFFECTS FOR INDIVIDUAL AND POPULATION DOSE-RESPONSE CURVES.

R. Conolly. *CIIT Centers for Health Research, Research Triangle Park, NC.*

The view that the dose-response for a carcinogenic stressor must be low dose linear when the stressor adds to an existing carcinogenic process has long held sway (Crump et al., Cancer Research 36:2973, 1977). As our understanding of biological complexity has increased, however, alternative possibilities have arisen. Interactions between the stressor and adaptive responses such as cell cycle checkpoint control and induction of DNA repair may lead to nonmonotonic dose response. In addition, data from radiation biology suggest that interactions between hit and bystander cells can modulate responses to radiation. The potential effects of adaptive responses can be readily illustrated with computational models. For example, a model describing a DNA-damaging agent and having the rate of DNA repair an inducible function of the level of DNA damage can generate a spectrum of dose-response shapes for DNA adduct burden. These shapes can vary from monotonically increasing to threshold to J-shaped depending on the potency with which the additional DNA damage induces repair and the degree to which repair can be induced. Another mechanism that can give rise to nonmonotonic dose-response involves low dose DNA damage that invokes cell cycle checkpoint control and high dose cytotoxicity, leading to a J-shape for the rate of cell division. The common theme in these mechanisms is the ability of the body to react to the environmental stress in a way that modulates the shape of the dose-response curve, responses that theoretical arguments for low dose linearity did not, at the time, have data to describe. Adaptive responses also have important implications at the population level. Cell cycle checkpoint controls and induction of DNA repair capacity are genetically mediated processes. Heterogeneity at the relevant loci could define segments of the population with different capacities for adaptive response and quite different dose-response behaviors in the low dose region. Study of these factors will inform considerations of uncertainty factors applied to intrahuman variability.

548 IMPLICATIONS OF EPIGENETIC EFFECTS FOR MODELING DOSE-RESPONSE.

C. J. Portier. *ETP, NIEHS, Research Triangle Park, NC.*

Dose-response analysis for cancer risks can be improved by the use of a broad array of data and biologically-based mechanistic models. Much of the mechanistic modeling around cancer risks has focused on the classical multistage model of carcinogenesis. The activity in this model is dominated by genetic events and then independent growth of individual cells. However, much of the recent work on carcinogenesis over the past few years has demonstrated that tissue structure and paracrine signalling pathways can play an important role in the development of tumors. There are two models in the literature that have addressed this issue; a model focusing on tissue structure and another on movement of clones of cells rather than individual cells. This talk will outline a general theory for carcinogenesis which includes both epigenetic and genetic events and the overall structure of the tissue. The existing models in the literature will be assessed against this broader based model and the implications for dose-response will be discussed.

549 GENOMICS AND PROTEOMICS IN REPRODUCTIVE AND DEVELOPMENTAL TOXICITY.

K. A. Treinen[1] and E. S. Hunter[2]. *[1]Reproductive Toxicology, Schering Plough Research Institute, Lafayette, NJ and [2]Developmental Biology Branch, NHEERL, USEPA, Research Triangle Park, NC.*

The focus of this symposium is to provide examples where proteomic and/or genomic data have been applied to better understand mechanisms of reproductive and developmental processes/toxicities. Unlike many biochemical studies previously used to characterize the effects of toxicants which often generate apical endpoints, the promise of genomic and proteomic analyses is to understand the underlying mechanisms that cause the specific cellular responses that mediate or are associated with the effects. A major challenge is determining the relationship of genetic/proteomic alterations, particularly the temporal relationship (primary or secondary effect) and generalized nature and quantity of the genes affected, to the end toxicity. Thus, the role and function of the gene products in normal as well as abnormal physiology must be addressed. The use of genomics and proteomics to determine general alterations in genes/proteins have been conducted for a few years now. The intent of this symposium is to provide a forum where the genes/proteins altered by toxicant exposure are consistent to what is known with respect to the altered biology, and likely play a role in the mechanism of toxicity.

550 CYBERTERATOLOGY: INVESTIGATING THE PHYSIOLOGICAL STATE OF THE EMBRYO *IN SILICO.*

T. B. Knudsen. *Department of Pathology, Anatomy and Cell Biology, Thomas Jefferson University, Philadelphia, PA.*

Functional genomics and computational biology provide new ways to unravel the complex responses of developing tissues to drugs and chemicals that increase or lower the risk for specific malformations. A major challenge in the application of microarray data to experimental teratology is relating the genome-wide changes in gene expression with cellular changes leading to pathogenesis. To address this issue, we generated a microarray dataset with RNA samples collected from tissues of early mouse embryos following exposure to different teratogens, doses, times, and intervention strategies. Computer analysis of the dataset revealed a higher order structure for genes functioning in the same biological process, sharing spatial-temporal expression domains, or mapping to chromosomal regions of conserved synteny. Many physiological changes predicted by higher order data structure could be confirmed utilizing independent experimental methodology. Some alterations were anticipated (receptor tyrosine kinase signaling pathway) and others not (coenzyme A and biotin-dependent carboxyl group transfers carried out by the mitochondrion). Therefore, a comprehensive gene expression matrix that captures the biological complexity of the embryonic transcriptome and its regulation provides a computational resource for deducing the physiological state of the embryo during development and disease. (Supported by grants AA13205 and ES09120 from the NIH and grant R 827445 from the EPA but does not reflect agency policy).

551 ZEN AND THE ART OF TERATOGENICITY SCREEN DEVELOPMENT: APPLICATIONS OF MECHANISTIC PROBLEM SOLVING TO GENERATION OF TAILORED TERATOGENICITY SCREENS.

K. Augustine. *Reproductive Toxicology, GlaxoSmithKline, King of Prussia, PA.*

Using problem solving approaches with a combination of *in vivo* and *in vitro* developmental systems, a platform of basic knowledge can be generated which facilitates teratogenicity screen development. Such screens have been utilized to achieve two goals: define the teratogenic mechanism and identify compounds with reduced teratogenic liability. The problem-solving tactics are multi-tiered, where at each tier, increasing knowledge is gained regarding the basis of compound-induced teratogenicity. These steps utilize data from the original *in vivo* embryo-fetal development study and then use a combination of *in vivo* critical drug-sensitivity window identification, applicable *in vitro* systems and finally genetic screens. This knowledge building approach enables a better understanding of the biological insults which result from embryo-fetal exposure to a teratogen as well as optimize selection of the most relevant developmental model systems and genetic pathways to pursue in generating sensitive and predictive gene expression screens. A case study of a compound identified to be a potent skeletal teratogen will be presented to illustrate how the multi-tiered approach has been applied in studying potential teratogenic mechanism(s) and development of screen design for identification of non-teratogenic back-up compounds for future drug development.

552 DISRUPTION OF PROSTATE GROWTH AND DEVELOPMENT BY DIOXIN.

R. E. Peterson and T. M. Lin. *School of Pharmacy, University of Wisconsin, Madison, WI.*

2, 3, 7, 8-Tetrachlorodibenzo-p-dioxin (dioxin) inhibits prostate growth and development in the mouse. The earliest effect is inhibition of the initial step in prostate development: emergence of prostatic buds of basal epithelial cells from the fetal urogenital sinus (UGS). Using wild type and aryl hydrocarbon receptor (AHR) knockout (AHRKO) fetuses exposed to dioxin on GD 13 (5 ug/kg dam) we found that ventral prostatic bud formation was totally blocked and dorsal lateral bud numbers were reduced in wild type but not AHRKO fetuses on GD 18 demonstrating that the effect of dioxin was AHR-dependent. To investigate the gene expression profile induced by dioxin in the urogenital mesenchyme (UGM) and urogenital epithelium (UGE) of the ventral and dorsal regions of the UGS; wild type

and AHRKO fetuses exposed to either vehicle or dioxin on GD 13 (5 ug/kg dam) were sacrificed on GD 16 when prostatic bud formation is just beginning. Total RNA preparations were pooled according to tissue (dorsal UGM, dorsal UGE, ventral UGM, or ventral UGE) and treatment (vehicle or dioxin). Using an Affymetrix microarray system dioxin inducible, AHR-dependent mRNA expression was discovered to be both UGS region-specific (dorsal versus ventral) and UGS tissue-specific (mesenchyme versus epithelium). The numbers of genes whose expression was altered by dioxin in an AHR-dependent fashion in the UGM were: TCDD inducible, TGF-beta related, homeobox related and IGF related whereas those altered in the UGE were: cytoskeleton related, calcium related, extracellular matrix related, TCDD inducible, fatty acid metabolism, homeobox related, cell fate determination, retinoid related, inositol phosphate related, myc related, ras related and wnt related. The most abundant mRNAs affected by dioxin in the UGE belonged to the cytoskeleton and extracellular matrix families which is consistent with the observed disruption of prostatic bud formation by dioxin

553 SAGA OF A NOVEL SPERM BIOMARKER : DISCOVERY TO PROOF OF CONCEPT.

G. R. Klinefelter. *Reproductive Toxicology Division, NHEERL, USEPA, Research Triangle Park, NC.*

There has been concern that semen quality is declining in men. It has been suggested that such decline is linked to exposures to environmental chemicals. Since sperm acquire fertilizing ability during epididymal transit, chemicals that perturb the function of the epididymis could compromise fertilizing ability, and this could be associated with altered expression of functionally important sperm proteins. Indeed, the epididymal toxicants ethane dimethanesulphonate, epichlorohydrin, and hydroxyflutamide each decreased fertility, and each of these toxicants caused diminutions in sperm membrane proteins. Out of 120 identified proteins, one specific protein (SP22) was found to be highly correlated with the fertility of epididymal sperm. HPLC purification and sequencing revealed that SP22 was unique to reproductive biology. Two SP22 transcripts are expressed in the testis. The probe specific for the longer 1.5 kB transcript detects SP22 mRNA in pachytene spermatocytes and spermatids, while probe specific for the 1.0 kB transcript detects this mRNA in all cell types. SP22 antibodies have now been shown to: 1) localize SP22 on the equatorial segment of the sperm head in all species examined; 2) inhibit fertilization of epididymal sperm from the rat both *in vivo* and *in vitro*; 3) inhibit fertilization of epididymal sperm from the hamster *in vitro*; 4) inhibit the binding of human sperm to the zona pellucida; and 5) identify samples from idiopathic infertile men. Upon discovering that SP22 originates in the testis, we hypothesized that testicular toxicants, specifically those that target the maturing post-meiotic germ cells, also would result in reductions in fertility associated with decreased levels in SP22. Indeed, when adult rats were exposed to the testicular toxicant bromochloroacetic acid, a disinfection by-product of drinking water, diminutions in SP22 levels were again highly correlated with the observed decreases in fertility. SP22 has now been incorporated into an epidemiology study to determine whether SP22 levels on human sperm vary with varying levels of disinfection by-products.

554 CONDUCTING PARALLEL GENOMICS AND PROTEOMICS STUDIES: COMPARATIVE RESPONSES IN GENE EXPRESSION.

B. A. Merrick and J. E. Hartis. *National Center for Toxicogenomics, NIEHS, Research Triangle Park, NC.*

A major challenge in toxicogenomics will be the development of strategies for conducting genomic and proteomic studies to give a comprehensive or 'global' view of gene expression response. Understanding how changes in protein abundance and posttranslational events over time and experimental treatment are related to changes in transcript levels will provide a more comprehensive picture of gene expression than either transcriptomic or proteomic analysis alone, and may be a better approach for identifying specific genes or important biochemical pathways involved in toxicity. Specific research objectives, desired data density, gene discovery, biological sample type and animal species will influence the selection of specific proteomic technologies or 'platforms' for the global measurement of cellular transcripts and gene products. The spatial and interactive character of proteins and their intracellular-extracellular localization are also prominent factors in transcript and protein comparisons. The challenge for bioinformatics will be to integrate transcript and proteomics datasets into a common framework to interrelate the results of many varied experiments by different investigators. Examples of parallel genomic and proteomic datasets will be presented and compared for complementarity, uniqueness and integration for gene expression.

555 RED TIDES: A RECURRING PUBLIC HEALTH PROBLEM.

D. G. Baden[2] and J. Benson[1]. [1]*Lovelace Respiratory Research Institute, Albuquerque, NM and* [2]*HABLAB, University of North Carolina, Wilmington, Wilmington, NC.*

Red tide is a discoloring of coastal ocean waters caused by dense populations of dinoflagellates. Over 20 dinoflagellate species produce toxins that cause death or disease in marine animals. Red tide events occur world wide and are increasing in number and duration. The red tide occurring off the Gulf and Atlantic Coasts of Florida produces are the most extensive, long lived, and recurrent of all red tides. The dinoflagellate responsible for this red tide, *Karenia brevis*, produces potent neurotoxins called brevetoxins (PbTxs). In addition to causing Neurotoxic Shellfish Poisoning following ingestion, PbTxs aerosolized by wind and surf cause coughing, sneezing, watery eyes, rhinorrhea, and shortness of breath. There are anecdotal reports that inhalation exposure to PbTxs can trigger or exacerbate bronchoconstriction in asthmatics. Little is known about the long term health effects associated with inhalation of aerosolized PbTxs during red tide events. Examination of marine mammals dying as a result of a *K. breve* event suggest that the respiratory tract, nervous, immune, and hematopoietic systems are potential targets for toxicity upon repeated exposure, but dose-response relationships have not been established. An interdisciplinary group of scientists is working to evaluate health effects in occupationally and recreationally exposed individuals along *K. breve* affected beaches. In addition, laboratory studies are being conducted to determine inhalation toxicity in animal models, determine mechanisms of toxiicty, and investigate potential antidotes to PbTx-induced health effects. This symposium will summarize the problem, approach to human exposure assessment and evaluation of human health effects as well as results of laboratory studies.

556 OVERVIEW OF HARMFUL ALGAL BLOOM TOXINS: POSSIBLE REASONS FOR PRODUCTION, AND RESULTS OF EXPOSURE.

D. G. Baden. *Center Marine Science, UNCW, Wilmington, NC.*

The effects of Harmful Algal Bloom (HAB) toxins have been recorded over the past four centuries, and result from the interaction of specific chemical poisons with endogenous receptors in living affected systems. Ion channel blockers and activators, enzyme inhibitors, and central nervous system agonists characterize the currently known HAB toxin molecular mechanisms. Are the toxins produced to kill? Are there vital HAB organism physiological processes in which the HAB toxins participate and/or regulate? Do the HAB organisms actually produce the toxins, or are the toxins produced by a parasitic or commensal contaminant? Alternatively, with the myriad of receptors in living systems, and the countless numbers of low molecular weight ligands produced by micro-organisms, is it possible that such deleterious ligand-receptor interactions occur by pure serendipity? The recent findings that the HAB dinoflagellate Karenia brevis produces toxins which interact by at least two, and perhaps three widely dissimilar molecular mechanisms gives credence to the latter alternative of pure serendipity, a chance interaction between ligand and receptor which results in enzyme inhibition, sodium channel activation, and bronchoconstriction. The finding of new antagonistic natural products in the same organism further supports the idea of collaborating structural homologies. P01 ES10594.

557 CHARACTERIZATION OF AIRBORNE BREVETOXINS.

Y. Cheng[1] and R. H. Pierce[2]. [1]*Lovelace Respiratory Research Institute, Albuquerque, NM and* [2]*Mote Marine Laboratory, Sarasota, FL.* Sponsor: J. Benson.

Red tides, produced by the dinoflagellate Karenia brevis, occur almost annually in the Gulf of Mexico. K. breve produces brevetoxins that are potent neurotoxins. Exposure to brevetoxins (PbTxs) aerosolized by wind and surf results in respiratory symptoms. Anecdotal reports also suggest that inhalation exposure may exacerbate existing respiratory disease. The objectives of the ongoing study are to characterize the physicochemical properties of environmental brevetoxin -containing aerosols, and to assess occupational, and recreational exposure of individuals during red tide events. Results from monitoring aerosolized brevetoxins during two red tide episodes in the Gulf of Mexico are presented: one in the fall of 2000, at Corpus Christi, Texas, and the other in the fall of 2001 at Sarasota, FL. Two Hi-Vol samplers were deployed during the TX bloom, one equipped with a glass-fiber filter and the other with a five-stage impactor used to aerodynamically classify the particles into different size fractions. Low airborne concentrations of PbTx, between 1.6 and 6.7 ng m-3 and the mass median aerodynamic diameter (MMAD) was between 7 and 9 um. A few incidents of upper respiratory symptoms (throat and nasal irritation), but no reports of lower respiratory symptoms were associated with this event.

During the Sarasota study, several Hi-Vol air samplers were deployed along two different beaches. Measured brevetoxin aerosol concentrations were 4 to 480 ng/m3. During this study, personal samplers also were deployed on lifeguards and field workers. There was a great deal of variability of personal exposures depending on the level of activity, location, and time spent on the beach. Our data showed that in general the lifeguards received higher exposures than the field workers. The particle size distribution obtained at Sarasota was similar to that measured in Texas. These data suggest that low environmental concentrations exposure to PbTx could result in upper respiratory symptoms. This is consistent with the particle size measurement indicating the possibility for particle deposition within the lungs.

558 PATHOPHYSIOLOGIC AIRWAY RESPONSES TO INHALED RED TIDE BREVETOXIN IN ALLERGIC SHEEP.

W. M. Abraham[1], A. Ahmed[1], A. J. Bourdelais [2] and D. G. Baden[2]. *[1]Research, Mount Sinai Medical Center, Miami Beach, FL and [2]Center for Marine Science, UNC Wilmington, Wilmington, NC.*

There is evidence to suggest that inhaled K. brevis (crude PbTx) causes shortness of breath and increased mucus production in humans, especially in those with underlying airway disease. To better understand these toxin-induced airway effects, we used sheep with airway hypersensitivity to Ascaris suum antigen (asthmatic sheep), as a surrogate for asthmatic patients, and studied changes in pulmonary airflow resistance (RL) and changes in tracheal mucus velocity (TMV), a marker of lung mucociliary clearance, after inhalation challenge with increasing concentrations of crude PbTx (0.1-1pg/ml), and with purified PbTx-2 and PbTx-3 (0.1-10 pg/ml). These two toxins were selected because they are present in highest concentration during the growth phase of K. brevis. Challenge with PbTx-2 and PbTx-3 produced 226± (s.e.m.) 21 % and 204±26% increases in RL over baseline, respectively at 10 pg/ml, whereas 1.0 pg/ml of crude PbTx induced a 201±9% increase in RL. Pretreating the animals with a histamine H1-antagonist, significantly blocked the constrictor effects of the crude and the purified toxins, suggesting a role for histamine containing (mast)cells in this response. The constrictor effects could also be blocked with B-Naphthoyl-PbTx-3, a synthetic brevetoxin derivative, or with AJB 6.0P, a natural antagonist, produced by the organism itself. Although PbTx-2 and PbTx-3 induced similar constrictor responses, only PbTx-3 significantly reduced TMV (59±12% of baseline); this reduction in TMV was blocked by both the B-Naphthoyl-PbTx-3 and the AJB 6.0P antagonists. We conclude that aerosols of K. brevis induce asthmatic-like airway responses in this sheep model, and so could adversely affect human health. The identification of agents that inhibit the effects of these toxins may lead to therapies for affected individuals.

559 BREVETOXIN-INDUCED ALTERATIONS IN NEURONAL Ca2+ DYNAMICS AND CELL SIGNALLING.

T. F. Murray and S. Dravid. *University of Georgia, Athens, GA.*

Brevetoxins are potent allosteric enhancers of voltage-gated sodium channel function. These toxins are distributed to the central nervous system following inhalation exposure. They produce acute neuronal injury and death in cerebellar granule cells in primary culture following acute exposure. This neurotoxic response is abrogated by coapplication of either tetrodotoxin, an antagonist of voltage-gated sodium channels, or antagonists of the NMDA receptor. Brevetoxins also produce a rapid and sustained elevation in cytoplasmic [Ca2+] in cerebellar granule cells with a potency consonant with that for neurotoxicity (PbTx-1 EC50=6.64nM). The influence of brevetoxins on neuronal Ca2+ dynamics generalizes to cerebrocortical neurons inasmuch as PbTx-2 produces a concentration dependent augmentation of the spontaneous Ca2+ oscillation amplitude in primary cultures of these neurons. At concentrations greater than 300nM PbTx-2 produced a sustained rise in cytoplasmic [Ca2+]. Brevetoxin produces this modulatory effect by influencing glutamatergic signaling, inasmuch as antagonists of NMDA, AMPA/kainate and mGluR receptors inhibit the sustained rise in [Ca2+]i induced by PbTx-2. Activation of glutamate receptors is associated with an increase in [Ca2+]i which triggers activation of the MAP kinase family members ERK1/2. We therefore evaluated the effect of brevetoxin exposure on ERK1/2 activation. PbTx-2 induced a concentration-dependent increase in ERK1/2 activation. PbTx-2 exposure also produced a concentration-dependent rise in phosphorylated Akt. Thus sodium channel neurotoxins, by modulating the Ca2+ oscillations through glutamatergic receptor signaling mechanisms, can enhance the phosphorylation of ERK1/2 and Akt and therefore influence gene expression. The ability of brevetoxins to affect calcium dynamics and MAP kinase cascade singaling may influence neuronal mechanisms involved in development and learning.

560 AN EPIDEMIOLOGIC APPROACH TO THE STUDY OF AEROSOLIZED BREVETOXINS DURING RED TIDE EVENTS.

L. E. Fleming[2] and L. C. Backer[1]. *[1]National Center for Environmental Health, Centers for Disease Control and Prevention, Atlanta, GA and [2]Epidemiology and Public Health, University of Miami School of Medicine, Miami, FL.* Sponsor: J. Benson.

Red tides are caused by blooms of the marine dinoflagellates Karenia brevis. The organism produces potent neurotoxins (brevetoxins) that result in massive fish kills. Eating shellfish contaminated with brevetoxins causes neurotoxic shellfish poisoning [NSP]. Anecdotal reports of respiratory irritation and investigations of recent Florida manatee deaths suggest that environmental exposure to aerosolized brevetoxins also has adverse health impacts. Research using sheep and other laboratory animals has indeed confirmed that aerosolized brevetoxins can cause reversible bronchospasm. We have a unique approach to assess the human health effects from environmental exposure to brevetoxins. We have created an interdisciplinary team of scientists and a network of public and environmental health workers in Florida. In response to information that a red tide is onshore and inducing human symptoms, our team assembles to collect environmental samples (air, sea water, sea foam) and epidemiologic data (symptom questionnaires, pulmonary function tests, and personal breathing zone monitoring). We are studying the acute effects of aerosolized brevetoxins on lifeguards and the chronic effects on sensitive subpopulations (elderly people with underlying respiratory disease and children with asthma). Members of the team are evaluating the respiratory effects of brevetoxins in rat and sheep models, refining toxin measurements, developing and validating biomarkers for brevetoxin exposure and biological effects, and exploring the pathophysiology of respiratory exposure to brevetoxins. This multidisciplinary approach will serve as a model for investigating the human health effects from exposure to other natural toxins.

561 STRESS ACTIVATED SIGNAL TRANSDUCTION PATHWAYS.

Q. M. Chen. *Pharmacology, University of Arizona, Tucson, AZ.*

An intriguing finding over the past few years is activation of the signal transduction pathways that are known traditionally as proliferative responses by a variety of chemical toxicants. Examples of these chemicals include, but are not limited to, oxidants, quinones, arsenic, heavy metals and aromatic hydrocarbons. Although the number of toxicants found to activate signal transduction pathways is increasing and the number of signaling molecules being activated by toxicants is expanding, the functional significance of these signaling events has been a puzzle. Progress has been made recently using state-of-the-art techniques in understanding the biological consequence of three families of stress activated kinases: MAP kinases, phosphoinositide 3-kinase (PI3K), and NF-kB inhibitory subunit kinases (IKKs). The application of gene array, transgenic and pharmacological approaches has resulted in elucidation of the cascade of signaling events and dissection of transcription factors responsible for cell survival, apoptosis, or inflammatory response. This symposium will present novel and exciting findings in the field of signal transduction that are most relevant to the toxicological science. With an increased interest in using genomic approaches and kinase activities in profiling toxicants, this symposium will provide a timely update and important insights.

562 ROLE OF MAP KINASES IN AH RECEPTOR ACTIVATION.

Y. Xia, A. Puga and Z. Tan. *Department of Environmental Health, University of Cincinnati, Cincinnati, OH.*

The aromatic hydrocarbon (Ah) receptor (AHR) is the only known cellular receptor of 2, 3, 7, 8-tetrachlorodibenzo-p-dioxin (TCDD) and of many other widespread environmental contaminants that cause diverse toxic effects in animals and humans, including immune, reproductive and developmental toxicity, cancer, wasting syndrome and death. The biological effects of TCDD are mediated by activation of the AHR, which functions as a ligand-activated transcription factor whose homozygous ablation protects mice from dioxin toxicity. Dioxin also promotes signaling pathways, believed to be critical for the Ah receptor to be fully functional. The molecular connections between dioxin-activated signaling pathways and AHR function have yet to be established. Many environmental agents cause the activation of Mitogen-Activated Protein Kinases (MAPKs), leading to the modulation of transcription factor function and the alteration of gene expression. In this study, we show that dioxin and other AHR ligands induce the immediate activation of the extracellular signal-regulated kinases (ERKs) and the Jun N-terminal kinases (JNKs), but not the p38 MAPKs. MAPK activation by dioxin does not require the AHR, since it takes place equally well in AHR-negative CV-1 cells and in Ahr (-/-) mouse

embryonic fibroblasts as in AHR-positive cells. Dioxin-stimulated MAPKs are critical for the induction of AHR-dependent gene transcription, which is suppressed by the inhibition of ERK and JNK activities. Correspondingly, AHR transcription activity is largely potentiated by constitutively active MEK kinase 1 and Raf-1, known upstream regulators of the JNK and the ERK pathways, respectively. The effect of MAPKs on AHR activity is likely achieved by directly catalyzing receptor phosphorylation, which occurs as a consequence of dioxin treatment and induction of the MAPK activities. These data indicate that AHR ligands elicit AHR-independent non-genomic events that are essential for Ah receptor activation and that the MAP kinases regulate the activity and function of the Ah receptor as a transcription factor.

563 FUNCTIONS OF APOPTOSIS SIGNAL-REGULATING KINASE-1 REVEALED BY RNA INTERFERENCE.

J. Kyriakis and D. N. Chadee. *Diabetes Research Laboratory, Massachusetts General Hospital, Charlestown, MA.* Sponsor: Q. Chen.

Apoptosis signal-regulating kinase-1 (ASK1) and mixed lineage kinase-3 (MLK3) are two of a large group of mammalian protein kinases-kinase-kinases (MAP3Ks) that couple to mitogen-activated protein kinases (MAPKs) of the Jun-N-terminal kinase/stress-activated protein kinase (JNK/SAPK) family. ASK1 also activates MAPKs of the p38 group. Genetic and biochemical studies indicate that ASK1 is necessary for prolonged, redox-dependent activation of JNK/SAPK and p38 by proinflammatory stimuli. Agonists that recruit MLK3 are unknown, although pharmacologic studies suggest that it is an effector for Rho family GTPases and protein kinases of the Ste20 family. We have exploited the novel method of small interfering RNA (siRNA)-mediated RNA interference (RNAi) to suppress expression of different MAP3Ks and, by loss of function analysis, determine the biochemical and biological functions of these enzymes. Our findings indicate a complex signaling web by which extracellular stimuli link through MAP3Ks to different biological effects.

564 PI3K AND NRF2-DEPENDENT ARE-DRIVEN GENE EXPRESSION IN NEURONS AND ASTROCYTES: DEFINING PROGRAMMED CELL LIFE.

J. A. Johnson[1,2,3], A. D. Kraft[1], J. Lee[2] and D. A. Johnson[1]. *[1]School of Pharmacy, University of Wisconsin, Madison, WI, [2]Molecular and Environmental Toxicology Center, University of Wisconsin, Madison, WI, [3]Waisman Center, University of Wisconsin, Madison, WI and [4]Kinsmen Laboratory of Neurological Research, University of British Columbia, Vancouver, BC, Canada.*

The antioxidant responsive element (ARE) is found in the promoter regions of phase II detoxification enzymes such as glutathione S-transferases and NAD(P)H:quinone oxidoreductase. The expression of ARE-driven genes is mediated by the transcription factor Nrf2. Oxidative stress and small electrophilic molecules disrupt the interaction of Nrf2 with its cytoplasmic chaperone Keap1 leading to nuclear translocation of Nrf2. Chemicals that induce the nuclear translocation of Nrf2 and mice null for Nrf2 were used to test the hypothesis that increasing Nrf2-dependent genes confers resistance to apoptosis. A potent ARE activator, tert-butylhydroquinone (tBHQ) increased ARE-driven genes in primary neuronal and astrocytic cultures. Pretreatment of both culture types with tBHQ resulted in increased resistance to oxidative stress-induced apoptosis (hydrogen peroxide and glutamate treatment). Phosphatidylinostol 3-kinase (PI3K) is an upstream regulator of tBHQ-mediated Nrf2 nuclear translocation and ARE activation. The protective effect manifest by tBHQ treatment was partially reversed by inhibition of PI3K. In addition, primary cultures from Nrf2 -/- mice were more sensitive to oxidative stress-induced apoptosis (hydrogen peroxide, glutamate, rotenone and 1-methyl-4-phenyl-pyridinium treatment). To identify the Nrf2-dependent ARE-driven genes involved in this protective mechanism, primary cultures treated with tBHQ, derived from Nrf2 +/+ and Nrf2-/- mice, and infected with adenoviral Nrf2 vector were used for oligonucleotide microarray analysis. A comprehensive list of Nrf2-dependent ARE-driven genes was compiled leading to the identification multiple genes involved in preventing oxidative stress. This genomic fingerprint lends further support to the idea that genes regulated by Nrf2 through the ARE define programmed cell life. *Supported by NIEHS and the BWF New Investigator Award*

565 IKK - A MASTER REGULATOR OF INNATE AND ADAPTIVE IMMUNE RESPONSES.

M. Karin. *Department of Pharmacology, University of California at San Diego, La Jolla, CA.* Sponsor: Q. Chen.

The IκB kinase (IKK) complex is composed of 3 subunits: IKKα, IKKβ, and IKKγ. The catalytical subunits IKKα and IKKβ display a high degree of biochemical and structural similarity, both functioning as IκB kinases *in vitro*. The physiological function of each of the duplicated IKK subunits was probed by gene disruption and knockin experiments, which demonstrated a critical function for IKKβ in activation of NF-κB in response to a large number of proinflammatory stimuli, including TNFα, IL-1, dsRNA, LPS and ISS-DNA. IKKβ is also essential for prevention of TNFα induced apoptosis, indispensable for activation of innate immune responses, required for suppressing the apoptosis of TLR4-activated mouse macrophages, and an essential mediator of acute inflammatory response and tissue protection following exposure to certain physical stresses. All of these functions are mediated through the canonical NF-κB activation pathway involving IκB phosphorylation and degradation. The biological functions of IKKα were rather complex and perplexing. Although IKKα was not required for activation of the canonical NF-κB pathway in response to proinflammatory stimuli, it is essential for skin and bone morphogenesis. The role of IKKα in epidermal differentiation does not depend on its protein kinase activity nor on NF-κB. Recently, the IKKα kinase activity was found to be required for activation of a second NF-κB pathway based on the processing of NF-κB2/p100 to p52, a function seems to be triggered only by select members of the TNF family, is required for adaptive immune responses and proper organization or development of lymphoid organs, and appears to be unique for the B lymphocyte compartment. A third function of IKKα depending on its kinase activity is in development of the mammary gland. This function is exerted *via* the canonical NF-κB pathway but is not triggered by standard proinflammatory stimuli. In summary, duplication of the IKK catalytic subunits has enabled the assumption of diverse biological functions that are differentially dependent on IKKα and IKKβ.

566 METAL SPECIATION IN TOXICOLOGY: DETERMINATION AND IMPORTANCE FOR RISK ASSESSMENT - INTRODUCTION.

R. A. Yokel[1,2]. *[1]College of Pharmacy, University of Kentucky Medical Center, Lexington, KY and [2]Graduate Center for Toxicology, University of Kentucky, Lexington, KY.*

Speciation can influence the handling of metals (toxicokinetics) and their toxicity (toxicodynamics) and should be considered in quality risk assessment. The speciation of metals will be defined, as valence state and associated ligand. The metals that have only one biologically relevant valence state, for which speciation is a function of the associated ligand, will be identified. Metals that have more than one biologically relevant valence state, for which speciation is a function of both valence state and the associated ligand, will also be identified. An overview of the five presentations will be provided and the audience reminded that there will be time for discussion at the end of the workshop.

567 THE ROLE OF METAL SPECIATION IN TOXICOLOGY: METAL TOXICOKINETICS.

R. A. Yokel[1,2]. *[1]College of Pharmacy, University of Kentucky Medical Center, Lexington, KY and [2]Graduate Center for Toxicology, University of Kentucky, Lexington, KY.*

Speciation can have a substantial impact on the fate and toxicity of metals. This will be illustrated by some methods that determine or predict the impact of speciation on the handling of metals. The importance of metal species on absorption/uptake, distribution and elimination in plants, invertebrates, fish and mammals, and the impact on toxicodynamics, will be illustrated with examples, including the influence of citrate on Al toxicokinetics. The interaction of metal speciation with diffusion and carrier-mediated processes on absorption/uptake, distribution and elimination will be considered. Methods to determine and predict the impact of metal speciation on oral absorption will be presented, including determination of oral bioavailability and application of the free ion activity model. Examples will include the complexation of some essential metals by phytates and other dietary ligands that reduce oral bioavailability, the complexation of Al by small carboxylic acids secreted by Al-tolerant plants to reduce Al uptake, and ongoing work to assess the impact of Al speciation on its oral absorption. The impact of chemical speciation on metal distribution within the organism will be illustrated with examples of metal-ligand complexes that enter the brain as substrates for carriers. Examples will include transport of the methylmercury-L-cysteine complex by the large neutral amino acid carrier due to its structural similarity to L-methionine and ongoing work with manganese. The role of biotransformation to change species that result in changes in metal absorption, distribution and elimination and resultant toxicity will be addressed. The rates of non-enzymatic biotransformation processes will be considered. The impact of metal speciation on selection of chelation/absorption methods to treat metal accumulation/toxicity will be illustrated with the choice of therapy to treat mercury to conclude this presentation of the potential importance of metal species on the handling of metals.

568 THE ROLE OF METAL SPECIATION IN TOXICOLOGY: METAL TOXICODYNAMICS.

S. M. Lasley. *Biomedical & Therapeutic Sciences, University of Illinois College of Medicine, Peoria, IL.*

An important relationship between chemical speciation and toxicity exists for several metals of toxicological importance. Such a relationship is highly relevant to an understanding of the mechanisms of toxicity and their reversal. This information is also important for sound risk assessment of metal toxicity. Data supporting this relationship are exemplified by toxicity that is a function of valence state (e.g., Hg, As) or the nature of metal binding ligands (e.g, Pb, Al). The metal that best illustrates the diversity of effects caused by different chemical species is Hg. This metal exists in three valence states (Hg^0, Hg^+, Hg^{+2}) and also can form stable organic compounds. Each oxidation state and organic species exhibits characteristic toxicities. Arsenic also is found in three valence states (As^0, As^{+3}, As^{+5}), and organic arsenicals are formed in the body and by aquatic organisms. Pentavalent As is rapidly converted *in vivo* to the trivalent species, the most toxic form. In contrast to Hg, organic As compounds are less toxic than their inorganic counterparts. Divalent Pb is the most biologically significant form and exhibits a complex speciation with anions in electrolyte buffers. Almost all blood Pb is located in erythrocytes with ~70% bound to hemoglobin; only a small fraction is found in plasma with half bound to albumin. Otherwise, speciation of Pb in physiological systems is largely undefined. Organic forms of Pb are more toxic than inorganic Pb compounds. Trivalent Al is the only biologically significant form of the metal, and binds strongly to O_2-donor ligands such as citrate and phosphate. Al chemistry is complicated by a tendency to hydrolyze and form polynuclear species, many of which are sparingly soluble. Most serum Al is bound to proteins, primarily to transferrin. Citrate enhances Al gastrointestinal absorption, so this combination promotes Al toxicity. In conclusion, it is evident that knowledge of valence and ligand speciation has considerable predictive value with respect to toxicity. In many cases the degree and severity of the hazard can be reliably identified.

569 SEPARATION AND DETECTION METHODS TO SPECIATE TOXIC METALS.

J. A. Caruso. *Chemistry, University of Cincinnati, Cincinnati, OH.* Sponsor: R. Yokel.

Determining specific metal species is important. The realization that some metal species are essential while others are toxic raises the question of which metal species are we dealing with? Such analyses require careful sample preparation, sophisticated separation techniques and then ultra-trace metal detection. This talk will discuss metal speciation focusing on extractions for sample preparation, chromatography and capillary electrophoresis for separation and inductively coupled plasma mass spectrometry (ICPMS) and electrospray MS (ESMS) for detection. Unlike total metal analyses, speciation analyses must preserve the original species. Mild extractions from hot water to enzymatic extractions are used, depending on the species to be determined. Chromatographic methods typically include size-exclusion chromatography (SEC) for separating by molecular size, gas chromatography (GC) for volatiles, liquid chromatography (LC) for species in solution, and capillary electrophoresis when sample injection volume is low. SEC may be part of sample preparation wherein the separated species of a molecular size range are further separated by ion-exchange or ion-pairing reversed phase chromatography. ICPMS provides sub-ppb detection levels and can serve as an excellent prescreening technique for ESMS when further species identification is necessary. By combining chromatography with ICPMS or ESMS detection analytical advantage is quickly realized in that we have both temporal and mass selectivity. For example, capillary GC produces very high chromatographic resolution, but that even for peaks that overlap in time, information at different masses may be obtained, enabling determination of most metal species. Selenium is essential and toxic depending on the species and the intake level. Discussion will include specific species determination within a common group such as selenoamino acids from proteins or peptides. Arsenic is generally thought of as toxic. Speciation studies for As are advanced, specifically As speciation from inorganic As, organoarsenicals, arsenosugars and arsenolipids. Appropriate illustration will be given.

570 MODELING METHODS TO DETERMINE Al AND Mn SPECIATION FOR TOXICITY ASSESSMENT.

W. R. Harris. *Chemistry and Biochemistry, University of Missouri-St. Louis, St. Louis, MO.* Sponsor: R. Yokel.

When labile metal ions enter the body, they interact with a large pool of biological ligands to form a variety of metal complexes. Computer programs are available that use known binding constants to calculate the concentration of each metal complex. Such calculations are most commonly used for divalent and trivalent first-row transition metals and a few metallic main group elements such as Pb(II), Al(III) and Ga(III). Kinetic inertness and/or a limited database of binding constants restricts the use of this method for Cr(III), Co(III), and less metallic main group elements such as arsenic. The basic features of this type of calculation will be described, and speciation calculations on Mn(II) and Al(III) will be presented as examples. From a computational view, these calculations are relatively simple and can be completed within a few seconds on a typical PC. The most critical factor in the design of an accurate model is the selection of the metal-ligand stability constants to be used. The literature often contains multiple, conflicting values for key stability constants. In choosing the "best" value, one must consider the experimental conditions, such as temperature and ionic strength, and the reliability of the experimental methods. It may be necessary to estimate stability constants for key complexes that have not been evaluated experimentally. It is critically important to include the ligand protonation constants, so that competition between the metal ion and the hydrogen ion for the ligand is included in the calculation. It is also important to include competitive metal ions such as calcium(II) and magnesium(II) that are present in serum at relatively high concentrations. The speciation models will be discussed with respect to the free ion activity model for metal transport across biological membranes, which emphasizes the transport only of the free metal ion. Speciation models can also be used to identify neutral complexes that may cross membranes by passive diffusion or other complexes that might be suitable substrates for selective membrane transport systems.

571 METAL SPECIATION IN HUMAN HEALTH RISK ASSESSMENT: CHALLENGES POSED BY MANGANESE, IRON, AND OTHER ESSENTIAL NUTRIENTS.

D. C. Dorman. *CIIT Centers for Health Research, Research Triangle Park, NC.*

Risk assessment (RA) considers pharmacokinetic and pharmacodynamic processes and often results in the setting of exposure standards. As has been shown in earlier presentations, the oxidation state of a metal can dramatically influence the pharmacokinetics, pharmacodynamics, and toxicity of a metal. In some cases, different exposure standards are established for different metal species. For example, the TWAs for chromium (Cr) differ depending on whether the metal is in the Cr(II) or Cr (VI) valence state. *In vivo* and *in vitro* toxicity data available for iron (Fe) and manganese (Mn) suggest that the species of the metal can influence toxicity. This observation could imply that exposure standards for these metals should consider speciation. However, this approach would ignore the fact that Fe exists in multiple valence forms in the body, and redox cycling between ferric (Fe3+) and ferrous (Fe2+) states is basic for many biological processes. Enzyme systems (e.g., methemoglobin reductase) exist to maintain Fe in the valence state needed for its normal functions. Like Fe, Mn can exist in a number of oxidation states, and also undergoes changes in its valence states within the body. The valence of Mn in most enzymes is Mn3+, while most Mn taken into the body exists as either Mn2+ or Mn4+. Mn2+ is the predominant form in biological systems. Biologically based dose response (BBDR) models can incorporate information about the pharmacokinetics and pharmacodynamics of different species of metals. BBDR models also can address issues related to metal speciation. This presentation will use Fe and Mn to illustrate how BBDR models that consider the essentiality of these metals as well as their toxicity could be developed and used to improve the RA process.

572 APPLICATION OF LASER CAPTURE MICRODISSECTION FOR THE CHARACTERIZATION OF GENOMIC MARKERS FOR KETOCONAZOLE TOXICITY IN DOG LIVER.

J. McNulty, F. M. Goodsaid, C. Pisani, L. Obert, G. Mandakas, R. Smith, H. Zairov and I. Y. Rosenblum. *Genetic and Molecular Toxicology, Schering-Plough Research Institute, Lafayette, NJ.*

A search for genomic toxicity markers focuses on an identification of changes in gene expression levels correlating with the development of histological endpoints. We have studied quantitative gene expression changes in livers of dogs dosed with Ketoconazole, a marketed antifungal drug. Identification of candidate predictive biomarkers may be defined as an early gene expression change intensifying with detection of histopathology. Quantitative gene expression normalized to total RNA with 18S endogenous control was used to identify candidate genes consistent with this definition, regardless of mechanism of toxicity. HMGCoA reductase, Annexin V, and Gap Junction Protein A were identified in whole tissue as biomarkers for ketoconazole-induced liver necrosis. In addition to analysis of whole tissue, we applied Laser Capture Microdissection (LCM) to map the distribution of gene expression for HMGCoA reductase within liver cells in normal tissues, necrotic lesions, or cells adjacent to lesions. Portal triad and vascular structures were not included in this analysis. HMGCoA reductase was selected for gene expression analysis in LCM samples because its basal expression levels were high enough (CT < 25) for an accurate measurement of gene expression in LCM samples. Mean expression

levels for HMGCoA reductase were highest in cells adjacent to lesions and lowest in lesions. A narrow range (less than 2-fold) in gene expression level was measured for cells in control and normal tissues, while a much wider range of expression values was measured for cells in lesions or adjacent to lesions. In addition, temporal changes in gene expression for histologically normal cells sampled by LCM closely matched those sampled in whole tissue. These data demonstrate the usefulness of LCM in isolating specific cells of interest within target organs. LCM sampling, in conjunction with qRT-PCR can identify gene expression changes that are temporally and spatially associated with lesion formation.

573 ALTERATIONS IN THE EXPRESSION OF TRANSLATION FACTORS AS MOLECULAR MARKERS OF CARCINOGENESIS AND CHEMICAL TOXICITY.

P. Joseph, Y. Lei, C. O'Kernick and T. Ong. *NIOSH, Morgantown, WV.*

Translation factors control the translation of all proteins including those vital for cell growth and differentiation as well as those involved in cellular response to chemical toxicity. Previously, we have identified, cloned, and characterized translation initiation factor 3 (TIF3) and translation elongation factor-1δ (TEF-1δ) as two novel cadmium-responsive proto-oncogenes. Cadmium-induced cell transformation and tumorigenesis were found, at least in part, to be mediated through overexpression of TIF3 and TEF-1δ. Further studies have been performed in our laboratory to determine whether alterations in the expression of various translation (initiation, elongation, and termination) factors can be used as molecular markers for carcinogenesis and chemical toxicity. By employing the real time PCR technique, we have investigated the expression levels of various translation factors in human cancer cell lines and their corresponding controls. Similarly, expression levels of the translation factors were investigated in human prostate epithelial cells, RWPE1, exposed to a cytotoxic concentration of cadmium chloride. Among the translation factors studied, the expression level of translation elongation factor 1A2 (TEF1A2) exhibited the highest alteration (approximately 2000-fold overexpression) in the cancer cell lines compared with the corresponding controls. Translation initiation factor 5A2 (TIF5A2) and translation elongation factor 1δ (TEF1 δ) also exhibited significant overexpression (10- and 5-fold overexpression, respectively) in the tumor cells compared with the corresponding control cells. Exposure of RWPE1 cells to a cytotoxic concentration of cadmium chloride also resulted in overexpression of several translation factors. These results thus demonstrate that translation factors may be cellular targets for carcinogenesis and chemical toxicity, and that alterations in their expression levels may be used as molecular marker for carcinogenesis and chemical toxicity.

574 MURINE EMBRYONIC STEM CELLS AS A MODEL TO IDENTIFY BIOMARKER PROFILES OF PPAR ACTIVATORS, THIAZOLIDINEDIONES AND FIBRATES.

A. Vickers[1], Y. Kim[2], N. Paladini[1], K. Rose[1], P. Bentley[1] and H. Snodgrass[2].
[1]*Novartis Institute for Biomedical Research, Novartis, E Hanover, NJ and* [2]*VistaGen Therapeutics, Burlingham, CA.*

Murine embryonic stem (ES) cell differentiation represents a dynamic biological system for investigating compound induced effects on a wide range of cell types and tissue-tissue interactions *in vitro*. Our goal in this study is to identify biomarker profiles that are characteristic of PPAR activators and to characterise the pathways contributing to organ injury. The PPAR activators included PPARγ-agonists (troglitazone, pioglitazone and rosiglitazone), PPAR αagonists (WY14643, fenofibrate, bezafibrate), and the mixed PPARα-γ agonists (KPR297 and AZ242). Initially concentration profiles eliciting a 50% decrease in cell number at the end of a 6-day differentiation embryoid body (EB) assay using the murine embryonic stem cell line CCE-Lena (derived from 129Sv mouse strain) were determined. The effect of each compound on ES differentiation and EB development on cultures exposed for either the 6-day duration or for the last 3-days following an initial 3-day EB development period is being investigated. At the concentrations tested the PPARγ agonists inhibited cell growth by 22-42% during 3-days of exposure and 56-68% over 6-days. The PPARα agonists WY14643 and bezafibrate decreased cell proliferation up to 37% at 6-days, while fenofibrate elicited a similar response as the thiazolinediones, inhibiting cell proliferation 33% and 65% with 3-days and 6-days of exposure. The mixed PPARα-γ agonist KPR297 inhibited cell proliferation 55% over 6-days, while AZ242 decreased cell proliferation only 12%. ES differentiation is being evaluated by gene expression profiles of 3-and 6-day compound exposures.

575 REGULATION OF THE HUMAN *CYP3A4* GENE IN LUNG CELLS.

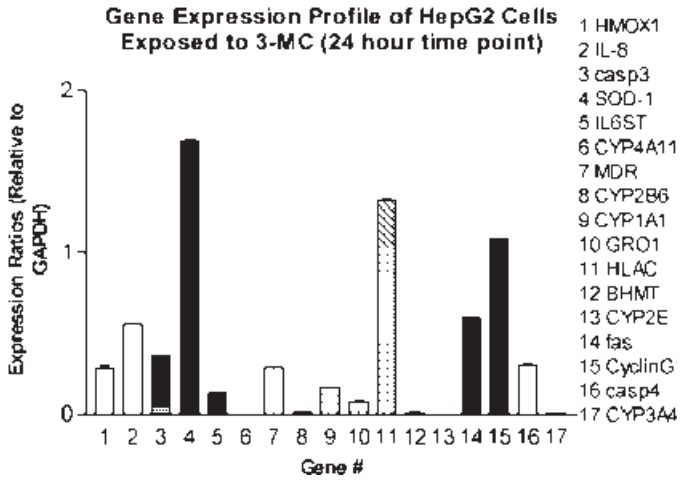
J. S. Biggs and G. S. Yost. *Pharmacology & Toxicology, University of Utah, Salt Lake City, UT.*

CYP3A4 and CYP3A5 are closely related P450 enzymes with distinctly different patterns of expression. CYP3A4 is the major human hepatic P450 enzyme, while CYP3A5 is highly expressed in human lung cells. The biochemical mechanisms responsible for the selective expression have not been fully characterized. Expression, as measured by luciferase reporter constructs, of these two genes in human lung A549 cells are dramatically different. A large (~3kb) clone of the *3A5* 5′-region activated luciferase gene expression by 5-fold in A549 cells, while an analogous fragment of the *3A4* gene did not. Comparing sequences of the 5′-flanking regions of *3A4* and *3A5* shows that a 58 bp insertion in the *3A4* promoter region (–70 to –127) corresponds to the luciferase data obtained by deletion analyses. Introduction of this 58 bp region significantly reduced luciferase activity of *3A5* clones. EMSA analyses of this region suggested two E-box motifs were the *cis*-acting elements within this region. These two binding regions may associate with as many as three A549 nuclear proteins. Preliminary EMSA supershift experiments with antibodies to known E-box binding factors (TAL1, δEF1, E2A, and HEB) failed to yield a supershifted band. Thus, these results demonstrate that the 5′-upstream region of *3A4* contains transcriptional motifs that are not present in the 5′-upstream region of the *3A5* gene, which may direct lung-selective expression of these two *CYP3A* genes. (Supported by PHS Grant HL60143).

576 MULTIPLEX PCR AND TOXICOGENOMICS.

G. Vansant and P. Pezzoli. *Althea Technologies, San Diego, CA.* Sponsor: F. Ferre .

a) Multiplex PCR is a process that is very complementary to the further development of toxicogenomics. Multiple primer pairs were designed for genes whose expression has been determined to be impacted by toxic compounds as well as some pathway specific genes. These primers are then used in a single multiplex PCR reaction to monitor the expression of up to 23 genes at once. The research presented here displays the use of multiplex PCR to determine the effect of compounds on the expression of genes relevant to potential toxicological effects and of other genes of interest for early lead compound screening. b) HepG2 cells were treated with 3-methylcholanthrene (3-MC). RNA was extracted and purified by standard methods. 100ng of total RNA was used as templates in RT reactions to produce cDNA. PCR reactions were carried out on each cDNA. PCR reactions were diluted and loaded onto the Applied Biosystems 3100 Genetic Analyzer. The data points obtained representing each PCR product were then normalized against a control data point and graphed. c) see Figure d) Multiplex PCR is an effective way to use gene expression analysis to prescreen compounds to determine their toxicological impact as well as their impact on pathways of interest.



577 ROLE OF CONSTITUTIVE ANDROSTANE RECEPTOR IN THE INDUCTION OF XENOBIOTIC TRANSPORTERS BY *trans*-STILBENE OXIDE.

A. L. Slitt, N. J. Cherrington and C. D. Klaassen. *Pharmacology, Toxicology, & Therapeutics, University of Kansas Medical Center, Kansas City, KS.*

Trans-stilbene oxide (TSO) induces Phase I and II drug metabolizing enzymes such as cytochrome P450 2b1/2 (Cyp2b1/2), epoxide hydrolase, and glutathione S-transferase. Coordinate regulation of phase I and phase II enzymes with xenobiotic transport proteins has been shown after treatment with microsomal enzyme inducers. The purpose of this study was to determine whether TSO also regulates xenobiotic transporter expression, and to determine the role of constitutive androstane receptor (CAR) in TSO induction. Total RNA was isolated from liver excised from male Sprague-Dawley rats treated with TSO for 4 days (200 mg/kg, ip, bid) and the mRNA for each gene was quantified by the branched DNA signal amplification assay. Increased levels of Cyp2b1/2, Cyp3a1/23, UGT1A6, and UGT2B1 mRNA

in liver were detected after TSO treatment. Coordinately, mRNA levels for Multidrug Resistance Proteins 2, 3, and 4 (Mrp2, 3, 4) and Multiple Drug Resistance Proteins 1a and 1b (Mdr1a, Mdr1b) were also increased in liver after TSO treatment. The expression of Mrp1, Mrp5, Mrp6, Mdr2, Oatp1, Oatp2, and Bsep transporters was unchanged by TSO treatment. Next, to determine whether TSO activates gene expression *via* CAR, male and female Wistar-Kyoto rats were treated with TSO for 4 days. Wistar-Kyoto females express lower levels of CAR protein, such that they exhibit significantly lower induction of Cyp2b1 by phenobarbital as compared to Wistar-Kyoto males treated with phenobarbital. TSO induced Cyp2b1/2, UGT2b1, and Mdr1b in males significantly higher than in females, suggesting that TSO activates their gene expression *via* CAR. However, TSO induced Cyp3a, UGT1A6, and Mrp3 equally in both genders, indicating that induction of each gene occurs independently of CAR. In summary, TSO coordinately increases liver xenobiotic transporter mRNAs, along with mRNA for phase I & II enzymes *via* both CAR-dependent and CAR-independent mechanisms. (Supported by NIH grants ES-09716, ES-09649, ES-07079, and ES-11239)

578 NRF2 DEFICIENCY IS LINKED TO LUPUS-LIKE AUTOIMMUNE DISEASE.

J. Li[1], T. D. Stein[2] and J. A. Johnson[1,3,4]. *[1]UW School of Pharmacy, Madison, WI, [2]Neuroscience Training Program, University of Wisconsin, Madison, WI, [3]Environmental Toxicology Center, University of Wisconsin, Madison, WI and [4]Waisman Center, University of Wisconsin, Madison, WI.*

Nuclear factor E2 p45-related factor 2 (Nrf2), a bZIP transcription factor, plays a central role in the regulation (basal and inducible expression) of antioxidant genes and phase II drug metabolizing enzymes through the antioxidant response element found in their promoters. Accumulating evidence indicates that Nrf2 is important for protection against carcinogenesis and oxidative stress through comparative studies on Nrf2 wild-type and knockout mice. Recently, our laboratory found 70% of the aged (over 12 months) female Nrf2-deficient mice displayed weight loss, splenomegaly, and multiple organs failure compared to 0% of the aged male Nrf2 deficient littermates. Pathological analysis demonstrated extensive mononuclear infiltration in liver, kidney, and heart, resulting in lupus-like vasculitis. Immunofluorescent staining of IgG, IgM, and C3b in multiple organs displayed massive mesangial deposits exclusively in the aged Nrf2 knockout female mice. Serum ELISA for autoantibody detection also indicated a high prevalence of anti-double-stranded DNA antibody in these mice. Taken together this suggests the aged Nrf2-deficient female mice develop lupus-like autoimmune disease. Microarray analysis had been applied for genetic dissection of the gene expression profiles linked to Nrf2 deficiency. Both genesets generated from five-month male and female knockout mice showed significant downregulation in certain antioxidant genes and phase II detoxifying enzymes. However, compared to the wild-type counterpart, female knockout mice demonstrated a dramatic increase in gene expression of anti-DNA immunoglobulin light chain IgG, Ig Kappa chain, Sm antigen, Sjogren's syndrome antigen, and other immunoregulatory factors that may be linked to lupus as early as seven months prior to pathological changes. These results suggest that Nrf2 may be involved in autoimmune regulation and may be one of the genes determining genetic susceptibility to lupus-like autoimmune disease.

579 ALTERATION OF PACLITAXEL DISPOSITION IN RATS BY ANTISENSE MORPHOLINO OLIGOMERS TARGETED TO CYTOCHROME P450 3A2.

V. Arora, D. L. Weller and P. L. Iversen. *Research & Development, AVI BioPharma, Inc., Corvallis, OR.*

Phosphorodiamidate Morpholino Oligomers (PMO) are non-ionic DNA analogs that are highly resistant to various nucleases and proteases, as well as extremely efficient inhibitors of translation *via* a non-RNase H, sequence-specific steric-blockade process. PMOs also have favorable organ distribution following systemic administration at all organ sites rich in cytochrome P450 (CYP) activity, namely the liver, kidneys and small intestines. CYP3A2 causes paclitaxel metabolism by a hydroxylation at the para position of the C3 phenyl group on the C13 side chain. The hypothesis for the current studies states that CYP3A2 inhibition by intraperitoneal antisense PMO pretreatment in rats will decrease metabolism of paclitaxel and reduce its clearance, thereby increasing its bioavailability. Vehicle, control or antisense PMOs targeted to CYP3A2 were injected intraperitoneally into male rats at the dose of 2.5 mg/kg/day for three days. PMO administration was started 48 hours prior to administration of paclitaxel, which was administered as a single bolus intravenous injection at the dose of 8.0 mg/kg. Antisense pretreatment resulted in sequence-specific decrease of (53.9 ± 8.2)% in CYP3A2 activity, as determined by erythromycin N-demethylation. Antisense pretreatment further resulted in a statistically significant alteration in various plasma pharmacokinetic parameters of bolus intravenously administered paclitaxel: increased area under curve and distribution half-life combined with decreased plasma clearance. It is concluded that CYP3A2 inhibition by antisense PMO in rats can alter paclitaxel disposition in a predictable manner.

580 BUCCAL-LUNG COMPARISON OF QUANTITATIVE EXPRESSION OF CARCINOGEN AND OXIDANT METABOLISM GENES IN HUMAN SUBJECTS.

R. Jain[1], S. D. Spivack[1], S. Varma[1] and G. J. Hurteau[2,1]. *[1]Human Toxicology, Wadsworth Center, NYS Department of Health, Albany, NY and [2]University Colorado Health Science Center, Denver, CO.* Sponsor: L. Kaminsky.

Buccal cells lining the inner cheek of tobacco smokers are carcinogen and oxidant-exposed, easily accessible, and potentially valuable surrogates for lung. Lung cancer susceptibility phenotyping might include carcinogen- and oxidant-metabolism gene expression. METHOD: For buccal cell analysis, we adapted techniques of RNA extraction, and employed our novel RNA-specific RT-PCR strategy that is unconfounded by gDNA pseudogene sequence. Precise real-time quantitation of the expression of these genes scales target to reference housekeeper (LightCycler, Roche). Genes analysed include Ahr, cytochromes P450 CYP1A1, CYP1B1, glutathione-S-transferases GSTM1, GSTM3, GSTP1, GSTT1, NAD(P)H-quinone oxidoreductase (NQO1), superoxide dismutase (CuZn-SOD), catalase (CAT)and glutathione peroxidase (GPx). For any given individual among our initial group of human subjects, we have compared buccal gene expression to laser capture microdissected lung quantitated gene expression. RESULTS: We have found close concordance of phase I, II and antioxidant genes in constitutive expression (CYP1A1, GSTM1, GSTM3 not expressed; GSTP1, GSTT1, NQO1, SOD, CAT, GPx all expressed) between the two tissues. There is often buccal-lung discordance for Ahr. However, for all 11 transcripts studied in our first 8 individuals to date, 94% of the gene-specific buccal-lung expression comparisons show concordant expression. CONCLUSION: In summary, we have in preliminary fashion shown that 1) gene expression is quantifiable in cytologically-collected buccal cells and 2) there appears to be good concordance between those carcinogen and oxidant metabolism genes expressed in the buccal mucosa and those expressed in the laser microdissected human lung epithelium. We have enlarged the group undergoing buccal-lung comparison, and commenced stratification of the expression data for covariation with tobacco exposure.

581 UV RADIATION ENHANCES *MYCOBACTERIUM ULCERANS* INFECTION IN A Crl:IAF(HA)-hrBR HAIRLESS GUINEA PIG MODEL OF BURULI ULCER DISEASE.

R. B. Cope[1], J. Hartman[2], W. Haschek[2], C. Morrow[2] and P. Small[3]. *[1]Veterinary Basic Sciences, Oregon State University, Corvalis, OR, [2]College of Veterinary Medicine, University of Illinois, Urbana, IL and [3]Department of Microbiology, University of Tennessee, Knoxville, TN.*

UV pre-exposure enhances intracellular mycobacterial infections, however its effect upon the pathogenesis of the extracellular *Mycobacterium ulcerans* parasite had not been previously examined. Groups of 5 animals were exposed to cumulative UVB doses of 0 (control), 3 or 30 kJ/m^2 of followed 3 days later by subcutaneous infection with 3 x 10^4 CFU of M. ulcerans in order to induce the nodular form of the disease. The resultant nodules were measured for the next 22 days. The experiment was then repeated using intradermal infection with 2 x 10^6 CFU in order to induce the ulcerative form of the disease. The resultant ulcers were measured for the next 30 days. In both experiments, the animals were tested for DTH reactivity to Burulin-S as a marker of the onset of the reactive phase of the disease. Following low inoculum infection, distinct, well demarcated, subcutaneously-situated skin nodules were present at infected skin sites between 7 and 22 days post-infection. Between days 14 and 21, the mean nodule diameters of the UV irradiated groups were significantly ($p < 0.03$) greater than that of the control group. UV pre-exposure resulted in significant ($p < 0.035$) suppression of DTH responses to Burulin-S challenge. High inoculum intradermal infection resulted in the development of ulcerative lesions. Between 10 and 30 days post-infection, the mean lesion diameters and mean ulcer development times of UV irradiated groups were significantly ($p < 0.05$) greater than those of the controls. However, UV irradiation did not affect DTH responses to Burulin in the high inoculum experiment. These results demonstrate that UV pre-exposure results in enhanced M. ulcerans infection in the hairless guinea pig model of Buruli ulcer disease and suggest that UV exposure may be a relevant factor in the pathogenesis of human forms of the disease.

582 CELL CYCLE DISRUPTION BY HYDROQUINONE AND CATECHOL.

J. McCue, S. Lazis and B. Freed. *School of Medicine, University of Colorado Health Sciences Center, Denver, CO.*

Cigarette smoke induces profound suppression of T cell responses in the lungs. We have reported that the two major phenolic components of cigarette tar, hydroquinone (HQ) and catechol, block DNA synthesis in proliferating lymphocytes by

reversibly inhibiting ribonucleotide reductase. However, exposure of resting lymphocytes to HQ or catechol at the time of stimulation also inhibits blast transformation and prevents normal progression through G0- and G1-phases of the cell cycle, despite up-regulation of IL-2, CD25 and CD69. Specifically, HQ or catechol exposure impaired induction of RNA synthesis and E2F-dependent genes, and diminished cell surface levels of transferrin receptors (TfR). The purpose of these experiments was to investigate the molecular basis of HQ- and catechol-induced cell cycle arrest. Peripheral blood mononuclear cells (PBMC) were activated with anti-CD3 and PMA in the presence or absence of 50 μM HQ or 50 μM catechol. Total TfR RNA and protein levels were decreased in HQ- and catechol-treated cells. Additionally, binding of iron-regulatory proteins (IRP) to iron-responsive-element (IRE)-containing RNA, which is known to increase TfR message stability, was impaired by HQ but not catechol. HQ or catechol exposure also prevented normal induction of CDK4 protein. Cyclin-dependent kinases (Cdk) inactivate the Rb family of pocket proteins (including p130), which leads to accumulation of E2F transcription factor activity. Consistent with these effects, HQ and catechol exposure prevented dissociation of E2F4 from p130. Lastly, HQ and catechol inhibited c-Myc protein levels by greater than 50%. Targets of c-Myc function in regulating protein translation and cell size, iron metabolism, and cell cycle control. As such, the absence of c-Myc protein alone could explain the pattern of inhibition seen in HQ- and catechol-treated cells. Such studies will provide the further indication of the regulatory pathways by which components of cigarette smoke inhibit T cell function in the lungs of smokers. Supported by NIEHS grants ES05673 and ES11062.

583 PERINATAL EXPOSURE TO ATRAZINE SUPPRESSES JUVENILE IMMUNE FUNCTION IN MALE, BUT NOT FEMALE SPRAGUE-DAWLEY RATS.

A. A. Rooney[2], R. W. Luebke[1] and R. A. Matulka[3]. *[1]USEPA, Research Triangle Park, NC, [2]Department of Anatomy, Physiological Sciences, and Radiology, NCSU/USEPA, Raleigh, NC and [3]Curriculum in Toxicology, UNC, Chapel Hill, NC.*

The ability of the chloro-triazine herbicide atrazine (ATR) to induce transitory hypoprolactinemia or hypothyroidism suggests that ATR may have perinatal immunomodulatory potential either directly or through the immunoregulatory properties of prolactin and thyroid hormones. Although there is no evidence of ATR immunotoxicity in juvenile or adult rats, we have previously shown that perinatal exposure to ATR decreased DTH responses in male offspring. Therefore, to further evaluate ATR as a developmental immunotoxicant, pregnant Sprague-Dawley rats were subjected to 4 separate treatment regimes from gestational day 10 through post-natal day (PND) 23: 1) ATR (35mg/kg/day) in methylcellulose *via* gavage, 2) bromocryptine (0.2mg/kg/2x/day) *s.c.* to induce hypoprolactinemia, 3) propylthiouracil (2mg/kg/day) *s.c.* to induce hypothyroidism, or 4) methylcellulose *via* gavage for control dams. Offspring were then tested after PND 50 for: 1) natural killer (NK) cell function, 2) delayed-type hypersensitivity (DTH) response to bovine-serum albumin (BSA), and 3) antibody response to SRBC. Exposure of pregnant dams to ATR decreased IgM production and DTH responses in male offspring; therefore, these ATR-affected measures were examined in 6 month old rats to test for persistence. No immunosuppression was found in 6 month old rats. These results demonstrate that perinatal exposure to ATR produced temporary gender specific changes in adult immune function. Although transitory hypoprolactinemia increased IgM production in female rats, neither hypothyroidism nor hypoprolactinemia altered NK or DTH responses, suggesting that immune changes associated with ATR exposure are not mediated through suppression of these hormones. *(This abstract does not reflect EPA policy and was supported in part by the NCSU/EPA Cooperative Training Program in Environmental Sciences Research, Training Agreement CT826512010 with North Carolina State University).*

584 PROPANIL (DICHLOROPROPIONANILIDE; DCPA) REDUCES NORMAL MACROPHAGE FUNCTION.

J. B. Barnett, L. Frost, K. Brundage and R. Schafer. *Micro, Immun & Cell Biol., West Virginia University, Morgantown, WV.*

DCPA is an herbicide known to alter macrophage function, including proinflammatory cytokine secretion. To determine if other macrophage functions are affected, we measured the direct effects of DCPA on phagocytosis, respiratory burst and bactericidal activity in primary mouse peritoneal exudate cells (PEC) and a human cell line (THP-1). DCPA caused significant reduction in the ability of THP-1 and PEC cells to phagocytize fluorescent beads ($p<0.05$) . The weighted phagocytic index for THP-1 cells was reduced from 0.730 (+/-0.303) in the ethanol control to 0.267 (+/-0.068) in the 100 microM DCPA group, a 63% decrease in phagocytosis. Significant differences ($p<0.05$) were also evident with both the 50 microM and 100 microM DCPA treatments in the PEC. Another function of macrophages is destruction of phagocytosed organisms *via* generation of free radical oxygen and nitrogen species. We employed a respiratory burst detection method utilizing luminol to amplify chemiluminescence generated by PMA-stimulated THP-1 cells and PEC. Our results demonstrate that 100 microM DCPA virtually shuts down the respiratory burst activity of both cell types, whereas 50 microM DCPA gave an intermediate response. The response of THP-1 cells treated with 25 microM DCPA was similar to ethanol control cells. The respiratory burst of PEC was more sensitive to the effects of DCPA, resulting in a significantly different dose-dependant decrease in relative light units upon exposure to 5, 50 or 100 microM DCPA ($p<0.05$). Finally, we measured the effects of DCPA on the ability of macrophages to kill the intracellular bacterium Listeria monocytogenes as a tangible indicator of a potential biological consequence. DCPA treatment at 100 microM abrogated the listericidal abilities of both THP-1 cells and PEC. These results demonstrate that DCPA causes a decrease in the functional activity of macrophages, and further support the earlier findings regarding the immunotoxic effects of DCPA. Supported by NIEHS grant ES7512 and ES11311

585 THE EFFECT OF DICHLOROPROPIONANILIDE (DCPA) ON C-JUN.

K. M. Brundage, R. Schafer and J. B. Barnett. *Microbiology, Immunology and Cell Biology, West Virginia University, Morgantown, WV.*

DCPA, the active ingredient in post-emergent herbicides such as WHAM!EZ™ is used extensively in the United States in the cultivation of rice. Using *in vivo* and *in vitro* exposure models, our laboratory has demonstrated that DCPA inhibits several important immune system functions including both T-independent and T-dependent antibody responses, cytokine production and natural killer (NK) cell function. Exposure of either the human T lymphoma cell line, Jurkat, or human peripheral blood lymphocytes (PBLs) to DCPA results in a dose-dependent decrease in the level of IL-2 secreted by these cells. This decrease in IL-2 production is due in part to a decrease in the DNA binding activity of several transcription factors essential for IL-2 gene transcription. One of these transcription factors, AP-1, is a heterodimer composed of the two proteins c-jun and c-fos. In order to elucidate the mechanism by which DCPA exposure alters AP-1 DNA binding activity, we examined the level of c-jun mRNA, protein and phosphorylation state in DCPA treated Jurkat cells compared to vehicle control. Preliminary data indicate that DCPA exposure decreases the level of total c-jun protein as well as the level of phosphorylated c-jun. In addition c-jun mRNA expression is delayed by DCPA exposure. Previous studies in the laboratory have demonstrated that c-fos transcription is not affected by DCPA exposure. Together these data suggest that DCPA exposure alters AP-1 DNA binding activity by decreasing the level of total c-jun protein and the level of phosphorylation of c-jun compared to vehicle control and may be the mechanism by which IL-2 production is reduced. Supported by NIEHS grants ES7512 and ES11311.

586 PESTICIDE MIXTURES INCREASED IMMUNOTOXICITY IN C57BL/6 MICE, *IN VIVO.*

S. Olgun[1], F. Adeshina[2], H. Choudhury[3] and H. P. Misra[1,4]. *[1]Veterinary Medicine, Virginia Tech, Blacksburg, VA, [2]USEPA, Washington, DC, [3]USEPA, Cincinnati, OH and [4]Edward Via Virginia College of Osteopathic Medicine, Blacksburg, VA.*

There is great uncertainty about how complex mixtures of xenobiotics affect human and animal health. Numerous risk assessment studies have been done to evaluate the severity of the threat that each toxic chemical posed; yet the exposure to chemicals is rarely limited to a single compound. We have studied the combined effects of lindane (L; an organochlorine), malathion (M; an organophosphate), and permethrin (P; a pyrethroid) on murine (C57Bl/6) immune system, *in vivo*. Animals were randomly divided into groups of six and injected intraperitoneally with three different doses (one-half, one-third, one-fourth, or one-eight of LD_{50}) of individual pesticide. The vehicle and positive (cyclophosphamide) control groups were included. Animals were injected with pesticides on day-1 and day-3, challenged with sheep red blood cells (sRBC) on day-4, and sacrificed on day-8. Exposure to individual pesticides did not alter the thymus/ and spleen/body weight ratios; thymic and splenic cell counts, or CD4/CD8 and CD45/CD90 phenotyping of cells. However, anti-sRBC plaque forming cell (PFC) counts were significantly lowered even at the lowest doses of pesticide exposure. Thus, the mean PFC counts/ 10^6 splenocytes were found to be 58 for corn oil; 39, 37, 37 for L 1/3, 1/4, 1/8 of LD_{50}; 36, 38, 46 for M 1/2, 1/3, 1/4 of LD_{50}; and 41, 34, 42 for P 1/2, 1/3, 1/4 of LD_{50}, respectively. Two other groups of animals were injected with the mixtures (L+M or L+P) of one-third of $LD_{50}$of each pesticide. Exposure to pesticide mixtures did not alter CD4/CD8 and CD45/CD90 cell subpopulations. However, the thymus/ and spleen/body weight ratios, thymic and splenic cell counts, and PFC counts were significantly lowered in pesticide mixture exposures. These data indicate that L, M, and P are potent immunotoxicants and mixtures of these pesticides cause significantly higher toxicity compared to individual exposures.* *The views expressed in this paper are those of the authors, and do not necessarily reflect the views and policies of the University.S.EPA.*

587 HCK- AND PKR-DEPENDENT MITOGEN-ACTIVATED PROTEIN KINASE PHOSPHORYLATION AND AP-1, C/EBP AND NF-KAPPAB ACTIVATION PRECEDE DEOXYNIVALENOL-INDUCED TNF-ALPHA AND MIP-2 EXPRESSION.

J. J. Pestka and H. Zhou. *Michigan State University, East Lansing, MI.*

The mechanism by which deoxynivalenol (DON, vomitoxin) upregulates TNF-alpha and MIP-2 expression in murine macrophage-like RAW 264.7 cells was investigated. PP1, a Src-family-selective tyrosine kinase (Hck) inhibitor and 2-AP, an inhibitor of dsRNA-dependent protein kinase (PKR) additively inhibited DON-induced TNF-alpha and MIP-2 production as well as phosphorylation of mitogen activates protein kinases (MAPKs). PP1 and 2-AP also inhibited DON-induced nuclear translocation and binding activity of AP-1, C/EBP and NF-kappaB. Furthermore, pretreatment with the p38 inhibitor SB203580, JNK inhibitor SP600125 and ERK inhibitor PD98059, ablated DON-induced binding activity of the transcription factors and subsequent production of TNF-alpha and MIP-2. Thus, DON induced a signalling cascade in the macrophage that sequentially involved Hck/ PKR →JNK/ ERK/ p38→ AP-1/ C/EBP/ NF-kappaB and that resulted in elevated TNF-alpha and MIP-2 gene expression (Supported by NIEH Grant ES-03358 and ES-09521)

588 ROLE OF AROMATIC HYDROCARBON (Ah) RECEPTORS IN MURINE SPLEEN CELL MITOGENESIS AND RESPONSES TO BENZO(a)PYRENE (BaP) AND ITS MAJOR METABOLITES.

S. W. Burchiel, F. T. Lauer, S. Dunaway, C. B. Marcus and M. K. Walker. *College of Pharmacy Toxicology Program, The University of New Mexico, Albuquerque, NM.*

Benzo(a)pyrene (BaP) is an environmental polycyclic aromatic hydrocarbon (PAH) that produces immunotoxicity resulting in either increased or decreased lymphocyte activity. Our lab has shown that BaP and certain BaP-metabolites (BaP-M) alter antigen/mitogen receptor and Ca2+-dependent signaling. Metabolism of BaP through P450-dependent (CYP1A1, CYP1B1) and independent (EPHX1, peroxidases, DD1) pathways generate products that each differentially regulate signaling. The purpose of these studies was to examine the effects of BaP and BaP-M on B and T cell proliferation in murine spleen cells, as well as to determine the role of AhR-dependent pathways in the immunotoxicity of BaP. The results of these studies show that while BPDE suppressed T and B cell proliferation at a concentration of 1 μM, BaP increased B and T cell proliferation by factors of 2-5 fold. In control WT (C57BL6/N) mice, BaP produced a dose-dependent increase in PHA-induced T cell proliferation and LPS-induced B cell proliferation. However, BaP-M produced a differential effect on murine spleen cells, with 1, 6-BPQ and 6, 12-BPQ increasing T cell proliferation, and BP-diol increasing B cell proliferation. These results suggest that murine splenic B and T cells may differentially metabolize BaP leading to proliferative effects. Because the AhR is important in the induction of BaP metabolism, we studied the effects of AhR on B and T cell proliferation and responses to BaP/BaP-T in WT, AhR +/-, and AhR -/- mice. AhR -/- mice had increased T and B cell proliferative responses to PHA and LPS in control cultures, suggesting that AhR may play a role in regulating cell proliferation. Knocking out AhR did not decrease BPQ-induced T cell proliferation. However, BP-diol-induced B cell proliferation was reduced in AhR -/- mice. Thus, we conclude that the AhR plays a differential role in B and T cell proliferation and that BaP-induced immunotoxicity is in part AhR-dependent. 589 PRENATAL AND LACTATIONAL EXPOSURE OF C57BL/6 MICE TO 2, 3, 7, 8 TETRACHLORODIBENZO-P-DIOXIN IMPAIRS THE IMMUNE RESPONSE TO INFECTION WITH INFLUENZA A VIRUS.

B. A. Vorderstrasse[1] and B. Lawrence[1,2]. *[1]Phar Sciences, Pharmacology/Tox Prog., Washington State University, Pullman, WA and [2]Pharmacology/Toxicology Program, Washington State University, Pullman, WA.*

Despite substantial investigation into the immunotoxic effects observed in adult animals exposed to TCDD, little is known about the immune function of mice exposed *in utero* and lactationally. This is of particular interest due to concerns regarding maternal transfer of Ah receptor ligands across the placenta and *via* breast milk in humans. The current study is part of an ongoing project to characterize primary and secondary immune function in mice exposed to TCDD during development. Impregnated C57Bl/6 mice were given 4 doses of TCDD: 0.25 ug/kg on gestational days (GD) 0 and 7, followed by either 1ug/kg (low dose) or 5 ug/kg (high dose) on GD 14 and postnatal day 2. Some neonatal mortality was observed, especially in the high dose group, which was likely due to decreased lactation in the dams. The immune response of 6-7 week old pups was tested by intranasal challenge with a dose and strain of influenza A virus which is not lethal in immunocompetent mice. Mice were sacrificed 8 days post-infection. In female pups, *in utero*/lactational exposure to TCDD was associated with decreased production of anti-viral antibodies, decreased numbers of CD8+ T cells in the lung, and reduced numbers of mediastinal lymph node cells. In addition, the number of IFNg-producing cells in the MLN was significantly suppressed in the TCDD-exposed female pups. In contrast to females, male offspring were generally resistant to TCDD-induced defects in response to infection with influenza virus. No effect of TCDD exposure on mortality or morbidity was observed in mice of either sex. Thus, female mice appear to be more sensitive to immune suppression induced by *in utero*/lactational exposure to TCDD, although additional studies using other antigens are necessary to verify if these effects are sex-specific. In summary, we have found that exposure to TCDD during development induces persistent deficits in immune function in female offspring.

590 SHORT-TERM EXPOSURE TO INHALED DIESEL EXHAUST PARTICLES ENHANCES ASTHMA-LIKE SYMPTOMS IN THE LOW IGE RESPONDER C57BL/6 MOUSE.

M. J. Whitekus[1], O. Hankinson[1] and D. Diaz-Sanchez[2]. *[1]Department of Pathology and Laboratory Medicine and Jonsson Comprehensive Cancer Center, UCLA, Los Angeles, CA and [2]Division of Clinical Immunology and Allergy at UCLA School of Medicine, UCLA, Los Angeles, CA.*

Although several epidemiological studies indicate a correlation between exposure to ambient particulate matter and adverse health effects in humans, there is still a fundamental lack of understanding of the mechanisms involved. Here we have established a mouse asthma model to study the adjuvant effects of diesel exhaust particles (DEP). We developed this asthma model using the C57BL/6 mouse strain as this will allow us to study the effects of DEP on several gene knock-out mice, all of which are on the C57BL/6 background. Furthermore, this mouse model is unique in that it represents a short-term model of exposure to DEP (10 days) compared with other models in the literature (usually 6 weeks or more). C57BL/6 mice (6/group) were exposed *via* inhalation to 2000 ug/m3 DEP for 10 days and to 1% ovalbumin (OVA) for 6 days. Mice treated with DEP+OVA had a 10-fold increase in total cells in the bronchoalveolar lavage (BAL) fluid compared to OVA only treated animals. Additionally, the percent of eosinophils in the BAL fluid of DEP+OVA treated mice was 80 %, compared with only 18 % in OVA only treated animals. Airway hyperresponsiveness (AHR) as measured by methacholine challenge was also significantly increased in the OVA+DEP mice compared to OVA only treated mice. In all endpoints measured, DEP treatment alone had no effect. Thus we have developed a mouse model with two key components of asthma: an increase in total cells and eosinophils in the lung and an increase in AHR. Supported by US Public Health Service Grant AI50495.

591 EFFECTS OF CO-EXPOSURES OF CONCENTRATED AMBIENT PARTICLES AND ALLERGEN ON THE LUNGS OF BROWN NORWAY RATS.

J. Wagner[1], J. Harkema[1], C. Sioutas[2], E. Timm[1], N. Kaminski[1], M. Kleinman[2] and J. Froines[2]. *[1]Pathobiology, Michgian State University, East Lansing, MI and [2]Southern California Particle Center and Supersite, Los Angeles, CA.*

Health effects of co-exposures of air pollutants and airborne allergens have not been thoroughly investigated. The purpose of our study was to determine the effects of inhalation exposure of concentrated ambient particles (CAPs) on the lungs of rats that were concurrently exposed to a pulmonary allergen (ovalbumin; OVA). A mobile air research laboratory, equipped with inhalation exposure chambers and ambient particle concentrators, was used to conduct the studies. The lab was parked in a residential site in Claremont, CA. OVA-sensitized, male, Brown Norway rats were exposed to filtered air (controls), concentrated ambient coarse (2.5-10μm; CCAPs), fine (0.15-2.5μm; FCAPs) or ultrafine (0.01-0.15μm; UFCAPs) particles for 5 h/day (11am-4pm) for 3 consecutive days. Immediately prior to each daily exposure, rats were intranasally challenged with saline alone or a 0.5% solution of ovalbumin in saline. Rats were exposed to average mass concentrations of 554, 515 and 45μg/m3 for CCAPs, FCAPs, and UFCAPs, respectively. 24 hours after the end of the exposures, rats were sacrificed, their airways lavaged with saline, and their lungs processed for microscopic or mRNA analyses. OVA-instilled rats had an allergic bronchiolitis with mucous cell hyperplasia and an allergic alveolitis with increases in eosinophils in the bronchoalveolar lavage fluid (BALF). OVA-instilled and air-exposed rats had 538% more eosinophils in the BALF, 104% more stored mucosubstances in the bronchiolar epithelium, and a 6-fold increase in mucin gene expression in bronchiolar airways than saline/air controls. Exposures to FCAPs or UFCAPs, but not CCAPs, caused attenuation (50-100%) of the OVA-induced allergic alveolitis, mucous cell metaplasia and mucin gene expression. These results indicate that fine and ultrafine particulate matter may interfere with allergen-induced airway responses during co-exposure of these airborne agents. (Research funded in part by USEPA Grant #R-82921601)

592 ENVIRONMENTAL TOBACCO SMOKE (ETS) ELICITS A TIME-DEPENDENT ALLERGIC AIRWAY RESPONSE TO INHALED ANTIGEN.

A. Penn[1], D. Paulsen[2], K. Bowles[2], C. Leblanc[2], M. Littlefield-Chaubaud[2], T. Ahlert[1], S. Pourciau[2], K. Ahlert[1], E. Boykin[1] and D. Horohov[2]. *[1]CBS, LSU School of Vet. Med., Baton Rouge, LA and [2]PBS, LSU School of Vet. Med., Baton Rouge, LA.*

Epidemiologic evidence supports a critical role for (ETS) in the occurrence and severity of allergies/asthma. However, neither the precise combination of ETS and allergen exposure nor the mechanism(s) by which these factors interact and contribute to asthma induction is known. Our hypothesis is that ETS inhalation provokes an asthmatic response by overcoming the normal airway tolerance to antigens. Our protocol combines daily ETS exposure with nose-only (N-O) sensitization to ovalbumin (OVA). Female A/J, Balb/c and C57Bl/6 mice inhaled steady-state ETS from 3 1R4F cigarettes, 5 hr/day, 9 wk. Mice were sensitized by N-O exposure (20 min/d, 10 d) to 1% aerosolized OVA at wks 2-3, 5-6 or 8-9 during ETS exposures. At 6-8 wks post-OVA sensitization, mice received a single OVA challenge (5%, 5 min). Airway responsiveness was assessed immediately after OVA challenge. Bronchoalveolar lavage (BAL) differentials, immunoglobin levels and lung inflammation were determined 24 hrs later. ETS exposure of A/J and Balb/c mice for >4 weeks prior to OVA sensitization elicited aggravated pulmonary responses, increased eosinophilia and production of OVA antibodies. The combined effect of inhaled ETS and OVA was more pronounced in Balb/c than in A/J mice. ETS exposure for only 1 week prior to OVA sensitization failed to elicit these responses. None of these responses was enhanced in C57Bl/6 mice regardless of the timing of ETS exposure and OVA sensitization. Together these results indicate that ETS exposure can elicit an asthmatic response to an allergen only a) in susceptible mice and b) when allergen sensitization follows prolonged ETS exposure. This is consistent with epidemiological data that ETS exposure exacerbates, rather than induces, asthmatic responses. Further, the results demonstrate that an asthmatic response can be elicited effectively by ETS + antigen administration *via* inhalation only, thereby overcoming aerosol tolerance. (Supported by PM External Research Group).

593 RESPIRATORY ALLERGY AND INFLAMMATION DUE TO AMBIENT PARTICLES (RAIAP), A EUROPEAN-WIDE ASSESSMENT. ALLERGY SCREENING.

T. Lovdal, E. Groeng, E. Dybing and M. Lovik. *Division of Environmental Medicine, Norwegian Institute of Public Health, Oslo, Norway.*

An objective of the RAIAP project is to examine whether qualitative differences in particulate air pollution at different locations in part explain differences in prevalence or severity of respiratory allergies throughout Europe. Ambient particulate matter (coarse and fine) was collected in Amsterdam, Rome, Lodz, and Oslo, during the spring, summer, and winter 2001/2002, as well as from a Dutch sea-side background location. In the part of the study presented here, these particles are screened for their capacity to induce, in an *in vivo* mouse model, either reactions associated with an immune response, using the popliteal lymph node assay, or an allergen specific IgE response, using an ELISA-based assay. The particulate matter is coded with respect to sampling site during the screening. So far, only the spring particles have been examined. Diesel exhaust particles from NIST (SRM 1650a) are included as a positive control. It turned out that both the coarse and fine fractions from all four sampling sites gave a significant increase in weight, cellularity, and proliferation responses to the model allergen ovalbumin, indicating that all particles have an adjuvant effect. No significant differences between the four sampling sites were observed. There seems, however, to be a locality difference in the irritant effect of the coarse particles. The adjuvant effect of the collected particles was confirmed by their ability to significantly increase the production of allergen specific IgE and IgG1. Although only significant for one location, the fine fractions seem to elicit stronger IgE responses than the coarse ones. A significantly stronger IgE response with fine particles from one, as compared to two other locations is seen. Thus, all RAIAP particles, both the coarse and fine ones, have an adjuvant effect in the doses examined (100-200 μg per mouse). However, no clear differences between the locations have been observed so far. (A European Commission Shared-Cost Research Project, QLK4-CT-2000-00792.)

594 INHALATION DOSIMETRY DIFFERENCES IN BALB/C AND B6C3F1 MICE INFLUENCE AIRWAY RESPONSIVENESS TO METHACHOLINE CHALLENGE.

O. R. Moss and M. P. DeLorme. *CIIT Centers for Health Research, Research Triangle Park, NC.*

The airway response to bronchoconstrictive agents is commonly used to measure airway reactivity. While the effect of aerosol concentration and size are well characterized factors in the inhalation toxicology field, the delivered dose of inhaled aerosols in the pulmonary system is often overlooked. It is common practice in these challenge procedures to report the airway reactivity as the concentration of methacholine in the solution being nebulized into an aerosol that causes a 200% increase in airway resistance (PC200R). However, the response may be due to differences in actual deposition in the upper airways of the animals. To investigate the effect of inhalation dosimetry, BALB/c and B6C3F1 mice were placed in an unrestrained barometric whole-body plethysmograph and subjected to challenge with aerosols generated from isotonic saline (control) and 7 methacholine solutions of increasing concentration (2.5 to 320 mg/ml) for 3 min. Measurements of airway resistance were recorded and averaged for 3 min following each aerosolization period. The concentration of aerosol in the plethysmograph was measured with filters using fluorscein as a tracer, and aerodynamic particle size distribution was determined with a MOUDI cascade impactor. The methacholine aerosol size distribution data were then used to estimate upper airway delivered dose according to the deposition curves for the two strains reported by Oldham and Phalen (Anat Rec, 268, 59-65, 2002). Based on PC200R, the BALB/c mouse was 14 times more sensitive than the B6C3F1 mouse. When the concentration of methacholine in the whole-body plethysmograph, total volume inhaled, and deposition fraction were included in the estimated inhaled dose, the BALB/c mouse was only 2.4 times more sensitive than the B6C3F1 mouse. Therefore, individual subject inhalation dosimetry may differ significantly from the dose normally indicated by PC200R and may explain a wide range of PC200R-based methacholine challenge sensitivities.

595 INCREASED LUNG DISEASE TO RESPIRATORY SYNCYTIAL VIRUS BY INHALED DIESEL ENGINE EMISSIONS.

K. S. Harrod, J. A. Berger, M. D. Reed and J. D. McDonald. *Asthma and Pulmonary Immunology, Lovelace Respiratory Research Institute, Albuquerque, NM.*

The role of air pollutants and engine emissions in the susceptibility to respiratory viral infections is not well understood. Respiratory syncytial virus (RSV) is the leading cause of wheezing and bronchiolitis in lungs of infants and young children. To determine the impact of relevant levels of whole diesel engine emissions (DEE) on RSV-induced lung disease, a resistant mouse model of RSV infection was exposed to inhaled DEE before infection and markers of lung inflammation, lung epithelial host defense, and homeostasis assessed. Inhaled DEE concentrations consisted of 30 $\mu g/m^3$, 200 $\mu g/m^3$, and 1000 $\mu g/m^3$ of total particulate matter (PM). RSV infection did not induce notable lung histopathology, inflammation, or viral persistence in air-exposed mice. Prior exposure to inhaled DEE (6 h/d, 7 consecutive days) prolonged the expression of RSV gene subsets, consistent with increased lung viral burdens. Lung inflammation to RSV was increased in DEE-exposed mice concomitant with increased viral gene expression. Lung inflammation endpoints exhibited a concentration-dependent response, with the highest inflammation in RSV-infected mice exposed to 1000 $\mu g/m^3$ PM DEE. Lung histopathology and specifically lung epithelial morphology were markedly altered during RSV infection by prior DEE exposure. Mucus production was increased in the airways of DEE-exposed, RSV-infected mice in a concentration dependent manner. Immunohistochemical studies of distinct lung epithelial cell subsets indicate spatial-temporal alterations in airway epithelial Clara cells and alterations in lung surfactant protein homeostasis, including important host defense proteins. These studies indicate that relevant levels of inhaled DEE exposure can exacerbate the susceptibility to RSV-induced lung disease and may provide a useful model for elucidating the molecular mechanisms of increased susceptibility to acute respiratory infections.

596 AIRWAY REACTIVITY IN ALLERGIC MICE AND RATS AFTER SHORT-TERM EXPOSURE TO CONCENTRATED AMBIENT PARTICULATE MATTER.

H. van Loveren, F. Cassee, J. Dormans, A. Boere and P. Steerenberg. *National Institute for Public Health and the Environment, Bilthoven, Netherlands.*

The present study was designed to find out whether exposure to ambient particulate matter (PM) causes exacerbation of the symptoms of asthma. We have used mouse and rat models in which characteristics of asthma, such as increased immune globulin levels and increased airway reactivity. Animals were exposed to concentrated ambient particulate matter (CAPs < 2.5 um; 500 - 2000 ug/m3) during 3 consecutive days. Allergic animals had an increase in eosinophils, IgE and IgG1 in the lung as well as a hypertrophy of the bronchiolar epithelium. However, CAPs did not only marginally affect the pathological conditions. The smooth muscle contraction due to increasing concentrations of metacholine exposure was assessed. Only slight effects of CAPs on the airway reactivity could be observed. We concluded that CAPs used in this study did not significantly affect airway pathobiology and reactivity. These data do therefore not provide support to the hypothesis that PM2.5 can exacerbate a pre-existing asthmatic condition.

597 EXACERBATION OF BRONCHIAL HYPERRESPONSIVENESS (BHR) BY URBAN PARTICULATE MATTER.

J. Cramton, A. J. Archer, J. C. Pfau and A. Holian. *Center for Environmental Health Sciences, University of Montana, Missoula, MT.*

Recent epidemiological studies have demonstrated a correlation between exposure to increases in urban particulate matter (PM) and exacerbation of bronchial hyperresponsiveness (BHR). However, the mechanism by which PM enhances the immune response contributing to the BHR is unknown. In this study, DO11.10 mice, which are transgenic for an ovalbumin-specific T-cell receptor, were used to assess the acute and delayed effects of PM on BHR. Based on preliminary dose-response studies, mice at 4 weeks of age were instilled intranasally with 750 μg of PM1648 (a model PM available from NIST) with or without 150 μg ovalbumin. Enhanced pause (Penh) was examined following methacholine challenge at 4 and 72 hours post-instillation using whole-body plethysmography (Buxco). BHR was increased at 4 hours following co-administration of PM and antigen compared to age-matched controls. Exacerbation of BHR also occurred at 72 hours with separate administration of PM and antigen. This data demonstrates that exposure to PM1648 increases both the acute and delayed BHR to antigen. These results could be explained by PM acting as an adjuvant-like cofactor to the antigen. Alternatively, in the acute model, PM may be acting as a carrier for the antigen, facilitating its presentation to the immune system. This work was supported by NIEHS grant ES 11120 and EPA grant R826782.

598 MOTOR ACTIVITY IN DEVELOPMENTAL NEUROTOXICITY TESTING: A CROSS-LABORATORY COMPARISON OF CONTROL DATA.

K. C. Raffaele[1], W. F. Sette[1], S. L. Makris[1], V. C. Moser[2] and K. M. Crofton[2]. *[1]OPP, USEPA, Washington, DC and [2]NHEERL, ORD, USEPA, Research Triangle Park, NC.*

The USEPA Developmental Neurotoxicity Study Test Guideline (OPPTS 870.6300) calls for a battery of functional and neuropathological assessments in offspring during and following maternal exposure. Motor activity is measured on post-natal days (PND) 13, 17, 21, and 60±2; inclusion of 3 time points during lactation allows assessment of the pattern of overall activity levels during this time and of the development of habituation. Although the Guideline specifies use of an automated motor activity recording apparatus, the type of device or duration of the testing period are not specified; many devices and session lengths are seen among the studies that have been submitted to the Agency. To evaluate whether some types of devices/testing conditions yield more reliable data than others, we compared motor activity data generated in control animals from 21 studies in terms of: 1) variability of data within a study, across time points; 2) variability of data across studies within a laboratory, by time point; 3) patterning of mean baseline motor activity counts over time, across studies within a laboratory; 4) variability for particular devices, across laboratories. Data from ten laboratories were evaluated; the number of studies available from a single laboratory varied from 1 to 5. Preliminary analysis found higher variability for earlier lactation time points than for later lactation time points in most laboratories. Variability for the adult time point was usually lower than for the lactation time points. Variability did not consistently correlate with type of device or with session duration. The pattern of baseline activity counts across postnatal age and studies varied among laboratories. For all laboratories, mean baseline activity counts were higher on PND17 than on PND13; for most laboratories, mean counts on PND21 were lower than on PND17. Further consideration of how to reduce variability of these motor activity measurements is warranted. *This abstract does not necessarily reflect the policy of the US Environmental Protection Agency.*

599 LACK OF EFFECT OF PERINATAL EXPOSURE TO A POLYBROMINATED DIPHENYL ETHER MIXTURE (DE-71) ON THE HABITUATION OF MOTOR ACTIVITY IN ADULT RATS.

R. MacPhail, J. D. Farmer, B. K. Padnos and K. M. Crofton. *Neurotoxicology Division, USEPA, Research Triangle Park, NC.*

Polybrominated diphenyl ethers (PBDEs) are used as flame retardants and are becoming increasingly evident in environmental media, wildlife and human breast milk. Published research in mice has shown that early postnatal exposure to some PBDEs attenuates the habituation of motor activity when the pups were tested as adults. This experiment determined the effect of perinatal exposure of rats to the PBDE mixture DE-71 on the habituation of motor activity in adult offspring. Pregnant Long Evans rats (N=8/group) received (p.o.) either corn oil (1 ml/kg) or DE-71 (5, 30 or 100 mg/kg) from GD6 to PND21. Doses were based on prior research showing alterations in thyroid hormone status. As adults, one male and one female from each litter (total: 8 rats/treatment/gender) underwent habituation testing. Test sessions (45 min) were carried out in photocell devices that separately recorded horizontal and vertical activity in five 9-min intervals. In general, motor activity was highest early in the session, but dropped by approximately 65-75% by the end of the session. Perinatal exposure to DE-71 did not affect either overall levels of motor activity or the within-session habituation of activity in either gender. These results suggest that effects in mice postnatally exposed to individual PBDE congeners may not predict effects in adult offspring of rats perinatally exposed to DE-71. This abstract does not necessarily reflect USEPA policy.

600 PERSISTENT IMPAIRMENTS IN SHORT-TERM, BUT ENHANCED LONG-TERM, SYNAPTIC PLASTICITY IN HIPPOCAMPAL AREA CA1 FOLLOWING DEVELOPMENTAL HYPOTHYROIDISM.

L. Sui[2,1], W. L. Anderson[1] and M. E. Gilbert[1]. *[1]Neurotoxicology, USEPA, Research Triangle Park, NC and [2]National Research Council, Washington, DC.*

Thyroid hormones (TH) are critical for nervous system development. Deficiency of TH during development impair performance on tasks of learning and memory that rely upon the hippocampus, but the mechanism underlying this impairment is not well understood. The present study was designed to identify hypothyroid-induced changes in hippocampal function using neurophysiological assessments in area CA1 of hippocampal slices. Hypothyroidism was induced by administration of 3 or 10ppm propylthiouracil (PTU) to pregnant and lactating dams *via* the drinking water from GD6-PN30. Synaptic transmission and plasticity using the long-term potentiation (LTP) model were assessed in area CA1 of hippocampal slices from treated offspring. Input/output and paired-pulse functions were collected to assess the integrity of synaptic transmission at PN85-101. Baseline synaptic transmission was not altered in PTU-exposed animals. However, significant dose-dependent reductions in paired-pulse facilitation of the EPSP were observed, indicative of perturbations in presynaptic transmitter release function. An increase in magnitude of LTP of the PS and increased phosphorylation of MAPK/ERK as a function of LTP induction were also observed in the high dose group. Neurophysiological assessments in the preweaning period and in adults in a different hippocampal subregion (i.e., dentate gyrus) demonstrate a different pattern of effects and more profound deficits (see accompanying Gilbert and Sui abstract). These results indicate that neonatal hypothyroidism produces long-term changes in hippocampal function that can be observed using field potential analysis *in vitro* and *in vivo*; that site is critical in determining the nature of the deficit; and that neurophysiological alterations may contribute to behavioral deficits associated with developmental hypothyroidism. (Does not reflect USEPA policy).

601 DEVELOPMENTAL HYPOTHYROIDISM IMPAIRS HIPPOCAMPAL LEARNING AND SYNAPTIC TRANSMISSION *IN VIVO*.

M. E. Gilbert[1] and L. Sui[2,1]. *[1]Neurotoxicology, USEPA, Research Triangle Park, NC and [2]National Research Council, Washington, DC.*

A number of environmental chemicals have been reported to alter thyroid hormone (TH) function. It is well established that severe hypothyroidism during critical periods of brain development leads to alterations in hippocampal structure and learning deficits, yet evaluation of modest perturbations of the thyroid axis coupled with more subtle alterations in brain function has been lacking. The present study examined the effects of developmental hypothyroidism on hippocampal function using behavioral and neurophysiological assessments in the intact animal. Thyroid hormone function was reduced in pregnant dams by propylthiouricil (PTU) *via* the drinking water (0, 3, 10 ppm) from GD 6 to weaning. This regimen reduced serum TH concentrations on PN14. All animals had returned to a euthyroid state at time of testing. At 5-6 mon of age, spatial learning was assessed in male offspring in a Morris water maze. Between 4-7 mon of age, neurophysiological examination of perforant path-dentate gyrus field potentials was performed *in vivo*. Input/output (I/O) functions probed the integrity of synaptic transmission. Paired pulses were delivered to examine inhibitory function (PPD) and presynaptic transmission (PPF). Long-term potentiation (LTP) was induced by theta burst stimulation to assess neuroplasticity. PTU induced dose-dependent impairments in spatial learning in the absence of cue learning deficits or reductions in swim speed. Electrophysiologically, population spikes and EPSP slopes were dose-dependently reduced, and LTP was impaired. In contrast, paired pulse tests revealed a shift to more facilitated responses as a function of PTU treatment. These findings corroborate earlier data from our laboratory demonstrating alterations in synaptic function following a higher dose of PTU exposure occurring primarily during lactation and suggest that hippocampal neurophysiological assessments may prove valuable in defining the lower end of the dose-response function for chemicals that alter thyroid function early in development. (Does not reflect USEPA policy).

602 PERINATAL EXPOSURE TO A POLYBROMINATED DIPHENYL ETHER MIXTURE (DE-71): DISRUPTION OF THYROID HOMEOSTASIS AND NEUROBEHAVIORAL DEVELOPMENT.

M. M. Taylor[1], J. M. Hedge[2], M. E. Gilbert[2], M. J. DeVito[3] and K. Crofton[2]. *[1]Department Environmental Medicine, University of Rochester, Rochester, NY, [2]Neurotoxicology Division, USEPA, Research Triangle Park, NC and [3]Experimental Toxicology Division, USEPA, Research Triangle Park, NC.*

Polybrominated diphenyl ethers (PBDEs), produced commercially as mixtures, are used as flame-retardants in numerous consumer products. Previous work has demonstrated that the DE-71 induces hypothyroxinemia in both adults and developing rats. In these studies, primiparous rats were orally administered DE-71 (1 - 100mg/kg/day) in 1.0 ml/kg corn oil from gestation day 6 (GD6) to postnatal day 21 (PND21). Offspring were evaluated at various ages for survival, body weight, serum thyroid hormones, age of eye opening, motor activity development, hepatic enzyme activity (EROD, PROD, UDPGT), auditory startle, auditory thresholds, and fear conditioning. There was no effect of DE-71 on body weight gain or survival in either the dams or offspring. There were dose-dependent decreases in thyroxine in offspring relative to controls on PND 5 (73.3, 49.3 and 43.5 % of control) as well as on PND 14 (75.6, 33.6 and 29.9%) for 5, 30 and 100mg/kg respectively. DE-71 caused increases in hepatic EROD, PROD and UDPGT activity in both offspring and dams. Motor activity and startle were unaffected by treatment. Tests of fear conditioning revealed a dose-dependent decrease in cue- but not context-based performance in male offspring tested as adults. There was no effect on fear conditioning performance in offspring tested as weanlings. Auditory thresholds are currently being evaluated. These data suggest that developmental exposure to DE-71 induces hepatic enzymes and hypothyroxinemia in both dams and offspring, and alters some aspects of offspring neurobehavioral development. This is an abstract of a proposed presentation and does not necessarily reflect University.S.EPA policy. Mention of trade names or commercial products does not constitute endorsement or recommendation for use.

603 DEVELOPMENTAL NEURO- AND CARDIOTOXICITY OF TERBUTALINE: DNA SYNTHESIS AND NEURAL BIOMARKERS.

M. C. Garofolo, F. J. Seidler and T. A. Slotkin. *Pharmacology & Cancer Biology, Duke University Med. Ctr, Durham, NC.*

Beta-2-adrenergic receptor (B2AR) agonists, such as terbutaline, are widely used to arrest preterm labor, despite the fact that this is not on FDA's list of approved uses. B2AR agonists cross the placenta to stimulate fetal BARs that control neural and cardiac cell differentiation. We administered terbutaline to developing rats in two different exposure periods corresponding to human development in the third trimester (postnatal days PN2-5) and in the perinatal period (PN11-14). We examined DNA synthesis in the heart and in brain regions with different maturational timetables. Exposure on PN2-5 reduced DNA synthesis in the heart and brainstem of females, with sensitization of the effect upon repeated terbutaline administration. Terbutaline treatment on PN11-14 decreased cerebellar DNA synthesis after one or four daily injections; in contrast, cardiac DNA synthesis decreased after the first injection but increased after the fourth injection. We next focused on neural biomarkers to determine which cell populations are being affected by terbutaline exposure. Terbutaline administered on PN2-5 resulted in immediate (PN6) increases in glial fibrillary acidic protein (GFAP) in all brain regions, suggestive of gliosis. Terbutaline exposure on PN11-14 did not significantly alter GFAP. Our results indicate that excessive BAR stimulation by terbutaline alters cell development in brain regions and peripheral tissues, with the net effect depending on sex and on the timing of exposure. These effects may contribute to the higher incidence of neuropsychiatric, cognitive, cardiovascular and metabolic abnormalities reported in the offspring of women who underwent therapy with BAR agonist tocolytics. We are currently investigating the effects of terbutaline on neuronal biomarkers and on cellular morphology in the brain and heart. (Supported by NIH HD09713)

604 SHORT-TERM NICOTINE EXPOSURE IN ADOLESCENT RATS ELICITS BRAIN CELL DAMAGE.

Y. Abreu-Villaça, F. J. Seidler and T. A. Slotkin. *Pharmacology & Cancer Biology, Duke University Med. Ctr, Durham, NC.*

Adolescence is when cigarette use typically begins. Recent studies suggest that the adolescent brain is particularly vulnerable to nicotine dependence. We investigated the effects of short-term nicotine exposure on indices of brain cell damage in adolescent rats. Beginning on postnatal day 30, rats were given a one week regimen of either continuous nicotine infusions (to simulate regular smoking) or twice-daily injections (to simulate intermittent smoking), at three doses (0.6, 2 and 6 mg/kg/day) set to achieve plasma nicotine levels found in occasional to regular smokers. During and after nicotine exposure, we assessed indices of nicotinic acetylcholine receptor activation (nAChR upregulation), cholinergic synaptic function (3H-hemicholinium-3 binding to the presynaptic choline transporter), cell number (DNA content), cell packing density (DNA concentration), cell size (protein/DNA ratio) and membrane surface area (membrane/total protein). Nicotine infusions elicited robust increases in nAChRs even at the lowest dose, with effects persisting for one week after the end of treatment. In the nicotine group, we observed reductions in cell number and packing density in the cerebral cortex and midbrain, accompanied by net increases in cell size for the remaining cells. Membrane surface area was reduced relative to cell size, suggesting a loss of neuritic projections, and indeed, [3H]hemicholinium-3 binding was reduced. Many of the effects persisted for at least one month posttreatment and were significant at 2 mg/kg/day, which produces plasma levels of nicotine found in light smokers. Intermittent nicotine exposure (injection route) elicited significant effects that were less consistent than those seen with infusions. Our results indicate that even short-term exposure to low doses of nicotine disrupts adolescent brain development; the degree of nAChR upregulation and cell damage are dependent on the pattern of exposure (continuous versus intermittent). Supported by a grant and fellowship from the Philip Morris External Research Program and by a fellowship from CNPq Brazil.

605 FETAL CHLORPYRIFOS EXPOSURE: ADVERSE EFFECTS ON BRAIN CELL DEVELOPMENT AND CHOLINERGIC BIOMARKERS.

D. Qiao, F. J. Seidler and T. A. Slotkin. *Pharmacology & Cancer Biology, Duke University Med. Ctr, Durham, NC.*

Fetal and childhood exposures to the widely-used organophosphate pesticide, chlorpyrifos (CPF), have raised concerns about developmental neurotoxicity. Previously, biomarkers for brain cell number, cell packing density and cell size indicated that neonatal rats were more sensitive to CPF than were fetal rats, yet animals exposed prenatally still developed behavioral deficits in adolescence and adulthood. We administered CPF to pregnant rats on gestational days 17-20, using regimens devoid of overt maternal or fetal toxicity. We then examined subsequent development of acetylcholine systems in forebrain regions, and compared the effects to those on general biomarkers of cell development. Choline acetyltransferase, a marker for cholinergic nerve terminals, showed only minor CPF-induced changes. In contrast, hemicholinium-3 binding to the presynaptic choline transporter, which is responsive to nerve impulse activity, displayed marked suppression that persisted into adulthood. There was no compensatory upregulation of cholinergic receptors, as m2-muscarinic cholinergic receptor binding was unchanged. CPF also elicited alterations in biomarkers of cell development, with reductions in cell packing density, increases in relative cell size and contraction of neuritic extensions; however, neither the magnitude nor timing of these changes were predictive of the cholinergic defects. The current findings indicate a wide window of vulnerability of cholinergic systems to CPF, extending from prenatal through postnatal periods, occurring independently of adverse effects on general cellular neurotoxicity. Support: NIH ES10356 & ES10387.

606 CHANGES IN SEROTONIN RECEPTORS IN BRAIN REGIONS OF RATS AFTER NEONATAL EXPOSURE TO CHLORPYRIFOS.

J. E. Aldridge, F. J. Seidler and T. A. Slotkin. *Pharmacology & Cancer Biology, Duke University Med. Ctr, Durham, NC.*

Chlorpyrifos (CPF), a commonly used pesticide, is a developmental neurotoxin, and animal studies indicate cognitive impairment after fetal or neonatal exposure. However, little or no attention has been paid to potential effects on serotonergic (5HT) systems, which similarly participate in cognitive function, but also regulate mood, appetite and other behaviors. Neonatal rats received 1 mg/kg CPF on postnatal days (PN) 1-4, or 5 mg/kg on PN11-14, doses that lie below the threshold for systemic toxicity. Twenty-four hours and 6 days after the last dose, we measured 5HT1A and 5HT2 receptor binding in cell membranes prepared from regions containing 5HT terminals (forebrain) and cell bodies (midbrain/brainstem). With exposure on PN1-4, 5HT receptor binding showed receptor upregulation at PN5 across both regions and both sexes. The elevations were still significant on PN10 in males, but in females deficits emerged in the midbrain/brainstem. With later exposure during the peak period of axonogenesis/synaptogenesis (PN11-14), the initial (PN15) increase in receptor binding occurred only in females. By PN20, significant deficits appeared in both sexes, both regions and for both receptor subtypes. Superimposed on the decrease in 5HT receptors, binding of paroxetine, a ligand for the presynaptic 5HT transporter, also showed a decrement. These results suggest that CPF exposure during a critical window centering around axonogenesis/synaptogenesis elicits deficits of 5HT synaptic biomarkers that are compatible with po-

tential emergence of affective dysfunction. Future work will address the persistence, underlying mechanisms and behavioral consequences of these effects of CPF exposure. (Supported by NIH ES10387 and ES10356)

607 PRENATAL EXPOSURE TO DIOXIN AND INHALED BENZO(a)PYRENE: REDUCED CAPACITY FOR LONG-TERM POTENTIATION IN THE F1 GENERATION.

D. Wormley[1], S. Chirwa[2], W. Zhang[1], T. Nayyar[1], M. Greenwood[1], F. F. Ebner[3] and D. B. Hood[1,3]. *[1]Pharmacology, Meharry Medical College, Nashville, TN, [2]Anatomy and Physiology, Meharry Medical College, Nashville, TN and [3]Institute for Developmental Neuroscience, Vanderbilt University, Nashville, TN.*

The purpose of this study was to assess the transplacental effects of exposures to 2, 3, 7, 8, tetrachlorodibenzo-p-dioxin (TCDD) or benzo(a)pyrene [B(a)P], or to a successive exposure to both compounds [TCDD On GD14 & B(a)P on GD14-17] in timed pregnant dams, on the characteristics of long-term potentiation (LTP; a cellular correlate of learning and memory) in F1 generation animals. After birth, F1 generation pups were weaned, randomly selected for treatment groups (i.e., unexposed control; TCDD; B(a)P; and TCDD/B(a)P groups), and housed separately by sex. On postnatal day 60-62 the animals were anesthetized and prepared for recording from the hippocampus. F1 rats exposed *in utero* to TCDD alone or in sequence with B(a)P, failed to develop LTP under the same conditions that produced robust LTP in the unexposed F1 control rats. In control cases, LTP was accompanied by a decrease in onset latencies and leftward shifts in input-output curves. F1 rats exposed *in utero* to B(a)P alone developed a weak but enduring potentiation. The results indicate that midgestational exposure to TCDD and B(a)P decrease the capacity for synaptic plasticity in F1 generation rats.

608 METABOLISM OF INHALED BENZO(a)PYRENE IN THE DEVELOPING CENTRAL NERVOUS SYSTEM AND PARTIAL ABLATION OF LONG-TERM POTENTIATION IN F1 GENERATION ANIMALS.

D. B. Hood, J. Wu, A. Ramesh, D. Wormley, T. Nayyar and M. Greenwood. *Pharmacology, Meharry Medical College, Nashville, TN.*

This study was undertaken to determine the bioavailable dose associated with the transplacental disposition of inhaled benzo(a)pyrene [B(a)P] metabolites and the resulting effects on synaptic plasticity in F1 generation pups. In this study, laparotomy on GD 8 was performed on timed-pregnant rats followed by dosing *via* nose-only exposure for four hours a day for ten days (GD 11- GD 20) to three concentrations of a B(a)P : carbon black aerosol (25, 75 and 100 micrograms/m3). A dose-dependent decrease in birth index was observed in the B(a)P: carbon black aerosol exposed group when compared to the unexposed control or carbon black exposed group ($p<0.05$). Analysis of cerebrocortical extracts from F1 generation pups revealed a dose-dependent increase in total B(a)P metabolites. The developmental expression profiles for AhR and CYP1A1 were analyzed from cerebrocortical and hippocampal tissue by RT-PCR and Northern Blotting. The results, using 18sRNA as the internal standard, demonstrate that inhaled B(a)P upregulates AhR and CYP1A1 during the first postnatal week when the regulatory synergism between neuronal-glial interactions is essential for programmed growth and differentiation. On postnatal day 60-62 randomly selected male rats were anesthetized with urethane and small access holes were made in the skull through which electrodes were lowered to stimulate the entorhinal cortex and analyzed for long-term potentiation (LTP) in the dentate gyrus. It was found that robust LTP was readily produced in the control group, in contrast, rats exposed to B(a)P at the highest dose did not develop LTP. Overall, our results suggest that gestational exposure to B(a)P decreases the capacity for synaptic plasticity in the F1 generation.

609 BENZO(a)PYRENE AND DIOXIN INDUCED DOWNREGULATION OF HIPPOCAMPAL NMDAR1 EXPRESSION AND DEFICITS IN FIXED-RATIO PERFORMANCE IN F1 GENERATION RATS.

J. Wu, T. Nayyar, T. Tu, S. Johnson, M. Greenwood and D. B. Hood. *Pharmacology, Meharry Medical College, Nashville, TN.*

Dioxin and B(a)P are widely distributed environmental contaminants which are suspected to impair advanced brain function in animal models and humans. The NMDAR1 receptor is a well characterized molecule that is responsible for plasticity and the development of synaptic connections in the central nervous system (CNS). To access the neurotoxicological effects of prenatal exposure to these compounds in F1 generation offspring, timed-pregnant F-344 rats were exposed to inhaled B(a)P aerosol (100µg/m3) for 4 hours a day on GD14 to 17 or to dioxin (700ng/kg BW) by gavage on GD 14. The mRNA and protein expression of NMDAR1 from the hippocampus of F1 generation pups was quantified by Real-time PCR and western blot analysis on PND 0, 5, 10, 20 and 30. Real-time PCR results revealed similar developmental expression profiles for the control and exposed groups from PND 0 to 30, where the mRNA expression level on PND 30 was increased to 150% relative to that on PND 0. The quantitation further revealed down-regulation in the B(a)P (10%) and Dioxin (15%) exposure groups as compared to controls. Western blot analysis revealed a significant 38% and 48% reduction in NMDAR1 protein levels on PND 30 subsequent to B(a)P and Dioxin exposure, relative to controls. On PND 80, the Fixed-Ratio (FR) Performance was conducted to evaluate the acquisition process of learning and memory. The analysis revealed that as the complexity of the task increased from a FR1 to FR5, the exposed animals showed deficits in the acquisition process of learning and memory that did not occur in the controls. The reduction in hippocampal NMDAR1 expression correlates well with the hippocampal based Fixed-ratio performance behavioral study. These results suggest that prenatal exposure to B(a)P and dioxin cause deficits in learning and memory and these deficits appear to persist through adulthood long after the end of exposure.

610 EYEBLINK CLASSICAL CONDITIONING OF RABBITS AS A POTENTIAL POSTNATAL BEHAVIORAL-FUNCTIONAL EVALUATION.

J. F. Barnett Jr., E. M. Lewis, A. M. Hoberman and M. S. Christian. *Argus Research - A CRL-DDS Division, Horsham, PA.*

Although most behavioral-functional evaluations are performed with rats or mice, some agents may require use of alternate species, for which there is little validated testing and/or control data. Our laboratory validated eyeblink classical conditioning in rabbits, a test of learning and memory, to address this deficit. Saline (S), scopolamine (SC, 1.0 mg/kg/day) or d-amphetamine (A, 1.85 mg/kg/day) were given subcutaneously on 8 consecutive days, 30 minutes pretest. Each group consisted of 4 rabbits/sex, 5-6 months of age. Each trial was 600 milliseconds (ms) in duration and had a conditioned stimulus (CS, a 100 ms tone), a "blank period" (400 ms without stimulus) and an unconditioned stimulus (US, a 100 ms corneal airpuff). The CS-US interval was 500 ms. Rabbits were restrained and adapted to classical conditioning equipment (San Diego Instruments) for a period of 3 consecutive days (15 min. on day 1, 30 min. on day 2 and 60 min. on day 3). Baseline data were collected without stimulation on day 3. A total of 60 trials/day were determined over the 8-day treatment period. Mean conditioned responses on day 8, when learning should be present, were 31.1% and 58.6%, 15.5% and 16.0% and 48.8% and 79.1% for male and female rabbits in the S, SC and A groups, respectively. In each group, female rabbits learned more rapidly than male rabbits. As compared with the S group, SC-treated rabbits had impaired learning, possibly associated with undetected sedation due to central cholinergic effects. A-treated rabbits learned faster and remembered better than S-group rabbits, possibly as the result of a combination of associative and nonassociative learning. Thus, this classical conditioning paradigm demonstrates changes in learning and memory in rabbits and can serve as a behavioral test in this species for safety evaluations.

611 EVALUATION OF THYROID FUNCTION USING SERUM T3, T4 AND TSH LEVELS (OBTAINED BY USING RIA KITS) IN CRL IGS MATERNAL, FETAL AND NEONATAL RATS.

E. M. Lewis, N. Trenton, A. M. Hoberman and M. S. Christian. *Argus Research - A CRL-DDS Division, Horsham, PA.*

Early neonatal hypothyroidism affects development of the brain and reproductive organs. EPA has recommended inclusion of thyroid hormone evaluations (T3, T4 and TSH serum levels and histopathology) in multigeneration and developmental neurotoxicology studies. Such endpoints have been minimally studied in neonatal rodent of commonly used strains. To identify time-dependent and/or sex-related differences in serum T3, T4 or TSH levels in maternal, fetal and neonatal rodents, control data were compiled from studies in which CRL IGS Sprague-Dawley rats were used. All values were obtained from serum, using RIA kits. Maternal values are for individuals. Fetal and pup values are for sera pooled by litter, except for LDs 21/22 values, which are for individual male and female weanling rats. Values are tabulated below. These findings show that RIA kits can be used to determine serum levels of T3, T4 and TSH in maternal and fetal, neonatal and juvenile rats and provide a relatively consistent, sensitive and appropriate means for detecting functional changes in the thyroid in rodents.

Serum Levels			
	T3 (ng/dL)	T4 (ug/dL)	TSH (ng/mL)
Dams			
GD21	99.7 (5)	2.31 (16)	5.05 (16)
LD 1	79.0 (5), 99.4 (16)	3.05 (5), 2.03 (16)	4.98 (5), 5.07 (16)
LD 21	57.8 (30), 61.5 (30)	2.03 (30), 2.22 (30)	2.05 (30), 1.62 (30)
LD 22	20.3 (15)	3.52 (15)	3.97 (15)
Pups			
GD 21	25.4 (31)	1.59 (16)	7.22 (16)
LD 5	62.1 (15)	2.08 (21)	4.86 (16)
LD 30	79.5 (16)	3.73 (16)	8.64 (16)
LD 21-22 M	105.9 (27), 106.3 (20), 91.0 (15)	2.41 (27), 3.23 (20), 3.03 (15)	1.24 (27), 0.82 (20), 0.63 (15)
LD 21-22 - F	106.0 (28), 108.2 (20), 103 (15)	2.27 (28), 3.42 (20), 3.02 (15)	1.24 (28), 0.94 (20), 0.26 (15)

612 LOW DOSE PERINATAL VINCLOZOLIN EXPOSURE IN THE LE RAT ALTERS *EX COPULA* PENILE ERECTIONS AND REDUCES PUP SIRING FOLLOWING GROUP MATING.

N. C. Pelletier, A. J. Tarr and V. P. Markowski. *Psychology, University of Southern Maine, Portland, ME.*

Vinclozolin is a dicarboximide fungicide applied to industrial park landscapes, golf turf, and numerous crops intended for human consumption. Health concerns have arisen because metabolites of this compound have been shown to bind to the rat, monkey, and human androgen receptor. Following perinatal exposure, vinclozolin permanently disrupts sex-specific development as indicated by significantly reduced male rat reproductive organ weights. Unfortunately, little is known about the functional implications of reduced organ weights measured post mortem. To fill this void, two androgen-mediated reproductive endpoints were examined in exposed male rat offspring. Pregnant Long-Evans rats were administered 0.0, 0.75, 1.5, 3.0, or 6.0 mg/kg vinclozolin p.o. from gestation day 14 to postnatal day 3. Endpoints following parturition such as pups per litter, sex ratio, gestational length, mortality, or body weights throughout the preweaning period were not affected. There was a dose-related increase in the number of male pups with visible areolas on postnatal day 12. Vinclozolin reduced the frequency of reflexive penile erections but not penile movements in adult males in a dose-related fashion during ex copula tests. Low intensity erections, characterized by distension of the glans and tumescence of the base, were the most sensitive to exposure. Exposure also reduced the ability of males to deliver sperm and sire offspring during five consecutive days of naturalistic group mating where an experimental male interacted with three free-cycling females and an unexposed competitor male. Exposed males were less likely than controls to initiate copulation, perhaps due to a lowered social status, impaired control of the penis, or a combination of both factors.

613 NEONATAL PBDE 99 EXPOSURE CAUSES DOSE-RESPONSE RELATED BEHAVIOURAL DERANGEMENTS THAT ARE NOT SEX OR STRAIN SPECIFIC IN MICE.

H. Viberg, A. Fredriksson and P. Eriksson. *Department Environmental Toxicology, Uppsala University, Uppsala, Sweden.*

Flame-retardants are used to suppress or inhibit combustion processes in order to reduce the risk of fire. One class of flame-retardants, polybrominated diphenyl ethers (PBDEs), have been found to increase in the environment and in human mother's milk. In recent studies we have seen that neonatal exposure to some brominated flame-retardants, such as PBDE 47, PBDE 99, PBDE 153 and PBDE 209, can cause permanent aberrations in spontaneous behaviour in male NMRI mice, an effect that worsen with age, and affect the cholinergic system. The present study was undertaken to investigate whether these behavioural defects are sex dependent and/or strain dependent. Male and female C57 Bl/J mice were exposed to 0.4, 0.8, 4.0, 8.0, or 16.0 mg PBDE 99/kg b.wt., as one single oral dose, on postnatal day 10. Spontaneous behaviour was observed in both male and female mice at the age of 2, 5, and 8 months. Male mice exposed to 0.8, 4.0, 8.0, or 16.0 mg PBDE 99/kg b.wt. on postnatal day 10 showed significantly impaired spontaneous motor behaviour at all three testing occasions. This effect was dose-response related and the deranged behaviour worsened with age. Female mice exposed to 0.8, 4.0, 8.0, or 16.0 mg PBDE 99/kg b.wt. on postnatal day 10 showed significantly impaired spontaneous motor behaviour at all three testing occasions. This effect was dose-response related and the deranged behaviour worsened with age. In conclusion, neonatal exposure to PBDE 99 induces behavioural derangements in adult C57 Bl/J mice of both sexes, an effect that is dose-response dependent and seem to worsen with age. PBDE 99 causes similar developmental neurotoxic effects in both C57 Bl/J and NMRI male mice.

614 PRENATAL LEAD (Pb) EXPOSURE AND SCHIZOPHRENIA: PRELIMINARY FINDINGS.

M. G. Opler[4,1], W. Zheng[1], A. Brown[4,2], M. Desai[3], P. Factor-Litvak[2], J. Graziano[1], M. Bresnahan[2] and E. Susser[2,4]. *[1]Environmental Health Sciences, Columbia University, New York, NY, [2]Epidemiology, Columbia University, New York, NY, [3]Biostatistics, Columbia University, New York, NY and [4]Psychiatry, Columbia University, New York, NY.*

Schizophrenia, a mental disorder with unknown etiology affecting more than 2 million Americans, is characterized by hallucinations, delusions, social withdrawal, and disorganized thinking. Prior studies suggest that environmental disruptions in prenatal development may be risk factors. A cohort established for the study of maternal and child health in Oakland, CA, enrolled 19, 044 live births between 1959 and 1966. Maternal serum samples were collected throughout pregnancy, and stored at -20°C. Potential cases of schizophrenia spectrum disorders (SSD) were identified from inpatient hospital records within a computerized database. Potential cases were diagnosed following a clinical interview or by chart review. A group of 71 SSD cases were identified. Matched controls were selected on the basis of gender, number of available sera samples, date of birth, and timing of membership and blood draw. Serum δ-aminolevulinic acid, a biological marker of Pb exposure, was measured in 2nd trimester samples of 44 cases and 75 controls using HPLC. The data was converted into exposure categories of high maternal blood lead (>15 μg/dL) and low maternal blood lead (<15 μg/dL). The odds of SSD given exposure, when measured using conditional logistic regression, gives an estimated odds ratio (OR)=1.83 (95% CI: 0.87-3.87, p=0.1.) A random effects model, adjusted for gravida's age at termination of pregnancy gives similar results, with an OR=1.7 (95% CI: 0.93-3.10, p=0.08). This finding suggests that prenatal Pb exposure may be associated with adult psychotic disorders.

615 INTERACTIONS OF PRE/POSTNATAL LEAD (Pb) EXPOSURE AND MATERNAL STRESS.

D. A. Cory-Slechta, M. R. Bauter, M. B. Virgolini and M. J. Thiruchelvam. *Environmental Medicine, University of Rochester Medical School, Rochester, NY.*

Children that continue to sustain the highest levels of Pb exposure in the US are also those that are socioeconomically disadvantaged and medically underserved, adding to the list of risk factors that hinder them from the ability to achieve their maximal potential. Pb could be predicted to interact significantly with such life stresses: both Pb and stress, for example, activate brain mesolimbic dopamine (DA) systems. Yet, current understanding of Pb largely reflects its study in isolation. The interaction of maternal stress with Pb exposure was studied here. Dams exposed to 0 or 150 ppm Pb (mean blood Pb= 38 ug/dl) in drinking water for 3 months prior to breeding and throughout lactation were subjected to 45 min restraint stress 3 times/day on gestational days 16-17. Both Pb and stress increased corticosterone levels measured after the final restraint stress on day 16 in dams, with highest levels produced by Pb+stress. Behavioral effects in male offspring (control, control/stress, Pb, Pb/stress) were examined on a fixed interval (FI) reinforcement schedule previously found sensitive to Pb and mediated by mesolimbic DA. Maternal stress alone (control/stress) had no evident effects on FI performance across 9 weeks of testing. Pre/postnatal Pb exposure (Pb group) produced sustained decreases (35%) in FI response rates that were modulated by maternal stress (Pb/stress), which increased FI rates back to levels equivalent to controls. A restraint stress imposed prior to FI testing in week 9 suppressed FI response rates in all groups. These reductions were attenuated by maternal stress (control/stress) and by Pb exposure (Pb group). Maternal stress modulated challenge restraint stress effects of Pb, decreasing FI rates (Pb/stress) relative to those produced by Pb alone. These findings support the assertion that the behavioral toxicity associated with developmental Pb exposure can be modulated by its interactions with environmental stress, and that stress responses to environmental challenges can be modulated by Pb exposure. ES05017, ES05903 and ES01247.

616 DEVELOPMENTAL EFFECTS OF MATERNAL EXPOSURE TO NICOTINE AND CHLORPYRIFOS, ALONE AND IN COMBINATION IN RATS.

M. B. Abou-Donia, A. M. Dechkovskia, X. Guan, A. A. Abdel-Rahman, L. B. Goldstein, S. L. Bullman and W. A. Khan. *Pharmacology and Cancer Biology, Duke University Medical Center, Durham, NC.*

In the present study, we evaluated the neurotoxic effects in offspring following maternal exposure with low doses of nicotine and chlorpyrifos. Pregnant rats (300-350 g) were treated daily with nicotine (1 mg/kg, s.c., in normal saline) and/or chlorpyrifos (0.1 mg/kg, dermal, in ethanol) for the gestational days 5-20. Male offspring from the mothers treated with nicotine alone gained significantly lower weight on PND 30 as compared with the control. On PND 7, there was a significant increase in the brain acetylcholinesterase (AChE) activity in the pups from nicotine and chlorpyrifos groups, whereas plasma butyrylcholinesterase (BChE) activity showed a significant increase (~167 and 176% of control) in the pups from chlorpyrifos alone or in combination with nicotine, respectively. There was no change in the ligand binding for muscarinic acetylcholine receptors. On PND 30 male pups showed a significant increase in the AChE activity in the brainstem (~134-148% of control) and cerebellum (~299-345% of control) in all the treated groups. PND 30 females showed a significant increase in the AChE activity in the brainstem of chlorpyrifos alone group and in the cerebellum of the pups from the combination of nicotine and chlorpyrifos. A significant increase in the immunostaining for glial fibrillary acidic protein was observed in the cortex, the CA1 and CA3 subfields of hippocampus, and dentate gyrus on PND 30 in the pups from nicotine and chlorpyrifos treated mothers. These data suggest that maternal exposure during the entire gestational period to low doses of nicotine and chlorpyrifos, in combination, may lead to neuropathological changes in different brain regions. Supported, in part by an EPA grant # R829399-01-0.

617 MULTIGENERATIONAL IN-LIFE DATA IDENTIFY TARGET ORGANS/SYSTEMS OF RATS EXPOSED TO CHLORDANE AT ENVIRONMENTAL LEVELS.

B. C. Datiri, V. V. St. Omer, M. M. Mansour, E. O. Abdalla and S. Lettsome. *Biomedical Sciences, Tuskegee University, Tuskegee, AL.* Sponsor: R. Dalvi.

Technical grade chlordane (TGC), a pesticide mixture of four main isomers (heptachlor, cis-chlordane, trans-chlordane, and trans-nonachlor), banned in 1988 is still persistent in the environment. Target organs/systems for long-term exposure of TGC at environmental levels used in this study are unknown in humans and other mammals. Sprague-Dawley rats (F0, F1 F2) were exposed to continuous levels of TGC at 0.0, 0.125, 0.25 and 1.0 mg/kg body weight/day by oral gavage and reproductive, developmental and neurobehavioral endpoints were used to identify in-life target organs/systems of TGC toxicity. TGC increased ($P<0.05$) F1 males and females pre-mating body weight at 0.25 and 1.0, and feed intake at 0.25 mg/kg. TGC increased F1 live male/female sex ratio; male anogenital distance at 0.125 & 0.25 mg/kg for F1 and 0.25 &1.0 mg/kg for F2, and pre-weaned body weight of F2 females on PND7 and PND21. TGC at 0.25 mg/kg advanced eye opening, incisor eruption, and preputial separation in F2 rats. Also, at 1.0 mg/kg incisor eruption was advanced in of F2 rats. Surface righting increased at 0.25 mg/kg for F2 females on PND3. TGC delayed negative geotaxis in F1 males at 0.125 on PND7 and 1.0 on PND8-9; F1 females at 0.125, 0.25 and 1.0 mg/kg on PND8; and F2 females at 0.125 on PND11. Percent success in olfactory discrimination was reduced at 0.125 mg/kg for F1 females on PND9. Data identified the reproductive system, developing neonates and the CNS as in-life targets for oral TGC exposure levels in this study. (Supported by MHPF/ATSDR - #U50/ATU398948)

618 *IN VIVO* ETHANOL DECREASES PHOSPHORYLATED MAPK AND P70S6 KINASE IN THE DEVELOPING RAT BRAIN.

R. Tsuji[1,2], M. Guizzetti[1] and L. G. Costa[1,3]. *[1]Environmental Health, University of Washington, Seattle, WA, [2]Environmental Health Science Laboratory, Sumitomo Chemical, Osaka, Osaka, Japan and [3]Pharmacology and Physiology, University of Roma La Sapienza, Roma, Roma, Italy.*

Exposure to ethanol during pregnancy is detrimental to fetal development, and individuals affected by the Fetal Alcohol Syndrome present a number of central nervous system dysfunctions including microencephaly and mental retardation. Recently, it has been suggested that ethanol-induced inhibition of glial cell proliferation may be relevant in the causation of microencephaly. In this study, we measured the developmental changes of MAPK(ERK1/2) and p70S6 kinase, which are considered to play a prominent role in cell proliferation, and their phosphorylated proteins in brain, and examined the effects of *in vivo* ethanol administration. MAPK and phospho-MAPK increased gradually after birth, and reached adult levels on postnatal day 21. In contrast, levels of both p70S6 kinase and phospho-p70S6 kinase decreased after birth. Exposure to ethanol (2-6 g/kg, from postnatal day 4 to 7) had no effects on MAPK or p70S6 kinase levels, but caused a dose-dependent decrease of both phospho-proteins. These results suggest that phosphorylation of MAPK and p70S6 kinase may represent relevant targets for the developmental neurotoxicity of ethanol, and may involved in microencephaly.

619 EFFECTS OF REPEATED DEVELOPMENTAL EXPOSURE TO CHLORPYIFOS AND METHYL PARATHION ON CHOLINE ACETYLTRANSFERASE AND MUSCARINIC RECEPTORS IN RATS.

C. A. Moore, J. Baravik, E. C. Meek, J. R. Richardson, R. L. Carr and J. E. Chambers. *Center for Environmental Health Sciences, Mississippi State University, Mississippi State, MS.*

The effects of early post-natal oral exposures to two organophosphorus insecticides on cholinergic parameters in whole brain and brain regions were investigated. Chlorpyrifos, a diethyl phosphorothionate, and methyl parathion, a dimethyl phosphorothionate, were studied. Incremental daily exposure regimens were used from post-natal day (PND)1 to 21: chlorpyrifos, low dosage, 1 mg/kg PND 1-21; medium dosage, 1 mg/kg PND 1-7, 2 mg/kg PND 8-14, 4 mg/kg, PND 5-21; high dosage, 1.5 mg/kg PND 1-7, 3 mg/kg PND 8-14, 6 mg/kg PND 8-14; methyl parathion, low dosage, 0.2 mg/kg PND 1-21; medium dosage, 0.2 mg/kg PND 1-7, 0.4 mg/kg PND 8-14, 0.6 mg/kg PND 15-21; high dosage, 0.3 mg/kg PND 1-7, 0.6 mg/kg PND 8-14, 0.9 mg/kg PND 15-21. Cholinesterase (ChE) activity was measured in freshly thawed and ground tissue with a 5-minute continuous assay because of the rapid reactivation of the dimethyl phosphorylated ChE. During the time of treatment, animals from the high dosages displayed about 60% brain ChE inhibition, about 50% for the medium dosage, and about 20% for the low dosage. Muscarinic receptor densities, as monitored with 3H-quinuclidinyl benzilate, were reduced about 20% during the times of greatest ChE inhibition in the whole brain preparations, with M1/M3 receptor levels [monitored with 3H-4-diphenylacetoxy-N-(2-chloroethyl) piperidine] affected more greatly than M2/M4 receptor levels (monitored with 3H-AF-DX-384); receptor densities were the same as controls after the cessation of treatment. Choline acetyltransferase activity, monitored radiometrically, showed a slight decrease after the cessation of treatment at PND 30. The minor reductions in choline acetyltransferase activity observed at PND 30 were not observed in brain regions at PND 40. The changes in receptors and enzyme activities observed during development did not appear to be permanent alterations of brain neurochemistry. (Supported by NIH R01 ES 10386).

620 BRAIN β1 INTEGRIN PROTEIN EXPRESSION IN RAT PUPS EXPOSED TO MONOMETHYLTIN (MMT).

H. N. Owen, V. C. Moser and J. E. Royland. *Neurotoxicology Division, US Environmental Protection Agency, Research Triangle Park, NC.*

Integrins are cell adhesion proteins composed of α and β protein subunits. These heterodimeric transmembrane proteins have been shown to be important in a number of critical functions during brain development, including cell migration, axonal elongation and myelination. As such they have the potential to act as markers of effect for developmental neurotoxicants. MMT is one of a family of organotins used as stabilizers in plastics' manufacture. Evidence exists that these compounds leach into drinking water from PVC and CPVC pipes and potentially represent a health risk. Cognitive deficits have been reported in rat pups exposed during gestation and early postnatal development to MMT (12-120 mg/L) in drinking water in an early study by Noland, et al. (1982). However, no NOEL (no-observable effect level) was reported and these data have not been reproduced. This study seeks to confirm and expand the findings of the Nolan study. Long-Evans rat dams were exposed to 0, 10, 50 or 245 mg MMT/liter in drinking water from 2 weeks prior to mating to pup weaning at 21 days postpartum. On postnatal day 22 rat pups were weighed, anesthetized, and brains removed, weighed and different brain areas dissected. Tissues were extracted for total protein and Western analysis carried out for β1 integrin subunit. No differences were found in any dosing group in body or brain weights. A non-significant decrease (15-20%) was seen in β1 integrin subunit protein expression in the hippocampus and cerebellum at the two higher doses with no difference in the frontal cortex. This abstract does not necessarily reflect USEPA policy.

621 DEVELOPMENTAL EXPRESSION, PHOSPHORYLATION AND BINDING ACTIVITY OF CREB IN LEAD EXPOSED RAT BRAIN.

C. D. Toscano and T. R. Guilarte. *Environmental Health Sciences, Johns Hopkins Bloomberg School of Public Health, Baltimore, MD.*

Developmental lead exposure results in learning and memory deficits in children. The NMDA receptor is a molecular target for lead effects and its activation is essential for the transcription of genes important for learning and memory. A crucial

nuclear protein involved in this process is the cyclic-AMP response element binding protein (CREB) which is phosphorylated by calcium-sensitive kinases and initiates transcription by binding to the cyclic AMP response element (CRE) in the promoter region of target genes. We recently reported that adult rats exposed to lead during development express altered CREB phosphorylation (Toscano et al, Toxicology Sciences 60 (1), 187, 2001). In the current study, developing rats exposed to lead were used to assess CREB expression, phosphorylation and binding activity in cortical and hippocampal nuclear extracts at postnatal (PN) day 7, 14, 21 and 50. Further, we developed a novel filter binding assay that provides a quantitative measure of the interaction of CREB in nuclear extracts with a CRE containing oligonucleotide. In control rats, CREB and phospho-CREB (pCREB) expression is highest at PN7 and decreases steadily until PN 50. Developmental lead exposure does not affect total CREB levels in either the cortex or hippocampus but decreases pCREB levels at PN14 and 50 in the cortex and at PN50 in the hippocampus. Electrophoretic mobility shift assay (EMSA) demonstrates a decrease in CREB binding activity in the hippocampus at PN 7 and 14 and an increase at PN50. No changes in CREB binding activity were observed in the cortex at PN7, 14 or 21 but binding was decreased at PN50. Our novel filter binding assay will allow us to further characterize the EMSA results by allowing quantification of Bmax and Kd for the CREB-CRE interaction. These disruptions in pCREB expression and binding activity during the ontogeny of the rat brain begin to decipher the effects of lead downstream from the NMDA receptor. [Supported by grant #ES06189 to TRG]

622 ACUTE ETHANOL EXPOSURE INCREASES CATALASE ACTIVITY, BUT DOES NOT ALTER GLUTATHIONE LEVELS IN POSTNATAL DAY 4 RAT PUPS.

K. H. Horn[1], L. M. Kamendulis[2], C. R. Goodlett[1,3] and J. E. Klaunig[1,2]. *[1]Program in Medical Neurobiology, Indiana University School of Medicine, Indianapolis, IN, [2]Pharmacology and Toxicology, Indiana University School of Medicine, Indianapolis, IN and [3]Psychology, Indiana University School of Medicine, Indianapolis, IN.*

Rats exposed to ethanol show selective cerebellar cell loss when the exposure occurs during postnatal days 4-6 (PD4-6), an effect not seen in other brain regions during this developmental period. While the exact mechanisms underlying vulnerability to ethanol-induced cell loss are unknown, evidence suggests that oxidative stress may play a role in ethanol pathogenesis. Recent work has shown that vitamin E supplementation provides protection against ethanol toxicity. In addition, studies measuring endogenous antioxidant levels following *in utero* ethanol exposure indicate significant ethanol-induced alterations in glutathione, superoxide dismutase, catalase, and vitamin E levels. The purpose of the current study was to investigate ethanol's effects on antioxidant levels following a single day of ethanol exposure during a period of development known to be vulnerable to ethanol-induced cerebellar cell death. PD4 Long Evans rat pups were matched for sex and rats within each pair received either sham intubations or 5.25g/kg ethanol (11.9% (v/v) solution in milk formula) in 2 intubations, 2 hrs apart. At 0, 4, 6, and 12 hrs after the initial intubation, the cerebellum, hippocampus, cortex, and liver were collected and assayed for either reduced glutathione levels or catalase activity (only cerebellum and hippocampus). Ethanol treatment resulted in a linear increase in catalase activity over time in the cerebellum [$F(1, 13)=9.506$, $p<0.01$] and the hippocampus [$F(1, 13)=6.010$, $p<0.05$]. Cerebellar catalase activity at 12 hrs was significantly higher in the ethanol group than the sham group ($t(3)=3.593$, $p<0.05$). In contrast, acute ethanol exposure on PD4 had no effects on glutathione levels. While these data do not rule out other mechanisms for cell loss, they do suggest a role for oxidative stress in ethanol-induced cerebellar cell death.

623 SUCCIMER CHELATION SIGNIFICANTLY AMELIORATES THE LASTING COGNITIVE AND AFFECTIVE DYSFUNCTION PRODUCED BY EARLY LEAD EXPOSURE IN A RODENT MODEL.

D. Stangle[1], M. Strawderman[1], D. Smith[2] and B. J. Strupp[1]. *[1]Cornell University, Ithaca, NY and [2]University of California, Santa Cruz, CA.*

Early lead exposure has been shown to cause changes in cognitive and affective functioning that last long past the period of exposure. The present study was designed to assess the efficacy of succimer chelation in alleviating these lasting areas of dysfunction. A 2 X 3 factorial design was used, including three levels of lead exposure (no lead, low lead, high lead) and two succimer conditions (succimer or placebo). Lead exposure was started at birth and continued until postnatal day 30. Succimer chelation was initiated immediately thereafter and lasted for 21 days. In adulthood, 120 rats (20 per group) were tested on a battery of tasks, designed to tap various aspects of cognition and emotional reactivity. First, early lead exposure produced lasting cognitive and affective changes that varied with the intensity of lead exposure. Specifically, both lead exposure groups showed deficits on learning, whereas rats in the higher exposure group showed additional dysfunction in attentional function and reactivity to committing an error on the previous trial. Second, succimer treatment prevented some, but not all, of these lead-induced alterations. Specifically, succimer ameliorated dysfunction in associative function and reactivity to errors in both groups, but to a greater extent in the lower exposure group. In contrast, succimer did not significantly ameliorate the attentional dysfunction seen in the higher exposure group. Finally, this study provided evidence that succimer treatment alone, in the absence of lead exposure, is not benign. Rats exposed to succimer, but not lead, showed deficits in learning and attention. These findings provide encouragement for the clinical use of succimer in ameliorating lead-induced cognitive and affective deficits, but urge caution in the widespread use of the drug in the absence of lead exposure or at very low levels of exposure. Supported by NIEHS grants ES07457, ES05950 & DK07158-27.

624 INFLUENCE OF CAGE DESIGN ON MEASUREMENT OF MOTOR ACTIVITY IN PRE-WEANLING RAT PUPS.

L. A. Malley, N. P. Betts, P. Mukerji and R. M. Parker. *DuPont Haskell Laboratory for Health and Environmental Science, Newark, DE.*

The purpose of this investigation was to optimize cage design for the detection of motor activity in pre-weanling rat pups. Motor activity was measured in pups on postnatal days 13, 17, and 21 in one of 4 cage types using a Coulbourn®automated motor activity system. Ten male and 10 female rat pups were treated with the vehicle, 80 mg/kg carbaryl, or 2 mg/kg amphetamine approximately 30 min prior to motor activity measurement. All 4 cages were stainless steel wire mesh. The 4 cage types were: 1)the standard adult cage (16" x 10" x 6") with the infrared sensor positioned 3" above the cage floor; 2)the adult cage with the infrared sensor in a lower position (located 0.5" above the cage floor); 3)a modified adult cage containing a semicircular insert in the rear of the cage and a semicircular insert in front of the infrared sensor (located 0.5" above te cage floor); and 4)a mouse cage (4" x 7" x 5") with the sensor 0.5" above the cage floor. Cage size, shape, and sensor height affected the total motor activity data (duration of movement and number of movements). Carbaryl decreased motor activity in day 13, 17, and day 21 pups. Increased motor activity was observed in day 21 pups treated with amphetamine; however, motor activity in day 13 and 17 pups was decreased or unchanged by amphetamine. The mouse cage provided the best results for day 13 and 17 pups, and the standard cage with the sensor in a lower position provided the best results for day 21 pups.

625 MATERNAL AND FETAL ACETYLCHOLINESTERASE ACTIVITIES AFTER REPEATED DERMAL EXPOSURE OF PREGNANT RATS TO METHYL PARATHION.

R. C. Baker, K. E. Schneider, S. E. Wellman and R. E. Kramer. *Pharmacology and Toxicology, University Mississippi Medical Center, Jackson, MS.* Sponsor: I. Ho.

It is unclear if exposure to organophosphates such as methyl parathion during pregnancy affects cholinergic activity in the fetus and neonate. Methyl parathion has been noted to cross the placenta after oral or IP administration and, in some cases, was associated with physical anomalies in the fetus. Since dermal exposure can cause more prolonged toxicity, it is interesting that after a single dermal administration of radiolabeled methyl parathion to pregnant rats, radioactivity was detected in the fetus within 2 h and disappeared with a half-life of 22 h. One aim of the present studies was to determine if repeated dermal exposure of pregnant rats to methyl parathion adversely affects the fetus. Dames were treated dermally with methyl parathion (1 or 2 mg/kg/day) beginning on gestation day 3-5 and ending on gestation day 18-19. Acetylcholinesterase activities in maternal blood and cerebral cortex, placenta, and fetal cerebral cortex were assayed as indices of toxicity. Administration of methyl parathion caused dose-dependent increases in blood concentrations in the dame (16.1±6.6 and 98.5±11.1 ng/ml; mean±SE) that were associated, respectively, with 25 % and 60% decreases in blood (control = 31.1±4.1 nmol/10 min/mg Hb) and cortical cholinesterase (control = 87.6±7.1 nmol/min/mg prot) activities. Placental cholinesterase activity was not affected at the lower dose of methyl parathion, but was decreased 30 % by 2 mg/kg/day. However, neither dose affected cholinesterase activity in the cerebral cortex of the fetus. Also, neither methyl parathion or its active metabolite, methyl paraoxon, were detected in the fetus. These data indicate that the placenta can protect the fetus from toxicity resulting from repeated low-level dermal exposure (1-2 % of the dermal LD50) to methyl parathion and perhaps other organophosphorus agents. The contributions of placental acetylcholinesterase and placental metabolism to the inactivation of methyl parathion or methyl paraoxon remain to be defined. (CDC Grant R06/CCR419466).

626 ASSESSING NEURODEVELOPMENTAL EFFECTS OF ENVIRONMENTAL EXPOSURES TO ANTI-THYROID AGENTS: HOW RELEVANT ARE HIGH DOSE RAT STUDIES?

R. C. Pleus, G. M. Bruce and M. K. Peterson. *Intertox, Inc., Seattle, WA.*

Substantial interest has arisen regarding the possibility of neurodevelopmental effects following low-level environmental exposures to chemicals that can have antithyroid effects. In studies of rats, maternal exposure to agents that cause severe hy-

pothyroidism, including propylthiouracil (PTU) and methimazole (MMI), has produced a range of biochemical, neurodevelopmental, and neurobehavioral outcomes in offspring. However, debate continues about the threshold at which these effects occur, the relevance of these studies to low dose environmental exposures, and in turn, the biological significance of small differences in these measures when seen at environmentally-relevant doses. We present a review of the published literature on biochemical/molecular, behavioral, and morphological endpoints in rat offspring *in vivo* when dams are treated through pregnancy with known anti-thyroid agents. Our findings reveal: the preponderance of studies have examined animals induced with severe hypothyroidism (*e.g.*, thryoxine [T_4] levels of 50% or more below control values); timing of exposure and age of testing significantly impact reported results; the most sensitive behavioral events appear to be auditory effects; at high doses an apparent morphological effect is a decrease in migration of external granule cells to the internal granular layer of the brain; and the few relatively lower dose studies suggest effect thresholds consistent with at least moderate or more significant hypothyroidism. Interpretative problems in assessing hazards associated with environmental exposures arise when small differences in these measures are reported at very low environmental doses and/or corresponding to small or transient changes in thyroid hormone or thyroid stimulating hormone (TSH) levels.

627 A ZEBRAFISH MODEL FOR STUDYING THE NEUROBEHAVIORAL IMPACTS OF DEVELOPMENTAL CHLORPYRIFOS EXPOSURE.

H. Swain[1], S. Donerly[2], E. Chrysanthis[1], K. Yacsin[2], E. Linney[2] and E. D. Levin[1].
[1]Department of Psychiatry and Behavioral Sciences, Duke University Med. Ctr, Durham, NC and [2]Department of Molecular Genetics and Microbiology, Duke University Med. Ctr, Durham, NC.

Chlorpyrifos is a widely used insecticide, which interferes with neurobehavioral development. Rat models have been key in demonstrating that prenatal chlorpyrifos exposure causes learning deficits and motor alterations, which persist into adulthood. Complementary non-mammalian models can be useful in determining the molecular mechanisms underlying these persisting behavioral effects. Zebrafish with their clear chorion and extensive developmental information base provide an excellent model for assessment of molecular processes of toxicant-impacted neurodevelopment. We have developed methods for assessing spatial discrimination learning in zebrafish, which can differentiate response latency from choice accuracy in a three chambered fish tank. Low and high doses of chlorpyrifos (10 and 100 ng/ml) were administered to zebrafish embryos on days 1-5 post-fertilization. The 100 ng/ml dose caused significant short-term slowing of swimming activity on days 6 and 9 post-fertilization and had persisting effects of impairing spatial discrimination and decreasing response latency in adulthood. The 100 ng/ml dose (1-5 days post-fertilization) also significantly accelerated mortality rates of the fish during the adult study from 20-38 weeks of age. Developmental exposure to 10 ng/ml of chlorpyrifos did not cause a significant change in locomotor activity during the period soon after hatching but did cause a significant slowing of response in adulthood. This dose also caused a significant learning impairment in adulthood, but did not cause increased mortality. Chlorpyrifos exposure during early development caused clear behavioral impairments, which lasted throughout adulthood in zebrafish. The molecular mechanisms by which early developmental chlorpyrifos exposure produces these behavioral impairments expressed in adulthood can now be studied in the zebrafish model. This research was supported by NIH grants #ES10387, ES10356 and ES9808.

628 THE MORRIS MAZE AS A TEST OF LEARNING AND MEMORY IN RATS - A CASE STUDY DEMONSTRATING THE VALUE OF RE-TESTING THE SAME SET OF ANIMALS.

D. P. Myers, S. D. Renaut and M. J. Collier. *Huntingdon Life Sciences, Huntingdon, Cambridgeshire, United Kingdom.* Sponsor: E. Blanchard.

Female Han Wistar rats derived from mothers treated with a novel pharmaceutical or vehicle control were tested in the Morris water maze at Day 31±1 of age, as part of the requirement for functional testing of selected F1 animals on a study of pre- and post-natal development. The animals were placed individually in the maze which contained an escape platform at a fixed point in the circular pool. The platform was concealed below the surface of the water which had been made opaque using Opacifier 621. Each animal received 3 trials on each of 4 consecutive days of testing using standard methods. All groups of animals showed a consistent improvement in mean trial times and sector entries, but the performance of animals derived from parent females treated at 10 or 50 mg/kg/day was somewhat inferior to that of controls. Although performance was similar in all groups on Day 1 of testing, trial times and sector entries for offspring derived from treated parent females were greater than in controls on Days 2, 3 and 4. The same animals were re-tested, using identical test procedures, 18±1 day after Day 1 of the original test. Animals in all groups showed excellent recall of the first test, with performance on the first day being similar to that on the 3rd or 4th day of the first test. In addition, all groups of animals continued to show further improvements in performance over the 4 days of testing on the second occasion. The re-test demonstrated that animals derived from treated parent females had learnt the position of the escape platform by Day 4 of the original test and that they were able to recall this information on Day 1 of the second test (a useful measure of long-term memory). In conclusion, the results demonstrate the value of re-testing animals in the Morris maze subsequent to some deficits in performance being detected on a previous occasion.

629 ESTABLISHMENT AND PERSPECTIVES OF AN AGING PRIMATE COLONY FOR THE STUDY OF GERIATRIC DISEASES.

R. Korte[1], M. Stanley[2], E. Buse[1], W. Mueller[1], F. Vogel[1] and G. F. Weinbauer[1].
[1]Covance Laboratories GmbH, Muenster, Germany and [2]Bioculture Mauritius Ltd, Senneville Riviere des Anguilles, Mauritius. Sponsor: P. Thomas.

According to a recent review, life expectancy of women is predicted to reach 100 years by 2050 (1) and the proportion of people older than 60 years is estimated to exceed 20% of the population by 2050. Inevitably, the prevalence of age-related diseases and deficiencies will gain further significance and the health status of the aged will have a great bearing on society and economy. This also presents a real challenge to industry for developing sufficient and appropriate medications for the elderly and the aged population. For the successful development of new therapies for geriatric diseases, relevant animal models will be of vital importance. The aim of the present work was to assemble a colony of aged nonhuman primates and to initiate a screening program for the prevalence of selected age-related diseases. Mauritian male and female cynomolgus monkeys (Macaca fascicularis) were retained as retired breeders (> 13 years old) from a breeding colony. Among 222 animals screened for fasted blood sugar levels, 16 females but no males had levels in the diabetic range. Among 56 females, 22 had blood estradiol levels clearly below normal or in the range of ovariectomized animals. Fundus examination of 50 animals for ocular pathology revealed abnormal findings in 37 animals. Screening for prostate-specific antigen in 56 males did not yield evidence for prostate pathology. In the cerebrospinal fluid of very old animals a clear increase of amyloid-beta-42 was detected. The screening program is still ongoing but our initial findings already suggest that aging cynomolgus monkeys can be used to develop models for spontaneous osteoporosis, diabetes and ocular disease and potentially also for Alzheimer disease. 1. Oeppen J, Vaupel JW (2002) Science 296 :1029-1031

630 COMPARISON OF DUAL-ENERGY X-RAY ABSORPTIOMETRY AND PERIPHERAL QUANTITATIVE COMPUTED TOMOGRAPHY FOR BONE MINERAL DENSITY ANALYSIS IN THE CYNOMOLGUS MONKEY.

M. Niehoff, S. Mohr and G. F. Weinbauer. *Covance Laboratories GmbH, Muenster, Germany.* Sponsor: P. Thomas.

Bone density is a pivotal parameter utilized to monitor the effectiveness of osteoporosis therapeutics as well as the side effects of other pharmaceutical compounds. Dual-energy X-ray absorptiometry (DXA) is the standard technique for measuring bone mineral density (BMD). Peripheral quantitative computed tomography (pQCT) is a more recent development that allows separate determination of cortical and trabecular BMD in the peripheral skeleton. Controversies exists which technique, DXA or pQCT, might be preferable in future, and whether separate analysis of trabecular and cortical bone by pQCT will permit earlier detection of BMD changes than DXA technology. The purpose of this study was to compare both techniques by measuring BMD using pQCT and DXA in intact and castrated male and ovariectomized female cynomolgus monkeys (Macaca fascicularis), a frequently used primate model in osteoporosis research. The results indicate that pQCT seems to be more sensitive than DXA, since pQCT measurements revealed an decrease in BMD in ovariectomized females, whereas DXA measurements did not. However, in elderly animals sites other than femoral neck should also be measured, i.e. radius and/or proximal tibia/distal femur, when pQCT measurements are performed without any DXA measurements. These comparative measurements allow the conclusion that both techniques are suitable and that, whenever possible, both techniques should be used for BMD measurements in preclinical studies to optimize results.

631 IMPACT OF BODY WEIGHT (BW) CHANGE ON THE EDSTAC TIER I MALE AND FEMALE PUBERTAL PROTOCOLS.

R. L. Cooper, T. E. Stoker, J. Ferrell, K. Leffler, K. Bremser and S. C. Laws. *RTD, NHEERL, ORD, USEPA, Research Triangle Park, NC.* Sponsor: R. Kavlock.

A primary concern with the Endocrine Disruptor Screening and Testing Committee's (EDSTAC) Tier I male and female pubertal protocol is that a nonspecific reduction in bw may potentially confound the interpretation of effects on the

endocrine endpoints of interest. To assess the relationship between bw and puberty, male and female Wistar rats were underfed to 90, 80, 70 and 60% of the ad libitum food consumption observed in controls. The females were underfed postnatal day (PND) 21-42. This regimen resulted in decreased terminal bw of 1.8, 4.1, 12.1, and 18.8% of the controls. Vaginal opening, uterine weight (wt) and thyroid hormone values were not altered in any of the underfed female groups. Although decreases in bw of 12.1 and 18.8% did significantly lower absolute ovarian wt, relative ovarian wt was not affected. Thus, there were no significant differences in any of the female reproductive endpoints measured in accordance with the female pubertal protocol. In the male, underfeeding from PND 23-53 resulted in terminal bw decreases of 2.0, 6.0, 9.0, and 19.5% of the controls. Preputial separation, epididymal or testes wts were not different from control in any of the underfed males. Although a decrease in the absolute wt of the ventral prostate and seminal vesicle was noted in those males with a 19.5% decrease in bw, the relative wts of these tissues were not different than controls. A decrease in thyroid stimulating hormone levels was observed in males with the 19.5% reduction in bw, while both T3 and T4 were significantly reduced in the males with a 9 and 19.5% reduction in bw. Importantly, there were no significant alterations of the male reproductive endpoints at less than 9.0% decreased bw. These data demonstrate that reduced bw over a range of 2-9% do not confound the reproductive endpoints in either pubertal protocols and that keeping the dose range below the MTD (defined as a 10% reduction in bw) will provide valid data concerning a compound's potential effect on these endocrine dependent events. (This abstract does not necessarily reflect EPA policy)

632 CALCIUM LIABILITY OF THE VITAMIN D ANALOG RO 65-2299 (BAL2299) IS INDEPENDENT OF THE DIETARY VITAMIN D3 INTAKE IN THE RAT.

T. Pfister[1] and H. Urwyler[2]. *[1]Preclinical Drug Safety (PRNS), F. Hoffmann-La Roche, Basel, Switzerland and [2]Toxicology, Basilea Pharmaceutica, Basel, Switzerland.* Sponsor: M. Stephan Gueldner.

Calcium-related toxicity, especially hypercalcemia, is the dose limiting factor for vitamin D (VitD) analogs in repeated dose toxicity studies. We examined whether the calcium liability of the VitD analog Ro 65-2299 in rats can be counteracted by lowering VitD supplement in the diet. In a first experiment, female rats were fed either a VitD3 free diet or a diet containing 400 IU or 800 IU VitD3/kg during a 5-day treatment period with Ro 65-2299 at 0.25 and 0.5 mg/kg/day given orally by gavage. At both doses, Ro 65-2299 caused a significant increase in urinary Ca excretion and hypercalcemia. The effect on serum Ca was dose-dependent but independent of the diet. A slightly smaller effect on urinary Ca excretion was observed in rats fed either a VitD3 reduced or a VitD3 free diet at a dose of 0.5 mg/kg/day, but not at 0.25 mg/kg/day. In a second experiment, female rats were fed a VitD3 free diet for more than 5 weeks before start of treatment. Thereafter, the feeding and treatment regimen of the first experiment was repeated but only a dose of 0.25 mg/kg/day was applied. Similar to the first experiment, there were increases in serum Ca and urinary Ca excretion without any relevant differences between rats having received different VitD3 supplements. In conclusion, lower dietary VitD3 supplement failed to counteract Ca liability of the VitD analogue Ro 65-2299. The reduction of VitD3 intake does not allow the use of higher doses of VitD analogs in repeated dose toxicity studies.

633 BROWN ADIPOSE TISSUE PROLIFERATIVE RESPONSE TO XENOBIOTICS: THE NEGLECTED ENDOCRINE TISSUE.

M. J. Iatropoulos[1], G. M. Williams[1] and J. Seng[2]. *[1]Pathology, New York Medical College, Valhalla, NY and [2]Charles River Redfield Laboratories, Redfield, AR.*

BAT controls thermogenesis in all mammalian species. Yet, BAT has not been routinely included in regulated safety assessment study protocols. Recent observations of proliferative and neoplastic changes of BAT in chronic toxicity studies have called attention to this neglected endocrine tissue. The present study is an attempt to characterize BAT responses to Phentolamine (PHEM). The finding that led to these investigations was the observation in the 24-mo. bioassay in S-D rats of hibernomas, mainly mediastinal, in males, in a comparable low incidence in all 3 dose groups. The tumor incidence was not related to dose or duration, despite the fact that there was dose-dispropor- tional high PHEM exposure in the high dose animals. The substance was negative in a 6-mo. p53-deficient heterozygous mouse model. To elucidate the pathogenesis of hibernomas, a one-year mechanistic study was conducted in younger (6 wk at start) and older rats (36 wk at start). The data obtained, including endocrine parameters, rectal temperature and PCNA, suggest that after chronic exposure in younger rats (15 mos old) and older rats (24 mos), PHEM induced sustained pharmacological effects which were reversible with 1 mo. recovery, indicating their adaptive nature. PHEM did not interfere with the rate of replication of BAT or adrenal cells. Thus, PHEM does not produce any BAT effect to lead to hibernomas. In addition, in both control and treated rats, the males have a higher UCP/Actin ratio value than females in both younger and older rats. Younger rats across all groups and genders have bigger vacuoles than older rats, and interscapular adipocytes have bigger vacuoles than either mediastinal or retroperitoneal adipocytes. Moreover, the rate of proliferation is at a steady state over time in all control groups. Thus, all these indices denote that the rate of BAT involution is very slow under normal or slightly hyperthermic conditions, and that BAT is very useful to monitor in safety assessment.

634 CYPROHEPTADINE ALTERS TRANSLATION INITIATION IN RINm5F CELLS.

B. S. Hawkins and L. J. Fischer. *Department of Pharmacology and Toxicology and Institute for Environmental Toxicology, Michigan State University, East Lansing, MI.*

The antihistaminic, antiserotonergic drug cyproheptadine (CPH) is known to inhibit insulin synthesis *in vivo* and *in vitro*. This inhibition of insulin synthesis occurs without a commensurate decrease in preproinsulin mRNA (PPImRNA) levels, suggesting a post-transcriptional mechanism of action. Using a subcellular fractionation technique followed by real-time RT-PCR, we have previously shown that a translational event, characterized by a decrease in the percentage of cellular PPImRNA associated with endoplasmic reticulum (ER) bound polysomes and increases in the percentage of translationally uninitiated PPImRNA and the percentage of PPImRNA associated with monoribosomes, is involved in CPH induced inhibition of insulin synthesis. Experiments in this study were performed to further investigate the effects of CPH on translation initiation in RINm5F cells. Polysome profile analysis after a 2 hour 10 μM CPH treatment confirmed an increase in the monoribosome peak. Further investigation into the CPH induced initiation block was undertaken by examining the phosphorylation state of the translation initiation factors eIF4E, 4E-BP1 and eIF2α after CPH treatment. After a 2 hour treatment with 10 μM CPH, decreased phosphorylation of both eIF4E and 4E-BP1 was observed. Hypophosphorylation of both eIF4E and 4E-BP1 is consistent with decreased translation initiation. Further, a 24 hour treatment with 10 μM CPH resulted in increased phosphorylation of eIF2α, also consistent with a block of initiation and suggesting the possible involvement of the unfolded protein response in CPH induced β-cell toxicity. Taken together, these results suggest that the inhibition of insulin synthesis elicited by CPH treatment in RINm5F cells involves alterations of initiation factor phosphorylation leading to decreased initiation of PPImRNA.

635 ADRENOCORTICOTROPIC HORMONE-LOADING TEST IN CONSCIOUS CYNOMOLGUS MONKEYS.

H. Tsusaki[1], H. Sameshima[1], M. Masuyama[1] and R. Nagata[1,2]. *[1]Shin Nippon Biomedical Laboratories, Japan, Kagoshima, Japan and [2]Shin Nippon Biomedical Laboratories, USA, Everett, WA.*

The adorenocorticotropic hormone (ACTH)-loading test is known to evaluate adrenal gland function. However, there were no comparative studies to evaluate the most appropriate administration route of ACTH. In previously conducted studies the animals were anesthetized. In this study, we conducted ACTH-loading in conscious cynomolgus monkeys *via* two routes, intravenous and intramuscular. Ten males and ten females, weighing 2.41 to 4.71 kg, were used. The animals received either 5 mcg/kg of tetracosactide acetate intravenously or 12.5 mcg/kg of tetracosactide zinc acetate intramuscularly. Half of the animals were initially administered ACTH intravenously and then intramuscularly at 3-day intervals. The other animals were initially administered intramuscularly and then intravenously at the same intervals as stated above. Serum samples for hormone analysis were collected periodically. Hormones analyzed were endogenous ACTH, cortisol and aldosterone. Endogenous ACTH decreased after administration by both routes, and recovered to basal levels after intravenous administration but not completely after intramuscular administration. Cortisol reached a maximum 2 hours after administration, and were approximately 1.5 to 2-fold basal levels after intravenous administration. Aldosterone reached a maximum 1 hour after administration, and were 2.5 to 4.5-fold of basal levels after intravenous administration. Conversely, cortisol and aldosterone peaks were lower and more prolonged after intramuscular administration. The 3-day interval diminished the reactivity of the adrenal hormones to exogenous ACTH. These results suggest that the effect of intramuscular ACTH-loading lasts longer than that by intravenous administration and the effect remains even after a 3-day interval. In conclusion, the intravenous ACTH-loading test is more appropriate than intramuscular administration. Furthermore, this test in conscious animals has the potential for inclusion as an evaluation parameter in general toxicity studies.

636 TH9507: EMBRYOFETAL AND FERTILITY STUDIES OF A GROWTH HORMONE-RELEASING FACTOR (GRF) ANALOGUE.

E. Ferdinandi[1], G. Washer[1], L. Pinsonneault[2], K. Robinson[2] and T. Abribat[1]. *[1]Theratechnologies, Inc., Montreal, QC, Canada and [2]CTBR, Montreal, QC, Canada.* Sponsor: G. Lulham.

TH9507 is a GRF analogue which has been stabilized by anchoring a hydrophobic moiety to the peptide, while preserving its amino acid sequence. TH9507 is in Phase II trials (doses range from 1.7 to 33.3 µg/kg) for multiple indications (muscle wasting in COPD, recovery after hip fracture surgery, sleep maintenance insomnia and immune dysfunctions). The mode of action involves induction of growth hormone (GH) release, followed by GH-induced release of Insulin-like Growth Factor–1 (IGF-1). Acute and sub-chronic toxicology studies have permitted continuation of clinical trials and helped establish doses for the rat embryofetal & fertility studies reported below. A SC range-finding embryofetal study was conducted in rabbits at 100 to 600 µg/kg/day (from gestation Day 7 to 19). In-life and Day 29 uterine and fetal examinations revealed no evidence of maternal toxicity, embryolethality, fetotoxicity or teratogenicity at any dose level. A subsequent definitive embryofetal development study in rabbits employed doses of 100 to 600 µg/kg/day and confirmed these results. A fertility and embryofetal development study was also conducted in rats. F0 males & females were treated at 0, 100, 300 or 600 µg/kg/day. Males were treated for at least 28 days prior to mating and throughout mating until necropsy. Females were treated for 14 days prior to mating, during mating and up to gestation Day 17, inclusive. F0 males & females exhibited dose-dependant increases in body weight and food intake which were attributed to pharmacological effects of TH9507. No adverse effect on F0 male & female reproduction was observed and there were no major external, internal or skeletal malformations in the F1 population. At 600 µg/kg/day increased fetal weight, accompanied by indications of advanced ossification, may have been related to the maternal effects.

637 NON-SPECIFIC ALTERATION OF STEROIDOGENESIS IN MA-10 LEYDIG CELLS BY SUPRA-PHYSIOLOGICAL CONCENTRATIONS OF THE SURFACTANT IN ROUNDUP® HERBICIDE*.

W. F. Heydens[1], S. L. Levine[1], D. R. Farmer[1], Z. Han[2], C. T. Wall[2] and V. Papadopoulos[2]. *[1]Toxicology/Product Safety Center, Monsanto, St. Louis, MO and [2]Cell Biology and Pharmacology, Georgetown University Medical Center, Washington, DC.*

A decrease in progesterone synthesis in MA-10 Leydig cells stimulated with a cAMP derivative and treated with supra-physiological concentrations of Roundup led Walsh, *et al.* 2000 to suggest that Roundup had endocrine disrupting potential. The authors demonstrated that the formulation, not the active ingredient, was responsible for the concentration-dependent but reversible decline in progesterone synthesis. We repeated this experiment with the inclusion of a sensitive cytotoxicity assay visualizing the loss of mitochondrial potential using fluorescent cationic JC-1 dye. It was shown that the concentration-dependent decrease in progesterone synthesis in hCG-stimulated MA-10 cells resulted from mitochondrial membrane damage by the polyethoxylated tallowamine (POEA) surfactant in Roundup. Decreased hormone-stimulated progesterone synthesis in MA-10 cells was only demonstrated at concentrations of POEA that caused loss of mitochondrial potential. In a separate set of experiments, a number of cationic (benzalkonium chloride), anionic (lauryl sulfate, linear alkyl benzene sulfonate) and non-ionic (alcohol ethoxylates) surfactants commonly found in household products were tested. It was found that all of these surfactants produced a comparable decrease on hCG-stimulated progesterone synthesis in MA-10 cells, at and below concentrations caused by Roundup. The results of this study underscore (1) the non-specific action of a variety of surfactants on cellular function in an *in vitro* test system and (2) how this secondary activity can confound the results when surface active agents are used in *in vitro* test systems. Based on routes and estimates of human exposure to Roundup from agricultural and residential uses, it is apparent that POEA will not disrupt testicular steroid synthesis *in vivo*. * *Roundup herbicide* refers to Roundup Concentrate Weed and Grass Killer (180 g/L).

638 EVALUATION OF THE MALE PUBERTAL ASSAY TO DETECT EFFECTS OF p, p'-DDE AND KETOCONAZOLE IN CD RATS.

T. Yamada, T. Kunimatsu, S. Ueda, S. Yabushita, S. Kawamura, T. Seki, Y. Okuno and N. Mikami. *Environmental Health Science Laboratory, Sumitomo Chemical Co., Ltd.,, Osaka, Japan.*

The male pubertal assay has been recommended by the Endocrine Disruptor Screening and Testing Advisory Committee (EDSTAC) as an alternative Tier I screening assay to detect potential endocrine-active chemicals. The present study was performed to evaluate the reliability of this assay. Two dosing regimens (20- and 30-day) were used to confirm and extend previous works on the assay's ability to detect a weak androgen receptor antagonist (p, p'-DDE, experiment 1) and steroid synthesis inhibitor (ketoconazole, experiment 2). In experiment 1, weanling male rats were dosed by gavage from day 22 to 41 of age (20-day treatment) or day 23 to 52 (30-day treatment) of age with vehicle (corn oil) or p, p'-DDE (100mg/kg/day). In experiment 2, male rats were dosed by gavage from day 21 of age (20-day treatment) or day 31 of age (30-day treatment) to 50 days of age with vehicle (0.25% methylcellulose) or ketoconazole (25 mg/kg/day). p, p'-DDE was positive for antiandrogenic effects, evidenced by decreases in androgen dependent tissue weights, and delayed preputial separation (PPS, 30-day dosing only). Organ weight changes after 20- and 30-day dosing were equivalent. Although a tendency for decreases in the weights of some androgen dependent tissues and serum testosterone levels were observed after 30-day dosing of ketoconazole, none achieved statistical significance. The 30-day dosing of ketoconazole resulted in a delay in PPS and a temporary decrease of anogenital distance. These findings suggest that this assay is reliable for detecting androgen receptor antagonists and steroid synthesis inhibitors if suitable protocol is used.

639 COMPARISON OF THE EFFECTS OF TWO AR ANTAGONISTS ON TISSUE WEIGHTS AND HORMONE LEVELS IN MALE RATS AND ON EXPRESSION OF THREE ANDROGEN DEPENDENT GENES IN THE VENTRAL PROSTATE.

V. S. Wilson, C. R. Wood, G. A. Held, C. S. Lambright, J. S. Ostby, J. R. Furr and L. E. Gray. *RTD, USEPA, ORD, NHEERL, Research Triangle Park, NC.*

The fungicides vinclozolin (V) and procymidone (P) are AR antagonists that alter androgen-dependent genes *in vitro* and induce antiandrogenic effects *in vivo*. V has been shown to alter AR-dependent genes; increasing TRPM-2 (testosterone repressed prostatic message) and repressing C3 (prostatein subunit C3) mRNA levels *in vivo*. The goal of this study was to determine if adult male rats exposed to P display effects similar to V on TRPM-2, C3 and AR message levels using real time reverse transcription polymerase chain reaction (QPCR). An extension of this study using microarray analysis is presented separately (Rosen, et al., 2003 SOT). Castrated SD rats (72) were assigned to treatments: corn oil vehicle + testosterone implant (T), oral V (200 mg/kg/d) + T implant (VT), oral P (200 mg/kg/d) + T implant (PT) and vehicle with an empty implant (Oil). Rats were necropsied after 20 hr, 4 days, and 7 days. Blood was collected for T and LH, organs were weighed and a portion of the ventral prostate (VP) was fixed for immunohistochemistry. RNA was extracted from ventral prostate (VP) tissue and TRPM-2, C3, and AR quantified using QPCR. As expected, castrate (Oil), VT, and PT decreased androgen dependent tissue weights and increased serum LH. Serum T levels did not differ among the T, VT and PT groups. TRPM-2 was increased at all time points in Oil, VT and PT groups versus the T controls. At 7 days, C3 mRNA levels were reduced in the Oil, VT and PT groups (significant for Oil only). In contrast to the AR mRNA levels, which were elevated, immunohistochemical evaluation indicated that AR protein was reduced by castration. These results indicate that VT and PT produce nearly identical morphological, endocrine and molecular alterations of androgen-dependent processes, which are similar to, but less robust than those produced by elimination of T by castration. Abstract of a proposed presentation and does not necessarily reflect EPA policy.

640 INCREASED EXPRESSION AND ACTIVATION IN ADULTHOOD OF CASPASE-3 AND -6 IN RAT GERM CELLS EXPOSED *IN UTERO* TO FLUTAMIDE.

M. Benahmed[1], A. Omezzine[1], S. Chater[1], C. Mauduit[1], A. Florin[1], E. Tabone[1], F. Chuzel[2] and R. Bars[2]. *[1]INSERM University 407, Faculté de Médecine Lyon-Sud, Oullins, France and [2]Experimental Toxicology, Bayer Cropscience, Sophia-Antipolis, France.* Sponsor: A. BLACKER.

In utero exposure to the antiandrogen flutamide induces a wide range of abnormalities in the adult male reproductive system including moderate to severe hypospermatogenesis. However, the cellular and molecular mechanisms underlying this testicular effect remain to be investigated. In this study where pregnant rats were treated with flutamide (0.4, 2, 10 mg/kg/day) by gavage, the resulting hypospermatogenesis observed in the adult male rats (which have been exposed *in utero*) was found to be related to an increase in apoptosis in germ cells. In addition, the number of apoptotic germ cells visualized by the TUNEL approach was increased with increasing concentration of flutamide. The chief effectors of the apoptotic cell death pathway are the caspases which are synthesised as inactive (pro-caspase) precursors and which are then cleaved to generate active enzymes. Pro-caspases-3 and 6 were immunodetected in Leydig and germ cells in both untreated or flutamide-exposed rats while cleaved active caspase-3 was immunodetected exclusively in

germ cells from *in utero*-exposed rats. No immunoreactive active caspase-3 was detected in control adult rat testes. Caspase-3 and -6 mRNA and pro-caspase-3 and -6 protein levels were increased in the adult rat testes exposed *in utero* to flutamide in a dose-dependent manner. Western blots analyses confirmed that *in utero* exposure to flutamide also induced effector caspase activation since cleaved active caspase-3 and -6 proteins were absent in control testes whereas they were detected in *in utero* exposed testes and their levels were increased with increasing concentration of flutamide. In summary, the present findings suggest that the hypospermatogenesis induced by an *in utero* exposure to the antiandrogen flutamide is related to a sustained increase in germ cell apoptosis which could be due to a permanent increase in the expression and activation in germ cells of two effector caspases, namely caspase-3 and -6.

641 *IN VITRO/IN VIVO* EVALUATION OF THE ANTI-ANDROGENIC ACTIVITY OF BENZO(a)PYRENE AND METHOXYCHLOR.

M. S. Marty, G. D. Charles, L. Kan, M. R. Schisler, B. B. Gollapudi and E. W. Carney. *Toxicology & Environmental Research, The Dow Chemical Company, Midland, MI.*

The androgen receptor (AR) transactivation and Hershberger assays are currently being developed for large scale screening of chemicals for endocrine activity. The goal of this study was to evaluate the correlation between the *in vitro* and *in vivo* anti-androgenicity of two compounds (methoxychlor [MXC] and benzo(a)pyrene [BAP]) previously reported to exhibit anti-androgenic activity. For the AR transactivation assay, AR(+) LNCaP cells were transfected with an inducible luciferase reporter construct with concatenated androgen-responsive elements (pGudLuc7ARE) and exposed for 24 h to concentrations of MXC and BAP up to 10 uM in the presence and absence of 1 nM of the AR agonist, R-1881. Neither MXC nor BAP produced significant agonist activity up to the concentrations evaluated. However, both BAP and MXC produced significant anti-androgenic activity *in vitro* as evidenced by their inhibition (37% and 88%, respectively) of the response to R-1881 at the highest concentrations tested. For assessment of anti-androgenic activity *in vivo*, the Hershberger assay utilized a 10-day oral gavage-dosing regimen in castrated CD rats, necropsied 24 h after the final dose of test material. MXC (10, 50, 100 and 200 mg/kg/day) or BAP (1, 10, 50 and 100 mg/kg/day) were dosed (8 animals/group) in the presence of 0.4 mg/kg/day of testosterone propionate (TP) with 0.5% methylcellulose as the vehicle. Neither compound produced significant decreases in ventral prostate, seminal vesicle, glans penis, Cowper's glands or levator-ani muscle weights relative to the TP control. However, the highest doses of MXC and BAP resulted in statistically significant decreases in body weight (p=0.019) and increased liver weight (p=0.003), respectively, relative to TP controls. These limited data demonstrate poor correlation between the *in vitro* and *in vivo* end points evaluated for anti-androgenic activity and further stress the importance of a weight of evidence approach in assessing endocrine activity of test materials.

642 RAINBOW TROUT ANDROGEN RECEPTOR ALPHA AND HUMAN ANDROGEN RECEPTOR: COMPARISONS IN THE COS WHOLE CELL BINDING ASSAY.

M. C. Cardon, P. C. Hartig, L. Gray and V. S. Wilson. *ORD, NHEERL, RTD, USEPA, Research Triangle Park, NC.*

Typically, *in vitro* hazard assessments for the identification of endocrine disrupting compounds (EDCs), including those outlined in the EDSTAC Tier 1 Screening (T1S) protocols, utilize mammalian receptors. However, evidence exists that fish sex steroid hormone receptors differ from mammalian receptors both structurally and in their binding affinities for some steroids and environmental chemicals. Most of the binding information available to date comes from studies conducted using cytosolic preparations. We sought to compare competitive binding using rainbow trout androgen receptor alpha (rtAR) and human androgen receptor (hAR) expressed in transfected COS cells. In this system, we can investigate the binding affinities of individual receptors without the potentially confounding effects of other steroid receptors present in cytosolic tissue extracts. Saturation ligand binding and Scatchard anaylsis using [3H]R1881, a synthetic androgen, revealed a Kd of 0.24 nM for the rtAR. In the same system, we found a Kd of 2.27 nM for the hAR. Binding studies in competition with [3H]R1881 were conducted using steroids and a selection of environmental chemicals shown to bind mammalian AR. All the chemicals and steroids studied competed for binding in both rtAR and hAR. The relative order of binding affinities of natural and synthetic androgens for the rtAR was methyltrienolone > trenbolone > 11-ketotestosterone > dihydrotestosterone(DHT) > testosterone(T) > androstenedione. The rank order for the hAR was similar except that DHT and T had higher affinity than 11-ketotestosterone. We also found in our system that androstenedione bound with lower affinity than what has been reported in the literature for the rtAR. Other steroids and antiandrogens were studied and their relative binding order was similar for the two species. Studies such as these will facilitate the identification of EDCs that affect many species and support future risk assessment protocols. [This abstract does not necessarily reflect EPA policy.]

643 INVESTIGATION OF HORMONAL CHANGES IN TESTICULAR TOXICITY INDUCED BY NEFIRACETAM IN DOGS.

K. Shimomura, M. Shimada, M. Hagiwara, S. Harada, M. Kato and K. Furuhama. *Daiichi Pharmaceutical Co., Ltd., Drug Safety Research Laboratory, Tokyo, Japan.*

Nefiracetam, a neurotransmission enhancer, induces testicular toxicity in rats, dogs and monkeys. In rats, nefiracetam decreased serum and testicular testosterone (T) levels 1-4 hours after single or 1-week repeated oral administration, but its reduction returned to the control level 8 hours later. We, therefore, considered that the transient decrease in the T level contributes in part to the testicular toxicity. In the present study, to know whether the testosterone level could be decreased in dogs and to consider the mechanism of the decreased T level, male adult beagle dogs were orally administered 300 mg/kg/day nefiracetam singly, or once daily for 1 or 4 consecutive weeks. Serum levels of T, estoradiol (E), luteinizing hormone (LH), follicule stimulating hormone (FSH) and inhibin B were measured every week during the 4-week administration period. After completion of the administration, the testis was histologically examined, and serum and testicular levels of T, E and progesterone (P) were also measured. As results, after the single administration, T level was decreased both in serum and the testis, with an increased serum P level and decreased testicular E level. After the 1-week administration, T level was also decreased in serum and the testis, and E level was increased and decreased in serum and the testis, respectively. However, testicular P level was not changed after the single or 1-week administration. During the 4-week administration, T level in serum was decreased after 1- and 2-week administration, but not later, while E level was continuously increased during the 4-week administration. There was no change in the other hormone levels. Histologically, atrophy of seminiferous tubules containing multinucleated giant cells was observed in the testis. In conclusion, the present results suggest that the decreased T level may be caused by impaired conversion of P to T in Leyding cells, and that the decreased T level may contribute to the testicular toxicity in the early stage.

644 EFFECT OF ETHYL *t*-BUTYL ETHER (ETBE) ON TESTOSTERONE IN MALE RATS.

B. Stanard, C. Westover, B. Hirakawa, J. Gonzalez and A. de Peyster. *Graduate School of Public Health, San Diego State University, San Diego, CA.*

Seminiferous tubule degeneration was observed in F344 rats after 13-week inhalation exposure to 1750 or 5000 ppm ETBE, a motor fuel oxygenate. Noting that the testis is also affected by MTBE, which is reported to have increased rat Leydig cell tumors when high doses were given by gavage or inhalation in cancer bioassays, we undertook the current studies to determine whether ETBE alters testosterone (T) levels by mechanisms similar to those studied previously with MTBE. A common mechanism was also suggested by the metabolism of both to t-butyl alcohol (TBA). Leydig cells were isolated from adult Sprague-Dawley rats and exposed to ETBE, MTBE, TBA and acetaldehyde (ACET), another metabolite of ETBE, with/without hCG stimulation for 3 hr. Formaldehyde (FORM), a metabolite of MTBE, was added to some cultures as formalin, controling for 10% methanol also present in this formulation. When potencies were compared, 50 mM concentrations of ETBE, MTBE or TBA inhibited hCG-stimulated T production to 67%, 69% and 57% of control, respectively. As little as 5 mM ACET reduced T to 44% of control, while 5% FORM completely inhibited T production (10% methanol had no effect in this system). ETBE effects on T were also studied in adult male F344 rats gavaged daily with 600, 1200 or 1800 mg/kg in corn oil for 14 days (n=12). 1800 mg/kg doses reduced mean serum T to 66% of corn oil control by necropsy 1 hr after the final dose; however, there was considerable individual variability in response (p>0.05). Suppressed body weight gain in this group may have exacerbated this effect. Testes and accessory sex organ unit weights also suggested a slight dose-related decline, although not statistically significant after this 14-day dosing period. Taken together these results suggest that high concentrations of ETBE (and metabolites) are capable of lowering testosterone if exposure is sufficiently high. The potency of ETBE in these studies was no greater than that seen previously with MTBE, yet their different metabolites may ultimately produce different effects *in vivo*.

645 ORGANOTIN COMPOUNDS ALTER ENDOCRINE FUNCTIONS OF HUMAN PLACENTAL CELLS.

T. Nakanishi[1], N. Itoh[1], N. Utoguchi[2] and K. Tanaka[1]. *[1]Grad Sch of Pharmacology Sciences, Osaka University, Suita, Osaka, Japan and [2]Sch of Pharmacology Sciences, Teikyo University, Sagamiko, Kanagawa, Japan.* Sponsor: G. Cherian.

Tributyltin (TBT) and triphenyltin (TPT) are known to induce an irreversible sexual abnormality of female neogastropod snails which is termed "imposex". However, in humans, no studies have investigated disturbances in sexual development and reproductive function as a result of exposure to organotin compounds. The placenta plays a vital role in the maintenance of a pregnancy by delivering oxygen and nutrients from the maternal circulation to the fetus and by returning fetal metabolites to the mother. The placenta also has many crucial endocrine functions such as human chorionic gonadotropin (hCG) production and the aromatization of androgen substrates to estrogens. Thus these placental functions might be at high risk due to the developmental and reproductive toxicology of environmental contaminants which have endocrine-disrupting effects. In the present study, to extend knowledge on the sexual developmental and reproductive toxicity of organotin compounds in humans, we assessed the possible effect of organotin compounds on aromatase activity and hCG secretion by human choriocarcinoma cells. Both TBT and TPT increased levels of hCG secretion and aromatase activity in a dose- and time-dependent fashion following exposure to non-toxic concentration ranges. In addition, these compounds enhanced 8bromo-cAMP-induced hCG secretion and aromatase activity in JAR cells. TBT caused dose-related increases in steady state mRNA levels of both hCG beta and CYP19 in JAR cells following exposure to non-toxic concentrations of TBT. Our studies suggest that TBT and TPT are potent stimulators of human placental hCG production and aromatase activity *in vitro*; and the placenta represents a potential target organ for these compounds, whose endocrine-disrupting effects might be the result of local changes in hCG and estrogen concentrations in pregnant women. Acknowledgments: This research was supported in part by Industrial Technology Research Grant Program in '01 from New Energy and Industrial Technology Development Organization (NEDO) of Japan.

646 THE ANTIESTROGENIC EFFECTS OF MOTORCYCLE EXHAUST PARTICULATE *IN VITRO* AND *IN VIVO.*

T. Ueng, H. Wang, Y. Hwang and C. Hung. *Institute of Toxicology, National Taiwan University College of Medicine, Taipei, Taiwan.*

The effects of motorcycle exhaust particulate (MEP) on estrogenic responses were determined using MCF-7 human breast cancer cells and immature female Wistar rats treated with organic extracts of MEP. Treatments with 0.01 to 50 μg/ml MEP extract for 2 days produced a dose-dependent inhibition of thymidine incorporation in untreated cells and cells treated with 1 nM 17β-estradiol (E2). Treatments with MEP extract for 6 days resulted in dose-dependent decreases of cell growth in untreated and E2-treated MCF-7 cells. Cotreatment with MEP extract and E2 plus α-naphthoflavone, a cytochrome P450 inhibitor and aryl hydrocarbon receptor antagonist, blocked the MEP-mediated decreases of thymidine incorporation and cell growth. MEP extract replaced [3H]E2 from the estrogen receptor in MCF-7 cells in a temperature-, time- and concentration-dependent fashion. Cotreatment with MEP and α-naphthoflavone blocked the inductive effects of MEP on binding to the estrogen receptor and activity of aryl hydrocarbon hydroxylase in MCF-7 cells. The results of E2 metabolism studies showed that treatment with MEP extract increased E2 2-hydroxylation in MCF-7 microsomes. These antiestrogenic effects were further confirmed using a rat uterotrophic bioassay in which treatment with 10 mg/kg MEP extract for 3 days decreased uterine weights of untreated immature female rats and rats induced with 10 μg/kg E2. In parallel studies, treatments of MCF-7 cells and immature female rats with benzo(a)pyrene, a constituent of MEP, produced antagonistic effects on the E2-induced thymidine incorporation, binding to the estrogen receptor, and uterotrophic activity, respectively. The present findings demonstrate that MEP extract has the ability to antagonize the E2-induced responses in MCF-7 cells and female rats. The antiestrogenic effect of MEP may be an important factor to consider in assessing the potential health effects associated with human exposure to the vehicle exhaust.

647 EFFECT OF ATRAZINE ON THE ESTROGEN AND PROGESTERONE INDUCED LUTEINIZING HORMONE SURGE AND GNRH NEURONAL ACTIVITY.

T. S. McMullin[1], R. J. Handa[3], W. H. Hanneman[1] and M. E. Andersen[2]. *[1]Environmental and Radiological Health Sciences, Colorado State University, Fort Collins, CO, [2]Biological Sciences, Colorado State University, Fort Collins, CO and [3]CIIT, Centers for Health Research, Research Triangle Park, NC.*

Atrazine (ATRA), a chlorotriazine herbicide, is widely used throughout agricultural areas in the United States. High doses of ATRA disrupt hypothalamic function, leading to, among other effects, suppression of the estrogen (E2) induced pro-estrous luteinizing hormone (LH) surge in ovariectomized (OVX) rats. To date, the effect of ATRA on the LH surge has only been examined after priming the rat with E2, not E2 and progesterone (PG). Yet, the combination of both gonadal steroids produces a hormonal environment more indicative of endogenous circulating hormones during pro-estrous. Our laboratory examined the ability of ATRA to suppress the LH surge in E2 and PG primed OVX rats. Female Sprague-Dawley rats were bilaterally OVX and jugular catheterized for serial blood sampling. Rats were treated with either 300mg ATRA/kg body weight in a 0.5% carboxymethylcellulose (CMC) vehicle or an equivalent volume of 0.5%CMC vehicle *via* oral gavage between 0900h to 1000h for 5 consecutive days, a treatment regimen that we have previously shown to significantly suppress the E2 induced LH surge in OVX rats. Animals received subcutaneous injections of E2 on days 2-4. On the morning of day 5, PG was administered and serial blood samples were taken hourly from 1200-2000. Serum was analyzed for LH *via* radioimmunoassay. E2 and PG priming produced an LH surge approximately four times greater (23.0±8.1ng/ml;n=11) than E2 priming alone(5.3±2.0ng/ml; n=20). Additionally, ATRA treatment significantly suppressed the E2–PG induced LH surge(3.42±2.6ng/ml;n=10) compared to control. The E2 and PG priming model provided a more robust LH surge that has allowed more sensitivity for dose-response studies with ATRA and comparisons of potency between ATRA and its metabolites. Funded by Syngenta Corporation and EPA STAR Grant (R-828610-01-0).

648 EFFECTS OF POLYBROMINATED DIPHENYLETHER (PBDE) ON REPRODUCTIVE ORGAN AND BRAIN DEVELOPMENT AND GENE EXPRESSION IN RATS.

W. Lichtensteiger, R. Ceccatelli, O. Faass, I. Fleischmann and M. Schlumpf. *Institute of Pharmacology and Toxicology, University of Zurich, Zurich, Switzerland.* Sponsor: R. Peterson.

PBDE, used as flame retardants, accumulate in the biosphere; levels in human milk have increased during the last decade. We are comparing developmental actions of PBDE99 (2, 2', 4, 4', 5-pentaBDE) and the PCB mixture, Aroclor1254. PBDE99 (1 or 10 mg/kg/day) or Aroclor1254 (10 or 30 mg/kg/day) were injected subcutaneously to time-pregnant Long Evans rats from gestational day 10 to GD 18. The onset of puberty was delayed in female offspring (vaginal opening) by PBDE99 and Aroclor1254 (higher dose), but unaffected in males (preputial separation). Sexually dimorphic behavior and estrous cycle of adult offspring are being analyzed. PBDE99 affected absolute and relative weight of ventral and dorsal prostate (increase), epididymis (decrease), and ovary (increase), with unchanged body weight. Aroclor1254 induced a different effect pattern. Prenatal PBDE99 exposure affected sex hormone target gene mRNA levels determined by Real Time PCR (reference cyclophilin), IGF-I mRNA in ventral prostate and uterus, progesterone receptor mRNA in uterus, androgen receptor and estrogen receptors alpha and beta mRNAs in prostate, with differences between ventral and dorsal prostate. mRNA levels in sexually dimorphic brain regions, and mRNA expression after acute estrogen challenge in gonadectomized offspring, are under investigation. Our date indicate that PBDE99 can interfere with sexual development and exhibits features of endocrine disruptors. (Supported by EU 5th Framework Program, Project PBDE-NTOX).

649 ENDOCRINE ACTIVITY AND DEVELOPMENTAL TOXICITY OF UV FILTERS.

M. Schlumpf, S. Durrer, K. Maerkel, R. Ma, M. Conscience, I. Fleischmann and W. Lichtensteiger. *Institute of Pharmacology and Toxicology, University of Zurich, Zurich, Switzerland.* Sponsor: R. Peterson.

UV filters used in sunscreens and other cosmetics have been found in the biosphere, in fish and human milk. In order to assess potential effects on reproductive functions, we are investigating endocrine activity in acute *in vitro* and *in vivo* systems, and developmental toxicity in rats. Several UV filters exhibit estrogenic activity on MCF-7 cells. Uterotrophic activity has been demonstrated for 4-methylbenzylidene camphor (4-MBC), octylmethoxy-cinnamate (OMC), benzophenone-3 (Bp-3) (Schlumpf et al., 2001), and recently for 3-benzylidene camphor (3-BC). The activity of 4-MBC was confirmed by Tinwell et al. (2002), 3-BC is also estrogenic in fish (Holbech, 2002). Further, Bp-3 and homosalate act as androgen antagonists in MDA-MB-453-KB2 cells. - Developmental Toxicity: When 4-MBC was administered in chow to Long Evans rats from 10 weeks before mating until adulthood of F1 offspring (1.0, 0.66, 0.33, 0.1 g/ kg chow, yielding daily doses of 70, 47, 24, 7 mg/kg), F0 animals did not exhibit adverse effects after 13 month exposure. Higher doses reduced F1 survival rate and neonatal thymus weight. Male puberty was dose-dependently delayed. Weight changes were noted for testis, epididymis, seminal vesicles, ventral and dorsal prostate. Estrogen target gene mRNA levels, determined by Real Time PCR (reference cyclophilin), were altered in adult F1 uterus (IGF-I mRNA, progesterone receptor (PR) mRNA, androgen receptor (AR) mRNA) and prostate (IGF-I mRNA, AR mRNA). Ventromedial hypothalamus (VMH) and medial preoptic region showed sex- and region-dependent

changes in PR and ER alpha mRNAs from 7mg/kg/day, with loss of sexually dimorphic PR mRNA expression in VMH. Our data indicate that 4-MBC can influence sexual development at peripheral and central levels of neuroendocrine organization. 650 ASSESSMENT OF DEMERSAL AND CULTURED FLATFISH SPECIES FOR EXPOSURE AND ADVERSE EFFECTS RESULTING FROM EXPOSURE TO ENVIRONMENTAL ESTROGENS IN THE SOUTHERN CALIFORNIA BIGHT.

W. Hwang[1], L. Roy[1], J. Armstrong[2], S. Steinert[3], K. Sakamoto[2], K. Kahara[1], S. Reddy[4], B. Brownawell[4], E. Sapozhnikova[1] and D. Schlenk[1]. *[1]UC- Riverside, Riverside, CA, [2]Orange County Sanitation District, Fountain Valley, CA, [3]CSC Biomarkers, San Diego, CA and [4]Stonybrook University, Stony Brook, NY.*

Previous studies with demersal flatfish species in the central Southern California Bight have indicated the uptake of environmental estrogens. Subsequent studies were carried out to determine whether adverse reproductive effects occur in these populations. In addition, sediment collected from the outfall of a local wastewater treatment plant was evaluated with a laboratory exposure to cultured California Halibut (CH) (Paralichthys californicus) and chemical residue analyses for 17-beta estradiol. Initial population metrics indicated no significant differences in hornyhead turbot (HT)(Pleuronichthys verticalis) or English sole (ES) (Parophrys vetulus) collected in this region over the past 10 years. In July of 2002, HT and ES were collected from 8 offshore sites by trawl. Gender ratios, age ratios, length, serum vitellogenin, sperm DNA damage and gonad somatic indices (GSI) were compared. There was a slightly higher percentage of females ES (42% n=59) at the outfall compared to the reference location (37% n=54), and a higher number of sexually mature female ES (25% vs. 0%) and male ES (42% vs. 6%) at the outfall. Although gender ratios were unchanged for HT (33%), there were higher numbers of sexually mature animals at the outfall for both genders. Lengths were greater for male and female ES as well as female HT at the outfall compared to the reference site. GSI for female ES was also significantly higher at the outfall compared to the reference fish. DNA damage of HT sperm was highest at the outfall. Vitellogenin in male CH exposed to sediments was not induced and estradiol concentrations were 0.048, and 0.42 ng/g for reference and outfall sediments. These results indicate estrogenic activity observed in demersal fish of So Cal. is not likely caused by a sediment-only exposure to xenoestrogens.

651 INTERACTION ANALYSIS OF SYNTHETIC XENOESTROGENS AND PHYTOESTROGENS *IN VIVO*.

G. D. Charles[1], C. Gennings[2], T. R. Zacharewski[3], B. B. Gollapudi[1] and E. W. Carney[1]. *[1]The Dow Chemical Company, Midland, MI, [2]Biostatistics, Virginia Commonwealth University, Richmond, VA and [3]Biochemistry & National Food Safety & Toxicology Center, Michigan State University, East Lansing, MI.*

The immature rat uterotrophic model was used to investigate interactions between reconstituted mixtures of estrogenic substances as evaluated by the change in slope of the dose-response curve of one chemical in the presence of other chemicals. Conceptually, if these dose-response curves are parallel, then there is zero or no interaction between the chemicals. A 2:1 phytoestrogen mixture of genistein and daidzein (based on general dietary ratios) was experimentally evaluated alone at doses of 0, 60, 120, 240 mg/kg/day or in combination with a synthetic xenoestrogen mixture (o, p-DDT, methoxychlor and beta-hexachlorocyclohexane) in which each chemical was present at 0.01, 0.1, or 1X of its respective NOEL based on their individual dose-response curves. Test materials were given for 3 days *via* gavage and wet and blotted uterine weights measured 24h after the last dose. A parameterized nonlinear Gompertz model was used to determine if the synthetic xenoestrogens altered the slope of the phytoestrogen dose-response curve. The phytoestrogen dose-response curve was not significantly changed by the addition of the synthetic xenoestrogen mixture at 0.01 or 0.1X NOEL levels for either the uterine wet (p=0.449 and 0.763) or blotted (p=0.294 and 0.663) weights, respectively. When the xenoestrogens were present at 1X NOEL levels there was a leftward shift in the phytoestrogen curve, however, with no significant change in slope for either the wet (p=0.677) or blotted weights (p=0.697), thus indicating no evidence of departure from additivity (i.e no interaction) between the phytoestrogen and 1X NOEL level of xenoestrogens. Since environmental levels of synthetic chemicals are generally well below their individual NOEL concentrations, a change in response from that due to phytoestrogen exposure would not be likely. Supported by the American Chemistry Council.

652 SPECIES DIFFERENCES IN THE CYTOCHROME P450 (CYP)-DEPENDENT METABOLISM OF 3, 3'-DIINDOLYLMETHANE (DIM): EFFECTS ON ESTROGENICITY.

S. C. Tilton[1], M. H. van Lipzig[2], N. E. Vermeulen[2], J. N. Meerman[2] and D. E. Williams[1]. *[1]Environmental and Molecular Toxicology and The Marine/Freshwater Biomedical Sciences Center, Oregon State University, Corvallis, OR and [2]Leiden/Amsterdam Center for Drug Research, Department of Pharmacochemistry, Section of Molecular Toxicology and Design, Vrije Universiteit Amsterdam, Amsterdam, Netherlands.*

Indole-3-carbinol (I3C) is a glucosinolate hydrolysis product from cruciferous vegetables that has been found to have chemoprotective effects in several animal models. However, I3C given long-term postinitiation modulates liver carcinogenesis similar to the actions of 17β-estradiol so that it promotes hepatic tumors in trout and rat models, but inhibits them in mice. A major acid condensation product of I3C, DIM, is estrogenic in precision trout liver slices and accounts for the majority of the estrogenicity of I3C in trout *in vivo*. In competitive binding studies with trout hepatic estrogen receptor (ER), we found the relative binding affinity of DIM was 17-fold higher than I3C. This evidence, along with the species selectivity of I3C as a hepatic tumor modulator, suggests an estrogenic mechanism of action for hepatocarcinogenesis. In this study, we demonstrate species differences in the relative binding affinity of DIM for the ER after CYP-dependent metabolism. DIM incubated with β-napthoflavone (βNF)-induced rat microsomes in the presence of NADPH generated a metabolite mixture with a binding affinity for the ER 33-fold higher than the parent compound. However, DIM incubated with βNF-induced trout microsomes did not result in metabolites with a different binding affinity from the parent. These data support previous work on the disposition of DIM in trout and rat *in vivo* and suggest that species differences in hepatic tumor promotion are due to the CYP-specific metabolism of DIM to estrogenic metabolites. Supported by NIH grant ES03850.

653 REGULATION OF UTERINE HSP90α, HSP72 AND HSF-1 EXPRESSION IN B6C3F1 MICE BY β-ESTRADIOL AND BISPHENOL A: INVOLVEMENT OF THE ESTROGEN RECEPTOR AND PROTEIN KINASE C.

A. D. Papaconstantinou[1], P. L. Goering[2], T. H. Umbreit[2] and K. M. Brown[1]. *[1]Biological Sciences, George Washington University, Washington, DC and [2]Center for Devices and Radiological Health, USFDA, Rockville, MD.*

We have previously demonstrated that the effects of bisphenol A (BPA), an estrogen-mimic, and β-estradiol (E_2) on heat shock proteins (hsps) in the uterus are mediated through the estrogen receptor (ER). However, the mechanism of the ER involvement in the regulation of uterine hsps remains unknown. The heat-inducible heat shock factor 1 (HSF-1) controls the transcription of hsp genes. HSF-1 is regulated by estrogen, but also by protein kinase C (PKC). PKC may also regulate hsp expression independent of HSF-1. It was therefore of interest to examine the role of PKC and of the ER on the time-related effects of E_2 and BPA on uterine hsp90α and hsp72 expression. Ovariectomized B6C3F1 mice were treated subcutaneously with corn oil (vehicle), 1 μg E_2/kg or 100 mg BPA/kg alone or in combination with 5 mg/kg of the antiestrogen ICI 182, 780 (ICI) or 0.5 mg/kg of the PKC inhibitor GF 109203X (GF), and uteri were collected at 6 or 24 hours post-administration. Both E_2 and BPA altered the expression of hsp90α and hsp72. E_2 appears to increase uterine hsps by regulating the transcription of these genes and/or of HSF-1. BPA may regulate the transcription of hsp90α and hsp72, but not HSF-1. PKC may be involved in the regulation of hsp72 by E_2 and in the regulation of hsp90α by BPA. Collectively, the results of the present study suggest a differential mechanism of regulation of uterine hsp90α and hsp72 levels by E_2 and BPA.

654 ESTROGENIC AND ANTIESTROGENIC ACTIVITIES OF BISPHENOL A AND RELATED BISPHENOLS IN ISHIKAWA CELLS.

H. L. Esch, E. Pfeiffer and M. Metzler. *Institute of Food Chemistry and Toxicology, University of Karlsruhe, Karlsruhe, Germany.*

Substantial interest has recently been evoked by the hormone-like effects of bisphenols, in particular bisphenol A (BPA), which is widely used in polymer chemistry. In the present study, we have determined the estrogenic and antiestrogenic activity of BPA, bisphenol B (BPB) and the ring-methylated BPA derivates 3, 3′-dimethyl-BPA (DMBPA) and 3, 3′, 5, 5′-tetramethyl-BPA (TMBPA) in Ishikawa cells. This cell line is derived from a human endometrial adenocarcinoma and responds to estrogens with a marked induction of alkaline phosphatase (AP). Maximal stimulation of AP is achieved using 1 nM 17β-estradiol (E2). Cells were seeded in 96-well plates and incubated for 48 h with bisphenol concentrations ranging from picomolar to micromolar. The AP activity was measured photometrically using p-nitro-

phenylphosphate as substrate and related to the activity obtained with 1 nM E2. All four bisphenols stimulated AP activity at concentrations of 1 to 5 μM, indicating a weak estrogenic activity (0.01-0.03% of E2 activity). However, the maximal AP activity induced by the bisphenols was only 40-60% of that obtained with E2. When micromolar concentrations of the bisphenols were co-incubated with 1 nM E2, a lower induction of AP as compared to E2 alone was noted. To exclude that this putative antiestrogenic effect was due to a reduction of cell viability or cell number, we determined cell viability by the methylthiazoletetrazolium (MTT) assay and cell number by the sulforhodamine B (SRB) test and by electronic cell counting. Incubation with 10-50 μM BPA or BPB alone, but not in the presence of 1 nM E2, gave rise to an elevated cell viability (120-140%) in the MTT test. However, no increase in cell number was observed in the SRB assay or by counting cell number. Furthermore, no direct effect of bisphenols on the activity of commercially available AP from human placenta was noted. Based on these results we conclude that bisphenols alter AP activity due to changes in AP expression and exhibit weak estrogenic and antiestrogenic activity in Ishikawa cells.

655 MCF-7 CELL MITOGENS DIFFERENTIALLY AFFECT MAPK ACTIVATION AND ESTROGEN RECEPTOR-α PHOSPHORYLATION.

S. L. Brower[1] and M. R. Miller[1,2]. *[1]West Virginia University, Morgantown, WV and [2]NIOSH, Morgantown, WV.*

Xenoestrogens are implicated in adverse health effects by modulating the activity of the estrogen receptor (ER) either directly by binding ER or indirectly by affecting signaling pathways that impact ER activity. Estradiol (E2), epidermal growth factor (EGF) and acetaminophen (APAP) each are mitogens in MCF-7 (ER+ human breast cancer) cells, and anti-estrogens inhibit their proliferation, implying ER is involved in the mitogenic pathway(s) they activate. E2 exerts its activity by binding to and enhancing phosphorylation of ER, activating it as a transcription factor; MAPK, PKA and CaM kinase II are implicated in E2-mediated ER phosphorylation. However, EGF reportedly activates ER independent of binding by promoting ER phosphorylation through the MAPK pathway. It is unclear how APAP exerts mitogenic activity, but like EGF it does not bind ER. Therefore this study tests the hypothesis that APAP activates ER in a ligand-independent manner *via* MAPK activation and ER phosphorylation. MCF-7 cells served as an *in vitro* model in which to profile the activity of these 3 mitogens on MAPK activation and ERα phosphorylation, both assessed by immunoblotting. Initial studies indicated E2 enhanced MAPK activity; however additional studies clearly showed this response was an artifact caused by the addition of a small amount of stripped serum when cells were dosed with E2. MAPK is not activated when E2 is given to cells in the absence of additional serum. As previously reported, E2 also increased ERα phosphorylation. In contrast, EGF transiently and robustly induced MAPK activation, but did not increase ERα phosphorylation. Unlike E2 and EGF, APAP had no effect on either MAPK activity or ERα phosphorylation. These findings indicate ER has complex involvement in MCF-7 cell growth, and estrogenic compounds can induce ER-mediated breast cancer cell proliferation through various signaling pathways. Additional studies are needed to determine what kinase(s) are responsible for E2-induced ERα phosphorylation, as it is clear from this study that MAPK is not activated above basal levels by E2.

656 IDENTIFICATION OF ERβ-RESPONSIVE GENES IN THE OVARIES OF ESTROGEN RECEPTOR α KNOCKOUT MICE.

C. Q. Sheeler[1], K. Walker[2], S. H. Safe[2] and K. W. Gaido[1]. *[1]CIIT Centers for Health Research, Research Triangle Park, NC and [2]Texas A&M University, College Station, TX.*

A number of compounds found in the environment are known to possess estrogen-like biological activity and have been linked to adverse effects on reproduction function in humans and wildlife. Some of these endocrine disruptors preferentially affect estrogen receptor β (ERβ). However, the physiological relevance of ERβ is not known. To gain a better understanding of the role ERβ plays in the reproductive tract, we used estrogen receptor α knockout (αERKO) mice, which only express ERβ, to identify ERβ-responsive genes. Sexually immature (24-day-old) female αERKO mice were injected subcutaneously in the dorsal cervical area with vehicle alone (0.1 ml corn oil), estradiol (E2) (10 μg/kg), ICI 182, 780 (ICI) (20 mg/kg), or E2 plus ICI. At 24 h after treatment, ovaries were collected, and total RNA was isolated from 4 to 5 animals per group. Microarray analysis was used to identify potential ERβ-responsive genes and reverse transcription polymerase chain reaction was used to confirm and quantitate gene expression. Expression levels of *Fas* and *klotho* were significantly decreased 2.5- and 3.6-fold, respectively, in mice treated with E2 compared to control mice and ICI blocked E2-induced down-regulation of these genes. In addition, ICI alone significantly increased *MAPKK4* expression by 1.3-fold compared to control mice, whereas E2 alone or in combination with ICI did not significantly alter *MAPKK4* expression. All three of these genes play a role in apoptosis. Our results suggest that ERβ may act as a repressor of genes involved in regulation of apoptosis in the ovary. Currently we are investigating inhibition of ERβ activity by ERβ-specific compounds in the ovary since these genes may be involved in decreased ovulatory capacity and impaired follicular development observed in ERβ knockout mice.

657 MECHANISM OF ESTROGEN RECEPTOR α/SP1-MEDIATED ACTIVATION OF GC-RICH PROMOTERS BY ESTROGENS AND ANTIESTROGENS.

K. Kim, T. Nguyen, B. Saville and S. Safe. *Veterinary Physiology & Pharmacology, Texas A&M University, College Station, TX.*

Estrogen receptor α (ERα)/Sp1 activation of estrogen-responsive GC-rich gene promoters in breast cancer cells is dependent on activation function 1 (AF1) of ERα; however, contributions of the DNA binding domain (DBD) and AF2 regions of ERα and promoter context on ERα/Sp1 action have not been determined. 17β-Estradiol (E2) induced reporter gene activity in MCF-7 and MDA-MB-231 cells cotransfected with human or mouse ERα (hERα or MOR), but not ERβ and GC-rich constructs containing three tandem Sp1 binding sites ($pSp1_3$) or estrogen-responsive GC-rich promoter inserts from the adenosine deaminase (pADA) or retinoic acid receptor α1 (pRARα1) genes in breast. The antiestrogens 4'-hydroxytamoxifen (4OHT) and ICI 182, 780 (ICI) also activated $pSp1_3$ in cells cotransfected with ERα. However, estrogen and antiestrogen activation of hERα/Sp1 was also dependent on overlapping and different AF1-independent domains (CDEF) of ERα. hERα/Sp1 was activated by E2 and antiestrogens in breast cancer cells transfected with hERα containing mutations in helix 12 (D538A, E542A and D545A) that block interactions with AF2-interacting coactivators and not surprisingly, prototypical steroid receptor coactivators did not enhance ERα/Sp1-mediated transactivation. In contrast, mutation of zinc fingers 1 or 2 resulted in loss of hERα/Sp1 activation by antiestrogens (but not E2) and deletion of the hinge or C-terminal helix 12/helix 13 (aa 538-595) regions resulted in loss of hERα/Sp1 activation by E2 but not antiestrogens. Thus, estrogen/antiestrogen-mediated activation of hERα/Sp1 is dependent not only on AF1 but also selected regions within the CDEF domains that are necessary for E2- or antiestrogen-responsiveness. (Supported by NIH ES09106 and CA76636)

658 ANTI-ESTROGENIC ACTIVITY OF POLYCYCLIC MUSKS IN THE ZEBRAFISH (*DANIO RERIO*).

R. Schreurs[1], J. Legler[2], P. Lanser[2], W. Seinen[1] and B. v.d. Burg[2]. *[1]Institute for Risk Assessment Sciences, Utrecht University, Utrecht, Netherlands and [2]Netherlands Institute of Developmental Biology, Utrecht, Netherlands.* Sponsor: M. van den Berg.

Polycyclic musks are an important group of synthetic fragrance ingredients with HHCB (Galaxolide) and AHTN (Tonalid) as the two largest volume products. They are used in perfumes, cosmetics and household cleaning products with a world-wide production volume of about 6000 t/year. They reach the aquatic environment *via* household wastewater and sewage plant effluents. Because of their high lipophilicity, AHTN and HHCB tend to bioaccumulate in the environment. They have been found in surface waters, sediment, fish, and also in human milk, fat and blood. Using a sensitive reporter gene assay we found that both musks showed anti-estrogenic activity towards the human estrogen receptor β and zebrafish estrogen receptor γ. Zebrafish, in which an estrogen responsive luciferase reporter gene has been stably introduced, were used for *in vivo* testing. In this transgenic zebrafish assay both musks showed anti-estrogenic activity. GC-MS analysis of both compounds was used to estimate the total body uptake of musks by the zebrafish.

659 ASSESSMENT OF DE-71, A COMMERCIAL POLYBROMINATED DIPHENYL ETHER (PBDE)MIXTURE, IN THE EDSP MALE PUBERTAL PROTOCOL.

T. E. Stoker[1], J. Ferrell[1], J. M. Hedge[2], K. M. Crofton[2], R. L. Cooper[1] and S. C. Laws[1]. *[1]RTD, NHEERL, ORD, USEPA, Research Triangle Park, NC and [2]NTD, NHEERL, ORD, USEPA, Research Triangle Park, NC.*

PBDEs are environmental contaminants that disrupt thyroid hormone homeostasis. To examine the ability of the Endocrine Disruptor Screening Program (EDSP) Tier 1 male pubertal protocol to detect thyroid active agents, we examined thyroid and reproductive endpoints of male Wistar rats following DE-71(DE)exposure. Rats were gavaged with 0, 3, 30 or 60 mg/kg DE in corn oil from postnatal day (PND) 23-53. Thyroid measures were also made on PND 28 to compare a 5 day exposure with this 31 day protocol. T4 was significantly decreased at 30 and 60 mg/kg (74 and 81% below control) on PND 28 and at 3, 30 and 60 mg/kg (20, 80,

and 86%) on PND 53. T3 was decreased only by 30 and 60 mg/kg (25 and 20%) on PND 53. TSH was increased on PND 53 at 30 and 60 mg/kg (64 and 113%). Increased liver to body weight ratios coincided with a induction of UDGPT (uridinediphosphate-glucuronosyltransferase; 2-4 fold), EROD and PROD (ethoxy- and pentoxy-resorufin-O-deethylase) predominantly at the two highest doses. EROD increased 10-14 fold on PND 28 and 53, while PROD increased 12-23 fold by PND 28 and 78-83 fold by PND 53. Of the androgen dependent tissues, seminal vesicle (SV) and ventral prostate (VP) wt were reduced at 60 mg/kg, while testes and epididymal wts were not. Preputial separation (PPS) was significantly delayed at 30 and 60 mg/kg by 2.0 and 2.3 days. Serum testosterone was decreased, but not significantly, at 60 mg/kg. Thus, the 31-day dosing required in the male pubertal protocol will detect thyroid hormone alterations of DE at doses as low as 3 mg/kg, while the 5 day exposure LOEL was 30 mg/kg. This data provides evidence that the 31 day alternative Tier 1 protocol is a sensitive test for thyrotoxic agents that act *via* up-regulation of hepatic metabolism. The delay in PPS and reduction in SV and VP wt may indicate a modification of endogenous androgenic stimulation directly by DE or a secondary effect that occurs in response to a DE-induced change in thyroid hormones. (Abstract does not necessarily reflect EPA policy).

660 THE EFFECTS OF DE-71, A COMMERCIAL POLYBROMINATED DIPHENYL ETHER MIXTURE, ON FEMALE PUBERTAL DEVELOPMENT AND THYROID FUNCTION.

S. C. Laws[1], J. M. Ferrell[1], J. M. Hedge[2], K. M. Crofton[2], R. L. Cooper[1] and T. E. Stoker[1]. *[1]Reprod. Toxicology. Division, NHEERL, ORD, USEPA, Research Triangle Park, NC and [2]Neurotox. Division, NHEERL, ORD, USEPA, Research Triangle Park, NC.*

PBDEs, used as flame-retardants, are persistent environmental contaminants that can alter thyroid homeostasis *via* their action on liver enzyme induction. DE-71 was used to test the sensitivity of the female pubertal protocol to detect thyroid active chemicals. This protocol is being evaluated for the USEPA's Endocrine Disruptor Screening Program as part of a Tier I Screening Battery. Wistar rats were gavaged from postnatal day (PND) 22-41 with DE-71 (0, 3, 30, 60 mg/kg) in corn oil. Females were monitored daily for vaginal opening (VO) as an assessment of pubertal development. To evaluate the temporal effects of DE-71 on serum thyroid hormones and liver microsomal EROD, PROD (ethoxy- and pentoxy-resorufin-O-deethylase) and UDPGT (uridinediphosphate-glucuronosyltransferase) activity, groups of animals were killed after 5 and 20 days of dosing. Serum total thyroxine (T4) was significantly decreased by 30 and 60 mg/kg at both time points. No significant changes were observed in triiodothyronine (T3), while a significant linear trend for increased thyroid stimulating hormone (1.6 X increase in the 60 mg/kg group) was detected in those animals exposed for 20 days. Increased liver to body weight (bw) ratios following exposure to 30 and 60 mg/kg were consistent with induction of hepatic enzymes. UDGPT activity was inducted 2.5-4 X over control. EROD and PROD activity were also induced at 30 and 60mg/kg. EROD increased 5-14 X, while PROD increased 10 and 72 X with 5 and 20-day exposures, respectively. The highest dose of DE-71 caused a small, yet statistically significant delay in the age of vaginal opening (i.e., 1.8 day delay vrs control). No treatment related changes were noted in growth, bw, or any reproductive tissue weights. In summary, these data demonstrate that this protocol will detect chemicals that alter thyroid hormone concentrations by inducing liver metabolic enzymes. This abstract does not necessarily reflect USEPA policy.

661 PERFLUOROOCTANE SULFONATE (PFOS) DISRUPTS THE THYROID STATUS IN LABORATORY RODENTS.

C. Lau, J. R. Thibodeaux, R. G. Hanson, B. E. Grey and J. M. Rogers. *Reproductive Toxicology Division, NHEERL, ORD, US Environmental Protection Agency, Research Trianlge Park, NC.*

PFOS is an environmental contaminant ubiquitously found in humans and wildlife. Reproductive and developmental toxicity of this fluorochemical have been indicated in laboratory animals. The current study examines if alterations of the thyroid status are involved in PFOS toxicity. Timed-pregnant Sprague-Dawley rats and CD-1 mice were given PFOS/K daily (1, 2, 3, 5 or 10 mg/kg, GD2-20, for rats; and 1, 5, 10, 15 or 20 mg/kg, GD1-17, for mice) by oral gavage; controls received 0.5% Tween-20 vehicle. Maternal blood was collected at three time intervals during pregnancy, serum T4, T3 and TSH were analyzed by the specific RIA. Some animals were allowed to give birth and thyroid status of the neonates was monitored during postnatal development. PFOS did not interfere with the performance of RIA. During pregnancy, a marked decline of serum T4 concentration, and to a lesser extent T3, was seen in the control rats, with a feedback elevation of serum TSH. Superimposed on these changes, T4 and T3 levels were significantly further reduced in the PFOS-treated dams in all dose groups and at all time points evaluated; while elevations of TSH were also seen in the PFOS-treated dams, the levels did not exceed those of the controls. Similar results were observed in the pregnant mice. Because the thyroid hormones fluctuate during pregnancy, these findings were extended to 90-day old non-pregnant rats who were given similar doses of PFOS daily. After 3 days of PFOS treatment, serum T4 was significantly lowered, while marked reductions of both T4 and T3 were seen after 20 days of exposure; however, an absence of feedback rise in serum TSH was noted in these animals. In the developing rats, hypothyroxinemia was observed without concurrent changes of T3 or TSH. Thus, exposure to PFOS led to disruption of thyroid status in the rats and mice; the underlying mechanisms of this hormonal imbalance as well as its physiological consequences warrant further investigation. (This abstract does not necessarily reflect EPA policy.)

662 ASSESSMENT OF THYROID MODULATING ACTIVITY AND ITS APPLICATION IN PRECLINICAL DRUG DEVELOPMENT: METHODS AND MECHANISMS.

J. L. Ambroso[1], J. Giridhar[2] and R. T. Miller[1]. *[1]Safety Assessment, GlaxoSmithKline, Research Triangle Park, NC and [2]International Nonclinical Registration-Regulatory Affairs, GlaxoSmithKline, Research Triangle Park, NC.*

Chemically diverse compounds can cause thyroid modulation (TM) by a number of direct or indirect mechanisms including alteration of thyroid hormone (TH) synthesis, secretion, distribution and biotransformation, or by modulation of tissue response. This presentation describes a decision tree approach for evaluating TM during preclinical drug development. In early toxicology studies, changes in thyroid gland weights and/or microscopic appearance suggestive of TM can be further investigated by examining serum hormone levels (TSH, T3, rT3 and T4), liver weights, and activities of TH metabolizing enzymes (such as UDP glucuronyl transferase). Alternatively, subsequent toxicology investigations can incorporate additional endpoints for evaluation of TM. Central to the decision tree approach are data from serum TH profiles, which guide the follow-up measurements. Assessment of thyroperoxidase and 5'-deiodinase activity, in light of serum hormones, allows comprehensive evaluation of TH synthesis and secretion. Assessment of serum TH carrier proteins, tissue uptake of TH, and UDP-TH conjugates leads to understanding of TH distribution and biotransformation. Assessment of tissue TH receptor (TR) expression and/or functionality further elucidates tissue TH responsiveness. In addition, routine and specialized thyroid histopathology studies, (e.g., BrdU/PCNA labeling) can provide valuable information for assessing TM. Finally, *in vitro* studies that assess drug activation of TR in transfected cells, TH-binding protein characteristics, and protein or RNA resulting from transcription of TH-responsive genes can clarify mechanism of TM. The decision tree provides a logical and comprehensive approach to addressing thyroid effects early in drug development and is useful in the design and interpretation of subsequent preclinical toxicology studies. Knowledge of species differences in the above endpoints aids in assessment of potential human risk.

663 ANALYSIS OF THYROID HORMONE AND RELATED IODINATED COMPOUNDS BY HPLC-ICP/MS.

P. A. Kosian, A. M. Cotter, S. J. Degitz and J. E. Tietge. *Mid-Continent Ecology Division, USEPA, Duluth, MN.* Sponsor: J. Nichols.

Quantifying the synthetic precursors and metabolic products of thyroid hormone is important toward understanding the effects of xenobiotics on thyroid function. Although various methods have been utilized to assess thyroid hormone status, few allow a comprehensive analysis of the suite of related iodinated compounds without the use of radiolabeled iodine. In this study, we describe the development of a high performance liquid chromatography-inductively coupled plasma/mass spectrometry (HPLC-ICP/MS) method that allows for the detection of MIT, DIT, T2, T3, rT3, and T4 in a single sample. This method has three main steps: sample preparation, chromatographic separation of analytes by HPLC, and detection of iodinated compounds by ICP/MS. Sample preparation uses a proteolytic treatment of tissue homogenates followed by analyte concentration using solid phase extraction (SPE). The eluate from the SPE step is dried and reconstituted in a known volume of buffer and introduced to an HPLC system for chromatographic separation of the analytes. The eluent from the HPLC is introduced directly to an ICP/MS operating in a time-resolve mode monitoring mass 127. The selectivity of the ICP/MS detector allows for quantification of the iodinated species only and does not detect non-iodinated chemicals that are present in a complex sample matrix. This method was validated using analytical standards and detection limits range from 70 to 150 pg as iodine. The method was applied to whole organism samples of *Xenopus laevis* larvae and document the relative concentrations of iodinated compounds in this species at specific developmental stages. This abstract does not necessarily reflect EPA policy.

663a EFFECT OF *IN UTERO* EXPOSURE TO COPLANAR PCBS ON THE THYROID HORMONE LEVELS AND LIVER MICOROSOMAL T4-UDP-GT IN THE RAT.

F. Akahori[1], K. Orito[1], M. Yamamoto[2], K. Arishima[2] and M. Shirai[1]. *[1]Department of Veterinary Pharmacology, Azabu University, Sagamihara, Kanagawa, Japan and [2]Department of Anatomy II, Azabu University, Sagamihara, Kanagawa, Japan.*
Sponsor: R. Nagata.

Both 2, 3, 7, 8-tetrachlorodibenzo-p-dioxin (TCDD) and coplanar PCBs are widely distributed, environmentally persistent organic compounds. It has repeatedly been demonstrated that these two compounds reduce circulating thyroxin (T4) levels. In this study, the effects of *in utero* exposure to two coplanar PCB congeners, PCB 126 (3, 3', 4, 4', 5-pentachlorobiphenyl) and PCB 169 (3, 3', 4, 4', 5, 5'-hexachlorobyphenyl) on the thyroid hormone status are evaluated and discussed. Sprague-Dawley rats were given, *via* gavage, PCB 126 (3 μg/kg/day), PCB 169 (30 μg/kg/day), or a corn oil compound, on days 7-21 of gestation. Later we collected specimens at a specific schedule and determined the plasma T4, thyroid stimulating hormone (TSH) levels and the liver microsomal T4-uridine diphosphate glucuronosyltransferase (UDP-GT) activities. After PCB 126 was administered to the pregnant rats, the plasma T4 levels were determined to be decreased on PND (postnatal day) 7, 42 and 105 for the male offspring and on PND 7, 21, and 105 for the female offspring. The plasma TSH values were decreased on PND 7 for the male offspring, but were unchanged for the female offspring. The liver microsomal T4-UDP GT activities were increased on PND 7 through 42 for both male and female offspring. When PCB 169 was administered parentally, the plasma T4 levels were decreased on PND 7 through 42 for the male offspring, and on PND 7 through 105 for the female offspring. The plasma TSH levels were unchanged for both male and female offspring. The liver microsomal T4-UDP GT activities were increased on PND 7 through 42 for the male offspring and on PND 7 through 105 for the female offspring. We concluded that *in utero* coplanar PCB exposure, with the specific compounds used, resulted in decreased plasma T4 levels and increased liver microsomal T4-UDP GT. The observed decrease in the T4 values may be partially attributable to the increased T4 glucuronidation by T4-UDP GT.

664 A FRAMEWORK FOR EVALUATING RELATIVE POTENCY DATA IN THE DEVELOPMENT OF TOXICITY EQUIVALENCY FACTORS (TEFS).

K. T. Connor[1] and B. L. Finley[2]. *[1]Exponent, Inc., Natick, MA and [2]Exponent, Inc., Santa Rosa, CA.*

The human health risk assessment for mixtures of polychlorinated dibenzo-*p*-dioxins (PCDDs), dibenzofurans (PCDFs), and biphenyls (PCBs) has utilized a toxicity equivalency (TEQ) scheme, centered on 2, 3, 7, 8-tetrachlorodibenzo-*p*-dioxin (TCDD), the prototypical dioxin. This scheme necessitates the development of toxicity equivalency factors (TEFs) for individual PCDD, PCDF, and PCB congeners. The importance of the TEF values is underscored by the fact that >85% of the background TEQ dose in humans is comprised of congeners other than TCDD. Yet the current international (WHO) TEFs remain order-of-magnitude estimates, largely due to the broad range of relative potencies (REPs) from which they are derived. The WHO TEF Workgroup addressed this issue by applying an *ad hoc* REP weighting scheme. However, we have observed considerable inconsistencies in the selection of TEFs from among the 28 PCDD/F and PCB congeners that were included in the WHO analysis. We propose a framework for a systematic evaluation of REP data, which could be used to support a REP weighting scheme based on data quality. Such a framework could enhance the development of probability density functions (PDFs) for the TEFs. This approach would retain a large degree of the heterogeneity of the REP data, but would also rank these data based on reliability and relevance. Relevance is based on the eventual use of TEFs in the human health risk assessment with cancer as the endpoint. Rating schemes are proposed for 16 and 10 methodological criteria that were identified as key elements of the *in vivo* and *in vitro* REP studies, respectively. We also propose criteria for converting cumulative scores into a simplified quality score (1 to 5), in accordance with Klimisch et al. (1997; Regul. Toxicol. Pharmacology 25(1):1-5.), which has been widely applied to the evaluation of other toxicology data. The use of this framework for evaluating REP data could advance the uniform development of TEFs for a growing list of chemical families.

665 A SCREENING-LEVEL RISK ASSESSMENT APPROACH FOR EVALUATING INTERACTIONS IN CHEMICAL MIXTURES.

K. Price and K. Krishnan. *Occupational and Environmental Health, Universite de Montreal, Montreal, QC, Canada.*

The conventional risk assessment approach for chemical mixtures involves the calculation of hazard index (HI) without accounting for the possible impact of interactions between components. Some interactions can modify the tissue dose of components, resulting in a change in the health risk during mixed exposures compared to single exposures. Given that metabolic interference is a common mechanism by which chemicals interact, this study developed an approach for screening and identifying mixtures that are of health concern due to the impact of metabolic inhibition. The methodology involved: (i) the establishment of the tissue dose corresponding to the threshold limit value (TLV) of each of the mixture components, (ii) the calculation of the maximal tissue dose of each component that can possibly result during mixed exposures, and (iii) the calculation of tissue dose-based HI by dividing the maximal tissue dose of components by the values corresponding to their TLVs. Whenever the resulting tissue dose-based HI values exceed 1, it indicates a mixture exposure scenario of health risk concern. The proposed screening level risk assessment method was applied to mixtures of varying concentrations of toluene, m-xylene and ethylbenzene (1 to 90 ppm). The maximal value of tissue dose (i.e., area under the blood concentration vs time curve) for each of these chemicals was calculated using physiologically-based pharmacokinetic models in which the hepatic extraction ratio value was set to 0. For inhalation exposures of 1 to 90 ppm, the corresponding maximal tissue doses were 0.06 and 2.35 mg/L for toluene, 0.11 and 10.3 mg/L for m-xylene, and 0.12 to 10.9 mg/L for ethyl benzene. These maximal tissue doses were then used along with the tissue dose associated with the TLV of each compound to calculate HI and thereby identify those mixtures that could be of concern, due to metabolic interactions. The approach developed in this study, for the first time, facilitates the calculation of HI of mixtures by accounting for the maximal influence of metabolic interactions on tissue dose.

666 STATISTICAL ANALYSIS OF AN INTERACTION THRESHOLD IN CHEMICAL MIXTURES ALONG A FIXED-RATIO RAY.

A. K. Hamm[1], C. Gennings[1], H. Carter[1], K. Liao[2] and R. S. Yang[2]. *[1]Biostatistics, Virginia Commonwealth University, MCV Campus, Richmond, VA and [2]Quantitative and Computational Toxicology Group, Center for Environmental Toxicology and Technology, Colorado State University, Fort Collins, CO.*

Humans are exposed to a variety of chemicals on a daily basis, thus mixture toxicology is an important and relevant issue. Risk assessors often assume additivity at low concentrations of mixture exposures. Recent studies on complex mixtures have revealed interaction thresholds in chemical mixtures through physiologically based pharmacokinetic (PBPK) modeling. We propose the use of empirical models to detect the presence of an interaction threshold along a fixed-ratio ray of the chemicals under study. Our approach is illustrated using a cytotoxicity study involving three metals (arsenic, chromium, lead) and Syrian Hamster Embryonic (SHE) cells. The fixed-ratio ray under study was chosen based on the LC50's of each metal estimated from individual metal studies. This corresponds to a fixed ratio of (5.4:3.6:100.0) As:Cr:Pb, or approximately (0.05:0.033:0.917) As:Cr:Pb. Total concentrations are taken along this fixed-ratio ray by specific dilution of the reference concentration, 1X, which represents the combination of 5.4 μM As, 3.6 μM Cr, and 100 μM Pb. Initial tests for overall departure from additivity along the ray were significant. Therefore, the interaction threshold model is used to detect the presence of a concentration where significant interactions start to occur. An interaction threshold was found to exist at approximately 7.9 mM total concentration. However, the model parameter was not significant. This could be due to the design of the experiment. Since design points were considered according to dilutions, there are "gaps" in the design that could influence the parameter estimates. Based on this initial model, Ds-optimal designs are presented that would minimize the variance of the interaction threshold parameter. (Supported by ATSDR U61/ATU 881475 and NIEHS T32-ES07334-01A1)

667 DO 'ESTROGEN EQUIVALENTS' MAKE SENSE FOR RISK ASSESSMENT?

C. J. Borgert[1,2], R. J. Witorsch[3] and L. S. McCarty[4]. *[1]Applied Pharmacology and Toxicology, Inc., Alachua, FL, [2]Department Physiological Sciences, University FL College of Veterinary Medicine, Gainesville, FL, [3]Department Physiology, Medical College of Virginia, Virginia Commonwealth University, Richmond, VA and [4]L.S. McCarty Scientific Research & Consulting, Markham, ON, Canada.*

Toxicity Equivalence Factors (TEFs) have been used to assess Ah-receptor-mediated toxicity and have been proposed for other modes of action, including toxicity mediated through estrogenic mechanisms. Applying an equivalence factor approach depends on the validity of a number of assumptions, including that 1) chemicals act through the same biochemical pathway, 2) have parallel dose-response curves, 3) exhibit dose-additive toxicity at sub-maximal doses in mixtures, 4) manifest identical toxic effects over the dose range of concern, and 5) that potency can be related to a reference chemical. Two assumptions necessary for applying an equivalence factor approach - dose additivity in mixtures and an unambiguous potency estimate relative to a reference chemical - were evaluated based on data published in more than 40 reports on binary combinations of putative estrogenic chemicals and in numerous other publications that reported estrogenic potencies at molecular and

physiological endpoints for various chemicals. Neither assumption appears to be supportable on the basis of the data analyzed. Although application of published criteria for evaluating interaction studies reveal fundamental inadequacies in many studies that purport to test combined estrogenic action, the assumption of dose additive combined toxicity does not appear to be supportable. Wide variations in estrogenic potency measurements preclude the derivation of single estrogenic potency estimates relative to a reference chemical. The inability to find support for these two fundamental assumptions argues strongly that an estrogenic equivalence approach is inappropriate for risk assessment of environmental estrogens. Alternative approaches will be required if mode-of-action assessments are to be made for mixtures of xenoestrogens.

668 CRITICAL REVIEW OF PRINCIPLES, PRACTICE AND TOXICOLOGY OF CHEMICAL MIXTURES: IMPLICATIONS FOR RISK ASSESSMENT.

L. S. McCarty[3] and C. J. Borgert[2,1]. *[1]Applied Pharmacology and Toxicology, Inc., Alachua, FL, [2]L.S. McCarty Scientific Research & Consulting, Markham, ON, Canada and [3]Physiological Sciences, University FL College of Veterinary Medicine, Gainesville, FL.*

A critical analysis of mixture theory and practice was conducted by examining reference texts, regulatory documents and journal articles investigating mixtures of one or more chlorinated chemicals. The objective was a judgement about the suitability of proposed regulatory risk assessment procedures given the current understanding of mixture toxicology. Recent guidance documents by ATSDR and EPA recommend using three different types of data for health risk assessment of chemical mixtures. When data on a particular mixture is unavailable, data on a similar mixture may be extrapolated to the scenario of concern. For some mixtures, the presence of only a few prominent constituents may be used to conclude similarity while for other mixtures, similarity may be assumed from a common toxicological effect or a presumed similar toxic mechanism. However, clear criteria are yet to be developed for determining when two mixtures are sufficiently similar to use one as a toxicological surrogate for the other. In particular, there is no generally accepted classification scheme for modes/mechanisms of toxic action. This is a prerequisite for judging whether two mixtures exert effects *via* a common toxicological pathway. Furthermore, it is currently not possible to reasonably predict toxicity interactions mechanistically because no methodology exists for classifying the mechanisms by which interactions occur. Current approaches do not account for the dose dependence of mechanisms of toxicity interaction because data from interaction studies that test a full dose-response range are unavailable (i.e., doses above and below the observed effect levels of individual chemical constituents. We argue the need to develop a mode/mechanism of toxicity classification scheme as well as a mechanism of toxicity interaction classification scheme in order to advance mixtures research in a way that will be useful for mixtures risk assessment and policy development.

669 TOXICITY ASSESSMENT OF COMPLEX MIXTURES REMAINS A GOAL.

K. Donnelly[1], E. Castiglioni[1], K. Ramos[1] and M. Mumtaz[2]. *[1], Texas A&M University, College Station, TX and [2]ATSDR, Atlanta, GA.*

One of the initial steps in remediating contaminated environments is to assess the human and ecological health risk associated with exposure to contaminants in a specific medium. This abstract summarizes the results of a five-year study investigating the toxicity of simple and complex mixtures. A series of model compounds and simple mixtures including polycyclic aromatic hydrocarbon (PAHs), pentachlorophenol (PCP), and halogenated aliphatic hydrocarbons (HAH) were analyzed. Mixture toxicity was studied using microbial genotoxicity assays and cytotoxicity assays using renal and neural cells. The majority of simple mixtures studied induced additive responses. A limited number of samples were identified where binary mixtures induced inhibitory effects. For example, benzo(a)pyrene (BAP) alone induced 30% renal cell death, whereas an equimolar dose of chrysene and BAP only produced 1.6% cellular death. In none of the mixtures tested did the mixture toxicity results deviate from the predicted results by an order of magnitude. Thus, the results from testing simple mixtures indicate that the results did not deviate significantly from additivity. Complex mixture results were more difficult to interpret. The toxicity of complex mixtures could not be accurately predicted based on chemical analysis. This could be due to chemical interactions or due to the presence of unidentified chemicals, such as alkyl PAHs or high molecular weight PAHs, that were not included in the risk assessment procedure. Even though the results from these *in vitro* studies indicate that additive assumptions will generally be accurate for simple mixtures, the risk associated with complex mixtures is more difficult to predict. Before the results of toxicity testing can be used to adjust risk assessment calculations, it is important to understand the mechanism of observed chemical interactions in animals chronically exposed to low doses of chemical mixtures. This research was supported by ATSDR Grant No. ATU684505.

670 ASSESSMENT OF WEIGHT-OF-EVIDENCE METHOD USING MIXTURES OF BENZENE, LEAD, METHYL MERCURY, AND TCE.

M. M. Mumtaz[1], H. A. El-Masri[1], C. T. De Rosa[1], D. B. Moffett[1], P. Durkin[2], E. D. Schoen[3], D. Jonker[3], J. P. Groten[3] and J. A. van Zorge[4]. *[1]ATSDR/CDC, Atlanta, GA, [2]SERA Inc., Syracuse, NY, [3]Nutrition and Food Research, TNO, Zeist, Netherlands and [4]Ministry of Environment and Spatial Planning, The Hague, Netherlands.*

A prospective *in vivo* study was conducted to evaluate a weight-of-evidence (WOE) method for assessing the joint toxicity of chemical mixtures. This methodology was used to predict interactions in liver, kidney, spleen, lymphocytes and hemoglobin. Groups of 5 rats were gavaged for 17 days with individual chemicals or their mixtures at mg/kg doses of benzene (200 or 400), lead [Pb] (50 or 100), methyl mercury [Hg] (0.25 or 0.75), and TCE (500 or 1, 500). Interactions were analyzed using both linear and quadratic models. For the kidney weight, less than additive statistically significant ($p=0.05$) interactions were observed for Hg and TCE that were consistent with the WOE methodology predictions. As predicted for the kidney, more than additive effects of Pb and benzene and less than additive effects of Pb and TCE based on response surface analysis (RSA) were observed, but the interactions were statistically insignificant. Contrary to prediction, no statistically significant interactions were observed in the kidney between Hg and Pb or between benzene and Hg. For the liver weight, the predicted less than additive interactions of Pb and TCE were observed with marginal significance ($p=0.08$). For the spleen weight, synergism was predicted for benzene and TCE, but the observations were statistically insignificant. Less than additive effects of Pb and TCE were observed to be significant ($p=0.001$). For the red blood cells, synergism between Hg and benzene, predicted based on the WOE method, was observed with marginal significance ($p=0.092$). For lymphocytes, antagonism was predicted for the mixtures of benzene with Pb or Hg, but were not significant. Only one of the RSA coefficients (TCE/Hg) was statistically significant ($p<0.05$), and it was found to be consistent with the WOE prediction. The WOE method appeared to be generally consistent with significant and marginally significant interactions.

671 HEPATOTOXICITY OF CHLOROFORM, ALLYL ALCOHOL, AND TRICHLOROETHYLENE TERNARY MIXTURE IS LESS THAN ADDITIVE.

S. S. Anand[1], V. S. Vaidya[1], B. Murali[1], M. M. Mumtaz[2] and H. M. Mehendale[1]. *[1]Department.of Toxicology, College of Pharmacy, The University of Louisiana at Monroe, Monroe, LA and [2]ATSDR, CDC, Atlanta, LA.*

Unusual toxicity from exposure to complex mixtures is a concern in public health. The role of interactions was studied in the hepatotoxicity of a ternary mixture (TM) of chloroform ($CHCl_3$), trichloroethylene (TCE), and allyl alcohol(AA). Male S-D rats (250-300 g) received single ip injection of 5-fold dose range of $CHCl_3$ (74 to 370 mg/kg), TCE (250 to 1250 mg/kg) in corn oil and 7-fold dose range of AA (5 to 35 mg/kg) in distilled water simultaneously. Liver injury was assessed by plasma ALT activity, and tissue repair by ^{3}H-thymidine incorporation into hepatonuclear DNA. Parent compounds and two major metabolites of TCE [trichloroacetic acid (TCA) and trichloroethanol (TCOH)] were quantified by GC. Blood and liver $CHCl_3$ and AA levels after TM administration were similar to $CHCl_3$ or AA alone. However, the TCE levels in blood and liver were substantially lower after TM administration. Decreased TCE levels were consistent with decreased production of metabolites and its elevated urinary excretion. The antagonistic interaction resulted in less than additive joint hepatotoxicity. However, tissue repair was unaffected and showed a dose-response leading to regression of injury explaining the lack of dose-response for injury. Although the liver injury was lower and progression was compensated by timely tissue repair, 50% mortality occurred at the highest mixture concentration. This could be due to CNS toxicity. Studies are underway to investigate the cause of death. Since the mortality occurred only at highest combination and there was no interaction at lower combinations, the present study supports the additivity assumption used in risk assessment of chemical mixtures for short-term exposures to defined mixtures. In addition, these data underscore the critical role of tissue repair in the outcome of liver injury. However, the role of interactions following multiple exposures to complex mixtures in toxicity outcome remains unknown (supported by ATSDR U61/ATD 681482).

672 EVALUATION OF MODE OF ACTION IN ASSESSMENT OF CANCER RISK ASSOCIATED WITH EXPOSURE TO 1, 4-DICHLOROBENZENE.

M. Odin, S. Bosch, M. Osier and P. McGinnis. *Environmental Science Center, Syracuse Research Corp, Syracuse, NY.*

1, 4-Dichlorobenzene (1, 4-DCB) has been shown to produce renal tubular cell adenomas in male F344 rats and hepatocellular adenomas and carcinomas in male and female B6C3F1 mice following chronic oral exposure. Inhalation studies found

no tumors in rats or mice, but were inadequate as cancer bioassays due to less than lifetime exposure duration and failure to achieve the maximum tolerated dose. Several lines of evidence indicate that the renal tumors in male rats are a consequence of 2 -globulin nephropathy, a male-rat specific condition that is not predictive of carcinogenicity in humans. The mode of action by which 1, 4-DCB produces mouse liver tumors is uncertain. Genotoxicity data for 1, 4-DCB are primarily negative. Evidence for a non-genotoxic mechanism is mixed. Several studies have found that 1, 4-DCB produces a mitogenic response in mouse liver. A sustained proliferative response to damage produced by 1, 4-DCB in the liver is a plausible mode of action for induction of liver tumors by this compound. In the cancer bioassay, liver tumors were found only at dose levels at which hepatotoxicity was also observed. However, the evidence for this mode of action is incomplete. Several studies observed no liver damage at doses that produce proliferative responses. Other studies found that the mitogenic effect is not sustained with long-term exposure, and that the effect is similar in rats, which do not develop liver tumors, and mice, which do. Hyperplasia was not among the hepatic effects associated with 1, 4-DCB exposure in the mouse cancer bioassay. Under EPA's proposed cancer guidelines, a chemical such as 1, 4-DCB with a plausible, but not fully established, nonlinear mode of action can be assessed using both linear and nonlinear dose-response approaches. The oral slope factor derived using the default linear dose-response methodology was compared with the results of the non-linear margin of exposure analysis. The results show how information regarding mode of action can influence the risk assessment of chemical carcinogens.

673 A THRESHOLD LINKAGE BETWEEN CHLOROFORM-INDUCED CELLULAR DAMAGE AND CYTOLETHALITY PROVIDES A BETTER FIT TO HEPATIC LABELING INDEX DATA THAN A LINEAR LINKAGE.

Y. Tan[1], B. Butterworth[2] and R. Conolly[1]. *[1]CIIT Centers for Health Research, Research Triangle Park, NC and [2]Butterworth Consulting, Raleigh, NC.*

Chloroform is carcinogenic to rat kidney and mouse liver and kidney in a manner dependent on dose, route of administration, gender, and animal model. Extensive experimental evidence indicates that tumor induction is secondary to events associated with toxicity and regenerative cell proliferation rather than to direct genotoxicity. In this study, a mode of action-based model was used to evaluate alternative dose-response linkages between chloroform-induced cellular damage and cytolethality. An established PBPK model for chloroform was extended as follows. Cellular damage is created at a rate proportional to the rate of chloroform metabolism. A saturable repair process removes the damage. The cellular death rate is a function of the amount of damage. A mechanism is described whereby the cell division rate increases to replace cells lost due to cytolethality, allowing for simulation of the labeling index (LI). LI data from a chloroform inhalation $C \times t$ (concentration $\times$ time) study in female B6C3F1 mice were simulated (Constan et al., Toxicol. Sciences. 66, 201-208, 2002). Two alternative linkages between damage and death rate were evaluated: threshold and low-dose linear. After formal optimization of parameter values, the log-likelihood ratios of the two models were compared. A X^2 statistic test showed that the threshold model provided a better fit to the data than the linear model at the $\alpha = 0.01$ significance level (df = 1). This result shows that dose-response data for chloroform-induced cytolethality in female B6C3F1 mice are preferentially described by a threshold model. Thresholds are generally thought to exist for chemically-induced cytotoxicity. The model described here thus appears relevant in the development of a mode of action-based human cancer risk assessment for chloroform.

674 NONMONOTONIC DOSE-RESPONSE RELATIONSHIPS: MECHANISTIC BASIS, KINETIC MODELING, AND IMPLICATIONS FOR RISK ASSESSMENT.

W. K. Lutz[1], D. W. Gaylor[2] and R. B. Conolly[3]. *[1]Toxicology, University of Wurzburg, Wurzburg, Germany, [2]Sciences International, Inc., Little Rock, AR and [3]CIIT Centers for Health Research, Research Triangle Park, NC.*

Dose-response curves for first-line interactions of a chemical with a biochemical target molecule are usually monotonic. However, for reactions of a complex biological system to a toxicant, nonmonotonic dose-effect relationships can be observed. This phenomenon has been accepted for a number of pharmacological examples, but is met with skepticism in toxicology, because it could mean that low dose of a high-dose toxicant may have beneficial effects. We present four examples to demonstrate that non-monotonic dose-response relationships can result from superimposition of monotonic dose responses of component biological reactions. Examples include (i) a membrane receptor model with receptor subtypes of different ligand affinity and opposing downstream effects (adenosine receptors A1 vs. A2), (ii) androgen receptor-mediated gene expression driven by homodimers, but not heterodimers formed with an exogenous ligand, (iii) repair of background DNA damage by enzymatic activity induced by adducts formed by a xenobiotic, (iv) rate of cell division modulated by cell-cycle delay at low-level DNA damage vs. cell-cycle acceleration due to regenerative hyperplasia at cytotoxic dose levels. Quantitative analyses based on biological models and physiological kinetics will be shown, with particular emphasis on the critical factors that determine the degree of nonmonotonicity. Statistical analysis indicates that continuous data are better suited than quantal data for the investigation of the low-dose part of the curve and that the higher the background effect level, the smaller the sample size required to detect significant nonmonotonicity. It is important to note that weakly nonmonotonic dose-response curves can be misinterpreted as being thresholded. Our analysis should promote a scientific discussion of a concept termed "hormesis", and encourage reconsideration of default procedures for low-dose extrapolation in toxicological risk assessment.

675 A RISK ASSESSMENT FOR INHALED ARSENIC BASED ON URINARY ARSENIC CONCENTRATION USING A PHARMACOKINETIC MODEL.

H. Clewell[1], K. Crump[1], T. Covington[1], R. Gentry[1] and J. Yager[2]. *[1]ENVIRON, Ruston, LA and [2]EPRI, Palo Alto, CA.*

Several epidemiological studies of copper smelter workers have demonstrated an association between inhalation exposure to arsenic in dust and increased lung cancer mortality. However, the nature of the dose-response relationship for the carcinogenicity of inhaled arsenic remains a matter of controversy. In particular, the dose-response from a study of workers at a copper smelter in Tacoma, Washington, was reported to be nonlinear, with a potency that decreased with increasing arsenic exposure. We considered it possible that this apparent nonlinearity was due to the impact of differences in particle size distribution and personal protective equipment use on arsenic bioavailability at high versus low dust levels In order to avoid the uncertainties associated with predicting the relationship between airborne dust burden and the bioavailable dose of arsenic, we have evaluated the dose-response relationship between lung cancer mortality and urinary arsenic concentrations in three published studies of workers at the Tacoma, Washington, smelter. In contrast with the nonlinear dose-response relationship reported for lung cancer and airborne arsenic, the dose-response relationship for lung cancer and urine concentration was found to be linear. A physiologically based pharmacokinetic (PBPK) model of arsenic was then used to estimate the urinary arsenic concentration associated with a given airborne arsenic concentration and particle size distribution. Risk estimates for environmental exposure were in the same range as the current EPA inhalation risk estimates in IRIS. However, the use of the PBPK approach makes it possible to incorporate empirical data on the bioavailability of arsenic for specific exposures of concern. As an example, use of data on the relative bioavailability of arsenic in fly ash as compared to copper smelter dust resulted in risk estimates for inhalation of arsenic in fly ash dust several fold lower than those obtained with the default EPA inhalation slope factor.

676 ESTIMATION OF METHYLMERCURY EXPOSURES IN US WOMEN OF CHILD-BEARING AGE USING MARKOV CHAIN MONTE CARLO ANALYSIS WITH A PHYSIOLOGICALLY BASED PHARMACOKINETIC MODEL.

B. Allen[1], H. Clewell[1], E. Hack[1], K. Crump[1] and J. Yager[2]. *[1]ENVIRON, Ruston, LA and [2]EPRI, Palo Alto, CA.*

A Bayesian approach known as Markov Chain Monte Carlo (MCMC) analysis was applied, together with a physiologically based pharmacokinetic (PBPK) model of methylmercury (MeHg), to evaluate the variability of MeHg exposure in the US population. The analysis made use of the newly available National Health and Nutrition Survey (NHANES) blood and hair mercury concentration data for women of childbearing age (16-49 years). Bayesian analysis was performed to estimate the population variability in MeHg exposure (daily ingestion rate) implied by the variation in blood and hair concentrations of mercury in the NHANES database. The measured variability in the NHANES blood and hair data represents the result of a process that includes inter-individual variation in exposure to MeHg and interindividual variation in the pharmacokinetics (distribution, clearance) of MeHg. The PBPK model includes a number of pharmacokinetic parameters (e.g., tissue volumes, partition coefficients, rate constants for metabolism and elimination) that can be varied from individual to individual within the subpopulations of interest. Using MCMC, it was possible to combine prior distributions of the PBPK model parameters with the NHANES blood and hair data, as well as with kinetic data from controlled human exposures, to MeHg, to derive posterior distributions that refine the estimates of both the population exposure distribution and the pharmacokinetic parameters. In general, the results of the MCMC analysis indicate that

a small fraction, on the order of ten percent, of the US population of women of child-bearing age may have mercury exposures greater than the EPA Reference Dose for MeHg of 0.1 micrograms per kilogram per day, and that a few percent may have exposures greater than the ATSDR MRL of 0.3 micrograms per kilogram per day. However, the predicted exposure distribution was sensitive to some assumptions and decisions made with regard to the formulation of the MCMC analysis.

677 FURTHER DEVELOPMENT OF A PBPK MODEL FOR GASOLINE USING A CHEMICAL LUMPING APPROACH.

J. E. Dennison[1], I. D. Dobrev[1], M. M. Mumtaz[2], M. E. Andersen[3] and R. S. Yang[1]. *[1]Center for Environmental Toxicology and Technology, Colorado State, Ft Collins, CO, [2]Agency for Toxic Substances and Disease Registry, Atlanta, GA and [3]Centers for Health Research, Research Triangle Park, NC.*

Gasoline consists of a few toxicologically significant components and a large number of other chemicals in a complex mixture. We have developed a method for assessing the pharmacokinetics (PKs) of selected target components (benzene, toluene, ethyl benzene, o-xylene (BTEX) and n-hexane) in gasoline by conducting gas uptake PK studies and physiologically based PK (PBPK) modeling of whole gasoline in rats. The PBPK model tracks a lumped chemical group representing all non target components, and includes competitive metabolic inhibition between all target compounds and the lumped chemicals. Gas uptake studies were performed with male F344 rats in a closed chamber, fitted with a metal ring and oxygen and CO_2 probes. NaOH scrubber solution did not adequately control CO_2 levels, increasing the rat's breathing rate, but solid Baralyme adsorbents did. Chamber air samples were analyzed every 10-20 minutes by gas chromatography/flame ionization detection and all non target chemicals were co-integrated. A 4-compartment PBPK model for gasoline was constructed using the BTEX, n-hexane, and the lumped chemical data. Estimates of kinetic parameters for target chemicals were refined by studies with either the single chemical or all five chemicals together. When o-xylene was present at high levels, alveolar ventilation decreased, consistent with respiratory irritation. A six-chemical model with the lumped chemical group was used to estimate lumped chemical parameters for a winter blend of gasoline with methyl t-butyl ether and a summer blend without oxygenate. Our model adequately simulated the data for all chemicals. The preliminary model indicated that total metabolism of components would be reduced by 4%-27% for a six hour exposure to 300 ppm gasoline. [Supported in part by a Cooperative Agreement from ATSDR (U61/ATU 881475) and the NIEHS Quantitative Toxicology Training Grant T32 ES07321].

678 IDENTIFICATION OF GASOLINE-RELATED AIR POLLUTANTS WITH HIGH EXPOSURE POTENTIAL AND/OR TOXICOLOGICAL CONCERN.

S. M. Hoover, E. W. Fanning, M. K. MacGregor and M. S. Sandy. *OEHHA, Cal/EPA, Oakland, CA.*

A baseline assessment of cancer and chronic respiratory health risks in California that can be attributed to air pollution resulting from the use of gasoline is being conducted. The assessment focuses on the period from 1996 to 1998, when California Reformulated Gasoline 2 (CaRFG2) was first introduced. This presentation reports on the results of the hazard identification component of the assessment. Because adequate health effects data on gasoline-related mixtures (e.g., gasoline engine exhaust) were unavailable, the assessment focused on the individual components of gasoline-related air pollution. Speciation profiles of gasoline-related sources generated by the California Air Resources Board were used to identify gaseous organic pollutants. Literature reports on the atmospheric chemistry of these emitted substances were reviewed to identify additional pollutants likely to be present in ambient air as breakdown products. Criteria air pollutants emitted from gasoline-related sources were also identified. The list of more than 300 gasoline-related substances was then screened for exposure potential and toxicological concern. The non-methane organic gas-phase pollutants with the highest primary emissions, a surrogate for exposure potential, were identified. Some of these high emitters were also recognized as carcinogens or respiratory toxicants. Toxicology data were unavailable for the majority of the gasoline-related substances. Using the limited toxicology database, gasoline-related substances having the potential to cause cancer or chronic respiratory toxicity were identified. The results of the hazard identification indicated that 49 gasoline-related substances had high exposure potential and/or toxicological concern. Of these, 14 substances were identified as carcinogens, 17 as recognized chronic respiratory toxicants, and 17 as suspected chronic respiratory toxicants.

679 APPLICATION OF A PHYSIOLOGICALLY-BASED PHARMACOKINETIC (PBPK) MODEL TO THE CALCULATION OF A REFERENCE CONCENTRATION (RfC) FOR XYLENES.

M. Osier and P. McClure. *Environmental Science Center, Syracuse Research Corp, Syracuse, NY.*

Physiologically-based pharmacokinetic (PBPK) models for inhalation exposure to xylene have been developed for both rats and humans. These models consist of five tissue compartments, representing the lung, adipose, liver/metabolism, slowly-perfused tissues, and richly-perfused tissues, and predict concentration in the tissue components, arterial blood, and venous blood. Based on a duration-adjusted NOAEL for neurological effects identified by a subchronic study in rats, several approaches for calculation of a human equivalent concentration (HEC), to be used in the calculation of an RfC, are being considered. The default approach for calculation of a HEC for a category 3 gas, based on USEPA's 1994 RfC guidelines, would be to calculate the HEC using the ratio of the blood-gas partition coefficients for the animal species and humans to adjust the duration-adjusted NOAEL. An alternate approach involves application of the PBPK model to calculate the HEC. The duration-adjusted NOAEL from the rat experimental data was used as the exposure concentration for the PBPK model, and pooled venous blood concentration was predicted; venous blood concentration was used as the dose metric (because validation experiments in rats and humans were most often performed using measurements of venous blood). The concentration in the venous blood at steady state (which occurred at ~20 hours for the rat) was used in the human model to calculate an airborne concentration of xylene that would result in the same venous blood concentration following continuous exposure. Calculation of RfCs using the two approaches result in similar numerical values. A discussion of the areas of uncertainty using each approach, and other possible approaches to reducing uncertainty in the RfC, is provided. (This document does not necessarily reflect EPA policy)

680 A CADMIUM PHARMACOKINETICS/PHARMACODYNAMICS (PKPD) MODEL FOR USE IN RISK ASSESSMENT.

G. L. Diamond[1], H. Choudhury[2] and W. C. Thayer[1]. *[1]Environmental Science Center, Syracuse Research Corp, Syracuse, NY and [2]USEPA, National Center for Environmental Assessment, Cincinnati, OH.*

Risks of kidney toxicity in humans exposed to cadmium from the ingestion pathway can be estimated using a PKPD model. The model was used to interconvert external and internal cadmium dose estimates from epidemiological studies, allowing direct comparison of dose-response relationships across studies that might otherwise be incomparable. Based on estimates from 15 epidemiological studies of diverse exposures (occupational, general environmental, environmental contamination), the median kidney cadmium level associated with a 0.1 probability (K10) of low molecular weight proteinuria was predicted to be 108 μg Cd/g renal cortex (95% confidence limits: 70-240). The model predicted that the lower confidence limit on the K10 (K10L, 70 μg Cd/g cortex) would be reached at age 55 years (the age at which kidney cadmium levels are predicted to peak) with a constant chronic intake of 1.1 μg/kg/day in females or 2.5 μg/kg/day in males. A lower cadmium intake in females is predicted to result in a similar kidney cadmium level as in males because females were assumed to absorb a larger fraction (10% vs 5%) of an ingested cadmium dose (Choudhury et al., 2001). The K10L exceeded the peak kidney cadmium level (at age 55 years) predicted to result from the average dietary intake of cadmium in US non-smokers (28 μg Cd/g cortex in female, 14 μg Cd/g cortex in males), and also exceeded the 95th percentile kidney cadmium levels predicted to result from dietary intakes in the US (43 μg Cd/g cortex in females or 23 μg/g cortex in males). That these values are lower than the K10L, suggests that, for most of the US population, risks of kidney toxicity from dietary intake of cadmium are negligible. (Views expressed in this report are those of the authors and do not necessarily represent the views or policies of the USEPA.)

681 THE CONCEPT OF BENCHMARK INTERNAL CONCENTRATION (BMIC) IN RISK ASSESSMENT.

D. W. Gaylor[2], J. A. Moore[3] and J. L. Butenhoff[1]. *[1]3M, Saint Paul, MN, [2]Gaylor and Associates, LLC, Little Rock, AR and [3]Hollyhouse, Inc., Arlington, VA.*

The concept of the benchmark internal concentration (BMIC) is presented as an appropriate alternative to derive risk-screening levels for chemicals which express toxicity that can be related to internal concentrations of the parent compound or a metabolite in body tissues or fluids. In certain cases, internal concentration of an agent may be more directly related to hazard and risk than measured or estimated external dose or exposure concentration. The authors illustrate this concept using data from toxicological studies of a non-metabolizable, poorly-eliminated compound that expresses cumulative toxicity, perfluorooctanesulfonate (PFOS). PFOS

has been found widely distributed in serum and liver samples from human and wildlife populations. Although the major producer (3M) has largely phased-out production, exposure to PFOS may have come from a variety of sources including its use as a surfactant, or through degradation of related chemistries that have been used in wide variety of commercial and consumer applications. This fact makes estimating external exposure for risk assessment problematic. Serum and liver PFOS concentrations represent an integration of exposures over time and can be directly related to toxicity. Most toxicology studies of PFOS have included evaluation of serum and liver tissue PFOS concentrations. The relationship of effect to external dose versus serum or liver PFOS concentration in toxicology studies suggest that toxicity is more a function of cumulative body burden than magnitude of external dose. In this illustration, benchmark doses from a variety of PFOS toxicology studies were calculated based on external dose-response, and corresponding BMICs were calculated based on the relationship of serum or liver PFOS concentration to effect. The BMIC provides a risk-based means of assessing margin of exposure based on population monitoring data.

682 ABSORPTION, DISTRIBUTION AND CLEARANCE OF 2, 6-DI-*TERT*-BUTYL-4-NITROPHENOL (DBNP), A SUBMARINE ATMOSPHERIC CONTAMINANT.

K. R. Still[1], G. D. Ritchie[2], A. E. Jung[2], R. J. Godfrey[3] and G. B. Briggs[2]. *[1]Toxicology Detachment, Naval Health Research Center, Wright-Patterson AFB, OH, [2]Geo-Centers, Inc., Wright-Patterson AFB, OH and [3]Man-Tech Environmental, Wright-Patterson AFB, OH.*

The nitrophenol, 2, 6-di-tert-butyl-4-nitrophenol (DBNP), is a submarine atmospheric contaminant. DBNP is produced when atmospheric oil mist from synthetic turbine lubricants containing the antioxidant additive 2, 6-di-tert-butylphenol (DNP) is nitrated during passage through the air filtration system. Submarine personnel can be exposed to DBNP for periods up to 6 months 24 hours a day during missions. While dermal or respiratory exposure may provide little human risk due to the minimal solubility of DBNP, there is a possible risk from the oral ingestion of the compound. For this reason, the present study measured the absorption, distribution and clearance of radiolabeled DBNP in rats following a single oral gavage exposure (in a 99.2% canola oil:0.8% DMSO vehicle). Sets of 16 rats were given a single oral dose of vehicle, 15, or 40 mg/kg DBNP. Two rats per dose were sacrificed daily from 1-11 days following the single exposure. Nine different tissue samples, as well as blood, urine, and feces, were collected for subsequent scintillation counting. It was clearly demonstrated that these doses of DBNP are readily absorbed from the gastrointestinal tract and differentially distributed to a wide range of tissues based upon their lipid content. The clearance of DBNP following oral ingestion involves a complex pattern where approximately 30% is excreted as the parent compound and the remaining 70% being absorbed from the GI tract into the blood. It is then metabolized to a glucuronide conjugate and eliminated through the urine and bile. DBNP has generally been eliminated from the body within 72-96 hours post exposure and is primarily cleared through the feces within 4 days. Because DBNP is deposed in various organ compartments for up to 96 hr, the possibility of significant organ accumulation in repeatedly exposed personnel must be considered in risk assessment.

683 EVALUATION OF THE GENOTOXIC POTENTIAL OF STYRENE.

E. R. Nestmann and B. Lynch. *Cantox Health Sciences Inc., Mississauga, ON, Canada.*

Styrene is a widely used monomer in the plastics industry. There has been considerable attention and scientific debate regarding the potential genotoxic effects in workers occupationally exposed to styrene. The genotoxicity of styrene in *in vitro* and *in vivo* assays was studied. Clastogenic effects in the peripheral blood lymphocytes of styrene-exposed workers were also evaluated. Styrene, *via* metabolism to styrene-7, 8-oxide (SO), is clastogenic *in vitro* and may have clastogenic activity *in vivo* at near lethal, exposures administered by i.p. injection. The results of *in vivo* studies demonstrated that inhalation exposure to styrene results in the formation of SO-associated DNA adducts; however, there was no indication of a genotoxic effect. The results of the human lymphocyte studies were difficult to interpret given that: the statistical significance of the observed effects was often marginal; dose- and/or temporal response relationships often were missing; confounding variables could not be excluded; and, concomitant exposures to other chemicals may also have occurred. No definitive causal relationships could be drawn from the study of lymphocytes from styrene-exposed workers. Overall, the cytogenetic studies in occupationally exposed persons were inconclusive. Analysis of the blood lymphocytes of styrene-exposed workers did, however, reveal the presence of DNA- and/or protein-adducts that occur from exposure to styrene and/or SO. The formation of DNA adducts per se does not lead to a conclusion of mutagenic activity. Only adducts that are made permanent, and which disrupt normal DNA replication, transcription, and translation processes can produce "mutagenic" effects. The significance, if any, of SO-specific adducts has yet to be determined.

684 STYRENE TOXICITY IN HEPG2 AND HEP3B CELLS.

D. Maurici, V. Campi, I. Malerba, G. Bowe and L. Gribaldo. *ECVAM, Joint Reseach Centre- IHCP, Ispra, Varese, Italy.* Sponsor: E. Sabbioni.

Environmental, occupational and recreational exposures to carcinogens contribute to cancer risk in humans. Styrene is one of the most important organic chemicals. It is mainly produced to prepare solid polystyrene foam, expanded polystyrene foam and styrene-butadiene rubber. It has been shown to be genotoxic after metabolic activation and to induce cytogenetic effects in many experimental systems. The toxic effect of styrene on HepG2 (wild-type p53) and Hep3B (deleted p53) cells was analysed. Both cell lines are considered to be metabolically competent to activate different classes of mutagens into biologically active metabolites. We exposed HepG2 and Hep3B cell lines at subtoxic concentrations (up to 0.5mM) of styrene to analyse the expression of genes and proteins involved in apoptosis and cell cycle regulation. We performed a cDNA macroarray on HepG2 cells and found an overexpression of TGFβ2, TGFβ receptor III and c-jun proto-oncogene. We also analysed the protein levels of Bax (pro-apoptosis) and Bclx-L (anti-apoptosis) in Hep3B and HepG2 cell lines treated with styrene. The endogenous level of Bclx-L increased according with the increasing concentration of the chemical. On the contrary, Bax protein level did not change in treated and untreated cells. Cell cycle analysis revealed no significant changes in cells treated with styrene at 0.5mM for 48 hours. Our data suggest that the activity of styrene on cell proliferation/cell death should be monitored as an early endpoint of exposure.

685 USING MECHANISTIC DATA FOR ASSESSING CANCER MODE OF ACTION: 1, 3-DICHLOROPROPENE AS A CASE STUDY.

A. Maier[1], L. T. Haber[1], M. L. Dourson[1] and W. T. Stott[2]. *[1]Toxicology Excellence for Risk Assessment (TERA), Cincinnati, OH and [2]The Dow Chemical Company, Midland, MI.*

There are increasing opportunities for mechanistic toxicology data to be a driving force in the outcome of cancer risk assessments. This advancement is clearly shown by proposed changes in the US Environmental Protection Agency (EPA) cancer risk assessment guidelines published in 1999. However, despite the availability of updated EPA guidelines, published human health risk assessments have been slow to move from default dose-response approaches. We conducted a critical analysis of the mechanistic data for 1, 3-dichloropropene, the active ingredient of the pesticide Telone II, as a case study to identify key uncertainties that might be responsible for differences in the outcomes of recent cancer risk assessments for this chemical. Key uncertainties included (1) determining the relative contribution of alternative metabolic pathways at environmentally-relevant doses, (2) identifying secondary responses that link the putative key precursor event of GSH depletion to increased tumor formation, (3) relating available short-term mechanistic data to chronic effects such as tumorigenesis, and (4) resolving questions about the *in vivo* genotoxic potential of 1, 3-dichloropropene in the face of mixed results in genotoxicity assays. Resolution of these data gaps is needed to meet USEPA criteria for moving away from the default dose-response approach of assuming linearity in the quantitative dose-response analysis. Ongoing experiments designed to resolve these key data gaps are described. The issues and data gaps identified here in the context of 1, 3-dichloropropene are similar to those of many other chemicals. Thus, the results of this analysis are useful in communicating to mechanistic toxicologists the types of data that are needed to present a persuasive argument for moving away from default assumptions of low-dose linearity in conducting cancer risk assessments.

686 ESTIMATION OF THE CARCINOGENIC POTENTIAL OF POLYCYCLIC AROMATIC HYDROCARBONS.

J. B. Faust, A. G. Salmon, C. D. Sherman, M. S. Sandy and L. Zeise. *Office of Environmental Health Hazard Assessment, California Environmental Protection Agency, Oakland, CA.*

Numerous polycyclic aromatic hydrocarbons (PAHs) are known to cause cancer in experimental animals. A subset of these compounds (chrysene, 5-methylchrysene, dibenzo[a, h]pyrene, dibenzo[a, i]pyrene, benzo[b]fluoranthene, benzo[j]fluoranthene, and benzo[a]pyrene) have produced tumors in the neonatal mouse model. In the published studies, dating from 1982 to 1994, mice developed lung and liver tumors following intraperitoneal injection in the early days of life. The route and time of administration used in these studies has presented a challenge for the estimation of carcinogenic potency for these PAHs by

the oral exposure route. Our approach has been to apply a dose correction for variable dosing over time based upon the model of Doll and Armitage (1954) and further developed by Crouch (1983). Estimation of potency also accommodated data sets for which the response was 100%, a special case in which the whole-life quantal multistage model fails. Where tumors developed at multiple sites, a combined distribution representing cancer potency for all sites affected by treatment with the carcinogen was derived through Monte Carlo analysis. In order to calibrate the extrapolation to the oral route, results from studies of the carcinogenicity of benzo[a]pyrene were used as an "internal standard, " since this PAH has been examined both in oral and intraperitoneal injection studies. The resulting oral potency estimates in animals for the PAHs under consideration here range from 0.83 to 140 $(mg/kg\text{-}day)^{-1}$.

687 DEVELOPMENT OF CANCER POTENCY ESTIMATES FOR CALIFORNIA'S PROPOSITION 65.

T. A. McDonald, S. M. Hoover, J. B. Faust, J. Rabovsky, M. K. MacGregor, C. D. Sherman, M. S. Sandy and L. Zeise. *OEHHA, California EPA, Oakland, CA.*

The Office of Environmental Health Hazard Assessment (OEHHA) develops cancer potency estimates for carcinogens listed under California's Safe Drinking Water and Toxic Enforcement Act of 1986, better known as Proposition 65. Cancer potencies - defined as the slope of the dose response curve (daily dose versus lifetime cancer risk) in the low dose region - are used to estimate risk-specific intake levels, which facilitate compliance with the law. For carcinogens that induce cancers at multiple sites, Monte Carlo analysis is used to sum cancer potencies calculated for different treatment related cancer sites, according to their probability distributions. The upper 95 percent confidence bound from the combined distribution of the sum of the potencies is taken as the multisite cancer potency. The potency derivation takes into account body size differences between humans and experimental animals. Recent cancer potency assessments for the following carcinogens are posted on the OEHHA website (www.oehha.ca.gov). Cancer potencies in units of (mg/kg-d)-1 are: 0.63 for benzofuran, 1.0 for carboxymethyl-N-nitrosourea, 3.7 for 3, 3'-dimethoxybenzidine dihydrochloride, 12 for 3, 3'-dimethylbenzidine dihydrochloride, 49 for NNK, 3.9 for 5-morpholinomethyl-3[(5-nitrofurfurylidene)-amino]-2-oxazolidinone, 0.17 for carbazole, 0.0047 for chloroethane, 0.0023 for di(2-ethylhexyl)phthalate (DEHP), 0.095 for isobutyl nitrite, 0.047 for lead (oral), 0.030 for lead acetate (oral), 0.012 for lead phosphate (oral), 0.017 for lead subacetate (oral), 1.5 for MeIQ, 1.7 for MeIQx, 0.0044 for methyl carbamate, 12 for methylhydrazine (oral), 7.8 for methylhydrazine (inhalation), 25 for 2-methylaziridine, 6.4 for MX, 0.025 for nalidixic acid, 0.016 for o-phenylenediamine dihydrochloride, 0.21 for p-chloro-o-toluidine, 0.14 for phenyl glycidyl ether, 0.68 for phenylhydrazine, 0.00060 for polygeenan, 12 for tetranitromethane, 0.029 for trimethyl phosphate, and 0.0063 for 2, 6-xylidine.

688 USE OF BENCHMARK CONCENTRATION METHODOLOGY IN RISK ASSESSMENT FOR AIR TOXICS.

J. F. Collins, A. G. Salmon, J. P. Brown, D. C. Lewis, D. E. Dodge, M. A. Marty and G. V. Alexeeff. *Office of Environmental Health Hazard Assessment, Cal/EPA, Oakland, CA.*

In risk assessment for non-cancer toxicity a NOAEL, or failing that a LOAEL, has generally been identified by inspection of toxicity data. Uncertainty factors are then applied to derive health protective levels. The LOAEL/NOAEL procedure suffers from reliance on a small portion of the available data, inability to quantify uncertainty, and susceptibility to experimental design factors. The benchmark dose (BMD) methodology was developed to help address these failings. The BMD methodology uses likelihood-based curve fitting to estimate a BMD or concentration (BMC), i.e. the dose to achieve a chosen incidence criterion (e.g. 5% or 10% incidence of the effect of interest), or its lower confidence bound. It avoids the statistical problems of the LOAEL/NOAEL methodology, but requires appropriate definition of the benchmark. The California Air Toxics Hot Spots program used this methodology to develop twelve chronic Reference Exposure Levels (cRELS), allowing comparison with the earlier approach in practical cases. The benchmark used (BMC05) was the lower 95% confidence bound on the 5% effect concentration. This reflects uncertainty and variability in the source data, and lies within or close to the range of those data. The relationship to the previously used criteria needs to be established in order to select uncertainty factors. In four cases, a NOAEL was also available, and the BMC05 was found to be close to the NOAEL (NOAEL/BMC05: chloropicrin 2.38, methanol 3.28, MDI 0.8, phosphoric acid 0.78). In the eight other cases, no NOAEL could be determined, but the overall ratio of the LOAEL to the BMC05 for all twelve compounds was 6.8, which is close to the acute LOAEL/NOAEL ratio observed by Alexeeff et al. (1997). In view of this concordance, similar uncertainty factors were used in deriving a cREL from a BMC05 as would apply to a NOAEL based on the same data. Use of the BMC05 resulted in a more reliable estimate, with defined confidence bounds, especially in cases with data quality problems, e.g. lack of an observed NOAEL.

689 NEW APPROACHES FOR DERIVING A REFERENCE CONCENTRATION FOR METHYL ETHYL KETONE.

M. H. Follansbee, P. R. McClure and P. McGinnis. *Environmental Science Center, Syracuse Research Corp, Syracuse, NY.*

MEK is listed on IRIS with a reference concentration (RfC) of 1 mg/m^3 based on developmental effects (decreased fetal body weight and increased incidence of misaligned sternebrae) reported in CD-1 mice exposed 7 h/day on gestation days 6-15 (Schwetz et al., 1991). This derivation used a NOAEL/LOAEL approach. A review of the available toxicity data for methyl ethyl ketone (MEK) uncovered no new data for inhalation exposures. Current EPA guidance provides for a number of alternative approaches to derive an RfC. A benchmark dose approach to derivation of an RfC for MEK was explored using the same data for developmental effects in CD-1 mice, as well as data for increased incidence of extra ribs in Sprague-Dawley rats as reported by an inhalation developmental study (Deacon et al., 1981). Modeling of these data and calculation of benchmark concentrations (BMC) and 95% confidence limits on the BMC (BMCL) identified points of departure for each endpoint. The points of departure for each endpoint fall between the NOAEL and LOAEL observed in the respective developmental studies; thus, all are equally plausible. The available pharmacokinetic, pharmacodynamic, and mechanism of action data do not provide sufficient evidence to argue convincingly for either peak exposure level or area under the curve as the most appropriate surrogate metric for internal effective dose; consequently, duration adjustment was also explored in order to time-weight the exposures used in the critical studies for each endpoint. In addition, an adjustment can be made to account for the difference in the blood:air absorption coefficient between rats and humans based on literature reports. This exercise identifies and explores a number of alternative approaches to derive an RfC for MEK, which primarily reflects new approaches to RfC derivation, rather than new data. The impact of each of these decisions on the RfC will be presented.

690 UPDATED PHENOL REFERENCE DOSE: CONSIDERATIONS IN APPLYING IMMUNOTOXICITY DATA AND THE ROLE OF ENDOGENOUS PRODUCTION.

M. A. Barron, L. Haber and M. Dourson. *Office of Solid Waste, US Environmental Protection Agency, Washington, D.C., DC.*

Phenol is an industrially-important chemical and is produced in bulk in the USA. The toxicity data for phenol have been reassessed. A reference dose (RfD) of 0.3 mg/kg-day has been derived based on a benchmark dose from a developmental toxicity study (Argus Research Laboratories, 1997). This RfD replaces the previous RfD of 0.6 mg/kg-day, which was based on the NOAEL from an earlier developmental toxicity study (Argus Research Laboratories, 1997). This RfD replaces the previous RfD of 0.6 mg/kg-day, which was based on the NOAEL from an earlier developmental toxicity study (NTP, 1983a), on the USEPA Integrated Risk Information System (IRIS) in 1989. Updating the assessment required delving into key scientific issues that have not been fully developed in the risk assessment community. For example, several newer studies suggested that phenol is immunotoxic. The updated phenol assessment provides a systematic examination of these data as an example of the level of analysis required to determine the adversity of immunotoxicity endpoints. This issue was resolved through the discussion of an uncertainty factor to address immunotoxicity. The assessment also presents an approach, and relevant discussion of alternatives, for deriving risk values for chemicals that are produced endogenously. The issue of endogenous production was addressed by applying the RfD to ingested phenol in addition to the normal daily endogenous level of production. Resolution of these issues as presented in the reassessment of phenol provides key learnings that are relevant for many other chemicals of environmental interest. Key words: RfD, phenol, endogenous production

691 SHORT-TERM INHALATION TOXICITY BENCHMARK FOR NICKEL OXIDE.

L. H. Fraiser[1] and I. Chaudhuri[2]. *[1]ENSR International, Austin, TX and [2]ENSR International, Westford, MA.*

EPA requires that short-term or acute health effects be considered from inhalation of compounds as part of the multi-pathway risk assessments that are conducted for hazardous waste combustion units. EPA has recommended a hierarchy of sources for acute toxicity benchmarks that are intended to protect the general public from discomfort or mild adverse health effects over one-hour exposure periods. EPA has

recommended the California EPA reference exposure level (REL) for nickel and nickel compounds of 6 ug/m3 as the acute criterion for evaluating potential short-term inhalation health effects associated with nickel emissions. California EPA's REL for nickel compounds is based on toxicity studies conducted on nickel sulfate. Although the nickel REL is being applied to all nickel compounds, there is considerable evidence indicating that different nickel compounds have different levels of toxicity when inhaled. Nickel emissions from hazardous waste combustion units are primarily in the form of oxides of nickel (NiO, NiO2, and Ni2O3). A literature analysis revealed that an alternative acute toxicity benchmark for nickel oxide is appropriate for use in evaluating potential acute toxicity associated with inhalation of nickel emitted from hazardous waste combustors, particularly if site-specific data support that nickel emissions are primarily in the form of nickel oxides. Based on several toxicity studies, an alternative acute toxicity benchmark was developed for nickel oxide.

692 ACUTE AND CANCER RISK ASSESSMENT VALUES FOR *TERT*-BUTYL ACETATE.

J. D. Budroe, A. G. Salmon and M. A. Marty. *Air Toxicology and Epidemiology Section, Office of Environmental Health Hazard Assessment (OEHHA), Oakland, CA.*

Tert-butyl acetate (TBAc) is an industrial chemical with potential uses as a degreaser and in architectural coatings. Limited toxicity data exist for TBAc. However, acute inhalation exposure data are available for TBAc. Additionally, although no TBAc carcinogenicity data are available, TBAc has been demonstrated to be substantially metabolized to *tert*-butanol (TBA) in rats. TBA genetic toxicity data are mixed, but information from a positive genotoxicity study for TBA suggests that TBA may cause oxidative DNA damage. TBA has been shown to induce tumors in both rats and mice, and OEHHA has calculated an oral cancer slope factor (CSF) for TBA of 3×10^{-3} $(mg/kg\text{-}day)^{-1}$. This raises a concern that exposure to TBAc may result in a cancer risk because of the metabolic conversion to TBA. It has been proposed that the TBA carcinogenicity data may not be relevant to human cancer risk assessment because 1) the male rat kidney tumors are the result of TBA-induced α2u nephropathy, a pathological effect specific for male rats, and 2) the female mouse thyroid follicular cell tumors may be due to an effect on thyroid hormone levels, which might have a threshold above the level of expected human exposures. However, in our opinion these data are insufficient to allow the determination that the TBA carcinogenicity data are not relevant to human cancer risk assessment. Therefore, TBAc should be considered to pose a potential cancer risk to humans. An acute one-hour Reference Exposure Level (REL) of 1 mg/m^3 (0.21 ppm) can be calculated from the extrapolated No Observed Adverse Effect Level (NOAEL) of 50 mg/m^3 (11 ppm) using a Haber's Law exposure time correction. A CSF of 0.002 $(mg/kg\text{-}day)^{-1}$ can be derived for TBAc, assuming 100% metabolism of TBAc to TBA and a molar conversion factor of 0.64 (TBA mw 74.12 / TBAc mw 116.16). An inhalation unit risk value for TBAc of 4×10^{-7} $(\mu g/m^3)^{-1}$ can then be derived from the CSF value for TBAc by assuming a human breathing rate of 20 m^3/day, 70% fractional absorption, and an average human body weight of 70 kg.

693 CYCLIC ACID ANHYDRIDES AS OCCUPATIONAL SENSITISERS - A NORDIC EXPERT GROUP CRITERIA DOCUMENT.

G. Johanson[1], H. Keskinen[2] and J. Järnberg[3]. *[1]Work Environment Toxicology, Inst of Environ Med., Karolinska Institutet, Stockholm, Sweden, [2]Finnish Inst of Occup Health, Helsinki, Finland and [3]Nat Inst for Working Life, Stockholm, Sweden.*

The Nordic Expert Group for Criteria Documentation of Health Risks from Chemicals (NEG) is a Nordic collaboration mainly financed by the Nordic Council of Ministers and the Swedish National Institute for Working Life. The main task is to produce criteria documents to be used by the regulatory authorities of the Nordic countries as the scientific basis for setting occupational exposure limits (OELs) for chemical substances. The actual setting of an OEL is a national concern. The NEG and the Dutch Expert Committee on Occupational Standards (DECOS) have jointly produced a criteria document on cyclic acid anhydrides (CAA) (Keskinen H, accepted for publication in Arbete och Halsa). CAAs are known as potent occupational sensitizers. Since the first published case of asthma due to phthalic anhydride (PA) in 1939, occupational asthma and rhinitis due to several CAAs have been reported. Contact urticaria is more usual than allergic contact exzema. In addition to their sensitizing properties CAAs, are also irritants of the skin and mucous membranes. IgE-mediated allergy due to several CAAs has been demonstrated in exposed workers as well as in animal studies. Apart from the allergic reactions, rhino-conjunctivitis due to irritation without sensitization has been reported frequently. The sensitising potency of CAAs varies greatly. According to the dose-response studies available, trimellitic (TMA), hexahydrophtalic (HHPA), and methyltetrahydrophthalic anhydride (MTHPA) seem to be more potent sensitizers than PA and tetrachlorophthalic anhydride (TCPA). In conclusion, there is a need to re-evaluate the present OELs in the Nordic countries and to establish OELs for the more recent anhydrides.

694 PROVISIONAL TOXICITY VALUES FOR 0-NITROTOLUENE FOR THE HEALTH EFFECTS ASSESSMENT SUMMARY TABLE (HEAST).

M. E. Fransen[1], M. Odin[1] and H. Choudhury[2]. *[1]Environmental Science Center, Syracuse Research Corp, Syracuse, NY and [2]Office of Research and Development, National Center for Environmental Assessment, Cincinnati, OH.*

EPA is updating toxicity values for chemicals listed in the 1997 HEAST. The previous assessment for o-nitrotoluene (o-NT) included a subchronic RfD of 1E-1 mg/kg-day and a chronic RfD of 1E-2 mg/kg-day, based on a LOAEL of 200 mg/kg for splenic lesions in a 6-month rat gavage study. Subchronic and chronic NTP feeding bioassays in rodents provide a basis for deriving new toxicity values for o-NT. In the subchronic assay, a LOAEL of 44 mg/kg-day was identified for increased levels of methemoglobin in female rats after 3 weeks; this LOAEL was considered minimal because other erythrocytic effects (anemia, splenic lesions) were limited to the higher doses. A provisional subchronic RfD of 4E-2 mg/kg-day was derived from the minimum LOAEL. A significant finding in the subchronic assay was the occurrence of malignant mesotheliomas in the epididymal tunica vaginalis in rats exposed at 353 mg/kg-day for 13 weeks. Similar mesotheliomas and a hepatic cholangiocarcinoma were observed in rats fed 292 mg/kg-day for 13 or 26 weeks in another assay. No provisional chronic RfD was derived because frank effects were observed at the lowest tested dose in the chronic feeding assay (25 mg/kg-day). In the chronic assays, clear evidence for multiple-organ carcinogenicity was observed: subcutaneous skin fibroma/fibrosarcoma in male and female rats, mammary fibroadenoma in female rats, hemangiosarcoma in male and female mice, and hepatocellular adenoma/carcinoma in female mice. o-NT is a genotoxic carcinogen following bioactivation; direct evidence for mutagenicity in cell regulatory genes (p53, K-ras, and -catenin) was shown in mice exposed for 2 years. Dose-response modeling was performed based on the most prominent tumor types. The provisional oral slope factor of 2.3E-1 (mg/kg-day)-1 was based on the incidence of skin tumors in male rats, the tumor type associated with the highest numerical risk. (This abstract does not necessarily reflect EPA policy.)

695 COMPARISON OF THE NUTRITIONAL REQUIREMENT AND RISK ASSESSMENT FOR ESSENTIAL TRACE ELEMENTS (ETES) BY THE INSTITUTE OF MEDICINE (IOM) AND THE USEPA: ZINC A CASE STUDY.

K. A. Poirier[1], J. Cicmanec[2], C. O. Abernathy[3] and J. M. Donohue[3]. *[1]TERA, Cincinnati, OH, [2]USEPA, Cincinnati, OH and [3]USEPA, Washington, DC.*

Recently, the IOM has reviewed the nutritional requirement and toxicity data for the ETEs. In addition to the Recommended Dietary Allowance (RDA), a Tolerable Upper Intake Level (UL) has been derived and published for the ETEs. The UL is somewhat analogous to the USEPA's Reference Dose (RfD), but unlike the RfD the UL relies on a case-by-case consideration for derivation and does not have published paradigm for data review and uncertainty factor (UF)application. The ETEs occupy a unique place among chemicals regulated by the USEPA as both nutritional deficiency and adequacy and toxicity data are available (and in many cases human data) that must be considered for review. Data on human requiremnts, exposure and bioavailability must be integrated with the toxicity data. The RDA makes recommendations based on sex, age and physiological status; whereas the RfD is calculated as a single lifetime exposure value for individuals. This creates difficulties in the risk assessment process. The RfD for zinc is 3E-1 mg/kg-day (20 mg/day) based on LOAEL of 60 mg/day (1.0 mg/kg-day) from a critical effect of 47% decrease in erythrocyte superoxide dismutase in adult females (60 kg) after 10 weeks, and an UF (LOAEL to NOAEL extrapolation) of 3. The zinc RDA for adults is 11 mg/day for males and 8 mg/day for females (11 mg/day for pregnancy; 12 mg/day for lactation). The UL adults is 40 mg/day and is 23 mg/day for children 9-13 years of age and 34 mg/day for adolescents 14-18 years of age. The current RfD exceeds the RDA for infants and children when adjusted for body weight. Thus, the current USEPA RfD recommendations are contrary to IOM recommended optimum zinc intake levels in these populations. Additionally, the IOM derived ULs are twice the USEPA's RfD. We recommend the creation of an RfD category for ETEs without UFs and/or the use of modifying factors in lieu of UFs to rectify differences. The opinions expressed in this abstract are those of the authors and not necessarily that of the USEPA.

696 CROSS SPECIES MODE OF ACTION INFORMATION ASSESSMENT FOR BISPHENOL A.

S. Y. Euling and B. Sonawane. *NCEA, USEPA, Washington, DC.* Sponsor: C. Kimmel.

The goal of the project was to identify the mode of action (MOA) information for Bisphenol A (BPA) across animal species and to explore how to use this information for evaluation of ecological and human health risk. BPA developmental and reproductive effects and MOA data were identified from the literature for only 17 species

representing 7 animal classes. For invertebrates, some species showed similar effects after estrogen (E) or BPA exposure but the significance of the findings is unclear since the role of E or E analogs in invertebrate development is not well understood. Within the vertebrates, *in vitro* binding data indicate that BPA can bind to the ER of reptiles, amphibians, fish, birds, and mammals at a much lower affinity than ethinyl estradiol. For amphibians, some developmental effects data were consistent with BPA acting as an E agonist and *in vitro* data suggest effects on thyroid hormone bioavailability. In birds, *in ovo* BPA treatment led to some effects consistent with an E agonist MOA. In fish, BPA effects data were consistent with a number of MOAs including E agonism and mechanistic data support BPA causing an increased E activity. Mammalian effects data, limited to rat and mouse, are consistent with a number of MOAs and most mechanistic studies support an E agonist MOA. In conclusion, BPA exposure can elicit effects in vertebrate and invertebrate species at sublethal concentrations and the majority of evidence supports BPA acting to increase E activity with mechanistic studies supporting E agonism. Limitations of the study were the small number of species with data, most mechanistic studies focused on E agonism, and the lack of knowledge of the role of hormones in invertebrate development. Studies to investigate if BPA affects alternative or multiple MOAs in different species, at different doses or under different conditions are needed. Disclaimer: The views expressed are those of the authors and do not necessarily reflect the views or policies of the US Environmental Protection Agency. Mention of trade names or commercial products does not constitute endorsement or recommendation for use.

697 ANALYSIS OF NESTED DATA FROM DEVELOPMENTAL STUDIES: A RE-EVALUATION OF AZINPHOSMETHYL DEVELOPMENT STUDIES.

Q. J. Zhao and M. Dourson. *Toxicology Excellence for Risk Assessment (TERA), Cincinnati, OH.*

In a developmental study, the maternal animal, but not the conceptus, is the individual treated during gestation, and study results usually have the characteristic of nested data. As suggested in EPA's guidelines for developmental toxicity, such data "generally are calculated as incidence per litter or as number and percent of litters with particular end points". In practice, however, some developmental responses in pups, such as survival index and lactation index, are calculated as number of live offspring (at lactation day 4 or 21) divided by number of live offspring delivered. This latter approach is based on an assumption that the response is from independently exposed individuals (pups). These two approaches of data analysis might result in a different conclusion in dose-response analysis, as shown in an evaluation of azinphosmethyl developmental studies. We present our results from the two approaches as well as EPA benchmark dose (nested models) analysis for the effect of azinphosmethyl on pup viability in two developmental studies. Based on the litter-based approach, the NOAEL for pup viability is 15 ppm azinphosmethyl while it is 5 ppm based on the pup-based approach; the BMD analysis also supports to use 15 ppm as the NOAEL. Our results suggest that a litter-based data analysis is more appropriate in an evaluation of development toxicity results.

698 HOW DIETARY IODINE AFFECTS THE DOSE-RESPONSE FOR PERCHLORATE INHIBITION OF IODIDE UPTAKE BY THE THYROID: A MODELING ANALYSIS OF CLINICAL EXPOSURE DATA.

G. Goodman. *Intertox, Inc., Seattle, WA.*

Perchlorate is a competitive inhibitor of iodide uptake from the serum into the thyroid. The site of this inhibition is the sodium-iodide symporter. Perchlorate inhibition of thyroidal radioiodine uptake in humans has been evaluated in three clinical studies (Lawrence et al., Thyroid 10: 659-663, 2000; Lawrence et al., Thyroid 11: 295, 2001; Greer et al., Environment Health Perspect. 110: 927-937, 2002). In each of these studies, the uptake measured during perchlorate exposure was compared to the baseline uptake, with each subject serving as his/her own control. Greer et al. (2002) evaluated the dose-response for perchlorate inhibition of uptake on day 14 of exposure (E14) at a dose of 0.007, 0.02, 0.1 or 0.5 mg/kg-day and extrapolated a no-effect level of 0.005 to 0.006 mg/kg-day using a linear-log dose model. The work presented herein addresses the influence of the ad libitum dietary iodine intake in that study. Goodman and Greer (unpublished data) found that the 24-hr urinary iodine excretion (IE), a surrogate for daily iodine intake, varied several-fold within subjects between baseline and E14 and an order of magnitude among subjects. [All quantitative analysis of iodine was expertly performed by M. Previti and S. Pino in the laboratory of L. Braverman at the Boston Medical Center.] I report here the development of a method to adjust the E14:baseline relative uptake (RU) for the relative change in IE between baseline and E14 (RIE) and to evaluate how the RIE-adjusted RU depends upon the absolute baseline IE. The results indicate that subjects in the lowest baseline IE category (49 to 137 microgram) tended to have higher RIE-adjusted RU values at a given perchlorate dose. Thus, the data indicate that in comparison to higher IE levels, an IE level between 49 and 137 microgram is associated with lesser sensitivity to perchlorate inhibition of thyroidal iodide uptake. These results suggest that persons at the low end of the US population's range of dietary iodine intake are not at increased risk for perchlorate inhibition of thyroidal iodide uptake.

699 WEIGHT-OF-EVIDENCE CHARACTERIZATION OF THE ENDOCRINE-MODULATING EFFECTS OF ATRAZINE: IMPLICATIONS FOR HUMAN HEALTH RISK ASSESSMENT.

A. M. Mahfouz[1], B. R. Stern[2] and L. T. Haber[3]. *[1]Office of Water, USEPA, Washington, DC, [2]BR Stern Associates, Annandale, VA and [3]TERA, Cincinnati, OH.*

Atrazine, a systemic triazine herbicide that blocks plant photosynthesis, is one of the two most widely-used agricultural pesticides in the US, primarily for weed control of corn, sorghum, sugarcane, and wheat, as well as on range, orchard, and turf grasses. Atrazine, and/or its primary metabolite, diaminochlorotriazine (DACT), have been suspected of having the potential to modulate hormonal activity by a variety of mechanisms, including mimicking the effects of estrogen or progesterone exposure; altering serum levels of reproductive hormones in normal, pregnant, and developing animals; inducing histomorphologic changes in reproductive organs and tissues; and disrupting the neuroendocrine feedback systems, specifically those involving the hypothalamus-pituitary-gonadal axis. Due to widespread population exposure, the endocrine-active effects have been extensively studied, and atrazine has a relatively large data base of both *in vitro* and *in vivo* specialized hormonal studies. Key studies are briefly reviewed and their strengths and limitations noted. The weight-of-evidence suggests that although there are no human data implicating atrazine and/or DACT as endocrine modulators, it is not unreasonable to expect that these compounds might cause adverse hormonal effects in humans at high exposures. However, concerns about the animal data are numerous, and include the validity of using a rodent model (Sprague-Dawley rat) whose reproductive patterns differ markedly from those in humans to characterize potential human health hazards; the intrinsic variability among strains/species of test animals with regard to sensitivity to atrazine; temporal and diurnal (circadian) variation in some chemically-induced responses; high-to-low dose extrapolation of observed effects; the use of new test protocols; and the lack of a rodent control data base for many of the developmental and other end points under study. [The opinions expressed are those of the authors and do not necessarily reflect USEPA policy.]

699a CANCER RISK ASSESSMENT OF ACRYLAMIDE IN FOODS.

T. Sanner[1] and E. Dybing[2]. *[1]Institute of Cancer Research, The Norwegian Radium Hospital, Oslo, Norway and [2]Division of Environmental Medicine, Norwegian Institute of Public Health, Oslo, Norway.*

The University of Stockholm, Sweden reported in April 2002 analyses demonstrating high concentrations of acrylamide in certain fried, baked and deep-fried foods. Acrylamide is classified as a Group 2A carcinogen by the International Agency for Research on Cancer and as a Category 2 carcinogen and Category 2 mutagen by the European Union. The Norwegian Food Control Authority has estimated the intake of acrylamide from food in Norway based on the content of acrylamide detected in Norwegian products, in addition to Swedish analytical data for those food items not covered by the Norwegian sampling. The mean dose of acrylamide was estimated to 0.36 and 0.33 mg/kg bodyweight/day for males and females, respectively. Quantitative estimations of lifetime cancer risk, given the assumption that there does not exist a dose threshold for this genotoxic carcinogen, have been performed based on long-term studies where rats was given acrylamide in drinking water. In the risk calculations a linear extrapolation was performed using the tumorigenic dose indicators T25, that has been used in several risk assessments of chemicals in the EU, and LED10, that the USEPA has proposed to use in its estimation of cancer risk. After adjustment using an animal to human scaling factor, the lifetime cancer risk was calculated to 0.5x10-3 for males (corresponds to 5 cases of cancer per 10, 000 individuals). For those 2.5% males with the highest intake, the lifetime risk was calculated to 1.7x10-3. For females the numbers were slightly lower. It should be emphasised that such a point estimate is uncertain, both because of uncertainties in the estimation of the intake and uncertainty in the assessment methodology. The given estimate is conservative, which means that the real figures may be lower. If it is presumed that approximately 30 per cent of all cancer cases are related to food consumption, the intake of acrylamide in Norway represents approximately 1% of all cases associated with food intake.

700 FEASIBILITY OF LONG-TERM CONTINUOUS INTRAVENOUS INFUSION IN UNRESTRAINED MARMOSET MONKEYS.

S. Korte, U. Zuehlke, P. Nowak, S. Tippkoetter, A. Wiederhold, B. Niggemann, G. F. Weinbauer, W. Mueller and F. Vogel. *Covance Laboratories GmbH, Muenster, Germany.* Sponsor: P. Thomas.

The marmoset monkey (Callithrix jacchus) has become an important nonhuman primate model to be used as the second species in the safety evaluation of new drugs. We demonstrated previously the feasibility of prolonged infusions in this species by using a suitable port-catheter technique. Owing to the increased demand for the marmoset in toxicology, the development of a continuous infusion model in the unrestrained animal became a requirement. The work conducted investigated the feasibility of long-term and continuous intravenous infusion (from 24 hours to 4 weeks) in the common marmoset. Current models for this administration technique still rely on a tethering system. Only the validation of a tether less-jacket infusion model for the unrestrained marmoset was considered to be best practice, as the marmoset exhibits a very complex and rich behavioural and mobility repertoire that would not be compatible with any tethering device. A light weighted (< 10% of nominal body weight incl. 5 mL respectively 5 mg for the fluid reservoir) backpack-minipump system was successfully tested and proved reliable over 7 and 14 continuous days, with a room temperature calibrated minipump delivering 5mL daily or weekly with an accuracy of 98%. The used system allowed free choice of the dosing volume to be administered hourly, as the minipump was either exchanged daily or weekly. The implantable port-catheter systems were successfully used for up to 90 days. Ongoing validation trials now will need to prove the usability of the developed delivery device (backpack system) for longer than 4 weeks. In conclusion, long-term continuous infusion proved feasible in the marmoset model and now extends the range of administration techniques available for toxicity studies in this small nonhuman primate.

701 A PHARMACOKINETIC STUDY OF CJC-1008, A NOVEL OPIOID, IN MONKEYS USING DUAL ISOTOPE LABELING DEMONSTRATES A LONG ELIMINATION HALF-LIFE AND DISTRIBUTION IN PERIPHERAL TISSUES.

V. Iordanova[1], D. Dunn[2], T. Zoetis[2], S. Wen[1], C. Gagnon[1], J. Castaigne[1] and B. Lawrence[1]. *[1]ConjuChem, Inc., Montreal, QC, Canada and [2]Milestone Biomedical Associates, Frederick, MD.*

CJC-1008 was designed by applying the Drug Affinity Complex (DAC) technology to the short acting peptide opioid agonist Dynorphin A (1-13) (Dyn A). This chemical modification with maleimidoproprionic acid (MPA) allows CJC-1008 to covalently bind to circulating plasma proteins, after parenteral administration, thus prolonging its half-life and maintaining it within the periphery. In order to study the pharmacokinetic (PK) and tissue distribution profile of CJC-1008, the compound was labeled with [^{14}C] on the MPA and with [^{3}H] on tyrosine at position 1 (Tyr^{1}) of the Dyn A molecule. Cynomolgus monkeys were dosed IV with the formulated [^{14}C/^{3}H]-CJC-1008 at a target level of 8 mg/kg. Quantifiable levels of [^{14}C] and [^{3}H] were observed in both plasma and blood up to 96 hours post dose. The elimination half-life ($t_{1/2el}$) was similar in blood and plasma for both isotopes, ranging between 49 and 79 hours. Radioactivity levels in tissues peaked quickly within 2-24 hours with the highest radioactivity concentrations observed in peripheral tissues including kidneys, liver, lungs, testes, ovaries, adrenal glands, prostate gland, and spleen for both isotopes, and in the pancreas and salivary glands for [^{3}H]. The highest percentage of administered dose was observed in the kidneys, liver, lungs, heart and bone for both isotopes, and in the brain (cortex) for [^{3}H] only, likely due to free Tyr^{1}. The rate of radioactivity elimination from tissues was faster than elimination from plasma. Recovery of radioactivity in excreta at 96 hours post dose was 52-67% and 11-19% of the dose for the [^{14}C] and [^{3}H] isotopes, respectively. In conclusion, the dual isotope labeling has provided a method to analyze the distribution of the protein-conjugated CJC-1008, showing rapid distribution of the intact molecule to peripheral tissues without crossing the blood-brain-barrier at toxicologically-relevant levels, and a long plasma $t_{1/2el}$ of 49-79 hours.

702 ORAL BIOAVAILABILITY OF DICHLOROACETATE IN HUMAN SUBJECTS.

I. Schultz[1], S. Saghir[1] and R. Shangraw[2]. *[1]Battelle PND, Sequim, WA and [2]Anesthesiology, Oregon Health Sciences University, Portland, OR.*

Dichloroacetate (DCA) is a drinking water disinfection by-product and a known rodent carcinogen. DCA has also been used therapeutically to treat a variety of metabolic disorders in humans, including diabetes, hypercholesterolemia and congenital or acquired lactic acidosis. An important question in the assessment of human risk to DCA is accurate exposure information from consumption of drinking water. Previous studies in rodents suggest the oral bioavailability of DCA becomes negligible at doses between 0.05 and 1 mg/kg depending on exposure history and capacity to metabolize DCA. The bioavailability of DCA in humans at lower dose rates (< 10 mg/kg) has not been studied. Estimation of DCA bioavailability is problematic as repeated exposures to DCA reduce metabolism and overall clearance, preventing the use of a crossover experimental design. Bioavailability estimation at actual exposure rates from drinking water is also difficult because of analytical detection limitations. We used two approaches to estimate DCA bioavailability: 1) in-vitro measurements of liver metabolism using human liver cytosol and PBPK modeling for simulation of blood profiles after an oral dose and 2) direct measurement in human volunteers using a semi-simultaneous experimental design. In human studies, volunteers were given a 2 mg/kg oral dose of 12C-labeled DCA followed 10 min later by a 0.25 mg/kg intravenous dose of 13C-labeled DCA which serves as the reference dose. To reduce the influence of prior DCA exposure, volunteers were provided purified drinking water as an alternative to municipal drinking water for 2 weeks prior to bioavailability measurements. *In vitro* metabolism / PBPK modeling exercises suggested oral bioavailability would be 22 % after a 2 mg/kg dose and approach zero at dose rates comparable to those found in drinking water. These predictions will be compared to values obtained from the ongoing human studies. Supported by EPA grant R828044.

703 TOLERABILITY AND REPEAT-DOSE PHARMACOKINETICS (PK) OF ACETAMINOPHEN (APAP) AT 4, 6, AND 8 G /DAY IN HEALTHY ADULTS.

C. K. Gelotte, J. F. Auiler, J. M. Lynch, A. R. Temple and D. L. Bowen. *Research & Development, McNeil Consumer & Specialty Pharmaceuticals, Fort Washington, PA.*

The objective of the study was to assess tolerability and PK of 1, 1.5 and 2 g APAP dosed every 6 h for 3 days (1, 1.5 and 2 times the currently recommended daily dose). The study had a double-blinded, placebo-controlled, three-regimen design. Subjects were housed for the duration of the study and were divided into two groups: (I) 6 adults on placebo and 12 on APAP at 4 g and 6g/day and (II) 6 adults on placebo and 12 on APAP at 4 g and 8 g/day. Safety was monitored daily during the baseline, treatment, and washout phases between dose levels. Blood samples were collected during the first and last dose of each dose regimen. PK results for 4, 6 and 8 g/day of APAP showed that plasma levels did not accumulate with repeat doses. Also, steady-state APAP levels were linearly related to these repeat doses up to 8 g/day, indicating apparent first-order kinetics. Mean peak levels for the last dose were 18±4, 24±6, and 31±7 μg/mL, and elimination half-lives were 2.8±0.3, 2.5±0.2, and 2.3±0.4 h, respectively. Multiple doses up to 8g/day over 3 days were well tolerated and aminotransferase values stayed within normal limits during the conduct of the study.

704 THE USE OF A VALIDATED METHOD FOR THE ANALYSIS OF THUJONE IN PRELIMINARY TOXICOKINETIC RODENT PLASMA AND BRAIN SAMPLES.

B. L. Burback[1], S. Graves[1], C. Smith[2] and L. Fomby[1]. *[1]Toxicology Columbus, Battelle, Columbus, OH and [2]NIEHS, Research Triangle Park, NC.*

Thujone is a ketone component of essential oils from a variety of plants and is found as a component of flavorings and fragrances. A headspace/gas chromatography/mass spectrometry method was developed to analyze plasma and brain specimens for the purpose of characterizing the disposition of alpha-thujone in rodents. Samples for validating the method were obtained by conducting a preliminary toxicokinetic study with male and female F344 rats and B6C3F1 mice given a single intravenous or gavage administration of alpha-thujone or alpha/beta-thujone and collecting samples at specified time points (one animal/species/sex/dosage level). Analytical standards were prepared (range 5 to 600 ng/mL for plasma, or ng/g for brain). A linear regression equation weighted 1/x was calculated relating the response (y) to the concentration (x) of the standards. The concentration of each sample was calculated using its individual response and the regression equation. Following a single intravenous dosage (3.2 mg/kg, rats; 6.4 mg/kg, mice), the maximum plasma and brain concentrations were approximately 1000 ng/mL and greater than 600 ng/g, respectively. Following a single intravenous dosage of alpha-thujone (1.6 mg/kg, rats; 3.2 mg/kg, mice), the maximum plasma and brain concentrations were approximately 350 ng/mL and 500 ng/g, respectively. After a single gavage dosage (75 mg/kg), the maximum plasma and brain concentrations were sex and species dependent. In rats, maximum plasma concentrations were approximately 800 (M) and 3000 (F) ng/mL and maximum brain concentrations approximated >1400 (M) and >5000 (F) ng/g. Mice concentrations were approximately one-half to one-third less than the rat concentrations after intravenous and gavage administration. The validation of an analytical method for alpha-thujone together

with the preliminary toxicokinetic study results will be used to design a definitive toxicokinetic study in order to determine toxicokinetic parameters after thujone administration.

705 ABSORPTION, ELIMINATION AND METABOLISM OF 1-PHENOXY-2-PROPANOL IN RATS?

S. A. Saghir, K. A. Brzak, M. J. Bartels and P. J. Spencer. *Toxicology & Environmental Research & Consulting, The Dow Chemical Company, Midland, MI.*

This study was conducted to determine the absorption, elimination and metabolism of 1-phenoxy-2-propanol in Fischer 344 rats following oral administration. Adult male F344 rats were administered a single oral dose of 10 or 100 mg/kg radiolabeled 1-phenoxy-2-propanol in 0.5% methylcellulose. Urine was collected at 0-12, 12-24, and 24-48 hr and feces at 0-24, and 24-48 hr post-dosing in dry-ice cooled traps and radioactivity was determined. Urine samples were pooled by timepoint and dose level and analyzed for metabolites using LC/MS/MS. Both of the administered doses were rapidly absorbed from the GI tract and excreted. The major route of elimination of 1-phenoxy-2-propanol was through urine, accounting for 88±12% of the low and 94±1% of the high dose. Most of the urinary excretion of 1-phenoxy-2-propanol derived radioactivity occurred within 12 hr after dosing; 81±9% of the low and 90±1% of the high dose. Total fecal elimination was <10%. Rats eliminated entire administered dose within 48 hr after dosing, with total recovery of the administered dose ranged from 100-104%. Metabolites tentatively identified in urine were conjugates of phenol (sulfate, glutathione) as well as conjugates of parent compound (glucuronide, sulfate) and a hydroxylated metabolite of parent. There was no free parent or phenol detected in non-acid-hydrolyzed urine. In acid-hydrolyzed urine, 61% of the dose was identified as phenol and 13% as 1-phenoxy-2-propanol. Although the parent compound was stable to acid hydrolysis, some of the phenol in acid hydrolyzed urine may have come from degradation of acid-labile metabolite(s) as well as hydrolysis of phenol conjugates.

706 CORTICOSTERONE IN DRINKING WATER ALTERED THE TIME AND PLASMA CONCENTRATION CURVE OF A SINGLE ORAL DOSE OF CORTICOSTERONE AND LEVELS OF PLASMA SODIUM, ALBUMIN, GLOBULIN, AND TOTAL PROTEIN.

T. Pung, K. Zimmerman, D. Moore, K. Fuhrman and M. Ehrich. *Virginia-Maryland Regional College of Veterinary Medicine, Virginia Tech, Blacksburg, VA.*

Effects of chronic exposure to corticosterone (CORT) in drinking water on CORT kinetics, blood chemistry, and brain catecholamines and esterases were studied in adult male Long Evans rats. Groups of rats (n=8) were given either water, 2.5% ethanol, or 400 mcg/ml CORT in 2.5% ethanol for 28 days. On Day 28, rats were gavaged either with corn oil or CORT 20 mg/kg (n=4). Blood samples were collected at 0, 15, 30, 60, 120, 240, 480, and 720 min for CORT levels. Day 14 after gavage blood samples were collected for clinical pathology and brains were dissected into hippocampus (H), cerebral cortex (CC), caudate putamen (CP), and pons (P) for levels of catecholamines and neurotoxic esterase (NTE), carboxylesterase (CbE), and acetylcholinesterase (AChE)activities. Plasma CORT levels of CORT-drinking rats (58+/-14 ng/ml) were lower than the water (433+/-40 ng/ml) and the ethanol group (387+/-25 ng/ml). Plasma CORT was at similar peak levels in 15 min in all rats gavaged with CORT. The change from basal to peak CORT in the CORT-drinking rats was greater than for naive and vehicle rats, with no return to baseline by 720 min. Plasma sodium levels were lower in CORT-drinking rats (137.8+/-0.8 mEq/dL) than water-drinking rats (141.9+/-0.8 mEq/dL), suggesting effect of the hormone on the adrenal gland. Plasma albumin, globulin, and total protein were higher in CORT-drinking rats, an additional effect of CORT treatment. Brain NTE, CbE and AChE were not different among the groups except in the CC (NTE lower in CORT-drinking rats). Brain catecholamines levels were similar except the norepinephrine in H was higher in CORT-gavaged rats (23.7+/-5.4 nmol/g tissue) than in the corn oil group (13.5+/-5.5 nmol/g tissue). The ethanol-drinking, CORT-gavaged rats had lower levels of CP norepinephrine than the ethanol-drinking, corn oil-gavaged rats. (Supported by DAMD 17-99-1-9489. This abstract does not necessarily reflect the position or policy of the US Government).

707 COMPARATIVE DISPOSITION OF N, N-DIMETHYL-P-TOLUIDINE (DMPT) IN MALE F344 RATS AND B6C3F$_1$ MICE.

K. J. Dix, M. W. Gurule, B. M. Hedtke and K. Ghanbari. *Lovelace Respiratory Research Institute, Albuquerque, NM.*

DMPT is a high-production-volume chemical used to accelerate polymerization in the manufacture of bone cements and dental materials, is found in industrial glues and artificial fingernail preparations, and is used as an intermediate in dye and pesticide synthesis. Human exposure to DMPT is possible in prosthesis users, people with dental plates, and occupational settings. The reported LD_{50} values for DMPT in rodents are as follows: oral, rat, 1650 mg/kg; intraperitoneal (IP), mouse, 212 mg/kg; 4-h inhalation (LC_{50}), rat, 1400 mg/m^3; and dermal, rat, >2000 mg/kg. We are investigating the disposition of [^{14}C]DMPT in male F344 rats and B6C3F$_1$ mice after a single dose. The objectives are to evaluate rates and routes of excretion, tissue distribution, and metabolism of [^{14}C]DMPT. Rats and mice received oral doses of [^{14}C]DMPT, then were housed individually in metabolism cages; urine, feces, volatile organics (VOCs), and CO_2 were collected for up to 72 h. At sacrifice the tissue distribution of carbon-14 was determined. By 6 h after dosing, all mice that received 250 mg DMPT/kg showed decreased activity and labored breathing. Following the death of one mouse at ~24 h, the remaining mice were euthanized. Mice excreted little urine and feces during the study. In contrast, rats that received 250 mg DMPT/kg exhibited no overt signs of toxicity and remained healthy for the duration of the 72-h study. Rats excreted ~82% of the dose by 72 h, with ~72% excreted in urine, 3% in feces, 6-7% as VOCs, and <1% as $^{14}CO_2$. By 24 h after dosing >60% of the dose was recovered. Based on results in rats at 250 mg/kg, orally administered DMPT is well absorbed. This appears to be the case in mice as well since the 250 mg/kg oral dose, which is close to the IP LD_{50} in this species, was acutely toxic. We continue to evaluate the metabolism and disposition of DMPT in rats and mice at lower oral doses to better understand the species-specific toxicity of DMPT to aid the National Toxicology Program in designing toxicity studies and assessing potential human health risk from DMPT exposure.

708 IODINE KINETIC BEHAVIOR IN TISSUES OF PND10 MALE AND FEMALE PUPS FOLLOWING ORAL DOSING.

K. O. Yu, R. A. Clewell, D. A. Mahle, J. M. Gearhart and D. R. Mattie. *Operational Toxicology, US Air Force, Wright-Patterson AFB, OH.*

The iodide ion is the essential element for synthesis of thyroid hormones (T_3 and T_4). Thyroid hormones are important for normal brain development in both fetuses and in neonates of rodents and humans. The objective of this study was to understand kinetic behavior of iodide in Sprague-Dawley PND10 pups and to determine if there were gender differences. PND10 male and female pups weighing 20 g were orally dosed with 1μg/kg ^{125}I and returned to their dams. Pups (n=6) received 0.3 μCi ^{125}I mixed with non-radiolabeled iodide and were sacrificed at 0.5, 2, 4, 8, 12, 24, and 72 h post dosing. Thyroid, blood, skin, gastrointestinal (GI) tract and GI contents (GC) were collected to study tissue distribution of iodide in males and females. The only statistically significant gender differences in iodide levels were in thyroid at all time points; skin at 2h; and GI tract at 72h post dosing. Levels of bound iodide in thyroid of male and female pups at 0.5, 2, 4, 8, 12, 24, and 72 h were 3.9, 58.5, 100.6, 172.8, 334.9, 429.6, 515.9 and 2.6, 38.8, 97.0, 194.9, 296.8, 387.9, 684.6 ng/g, respectively. Free iodide levels in serum of males and females at the same time points were 0.36, 0.57, 0.56, 0.50, 0.45, 0.35, 0.14 and 0.35, 0.53, 0.55, 0.50, 0.44, 0.33, 0.13 ng/mL, respectively. Iodide levels in thyroid for both male and female pups were increasing until the end of experimental period (72h) while concentrations in serum were decreasing after 4h post dosing. Iodide levels in skin of male pup at the same time points were 0.29, 1.12, 1.14, 1.21, 1.24, 1.06 and 0.99 ng/g. Iodide levels of skin in both males and females were increased until 12 h post dosing and started to decrease until the end of study. Iodide concentrations in thyroid, skin, GC and GI tract were higher than serum levels, indicating sequestration of iodide in these tissues. This information will be used to develop a physiologically based pharmacokinetic model for postnatal pups.

709 PHARMACOKINETICS OF GENISTEIN FOLLOWING INTRAVENOUS AND ORAL ADMINISTRATION TO ADULT FEMALE SPRAGUE-DAWLEY RATS.

A. Upmeier, B. A. Elswick, H. D. Parkinson, W. L. Krol and S. J. Borghoff. *Division of Biological Sciences, CIIT Centers for Health Research, Research Triangle Park, NC.*

Genistein is a phytoestrogen present in soy-based food. It has been associated with potential health benefits in the chemoprevention of cancer and for relief of menopausal symptoms. Genistein is also present in virtually all rodent diets and has been reported to elicit estrogenic effects in developing rodents. Understanding the metabolism and distribution of genistein in rats is important for evaluating both the risks and benefits from exposure to this compound. Most kinetic studies only report total genistein levels (after hydrolysis of all metabolic conjugates) or only the nonconjugated parent compound in plasma. The objective of this study was to evaluate the elimination of both genistein and its conjugated metabolites from blood of female Sprague-Dawley rats following intravenous (i.v.) and oral administration of 4 or 40 mg genistein/kg b.w. Blood samples from cannulated (jugular vein) rats were collected at various time points. Genistein, genistein-7-O-glucuronide (C-7), genistein-4`-O-glucuronide, and 2 sulfate conjugates were quantitated in plasma by LC-MS/MS. Fitting the genistein plasma concentration-time

curves following i.v. administration to a 2-compartment model, the initial half-life (alpha-phase) for genistein was estimated to be ~ 6 min for the 40 mg/kg b.w. dose and ~ 5 min for the 4 mg/kg b.w. dose. The terminal half-life (beta-phase) for genistein following the high dose was estimated to be 30 min. Following oral administration, genistein and its conjugated metabolites were detectable in plasma as early as 5 min, indicating rapid uptake from the gastrointestinal tract. The level of conjugated genistein exceeded the level of parent compound at all time points by an average factor of 10, with C-7-glucuronide being the major metabolite (~ 63 % of all metabolites). In this study, the metabolism and distribution of genistein is described by time profiles distinguishing parent from conjugated forms. This study was funded by the American Chemistry Council.

710 TRANSPLACENTAL TRANSFER OF GENISTEIN AND CONJUGATED METABOLITES IN SPRAGUE-DAWLEY RATS.

S. Borghoff, C. C. Willams, H. D. Parkinson and A. Upmeier. *CIIT Centers for Health Research, Research Triangle Park, NC.*

Genistein is a phytoestrogen present in soy and virtually all rodent diets. It has been reported to elicit estrogenic effects in developing rodents. Understanding the placental transfer of genistein in rats as a route of fetal exposure is important for evaluating the dose of genistein associated with a biological effect in the developing fetus. The objective of this study was to determine whether genistein and selected metabolites transfer across the placenta to the fetuses of pregnant Sprague-Dawley rats (gestation day 19) administered 40 mg/kg genistein. At 1 hr after administration, rats were asphyxiated with CO_2, and blood was removed by cardiac puncture. Blood from each fetus in the litter was taken from the jugular vein and pooled by gender. The concentration of genistein and several of its conjugated metabolites (genistein-7-O-glucuronide (C-7), genistein-4-O-glucuronide (C-4), and sulfate conjugates (S1 and S2) were quantitated in plasma by LC-MS/MS. C-7 was the major metabolite in the maternal plasma, whereas S2 and C-7 were the major metabolites in fetal plasma. S1 was detected in maternal, but not fetal, plasma. There were no differences in concentrations of genistein or conjugated metabolites present in male and female fetal plasma. The fetal:maternal plasma ratios for genistein, C-7, C-4, and S2 were approximately 0.25, 0.04, 0.05, and 0.55, respectively. These data suggest that the glucuronide conjugates may not be transported across the placenta as readily as genistein or the sulfate conjugate S2. Conjugation may also take place in the fetal liver and contribute to the concentration measured in fetal plasma. Since genistein, but not its conjugates, interacts with the estrogen receptor, the level of genistein that gets transferred to the developing fetus and remains unconjugated is critical in understanding the exposure of this compound to the developing fetus. (This study was funded by the American Chemistry Council.)

711 DISPOSITION OF JUGLONE IN MALE F344 RATS.

E. H. Lebetkin, L. Chen and L. T. Burka. *LPC, NIEHS, Research Triangle Park, NC.*

Juglone, 5-hydroxy-1, 4-napthoquinone, has been extracted from black walnut hulls. Black walnut extract (BWE) is marketed as a natural product folk medicine to treat various ailments, eg. constipation, warts, eczema, herpes, psoriasis, fungal infections, and internal parasites. As part of the National Toxicology Program studies on BWE, the disposition of juglone was studied in male F344 rats with oral, iv, and dermal administration of ^{14}C-juglone. Juglone-derived radioactivity is excreted primarily in the feces (63-69%) and urine (18-24%) 24 hours after a single oral dose (0.1 or 1.0 mg/kg). Only trace amounts are found in respired air. After iv administration (0.1 mg/kg), juglone binds with blood components (13% of dose in blood after 24 h) and is excreted in urine (33%) and feces (23%); bile collection after iv dosing yielded 23.5% of the dose after 6 h. Twenty-four hours after 4 mg/kg dermal administration 85% of the dose remained at the dose site. Based on the iv and oral excretion data it is estimated that 40-50% of the oral dose is absorbed. Tissue levels are highest in the kidney and forestomach after oral dosing. The tissue to blood ratio is 2 to 27 in the kidney after all dosing routes while it is less than one for tissues other than the gastrointestinal tract. The high tissue concentrations of radioactivity are at the site of administration (SOA) for the three routes, forestomach, blood, and skin, as expected for a reactive chemical. Kidney is the only non-SOA tissue with high concentration of radioactivity. There is precedent for thioethers formed from quinone/GSH adducts to react with protein in kidney. This in turn is postulated to be responsible for the nephrotoxicity of some quinones or chemicals with quinones as metabolic intermediates.

712 DISPOSITION OF 5-NITROACENAPHTHENE IN F-344 RATS.

A. F. Austin and A. M. Nyanda. *Pharmacology, Meharry Medical College, Nashville, TN.*

Acenaphthene, a polycyclic aromatic hydrocarbon, occurs naturally in the environment by carbonization or pyrolysis of organic materials. With excess NO2 in the atmosphere, acenaphthene becomes nitrated, thus, producing 3- and 5-nitroacenaphthene (3- and 5-NAN). 5-NAN is the predominant compound formed and is present in environmental samples such as air particulates, cigarette tar, diesel exhaust, and in occupational settings such as the tire industry and power generators. 5-nitroacenaphthene is a suspected carcinogen and/or mutagen. Whether this compound is accumulated in tissues or undergoes rapid biological disposition and eliminated through urine or feces is not yet known. The objective of this study is to understand the disposition of pure 5-NAN in F-344 rats. This compound was administered at a dose of 50mg/kg *via* oral gavage and the animals were sacrificed at specific time intervals ranging from 0 to 15 hours. We used HPLC to quantify concentrations of 5-NAN in biological tissues and fluids. The extraction procedure involved homogenization of different tissues and liquid-liquid extractions using water, methanol, and chloroform (3:10:5). After centrifugation of the extracts, the organic phases were concentrated under N2 and reconstituted with acetonitrile. The results of the time course study show that 5-NAN is detected in the brain at a concentration of 11ng/g but not in the testes or adipose tissue at 1 h. This suggests that 5-NAN crosses the blood-brain barrier but not the testicular-blood barrier. 5-NAN is not sequestered in adipose tissue prior to the 2 h time point. There was a biphasic distribution of 5-NAN in the liver at 0.5, 2, and 6 h time points with concentrations of 3.5ng/g, 0.88ng/g, and 48ng/g, respectively. A similar biphasic distribution was seen in the small intestine at 0.5, 2, and 6 h time points with concentrations of 5.7ng/g, 63ng/g, and 16ng/g, respectively. In this study, we were able to show that trace concentrations of 5-NAN are detectable and quantifiable in biological tissues. We believe that 5-NAN is sequestered in tissues and can cause organ-specific toxicity in F-344 rats.

713 SULFURYL FLUORIDE: PHARMACOKINETICS AND METABOLISM IN F344 RATS.

A. L. Mendrala[1], D. L. Eisenbrandt[2], D. A. Markham[1], A. J. Clark[1], S. M. Krieger[1], C. E. Houtman[1] and D. L. Rick[1]. *[1]The Dow Chemical Company, Midland, MI and [2]Dow AgroSciences LLC, Indianapolis, IN.*

This study was conducted to determine the pharmacokinetics and metabolism of inhaled sulfuryl fluoride in the rat. Rats were exposed to 30 or 300 ppm sulfuryl fluoride for 4-hr. Blood, urine and feces were collected from rats exposed to 35S-labeled sulfuryl fluoride during and after the exposures and samples were analyzed for radioactivity, 35S-labeled fluorosulfate and sulfate, and fluoride (urine and feces only). Selected tissues were collected 7-days post-exposure and analyzed for radioactivity. Blood, brain and kidney were collected from rats exposed to unlabeled sulfuryl fluoride during and after the exposures and these tissues were analyzed for fluoride ion. Sulfuryl fluoride was rapidly absorbed, achieving maximum concentrations of 35S in both plasma and red blood cells (RBC) near the end of the exposure period. The 35S was rapidly excreted, mostly *via* the urine. Seven days post-exposure, small amounts of 35S were evenly distributed among the tissues, possibly a result of incorporation of 35S into amino acids. The highest concentration of 35S was detected in portal of entry tissues. The lungs had the highest levels of 35S 7 days post-exposure and the nasal turbinates also had detectable 35S. Radioactivity associated with the RBC remained elevated 7 days post-exposure and highly perfused tissues such as the spleen and kidneys had higher levels of 35S than other non-respiratory tissues. Radioactivity was cleared from plasma and RBC with initial half-lives of 2.5 hr after the 30 ppm exposure and 1-2.5 hr after the 300 ppm exposure. The terminal half-life of radioactivity was 2.5-fold longer in RBC than plasma. Although not directly assayed, there was no evidence of parent 35S-sulfuryl fluoride in the blood based on the radiochemical profiles. The identification of fluorosulfate and sulfate in blood and urine suggests that sulfuryl fluoride is first hydrolyzed to fluorosulfate, with release of fluoride, followed by further hydrolysis to sulfate and release of the remaining fluoride.

714 INCREASED ORAL BIOAVAILABILITY OF PYRIDOSTIGMINE BROMIDE FOLLOWING DERMAL CO-EXPOSURE TO DEET AND/OR PERMETHRIN IN RATS.

A. W. Abu-Qare[1], A. A. Abdel-Rahman[1], G. M. Blumenthal[2] and M. B. Abou-Donia[1]. *[1]Pharmacology and Cancer Biology, Duke University Medical Center, Durham, NC and [2]ICF Consulting, Durham, NC.*

Since their return from Persian Gulf War (PGW), many veterans have complained of symptoms including muscle and joint pain, ataxia, chronic fatigue, headache, and difficulty with concentration. The causes of the symptoms remain unknown. Because these veterans were exposed to a combination of chemicals including pyridostigmine bromide (PB), DEET, and permethrin, we investigated the pharmacokinetics of these agents, alone and in combination, in rats. Male Sprague-Dawley rats (200-250 gm, 5 per treatment group) were treated with a single oral dose of PB (13 mg/kg) alone and in combination with DEET (400 mg/kg, dermal) and/or permethrin (1.3 mg/kg, dermal). Plasma concentrations of PB, DEET, and permethrin were simultaneously determined by a method previously developed in our lab

(J. Chromatogr. B. Biomed. Sciences. Appl. 749:171-178, 2000). When administered alone, PB was moderately rapidly absorbed, with a C_{max} of approximately 7 μg/mL at a T_{max} of 2 hr. Elimination was biphasic, with an initial phase half-life of approximately 3 hr and a terminal phase half-life of approximately 25 hr. The calculated AUC∞ was approximately 80 μg·hr/mL. Co-administration of DEET or permethrin increased the Cmax to over 10 μg/mL and increased the AUC∞ to 140 μg·hr/mL without significantly altering the elimination half-lives. Co-administration of both DEET and permethrin increased the C_{max} to over 10 μg/mL, increased the AUC∞ to 140 μg·hr/mL, and reduced the terminal elimination half-life to 13 hr. These results suggest that DEET and/or permethrin, given dermally, can significantly increase the bioavailability of oral doses of PB. Therefore, administered doses of PB should be adjusted for those individuals who are being co-administered DEET and/or permethrin. (Supported in part by a grant from the US Army Medical Research and Materiel Command (DAMD) 17-99-1-9020 to MBA)

715 DISPOSITION OF DECAMETHYLCYCLOPENTASILOXANE IN F344 RATS FOLLOWING A SINGLE ORAL DOSE.

M. L. Jovanovic, D. A. McNett, J. M. Regan and K. P. Plotzke. *Health and Environmental Sciences, Dow Corning Corporation, Midland, MI.*

The disposition of ^{14}C-decamethylcyclopentasiloxane (^{14}C-D5) was evaluated in male and female Fischer 344 rats following a single oral administration of 1000 mg of ^{14}C-D5 in corn oil/kg of body weight. Animals (N=4/sex) were housed in glass metabolism cages for collection of urine, feces and expired volatiles. At 168 hr postdose, animals were sacrificed and selected tissues and remaining carcasses were collected. All samples were analyzed for radioactivity content. Feces and expired volatiles were also analyzed for parent D5 concentration. A separate group of animals (N=6/sex) was used to determine radioactivity and parent D5 concentration in blood at 15 min, 1, 6, 12, 24, 48, 72, 96, 120, 144 and 168 hr post dosing. Whole-body autoradiography (WBA) was used for qualitative *in vivo* assessment of tissue distribution of radioactivity. Rats in the WBA groups were sacrificed at 3, 12, 24, 48, 96 and 168 hr post-dose. The majority of administered radioactivity, regardless of sex, was eliminated in the feces (81.43% for males and 80.03 % for females). Total absorption (radioactivity recovered in urine, expired volatiles, expired CO_2, tissues and carcass) in males and females was 21.82 and 19.62%, respectively. Both sexes showed similar patterns of disposition (Urine: 4.70 and 4.37%; Expired volatiles: 13.36 and 10.37%; Expired CO_2: 0.92 and 0.97%; Tissues: 0.38 and 0.49%; Carcass: 2.46 and 3.43% for males and females, respectively). Qualitative assessment of tissue distribution (WBA) showed that the radioactivity was systemically available and distributed to major organs such as bone marrow, liver, kidney and fat. All of the radioactivity in the expired volatiles was attributed to parent D5. Metabolic profile evaluation of urine and feces showed that the entire radioactivity in the urine consisted of metabolites, whereas in the feces the majority was parent D5 with a trace metabolite. In summary, approximately 20% of ^{14}C-D5 was absorbed after single oral administration in corn oil in Fischer 344 rats.

716 PHARMACOKINETICS OF PERFLUOROOCTANOIC ACID IN MALE AND FEMALE RATS.

R. A. Kemper and G. W. Jepson. *Biochemical and Molecular Toxicology, Haskell Laboratory for Health and Environmental Sciences, Newark, DE.*

Perfluorooctanoic acid (PFOA) is a perfluorinated fatty acid analogue used in surfactant and emulsifier applications. In the current study, the plasma pharmacokinetics of PFOA in male and female Sprague-Dawley rats were investigated. PFOA was administered by oral gavage at doses of 0.1, 1, 5, and 25 mg/kg. In order to estimate oral bioavailability, PFOA was also administered at a dose of 1 mg/kg by i.v. injection. PFOA in serial plasma samples was quantitated by LC/MS/MS. Following oral administration, maximum plasma concentrations of PFOA were observed at approximately 10.5 and 1.25 hours in males and females, respectively. In male rats, elimination kinetics of PFOA were monophasic and independent of the administered dose, with an average elimination half life of approximately 171 hours. In female rats, plasma kinetics appeared biphasic at higher dose levels, with elimination half lives of ranging from approximately 3-15 hours, depending on the dose level. Areas under the plasma concentration vs time curves (AUC) for oral and i.v. 1 mg/kg doses were similar in both sexes, indicating that oral bioavailability of PFOA was approximately 100%. To further characterize sex differences in persistence of PFOA, male and female rats were administered 0.1 mg/kg PFOA by oral gavage, and serial plasma samples were analyzed until plasma PFOA concentration fell below detection limits of the analytical method. PFOA was detectable for at least 84 days in male rats, with an apparent plasma half life of approximately 288 hours. In females, plasma PFOA had dropped below detection limits within 36 hrs, with a half life similar to that observed in previous experiments. These studies confirm the marked sex differences in elimination of PFOA in rats and serve to more fully characterize plasma pharmacokinetics of PFOA at multiple dose levels. This research was sponsored by the Association of Plastics Manufacturers in Europe (APME).

717 COMPARATIVE TISSUE DISTRIBUTION AND URINARY EXCRETION OF INORGANIC ARSENIC (iAs) AND ITS METHYLATED METABOLITES IN MICE FOLLOWING ORAL ADMINISTRATION OF ARSENATE (AsV) AND ARSENITE (AsIII).

E. M. Kenyon[1], L. Del Razo[2] and M. F. Hughes[1]. *[1]ORD/NHEERL/ETD/PKB, USEPA, Research Triangle Park, NC and [2]CINVESTAV-IPN, Mexico City, Mexico.*

Valence state is a critical determinant in the disposition and metabolism of pentavalent compared to trivalent inorganic arsenic. In this analysis, the time-course tissue distribution of iAs and its methylated metabolites, monomethyl arsenic (MMA) and dimethyl arsenic (DMA), were compared in blood, liver, lung, kidney and urine of female B6C3F1 mice given equivalent oral doses (0, 10 or 100 micromol/kg) of sodium arsenate or sodium arsenite. The concentration of iAs in both blood and liver were very similar at earlier time points (1 to 8 hours post dosing); however by 24 hours levels of iAs in liver of AsIII-dosed mice were 5-fold higher, most likely due to binding of AsIII. MMA and DMA levels in blood were generally higher following AsIII compared to AsV administration; this is most likely a consequence of more rapid initial absorption at early time points and release from bound sites with subsequent metabolism at later time points. Kidney concentrations for iAs, MMA and DMA were generally higher (up to three-fold) following AsV compared to AsIII administration reflecting the more rapid urinary excretion of total As following AsV administration. Levels of MMA measured in kidney following AsV administration are not reflected in amounts excreted in urine suggesting the possibility of sequestration. DMA is preferentially accumulated in lung following either AsV or AsIII administration; two-fold higher levels are achieved following AsV administration, but levels are maintained higher for a longer time period following AsIII administration. These data demonstrate distinct organ-specific differences in the distribution of metabolites following administration of comparable doses of AsV and AsIII that will be important to consider when investigating mechanisms of arsenic-induced toxicity. (This abstract does not necessarily reflect EPA policy.)

718 TOXICOKINETICS OF AZT WHEN ADMINISTERED IN COMBINATION WITH TRIMETHOPRIM AND SULFAMETHOXAZOLE TO MICE.

J. L. Valentine[1], S. A. Anderson[1], Y. Yueh[1], D. R. Brine[1], C. M. Sparacino[1] and B. J. Collins[2]. *[1]RTI, Research Triangle Park, NC and [2]NIEHS, Research Triangle Park, NC.*

Trimethoprim (TMP) and sulfamethoxasole (SMX) are administered in combination for prophylactic *Pneumocysti carinii* pneumonia infection; the most common complication of AIDS, and a major recurrent cause of illness in HIV-infected patients. Since these medications are likely to be dosed together with AZT to many HIV-infected patients, it is important to assess the potential for adverse interactions. The objective of the present study was to evaluate the pharmacokinetics of AZT when administered in combination with TMP/SMX. In an AZT toxicokinetic study, mice were administered a single iv or oral dose of AZT (15, 25, 50 or 100 mg/kg). In combination studies, mice were administered a single iv (100 mg/kg) or oral (25, 50, or 100 mg/kg) dose of AZT and an oral dose of 250, 500 or 1000 mg/kg TMP/SMX. In repeated dose studies, mice were administered oral doses of 25, 50 or 100 mg/kg AZT and oral doses of 250, 500 or 1000 mg/kg TMP/SMX twice daily for 7 days. A single blood sample was collected from each animal at a predetermined time point from 5 min to 24 h (n = 3 per time point) following the last dose. Blood samples were processed for plasma and analyzed for AZT by HPLC. Pharmacokinetic parameters were estimated after constructing plasma concentration-time curves for each of the dose regimens. After iv dosing of AZT alone, AUC increased greater than expected at 100 mg/kg compared with lower doses. No substantial differences were noted in iv AZT pharmacokinetics when coadministered with oral TMP/SMX. After oral dosing of AZT alone, AUC and Cmax increased greater than expected across all doses. Coadministration with 1000 mg/kg TMP/SMX reduced Cmax with little change in AUC estimates compared with respective oral doses of AZT alone. Repeated dosing of AZT+TMP/SMX resulted in greater than proportional increases in AUC only at 1000 mg/kg TMP/SMX, but not at lower doses. Thus, the highest TMP/SMX dose resulted in changes in AZT pharmacokinetics when administered in combination with oral AZT after single and repeated dosing.

719 DISTRIBUTION OF PCB 84 ATROPISOMERS IN FEMALE C57BL/6 MICE.

H. Lehmler[1], D. J. Price[2], W. Garrison[3], W. J. Birge[2] and L. W. Robertson[1]. *[1]Graduate Center for Toxicology, University of Kentucky, Lexington, KY, [2]School of Biological Sciences, University of Kentucky, Lexington, KY and [3]USEPA, Athens, GA.*

Nineteen of the 209 possible PCB congeners exist as pairs of stable rotational isomers that are enantiomeric to each other. A racemic mixture of PCB atropisomers is present in technical PCB mixtures, thus raising concerns about enantioselective dis-

tribution, metabolism, and disposition of these congeners. We investigated the distribution and enantiomeric fractions (EF) of PCB 84 in untreated female C57BL/6 mice. PCB 84 was injected intraperitoneally with 600 µmol/kg body weight, and the EFs were determined by chiral gas chromatography in liver, brain, lung, heart, spleen and kidney after three or six days. The EFs in brain, liver, lung and heart were significantly different from the racemic PCB 84 standard at days three and six, with an enrichment of (+)-PCB 84 in all four tissues. A significant enrichment of (+)-PCB 84 in the kidney was observed for day six. No significant difference was observed for the spleen on both time points. Tissue EFs for the brain showed the highest EF, whereas the EFs in the spleen were almost identical with the PCB 84 standard. The EFs did not change significantly between day three and six, suggesting that the differential distribution of (+)-PCB 84 may primarily occur during the initial distribution phase. (Supported by ES 07380)

720 CHLOROTRIAZINE KINETICS IN FEMALE RATS FOLLOWING A SINGLE ORAL GAVAGE DOSE OF ATRAZINE OR ITS CHLORINATED METABOLITES.

J. Brzezicki, B. K. Cranmer, J. D. Tessari and M. E. Andersen. *Environmental and Radiological Health Science, Colorado State University, Fort Collins, CO.*

Atrazine (2-chloro-4-ethylamino-6-isopropylamino-s-triazine, ATRA) is a selective triazine herbicide commonly used to control broadleaf and grassy weeds in corn, sorghum, sugarcane, and other crops. Diaminochlorotriazine (DACT) is the major metabolite seen in *in vivo* studies following oral ATRA administration. We have developed an analytical method to identify and quantitate ATRA and all chlorinated metabolites in plasma, and then used this method to assess plasma time courses of ATRA and its three chlorinated metabolites, DACT, des-ethyl (DE-ATRA), and des-isopropyl (DI-ATRA) after oral dosing. A single oral gavage dose was administered at 90 mg ATRA/kg in a 1% methyl- cellulose suspension. The majority of total area under the curve (AUC) for chlorotriazines in plasma was DACT (>95% total AUC) followed in order by DI-ATRA, DE-ATRA and ATRA. Equimolar oral dosing studies were completed with DACT, DE-ATRA and DI-ATRA. Maximum absorption of DACT was observed 8 hours post dosing, followed by approximate first-order elimination with a plasma half-life of 12 hours and a rate of elimination equal to 0.0578. DI-ATRA reached higher initial plasma concentrations than did DE-ATRA following oral doses of each compound. With each compound, absorption appeared to be multi-phasic, probably representing solubilization of the slurried dosing solutions after gavage. Due to rapid metabolic clearance from plasma, the blood AUC observed after oral dosing with DE-ATRA, DI-ATRA or ATRA itself, is dominated by DACT. Work supported by STAR grant (R-828610-01-0).

721 USE OF WHOLE-ORGANISM CHEMICAL RESIDUE ANALYSIS AND LASER SCANNING CONFOCAL MICROSCOPY TO DESCRIBE THE DISTRIBUTION OF PBTS IN FISH EARLY LIFE STAGES.

M. Hornung, P. M. Cook and J. W. Nichols. *NHEERL, MED, USEPA, Duluth, MN.*

Fish early life stages (ELS) are more sensitive than juveniles or adults to many persistent bioaccumulative toxicants (PBTs). To better understand the mechanisms by which these chemicals produce toxicity during fish ELS, dose-response relationships need to be determined in relation to the distribution of chemicals in sensitive tissues. In this study, whole-organism residue analysis was combined with *in situ* imaging using a multi-photon laser scanning confocal microscope (LSCM) to describe the tissue distribution of PBTs during fish ELS. The method was tested in Japanese medaka (*Oryzias latipes*)using pentamethyl-difluoro-boro-indacene (BODIPY), a model chemical having high fluorescence efficiency and a log K_{ow} value near 5.0, and the polyaromatic hydrocarbon benzo[a]pyrene (BaP). The tissue distribution of fluorescent signal was compared to the whole-embryo chemical concentration at time points during the embryo and early larval stages. The fluorescent signal of BODIPY was initially very strong in yolk lipid droplets with moderate signal in the yolk. During development the fluorescent signal became diffusely distributed throughout the embryo with strong signal remaining in the yolk and yolk lipid droplets. As embryonic development progressed, fluorescence became evident in the gall bladder, bile ducts, and gut. The distribution of BaP signal was similar to that of BODIPY at 1 d post-fertilization (dpf); however, by 5 dpf much of the signal was gone from the lipid droplets, and strong signal was observed in the bile ducts, gall bladder and gut. Analysis of tissue extracts indicated that BaP was metabolized during early development. This metabolism is thought to account for the difference in distribution of the two chemicals as determined with the LSCM. The LSCM is a useful tool for describing the tissue distribution of PBTs during fish ELS and can be employed to understand how metabolism affects this distribution. This abstract does not necessarily reflect EPA policy.

722 MACROPHAGE ACTIVATOR GENE EXPRESSION PROFILE DETERMINED USING cDNA MICROARRAYS.

A. M. Leone[1], J. B. Parker[1], M. McMillian[1], A. Nie[1], M. Kemmerer[1], S. Bryant[1], J. Herlich[1], L. Yieh[2], A. Bittner[2], X. Liu[2], J. Wan[2] and M. D. Johnson[1]. *[1]Drug Discovery Support, Johnson & Johnson Pharmaceutical Research & Development, L.L.C., Raritan, NJ and [2]Bioinformatics, Johnson & Johnson Pharmaceutical Research & Development, L.L.C., La Jolla, CA.*

Macrophage activation contributes to the adverse effects produced by a number of hepatotoxic compounds. We used cDNA microarray technology to compare transcriptional profiles elicited by two macrophage activators, lipopolysaccharide (LPS) and zymosan A, to those produced by approximately 100 prototypical hepatotoxicants to determine a shared signature profile for predicting macrophage activation-associated hepatotoxicity. Male rats, three per group, were administered each compound at a toxic dose determined by review of the literature and livers were harvested at a 24 hour time point. RNA was extracted, purified, amplified, fluorescently labeled, and hybridized to cDNA microarrays containing probes for 3434 rat genes. A database was constructed from hybridized chip images and the data were normalized and ratioed to vehicle control data. Multiple approaches to gene selection were compared and most of the resultant gene sets yield similar results by clustering analysis. Transcriptional profiles of the macrophage-specific toxin gadolinium and the lymphocyte activator concanavalin A co-cluster with LPS and zymosan, as do several other compounds (carbon tetrachloride, thioacetamide, dimethylnitrosamine, a-naphthyl isothiocyanate (ANIT), galactosamine and allyl alcohol) that are reported to act at least partially *via* macrophage activation. A number of NSAIDs share the same pattern, possibly as a consequence of endotoxin exposure secondary to their adverse effects on the gastrointestinal system. A few compounds such as coumarin whose toxicities have not previously been linked to macrophage activation also clustered with LPS and zymosan.

723 AROCLOR 1254 INDUCED TRANSCRIPT PROFILES IN RAT.

J. D. Retief[2], J. Martin[2], C. Wanke[1], H. Martus[1], S. Chibout[1] and F. Staedtler[1]. *[1]Preclinical Safety, Novartis Pharmacology AG, Basel, Switzerland, Switzerland and [2]Genomic Collaborations, Affymetrix, Inc., Santa Clara, CA.* Sponsor: V. Nogues.

Aroclor 1254 (polychlorinated biphenyl) is known to be a strong inducer of xenobiotic metabolizing enzymes such as various cytochrome P450 isoenzymes and a few phase II activities. Liver homogenate from Aroclor 1254 treated rats is widely used as metabolic activation system for xenobiotics in *in vitro* assay systems for genotoxicity testing. In contrast to the widespread use of this exogenous metabolizing system, relatively little is known about the enzyme induction profile of Aroclor 1254 in the liver and other organs. In the present study we have chosen a DNA microarray approach to evaluate the Aroclor 1254 induced mRNA levels in different rat organs. A group of male rats received a single intraperitoneal injection of 500 mg/kg Aroclor 1254. The control animals received only the vehicle. Five days later liver, jejunum and lung samples were taken and the RNA analyzed on Rat UG34A GeneChip expression probe arrays. The effects in the different tissues are compared and discussed, in particular the mechanism of induction and metabolic competence of the liver.

724 A COMPARISON OF ARRAY HYBRIDIZATION, MRNA DIFFERENTIAL DISPLAY, AND REAL-TIME PCR IN THE EVALUATION OF THE EFFECTS OF TROGLITAZONE ON GENE EXPRESSION IN PRIMARY HUMAN HEPATOCYTES.

L. Tang[1], B. Komoroski[2], K. Tiegler[1], J. Tibbits[1], T. Nolan[1], R. Suizu[1], R. Neft[1], L. Kier[1], S. Strom[2] and A. P. Li[1]. *[1]Phase-1 Molecular Toxicology, Inc., Santa Fe, NM and [2]Pathology, University of Pittsburgh, Pittsburgh, PA.*

Troglitazone, a 2, 4-thiazolidinedione antidiabetic, was found to be associated with fatal liver toxicity, leading to its withdrawal from the US market in March 2002. The mechanism responsible for the idiosyncratic hepatotoxicity in humans remains unknown, but is believed to be related to the interaction of the parent compound or its metabolites with the liver parenchymal cells (hepatocytes). Freshly isolated human hepatocytes represent a relevant experimental model for the evaluation of troglitazone toxicity for two important reasons: 1. The cells retain human-specific drug metabolizing enzyme activities; and 2. The cells are the *in vivo* target cells for troglitazone hepatotoxicity. In our laboratory, we have initiated the application of toxicogenomics to advance our understanding of the hepatotoxicity of troglitazone. Our initial goal is to establish the validity of the cDNA human microarray studies by comparing gene expression data using gene arrays with two additional platforms, mRNA differential display and real-time PCR. Using the PHASE-1 human microarray that contains cDNAs for 600 genes involved in various toxic response pathways we show that median cytochrome P450 3A4 mRNA levels increased 2.5-3.9 fold in human hepatocytes from three different donors treated with 25 uM troglitazone for 24hr. This is consistent with the finding that troglitazone is an inducer of hepatic P450 3A4. These results were confirmed using two additional gene

expression platforms: Real-time PCR and mRNA differential display. Further, mRNA differential display also clearly demonstrated the induction of not only CYP3A4, but also unique genes by troglitazone. Our results suggest that toxicogenomics studies using human hepatocytes and gene arrays as the experimental platform, can be used to further our understanding of the mechanism of the toxicity of troglitazone.

725 A SEARCH FOR MOLECULAR TARGETS OF LEAD: A NOVEL PROTEOMIC APPROACH.

F. I. Carvalho and M. E. Gillespie. *Pharmaceutical Sciences, St John's University, New York, NY.* Sponsor: F. Schanne.

Proteomics provides a powerful approach for detecting protein:protein interactions involved in cellular function or dysfunction. We have modified a bacterial two-hybrid system as a proteomic approach to identify potential protein targets of the neurotoxin lead. Lead is known to interfere with neurotransmitter release. Low levels lead toxicity produces subtle chronic neurological dysfunction, including biochemical and electrophysiological effects. The SNARE complex of proteins is required for neurotransmitter release *via* vesicular membrane fusion and exocytosis. Numerous proteins are involved in the formation and disassembly of active SNARE complexes during membrane fusion. We hypothesize that neurological dysfunction is the result of lead 's effects on the SNARE complex and it 's associated partner proteins. To identify the molecular targets of lead we used two approaches. In an "anchored screen", the SNARE complex was used to focus the search for associated proteins. In an "unanchored screen", numerous proteins encoded by human brain cDNA libraries were screened against each other, in order to identify any protein complex effected by the presence of lead. In both screens a primary antibiotic selection to identify potential protein complexes was followed with a secondary blue/white screen to confirm protein:protein interactions and to exclude false positives. A tertiary toxicology screen in the presence of 10^{-12}M, 10^{-9}M and 10^{-6}M lead identified protein:protein interactions affected by the presence lead, see Table 1. The molecular targets of lead included the SNARE complex as well as associated proteins. The small subset of protein complexes detected illustrates the power of such a simple proteomic screen to identify potential targets of any compound, drug or toxin, for further research. Table 1-Protein:protein interactions profiles for 1°, 2°and 3°screens|

Type of screen	Theoretical #of program complexes	Primary selection	Secondary screen	Tertiary toxicology screen
Unanchored	$\sim 10^{6}$	293	59	6
Anchored	5.6×10^{6}	50	11	1

726 CLUSTER ANALYSIS OF GENE EXPRESSION IN PRIMARY HUMAN HEPATOCYTES AND HEPG2 CELLS TREATED WITH HEPATOTOXICANTS AND HEPATOCARCINOGENS.

A. J. Harris[1], S. Dial[1] and D. A. Casciano[2]. *[1]Center for Hepatotoxicity, NCTR, Jefferson, AR and [2]Office of the Director, NCTR, Jefferson, AR.*

Macroarray and microarray data are currently being widely used to develop signature chemical profiles that have the potential to be used for the prediction of adverse properties in new drugs and chemicals. Another significant outcome may be the identification of new pathways by which toxicants and carcinogens affect the target cell. In this study, primary human hepatocytes from 3 male donors and HepG2 cells were treated for 18 hours with three genotoxic compounds, aflatoxin B_1, 2-acetylaminofluorine and dimethylnitrosamine as well as two non-genotoxic drugs, acetaminophen and methapyrilene. ^{33}P-radiolabeled cDNA from each sample was hybridized to seven individual Gene Filters® screening > 35, 000 distinct human genes. The data were analyzed to identify 1) patterns consistent with genotoxic or non-genotoxic agents and specific chemicals, 2) individual genes with altered expression after exposure to one or more toxicants, 3) subsets of genes that are consistently expressed or have variable expression in cultured primary human hepatocytes and 4) differential gene expression between cultured primary hepatocytes and HepG2 cells.

727 IDENTIFYING POST-TRANSLATIONAL MODIFICATIONS INDUCED BY CHEMICAL TREATMENT USING MALDI-MS AND HPLC-ESI-MS/MS.

M. D. Person, H. Lo, K. Tikoo, T. J. Monks and S. S. Lau. *Center for Molecular and Cellular Toxicology, The University of Texas at Austin, Austin, TX.*

Identification of novel post-translational modifications (PTM) of proteins remains a major challenge. Natural PTM induced by chemicals are usually reversible and alter protein function, whereas "unnatural" PTM (covalent adduct formation) may be irreversible and result in loss of protein function. To identify chemically-induced PTM we use comparative analysis of proteolytic digest MALDI-MS spectra of control and treated proteins to target differences due to PTM without initial assumption as to type or residue localization. Differences between modified and unmodified digest spectra highlight peptides of interest for MS/MS analysis. HPLC-ESI-MS/MS is then used to fragment peptides, and *de novo* sequencing to determine the type and location of the PTM. This approach presents a broad strategy for identifying reasonably abundant PTM in an unbiased manner, and is useful for identification of novel toxicant induced PTM. Successful characterization of a multiply modified histone protein and chemically adducted cytochrome c represent examples of this strategy. The PTM of histones plays an important role in regulating chromatin structure and function. Hyperacetylated histone 4 from LLC-PK1 cells was separated on a triton-acid-urea gel into 5 bands representing different levels of acetylation. Bands were digested in-gel and then analyzed by MALDI-MS and HPLC-ESI-MS/MS to identify the sites of methylation and acetylation. Benzoquinone (BQ) is a model non-redox-cycling quinone capable of alkylating proteins. Cytochrome c, a key protein involved in apoptosis, is adducted with BQ *in vitro*. A novel di-quinone species is the major adduct and is detected at two positions on the protein. The adduct targets lysine residues on cytochrome c, in contrast to peptide studies where single BQ and N-acetylcysteine-BQ adducts are seen preferentially adducting to cysteine residues. This result emphasizes the importance of sequence context in directing sites of adduction. (GM39338, ES07784, DK54991).

728 THE COMPARATIVE TOXICOGENOMICS DATABASE (CTD).

C. J. Mattingly[1], G. T. Colby[1], J. N. Forrest[2,1] and J. L. Boyer[2,1]. *[1]Bioinformatics, MDI Biological Laboratory, Salsbury Cove, ME and [2]Medicine, Yale University School of Medicine, New Haven, CT.* Sponsor: W. Toscano.

Over 70, 000 existing toxic chemicals are described by the Environmental Protection Agency (http://www.epa.gov/nheerl/research/ecosystems.html); however, the toxic potential of these chemicals and the molecular mechanisms underlying their action are not well understood. To promote understanding about the impact of environmental agents on genes and proteins, the Mount Desert Island Biological Laboratory (http://www.mdibl.org/) is developing the Comparative Toxicogenomics Database (CTD). CTD will be the first community-supported, publicly available resource to: 1) provide annotated associations between genes, references, and toxic agents; 2) include nucleotide and protein sequences from diverse species with a focus on aquatic and mammalian organisms; 3) offer a range of analytical tools for customized comparative studies; and 4) provide information to investigators on available molecular reagents. This collection of features will facilitate cross-species comparisons of toxicologically significant genes and proteins. The goal is to promote understanding of molecular evolution, the significance of conserved sequences, the genetic basis of variable sensitivity, and the complex interactions between the environment and human health. The planned scope and functions of CTD are described in this poster presentation (ctd@mdibl.org).

729 SOURCES OF VARIABILITY IN TRANSCRIPT PROFILING EXPERIMENTS.

D. M. Zimmer, J. M. Fostel, Y. Gu, P. R. Harbach, J. W. Davis and W. B. Mattes. *Investigative Toxicology, PCD Genomics, Pharmacia, Kalamazoo, MI.*

A critical question in toxicology is how individual animals respond to any given stimulus and how to generalize interpretations made from a small sample number. Frequently the assumption is made that the greatest source of variability is due to the treatment effect. However with a small biological response to the treatment other sources of variability become significant. In the area of safety evaluation this bears not only on the interpretation of toxicity studies (if inter-animal variability is observed) but also in extrapolation of animal responses to heterogeneous human populations. For toxicogenomics, this question has enormous bearing on whether samples from individual animals may be pooled prior to transcript profile analysis (TxPA) without affecting the overall results. An ancillary question is whether variability is greater at the level of the individual animal or the TxPA procedure. To this end we have examined four sources of variability: inter-animal, inter-scientist, tissue preparation and RNA preparation. Replicate samples from vehicle-treated animals were assessed using Affymetrix DNA arrays, and the variability in subsets of genes estimated using ANOVA. In the case of rat liver samples, the greatest contribution to variability was due to differences in gene expression seen between individual animals. Most genes had consistent expression patterns in all the samples but a few genes had biphasic expression patterns, i.e. were expressed at levels 5-fold or lower in some animals compared to age-matched animals housed in adjacent cages. It is possible that such expression differences could correlate with important biological responses, and may provide a means to identify factors contributing to apparent outlier responses seen in some in-life studies.

730 ADDUCTION AND INHIBITION OF HUMAN GSTP1-1 BY ACROLEIN: A PARALLEL PROTEOMICS APPROACH.

A. L. Ham, C. R. Orton and D. C. Liebler. *Southwest Environmental Health Sciences Center, College of Pharmacy, University of Arizona, Tucson, AZ.*

α, β-Unsaturated aldehydes and ketones are reactive electrophiles that are formed from numerous endogenous and environmental chemicals. These compounds can react with nucleophilic centers in proteins to form adducts and possibly inhibit their activity. We are using mass spectrometry-based proteomic approaches to map and quantify modifications on human GSTP1-1 to examine the relationship between adduct formation and the inhibition of enzyme activity. We are developing this system for use in parallel analysis of protein adduction and its effects on protein functions and protein-protein interactions. N-terminally hexahistidine-tagged human GSTP1-1 (His-GSTP1-1) was expressed in BL21(DE3) cells. The His-GSTP1-1 was purified from the bacterial lysate on a Ni-coated 96-well plate resulting in approximately 8.0 ± 1.1 μg of pure His-GSTP1-1 protein per well. The activity of His-GSTP1-1 was measured by the conjugation of 1-chloro-2, 4-dinitrobenzene with glutathione spectrophotometrically and correlated with the amount of protein per well. The resulting His-GSTP1-1 plate was then incubated with 0.25 μM, 2.5 μM and 25 μM acrolein for 1 hr at 37°C. This resulted in a 47%, 92% and 100% inhibition of activity, respectively, as compared to control. The His-GSTP1-1 was then digested in the wells and analyzed by LC-MS-MS analysis of tryptic and chymotryptic peptides. Tandem mass spectral data confirmed the formation of a Michael addition adduct at cysteine 47. This adduct increased in a dose-dependent manner and increased adduct levels correlated with decreases in enzyme activity. This system will enable studies of other adducts, adduct stoichiometry, and site specificity as well as the effects of adduction on protein-protein interactions.(Supported by NIH Grants ES10056 and ES06694).

731 DEVELOPMENT OF A RAT LIVER GENE EXPRESSION REAL-TIME PCR DATABASE FOR TOXICOGENOMICS USING RAT TOXICOLOGY CARDS.

R. Neft[1], B. Breitinger[2], S. Amur[2] and L. Kier[1]. *[1]Phase-1 Molecular Toxicology, Inc., Santa Fe, NM and [2]Applied Biosystems, Inc., Foster City, CA.* Sponsor: A. Li.

Real-time PCR is a sensitive, accurate and specific method for determining differential gene expression following exposure to toxic agents. Two rat toxicology Cards were developed for the ABI Prism 7700 Sequence Detection System. Each Card contains 24 sets (quadruplicates) of primers and TaqMan MGB probes for targets involved in pathways relevant to toxic response such as: DNA repair, metabolism, oxidative stress, carcinogenesis, apoptosis, detoxification and cell proliferation. Three male Sprague-Dawley rats (2.5 months old) were dosed with one of 52 compounds or vehicle control. The compounds used for real-time PCR database generation were hepatotoxins, nephrotoxins, apoptosis inducers, carcinogen/mutagens and teratogens. At 24 hours post-exposure, the rats were sacrificed and total RNA was isolated from exposed and control rat livers. The RNA was reverse transcribed and the RT-PCR data was evaluated using the ABI Prism 7700 Sequence Detection System. The Cards produced relevant, highly reproducible differential gene expression patterns. Linear regression analysis of gene expression data showed a range of correlations (0.9-0.2) between real-time PCR differential gene expression data and the cDNA rat microarray data from the PHASE-1 TOXbank Rat Database. The degree of correlation for many genes was excellent to good (0.9-0.5) for these two expression measurement methods.

732 REFINEMENT OF A HIGH-THROUGHPUT 2D-PAGE TECHNIQUE FOR THE EVALUATION OF UBIQUITIN-CONJUGATED PROTEIN STATUS INDUCED BY DEVELOPMENTAL TOXICANTS.

S. Hong, J. S. Sidhu, E. Kim and E. M. Faustman. *Env Health, University of Washington, Seattle, WA.*

The tremendous contributions made by the genomics revolution have allowed toxicologists to reexamine mechanisms of toxicity associated with environmental chemicals. However, limitations exist with the extrapolation of genomic data without a thorough understanding of the complex issues linked with post-transcriptional and post-translational modifications attributable to the proteome, such as ubiquitination. The standard method for quantitative proteomic analysis relies on a combination of high-resolution (isoelectric focusing, IEF) two-dimensional gel electrophoresis (2D-PAGE) and mass spectrophotometric (MS) identification of selected protein spots. Due to the laborious and often irreproducible nature of established 2D-PAGE techniques, we have attempted to refine various steps enabling a high-throughput and sensitive analysis of proteomic function. Samples were prepared from mouse embryonal fibroblasts (MEF). Using a commercial 2D-PAGE system, we optimized all steps involving sample isolation, purification, quantity, IEF, PAGE, staining and detection. These modifications resulted in significant reduction or removal of various artifacts, such as sample overload, streaking, and spot loss or gain that otherwise render 2D-PAGE highly problematic. SYPRO Ruby fluorescence staining and laser scanning with PD Quest software significantly enhanced spot identification and detection versus a traditional silver-stain procedure. In parallel analyses we used the refined system to compare ubiquitin-conjugated protein profiles in cells treated with methyl mercury (MeHg) or lactacystin, a potent inhibitor of proteosomal degradation, which induces the accumulation of ubiquitin-protein conjugates. Using western-blot detection, we were able to identify both conserved as well as unique patterns of spots associated with ubiquitinated protein targets in the various treatments. Our refined 2D-PAGE technique in combination with MS analysis will enhance our understanding of MeHg-associated toxicity. Supported by NIH Grants ES10613-01, ES09601-02, ES07033

733 GENE EXPRESSION BIOMARKERS THAT ACCURATELY PREDICT KIDNEY TUBULAR NECROSIS.

L. Kier and T. Nolan. *Phase-1 Molecular Toxicology, Inc., Santa Fe, NM.* Sponsor: A. Li.

Phase-1 TOXBank(TM) gene expression data for kidney samples from rats treated with 44 compounds (single i.p. injection) were analyzed to identify patterns of gene expression that could accurately predict or classify treatments that produced tubular necrosis at 72 hours after treatment. The data used were produced using Phase-1 Rat CT microarrays of some 700 toxicology-responsive genes. Several groups of genes were identified whose expression could accurately predict or classify tubular necrosis using predictive models such as the K-nearest neighbor model. Using randomized training and test sets of data predictive accuracy of >90% was observed for gene sets using expression data measured at 24 h. Accurate prediction of dose levels producing toxicity was observed for two compounds that produced tubular necrosis at a high dose but not at a low dose. Significant, but lower, predictive accuracy was observed for gene sets using expression data from samples obtained 6 and 72 hr after dosing. There appeared to be a fair level of redundancy in the predictive genes. Several different small subsets of genes (3-10 genes) had almost as high predictive accuracy as larger sets of genes. In addition to using multiple randomized training and test sets predictive accuracy was confirmed by using randomly classified data, which removed the predictive accuracy, and by accurately predicting tubular necrosis in samples that were not present in the original database. These results clearly demonstrate the ability of gene expression data to accurately predict or classify a specific conventional toxic endpoint.

734 ACUTE SARIN EXPOSURE-INDUCES EARLY AND PERSISTENT ALTERED GENE EXPRESSION IN THE NERVOUS SYSTEM: A MICROARRAY STUDY-BASED MODEL IN RATS.

T. V. Damodaran, A. G. Patel, H. A. Dressman, S. A. Lin and M. B. Abou-Donia. *Pharmacology and Cancer Biology, Duke University Medical Center, Durham, NC.*

Sarin induced gene expression patterns for an early time point (15 minutes:0.5 X LD50) and late time point (3-months:1 X LD50) have been studied in the nervous system of male Dawley-Sprague rats using affeymetrix: Rat neurobiology U34 chips. We have identified a total number of 65 and 38 genes showing statistically significant alteration from control levels at 15 minutes and 3-months, respectively. At the early time point, there were more altered genes, classified as ion channels, cytoskeletal and cell adhesion molecules, as well as neuropeptides and their receptors. They were followed by genes of cholinergic signalling, calcium channels and binding proteins, transporters, chemokines, GABAergic, glutamergic, aspartate, catecholaminergic, nitric oxide, purinergic, and serotonergic signalling molecules. At the late time point, there were more altered genes, classified as calcium channels and binding proteins, cytoskeletal and cell adhesion molecules, and GABAnergic sinalling molecules than any other groups. A total number of 6 genes were identified to be showing persistent altered expression in both time points. Selected genes from each of these time points were further validated using RT-PCR approaches. Some of the genes, identified in the present study were shown to be involved in the organophosphate-induced pathology by our and other groups. Principle component analysis of the expression data of the time points was used for comparative analysis of the gene expression, which indicated that the changes in gene expression is a function of dose and time of termination after the treatment. Our model also predicts that besides dose and duration of post-treatment period, aging and possibly other factors may be playing important roles in the regulation of pathways, leading to patho-physiological developments.Supported in part by the US Army contact No: DAMD-17-98-C-8027.

735 GENE EXPRESSION PROFILES: EVALUATION OF ANALYTICAL AND BIOLOGICAL NOISE IN CELL LINES.

M. C. Miller[1], G. S. Pittman[1], J. B. Collins[2], S. F. Grissom[2], C. J. Tucker[2], P. R. Bushel[2], R. S. Paules[2] and D. A. Bell[1]. *[1]DIR LCBRA GR, NIEHS, Research Triangle Park, NC and [2]DIR OSD OSD MA, NIEHS, Research Triangle Park, NC.* Sponsor: C. Portier.

Quadruplicate oligonucleotide microarrays were used to measure relative gene expression levels in 6 Epstein Barr virus transformed lymphoblast cell lines and 3 lymphoid tumor lines, in duplicate cultures, compared to a pooled control RNA reference sample. Clustering of expression profiles should be improved if analytical and biological noise can be omitted from data analysis. Analytical variability is being examined by comparing expression values on each chip using analysis at 95% or 99% CL, and identifying outliers based on 3 of 4 versus 4 of 4 replicate hybridizations. Experiments were designed to identify genes: 1) uniquely expressed in a cell line; 2) that differ among replicate cell culture samples (that may represent biological noise); 3) that change expression level over several weeks in culture. We evaluated expression of ~18, 000 genes in 9 cell lines. At the least stringent analysis level (95% CL; 3 or 4 of 4 replicates), we observed a total of 2208 genes as expression outliers relative to the pooled reference sample. Cell lines had an average of 310±183 expression outliers. An average of 53.3%±15.5% of expression outliers appeared in both biological replicates for a given cell line. Preliminary analysis of biological replicates allowed identification of a large number of genes (1451) whose expression level varied in culture (biological noise). Of these, 306 genes disagreed between replicates in more than one cell line. Removing genes identified as biological noisy left 756 "reliable" expression outliers. Examining the reliable genes in lymphoblast cell lines, we observed an average of 11±4 expression outliers unique to each cell line; in tumor cell lines an average of 44±27. These expression profiles may represent genetic traits of each cell line. Preliminary evaluation of data at more stringent levels (99% and 4/4 replicates) reduced total outliers by 75% and we are determining how this improves the reliable v noise classification in replicate cultures, and if it can improve the hierarchical clustering of cell lines.

736 MECHANISM OF RAT RENAL TOXICITY PRODUCED BY A KINASE INHIBITOR: A TOXICOGENOMIC APPROACH.

Z. Jayyosi[1], M. Hower[1], M. Wojke[1], J. Dwyer[1], M. Wang[2], N. Ge[3], M. Valerio[1], T. Monticello[1], K. Morgan[1] and P. Rao[1]. *[1]Drug Safety Evaluation, Aventis Pharmaceuticals, Bridgewater, NJ, [2]Bioinformatics, Aventis Pharmaceuticals, Bridgewater, NJ and [3]Biostatistics, Aventis Pharmaceuticals, Bridgewater, NJ.*

Kinase inhibitors are important cellular targets in a number of therapeutic areas. Due to the large number of intracellular kinases involved in physiological processes, specificity of a selected kinase inhibitor is crucial for exerting its pharmacological action without undue toxic effects. Compound X is a kinase inhibitor that was being developed for the treatment of asthma and rheumatoid arthritis. In preclinical studies, treatment-related effects were observed in the rat kidney (tubular degeneration) and liver (hepatocellular hypertrophy) in rats. The objective of the present study was two fold: 1) utilize toxicogenomics to evaluate gene expression alterations in the kidney to help elucidate the potential mechanism(s) of toxicity and, 2) determine the overall utility of toxicogenomics in drug safety. Male rats were dosed orally at 0, 10 or 200 mg/kg/day for 1 or 14 days. Kidney and liver target organs were collected at necropsy for toxicogenomic analysis and histopathology. Toxicogenomics experiments were performed using the Affymetrix rat RgU34A chip. Treatment-related tubular degeneration of the kidney was observed at 200 mg/kg/day and a mild hepatocellular hypertrophy. Principal component analysis of individual kidney tissue showed that the affected rats clustered separately from the controls. Specific mRNA transcript involved in intermediary metabolism, redox regulation, fatty acid metabolism, signal transduction, and transcription were altered. These alterations were associated with treatment-related histopathologic changes in the kidney. Results from this study indicate that toxicogenomic evaluation may provide useful information in regards to molecular mechanisms of drug-induced toxicity.

737 PROTEOMIC PROFILING OF SUMO-1 AND SUMO-2/3 PROTEIN CONJUGATION IN HEK 293 CELLS FOLLOWING EXPOSURE TO 4-HYDROXYNONENAL.

L. L. Manza and D. C. Liebler. *Southwest Environmental Health Sciences Center, University of Arizona, Tucson, AZ.*

Stress conditions such as heat shock, UV, alkylating agents and H_2O_2 have been shown to result in the modification of a variety of protein targets *via* the production of reactive electrophiles. These modifications can directly impact protein function or can alter posttranslational modifications and protein turnover, thus leading to a disruption of cellular regulatory processes. Recent studies have shown that stresses affect posttranslational modification by the small ubiquitin related modifier (SUMO) proteins. Sumo affects protein-protein interactions, localization and ubiquitination. Previous work in this lab has demonstrated that protein damage by the alkylating agent 4-hydroxynonenal results in a dose-dependent increase in the formation of both SUMO-1 and SUMO-2/3 conjugates and that SUMO-1 and SUMO-2/3 have unique protein targets. The purpose of the current studies is to identify proteins targeted by SUMO-1 and SUMO-2/3 and to localize the SUMO and SUMO-conjugates before and after treatment. HEK 293 cells were treated with 4-hydroxynonenal at doses of 10and 250 μM or equal volumes of vehicle (0.1% ethanol). After 60 minutes the medium was removed for determination of LDH leakage and the cells were lysed and separated into cytoplamsic and nuclear fractions. The fractions were then immunoprecipitated with anti-SUMO-1 or anti-SUMO-2/3 antibodies and processed for analysis by western blot and LC-MS-MS. Ten proteins containing the general consensus sequence for sumoylation have been identified in digests of immunoprecipitates of the treated cell fractions. This represents a list of potential targets of SUMO-1 and SUMO-2/3 conjugation not previously identified. Western blot analysis indicates that the sumoylated proteins are preferentially located in the nuclear fractions, especially for SUMO-1. Whole cell localization studies utilizing confocal microscopy are in progress. (Supported in part by NIH grants ES06694 and ES10056.)

738 ANALYSIS OF GENE EXPRESSION PATTERNS IN LARGEMOUTH BASS THROUGHOUT THEIR REPRODUCTIVE CYCLE AND WITH EXPOSURE TO p, p' DDE USING GENE ARRAYS.

P. M. Larkin[1,2], T. Sabo-Attwood[3], J. Kelso[2] and N. D. Denslow[2,4]. *[1]EcoArray LLC, Alachua, FL, [2]Biotechnology Program, University of Florida, Gainesville, FL, [3]Interdisciplinary Program in Pharmacology and Therapeutics, University of Florida, Gainesville, FL and [4]Department of Biochemistry and Molecular Biology, University of Florida, Gainesville, FL.*

The goal of this study was to determine changes in the specific expression profile of 132 genes in livers of female and male largemouth bass (*Micropterus salmoides*) throughout their reproductive cycle and as a consequence of exposure to the endocrine disrupting chemical, 1, 1-dichloro-2, 2-bis (p-chlorophenyl) ethylene (p, p-DDE). A custom built, targeted array containing many genes that are estrogen responsive, was used for the experiment. Fish were housed in outdoor holding pens and were sampled throughout the year. For experiments testing normal seasonal changes, largemouth bass were sampled before, during, and after vitellogenesis. As expected, gene expression patterns in the livers of male and female bass are different, especially for genes that are involved in oogenesis. Genes that change in females include those that encode vitellogenin and the zona radiata proteins, among others. The up-regulation of these genes coincided with the peak of plasma estradiol and peak plasma vitellogenin protein in these animals. Female and male LMB were also exposed to p, p-DDE in a laboratory setting. In males, exposure to DDE resulted in an increase in some estrogen-responsive genes including the vitellogenins and choriogenins. In females, the results were reversed; there was a down-regulation of these estrogen responsive genes. Other genes were also down-regulated. The results from these experiments suggest that gene arrays can be used in order to gain a better understanding of critical windows in reproduction in largemouth bass, and to assess sensitive life stages for exposure to various pollutants.

739 DIFFERENTIAL EXPRESSION OF PROTEINS DURING EARLY MOUSE LIVER CARCINOGENESIS INDUCED BY NON-GENOTOXIC MODEL CARCINOGENS OXAZEPAM AND WYETH-14, 643.

M. E. Bruno, B. A. Merrick, M. Iida, C. H. Anna, J. E. Hartis, J. R. Dubin, K. B. Tomer, R. C. Sills and T. R. Devereux. *NCT, NIEHS, Research Triangle Park, NC.*

The effects of two dietary non-genotoxic carcinogens in mouse liver, the anti-anxiety agent, oxazepam (Ox) and hypolipidemic agent, Wyeth 14, 643 (Wy), were studied by proteomics with the hypothesis that early common and unique protein expression changes might be observed prior the the onset of malignancy. Livers from untreated B6C3F1 mice were compared to those of mice receiving dietary 2500 ppm of Ox and 500 ppm of Wy for either two weeks or six months. Livers were homogenized and fractionated into cytosol, microsomes and nuclei prior to two dimensional gel electrophoresis and protein identification by mass spectrometry. A total of 146 proteins were identified of which 66 were cytosolic, 59 microsomal and 21 nuclear proteins. Peroxisome bifunctional enzyme was greatly induced by Wy (10-20 fold increase)at 2 week and 6 months and was also increased by Ox (3-4 fold increase). Biochemical markers of oxidative stress were indicated by increases in GSH-peroxidase, superoxide dismutase, epoxide hydrolase, peroxiredoxin-1 and GST-zeta 1 and were increased 2-4 fold in Ox and Wy treated mice. Several proteins were induced specific to Wy treatment at 6 months including fu-

marylacetoacetate hydrolase (7 fold), aconitase (11 fold), farnesyl pyrophosphate synthase (3 fold) and ENO1 (5 fold), the latter often being inducible during hypoxia. Ox treatment produced increases in a homolog to human PTD012 at 2.5 fold at 2 weeks and 4 fold at 6 months compared to unchanged levels in Wy. Histopathology data demonstrated that although no tumors were detected at 6 months, mice exposed to Ox exhibited centrilobular hypertrophy whereas Wy treated mice showed a generalized hepatocellular hypertrophy. While there are many similarities in protein expression after Wy and Ox exposure, proteomics may assist in biomarker discovery of early biochemical changes produced by non-genotoxic agents that ultimately lead carcinogenesis.

740 GENE MODULATION PATTERNS ASSOCIATED WITH AROMATIC GAMMA-DIKETONE NEUROTOXICITY.

M. Kim[1], M. Lasarev[1], S. B. Hashemi[1], S. Nagalla[2], M. I. Sabri[1] and P. S. Spencer[1]. *[1]CROET, Oregon Health & Science University, Portland, OR and [2]Pediatrics, School of Medicine, Oregon Health & Science University, Portland, OR.*

The neurotoxic gamma-diketone metabolites of n-hexane and 1, 2-diethylbenzene, namely 2, 5-hexanedione (2, 5-HD) and the more potent 1, 2-diacetylbenzene (1, 2-DAB), respectively, form colored protein adduct polymers and induce neurofilament(NF)-filled giant axonal swellings [Kim et al., Toxicol Appl Pharmacology 177:121-31, 2001; 183:55-65, 2002]. We have used 1, 2-DAB and 1, 3-DAB, a non-protein-reactive, non-chromogenic and non-neurotoxic isomer, to assess gene modulation and attempt to isolate the neurotoxic component. Forty-eight hours after a single i.p. dose of 20 mg/kg body weight of either isomer (n=3) dissolved in 2% acetone in saline (vehicle, n=4), animals were anesthetized, the spinal cord removed by saline extrusion, and RNA isolated by the Trizol method. cDNAs were hybridized using a single label (Cy5) to mouse cDNA spotted arrays containing ~13, 000 sequence-verified clones. Signal intensity was background-corrected, the data normalized, and significance assessed in pair-wise comparisons among the three groups using t-tests with a common standard deviation. False discovery rate was used to correct for numbers of genes examined. Approximately 400 genes showed significant differential modulation in vehicle- and DAB-treated data sets. Gene expression profiles for DAB isomers and vehicle were compared to identify differentially expressed genes selective for the neurotoxic isomer. These included genes coding for structural proteins (tubulin), myelin (myelin basic protein, proteolipid protein) and a glycolytic enzyme (glyceraldehyde-3-phosphate dehydrogenase). These proteins differ from those identified to date as direct protein targets of 1, 2-DAB, such as the NF proteins NF-H & NF-M. Future studies will compare the gene expression profiles for 1, 2-DAB and 2, 5-HD to determine whether a common gamma-diketone neurotoxic signature can be identified. Supported by NIEHS Superfund Basic Research Center #ES10338, a NIEHS Neurotoxicogenomics and Child Health Center Cooperative Agreement #ES11384, and the Oregon Workers' Benefit Fund.

741 INDENTIFICATION OF MOLECULAR TARGETS OF HEPATOTOXICANT THIOACETAMIDE USING 2-DIMENSIONAL ELECTROPHORESIS AND MALDI-MS.

H. M. Mehendale[1], U. M. Apte[1], J. Li[2], H. Coppage[2], N. Pedrick[2] and F. A. Witzmann[2]. *[1]Department of Toxicology, The University of Louisiana at Monroe, Monroe, LA and [2]Department of Cellular and Integrative Physiology, Indiana University School of Medicine, Indianapolis, IN.*

Thioacetamide (TA) is used as a model hepatotoxicant to study toxicant-induced liver injury and regeneration. The specific molecular targets of TA are largely unknown. Molecular targets of TA were resolved by 2-dimensional electrophoresis and identified by MALDI mass spectrometry. Total homogenates of livers of male S-D rats treated with a lethal dose (600 mg/kg, ip) were subjected to isoelectric focusing on either tube gels (pH 4-8) or IPG strips (pH 3-10) and the second dimension was run on 20 x 25 cm polyacrylamide gels. The gels were stained by Coomassie brilliant blue and densitometric analysis was performed by PDQuest software (BioRad). The data indicate that TA modifies more than 50 predominantly microsomal proteins. Charge modified proteins by TA include endoplasmic reticulum proteins, cytochrome b5, calreticulin, cellular chaperons such as grp75 and 94, hsp90, and hsc70. TA rendered oxygen-regulated protein (ORP150) undetectable and adducted protein disulfide isomerase and estrogen sulfotranferase. Interestingly, TA down regulated expression of carbamoyl phosphate synthase, a mitochondrial protein even though most of the molecular targets of TA are microsomal. The identification of other proteins adducted by TA using MALDI-MS is currently underway. These data indicate that the molecular targets of TA include proteins in endoplasmic reticulum where TA is bioactivated to its reactive metabolite (TA-sulfone). Modification of carbamyl phosphate synthase indicates that TA is capable of adducting proteins in mitochondria of liver cells, a novel finding suggesting the penetration of TA reactive metabolites into mitochondria. The outcome of this study will lead eventually to identification of TA-adducted proteins and shed light on the mechanism of TA-induced liver injury (Supported by ES-9870).

742 DBZACH: AN INTEGRATIVE TOXICOGENOMIC SUPPORTIVE RELATIONAL DATABASE SYSTEM.

S. S. Pai[2,4], L. D. Burgoon[1,3,4], P. C. Boutros[2,4], E. Dere[2,4], Y. Sun[2,4], R. Aiyar[2,4], J. Vakharia[2,4] and T. Zacharewski[2,3,4]. *[1]Pharmacology & Toxicology, Michigan State University, East Lansing, MI, [2]Biochemistry & Molecular Biology, Michigan State University, East Lansing, MI, [3]Institute for Environmental Toxicology, Michigan State University, East Lansing, MI and [4]National Food Safety & Toxicology Center, Michigan State University, East Lansing, MI.*

The dbZach toxicogenomic system couples dbZach (http://dbzach.fst.msu.edu), a Minimum Information About Microarray Experiments (MIAME) supportive toxicogenomic relational database, with Java-based data mining and visualization tools. The dbZach database indexes large microarray datasets and currently consists of six functional subsystems (i.e. Clones, Genes, Microarray, and Protocols, Sample Annotation, Toxicology) with three more in development (Real-Time Polymerase Chain Reaction (Real-Time PCR), Affymetrix, Pathway, and Promoter). The Microarray, Clones and Genes subsystems relate features spotted on our internally developed arrays to gene annotation information such as name, abbreviations, chromosomal locations, and function. The Sample Annotation, Toxicology, and Microarray subsystems relate annotative information about experimental samples and their sources to microarray data, in addition to integrating data from pathology, biochemical assays, clinical chemistry, pathway maps, and real-time PCR, thus facilitating an integrative analysis solution for toxicogenomic studies. dbZach is currently populated with human and mouse data with the incorporation of rat data in the next year. The Java-based data mining and visualization tools facilitate microarray data mining, quality control monitoring, and correlation analyses between microarray and real-time PCR data. The dbZach system is built on Oracle 9i, Java2SE, and Java2EE technologies within a Linux-Windows mixed environment. The dbZach system represents a comprehensive solution to the informatic impediments that toxicologists face regarding microarray data management and the integration of other relevant toxicological, pathological, and chemoinformatic data. Supported by NIH grants ES 04911-12, ES 011271 and ES 011777.

743 TOXICANT CLASS SEPARATION USING GENE EXPRESSION PROFILES DETERMINED BY cDNA MICROARRAY.

J. B. Parker[1], A. M. Leone[1], M. McMillian[1], A. Nie[1], M. Kemmerer[1], S. Bryant[1], J. Herlich[1], L. Yieh[2], A. Bittner[2], X. Liu[2], J. Wan[2] and M. D. Johnson[1]. *[1]Drug Discovery Support, Johnson & Johnson Pharmaceutical Research & Development, LLC, Raritan, NJ and [2]Bioinformatics, Johnson & Johnson Pharmaceutical Research & Development, LLC, La Jolla, CA.*

Traditional drug development programs soon will be overwhelmed using only established patho-histological evaluations of toxicity. Toxicogenomics-monitoring gene expression changes in response to compounds and comparing them to prototypical toxicant induced gene expression signatures-shows promise for detecting toxicity prior to pathological manifestation. A microarray determined gene expression database of over 100 paradigm compounds was constructed using a maximal tolerated dose at a single 24 hour timepoint in 3 male rats per treatment. Three types of hepatotoxicity were examined: peroxisome proliferation, macrophage activation and oxidative stress. Each type of toxicity was easily distinguished from control based on gene expression, and by a variety of statistical and multivariate analyses, gene sets were identified selective for each toxicity. Training set compound selection was straightforward for peroxisome proliferators (PPAR agonists) and macrophage activators (LPS and zymosan). The training set for oxidative stress was chosen from compounds known to be oxidative stressors at high dose; many genes selected using this training set contain the anti-oxidant/electrophilic response element in their promoter. Many peroxisome proliferators and macrophage activators are oxidative stressors. Even so, a subset of 100 genes could be selected which clearly separate controls, peroxisome proliferators, macrophage activators and oxidative stressors. This allows a two-dimensional representation of multi-dimensional space where proprietary compounds can be compared to these paradigm compounds and their liabilities extrapolated from well characterized nearest neighbor compounds. The long-term goal is to determine additional toxicity specific gene expression patterns and perform similar (or improved) analyses to prioritize drug candidates before they move into traditional development.

744 SUPPRESSION OF INDUCIBLE NITRIC OXIDE SYNTHASE AND TUMOR NECROSIS FACTOR-A EXPRESSION BY BISPHENOL A *VIA* NUCLEAR FACTOR-KB INACTIVATION IN MACROPHAGES.

J. Kim[1] and H. Jeong[1,2]. *[1]Pharmacy, Chosun University, Kwangju, Kwangju, South Korea and [2]Research Center for Proteineous Materials, Chosun University, Kwangju, South Korea.*

Bisphenol A [BPA, 2, 2-bis(4-hydroxyphenyl)propane] is reported to have estrogenic activity; however, its influence on cytokine production or immune system function remains unclear. In this study, we investigated the effects of BPA on the

production of nitric oxide (NO) and tumor necrosis factor-a (TNF-a), and on the level of inducible nitric oxide synthase (iNOS) and TNF-a gene expression in mouse macrophages. BPA alone did not affect NO or TNF-a production. In contrast, BPA inhibited lipopolysaccharide (LPS)-induced NO and TNF-a production, and the levels of iNOS and TNF-a mRNA in a dose-dependent manner. Treatment with ICI 182.780, an estrogen-receptor antagonist, inhibited the suppressive effects of BPA. Transient expression and electrophoretic mobility shift assays with NF-kB binding sites revealed that BPA reduced the levels of the LPS-induced NF-kB transcription factor complex. These results demonstrate that BPA may affect the regulation of the immune system function by reducing NO and TNF-a production *via* the inhibition of NF-kB transactivation mediated through the estradiol receptor.

745 USE OF THE MCF-7 FOCUS ASSAY TO CHARACTERIZE PCB ESTROGENIC MODULATION.

K. F. Arcaro[3], D. D. Vakharia[1], Y. Yang[1] and J. F. Gierthy[1,2]. *[1]Wadsworth Center, New York State Department of Health, Albany, NY, [2]School of Public Health, State University of New York at Albany, Albany, NY and [3]UMass, Amherst, MA.*

Characterization of human risks resulting from exposure to xenobiotics that modify natural endocrine function continues to be a major public health issue. Detection and assessment of PCB and other xenobiotic estrogenicity has been proposed using various methods. These methods are weighted towards sensitivity, efficiency and physiological relevancy. We have developed an efficient, relevant *in vitro* assay which measures specific estrogen dependent induction of cell proliferation in estrogen responsive human breast cancer cell cultures which results in tissue restructuring analogous to that observed *in vivo*. This system is the MCF-7 focus assay, in which confluent cultures of MCF-7 human breast cells respond to 17β -estradiol (E2) treatment by post-confluent cell proliferation and formation of multicellular nodules or foci with an EC50 of 0.01 nM. The characterization of estrogenic and antiestrogenic activity of various polychlorinated biphenyls (PCBs) and their hydroxylated metabolites, obtained through this assay, is reported here. One hundred PCB congeners and hydroxyated metabolites were assessed for estrogen modulation using the MCF-7 focus assay. Of the PCBs tested, 13 demonstrated estrogenic activity with the most potent being 1/200, 000th that of E2 while 10 hydroxyated PCBs were estrogenic with the most potent being 1/10, 000th that of E2. Orthochlorinated PCBs and most frequently their para-hydroxylated metabolites showed the highest structure specific activity. These results complement the results from other short term *in vitro* assays to demonstrate thorough characterization of estrogenic activity. These results indicate that the MCF-7 focus assay is a useful, efficient, and physiologically relevant *in vitro* estrogen responsive assay which allows quantitative detection of xenoestrogens and the study of their mechanisms of action. Further refinement and automation of this assay system will allow its extended applicability. Supported by NIH grant P42 ES04913

746 MEASUREMENT OF FREE CONCENTRATION WITH ND-SPME IN AN *IN VITRO* ASSAY FOR ESTROGENIC ACTIVITY.

M. B. Heringa[1], R. Schreurs[1], B. van der Burg[2] and J. L. Hermens[1]. *[1]Institute for Risk Assessment Sciences (IRAS), Utrecht University, Utrecht, Netherlands and [2]Netherlands Institute of Developmental Biology, Utrecht, Netherlands.*

It is generally assumed that only freely dissolved molecules can pass cell membranes and can therefore be available to cells and receptors. Cells of *in vitro* assays are usually maintained in medium containing some percentage of serum, including serum proteins that can bind test compounds. The resultant dose-response curves of these assays are usually based on the nominal (i.e. added) concentration of test compound. However, various authors have shown that the response of test compounds in *in vitro* assays decreases as more protein is present in the assay medium. Some suggested that calculating the free concentration of the test compound would give a better, independent measure for the dose. Calculating free concentrations is not straightforward, however, as reliable values for the necessary parameters are hard to find, if not absent. Instead, it would be better to measure the free concentrations directly. We have for the first time, applied nd-SPME (negligible depletion-solid phase microextraction), an accepted method to measure free concentrations, to an *in vitro* assay. The free concentration of [^{3}H]estradiol was measured during an ER-CALUX assay, performed with different protein concentrations in the assay medium. As we expected, the dose-response curves shifted to the right with increasing protein concentration when using nominal concentrations. However, plotting the free concentration instead of the nominal concentration as dose parameter, resulted in one single dose-response curve. Calculated free concentrations, based on binding affinities and a multiple compartment equilibrium model, did not correspond well with measured free concentrations. These results not only confirm the importance of the free concentration in dose-response curves, but also show that directly measuring is better than calculating it. Nd-SPME proves to be applicable for measuring free concentrations in an in *vitro* assay.

747 OPTIMIZATION OF HUMAN LIVER AND KIDNEY SLICE INCUBATION IN DYNAMIC ORGAN CULTURE.

R. Fisher[1] and A. Vickers[2]. *[1]Vitron, Inc., Tucson, AZ and [2]Novartis Institute for Biomedical Research, East Hanover, NJ.*

Donated human liver and kidney, in the form of precision-cut tissue slices, are increasingly being used to predict drug metabolism and organ-specific toxicity of xenobiotics in man. In this study, an optimized procedure to incubate human liver and kidney slices has been developed. Slice viability was monitored by using various cellular viability parameters which included ATP content, K^+ retention, GSH content, morphology, and gene expression. This improved incubation procedure involved using organs which had been perfused with Viaspan cold preservation solution and selecting only those organs which were highly viable and fully functional. Immediately after the organs arrived at the laboratory, they were cut into 2 cm thick slabs, cored, and precision-cut into 200 μm thick slices using the Brendel/Vitron tissue slicer and V-7 cold preservation solution. Each slice was loaded onto a roller insert (Vitron, Inc.) which had a 13 mm Immobilon-NC HATF membrane disc (Millipore Corporation) placed on the medical-grade titanium screen. Each roller insert, containing the slice and membrane, was placed in a scintillation vial containing Waymouth's media with or without various supplements (ascorbate, sodium pyruvate, glucagon, insulin, epidermal growth factor, corticosterone, fetal calf serum, and heat-inactivated fetal calf serum. These vials were then placed in a 37°C Dynamic Organ Culture incubator with 95% O_2 and CO_2 flowing at 0.5 liters/min for 7 days. Each day an appropriate number of vials were taken out of incubation, the slices frozen in liquid nitrogen and stored in a -80°C freezer. To the remaining vials; their medium was changed every day with media prepared fresh that day and warmed to 37°C. This optimized incubation procedure allows one to incubate human liver and kidney slices for at least 7 days with only slight changes in cellular viability. The ability to incubate human tissue slices for longer periods of time may allow one to investigate correlations between viability, morphology, and gene expression and how they relate to the mechanism of toxicity.

748 A COMPARISON OF CYTOTOXICITY INDUCED BY SULFUR MUSTARD AND LEWISITE.

H. Meier. *USAMRICD, APG, MD.* Sponsor: S. Baskin.

Using a human leukocyte (HL) model, it was shown that both sulfur mustard (SM) and lewisite (L) (potent chemical warfare vesicating agents) caused a concentration and time dependent loss of cellular viability. Comparable levels of cytotoxicity were seen with both agents but at different concentrations and different post exposure times. HL from the same individual were exposed to either L or SM for 1, 2, 4, 8, 12, 16, and 20 hrs at 37oC, and then assayed by flow cytometry for their ability to exclude propidium iodide (PI). Cells that stained with PI were consider dead. Cytotoxicity was recorded after a 1-hr exposure to L. At concentrations of 3x 10-5 M and higher, L exposure reduced the number of viable cells to 20% of control level during the first 4 hrs post-exposure. During the next 16 hrs, there was no increase in cytotoxicity. When HL from the same individuals were exposed to SM at concentrations from 10-3 to 3x 10-6 M under the same conditions as the L exposure, there was no cytotoxicity detected during the first 4 hrs post exposure. However, after the 4-hr latent period, the number of PI positive cells increased in number and rate of appearance. At concentrations of 3x 10-4 M and higher, SM with time produced an almost linear increase in the number of PI positive cells that was independent of SM concentration, while at concentrations below 3x 10-4 M the cytotoxic responses were concentration-dependent.

749 OPTIMIZATION AND VALIDATION OF THE MCF-7 FOCUS ASSAY FOR ESTROGEN MODULATORS.

J. F. Gierthy[1,2], K. F. Arcaro[3], A. Li[4], P. Silber[4], S. Lloyd[4] and Y. Yang[1]. *[1]Wadsworth Center, New York State Department of Health, Albany, NY, [2]School of Public Health, State University of New York at Albany, Albany, NY, [3]University of Massachusetts, Amherst, MA and [4]In Vitro Tecnologies, Inc., Baltimore, MD.*

It is now known that many commercial and natural substances in the environment have estrogenic or antiestrogenic activity. Inappropriate exposure to these compounds may result in health risks, both to humans and wildlife. It is also recognized by the pharmaceutical industry that potent estrogens and antiestrogens are useful for hormone replacement therapy and treatment of estrogen dependent cancer, respectively. The MCF-7 focus assay for estrogen modulators is based on an *in vitro* model of estrogen dependent breast cancer. Cultures of MCF-7 breast adenocarcinoma cells display pre-confluent cell proliferation in the presence or absence of 17β-estradiol (E2). Furthermore, in the presence of E2 (EC50 0.01nM), these cultures also exhibit focal accumulations of cells. These multicellular, multilayered nodules are discrete foci of estrogen dependent post-confluent cell proliferation analogous to tumor development in estrogen dependent breast cancer. This estrogen dependent foci formation provides a physiologically relevant endpoint for es-

trogen modulator activity. Using cloned MCF-7 cell lines, the MCF-7 focus assay conditions have been optimized for media, duration, and quantification. A validation series of 65 estrogens or antiestrogens, which include natural products, pesticides, herbicides, and other commercial products, has been tested in the MCF-7 focus assay. The results indicate that the MCF-7 focus assay can detect and differentiate between weak and strong estrogen modulators. These data indicate that the MCF-7 focus assay will be useful in bridging the gap between high throughput receptor-based screening assays and *in vivo* studies to address both pharmaceutical development as well as environmental concerns. Supported by NIH grant R42ES0946702

750 DIMETHYL SULFOXIDE AND ETHANOL, ORGANIC SOLVENTS MOST COMMONLY USED AS VEHICLES *IN VITRO*, AFFECT PRECISION-CUT LIVER SLICE VIABILITY.

J. B. Ulreich, M. H. French, W. Ho and P. Z. Nakazato. *Surgery, University of Arizona, Tucson, AZ.*

For *in vitro* studies, dimethyl sulfoxide (DMSO), a dipolar solvent, and ethanol, a polar low molecular weight alcohol, are the most commonly used vehicles for test agents that are not miscible with aqueous media. We have shown previously that DMSO is hepatoprotective *in vitro* and *in vivo*. DMSO has antioxidant properties among other effects, and ethanol can cause liver protein modification and impair protein synthesis and secretion. However, the relative effects of these vehicles in precision-cut liver slice assays have not been defined. Our goal was to investigate the effects of concentrations of DMSO and ethanol commonly used *in vitro* on the viability of precision-cut liver slices. A second objective was to determine whether either vehicle reacted with filters used to maintain the integrity of liver slices during incubation. Livers of Fischer F344 rats were cored (8mm) and precision-cut at 250μ. Some slices were placed on filters (10mm diameter, 0.45μ pores) prior to loading on titanium carriers. Incubation was in a Vitron rolling incubation system under 95% oxygen/5% carbon dioxide for 24, 48, or 72h in complete Waymouths medium. DMSO was added at 1 (0.1%), 3 (0.3%), 5 (0.5%), 10 (1%), or 20 μl/ml) (2%) and ethanol was added at 1, 5 or 10 μl/ml). At various time points, liver slices were harvested and weighed. As indices of slice viability, potassium was measured by flame photometry and lactate dehydrogenase (LDH) release was measured spectrophotometrically using a Sigma kit. At 48h incubation, DMSO in the medium resulted in dose-related significantly higher potassium levels and reduced release of lactate dehydrogenase (LDH) than in control slices with no additions. Ethanol in the medium caused reduced potassium, thus reduced slice viability. The presence of filters under the slices during incubation better retained the integrity of the slices but did not appear to alter the effects of the vehicles. This research demonstrates the necessity of studying the influence of vehicles that might alter or mask compound-specific effects.

751 DETOXIFICATION AND MUTAGENIC RESPONSE IN MEDAKA (ORYZIAS LATIPES) EXPOSED TO 3-CHLORO-4-(DICHLOROMETHYL)-5-HYDROXY-2-[5H]-FURANONE (MX).

D. R. Geter[3,1], J. W. Fournie[2], M. H. Brouwer[3], A. B. DeAngelo[1] and W. E. Hawkins[3]. *[1]NHEERL, USEPA, Research Triangle Park, NC, [2]NHEERL, USEPA, Gulf Breeze, FL and [3]Gulf Coast Research Laboratory, Ocean Springs, MS.*

Ames assays have shown the drinking water disinfection by-product, MX, to be one of the most potent mutagens tested and accounting for about one-third of the mutagenicity of chlorinated drinking water. In this study, we investigated the effect of exposure to MX on cytochrome P4550E1 (CYP2E1)-like activity, total glutathione (GSH) levels, and mutation s in the liver of the medaka small fish model. The positive control chemical was methylazoxymethanol-acetate (MAMAc), an alkylating carcinogen in medaka. For mutation induction, we utilized the cII transgenic medaka strain that allow detection of *in vivo* mutations. The 96 hr LC50 of MX was 60 ppm in adult medaka. Both medaka liver microsome preparations and S-9 fractions catalyzed the hydroxylation of p-nitrophenol (PNP), suggesting CYP2E1-like activity. Male medaka exposed for 96 hr to the CYP2E1 inducers, ethanol and acetone under fasted conditions showed significant increases in PNP-hydroxylation activity. Furthermore, total reduced hepatic GSH was reduced in fish fasted for 96 hr, indicating that normal feeding is a factor in maintaining xenobiotic defenses. Exposure to MX and MAMAc induced significant increases in hepatic CYP2E1-like activity, but MX exposure did not alter hepatic GSH levels. Liver mutation induction was not observed in the cII transgenic medaka exposed to MX. However, a dose and time dependent increase was observed from the livers of fish exposed to 1 and10 ppm MAMAc. The lack of mutation induction following MX exposure correlates with mammalian studies which show MX to be effectively detoxified *in vivo*. These data strengthen the role of medaka as a suitable species for examining waterborne xenobiotic compounds. (This is an abstract of a proposed presentation and does not necessarily reflect the views of the EPA)

752 ACTIVITY OF BIOTRANSFORMATION ENZYMES IN EMBRYONIC TURKEY LIVER AND BIOACTIVATION OF 2-ACETYLAMINOFLUORENE.

C. E. Perrone[1], J. D. Duan[1], A. M. Jeffrey[1], G. M. Williams[1], U. Schmidt[2], H. J. Ahr[2] and H. G. Enzmann[2]. *[1]Pathology, New York Medical College, Valhalla, NY and [2]Institute of Toxicology, Bayer A.G., Wuppertal, Germany.*

Avian embryos are potential alternative species for chemical carcinogenicity studies (Enzmann, Kaliner *et al.* (1992) Carcinogenesis 13(6) 943-946; Brunnemann, Enzmann, *et al.* (2002) Arch. Toxicol. http://link.springer.de/link/service/journals/00204/contents/02/00380/). In the present investigations, the capability of embryonic turkey liver to biotransform xenobiotics was investigated. Biochemical analyses of 21-day *in ovo* turkey liver post-mitochondrial fractions revealed average basal activity levels for biotransformation enzymes as follows: 7-ethoxycoumarin de-ethylase (ECOD), 3.7 nmol/g/min; 7-ethoxyresorufin de-ethylase (EROD), 0.20 nmol/g/min; aldrin epoxidase (ALD), 1.47 nmol/g/min; epoxide hydrolase (EH), 308 nmol/g/min; glutathione-S-transferase (GS-T), 25 umol/g/min; and UDP-glucuronyl transferase (GLU-T), 25 nmol/mg/min. Enzyme activities of ECOD, EROD, ALD, EH and GLU-T, but not of GS-T, were increased by two-fold or greater activity levels following the acute administration of phenobarbital (24 mg/egg) on day 20, 24 hours before harvesting. In contrast, acute administration of methylcholanthrene (5 mg/egg on day 20) only induced changes in ECOD and EROD activities. Bioactivation of the aromatic amine carcinogen 2-acetylaminofluorene (AAF) was also examined using ^{32}P-postlabeling for DNA adducts. Single doses of 1 or 5 mg AAF/egg administered on day 20 *in ovo* resulted in a dose-dependent formation of AAF adducts with chromatographic migration patterns similar to those of C8- and N^2-AAF adducts observed in rat liver. Moreover, high levels of two other AAF adducts with migration patterns similar to those of unidentified AAF adducts in rodents were also observed in embryonic turkey livers. We conclude that 20-day *in ovo* turkey liver is capable of biotransformation of chemical carcinogens. Thus, turkey embryos could be utilized for the identification of genotoxic carcinogens.

753 *IN VITRO* CYTOTOXICITY TESTING WITH CULTURED NORMAL AND IMMORTAL HUMAN MAMMARY CELLS.

F. A. Barile, V. M. Abramoff and V. Wong. *Pharmaceutical Sciences, St. John's University College of Pharmacy & Allied Health Professions, Jamaica, NY.*

An *in vitro* study was conducted to determine the effects of trace metals on cultured human mammary cells. Confluent monolayers of human normal (MCF-12) and immortal (MDA-MB231) mammary epithelial cells were incubated in the absence or presence of increasing concentrations of trace metals for 24-hours, 4-days, and 7-days. Cell proliferation, MTT assay, and fluorescent-labeled probes, including calcein-AM and Sytox^R, were used to assess cytotoxicity. Inhibitory concentrations (IC50s) were extrapolated from concentration-effect curves after linear regression analysis. Arsenic, mercury, copper, nickel and cadmium were tested with each cell line. The data suggest that MDA-MB231 cells reveal some significant differences from normal mammary cells in their response to toxic insult. In addition, fluorescent probes are not as sensitive indicators of toxicity as the traditional MTT assay for cell viability. However, fluorescent indicators contribute to understanding the mechanisms of cytotoxicity. In combination with previously published reports, our study suggests that a basal cytotoxic phenomenon may only be used to compare either finite or continuous cell lines alone, but not to each other. In addition, the study suggests possible roles of metals in mammary cell carcinogenesis development.

754 SYNERGISTIC INTERACTION IN SIMULTANEOUS EXPOSURE TO *STREPTOMYCES CALIFORNICUS* AND STACHYBOTRYS CHARTARUM.

K. J. Huttunen[2,1], J. J. Jussila[2] and M. Hirvonen[2]. *[1]Division of Environmental Health, National Public Health Institute, Kuopio, Finland and [2]University of Kuopio, Kuopio, Finland.* Sponsor: M. Viluksela.

Bioaerosols deriving from the microbial growth in moldy buildings have been associated with adverse health effects. However, the causal relationship between detected exposures and health end points are not known because the most important causative microbes among the mixed population of microbes and interactions between them have not been identified. In this study, the inflammatory responses and cytotoxicity induced by a low dose of *Streptomyces californicus* (10^5 spores/ml) alone and together with three different doses (10^4-10^6 spores/ml) of *Aspergillus versicolor, Penicillium spinulosum, Stachybotrys chartarum* and bacterial strains *Mycobacterium terrae, Bacillus cereus* and *Pseudomonas fluorescens* were studied in mouse RAW264.7 macrophages. Inflammatory mediators were measured from the cell culture medium; cytokines (IL-1β, TNF-α and IL-6) immunochemically and nitric oxide

(NO) by Griess-method. Cytotoxicity was determined by using the MTT-test. The low dose of spores of *S. californicus* alone induced only minor production of IL-6 (up to 11±5 pg/ml). Out of the studied microbes, *P. fluorescens* and *B. cereus* caused a dose-dependent production of IL-6 (up to 2160±30 and 72±25 pg/ml, respectively) but these responses were not significantly increased by co-exposure with *S. californicus*. Interestingly, no inflammatory responses were detected by the fungal species, but simultaneous exposure to the low dose of *S. californicus* and *S. chartarum* caused a synergistic increase (up to 560±270 pg/ml) in production of IL-6. The cytotoxicity of the *S. californicus* was also increased by simultaneous exposure to *S. chartarum*. Altogether this data indicate that *Stachybotrys chartarum* and *Streptomyces californicus* are able to induce synergistic inflammatory and cytotoxic effects in mouse macrophages, which may be one plausible explanation to the adverse health effects already at fairly low microbial concentrations in moldy buildings.

755 E-LLNA: AN ENHANCED, FLOW CYTOMETRY-BASED LOCAL LYMPH NODE ASSAY WITH IMMUNOPHENOTYPE ANALYSIS.

D. Kim, E. J. Yurkow, T. L. Ripper, T. L. Fox, S. H. Young, A. C. Gilotti and G. DeGeorge. *MB Research Laboratories, Spinnerstown, PA.*

The local lymph node assay (LLNA) is an alternative to the guinea pig sensitization test used to identify and characterize dermal sensitizers. Although the LLNA is a useful test, its disadvantages include: 1) the basic assay cannot readily differentiate some types of irritants and sensitizers, 2) it uses moderate amounts of radioactivity, generating hazardous waste, and 3) with idiosyncratic or highly irritating chemicals, increased numbers of mice are required to determine multiple endpoints (i.e., proliferation, immunophenotype) necessary to properly characterize the sensitization potential. We have applied flow cytometric techniques to the ICCVAM-validated LLNA protocol to enhance the basic test and to increase sensitivity/specificity. Proliferation of lymph node cells (LNC) is measured by BrdU incorporation, and immunophenotypic markers such as B220 (CD45R), CD69, CD3, CD4, CD8, I-A^K, CD80 and CD25, were evaluated for predictivity of sensitization potential. The most useful endpoints in the E-LLNA were the number of BrdU+ cells, B:T cell ratio, %B220+, %CD69+ and %I-A^K+ cells. Several known sensitizers including oxazolone, DNCB, hexylcinnamaldehyde, mercaptobenzothiazole and chlopromazine+UVA were correctly classified. SLS, which is a false positive in the standard radiometric LLNA, was correctly classified, failing to changes characteristic of true sensitizers in %B220+, %CD69+, %I-A^K+ and the B:T cell ratio. The E-LLNA yields stimulation indices (SI) comparable to those in the ICCVAM study for DNCB, HCA and several other chemicals. In the E-LLNA, the EC_3 (concentration which induces a SI > 3) for HCA ranges from 4.2% to 9.8%, and for DNCB it ranges from 0.01% to 0.05%, consistent with standard assay results using ^{3}H-thymidine. In summary, we have developed an enhanced, flow cytometry-based LLNA which 1) can sensitively and specifically identify and characterize dermal contact sensitizers; 2) is non-radiometric; 3) allows better discrimination of false-positive irritants from true sensitizers when compared to the standard LLNA.

757 PHOTO-LLNA: AN ALTERNATIVE PHOTOSENSITIZATION TEST USING FLOW CYTOMETRY AND IMMUNOPHENOTYPIC MARKERS TO IDENTIFY AND CHARACTERIZE PHOTOALLERGENS.

G. L. DeGeorge, T. L. Ripper, T. L. Fox, E. J. Yurkow and D. R. Cerven. *MB Research Laboratories, Spinnerstown, PA.*

Although the Local Lymph Node Assay protocol has been validated by ICCVAM for several years, factors have limited its widespread application and development. These include the propensity for irritants to cause false-positive results in the assay, and the need to use radioactive chemicals. We have developed an alternative photosensitization test which uses a non-radiometric method to assess proliferation of lymph node cells (LNC), using solar simulator irradiation to photo-activate test chemicals. The PHOTO-LLNA measures bromodeoxyuridine uptake into the DNA of proliferating cells using a BrdU-specific antibody and flow cytometry. Other immunophenotypic parameters including the B:T cell ratio, B220+, CD3+, CD4+, CD8+, CD69+, CD25+, I-A+ cells which permit the discrimination of false-positive irritants from true photosensitizers. The PHOTO-LLNA correctly classified several photosensitizers including chlorpromazine (EC_{3UV} = 0.095%), promethazine, bithionol, sodium omadine and tetrachlorosalicylanilide (TSCA), as well as the sensitizers DNCB and oxazalone, and the irritants benzalkonium chloride and SLS. In general, multi-component vehicles such as DMSO:Acetone:Ethanol (4:3:3) and Acetone:Olive Oil (4:1) were more useful than single-component vehicles. The immunophenotypic markers CD69, I-A^K, B220 (CD45R) and the B:T cell ratio were the most useful immunophenotypic endpoints for characterizing sensitizers and photosensitizers, and discriminating them from false positive irritants such as SLS. In summary, we have developed a modified non-radiometric PHOTO-LLNA test to identify and characterize photosensitizers, which is sensitive enough to characterize several weak photosensitizers. In addition, the enhanced PHOTO-LLNA can employ multiple immunophenotypic markers to discriminate between true photosensitizers and false-positive irritants which interfere with the interpretation of the results in standard sensitization tests.

758 EVALUATION OF MTT METABOLISM AS A MEANINGFUL INDICATOR OF VIABILITY IN HUMAN CORNEAL EPITHELIAL TISSUE MODELS.

M. D. Hines, B. C. Jones and S. D. Gettings. *Avon Products Inc., Suffern, NY.*

Cellular viability is routinely measured by the uptake and reduction of tetrazolium salt, MTT, to an insoluble formazan dye by cellular microsomal enzymes. With the emerging utilization of tissue equivalent models, the MTT bioassay has often been used for measuring cellular viability, however it has recently been reported that MTT only measures the viability in the basal layer of cells while cells in the suprabasal layers go undetected. To evaluate the ability of the MTT assay to measure the cell viability in tissue equivalent models, we examined the cellular viability of two commercially available human corneal models (MatTek EpiOcular OCL-200 and SkinEthic HCE) with multiple viability markers. First, we determined that the amount of formazan formed by healthy, non-treated tissue constructs increased linearly between 0.5 and 3 hr. of exposure to MTT. Histological analysis of cryopreserved tissue models incubated with MTT revealed that all nucleated cell layers in both tissue models reduced MTT demonstrating metabolically viable cells in the appropriate cell layers. An opposite staining pattern was visualized in tissue models treated with propidium iodide, a dye that penetrates nonviable cells, with only cells in the upper most (granular) layer retaining the dye. Further, rhodamine 123, which localizes to the mitochondria of viable cells, produced a similar distribution pattern to MTT in both tissue models. When the tissue constructs were treated with Triton X-100 to induce cellular damage, we measured expected decreases in MTT reduction after 10, 30 and 60 min exposures. Visual assessment of histological sections after Triton X-100 supports these quantified values with an approximate amount of cells retaining the formazan crystals. Our experiments demonstrate that the traditional MTT method exhibited conversion linearly with time and by multiples cell layers in the tissue constructs. In addition, results from the MTT method were comparable to other cytotoxicity dyes. Thus, we conclude that our data support the use of MTT as a cell viability marker as a stand-alone method.

759 APPLICATION OF AMPHITOX ASSAY TO DETERMINE THE TOXICITY OF DICHLOROACETIC AND TRICHLOROACETIC ACIDS.

J. Herkovits[1], L. M. Munoz[1], C. M. Asorey[1] and J. C. Lipscomb[2]. [1]*Fundacion PROSAMA, Instituto de Ciencias Ambientales y Salud, Buenos Aires, Argentina and* [2]*ORD / National Center for Environmental Assessment, USEPA, Cincinnati, OH.*

Epidemiological studies point out that chlorinated drinking-water could be related to cardiovascular disease, cancer, adverse pregnancy outcomes, etc. AMPHITOX, an *in vitro* toxicity test conducted with amphibian (Bufo arenarum) embryos may be valuable as an alternative method for screening agents for developmental effects. The acute (96 hr) and short-term chronic (7 days) toxicity of trichloroacetic acid (TCA) and dichloroacetic acid (DCA) was evaluated. Triplicates of 10 embryos, at complete operculum stage (S25) were maintained in AMPHITOX Solution containing TCA and DCA in concentrations ranging from 25 to 10, 000 mg/L. As DCA and TCA changed media pH markedly; normal embryo development was confirmed at this pH. TCA at 100mg/L reduced the pH to 4 and lethality was 50% at 24hr; DCA at 70mg/L also reduced the pH to 4 and lethality was 100%. Up to 8, 000 mg/L of TCA at pH 4.6 did not exert lethality in the amphibian embryos until 96 hr of exposure; DCA at 60mg/L resulted in 30% lethality; the toxicity of neither compound increased markedly when exposure period was extended to 7 days. The results indicate i) the toxicity of both DCA and TCA may related to the decreasing of pH in the maintaining media and ii) DCA is more toxic than TCA at equivalent pH. This may be related to the metabolic pathways of these haloacetic acids. The results are consistent with the developmental and reproductive potencies of these two compounds and demonstrate the validity of the AMPHITOX assay in the evaluation of the adverse effects of these disinfectant byproducts.

760 ESTABLISHMENT OF RAT LD50 REFERENCE VALUES FOR CHEMICALS TESTED IN A VALIDATION STUDY OF *IN VITRO* CYTOTOXICITY ASSAYS.

M. W. Paris[1,2], J. A. Strickland[1,2], R. R. Tice[1,2] and W. S. Stokes[2]. [1]*ILS, Inc., Research Triangle Park, NC and* [2]*NICEATM, NIEHS, Research Triangle Park, NC.*

The Interagency Coordinating Committee on the Validation of Alternative Methods (ICCVAM) and NICEATM convened an international workshop in October 2000 that evaluated the validation status of *in vitro* methods for predicting

acute systemic toxicity (http://iccvam.niehs.nih.gov). Workshop participants recommended further validation of *in vitro* methods for predicting rodent and human acute toxicity. NICEATM and ECVAM subsequently designed a multi-laboratory validation study to evaluate two *in vitro* basal cytotoxicity tests using 72 coded chemicals representing the six globally harmonized acute oral toxicity hazard categories. In order to assess the predictive performance of the *in vitro* data, it was necessary to establish rodent LD50 reference values for each chemical. LD50 studies were located through literature searches and references from major toxicity databases such as RTECS. Studies were reviewed to identify the most appropriate LD50 reference value for each chemical. Criteria used to select reference LD50 values included: 1) consistency of age, gender, and species with that recommended in current acute oral toxicity testing guidelines, and 2) adequacy of the study based on documentation of experimental parameters such as method of administration, doses used, number of animals and deaths at each dose, and confidence interval for the LD50. Completeness of data for individual chemicals ranged from sparse summaries to detailed GLP compliant studies. Some LD50 values were unsupported by experimental details. The number of available rat oral LD50 values for each chemical ranged from 1 to 29, while oral LD50 values varied by as much as tenfold. Chemical-specific examples of the selection decisions for reference LD50 values will be provided. These reference data will be used to evaluate the extent that *in vitro* test methods can predict rodent LD50 values. Supported by NIEHS contract N01-ES 85424 and EPA IAG DW-75-93893601-0.

761 DESIGN OF A VALIDATION STUDY TO EVALUATE *IN VITRO* CYTOTOXICITY ASSAYS FOR PREDICTING RODENT AND HUMAN ACUTE SYSTEMIC TOXICITY.

J. A. Strickland[1,2], W. S. Stokes[2], S. Casati[3], M. W. Paris[1,2], A. P. Worth[3], H. Raabe[4], C. Cao[5], R. Clothier[6], J. Harbell[4], R. Curren[4], J. Haseman[7] and R. R. Tice[1,2]. *[1]ILS, Inc., Research Triangle Park, NC, [2]NICEATM, NIEHS, Research Triangle Park, NC, [3]JRC, ECVAM, Ispra, Italy, [4]IIVS, Inc., Gaithersburg, MD, [5]Edgewood Chemical Biological Center, US Army, APG, MD, [6]University of Nottingham, Nottingham, United Kingdom and [7]NIEHS, Research Triangle Park, NC.*

An international expert workshop convened by the Interagency Coordinating Committee on the Validation of Alternative Methods (ICCVAM) and NICEATM in October 2000 recommended that two *in vitro* basal cytotoxicity methods should be further evaluated to determine their usefulness for predicting rodent and human acute toxicity. NICEATM and ECVAM subsequently designed and initiated a multi-laboratory validation study to evaluate the relevance and reproducibility of two neutral red uptake assays using a mouse 3T3 fibroblast cell line and normal human epidermal keratinocytes. Seventy-two coded chemicals provided from a central repository and representing 12 chemicals from each of six hazard classification categories will be tested three times in each of three laboratories. The study is proceeding in three phases. Phase Ia established the historical databases for the positive control (sodium laurel sulfate) for each laboratory. The protocol will then be optimized to further minimize intra- and inter-laboratory variation after testing 3 chemicals in Phases Ib and 9 chemicals in Phase II. Sixty chemicals will then be tested in Phase III. The Registry of Cytotoxicity prediction model will be used to evaluate the prediction of rodent oral LD50 tests. Prediction of human toxicity will be evaluated using a prediction model based on human poisoning data. This study will characterize the usefulness of these cytotoxicity tests for predicting acute systemic toxicity and the extent that they may reduce or replace animal use. Supported by NIEHS contract N01-ES-85424 and EPA IAG DW-75-93893601-0.

762 CHARACTERIZATION OF DRUG METABOLIZING ENZYMES IN LLC-PK1 CELLS.

J. B. Tarloff and R. J. Gonzalez. *Pharmaceutical Sciences, University of the Sciences in Philadelphia, Philadelphia, PA.*

The biochemical mechanism leading to para-aminophenol (PAP) toxicity in LLC-PK_1 cells, a porcine-derived proximal tubule cell line, is unknown. While investigating the mechanism of para-aminophenol bioactivation, the drug metabolizing capabilities of this cell line were determined. Four enzyme systems were chosen based on their wide substrate specificity and their tissue distribution. These included cytochrome P450, flavin monooxygenase (FMO), lipoxygenase (LO), and prostaglandin H synthase (PHS). Activities of each enzyme were determined in LLC-PK_1 S9 and compared to activities in rat liver and kidney S9. The expression of each enzyme was also determined by Western blotting. CYP450 1A1/1A2 activity and expression was greatest in hepatic S9, markedly lower in renal S9 and virtually undetectable in LLC-PK_1 S9. Similar results were obtained for CYP 2E1. FMO and PHS activities and expression were greatest in hepatic S9, reduced in renal S9 and barely detectable in LLC-PK_1 S9. LO activity and expression was highest in liver S9, very low in renal S9 and intermediate in LLC-PK_1 S9. These data suggest that the drug metabolizing capability of LLC-PK_1 cells is very low. For toxicants that require metabolic bioactivation, LLC-PK_1 cells may not represent a suitable model. Further, this lack of drug metabolizing ability needs to be considered when using LLC-PK_1 cells.

763 ICCVAM/NICEATM EXPERT PANEL RECOMMENDATIONS FOR THE STANDARDIZATION AND VALIDATION OF *IN VITRO* ESTROGEN RECEPTOR (ER) AND ANDROGEN RECEPTOR (AR) BINDING ASSAYS.

R. R. Tice[1,2], G. Daston[3], T. Brown[4], B. S. Shane[1,2], C. J. Inhof[1,2], E. Zeiger[5] and W. S. Stokes[2]. *[1]ILS, Inc., Research Triangle Park, NC, [2]NICEATM, NIEHS, Research Triangle Park, NC, [3]Procter & Gamble, Cincinnati, OH, [4]Johns Hopkins University, Baltimore, MD and [5]Errol Zeiger Consulting, Chapel Hill, NC.*

A number of published studies indicate that a variety of natural and anthropogenic substances can interact with the endocrine system. As a result, legislation was enacted requiring the USEPA to develop a screening and testing program to identify substances with endocrine disrupting activity. Within the Tier 1 battery of screening test methods, *in vitro* ligand binding assays are proposed to identify substances that might interact with the ER or AR. The *in vitro* results would be considered with data from other Tier 1 assays in a weight-of-evidence evaluation of the need for testing in the more definitive Tier 2 *in vivo* assays. A comprehensive literature review indicated no adequately validated *in vitro* ER or AR binding assays. After considering the available data, an ICCVAM/NICEATM-sponsored Expert Panel developed recommendations for future standardization and validation efforts. For both types of binding assays, the Panel recommended recombinant human receptors and high-throughput procedures for validation; however, patent issues with the human AR may make it necessary to use a recombinant receptor derived from a non-human primate. For ER binding assays, the Panel recommended the use of intact human ERa or b proteins or the equivalent proteins from the rat. When screening for ecological effects, recombinant receptors from wildlife should be evaluated. Recommendations were also provided for minimum procedural standards and substances for validation studies. These recommendations should facilitate standardization and validation of protocols for ER and AR binding assays. Supported by NIEHS Contract N01-ES-85424.

764 ASSESSMENT OF PROTOCOL VARIABLES IN CYTOTOXICITY ASSAYS UTILIZING BALB/C 3T3 CELLS AND NORMAL HUMAN KERATINOCYTES.

R. D. Curren, G. O. Moyer, N. Wilt, M. L. Clear, A. M. Sizemore and G. Mun. *Institute for In Vitro Sciences, Inc., Gaithersburg, MD.*

The NTP Interagency Center for the Evaluation of Alternative Toxicological Methods (NICEATM) and the European Center for the Evaluation of Alternative Methods (ECVAM) are currently sponsoring a study to determine the usefulness of two *in vitro* basal cytotoxicity methods [employing BALB/c 3T3 (3T3) cells and normal human keratinocytes (NHK)] for predicting rodent and human acute toxicity. Although cytotoxicity protocols for these two cell types were available (and were used to qualify these cell types with the Registry of Cytotoxicity prediction model), it was thought prudent to reevaluate certain variables before starting a formal study. We examined acceptable solvent concentrations, the effect of exposure time on correct toxicity predictions, and the appropriate seeding density to match the desired exposure time. For solvent concentration, we concluded, based on cytotoxicity at higher doses, that 0.5% should be the highest concentration for both ethanol and DMSO for both cell types. To assess exposure time, we tested 6 chemicals whose cytotoxicity had been reported to increase significantly at exposures greater than 24 h [Riddell, *et al.* (1986) ATLA 14:86-92]. After testing the chemicals using 24, 48 and 72 h exposures, we concluded that a 48 h exposure was optimal for either 3T3 or NHK cells. Finally, we found that the appropriate cell seeding densities that permitted just subconfluent growth in the solvent-alone control wells after a 48 h exposure period were $2.5X10^3$ cells/well (96-well plates; 24 h prior to treatment) for 3T3 cells and $2.5X10^3$ cells/well (96-well plates; 48-72 h prior to treatment) for NHK cells. These new parameters have been incorporated into the protocols that are now being used in the ICCVAM/ECVAM sponsored multi-laboratory study to evaluate *in vitro* cytotoxicity assays.

765 HUMAN MICROVASCULAR ENDOTHELIAL CELLS AND COCAETHYLENE-INDUCED VASCULAR TOXICITY.

D. P. Tacker, G. S. Ansari and A. O. Okorodudu. *Pathology, University of Texas Medical Branch, Galveston, TX.*

Cocaethylene (CE) is a toxic compound formed in the human liver after co-exposure to cocaine and ethanol. Such exposure occurs in over 80% of cocaine abusers. CE is more potent, lethal, and persistent relative to either cocaine or ethanol. Case

and clinical studies have revealed an association between peak CE serum levels, vascular pathology, and ischemic organ damage and failure. To further investigate the pathogenic mechanisms uderlying these findings, we evaluated the direct effects of CE on immortalized human microvascular endothelial cells (HMEC-1). When HMEC-1 were exposed to physiologically relevant doses of CE (0, 0.1, 0.5, and 1mM) during log-phase growth, a dose-dependent decrease in average adherent cell number (n=8, p<0.05) was observed in treated versus non-treated HMEC-1 (controls). Trypan blue exclusion testing showed decreased average viability in 1mM-treated cells (83%) versus controls (94%, n=8, p<0.01) during log-phase growth. However, significant changes in cell number and viability were not observed when exposure occurred in confluent cultures of HMEC-1 versus controls. Analysis of media from 1mM-treated post-confluent cultures resulted in decreased pH (n=9, p<0.05) and changes in gas consumption as reflected by decreased media bicarbonate levels (n=9, p<0.05) versus controls. Cation analysis in media samples from 1mM CE-treated HMEC-1 showed significant decreases in Ca(2+) and Na(+), and increased K(+), versus controls (n=9, p<0.05 for all). Glucose levels in media from 1mM-dosed HMEC-1 were significantly higher (n=9, p<0.01) than controls. Such changes suggest a loss of cellular regulation of cations and mitochondrial metabolism after exposure to CE. MTT assays showed significantly increased metabolic activity in CE-treated cells (n=18, p<0.05) versus controls. All significant changes were time-dependent and observed over 72 hours after dosing. These results showed that CE is capable of direct, toxic interaction in HMEC-1.

766 PROGRESS REPORT ON THE DSSTOX DATABASE NETWORK: NEWLY LAUNCHED WEBSITE, APPLICATIONS, FUTURE PLANS.

A. M. Richard[1] and C. R. Williams[1,2]. *[1]NHEERL, USEPA, Research Triangle Park, NC and [2]NC Central University, Durham, NC.* Sponsor: L. King.

Progress will be reported on development of the Distributed Structure-Searchable Toxicity (DSSTox) Database Network and the newly launched public website that coordinates and serves as the central hub for this effort. DSSTox is an EPA-sponsored, community-wide project whose goals are to: 1) create and promote the use of standard format, chemical structure-inclusive data files for storing public chemical toxicity data; 2) involve the international user community in the effort to migrate more public toxicity data into the standard format for sharing; and 3) facilitate structure-searchability across toxicity databases and more complete access to data for use in toxicity prediction model development. DSSTox toxicity data files for a variety of public toxicity databases have been created for carcinogenicity, mutagenicity, aquatic toxicity, pesticide toxicity, and estrogen-receptor binding; a variety of other database files are in development. Importing of these files into commercial chemical relational database applications and other public web-based applications provide sophisticated structure-searching capability for exploring the structural basis for toxicity across multiple types of biological endpoints. Essential to the ultimate success of this effort will be community involvement in propagating the proposed data standards and hosting DSSTox standard format data files. Hence, one of the most important roles of the central DSSTox website is that of enlisting and coordinating the efforts of the larger toxicology and modeling communities in contributing to this public database project. This abstract does not reflect EPA policy.

767 ASSESSMENT OF COLONY NUMBER AND MORPHOLOGY HIGHLIGHTS TOXICITY FOR HEMATOPOIETIC AND MESENCHYMAL PROGENITORS.

E. Clarke and J. E. Damen. *Contract Assay, Stem Cell Technologies Inc., Vancouver, BC, Canada.* Sponsor: M. Ehrich.

Standardized and robust clonogenic assays for myeloid, erythroid and megakaryocytic progenitors can be used to assess the toxicity of lead compounds on the various precursors of mature blood cells. In addition, assays for mesencymal progenitors can be used to assess potential toxicity of compounds being developed for use in tissue engineering. Inhibitory activity can be determined in media formulations containing optimal cytokine combinations. This allows the identification of either gross effects i.e. reduction of colony numbers or subtle effects where colony number is consistent but the morphology of the colony is compromised. This morphological discrimination may be important to identify compounds that may have escaped toxic surveillance using other assays, and which may be used over an extended time period clinically. Unlike other surrogate assays that rapidly assess antigen expression or cell death, these clonogenic assays require culturing bone marrow, mobilized peripheral blood or cord blood cells for 14 days. This promotes the proliferation and differentiation of primitive cells into lineage specific colonies. In the semi-solid methycellulose based assay, the simultaneous proliferation of erythroid and myeloid colonies allows the identification of compounds that have lineage specific effects. Studies performed have shown that when cells are cultured in the presence of a toxic compound, colony number or morphology of one lineage type can be unaffected but there can be complete ablation of the other progenitors. The flexibility of these assays also facilitates the assessment of potential stimulatory molecules like chemokines or cytokines using sub-optimal cytokine concentrations. Using specific cytokine combinations, direct or synergistic effects of compounds on hematopoieitic progenitors can be elucidated. Although not useful for high throughput preliminary screening, these assays have proved important in pre-clinical studies.

768 EPIDERM™ FULL THICKNESS (EPIDERM-FT), A DERMAL-EPIDERMAL SKIN MODEL WITH A FULLY DEVELOPED BASEMENT MEMBRANE.

P. J. Hayden, J. Kubilus, B. Burnham, G. R. Jackson and M. Klausner. *MatTek Corp., Ashland, MA.*

Paracrine signaling between dermal fibroblasts (FB) and epidermal keratinocytes (KC) is believed to modulate skin responses during contact irritant or allergic reactions. Dermal FB also play an important role in photo-aging and photo-damage, wound healing and cancer progression. To enable *in vitro* study of these and other dermal phenomena in which FB-KC interactions are important, a full thickness skin model composed of a FB-containing dermis/KC-containing epidermis was developed. Normal human epidermal KC and dermal FB were cultured to produce highly differentiated full-thickness tissues extending wall-to-wall in cell culture inserts. Histologic examination of the tissue shows a collagen dermis populated by numerous viable FB and an epidermis consisting of stratified KC including basal, spinous, granular and stratum corneum components. The ultrastructure of the dermal/epidermal junction was examined by transmission electron microscopy. A well-developed basement membrane was evident. Hemidesmosomes were observed at the basal membranes of KC, with associated tonofilaments extending into the cytoplasm. Well-defined, continuous lamina lucida and lamina densa and fine anchoring filaments were present beneath the basal KC. Anchoring fibrils with characteristic striated structure connected the lamina densa to the underlying collagen matrix. Tissue responses to ultraviolet irradiation (UVR) were also evaluated. Twenty-four hours after irradiation with 40 J/cm2 of UVR, tissues were examined histologically, and culture media was assayed for pro-MMP-1 secretion by ELISA. Irradiation produced numerous sunburn cells and disruption of basal KC organization compared to control tissues. Also, pro-MMP-1 secretion was significantly increased compared to controls. EpiDerm-FT overcomes shortcomings of previous models in terms of providing a wall to wall tissue as well as appropriate *in vivo*-like basement membrane development. These attributes will enable more realistic *in vitro* toxicological studies of dermal/epidermal phenomena.

769 VALIDATION AND AUTOMATION OF AN *IN VITRO* TOXICITY SCREEN USING ACTIVTOX C3A HEPATOCYTE CELL LINE ON A FAMILY OF NSAIDS.

M. Walterscheid[2], A. V. Rizvi[1], T. L. Guthrie[1], J. Kelly[2] and T. M. Fletcher[1]. *[1]Cancer Therapeutics and Immunology, Southern Research Institute, Birmingham, AL and [2]Amphioxus Cell Technologies, Houston, TX.* Sponsor: J. Page.

Rational: Approximately half of all drug candidates fail due to poor toxicological profiles that are not identified prior to the commitment of lead compounds to costly trials. Despite advances in the development of high throughput technologies that benefit early phases of discovery, there is a lag in selection of early lead compounds that will prove non-toxic in pre-clinical and clinical development. By creating a way to conduct high throughput screening technologies with a cell line that accurately and reproducibly detects toxicity, a novel method for drug development could be established. Structure-activity relationships (SAR) can be derived allowing undesirable properties of molecules to be designed out early in the development, without necessarily affecting the potency of the compound. **Experimental Procedure:** All assays were performed using Amphioxus Cell Technologies' ACTIVTox human hepatocyte cell line. All liquid handling, fluorescence detection and incubations were fully automated on a high throughput system (HTS). Toxicity was evaluated using proliferation inhibition and membrane integrity in two different fluorescent based assays. **Results:** The nonsteroidal anti-inflammatory drugs (NSAIDS) present a structurally related group of compounds where there is an extensive scientific literature that can be used for standardization and comparison. . Upon ranking of the NSAIDS according to their toxicity, a clear structural progression was observed. As part of testing the reliability and quality of these high throughput toxicity screens, Z-factor analysis was performed in order to demonstrate the ease and reliability of these assays when adapted to a fully automated system. **Conclusions:** Our results demonstrate that ACTIVTox provides a set of high throughput toxicity assays that can be used to sort and rank compounds according to structure. Additionally, Z-factor values of 0.8 demonstrate it's use as a HTS early toxicity discovery tool.

769a EVALUATION OF THE METABOLISM OF TOXIN T514 (PEROXISOMICINE) IN HEPATOCYTES AND LIVER MICROSOMES.

M. Gomez-Silva, L. Garza-Ocanas, N. Waksman de Torres and A. Pineyro-Lopez. *Pharmacology and Toxicology, Medicine School, Universidad Autónoma de Nuevo León, Monterrey, Nuevo León, Mexico.*

Toxin T-514 (Peroxisomicine) is a dimeric hydroxyantrhacenone with selective citotoxic effect for malignant cells.In this study we have evaluated the metabolism of this compound in two *in vitro* systems (liver microsomes from rat, mouse, dog and monkey, and rat and human hepatocytes).The microsomes (12.5, 125 and 250 micrograms/mL) and hepatocytes (1x106 cel/mL) were incubated with the toxin (25 micromolar) for 0.5, 1, 3, 6, 9, 12 and 24 hours, and the samples were examined by chromatographic analysis and UV-Vis spectra. Two chromatographic peaks were detected besides the toxin peak in the rat microsomes samples and one in the monkey microsomes.The Tr and UV-Vis spectra of the peaks were very similar to those of the toxin suggesting that they would corresponde to semiquinone metabolites.The cytotoxicity of the two metabolites was evaluated in Chang liver cells and Hep G2 cells and they did not show the selective cytotoxic effect on tumoral cells as the original compound.

770 LOW-LEVEL CYCLO-SARIN (GF) VAPOR EXPOSURE IN RATS: EFFECT OF EXPOSURE CONCENTRATION AND DURATION ON PUPIL SIZE.

C. Whalley[1], B. Benton[1], J. Manthei[1], R. Way[1], E. Jakubowski[1], D. Burnett[1], B. Gaviola[1], J. Scotto[2], J. Forster[1], R. Crosier[1], D. Sommerville[1], D. Miller[2], C. Crouse[2], K. Matson[2], W. Muse[1], R. Mioduszewski[1] and S. Thomson[1]. *[1]Edgewood Chemical Biological Center, Aberdeen Proving Ground, MD and [2]Geo-Centers INC., Gunpowder, MD.*

Objective of the study was two-fold: a) to determine the EC50 for GF vapor-induced miosis and associated probit slope in the rat and b) to model the relationship between GF vapor concentration (C), exposure duration (t) and the probability of miosis. The probability of GF vapor-induced miosis (defined as a post-exposure pupil diameter 50% or less of pre-exposure pupil diameter) was estimated in rats exposed to various combinations of exposure concentration and duration. Groups of male and female Sprague-Dawley rats were exposed to one of a series of GF vapor concentrations for a single duration (10, 60 or 240 min) in a whole-body dynamic chamber. Miosis was measured using an infrared camera technique. For each exposure time, separate effective concentrations for miosis in 50% of the exposed population (EC50) and the corresponding dose-response slopes were determined by the Bliss probit method. Contrary to Haber's rule, ECt50 values increased with exposure duration (i.e., the Ct for 50% of the exposed population to show miosis was not constant over time). Female rats were more sensitive to GF vapor toxicity than male rats. Miosis was the only clinical sign noted following GF vapor exposure. Possible depression of blood esterase (acetylcholinesterase, butyrylcholinesterase and carboxylesterase) activities due to low-level range of GF vapor concentrations was also investigated. GF was regenerated from blood samples of vapor-exposed rats by the addition of fluoride ion at pH 4 and the samples were analyzed by GC-FPD and GC-MS. Levels of regenerated GF in the red blood cell (RBC) fraction of the samples were four to 20 times lower than in plasma. All controls were negative for regenerated GF. The primary conclusions were: a) the probability of GF vapor-induced miosis was not described by a toxic load model and b) no correlation was found between miosis and circulating esterase activity.

771 INHALATION TOXICITY OF SARIN (GB) VAPOR IN THE GOTTINGEN MINIPIG: LOW-LEVEL THRESHOLD EFFECTS.

S. Hulet[1,2], R. B. Crosier[1], D. R. Sommerville[1], B. J. Benton[1], J. S. Forster[1], J. H. Manthei[1], D. B. Miller[2], J. A. Scotto[1], R. A. Way[1], W. T. Muse[1], C. L. Crouse[2], K. L. Matson[2], R. J. Mioduszewski[1] and S. A. Thomson[1]. *[1]Toxicology, US Army - SBCCOM, Aberdeen Proving Grounds, MD and [2]Geo-Centers, Inc., Aberdeen Proving Grounds, MD.*

In order to estimate the potential impact of a chemical warfare agent vapor contamination on battlefield operations, it is necessary to fill critical gaps in data involving acute low-level exposures. While the initial signs of such an exposure may not be immediately life threatening, it is possible that they may become a physiological dysfunction, affecting performance of some military tasks. The ability to estimate threshold conditions of exposure (concentration and duration) that are likely to result in physiologically significant effects is an essential prerequisite for predicting the potential impact on task performance or military operations. The goal of these experiments was to determine the lowest sarin (GB) vapor concentration of physiological significance. During a whole-body exposure to GB vapor, the first noticeable effect, at such concentrations, is constriction of the pupil (miosis). The minipig was chosen as a model for studying the effects of GB vapor on the pupil because of anatomical and physiological similarities to humans. The minipigs were secured in a sling that allowed continuous monitoring of one eye. The pigs were individually exposed to fixed concentrations of GB vapor ranging from 0.03-2.0 mg/m^3 for 60 minutes. Pupil constriction was assessed, under dim-light conditions, using an infrared light sensitive video camera. Pupil size was continuously monitored by capturing high-resolution images of the eye before, during and after exposure to GB vapor. Pupil area was then quantified, off-line, using a custom-designed software package. Pupil area was graphed as a function of time. The relationship between the dose-response curve (percent pupil constriction as a function of time) and vapor concentration was investigated. The calculated EC_{50} (miosis) was 0.04267 mg/m^3 with 95% confidence intervals of 0.041 to 0.047 mg/m^3.

772 SUBCLINICAL DOSES OF THE NERVE GAS SARIN IMPAIR T CELL RESPONSES THROUGH THE AUTONOMIC NERVOUS SYSTEM.

R. Kalra, S. P. Singh, S. R. Boroujerdi, R. Langley, R. F. Henderson and M. L. Sopori. *Pathophysiology, Lovelace respiratory research institute, Albuquerque,, NM.*

The nerve gas agent sarin is a lethal tool in the hands of terrorists, and exposure to it may lead to neurotoxicity and death. Even low doses of sarin may cause subtle electrical changes in the brain. Because the brain communicates with and regulates the immune system, we examined the effects of inhalation of subclinical doses of sarin on the immune system. Spleen cells from F344 rats, inhaling low levels (0.2-0.4 mg/m3) of sarin for 1 h/day for 5 or 10 days, but not for 1 day, exhibited significant reductions in the primary antibody-forming cell response and T cell proliferation in response to concanavalin A and the anti-T cell receptor mAb. Moreover, sarin suppressed the increase of the intracellular calcium concentration in response to anti-T cell receptor mAb, indicating that sarin might affect the antigen-mediated signaling in T cells. The immunological effects of sarin were not associated with increased serum corticosterone levels or changes in the brain cholinesterase activity. However, pretreatment of animals with the ganglionic blocker chlorisondamine abrogated the effects of sarin on T cell mitogenesis. These results suggest that subclinical doses of sarin may suppress the immune system *via* the autonomic nervous system.

773 FLUORIDE ION REGENERATION OF GB FROM MINIPIG TISSUE AND FLUIDS AFTER GB INHALATION EXPOSURE.

E. M. Jakubowski[1], R. Mioduszewski[1], S. Hulet[1], J. Manthei[1], B. Benton[1], J. Forster[1], D. Burnett[1], R. Way[1], B. Gaviola[1], J. Edwards[2], W. Muse[1], J. Anthony[1], K. Matson[2], D. Miller[2], C. Crouse[2] and S. Thomson[1]. *[1]Operational Toxicology, US Army SBCCOM, APG-EA, MD and [2]Geo-Centers, Edgewood, MD.*

Fluoride ion regenerated sarin (R-GB) was found in minipig blood and tissue after whole-body sarin vapor exposure at miosis and lethal levels. R-GB in these samples was analyzed by GC-FPD or GC-MS after a C18 solid-phase extraction (SPE) sample preparation that included fluoride ion addition and pH adjustment. The highest levels detected after a lethal level exposure were seen in the lungs (22.8 ng/g) and red blood cells (18.8 ng/g) as expected after an inhalation exposure. Concentrations of R-GB in red blood cells were approximately 100 times greater than in the plasma. Outside of the lungs and blood, sections of the brain had significant levels of R-GB such as the frontal lobes (2.28 ng/g), the temporal lobes (1.68 ng/g) and the caudate nucleus (5.46 ng/g), which by itself was comparable to liver levels (5.84 ng/g). Other significant depots of regenerated GB included saliva (137 ng/g), nasal discharge (72 ng/g), and lachrymal discharge (186 ng/g). Limited amounts of free GB were also isolated from saliva (6.91 ng/g) and nasal discharge (0.65 ng/g). Serial blood samples taken before and during miosis-level GB vapor exposures resulted in red blood cell R-GB levels that steadily rose during the exposure. This clearly demonstrated the ability of the R-GB assay to monitor systemic dosage. The slopes of the lines created by plotting R-GB versus time closely correlated to the experimental exposure level. Therefore, the rates of GB absorption in these animals were proportional to the GB exposure concentration. Acetylcholinesterase activity, which is typically used to verify and monitor exposure to nerve agents, was an ineffective indicator of exposure at miosis levels in these experiments.

774 ACUTE EXPOSURE GUIDELINE LEVELS (AEGLS) FOR HYDROGEN CYANIDE.

S. Talmage[1], G. Rodgers[2], D. Krewski[3], K. Bakshi[4] and R. Garrett[5]. *[1]Oak Ridge National Laboratory, Oak Ridge, TN, [2]University of Louisville, Louisville, KY, [3]University of Ottawa, Ottawa, ON, Canada, [4]National Research Council, Washington, DC and [5]USEPA, Washington, DC.*

AEGL values represent one-time exposures for emergency situations. AEGL values were developed for hydrogen cyanide (HCN), a colorless, rapidly-acting, highly poisonous gas having an odor of bitter almonds. HCN is a systemic poison that inhibits cytochrome oxidase, thus preventing cellular utilization of oxygen. Data on

human exposures were limited to monitoring studies. Animal studies with several species addressed lethal as well as sublethal effects (incapacitation and changes in respiratory and cardiac parameters). Time scaling was based on C^n x t = k. Regression analysis of the exposure duration-concentration relationships for incapacitation and lethality for the monkey determined that n = 2 and that for the relationship for lethality in the rat, n = 2.6. The AEGL-1 values for 10 and 30 min and 1, 4, and 8 hr of 2.5, 2.5, 2.0, 1.3, and 1.0 ppm, respectively, were based on human monitoring studies in which the preponderance of data indicated that an 8-hour exposure to 1 ppm would be without adverse health effects for the general population. Time scaling utilized the default value of n = 3. The AEGL-2 values (17, 10, 7.1, 3.5, and 2.5 ppm for 10 and 30 min and 1, 4, and 8 hr, respectively) were based on exposure of cynomolgus monkeys to a concentration of 60 ppm for 30 minutes. This exposure was the threshold for a physiological response of increased respiration and central nervous system depression. The 60 ppm value was adjusted by a total uncertainty factor (UF) of 6. For time-scaling, n = 2 was used. AEGL-3 values (10 and 30 min and 1, 4, and 8-hr values of 27, 21, 15, 8.6, and 6.6 ppm, respectively) were based on the threshold for lethality in the rat following various exposures (15- and 30-min and 1-hour LC_{01} values of 138, 127, and 88 ppm, respectively). Values were adjusted by a total UF of 6; time scaling to the 4- and 8-hr exposure durations was based on the empirical data for lethality in the rat in which n = 2.6.

775 ACUTE EXPOSURE GUIDELINE LEVELS (AEGLS) FOR NERVE AGENTS.

A. P. Watson[1], R. Young[1], D. Opresko[1], V. Hauschild[2], G. Leach[2], J. Hinz[3], L. Koller[4], W. Bress[5], K. Still[6], D. Krewski[7], K. Bakshi[8] and R. Garrett[9]. *[1]Oak Ridge National Laboratory, Oak Ridge, TN, [2]US Army CHPPM, APG, MD, [3]US Air Force AFIERA, Brooks AFB, TX, [4]Environmental Health and Toxicology, Corvallis, OR, [5]Vermont Department Health, Burlington, VT, [6]US Navy NHRC, Wright-Patterson AFB, OH, [7]University of Ottawa, Ottawa, ON, Canada, [8]National Research Council, Washington, DC and [9]USEPA, Washington, DC.*

Nerve agents are potent anticholinesterase compounds. For AEGL development, human and laboratory animal exposure data were analyzed. In comparison to agent GB, the data sets characterizing toxicity of agents GA, GD, GF and VX are sparse. AEGL estimates for these latter agents were developed by a comparative method of relative potency from the more complete data set for agent GB. The critical effect for agent GB AEGL-1 values (0.0069, 0.0040, 0.0028, 0.0014, and 0.0010 mg/m3 for 10 min, 30 min, 1 hr, 4 hrs, and 8 hrs, respectively) is EC50 for miosis in female SD rats, with supportive studies for other species. Because the miotogenic response of mammal eyes to GB vapor exposure is similar across multiple species, the interspecies uncertainty factor (UF) for AEGL-1 is 1; the intraspecies UF of 10 is for protection of potentially susceptible individuals. AEGL-2 values for agent GB (0.087, 0.050, 0.035, 0.017, and 0.013 mg/m3 for 10 min, 30 min, 1 hr, 4 hrs, and 8 hrs, respectively) were developed from human experimental data for miosis plus dyspnea, RBC-ChE inhibition, and single fibre electromyographic changes. The interspecies UF is 1, and the intraspecies UF is 10. AEGL-3 values for agent GB vapor exposure (0.38, 0.19, 0.13, 0.070, and 0.051 mg/m3 for 10 min, 30 min, 1 hr, 4 hrs, and 8 hrs, respectively) are based upon LC01 values for female SD rats exposed to GB vapor for durations of 3 to 360 min. The interspecies UF is 3, and the intraspecies UF is 10. Scaling of exposures to AEGL-specific durations was linear (C^n x t = k, where n=2). Oak Ridge National Laboratory, managed by UTBattelle, LLC, for the US Department of Energy under contract DEAC0500OR22725

776 ACUTE EXPOSURE GUIDELINE LEVELS (AEGLS) FOR SULFUR MUSTARD (AGENT HD).

D. Opresko[1], R. Young[1], A. Watson[1], K. Still[2], V. Hauschild[3], G. Leach[3], D. Krewski[4], K. Bakshi[5] and R. Garrett[6]. *[1]Oak Ridge National Laboratory, Oak Ridge, TN, [2]NHRC, US Navy, Wright-Patterson AFB, OH, [3]CHPPM, US Army, APG, MD, [4]University of Ottawa, Ottawa, ON, Canada, [5]National Research Council, Washington, DC and [6]USEPA, Washington, DC.*

Sulfur mustard (Agent HD) is an alkylating chemical vesicant that affects any epithelial surface with which it comes in contact; it has been historically developed and used as a warfare agent. For AEGL estimation, both human and animal exposure data were analyzed. AEGL-1 values (0.40 mg/m3, 0.13 mg/m3, 0.067 mg/m3, 0.017 mg/m3, and 0.008 mg/m3 for 10 min, 30 min, 1 hr, 4 hrs, and 8 hrs, respectively) were based upon data from informed human volunteers. An exposure concentration-time product (Ct) of 12 mg-min/m3 represented a threshold for conjunctival injection and minor discomfort but no functional decrement. An intraspecies uncertainty factor (UF) of 3, applied to protect potentially sensitive individuals, was considered appropriate. AEGL-2 values (0.60 mg/m3, 0.20 mg/m3, 0.10 mg/m3, 0.025 mg/m3, and 0.013 mg/m3 for 10 min, 30 min, 1 hr, 4 hrs, and 8 hrs, respectively) were based upon human exposure data showing a Ct of 60 mg-min/m3 as a lower margin of the concentration-effect zone to the eye that resulted in ineffective military performance. Variability in the ocular responses was minimal among the volunteers, thereby justifying an intraspecies adjustment of only 3. A 3-fold reduction accommodated potential onset of long-term ocular or respiratory effects. AEGL-3 values (3.9 mg/m3, 2.7 mg/m3, 2.1 mg/m3, 0.53 mg/m3, and 0.27 mg/m3 for 10 min, 30 min, 1 hr, 4 hrs, and 8 hrs, respectively) were based upon an estimated lethality threshold of 21.2 mg/m3 in mice exposed for 1 hr. A 3-fold downward adjustment accounted for intraspecies variability and a UF of 3 was applied to account for interspecies variability in the lethal response to sulfur mustard. Scaling of exposures to AEGL-specific durations utilized Cn x t = k, where n=1 or 3. Oak Ridge National Laboratory, managed by UTBattelle, LLC, for the US Department of Energy under contract DEAC0500OR22725.

777 ACUTE EXPOSURE GUIDELINE LEVELS (AEGLS) FOR ARSINE.

R. Young[1], R. Thomas[2], R. Garrett[3], D. Krewski[4] and K. Bakshi[5]. *[1]ORNL, Oak Ridge, TN, [2]INTERCET, Ltd.,, McLean, VA, [3]USEPA, Washington, DC, [4]University of Ottawa, Ottawa, ON, Canada and [5]National Research Council, Washington, DC.*

AEGL values represent one-time exposures for increasingly severe effects with AEGL-1 being least and AEGL-3 being most severe. AEGLs were developed for arsine, a colorless gas and potent hemolytic agent, using exposure-response data from animal studies. Values for AEGL-specific exposure durations of 0.5 hr, 1 hr, 4 hr, and 8 hr were scaled from the experimental exposure duration using exponential scaling (Cn x t = k, where n= 3 when extrapolating to shorter durations and n = 1 when extrapolating to longer durations). Numeric values for AEGL-1 were not recommended due to the lack of data and the inability to define an exposure that would be consistent with AEGL-1 effects. AEGL-2 values (0.21 ppm, 0.17 ppm, 0.04 ppm, and 0.02 ppm for 0.5 hr, 1 hr, 4 hr, and 8 hr, respectively) were based on experimental exposures that did not result in significant alterations of hematologic parameters in mice exposed to arsine for 1 hr. Uncertainty factor application included a factor of 10 to account for possible interspecies variability and a factor of 3 was applied for individual variability. The AEGL-3 values (0.63 ppm, 0.50 ppm, 0.13 ppm, and 0.06 ppm for 0.5 hr, 1 hr, 4 hr, and 8 hr, respectively) were based upon an exposure producing hemolysis and lethality in mice exposed to arsine for 1 hr. Total uncertainty factor adjustment was 30; 10 for interspecies variability and 3 for intraspecies variability. The AEGLs reflect the narrow margin between exposures resulting in minor effects and those producing lethality. The approach used to develop the AEGLs for arsine was justified by the known steep exposure-response relationship, the induction of hemolysis by arsine at extremely low concentrations, and the potential of arsine-induced hemolysis to irreversibly progress to life-threatening renal failure. All of the AEGL values are near or below the odor threshold for arsine. Oak Ridge National Laboratory is managed by UTBattelle, LLC for the US Department of Energy under contract DEAC0500OR22725.

778 ACUTE EXPOSURE GUIDELINE LEVELS (AEGLS) FOR PHOSGENE.

C. Bast[1], W. Bress[2], R. Garrett[3], D. Krewski[4] and K. Bakshi[5]. *[1]Oak Ridge National Laboratory, Oak Ridge, TN, [2]Vermont Department of Health, Burlington, VT, [3]USEPA, Washington, DC, [4]University of Ottawa, Ottawa, ON, Canada and [5]National Research Council, Washington, DC.*

AEGL values represent one-time exposures for increasingly severe effects with AEGL-1 being least and AEGL-3 being most severe. Appropriate data were not available for deriving AEGL-1 values for phosgene. Odor cannot be used as a warning for potential exposure. The odor threshold is reported to be between 0.5 to 1.5 ppm, a value above or approaching AEGL-2 and AEGL-3 values, and tolerance to the pleasant odor of phosgene occurs rapidly. Furthermore, following odor detection and minor irritation, serious effects may occur after a clinical latency period of 24 hours. AEGL-2 values (0.6 ppm, 0.6 ppm, 0.3 ppm, 0.08, and 0.04 ppm for 10-min, 30-min, 1-hr, 4-hr, and 8-hr, respectively) were based on chemical pneumonia in rats exposed to 2 ppm for 90 min. The 90 minute value was then scaled to the 30-minute, 1-, 4-, and 8-hour AEGL exposure periods, using cn x t = k, where n=1. The 30-minute value was also adopted as the 10-minute value because extrapolation would yield a 10-minute AEGL-2 value approaching concentrations producing alveolar edema in rats. The 30-min, 1-, 4-, and 8-hr AEGL-3 values (1.5 ppm, 0.75 ppm, 0.20 ppm, and 0.09 ppm, respectively) were based on the highest concentration causing no mortality in rats after a 30-minute exposure (15 ppm). The value was scaled to the 1-, 4-, and 8-hour AEGL periods, using cn x t = k, where n=1. The 10-min AEGL-3 value (3.6 ppm) was based on the highest concentration causing no mortality in the rat or mouse (36 ppm) after a 10-minute exposure. For all AEGL-2 and -3 values, an uncertainty factor (UF) of 3 was applied for interspecies extrapolation because little species variability is observed for both lethal and non lethal effects after exposure to phosgene. A UF of 3 was applied to account for sensitive individuals due to the steep concentration-response curve

which implied limited variability. Oak Ridge National Laboratory, managed by UT-Battelle, LLC, for the US Department of Energy under contract DEAC0500OR22725.

779 EXPOSURE OF HUMAN EPIDERMAL KERATINOCYTES TO SULFUR MUSTARD INDUCES THE FORMATION OF HIGH MOLECULAR WEIGHT PROTEIN AGGREGATES CONTAINING KERATIN 5 AND KERATIN 14.

J. F. Dillman, K. L. McGary and J. J. Schlager. *Applied Pharmacology, USAMRICD, Aberdeen Proving Ground, MD.*

The chemical warfare agent sulfur mustard (SM) is a vesicant and alkylating agent that has the capacity to crosslink biological molecules. We are interested in identifying specific proteins that are altered upon SM exposure. Keratins are particularly important for the structural integrity of skin, and several genetically inherited blistering diseases have been linked to mutations in keratin 5 (K5) and keratin 14 (K14). We examined whether SM exposure alters keratin biochemistry. Cultured human epidermal keratinocytes (HEK) were exposed to SM. Western blotting with specific monoclonal antibodies revealed the formation of stable high molecular weight aggregates containing K14 and K5. These aggregates begin to form within 15 minutes after SM exposure, form only at SM concentrations that are considered vesicating-equivalent doses, and persist until cell death. These aggregates display a complex gel electrophoresis pattern between ~100 kD and ~200 kD. Biochemical purification of these aggregates allowed analysis of the aggregate components by mass spectrometry. These approaches confirmed the presence of K14 and K5 in the aggregates and suggest that at least some of the aggregates are composed of K14-K14, K14-K5, or K5-K5 dimers. These studies demonstrate that SM is capable of inducing keratin aggregation in HEK and support further study into the role of keratin aggregation in SM-induced vesication.

780 ACUTE ORAL TOXICITY OF NITROSO DEGRADATION PRODUCTS OF HEXAHYDRO-1, 3, 5-TRINITRO-1, 3, 5-TRIAZINE (RDX).

S. A. Meyer[1], A. J. Marchand[1], J. L. Hight[1] and D. K. MacMillan[2]. *[1]Toxicology, University of Louisiana-Monroe, Monroe, LA and [2]US Army Corps of Engineers, Engineer Research and Development Center, Omaha, NE.*

Anaerobic degradation of the munition hexahydro-1, 3, 5-trinitro-1, 3, 5-triazine (RDX) in the environment and during bioremediation results in nitroreductase-catalyzed formation of hexahydro-1-nitroso-3, 5-dinitro-1, 3, 5-triazine (MNX), hexahydro-1, 3-dinitroso-5-nitro-1, 3, 5-triazine (DNX), and hexahydro-1, 3, 5-trinitroso-1, 3, 5-triazine (TNX). Although parent RDX has been identified as a central nervous system toxicant in both humans and rats upon acute oral exposure, toxicity of the degradation products is unknown. The objective of this study was to determine the most potent RDX N-nitroso product in acutely exposed rats, then estimate its oral LD50 and identify critical adverse effects. An abbreviated up-and-down procedure (UDP) with dose progression of 2.13 (1/3 log unit) and 400 mg/kg starting dose, chosen to exceed previous estimates of RDX LD50 of ~100 mg/kg, were used for comparative studies. Compounds emulsified in corn oil plus 4% DMSO were administered by gavage to female Sprague-Dawley rats (175 - 200 gm) and clinical observations made over 14 days. Lethality at 400 mg/kg of MNX, DNX and TNX was 2/2, 2/3 and 2/3 and at 187 mg/kg was 2/3, 0/3 and 0/3, respectively. CNS toxicity, as indicated by onset of forearm clonic seizures as early as 10 min, occurred with a prevalence of 2/2, 3/3 and 2/3 at 400 mg/kg and 2/3, 0/3 and 1/3 with 187 mg/kg MNX, DNX and TNX, respectively. A complete UDP test with starting dose of 87 mg/kg MNX and analyzed with the AOT425StatPgm yielded a maximum likelihood LD50 estimate of 187 mg/kg and 95% confidence interval of 118 to 491 mg/kg. Seizures were again observed, while histopathological splenic congestion and siderosis were noted for 14-day survivors dosed with 187 mg/kg MNX. These results indicate that MNX, with an LD50 comparable to parent RDX, is the most potent N-nitroso degradation product and shares CNS toxicity as a critical toxic effect. Support: US Army Corps of Engineers

781 VARIATION OF SERUM BUTYRYLCHOLINESTERASE IN A MILITARY POPULATION.

N. Johnson[1], J. Labit[2], K. Johnson[2], R. Wills[3], H. Chambers[4] and J. Chambers[1]. *[1]Center for Environmental Health Sciences, Miss. St. University, Miss. St., MS, [2]14th Medical Group, CAFB, MS, [3]Department of Pathobiology and Population Medicine, Miss. St. University, Miss. St., MS and [4]Department of Entomology and Plant Medicine, Miss. St. University, Miss. St., MS.*

Butyrylcholinesterase (BChE) is often used in the occupational monitoring of individuals exposed to carbamate or organophosphorus insecticides. BChE is used as a surrogate marker for acetylcholinesterase inhibition. One drawback of BChE is the large variation it exhibits. This variation makes this enzyme impractical for spot analysis. In practice, baseline values must be obtained for later comparison to individual values. To date, the majority of variation has not been explained. A military population may be more homogeneous in unknown variables which may reduce the variation. Elucidation of the baseline variability in this population may aid in the development of spot testing procedures among groups of military members without the use of individual baseline results. This study involved analysis of previously collected samples for BChE activity. The samples were taken from an active duty male population with an age distribution of 18 to 57 years. After removal of unique identifiers, samples were frozen at minus 20C until analyzed. A modified version of the Ellman assay, using butyrylthiocholine as the substrate, was used to measure BChE. A total of 445 unique samples were analyzed over a twelve-month period. The mean activity and range were 9.1 University/mL and 0.1 to 23.0 University/mL respectively. The overall variation (37% coefficient of variation) of these samples indicates that the variability is not lower than civilian counterparts. Samples from individuals under age 26 had lower ($p = 0.008$) variation as compared to those over age 26. There was also a statistically significant difference ($p < 0.001$) between the total BChE activity measured among the months of the year. These findings suggest that the amount of variation in a military population does not warrant spot individual testing of BChE activity.

782 RELATIONSHIP BETWEEN THE DOSE-RESPONSE CURVES FOR LETHALITY AND SEVERE EFFECTS FOR CHEMICAL WARFARE NERVE AGENTS.

D. R. Sommerville. *US Army Edgewood CB Center, Aberdeen Proving Ground, MD.* Sponsor: S. Thomson.

In recent years, the US Environmental Protection Agency has developed a categorical (or ordinal) logistic regression approach for regressing ordered categories of toxic responses to a toxicant exposure on one or more factors. This approach permits the simultaneous fitting of two types of dose-response curves (severity of effect and percent of individuals versus dose). It is also possible to statistically demonstrate and quantify the steepness of both types of dose-response curves for acute exposures to organophosphate-type chemical warfare agents. Data from three previous acute inhalation studies were separately reanalyzed using a probit link-function: monkeys exposed separately to GA (tabun), GB (sarin) or GF (cyclosarin) (from a 1957 study); rats exposed to GB; and rats exposed separately to GB or GF. For the three studies, vapor concentration and exposure time were varied; and in the recent rat studies, identifying differences between genders was an objective. Clinical signs and mortality were recorded in all three studies, from which three categorical responses were defined: death, severe effects and less than severe effects. An animal was categorized as having severe effects if it exhibited at least one of the following signs (yet did not die): convulsions, gasping, collapse or prostration. The regression analysis found that for all three studies slightly more than one standard deviation (1.0 to 1.4) separated an effective concentration (ECXX) for severe effects from a lethal concentration (LCXX) for XX% effected. The immediate benefit from this finding is the establishment of a method for estimating threshold lethality for nerve agents. Threshold lethality (approximately a LC01 or LC05) is roughly equivalent to an EC16 (severe) for the data analyzed. The 16% effect level can be estimated with greater confidence from experimental quantal data *via* probit analysis than the 1% effect level. Thus, questionable extrapolation of the dose-mortality curve down to the 1% level can be avoided by using the dose-severe effect curve in its place.

783 INHALATION MEDIAN LETHAL DOSES OF *BACILLUS ANTHRACIS*, AMES, AND VOLLUM STRAINS IN THE RHESUS MONKEY.

J. E. Estep[1], R. Barnewall[1], R. DeBell[2] and N. Niemuth[1]. *[1]Battelle Memorial Institute, Columbus, OH and [2]Battelle Crystal City, Arlington, VA.* Sponsor: R. Casillas.

Bacillus anthracis, the etiologic agent of anthrax in both humans and animals, is a large, Gram-positive rod in its vegetative form. More importantly, *B. anthracis* is capable of forming spores that are highly resistant to environmental deterioration. Aerosolized spores can cause inhalational anthrax, which is greater than 50% fatal in humans, despite appropriate treatment. Thus, weaponized *B. anthracis* is considered a serious threat. This study was to determine the median lethal dose (LD_{50}) of *B. anthracis* Ames and Vollum strains in a rhesus macaque model of inhalational anthrax. Rhesus macaques were exposed to Ames or Vollum strains of *Bacillus anthracis* by the pulmonary route. The cumulative average mass median aerodynamic diameter of the generated particles for all exposures was 1.31 mm, with a geometric standard deviation of 1.8 as determined by an API Aerosizer. For each strain, probit dose-response models were fitted to dose-lethality data using the method of maximum likelihood. Estimated parameters of probit dose-response models were used to compute LD_{50} values for each strain. Fieller's method was used to compute a 95% confidence interval for the inhaled LD_{50}. In rhesus macaques, the inhaled LD_{50}s and 95% confidence intervals were 10, 900 (1, 320 to 241, 000) and 6, 750

(21 to 116, 000) CFUs for the Ames and Vollum strains, respectively. There was no statistical significant difference in the survival time for either strain with an average day to death of 6.8 days for Ames strain, and 4.7 days for Vollum strain. These results demonstrate that both strains are lethal by the inhalation route. The inhaled LD_{50}s of the Ames and Vollum strains of *B. anthracis* were not significantly different from each other and are within the expected experimental difference of previously reported values in the rhesus monkey. The results of these data are important for the estimation of the human inhalation *B. anthracis* dosage.

784 EFFECTS OF SULFUR MUSTARD ON SKIN TOXICITY IN COX-1- AND COX-2-DEFICIENT MICE.

R. Langenbach[1], A. Nyska[2], B. Brodsky[3] and U. Wormser[3]. *[1]Laboratory of Molecular Carcinogenesis, National Institute of Environmental Health Sciences, NIH, Research Triangle Park, NC, [2]Laboratory of Experimental Pathology, National Institute of Environmental Health Sciences, NIH, Research Triangle Park, NC and [3]Institute of Life Sciences, The Hebrew University, Jerusalem, Israel.*

Sulfur mustard (SM) is a potent vesicant employed as a chemical-warfare agent. Exposure results in erythema, edema, and blisters. The evolution of tissue damage is associated with an inflammatory response including vasodilatation, polymorphnuclear infiltration, and production of inflammatory mediators and cyclooxygenase (COX) activity. In order to evaluate the role of COX-1 and COX-2 in SM-induced skin toxicity, we tested the effect of SM on the ear of COX-1- and COX-2-deficient mice. In the latter, the degree of ear swelling 24 and 48 hr- after SM exposure was significantly reduced by 54% and 33%, respectively, compared to the wild-type mice. Histopathological analysis 48 hr after exposure revealed a statistically significant reduction of 58% and 64% in epidermal necrosis and acute inflammation, respectively. A similar trend was observed in subepidermal microblister formation, hemorrhage, and dermal necrosis. Although not statistically significant, COX-1-deficient mice showed a higher degree of subepidermal microblister formation, epidermal ulceration, and epidermal necrosis in comparison to the wild type. These findings indicate that COX-2 plays a central role in SM-induced skin toxicity and that COX-1 might exert a protective function against this chemical insult. (This study was supported by US Army Medical Research and Material Command under Cooperative Agreement DAMD17-98-2-8009.)

785 PROTECTIVE EFFECTS OF TOPICAL IODINE CONTAINING ANTI-INFLAMMATORY DRUGS AGAINST SULFUR MUSTARD-INDUCED SKIN LESIONS.

U. Wormser[1], B. Brodsky[1], A. Sintov[2], R. P. Casillas[3] and A. Nyska[4]. *[1]Institute of Life Sciences, The Hebrew University, Jerusalem, Israel, [2]Institutes for Applied Research, Ben Gurion University of the Negev, Beer-Sheva, Israel, [3]Medical Research and Evaluation Facility, Battelle, Columbus, OH and [4]Laboratory of Experimental Pathology, National Institute of Environmental Health Sciences, NIH, Research Triangle Park, NC.*

Previous studies with sulfur mustard (SM), a potent vesicatory chemical-warfare agent, showed the antidotal efficacy of topical iodine at short intervals of 15 and 30 min between exposure and treatment. We demonstrate efficacy at longer intervals (20-, 30-, 45-, and 60-min) in mouse and guinea pig using an improved topical povidone-iodine preparation termed N66 containing steroidal and non-steroidal anti-inflammatory agents. In the mouse, ear edema was reduced by 43%, 47%, 44%, and 36%, ear epidermal ulceration by 74%, 58%, 45%, and 58%, and epidermal necrosis by 54%, 34%, 26%, and 31% at the respective intervals; a similar effect was seen with encrustation. The grade of acanthotic area, a healing marker, showed dramatic increases of 40-, 25-, 21-, and 22-fold, respectively. Two dermal parameters showed marked improvement; acute inflammation was reduced by 63%, 34%, 34%, and 38% and dermal necrosis by 80%, 54%, 54%, and 59%, respectively. In the guinea pig, topical treatment 45 min after exposure reduced the SM-induced ulceration area by 75%. Histologically, subepidermal microblister formation, epidermal ulceration, epidermal necrosis, and encrustation were reduced by 63%, 61%, 41%, and 41%. The grade of acanthotic area was elevated by 73% compared to control. N66 also caused a statistically significant reduction in acute inflammation (33%) and dermal necrosis (48%). Reduced damage was also observed in skin areas adjacent the treated sites. These findings suggest that the povidone-iodine preparation combined with anti-inflammatory agents functions as an antidote against skin lesions induced by SM (supported by USAMRMC DAMD17-98-2-8009).

786 SOY PHYTOESTROGENS PROTECT AGAINST GAMMA IRRADIATION.

M. R. Landauer, V. Srinivasan, A. M. Nguyen and T. M. Seed. *Radiation Casualty Managemnet Team, Armed Forces Radiobiology Research Institute, Bethesda, MD.*

Chemical compounds that provide protection from ionizing radiation induced injury are known as radioprotectors. They have applications in clinical oncology, space travel, radiation site cleanup, radiological terrorism, and military scenarios. Soy phytoestrogens, such as the isoflavones genistein and daidzein, have beneficial health effects. We previously reported that both oral and subcutaneously administered genistein are radioprotective in mice. In this study, we further characterized the radioprotective effects of genistein and also evaluated daidzein for protective efficacy. Pharmacologic doses of the isoflavones were administered to CD2F1 male mice. The traditional 30-day survival endpoint for the evaluation of radioprotectors was used. In the first experiment, mice received a single subcutaneous dose of 3 to 400 mg/kg of genistein either 1 hr or 24 hr before cobalt-60 gamma irradiation (9.5 Gy at 0.6 Gy/min). When administered 24 hr before irradiation, doses of 25 to 400 mg/kg of genistein, with the optimal dose being 200 mg/kg, provided significant ($p < 0.01$) radioprotection compared with that provided by vehicle controls. In contrast, the 30-day survival rates of mice treated with genistein 1 hr before irradiation were not significantly different from those of the vehicle control group. In a preliminary experiment, mice were injected subcutaneously with 200-mg/kg daidzein 24 hr before 9.5 Gy irradiation. Significantly more daidzein-treated mice survived than did control mice ($p < 0.01$). The level of protection was similar to that observed with 200 mg/kg of genistein. The effect of administration of daidzein at 1 hr before irradiation is currently under investigation. These results demonstrate that both genistein and daidzein provide protection against ionizing-induced radiation injury.

787 A 7-DAY MOUSE MODEL TO ASSESS PROTECTION FROM SULFUR MUSTARD (SM) SKIN INJURY.

M. C. Babin[1,2], M. Y. Gazaway[1], R. C. Kiser[2], I. Koplovitz[1], N. Krogel[1], L. W. Mitcheltree[1], D. M. Moore[2], N. A. Niemuth[2], K. M. Ricketts[1], K. Skvorak[1], R. E. Sweeney[1] and R. P. Casillas[2]. *[1]US Army Medical Research Institute of Chemical Defense, Aberdeen Proving Ground, MD and [2]Battelle Memorial Institute, Columbus, OH.*

The mouse ear vesicant model (MEVM) has been successfully used as a screening tool to identify protective compounds against sulfur mustard [bis(2-chloroethyl)sulfide]-induced skin injury. The MEVM provides an edema response and histopathological endpoints as measurements of inflammation and tissue damage 24 h following a topical SM (0.16 mg) exposure. Compound effectiveness is defined as a statistically significant ($p<0.05$) reduction in these endpoints. To further evaluate compounds, the MEVM was modified for use as a 7-day model. Dose response studies were conducted with SM (0.01 mg to 0.16 mg) to determine the optimal dose for producing widespread necrosis at day 7. A modified Draize scoring system of 0-4 (no damage to extensive necrosis) was incorporated as an endpoint to evaluate the extent of ear tissue damage out to day 7. Draize results revealed an optimum SM dose of 0.08 mg. Edema response and the existing histopathological scoring system were not feasible endpoints in the 7-day model. Octyl homovanillamide (OHV), a protective compound in the MEVM, and 2 pharmacologically inactive analogs were tested as topical pretreatments 15 min prior to a 0.08 mg SM challenge. OHV significantly reduced Draize scores whereas the inactive analogs had no effect. OHV was also evaluated as a pretreatment 15 min before exposure to 0.06, 0.08, and 0.16 mg SM. OHV protection at day 7 was similar for the 0.06 and 0.08 mg doses but not effective against the severely necrotizing 0.16 mg SM dose. OHV also significantly reduced SM injury when a single topical 2 µmol dose was administered 10 min after SM challenge. These data support the use of the Mouse Ear Vesicant Treatment Model (MEVTM) for evaluating candidate antivesicant compounds. This work was supported by the US Army Medical Research and Materiel Command under Contract DAMD17-99-D-0010, Task Order 0002.

788 ANTI-INFLAMMATORY EFFECT OF PARENTERALLY INJECTED H2A HISTONE FRAGMENT AGAINST SULFUR MUSTARD-INDUCED SKIN LESIONS.

B. Brodsky and U. Wormser. *Institute of Life Sciences, The Hebrew University, Jerusalem, Israel.*

Skin exposure to sulfur mustard (SM), a potent chemical-warfare agent, results in erythema, edema, and blisters. Previous studies demonstrated the protective effect of topical iodine treatment against SM-induced skin damage. Iodine exerts its beneficial activity by induction of endogenous protective peptide, identified as 9 amino acids fragment of histone H2A (termed IIIM1). The anti-inflammatory/anti-vesicating activity of the peptide was evaluated by the mouse ear edema model. Intravenous administration of 1 and 10mg/kg IIIM1 5 min prior to SM exposure caused statistically significant reduction of 33% and 28%, respectively, in mouse ear swelling as compared to control animals injected with saline. Injection of 10mg/kg IIIM1 2 hrs prior to SM exposure significantly reduced mouse ear swelling by 23%. Post-exposure administration of metabolically stable N-methylated analog of IIIM1 reduced ear swelling by 19%. These findings indicate that parenteral administration of H2A fragment and its analogs decreases SM-induced skin toxicity. It is suggested that the antidotal effect of IIIM1 and its analogs might be of therapeutic value in protecting other sensitive tissues such as lung and bone marrow and in treatment of inflammation-associated disorders. (This study was supported by US Army Medical Research and Material Command under Cooperative Agreement DAMD17-98-2-8009.)

789 MODULATION OF CYTOKINE GENE EXPRESSION BY ANTI-INFLAMMATORY AGENTS FOLLOWING *IN VIVO* SULFUR MUSTARD INJURY.

C. L. Sabourin[1], M. L. Stonerock[1], N. A. Niemuth[1], R. C. Kiser[1], S. L. Casbohm[1], R. P. Casillas[1], M. C. Babin[1] and J. C. Schlager[2]. *[1]Battelle Memorial Institute, Columbus, OH and [2]Pharmacology Division, US Army Medical Research Institute of Chemical Defense, Aberdeen Proving Ground, MD.*

Sulfur mustard [bis(2-chloroethyl)sulfide, SM] is a chemical warfare agent that penetrates the skin rapidly and causes extensive blistering after a latent period. We have used the mouse ear vesicant model for cutaneous SM injury quantitation to evaluate pharmacological agents in a number of drug classes, including anti-inflammatory drugs. Topically applied anti-inflammatory agents, including indomethacin and vanilloids, have been shown to reduce SM-induced skin inflammation and tissue damage. We previously identified an early increase in the *in vivo* expression of the inflammatory cytokines GM-CSF, IL-1β, and IL-6 following murine cutaneous exposure to SM. The goal of this study was to determine the effect of topically administered anti-inflammatory agents in reversing inflammatory mediator gene expression following SM-induced injury. Alterations in mouse (n=6) cutaneous GM-CSF, IL-1β, and IL-6 gene expression from ears with and without pre-treatment with indomethacin, heptylisovanillamide, and octyl homovanillamide were examined using real time quantitative RT-PCR. Indomethacin pretreatment produced a significant reduction in the SM-mediated increase of IL-1β and IL-6 mRNA levels. Heptylisovanillamide pretreatment produced significant reductions of GM-CSF, IL-1β, and IL-6 mRNA levels. Octyl homovanillamide produced an apparent reduction of cytokine mRNA levels; however, the reduction did not reach statistical significance at the present animals numbers. SM-induced inflammation was significantly modulated by all three anti-inflammatory agents as determined by reduction in tissue edema (n=10). The alteration in cytokine gene expression suggests that these drugs play a role in modulating SM-induced injury by reducing inflammatory pathways. Supported by the US Army Medical Research and Materiel Command under Contract No. DAMD17-99-D-0010, Task Order 0002.

790 TEMPORAL AND DOSE ANALYSIS OF MURINE GENE EXPRESSION BY MICROARRAY DURING CUTANEOUS SULFUR MUSTARD INJURY.

J. Schlager[1], Y. W. Choi[2], R. C. Kiser[2], R. P. Casillas[2], M. C. Babin[2] and C. L. Sabourin[2]. *[1]Pharmacology Division, US Army Medical Research Institute of Chemical Defense, Aberdeen Proving Ground, MD and [2]Medical Research & Evaluation Facility, Battelle Memorial Institute, Columbus, OH.*

The chemical warfare agent sulfur mustard (SM) produces skin blister formation with a severe inflammatory reaction in exposed individuals. The development of efficacious countermeasures against SM vesication requires an understanding of the cellular and molecular mechanism of SM-induced tissue injury. Our previous studies identified alterations in gene expression by cDNA array for 6 SM doses at a single 24h timepoint using an *in vivo* mouse skin model. This study examined SM-induced alterations in gene expression in mouse skin using microarrays (5002 genes) to identify transcriptional events associated with SM toxicity. Using 3 mice/experiment, paired exposed/unexposed (right/left) mouse ear transcript comparisons were made using either 40, 80, and 160μg exposure SM ear skin doses, and tissue harvested at 1.5, 3, 6 and 12h post-exposure. The 40μg dose was selected as representative of a low level exposure that would not produce sufficient damage to increase ear inflammation at 24h. The 80μg and 160μg doses are used for screening candidate treatments in the mouse ear vesicant model. Using a gene transcript alteration criteria of >2-fold increase for all 3 mice in the same dose-time group, 498 transcripts were altered with exposure to SM, 135 transcripts at 40μg, 247 transcripts at 80μg and 126 transcripts at 160μg SM, respectively, for the currently analyzed 1.5, 3, and 12 h time points. Although a few of these genes have previously been reported as differentially regulated by SM exposure, many new target genes were identified. Interestingly, only 3 transcripts were detected as increased at all doses and 32 transcripts for any 2 doses without regard to time; and only 3 transcripts were found at the same dose but at a different time. These data will be further mined for temporal cell pathway changes, which can be used as biomarkers in drug treatment studies.

791 GENE EXPRESSION CHANGES FOLLOWING LOW-LEVEL EXPOSURE TO SARIN (GB) VAPOR.

J. W. Sekowski[2], J. R. Bucher[2], D. Menking[2], J. J. Valdes[2], R. Mioduszewski[2], S. Thomson[2], C. E. Whalley[2], M. Vahey[1] and M. Nau[1]. *[1]ECBC, US Army SBCCOM, APG-EA, MD and [2]US Army WRAIR, Rockville, MD.*

The acute effects of chemical weapons have been widely studied since World War I and are well understood. Since the description of Gulf War and Balkans Syndromes, however, there has been increased concern for exposure of personnel to sub-acute and low-level doses of chemical warfare (CW) agents that may occur as a result of decontamination procedures or due to use of such agents by an adversary. There is a considerable body of literature suggesting that exposures to organophosphorus (OP) compounds used as pesticides result in significant cognitive and neurological decrements. However, there is a paucity of literature regarding the molecular effects of low-level exposures to such agents. Although low-level exposures may not cause obvious pathology at the time of exposure, they may cause genetic alterations or changes in gene expression that may predispose personnel to injury or disease later in life. In this study, male and female Sprague-Dawley rats were exposed to low-level doses (0.010-0.033 mg/m3) of the aerosolized nerve agent Sarin (GB) *via* whole body inhalation for 4 hours. Control animals were exposed to air under the same conditions for the same time period. Alteration of gene expression levels in the liver and brain of the exposed animals was assessed using DNA microarray analysis. To date, our results indicate that low-level inhalation exposure to Sarin results in the alteration of expression of a number of important genes. Many of the altered genes participate in cellular processes critical to detoxification pathways and neurological homeostasis. Furthermore, our analyses reveal several differently altered genes between the female and male animals. Additional studies with Sarin and other OP nerve agents such as GF will reveal whether these differences translate into true sex-linked susceptibility to increased OP toxicity, and whether a genetic fingerprint can be defined for a class or a particular OP agent.

792 TEMPORAL TRANSCRIPTIONAL CHANGES IN RAT LUNG TISSUE FOLLOWING AN INTRAVENOUS EXPOSURE TO SULFUR MUSTARD (SM).

A. M. Sciuto, C. Philips, T. Moran, Z. Hess and J. Schlager. *Pharmacology Division, US Army Medical Research Institute of Chemical Defense, Aberdeen Proving Ground, MD.*

Sulfur mustard [bis (2-chloroethyl) sulfide; SM] is a well-known chemical warfare agent and a suspected industrial carcinogen. SM is known for its vesicating properties following dermal exposure. However, SM can pose a particularly insidious threat to the respiratory tract, with exposure resulting in acute lung edema characteristic of an unregulated inflammatory response. Owing to the physico-chemical nature of SM, aerosol inhalation models are particularly difficult because of the uncertainty of delivered dose. This study was designed to deliver SM intravenously in a dose-response manner to investigate possible molecular markers of lung injury. Male Sprague-Dawley rats (240-270 g) were anesthetized i.p. with 50 mg/kg sodium pentobarbital. Following anesthesia, rats were placed in a supine position, and a small surgical incision was made in the femoral region of the left leg. The femoral vein was isolated, and vehicle (isopropanol) or vehicle plus SM in a concentration of 1, 3, or 6 mg/kg was slowly injected over 3-4 min using a sterile 1-mL syringe. The injection volume was 600-650 μ L/kg body weight. Rats were allowed to recover and had full access to food and water. At 0.5, 1, 3, 6, or 24 hr after exposure, rats were euthanatized with 100% CO_2, and the left lung was dissected, perfused in situ with RNA-Later, stored at 4° C overnight, and frozen at -80° C. Frozen lungs were ground in liquid nitrogen with a mortar and powder homogenized in buffered 4M guanidium isothionate with a Polytron. Total RNA was purified and 33P-labeled cDNA prepared for probing Clontech rat arrays containing 1, 176 cDNAs. Multiple transcripts were induced over dose and time. Preliminary results showed induction of specific pro-inflammatory and stress genes including the predominant expressed genes cytochrome oxidase I, IkB, cysteine-rich protein 2, and glutathione S-transferase P, subunit 7 over dose and time. Numerous gene transcripts were expressed at lower levels following SM exposure.

793 FURTHER EVIDENCE THAT VANILLOIDS MODULATE CUTANEOUS SULFUR MUSTARD INJURY *IN VIVO.*

R. P. Casillas[1], S. T. Hobson[2], R. C. Kiser[1], D. Smithson[2], J. Boeckers[2] and M. C. Babin[1]. *[1]Battelle Memorial Institute, Columbus, OH and [2]US Army Medical Research Institute of Chemical Defense, Aberdeen Proving Ground, MD.*

Presently, no pre- or post-treatment pharmacological medical countermeasure is established to protect against sulfur mustard (SM)-induced skin injury. In previous studies using the mouse ear vesicant model, we found that three analogs (retro olvanil [ROLV], olvanil [OLV], and retro synthetic capsaicin [RSCAP]) of the vanilloid, capsaicin, effectively modulated cutaneous SM injury. The present study was undertaken to exploit our premise that a structure-activity relationship is involved in the effectiveness of vanilloids against SM injury. We first demonstrated that both natural capsaicin (NCAP) and synthetic capsaicin (SCAP) significantly modulated cutaneous SM injury as effectively as ROLV, OLV, and RSCAP. Secondly, pharmacologically inactive structural analogs of the active RSCAP and SCAP did not modulate SM injury. Finally, a structure activity relationship study was conducted, yielding 17 new synthetic vanilloid candidates based on the structure of RSCAP. Several of these new analogs modulated SM injury as effectively as

the previously evaluated vanilloids. A pharmacologic role for vanilloids is the blockage of cutaneous vascular leakage (anti-edema) following exposure to certain irritants. Since vascular leakage occurs early after SM exposure, it is reasonable to suggest that the anti-edema action of the vanilloids observed throughout these studies is consistent with their known pharmacology. Furthermore, we conclude that the data demonstrate a strong case for a structure-activity relationship for vanilloids involved in protecting against SM injury, warranting specific investigation into the mechanism of action of vanilloids against SM. This work was supported by the US Army Medical Research and Materiel Command under Contract DAMD17-99-D-0010, Task Order 0002.

794 ANALYSIS OF 2-IMINOTHIAZOLIDINE-4 CARBOXYLIC ACID (ITCA) AS A METHOD FOR CYANIDE MEASUREMENT.

S. I. Baskin[1], J. S. Kurche[1], I. Petrokovics[1] and W. L. James[2]. *[1]Pharmacology Division, US Army Medical Research Institute of Chemical Defense, Aberdeen Proving Ground, MD and [2]Medical Pharmacology & Toxicology, Texas A&M University, College Station, TX.*

Methods of directly evaluating cyanide levels in tissue are limited by the volatility of cyanide and by the difficulty of establishing steady state cyanide levels with time. To circumvent the challenge of measuring cyanide in tissue, we are interested to see whether measurement of a stabile, toxic metabolite, ITCA, could replace measurement of cyanide as the method of detecting and monitoring cyanide toxicity. This study focused on a spectrophotomeric ITCA determination in the presence of CN, SCN, cysteine, rhodanese, thiosulfate and other sulfane sulfur donors, e.g., organic thiosulfonates. Specific detection of ITCA involves a thiazolidine ring opening in the presence of p-hydroxy-mercury benzoate, followed by the reaction of diphenylthiocarbazone. The absorbance was measured at 625 nm in organic solvent carbon tetrachloride. The method was validated; the standard curve was linear with a regression line of $Y = 2.687X - 0.0168$ ($r^2 = 0.987$). The validity of this method in the presence of the cyanide antidotes is discussed in comparison with other analytical methods. CN, thiocyanate and cysteine significantly shifted the standard curve for analysis. The method of determining presence of ITCA should serve as a substitute for the measurement of the less stable cyanide and allow for a more reliable assay.

795 IDENTIFICATION OF BIOTOXIN VARIANTS AND VIRAL SIGNATURES USING THE HAND PORTABLE μCHEMLAB™/CB DETECTION SYSTEM.

J. A. West, B. A. Horn, T. W. Lane and J. A. Fruetel. *Microfluidics, Sandia National Laboratories, Livermore, CA.*

μChemLab™ /CB is a hand portable rapid detection system that can be used to identify chemical, biotoxin and viral agents in the liquid phase. The technical approach makes use of parallel electrophoretic analyses combined with a highly sensitive laser-induced fluorescence detector that are integrated at the microchip scale. Using capillary zone electrophoresis and capillary gel electrophoresis as independent separation techniques, the goals of these studies was to determine whether current μChemLab methods are sufficient for: 1) detecting all toxin isoforms of the protein biotoxin ricin; 2) discriminate between close but functionally distinct toxin isoforms of six other biotoxins and; 3) identify specific protein signatures for viral agents. Analysis of ricin isoforms revealed the separation profiles between ricin species was similar. For other biotoxins, such as S. enterotoxins, we were able to clearly distinguish between closely related specie isoforms (S.enterotoxin A & B) using two-channel analysis. In a separate set of experiments we performed analysis of the Tphage virus proteome. The analysis was rapid, complete in 10 minutes, and indicated good correlation with slab gel electrophoretic analysis of viral stocks. From these studies we conclude that: 1) ricin isoforms can be readily identified by μChemLab, 2) variant isoforms known to have different functional qualities could be discriminated by two-channel analysis and 3) viral protein signatures observed by dual channel analysis may be useful for phenotypic discrimination of such organisms.

796 SYSTEM OF DECONTAMINATION OF RADIOACTIVE EFFLUENTS.

P. Gerisimo[2], A. H. Hall[1], J. Blomet[3] and L. Mathieu[3]. *[1]Department of Emergency Medicine, Texas Tech University Health Sciences Center, El Paso, TX, [2]Service de Protection Radiologique, Armees Francais, Clamart, France and [3]Laboratoire Prevor, Laboratoire Prevor, Valmondois, France.*

An on-site radioactive element decontamination facility, or preferably, a mobile radioanalysis laboratory which can be deployed in the field to detect these contaminating radioelements that can pollute the environment. Before being released into the environment, it is necessary to assure that there are negligible amounts of radioelements. The purpose of this study is to establish the binding to ion exchange resin, a technique of treatment of these contaminating radioelements for the environment. We have considered two cases. -The radioelements in free form in solution -The radioelements which are found in a complex form such as bond to Diphoterine. The binding of the principal toxic radio elements Ce137, Sl90, U235, Pu239, as well as tritium to ion exchange resins such as Amberlite (cationic or anionic) has been studied by passing solution containing these radioelements into columns containing these resins. The decontamination factor varies according to the radioelement and according to the resins between 1/1000 and 500/100. In the case of complexed radioelements, the factor of decontamination varies between 1/1000 and 10/100 except in the case of tritium that is 9/200 and 50/100. The different decontamination factor will be discussed. From these results, a system of treatment of these contaminating radioelements is proposed which comprise the two types of resins and one system of measurement of the radioactivity by release of the contaminating radioelements.

797 ASSESSMENT OF RSDL AS A DECONTAMINANT AGAINST SULFUR MUSTARD AND VX.

T. H. Snider[1], T. L. Hayes[1], R. J. Jarvis[1], M. C. Matthews[1] and D. K. Liu[2]. *[1]Battelle Memorial Institute, Columbus, OH and [2]US Army Medical Materiel Development Activity, Fort Detrick, MD.*

Reactive Skin Decontamination Lotion (RSDL), developed by the Canadian Defense Research Establishment Suffield, has been proposed for use by US troops as a substitute for the M291 Skin Decontamination Kit (SDK) against exposure to chemical agent. Approval of RSDL as a medical device by the US Food and Drug Administration requires safety testing and demonstration that RSDL efficacy is "substantially equivalent to" that of the existing predicate device. Rabbit models previously used to establish the efficacy of M291 SDK were used to evaluate and compare RSDL with M291 SDK against topical challenges of sulfur mustard (SM). In SM studies, a grid with eight test sites was drawn on each rabbit's back, and a 1-μL dose of SM applied at each test site. At 2 min after SM application, each test site was treated with either the M291 SDK or RSDL decontamination applicator, or a gauze applicator wetted with distilled water. Lesion areas were estimated at 24 h after dosing and normalized by dividing by the lesion area at the no-treatment site on each rabbit to determine lesion area ratios (LARs). Mean LARs were 0.13 for RSDL, 0.25 for M291 SDK, and 3.16 for water-treated sites relative to the no-treatment control sites. RSDL was significantly more effective than M291 SDK against SM. In studies with VX, 24 h median lethal doses (LD_{50}s) were determined from separate dose-response curves for rabbits either left untreated, or treated with either M291 SDK or RSDL. The LD_{50}s (and protective ratios) were 0.33 mg/kg (9.6) for M291 SDK, and 2.3 mg/kg (66) for RSDL. Untreated rabbits had an LD_{50} of 0.035 mg/kg. RSDL was significantly more effective than M291 SDK against VX. The results indicate that significant protection is afforded by RSDL against SM and VX and establish its equivalency with M291 SDK. This work was conducted under the USAMRMC Contracts DAMD17-99-D-0010, Task Order 0008, with support from the US Marine Corps Foreign Comparative Testing Skin Decontamination Project.

798 INVESTIGATING THE *AEDES AEGYPTI* MOSQUITO LARVAE AS AN *IN VIVO* BIOASSAY FOR CHEMICAL AND BIOLOGICAL WEAPONS AGENTS (CBWA).

R. S. Mackie, B. W. Gutting and A. Rayms-Keller. *Chemical Biological Systems Technology Division, Naval Surface Warfare Center, Dahlgren, VA.*

CBWA are an emerging threat and at present there are no reliable detection/identification systems. Thus, there is a need to develop novel assays that can identify the presence of CBWA in environmental samples. A system that can measure CBWA-specific markers of toxicity in a living organism represents a viable solution. We investigated a novel *in vivo* detection system that monitors the toxicity of CBWA in Aedes aegypti mosquito larvae. Larvae were incubated in water that contained a test agent. Tests included chemical (aflatoxin: AF), protein (ricin: RC and botulinum toxin: BT) and bacterial (B. globigii: BG, a simulant for anthrax) agents. The endpoints were LD50 (2-hour exposure), lactate dehydrogenase (LDH) activity in the exposure media, and CBWA-induced alterations in proteins that are known to play key roles in cell signaling, apoptosis, and metabolism. Protein activity levels were monitored using 2 separate ELISA systems (FITC- and peroxidase-conjugated antibody). Based on LD50, larvae were susceptible to the acute toxic effects of several CBWA (RC>AF>>BT>>BG). When exposed to RC and AF, a significant increase in LDH activity was detected in the exposure media (2-hour exposure), suggesting a direct toxic effect on larvae gut epithelial cells. We also detected changes in protein activities at the LD50 dose (1-hour exposure) that were CBWA-specific. In an attempt to increase the number of proteins examined per experiment, we investi-

gated an antibody microarray using the toxic industrial chemical trichloroethylene (TCE). Of >250 proteins examined, we detected TCE-induced alteration in 16 proteins, suggesting this application may be useful in further developing this detection system. Collectively, these observations suggest that larvae are sensitive to the acute toxic effects of certain CBWA and from this we have been able to generate CBWA-specific toxicity biosignatures. This information may be useful in identifying the presence of CBWA in an unknown sample. (Supported by DARPA)

799 EVALUATING THE THREAT OF CHEMICAL AND BIOLOGICAL WARFARE *VIA* MAIL OR DRINKING WATER DELIVERY SYSTEMS.

J. S. Duffy, J. Fessler, T. Gauthier, J. Greene, S. Medhekar, R. Mongia, B. Murphy and D. Paustenbach. *Exponent, Tampa, FL.*

A literature survey of known potential, biological, chemical, explosive and radiological threats that could be delivered through the public mail delivery system (e.g., US Postal Service, UPS, etc.) was conducted. In addition, a survey of known potential biological, chemical and radiological threats to the public drinking water system was undertaken. For mail threats, it was found that biological agents posed a moderate to high risk due to the ease of production and ease of mailing. Infectious biological agents (e.g., smallpox, plague, etc.) may be of particular concern because they pose epidemic potential. In an aerosolized form, they are easily spread person-to-person, and they require more than the standard infection control precautions. Chemical agents were found to pose low to moderate risk as a mail threat. They are relatively easy to obtain or synthesize, but are not well suited to delivery by mail since they are typically in the form of liquids or gases and would likely be shipped in appropriate containers which have a reasonable chance of being detected. The risk from explosive agents was found to be relatively small for letter-sized pieces of mail with the possible exception of plastic explosives. Radiological agents were found to pose low to moderate risks. The greatest threat for radiological sources comes from the accidental ingestion or inhalation of these substances. For water delivery systems, the magnitude of the threat is dependent on the solubility of the agent in water. Biological agents are soluble and generally have a low LD50 but are unstable in the presence of chlorine. Chemical toxins are likely a viable threat *via* water delivery systems although overall stability remains a question. Finally, radiological threats also seem to be a low to moderate threat based on their solubility, low hydrolysis potential and stability under chlorinated conditions.

800 *IN VITRO* STUDIES OF DIPHOTERINE FOR DECONTAMINATION OF ORGANOPHOSPHORUS COMPOINDS, INCLUDING DFP AND THE NERVE AGENTS SOMAN AND VX.

A. H. Hall[1], J. Blomet[2], B. Viala[2], P. Masson[3] and M. Froment[3]. *[1]Department of Emergency Medicine, Texas Tech University Health Sciences Center-El Paso, El Paso, TX, [2]Prevor Laboratories, Valmondois, France, [3]Prevor Laboratories, Valmondois, France, [4]CRSSA, La Tronche, France and [5]CRSSA, La Tronche, France.*

Diphoterine is a proposed organophosphate (OPs) decontaminant. To evidence the potent OP-scavenging property of Diphoterine, measurements of decreases in OP concentration were done indirectly measured using OP-interacting enzymes (human butyrylcholinesterase). BuChE activity was measured by the Elman's method. Human paraoxonase (PON1) and Pseudomonas diminuta phosphotriesterase (PTE), and the G117H mutant of BuChE were used. OPs were paraoxon, DFP), echothiophate, racemic soman and VX). The final concentrations of Diphoterine® in buffers ranged from 0 to 0.6 M. Diphoterine did not promote hydrolysis of OPs when incubatated with paraoxon. Diphoterine did not inhibit or activate wild-type BuChE and its G117H mutant, even with 24h preincubation at 20° C. Diphoterine in the medium slowed down the progressive inhibition of BuChE caused by OPs. The effect was greater with increasing the Diphoterine concentration. Increasing incubation time for OPs and Diphoterine® had no effect. This can be explained by depletion of OP in the medium by rapid formation of an inactive complex. The apparent estimated dissociation constant of OP-Diphoterine complex about 10-20 mM. The affinity of Diphoterine for OPs ranked as follows: Echothiophate>VX>Soman>DFP>paraoxon. Diphoterine alone did not inhibit PON1 up to 0.1 M. PTE was not inactivated in the presence of higher Diphoterine concentrations. With increasing concentrations of Diphoterine, the OP-hydrolase activity of PON1, PTE and G117H mutant of BuChE towards different concentrations of paraoxon as a substrate progressively decreased. This indicates that Diphoterine caused a reduction in substrate concentration, corroborating inhibition data. Inhibition of BuChE by OPs in the presence of Diphoterine as well as results about activity of OP hydrolases under similar conditions support the conclusion that Diphoterine acts by scavenging OPs.

801 ADVANCES IN TOXICOGENOMICS: NIEHS NATIONAL CENTER FOR TOXICOGENOMICS.

R. Tennant[1] and S. Wilson[2]. *[1]Division of Intramural Research, NIEHS, Research Triangle Park, NC and [2]Office of Deputy Director, NIEHS, Research Triangle Park, NC.*

Toxicogenomics represents the interface between toxicology and gene expression technology; it combines studies of genetics, genomic-scale mRNA expression, cell and tissue-wide protein expression, metabolite profiling and bioinformatics in order to understand the role of gene-environment interactions in disease. The NIEHS National Center for Toxicogenomics was established to facilitate research to improve our understanding of mechanisms underlying toxic responses of environmental agents and to develop an extensive knowledge-base of Chemical Effects in Biological Systems (CEBS). In order to catalyze these efforts the NCT has established a Toxicogenomics Research Consortium, comprised of six institutions including Duke University, MIT, Oregon Health Sciences Center, University of North Carolina, The Fred Hutchinson Cancer Center and the NIEHS Microarray Center. Studies conducted by this consortium will facilitate the development of the field of toxicogenomics.

802 INTEGRATION OF GENOMIC AND PROTEOMIC APPROACHES TO STUDY TOXICOLOGICAL PHENOTYPES.

S. Nagalla[1], G. Kisby[2], P. Pattee[1], B. Searles[1] and D. Sproles[1]. *[1]Department of Pediatrics, Oregon Health and Sciences University, Portland, OR and [2]CROET, Oregon Health Sciences University, Portland, OR.* Sponsor: R. Tennant.

To define the molecular state of a given phenotype resulting from toxicant exposure a comprehensive measure of genes and their products expressed in a given organ or cell system will greatly facilitate the identification of potential pathways and their interactions. To develop these methods we utilized the genotoxin methylazoxymethanol (MAM), a developmental neurotoxin implicated in western Pacific Amyotrophic Lateral Schlerosis (ALS), Parkinson's disease, and an Alzheimer-like dementia (ALS/PDC). The mechanism of MAM induced acute or chronic brain injury is poorly understood. To characterize the gene and protein expression changes in MAM induced toxicity and the developing nervous system, C57BL6 (postnatal mice, 3-days old), were administered saline or a sub-lethal dose of MAM (43 mg/kg, s.c.), and 1, 8, 15, and 22 days later RNA and protein were isolated from various brain regions (cortex, hippocampus, striatum, thalamus, midbrain, cerebellum). Using high-density cDNA arrays we examined expression levels of ~26, 000 mouse sequence verified clones. Using 2D-electrophoresis and MALDI-TOF methods we examined the protein expression changes. "In silico" we combined the gene and protein expression patterns to generate clusters that are unique to this toxicant. We used the combined approaches to identify pathways regulated by MAM in the developing CNS.

803 COMPLEX RESPONSES TO ALKYLATING AGENTS.

L. Samson. *Center for Environmental Health Sciences, MIT, Cambridge, MA.*

Using Affymetrix oligonucleotide GeneChip analysis, we previously found that, upon exposure to the simple alkylating agent methylmethane sulfonate (MMS), the transcript levels for about one third of the Saccharomyces cerevisiae genome (~2, 000 transcripts) are induced or repressed during the first hour or two after exposure. This increased the number of S. cerevisiae genes previously known to be responsive to a DNA damaging agent by about 100 fold. In order to determine whether the responsiveness of these genes has any relevance to the protection of cells against alkylating agents we have undertaken several follow-up studies. First, we explored the specificity of this global transcriptional response to MMS by measuring the global response of S. cerevisiae to a broad range of agents that are known to induce DNA damage. We found that each agent produced a very different mRNA transcript profile, even though the exposure doses produced similar levels of toxicity. We also found that the selection of genes that respond to MMS is highly dependent upon what cell cycle phase the cells are in at the time of exposure. Computational clustering analysis of the dataset derived from a large number of exposures identified several promoter motifs that are likely to control some of the regulons that comprise this large set of genes that are responsive to DNA damaging agents. However, it should be noted that these agents damage cellular components other than DNA, and that the responsiveness of each gene need not be in response to DNA damage per se. We have also begun to study the response of other organisms to alkylating agents, and these include E. coli, cultures of mouse and human cells, and mice. Finally, we have developed a high throughput phenotypic screening method to interrogate the role of all non-essential S. cerevisiae genes (about 4, 800) in protecting S. cerevisiae against the deleterious effects of alkylating agents; we

have termed this analysis 'genomic phenotyping'. This study has uncovered a plethora of new pathways that play a role in the recovery of eukaryotic cells after exposure to toxic/mutagenic agents.

804 AN APPROACH TO THE CLASSIFICATION OF TOXICOLOGICAL EFFECTS USING MICROARRAY AND PROTEOMIC TECHNOLOGIES.

R. Tennant. *National Center for Toxicogenomics, NIEHS, Research Triangle Park, NC.*

Data from microarray analysis of tissues of rats exposed to selected chemicals/drugs have shown that specific patterns can be recognized that are representative of chemical class (Hamadeh et al., Toxicology. Sciences. 67:219). It has also been possible to demonstrate that even with a relatively small learning set, compound classification is possible (Hamadeh et al., Toxicology. Sciences. 67:232, 2002). Such "signature patterns" of gene expression changes were derived from tissues within 24 hours to two weeks of exposure to nontoxic doses of agent and thus are likely to be representative of the pharmacological properties of the agents. It is therefore important to determine if similar signature patterns can be identified representing toxic effects. Agents selected for the induction of prototype toxicities (e.g., hepatic portal necrosis) are being analyzed in experiments in which target and non-target tissues are examined. Microarray and proteomic methodologies are applied to identify candidate biomarkers of toxicity.

805 USING TOXICOGENOMIC ANALYSIS TO ASSESS THE PROTECTIVE EFFECTS OF ENHANCED GLUTATHIONE SYNTHESIS IN GLUTAMATE-CYSTEINE LIGASE TRANSGENIC MICE.

T. Kavanagh[1], S. Shi[1], D. Botta[1], C. White[1], M. Dabrowski[1], C. Shephard[1], S. Quigley[1], F. Farin[1], R. Beyer[1], R. Pierce[2], C. Franklin[1], H. Zarbl[3] and T. Bammler[1]. *[1]University of Washington, Seattle, WA, [2]Medical Center, University of Rochester, Rochester, NY and [3]Fred Hutchinson Cancer Research Center, Seattle, WA.*

Glutathione (GSH) is a major free radical scavenger and is important in detoxification of reactive oxygen species and xenobiotics. The rate-limiting enzyme in GSH synthesis is glutamate-cysteine ligase (GCL) which is composed of catalytic (GCLC) and modifying (GCLM) subunits. GCL expression has been shown to be variable in a number of disease states, including cancer, fibrotic lung diseases and cardiovascular disease. We have created transgenic mice that conditionally overexpress GCLC and/or GLCM in the liver. In order to test the hypothesis that enhanced GSH synthesis can ameliorate toxicant-induced oxidative stress, we are examining the influence of GCLC and GCLM overexpression on CCl4 or acetaminophen induced liver injury, as assessed by histopathology, lipid peroxidation and global gene expression changes using cDNA microarrays. Transgenic mice overexpressing GCL show diminished histopathological changes in the liver, less lipid peroxidation and lower serum ALT activity after CCl4 treatment. Relatively few changes in gene expression were noted when mice were treated with the inducing agent alone (mifepristone) to up-regulate GCL expression. Experiments are currently underway to examine the effects of GCL overexpression on CCl4 and APAP -induced changes in global gene expression. Combining toxicogenomic analyses with transgenic mouse models can provide additional insights into the mechanisms of toxicant induced injury. Supported by NIH Grants 1P42ES04696, 1P30ES07033 and 1U19ES11378.

806 DISSECTING THE ROLE OF PLEIOTROPIC TOXICANTS AND CELL TYPE SPECIFIC RESPONSES USING DNA MICROARRAYS.

C. M. Perou. *Lineberger Comprehensive Cancer Ceneter, University of North Carolina, Chapel Hill, NC.* Sponsor: R. Tennant.

Many environmental toxicants have pleiotropic effects, and it is often uncertain which of the mechanisms of action are responsible for observed toxic endpoints. The toxicant doxorubicin (DOX) represents an excellent model compound for dissecting the pleiotropic effects of a toxicant that induces oxidative stress. DOX is a commonly used chemotherapeutic that has been found to inhibit topoisomerase II (TOP2) and cause oxidative damage. Using RNA from treated cell lines, we performed DNA microarrays to obtain detailed information on networks of DOX-responsive genes. We treated a panel of breast epithelial cell lines with DOX using two doses: the first dose corresponds to the IC50 for each cell line and the second was a lower dose, common to all cell lines. Gene expression profiles associated with topo-II inhibition and oxidative stress were identified in these cell lines by comparison with a panel of toxicants thought to only inhibit TOP2 activity or only to induce oxidative stress. Sets of genes were identified that were repressed in all treatments and are largely involved in proliferation and cell cycle progression including v-myb2, TOP2 and cyclin A2. Sets of genes that were potentially p53-dependent, notably p21, were induced following DOX and etoposide treatment. The potency of a toxicant is also determined by the genetic background of the treated cells. Recent studies have identified breast tumors with characteristics of basal epithelium that show a poor prognosis and potentially, a different response to therapy than tumors derived from luminal cells. Thus, we compared the expression profiles of to DOX treated cell lines derived from basal and luminal epithelium and found unique sets of genes that were specifically induced in either the basal or luminal lines, indicating that the cell type of origin impacts upon the response to therapeutics. Notably, RERG was induced in basal epithelial lines and not in luminal lines in response to DOX, with the induction of this gene being previously shown by our lab to correlate with decreased cell proliferation rates.

807 MOLECULAR MECHANISMS OF CARDIOVASCULAR TOXICITY OF METALS AND METALLOIDS.

Y. Kang[1] and M. P. Waalkes[2]. *[1]Medicine, University of Louisville School of Medicine, Louisville, KY and [2]NIEHS, Research Triangle Park, NC.*

Cardiovascular toxicity of metals and metalloids has long been recognized. However, molecular mechanisms leading to cardiovascular injury by these agents are not understood. A major reason for the lack of this knowledge is that toxicologists have not investigated cardiovascular toxicology in general to the same extent as the toxicology of the liver, kidneys, lungs, or brain. As a result, cardiovascular toxicology is extremely under-represented in the discipline of toxicology. Advances in molecular biology of cardiovascular system have provided tremendous opportunities to explore cardiovascular toxicology at cellular and molecular levels. Improved understanding of signaling pathways and molecular mechanisms leading to cardiovascular diseases such as acute myocardial infarction, heart failure and hypertension requires expanding our knowledge to the interaction between the myocardium and environmental agents including metals and metalloids. There is no doubt that environmental and medical exposure to metals and metalloids play a significant role in cardiovascular diseases. Interactions between toxic metals such as cadmium with essential minerals such as calcium and zinc can directly interfere with signal transduction and gene expression. Crucial molecules such as vital protein thiols in cardiovascular system are very sensitive to toxic metalloid arsenic. The role of toxic metals and metalloids in activation of transcription factors and post-translation modifications is also of great concerns in cardiovascular medicine. A comprehensive discussion of up-to-date understanding of these molecular and cellular events involved in the cardiovascular toxicity of metals and metalloids will thus provide novel insights into the role of metals and metalloids in the development of cardiovascular diseases.

808 NOVEL INSIGHTS INTO THE CARDIOVASCULAR TOXICITIES OF METALS AND METALLOIDS.

M. P. Waalkes. *NIEHS, Research Triangle Park, NC.*

Metallic compounds, including heavy metals and metalloids, cause a wide variety of toxic manifestations in humans. Although understudied, the cardiovascular system is often a critical target of inorganic compounds, such as cadmium, nickel, lead and arsenic. Through as yet poorly defined etiologies, exposure to metals and metalloids can induce dramatic cardiovascular effects, ranging from hypertension to peripheral vascular disease. Metals can also have effects on myocardial and/or vascular function by attacking endothelial or myocardial cells and causing dysfunction. Indirect attack, as through disruption of mediators of vascular tone, can also play a role. Toxic metallic agents have many intricate effects within cells, including aberrant gene expression, disruption of signal transduction, perturbation of membrane transport, and mimicry of essential elements, that all likely contribute to cardiovascular toxicity. Our understanding of the mechanisms of metallic cardiotoxicity is, at present, incomplete. The advent of powerful molecular techniques, such as toxicogenomics and proteomics, as well as the use of transgenic animals should allow for significant advances in our understanding of the mechanistic basis of metal-induced cardiovascular toxicities. The knowledge of the impact of metal exposure on gene and protein expression profiles in cardiovascular target tissue should provide important candidate genes or pathways for more detailed mechanistic study. Targeted disruption of genes involved in metal metabolism or tolerance should allow for the definition of the role of such genes in cardiovascular toxicity. As with all areas of toxicology, the recent advances in the methods of molecular toxicology will likely create many new and exciting research avenues in defining the mechanisms of the cardiovascular toxicity of metals.

809 INTERACTIONS OF NICKELS AND CADMIUM WITH CARDIAC SR CALCIUM RELEASE CHANNELS.

J. A. Wasserstrom, J. E. Kelly and R. G. Tsushima. *Department of Medicine, Northwestern Medical School, Chicago, IL.* Sponsor: Y. Kang.

The heavy metals Cd^{2+} and Ni^{2+} are known to block cardiac contraction. These divalent cations are known to inhibit the L-type Ca^{2+} channel but it is not known if they also interfere with the Ca^{2+} release process itself. The purpose of this study was to investigate the direct effects of these metals on cardiac sarcoplasmic reticulum (SR) Ca^{2+} release channels (ryanodine receptors, RyRs). Purified RyRs was isolated from dog ventricular heavy SR and single channel activity was recorded in artificial planar lipid bilayers. Cd^{2+} (10-30mM) caused a time-dependent reduction in single channel activity that eventually resulted in complete channel block. Unitary current amplitude was decreased immediately before block occurred, probably as the result of a rapid flicker-type interaction with the channel. Block occurred when Cd^{2+} was applied to either side of the bilayer. Reducing [Cd^{2+}] by successive dilutions did not permit recovery of channel activity but temporary recovery from block did occur in the presence of the methane thiosulfonate derivative MTSES (1mM) shortly before permanent block occurred. Ni^{2+} also blocked single channel activity but this block could not be relieved, even temporarily, by MTSES. These results indicate that Cd^{2+} probably interacts with free sulfhydrl groups in the pore of the channel protein. However, this interaction can be broken by the preferential binding of the MTSES with the sulfhydryl groups, displacing the Cd^{2+} and allowing the temporary recovery of channel activity. The slower interaction between MTSES and the sulfhydryl groups then is responsible for the eventual and permanent block of the channel. The interaction between Ni^{2+} and the channel protein is fundamentally different but also leads to block of channel activity. The effects of these heavy metals to inhibit the activity of the SR Ca^{2+} release channel might contribute to their negative inotropic effects in the heart

810 MYOCARDIAL APOPTOSIS AND CARDIOMYOPATHY INDUCED BY ARSENIC.

Y. Kang, Y. Li and X. Sun. *Medicine, University of Louisville School of Medicine, Louisville, KY.*

Arsenic is an environmental toxic agent, however, it has been used in the form of arsenic trioxide in the treatment of acute promyelocytic leukemia (APL) due to its irreplacible efficacy. Recent clinical trials in the United States have shown a serious ventricular tachycardia at the therapeutic doses of arsenic trioxide in APL patients. Using a mouse model, we have observed that treatment with arsenic trioxide at 5 mg/kg/day for 30 days produced plasma concentrations of arsenic within the range of those present in arsenic-treated APL patients and caused cardiac toxic manifestations similar to humans. The cardiac toxic effects monitored by electrocardiogram include prolonged QT intervals and prominent University waves, a torsade de pointes form of ventricular tachycardia. An in situ left ventricle performance analysis revealed that arsenic caused a siginificant decrease in the maximum rate of rise in intraventricular pressure during ventricular contraction and significant increases in the end diastolic pressure and ventricular minimum diastolic pressure. Arsenic-induced cardiomyopathy was also observed by histopathological and ultrastructural examination. Myocardial apoptosis along with increased voulme of the remaining cardiomyocytes were predominant cellular events. Caspase-3 activation and mitochondrial cytochrome c release were accompanied with apoptosis. Interestingly, elevation of myocardial metallothionein concentrations significantly prevented all of these toxic manifestations along with suppression of arsenic-induced decrease in the ratio of reduced glutathione to glutathione disulfide. The inhibition of thiol-containing enzymes such as oxidoreductases by arsenic was also prevented by metallothionein. These results thus demonstrate that arsenic-induced cardiotoxicity is associated with apoptosis mediated by mitochondrial cytochrome c release. The interaction of arsenic with essential thiols is likely involved in the mechanism of arsenic cardiotoxicity.

811 SIGNALING PATHWAYS INVOLVED IN ARSENIC-INDUCED VASCULAR DISEASE.

A. Barchowsky[1], L. R. Klei[1], M. Ihnat[2], C. Kamat[2] and N. V. Soucy[1]. [1]*Pharmacology and Toxicology, Dartmouth Medical School, Hanover, NH and* [2]*Cell Biology, University of Oklahoma Health Sciences Center, Oklahoma City, OK.*

Chronic, low level exposure to arsenite increases the incidence of proliferative cardiovascular diseases, such as arteriosclerosis and ischemic heart disease. Arsenic-associated changes in blood vessels may also contribute to the vascular components of diabetes and tumor growth. Angiogenesis is fundamental to these pathological changes and may underlie effects of arsenic on vascular remodeling. In support of this hypothesis, nanomolar to low micromolar levels of arsenite increased blood vessel density *in vivo* in both chicken and mouse models. However, higher levels of arsenite inhibited blood vessel growth. Investigation of the potential angiogenic factors induced by arsenite revealed increased expression of both vascular endothelial cell growth factor (VEGF) and plasminogen activator inhibitor-1 (PAI-1). Mechanistic studies indicated that separate signaling pathways mediated induction of these two angiogenic factors. These pathways were associated with increased signaling through a Src family tyrosine kinase, protein kinase C, and stabilization of hypoxia inducible factor-1alpha. Induction of VEGF in vascular smooth muscle cells was directly correlated to increasing doses of arsenite, whereas PAI-1 induction was stimulated at low doses and inhibited at higher levels. This may indicate that signaling mechanisms for expression of PAI-1 may be better predictors of the pro-angiogenic potential of arsenite. Supported by SBRP grant ES07373.

812 NOVEL INSIGHTS INTO THE TOXICOLOGY OF LUNG OXIDATIVE STRESS.

M. C. Madden[1] and M. Kadiiska[2]. [1]*ORD, NHEERL, HSD, Clinical Research Branch, USEPA, Chapel Hill, NC and* [2]*Laboratory of Pharmacology and Chemistry, NIEHS, Research Triangle Park, NC.*

Oxidative stress is derived from an overproduction of oxidants such as reactive oxygen and nitrogen species relative to the detoxification of the oxidants. The increased production of such oxidants can lead on one hand to fairly nonspecific damage to lipids, proteins, and DNA as well as to rather specific changes related to receptor binding and signal transduction. Oxidative stress is present in all lung disease states and has been associated with toxicity induced by radiation and most, if not all, lung toxicants. Lung oxidative stress can be derived from both endogenous sources (*e.g.*, induction of inflammation and disruption of normal O_2 metabolism) and exogenous sources (*e.g.*, exposure to gaseous and particulate air pollutants). The possibility exists that extrapulmonary organ systems can be affected by lung oxidative stress as increased production of oxidant species in the lung can lead to transport of the oxidant species or reaction products outside the lung with possible biological effects. The focus of this session will be to present recent advances in the measurement of oxidative stress primarily in the lung as well as new insights related to the pathobiology of oxidant formation within this organ. Findings that will be presented will range from the detection of endogenously and exogenously derived oxidants in pulmonary and extrapulmonary tissue, to involvement of oxidants in lung responses and clinical disease. The role of oxidant-induced activation of important lipid signaling pathways related to acute lung injury and strategies to attenuate the injury will be described. Validation studies of air pollutant biomarkers of exposure and effects using ozone and other lung toxicants will be shown. Relevant to the great interest in particulate matter (PM) toxicology, the mechanisms by which lung cells transport and metabolize transition metals on PM will be discussed, as will early markers of oxidant production with PM using cobalt as a model PM. [This abstract does not necessarily reflect EPA policy.]

813 ROLE OF OXIDATIVELY MODIFIED PHOSPHOLIPIDS IN ACUTE LUNG INJURY.

T. McIntyre[1,2,4], G. A. Zimmerman[1,3,2], A. S. Weyrich[1,3] and S. M. Prescott[3,2]. [1]*Program in Human Molecular Biology and Genetics, University of Utah, Salt Lake City, UT,* [2]*Department of Medicine, University of Utah, Salt Lake City, UT,* [3]*Huntsman Cancer Institute, University of Utah, Salt Lake City, UT and* [4]*Department of Experimental Pathology, University of Utah, Salt Lake City, UT.* Sponsor: M. Madden.

The Platelet-Activating Factor (PAF) signaling system mediates cellular activation, and its dysregulation contributes to pathologic inflammation and thrombosis in syndromes that include shock, sepsis and acute lung injury (ALI). The PAF receptor, a member of the seven membrane spanning G protein-linked family, is constitutively expressed on human platelets and myeloid leukocytes, which are key effector cells in thrombotic and inflammatory disorders. The PAF receptor recognizes not only PAF (1-0-alkyl-2-acetyl-sn-glycero- 3-phosphorylcholine), a phospholipid that is enzymatically synthesized by endothelial cells and several other cell types in response to inflammatory agonists and oxidants, but also a group of structurally-related ligands termed PAF-like lipids or oxidatively-modified phospholipids (OX-PL) that are generated by oxidant attack on membrane phospholipids rather than by regulated enzymatic synthesis. This provides a mechanism by which ligands that activate the PAF signaling system are generated in uncontrolled fashion. A variety of observations indicate that this mechanism operates in experimental ALI and in acute respiratory distress syndrome (ARDS), the most severe form of human ALI. The signals triggered by PAF and oxidatively-modified PAF-like lipids are terminated by their hydrolysis by a group of intra - and extracellular enzymes termed PAF acetylhydrolases (PAF AH); the extracellular, or plasma, form of PAF AH is particularly important because it limits the half-life of PAF to minutes in human blood. Plasma PAF AH is inactivated by oxidants *in vitro* and *in vivo*, establishing a mechanism for pathologic imbalance between generation of ligands for the PAF receptor and their degradation. Plasma PAF AH has been cloned and characterized at

the molecular level, and a recombinant form is under study as a novel anti-inflammatory agent. Preliminary evidence indicates that it terminates signals in human ALI.

814 USE OF OXYGEN-18 ISOTOPE LABELING FOR MEASUREMENT OF OXIDATIVE STRESS.

G. E. Hatch. *Pulmonary Toxicology. Branch, US E.P.A., Research Tri. Park, NC.*

Oxygen-18 (18-O) labeling provides a sensitive means for quantifying oxygen binding that occurs during *in vivo* oxidations. Oxidants (ozone, nitrogen oxides, hydrogen peroxide, etc.) are synthesized using 18-O, then cells or tissues are exposed to the labeled oxidants, after which the tissues can be assayed for excess 18-O to indicate the extent of oxidation that occurred in them. Use of this stable isotope allows samples to be stored indefinitely. In addition to exposure to labeled oxidants, animals can be exposed to 18-O_2 gas at the same time they are exposed to free radical generating toxicants (metal, CCl_4, etc.) to yield an estimate of "secondary oxidations." Separation of tissue fractions (protein, lipid, DNA, etc.) provides individual assessment of oxidation in these pools, yielding valuable information about mode of action of the oxidants studied. Measurement of the elimination of 18-O in urine appears to provide a quantitative assessment of tissue repair following oxidative injury. Since 18-O is not radioactive this isotope is easily used in human studies. We have used 18-O isotopically labeled pollutants to compare human and animal ozone dose to target sites in the nose and lung. Interactions between ozone and inhaled diesel particles have also been elucidated using 18-O. Comparisons between 18-O measurements and more traditional measures of oxidative stress indicate that the former method is often more sensitive and less subject to interferences and artifacts. However, further work is needed to distinguish between pathological and "normal" oxidations. In summary, use of oxygen-18 provides a unique research tool to study oxidative processes occurring *in vivo*.

815 OXIDATIVE DAMAGE INDUCED BY CCL4 AND OZONE: VALIDATION OF BIOMARKERS.

M. B. Kadiiska. *NIEHS, Research Triangle Park, NC.*

Oxidation products of lipids, proteins and DNA in the blood, plasma and urine of rats were measured as part of an international multilaboratory validation study searching for non-invasive biomarkers of oxidative stress. Acute CCl_4 poisoning and the ozone exposure were used as two different rodent models of oxidative stress. The time (2, 7, and 16h) and dose-dependent effects of CCl_4 (120 and 1200 mg/kg ip) or ozone (1 and 5 ppm) on concentrations of lipid hydroperoxides, thiobarbituric acid reactive substances (TBARS), malondialdehyde (MDA), isoprostanes, protein carbonyls, methionine sulfoxidation, tyrosine products, 8-hydroxy-2-deoxyguanosine (8-OHdG), and leucocyte DNA-MDA adducts and DNA-strand breaks were investigated to determine whether the oxidative effects of CCl_4 or ozone would result in increased generation of these oxidation products. Plasma concentrations of MDA and isoprostanes (measured only by GC/MS) and urinary concentrations of isoprostanes (measured with an immunoassay) were increased in CCl_4 treated rats. All other products were not changed by CCl_4 and ozone, or showed only high-dose and/or single time point effects. Interestingly, in the ozone exposed rats no changes in the plasma isoprostanes were found. Measures of oxidation products of proteins and DNA were not reliable biomarkers for free radical damage induced by CCl_4 and ozone.

816 MODULATION OF TRANSITION METAL-INDUCED INJURY BY METAL TRANSPORT PROTEINS.

A. Ghio. *NHEERL\HSD\Clinical Research Branch, USEPA, Research Triangle Park, NC.* Sponsor: M. Madden.

The capacity of divalent metal transporter 1 (DMT1) to transport iron and its ubiquitous expression make it a likely candidate for transferrin-independent uptake of iron in peripheral tissues. Airway epithelial cells increase both mRNA and expression of that isoform of DMT1 without an iron response element (-IRE) following exposure to iron. We tested the hypothesis that -IRE DMT1 participates in the detoxification of metals in the lung. Exposure for 24 hours of human bronchial epithelial cells to oil fly ash particles that were high in iron and other transition metals content unexpectedly resulted in a decrement in mRNA by RT-PCR for the -IRE isoform of DMT1 and the protein by Western blot analysis. Similar decreases in mRNA and protein expression were demonstrated following exposure of bronchial epithelial cells to vanadyl sulfate, a metal in high concentration in this specific oil fly ash. Pre-exposures of respiratory epithelium to iron and vanadium were associated with an increased and a decreased uptake of metal respectively. Pre-exposure of an animal model to iron was associated with both an increased expression of DMT1 and diminished injury after particle exposure. In contrast, vanadium pre-exposure decreased DMT1 expression and increased injury after the same particle. Exposure of Belgrade rats (an animal model deficient in functional DMT1) to the particle resulted in a greater injury relative to control animals. We conclude that levels of -IRE DMT1 expression are associated with both metal transport in the lower respiratory tract and injury following exposure to a particle. [This abstract may not reflect EPA policy.]

817 ACTIVATION OF THE HEXOSE MONOPHOSPHATE SHUNT: AN EARLY MARKER OF OXIDATIVE STRESS CAUSED BY COBALT PARTICLES.

P. H. Hoet, G. Roesems and B. Nemery. *Pneumologie - Longtoxicologie, K.U.Leuven, Leuven, Belgium.*

Airborne cobalt-containing particles can lead to the development of interstitial lung disease and lung cancer in workers. In cell free experiments, it has been shown that Co ions (Co^{2+}) are able to react with H_2O_2 to produce reactive oxygen. Moreover, freshly suspended hard metal (cobalt tungsten carbide, CoWC = 6% Co + 94% tungsten carbide) particles generate activated oxygen species in water as a result of the WC-catalyzed reduction of oxygen and, consequently, the oxidation of the metal cobalt (mCo) at the surface of the carbide. Changes in the activity of the hexose monophosphate shunt (HMS) or pentose phosphate pathway of glucose oxidation, as well as increased thiol oxidation have been shown in hamster lung exposed in vivo to $CoCl_2$ and in hamster lung slices exposed *in vitro*. Recently we have shown that mCo particles freshly immersed in medium lead to an early stimulation of the HMS activity in primary rat alveolar type II pneumocytes (AT-II) in a dose dependent way. The combination of mCo and WC, as present in hard metal, also increased the HMS activity in rat AT-II. However, this increase did not differ from that caused by an equivalent amount of pure mCo. We were not able to show a simple relationship between the stimulation of the HMS activity and the subsequent cell damage as measured using the microtetrazolium (MTT) cytotoxicity assay. The HMS activity was not stimulated by other particles (such as pure WC, positively or negatively charged latex beads or PVC particles), by "aged" mCo particles, or by $CoCl_2$. The peroxides H_2O_2 and t-BOOH stimulated the HMS activity in a comparable way to mCo, and catalase abolished the mCo-induced stimulation of the activity, suggesting that the observed stimulation of the HMS may be due to the production of peroxide. Consequently, the early observed HMS stimulation is possibly a sign of toxicity. Although the exact mechanism of toxicity still needs to be elucidated fully, in particular with regard to type of Co (e.g. metalic, ionic) and the role of other substances (e.g. WC), the evidence exists for an oxidant-mediated toxicity of Co upon inhalation.

818 INTRODUCTION: CHALLENGES OF THE DEVELOPMENTAL NEUROTOXICITY STUDY.

S. L. Makris[1] and M. L. Weiner[2]. *[1]OPPTS/OPP/HED (7509C), USEPA, Washington, DC and [2]FMC Corporation, Princeton, NJ.*

The developmental neurotoxicity (DNT) study is a key study for identification of potential damage to the nervous system of the developing organism. In this study, exposure to the test substance occurs during fetal and postnatal development. Neurobehavioral and neuropathological assessments are performed on treated individuals in early life, and as adults following a period without exposure. These evaluations include functional observational battery, motor activity, auditory startle, and cognitive (learning and memory) testing, and histopathology of nervous system tissues, including morphometry of several areas of the brain. This Workshop will summarize the evolution of the DNT study as a regulatory guideline and the use of the rat model as a predictive species for nervous system effects in the young human. Some of the challenges of conducting a study with its inherent complexity in terms of the number of animals evaluated, the number and types of neurological tests, and the large amounts of data to process and interpret, will also be included. Finally, the use of the DNT study for hazard identification and risk assessment of new chemicals will be discussed in light of the current regulatory framework. Ample time will be allotted for a full discussion of the technical and regulatory challenges involved in conducting and interpreting the DNT.

819 OVERVIEW OF THE DEVELOPMENTAL NEUROTOXICITY (DNT) STUDY.

C. A. Kimmel. *NCEA/ORD, USEPA, Washington, DC.*

Behavioral impairments in humans following prenatal and early postnatal exposures to several drugs, physical, and chemical environmental agents have been recognized for over a half century and have raised concerns that such effects might re-

sult from exposure to a wider array of agents. Due to the concerns of regulatory agencies that recognized the need to standardize testing for such effects, reliable and routine testing procedures were developed. The Collaborative Behavioral Teratology Study (CBTS), a six-laboratory comparison study funded by FDA and NIOSH, showed that behavioral tests conducted in a standardized manner could provide reliable and reproducible findings. The DNT testing battery developed in the late 1980s by EPA built on earlier studies and was evaluated for its ability to detect agents known to cause DNT in humans. The final EPA DNT protocol published in 1991 was designed to include apical tests of a number of structural and functional aspects of nervous system development. These include measures of growth and development, motor activity, auditory startle habituation, learning and memory, and neuropathology. The challenge of DNT testing is to ensure that exposure is adequate during the major periods of nervous system development, that the major domains of neurobehavioral function are evaluated, that the appropriate times for evaluation are included, and that appropriate signals will result from the testing battery to indicate when there is a need to conduct further testing of potentially more subtle effects.

820 COMPARATIVE SCHEDULES OF DEVELOPMENT IN RATS AND HUMANS: IMPLICATIONS FOR DEVELOPMENTAL NEUROTOXICITY TESTING.

J. Buelke-Sam. *Toxicology Services, Greenfield, IN.* Sponsor: M. Weiner.

The USEPA developmental neurotoxicity study (DNT) guideline provides a relatively fixed design approach in rats for hazard identification following maternal exposure during gestation and a portion of lactation. The CNS is not a unitary organ; component morphology and function develop on separate schedules in both rats and humans. In spite of a multitude of subsystem schedules, the postnatal day 10 (PND10) rat brain has been considered at a similar developmental stage to that of a term infant, and by PND21 at a similar stage to that of a 2-year-old. Maternal exposure begins on GD6 and ends on PND10 (or PND21) in the current EPA guideline. Continuing maternal treatment throughout lactation continues some level of offspring exposure through a portion of additional CNS development, eg, blood brain barrier maturation and myelination processes. Other organ systems that have implications for developmental exposure in a DNT study may develop on similar or rather different schedules. For example, nephrogenesis is complete at ca PND7 in rat and ca 35 weeks gestation in the human, with renal glomerular filtration rates reaching adult rates by ca PND21-28 in rats and ca 2 years of age in humans. Hepatic conjugation patterns in the rat do not reach mature levels until a few weeks after puberty. Behavioral assessment and neuropathology evaluations are conducted during the preweaning period through ca PND60, a range of development from infancy through mid-adolescence in the rat. Many of these test procedures have been used effectively to characterize CNS damage in rats following developmental exposure to known human developmental neurotoxicants, e.g., methylmercury, lead, PCBs, alcohol, and several anticonvulsants. At present, the DNT study approach is expected to function as other current toxicological screening tools: high dose effects observed in rats should be assumed to be predictive of an increased risk to the human fetus, infant and/or toddler up to 2 years of age following maternal or direct infant exposure to lower doses.

821 EXPERIENCE CONDUCTING THE DEVELOPMENTAL NEUROTOXICITY STUDY.

L. P. Sheets. *Toxicology, Bayer Corporation, Stilwell, KS.*

The developmental neurotoxicity study (OPPTS 870.6300) is a very large and technically demanding study, with behavioral and morphometric assessments that are unfamiliar to many industry toxicologists. Approximately 1000 animals are included in the study design, representing 20-25 litters at each of four dose levels, with the treatment administered *via* the dam (e.g., by gavage or *via* the diet) from gestation day 6 through postnatal day 10. Subsets of the offspring are assessed using detailed observations or tests of motor activity, auditory startle habituation and cognitive function at specific days of age, with neural tissues collected at specific ages for microscopic examination and morphometry. Challenges associated with this study type include managing the logistics, maintaining attention to details that may affect the behaviors, the selection and validation of test devices and procedures, development and validation of analysis software, and data interpretation. This paper examines these and other practical issues (e.g., the selection of doses and means of administration), along with some study results, and considers how certain changes in experimental design that were recently instituted by the EPA (e.g., extending the dose interval) affect the logistics and introduce confounding factors that compromise interpretation. Discussion will include consideration of the interpretation and value of findings at maternally-toxic doses and the interpretation of findings during the period of exposure, prior to weaning.

822 APPLICATION OF THE DNT STUDY RESULTS TO RISK ASSESSMENT UNDER FQPA.

E. A. Doyle. *OPP/OPPTS, USEPA, Washington, DC.*

The EPA Office of Pesticide Programs (OPP) requires the DNT study for chemicals that have neurotoxic potential. A weight-of-evdence assessment is conducted, and information on structure activity relationships, mode of action, and toxicological response (e.g., neurobehavioral or neuropathological, alterations in development of the nervous system, or endocrine perturbations) are used to determine the need for DNT testing. OPP may request a more specific, tailored study to assess special sensitivity to the young. Such studies are often adapted from the DNT protocol and evaluate specific endpoints not included in the DNT. Studies requested to date include cholinesterase activity, glutamine synthetase activity, and thyroid hormones. These data are requested if a known effect is seen in adult animals and may impact offspring. DNT data studies are useful in evaluating potential risk to the fetus, and to infants and children. DNT results are used most frequently for acute and short-term risk assessments. In a few cases the results were used for intermediate-term and chronic endpoints. Treatment-related effects observed in DNT testing are used to assess the level of concern, and residual uncertainties (i.e., those not addressed by the traditional uncertainty factors). The presence of residual uncertainties may justify the retention of a special FQPA safety factor. Evaluation of DNT studies submitted to OPP has provided a basis for determining the need for (and magnitude of) uncertainty factors. These factors may be applied to the risk assessment to account for the absence of the guideline DNT study, the absence of other data that are expected to more fully characterize the potential for developmental neurotoxicity, or the identification of treatment-related effects or offspring susceptibility in DNT testing.

823 MODE OF ACTION IN ASSESSING HUMAN RELEVANCE OF ANIMAL TUMORS: IMPROVING THE FRAMEWORK FOR ANALYSIS.

P. A. Fenner-Crisp and S. M. Cohen. *Pathology/Microbiology, University of Nebraska Medical Center, Omaha, NE.*

Developing an understanding of the mode(s) of action (MOA) by which chemicals induce tumors in animals has become a key element in determining whether or not the tumors observed are relevant/applicable for use in human cancer risk assessment, and, if so, what might be the characteristics of the human dose response. This workshop, the product of an ILSI Risk Science Institute administered project funded by USEPA and Health Canada, includes 1) Discussion of proposed enhancements to the IPCS MOA Framework and EPA's MOA Framework in its 1999 draft cancer guidelines to strengthen the building of the bridge from "I think I understand the animal MOA(s)" to "I am able to articulate the importance of this animal tumor and its MOA(s) for the human, " 2) Implications of the Human Relevance Framework for cancer risk assessment, using several well-examined tumor types as examples; 3) An update on the understanding of the MOA(s) by which PPARα agonists induce liver and other tumors in rodents; and 4) Application of the enhanced Framework to PPARαagonist-induced tumors as an example of a newly-developed consensus on MOA.

824 UPDATING CANCER ASSESSMENT PRINCIPLES: AN EPA PERSPECTIVE.

V. L. Dellarco. *US Environmental Protection Agency, Washington, DC.* Sponsor: P. Fenner-Crisp.

In 1996, University.S.EPA proposed revisions to its 1986 Guidelines for Carcinogen Risk Assessment. Several areas were given particular attention. They included the development of a new set of hazard descriptors; an expanded explication of the nature and use of default assumptions; guidance on the use of the margin of exposure analysis; the consideration of the relevancy of the assessment for children, and an analytical framework for identification and characterization of the mode(s) of action for tumors observed in animal bioassays to determine the applicability and relevance of the tumors for human cancer assessment. Beginning in 1996, the Agency began testing the usefulness of the proposed revised guidelines. At the same time, it was attempting to develop a consensus on the relevance and use of tumors produced by peroxisome-proliferating chemicals. The International Programme on Chemical Safety also was developing a framework for use worldwide. Application of these frameworks soon revealed that, while they were adequate in providing guidance on determining whether or not the animal mode of action was adequately understood, they were not sufficiently robust to guide the analysis for establishing the applicability/relevance of the tumor MOA(s) for use in human cancer risk assessment. The Agency asked the ILSI Risk Science Institute to convene an expert

panel to define an expanded scientific process for utilizing a chemical's mode of action in animals to evaluate the human relevance and applicability of this information, with special attention to be given to the peroxisome proliferators. The subsequent presentations will describe the efforts of the panel with regard to the development of an expanded Framework and an update on the state-of-the-science of our understanding of the mode(s) of action of rodent tumors induced by certain peroxisome proliferators followed by application of the Framework to reach conclusions about the applicability of these tumors for human cancer assessment. (The opinions expressed are those of the author and should not be construed as Agency policy).

825 DEVELOPING THE HUMAN RELEVANCE FRAMEWORK.

S. M. Cohen. *Pathology/Microbiology, University of Nebraska Medical Center, Omaha, NE.*

To evaluate the human relevance of a particular mode of action for a tumor type observed in an animal bioassay and its applicability in cancer risk assessment, a process involving three questions was developed: 1) Is the animal mode of action known? 2) Are the key events qualitatively applicable to humans? 3) Are the key events quantitatively applicable to humans? To conduct this exercise, the frameworks developed by the IPCS and EPA were used as the initial basis for evaluation. It was soon noted that these frameworks provided adequate guidance for answering the first question, but relatively little for answering the other two questions. It became necessary to modify the existing frameworks to incorporate guidance for reaching conclusions about the applicability of the tumor type and its MOA to human cancer assessment. As part of this process, the specific key events in the animal mode of action were identified, and the concordance between these key events in the animal model and in humans were explicitly evaluated. Human data could be chemical-specific or related to what is known about mode of action based on information with other chemicals or the biology of the process. If there was concordance qualitatively for each of the key events, they were then evaluated on a quantitative basis, taking into account toxicokinetic and toxicodynamic parameters, physiologic processes, and relative sensitivities in the animal and human. Case studies involving seven chemicals with known information regarding mode of action in animals were used in an iterative process to develop an approach for incorporating mode of action into the risk assessment process. Case studies were acrylonitrile, d-limonene, atrazine, melamine, chloroform, phenobarbital, ethylene oxide and DEHP.

826 THE MODE(S) OF ACTION FOR PPARα AGONIST-INDUCED RODENT TUMORS.

R. Roberts. *Aventis Pharmacology, Paris, France.*

Peroxisome proliferators are rodent nongenotoxic carcinogens. The mode of action for liver tumors is *via* activation of the peroxisome proliferator activated receptor α (PPARα) which regulates gene transcription leading to perturbations in cell proliferation, apoptosis and peroxisome proliferation (PP). Suppression of apoptosis coupled with cell proliferation allows DNA damaged cells to persist and proliferate giving rise to pre-neoplastic foci and ultimately to tumors *via* further clonal expansion. PPARα ligands also may cause oxidative stress, inhibit GJIC and stimulate non-parenchymal hepatic Kupffer cells; these effects could contribute to the MOA *via* several routes such as induction of cell proliferation or oxidative DNA damage. Several PPARα ligands also have been shown to induce Leydig cell tumors (LCTs) and/or pancreatic acinar cell tumors (PACTs) in rats. PPARα agonists do not induce peroxisomes in either tissue, and hence, may induce these extrahepatic tumors *via* different mechanisms. LCTs may be secondary to the changes in liver function associated with exposure to PPARα agonists since these substances induce liver aromatase and may thus alter levels of circulating hormones. Alternatively, LCTs could arise from direct inhibition of testosterone biosynthesis within the testis. For PACTs, data suggest that PPARα ligands decrease bile acid flow, a phenomenon associated with choleostasis and tumorigenesis in PACs. For both LCTs and PACTs, activation of PPARα and subsequent changes in target gene expression may play a role, but this remains to be determined. Based on an evaluation of the published literature, we propose a number of key steps in PPARα-mediated rodent liver, Leydig cell or pancreatic acinar cell tumorigenesis. We propose for each key step an evaluation of causality (role of the event in the tumors), strength (strength of the evidence for or against) and specificity (a specific response to PPARα ligands or ubiquitous?). This reductive approach to evaluating rodent MOA(s) facilitates the evaluation of the relevance of each MOA to humans and provides guidance on the required data elements.

827 APPLICATION OF THE FRAMEWORK TO THE PPARα AGONIST CASE EXAMPLE.

J. E. Klaunig. *Indiana University School of Medicine, Indianapolis, IN.*

An update and summarization of our understanding of the mode(s) of action by which PPARα agonists (peroxisome proliferators) induce liver, Leydig cell and pancreatic acinar cell tumors in rodents has recently been conducted. This information is necessary for a scientifically based assessment of the carcinogenic potential of this group of agents in humans. The determination of the rodent tumor mode of action for PPARα agonists is not sufficient by itself for reaching a conclusion about whether or not these modes of action are applicable for use in human cancer risk assessment. Two additional questions must be addressed: 1) Are the key events of the mode of action qualitatively applicable to humans? and 2) Are the key events quantitatively applicable to humans? This presentation will describe the application of the proposed Human Relevance Framework to the experimentally supported mode(s) of action for selected PPARα agonists that have been shown to induce hepatocyte peroxisome proliferation as well as hepatic, Leydig and/or pancreatic acinar cell tumors in rodents following long-term administration. A comparative analysis will show whether or not the data for each of four case study chemicals (clofibrate, DEHP, oxadiazon, PFOA) are sufficient to support the characterization of the MOA(s) for each tumor type as being that/those hypothesized for PPARα agonists. For those substances that satisfy the criterion of sufficiency, additional analysis will be presented to demonstrate how the conclusions were reached with regard to the qualitative and quantitative applicability of these data to the human and the relevance of this information for human cancer risk assessment.

828 EVIDENCE FOR EGFR PATHWAY MEDIATION OF CLEFT PALATE INDUCTION BY TCDD.

B. D. Abbott, A. R. Buckalew and K. E. Leffler. *RTD, NHEERL, ORD, USEPA, Research Triangle Park, NC.*

2, 3, 7, 8-Tetrachlorodibenzo-p-dioxin (TCDD) is teratogenic in C57BL/6J mice, producing cleft palate (CP) after exposure *in utero*. Epidermal growth factor receptor (EGFR), EGF and TGF-alpha (TGF) expression in the palate is disrupted by TCDD affecting proliferation and differentiation. The key role of EGF in mediating the teratogenicity was confirmed using EGF knockout (KO) mice. The EGF KO embryos were less responsive for the induction of cleft palate than the wild type mice (WT=C57BL/6J x 129). However, exposure of TGF KO mice (having C57BL/6J background) produced incidences of CP that were similar to that observed in C57BL/6J wild type mice. In this study, the pivotal role of EGF in the response to TCDD was confirmed using palatal organ culture. Embryonic mouse palates from C57BL/6J, TGF KO, WT and EGF KO mice were placed in organ culture on gestation day (GD) 12 and cultured with or without TCDD ($1x10^{-8}$ M) in presence or absence of growth factor supplements (2 ng/ml EGF or TGF). After 5 days in culture, the effects of the treatments on palatal fusion were evaluated. The palates from all of the genotypes fused in the serum-free, defined control medium. Similar to the *in vivo* response, EGF KO palates exposed to TCDD fused and the rate of fusion did not differ from the control cultures. EGF KO palates exposed to TCDD in presence of EGF (2ng/ml) failed to fuse ($p<0.05$ vs control medium or TCDD without EGF). The responses of TGF KO palates differed as only TGF supplementation significantly reduced fusion rates in the presence of TCDD. Our lab and others have reported a requirement for serum for many cell types to respond to TCDD in culture. The present study demonstrates that addition of EGF or TGF alone can be sufficient to mediate responses to TCDD. The palatal culture model also confirms that providing EGF to the palates of EGF KO mice restores the responsiveness to TCDD. These studies support the hypothesis that the mechanism for induction of CP by TCDD is mediated *via* the EGFR pathway. Disclaimer: This abstract does not necessarily reflect EPA policy.

829 DIVERSE NON-SPECIFIC MATERNAL IMMUNE ACTIVATION PROCEDURES REDUCE SEVERITY OF DIABETIC EMBRYOPATHY IN MICE.

K. Punareewattana[1], S. D. Holladay[1] and L. Sharova[1]. *[1]Veterinary Medicine, Virginia Tech, Blacksburg, VA and [2]Veterinary Medicine, Virginia Tech, Blacksburg, VA.*

Diabetic embryopathy is a complication occurring in pregnant women with type-1 or insulin-dependent diabetes mellitus. Several biochemical pathways have been proposed for its pathogenesis, including myo-inositol and prostaglandin deficiencies and free radical toxicity. In the present study, we hypothesized that the local immune response in the uterus may be disrupted by diabetes, which may play a role in producing teratogenic results. Maternal immune stimulation prevents or reduces

diabetes-induced dysmorphogenesis, possibly through normalizing of the uterine cytokine production and secretory profile. Streptozocin (STZ)-induced diabetic mice were used to produce malformed fetuses. Tree techniques of immune stimulation, complete Freunds adjuvant (CFA), granulocyte-macrophage colony stimulating factor (GM-CSF), and interferon-g (IFNg) were used to stimulate immune cells of pregnant ICR mice. Approximately 50% of live fetuses from diabetic mice were malformed with neural tube defects. Immune stimulated diabetic mice produced significantly lower numbers of malformed fetuses: CFA 19.6%; GM-CSF 22.1%, IFNg 15.0%. These results suggest that diverse procedures to activate nonspecific maternal immune cells cause, for unknown reasons, approximately equal suppression of the dysmorphogenic effects of diabetes mellitus.

830 PERINATAL EXPOSURE TO THE PESTICIDE HEPTACHLOR PRODUCES ALTERATIONS IN IMMUNE FUNCTION PARAMETERS IN SPRAGUE-DAWLEY RATS.

R. A. Matulka[1], A. A. Rooney[3], W. Williams[2], C. B. Copeland[2] and R. J. Smialowicz[2]. *[1]Curriculum in Toxicology, UNC, Research Triangle Park, NC, [2]ITB, ETD, NHEERL, USEPA, Research Triangle Park, NC and [3]CVM, Anatomy, Physiological Sciences and Radiology, NCSU, Raleigh, NC.*

Pesticides, and other environmental contaminants, recently have been implicated as potential causes of recent increases in childhood asthma and leukemia. The objective of this study was to determine the effect that the pesticide heptachlor (H) has on the developing immune system of Sprague-Dawley rats. Dams were dosed from gestational day 6 (GD6) through post-natal day 21 (PND21), at which time the pups were weaned and dosed directly with H until PND42. The doses of H were 0 (control), 0.03, 0.1, 0.3, 1.0 and 3.0 mg/kg/day. Rats were tested for the delayed type hypersensitivity (DTH) response to bovine serum albumin (BSA), the phagocytic ability of peritoneal macrophages, and the IgM and IgG antibody responses to sheep red blood cells (SRBC). H did not affect the DTH response in eight week-old male rats, while the females at eight weeks showed a dose-related increase in the DTH responses from control to 3.0 mg H/kg/day. The phagocytic ability of peritoneal macrophages from 12 week-old rats was suppressed at the lowest dose of H, with higher doses not significantly different from controls. Primary (IgM) antibody responses were significantly suppressed in a dose-dependent manner in eight week old rats treated with H (i.e., a mean $\log_2$ titer of 9.0 in controls versus 7.5 in 3.0 mg H/kg/day dose group). Rats re-immunized with SRBC and evaluated for IgG titers revealed a dose-dependent effect, with control rats at a mean $\log_2$ titer of 11.3 and the high dose group at a mean log2 titer of 8.1. These results support and extend our earlier work with H, indicating suppression of the primary and secondary response to SRBC following perinatal exposure to H is consistently observed. (This abstract does not reflect EPA policy. Supported in part by the American Chemistry Council under CRADA 0215-02.)

831 MATERNAL IMMUNE STIMULATION REDUCES BOTH PLACENTAL MORPHOLOGIC DAMAGE AND DOWN-REGULATED PLACENTAL GROWTH-FACTOR AND CELL CYCLE GENE EXPRESSION CAUSED BY URETHANE: ARE THESE EVENTS RELATED TO REDUCED TERATOGENESIS?

S. D. Holladay, L. Sharova, A. Sharov, P. Sura, R. M. Gogal and B. J. Smith. *Veterinary Medicine, Virginia Tech, Blacksburg, VA.*

Activation of the maternal immune system in mice decreased cleft palate caused by the chemical teratogen, urethane. Direct and indirect mechanisms for this phenomenon have been suggested, including maternal macrophages that cross the placenta to find and eliminate pre-teratogenic cells, or maternal immune proteins (cytokines) that cross placenta to alleviate or partially alleviate toxicant-mediated effects in the developing fetus. A third mechanism to explain improved fetal developmental outcome in teratogen-challenged pregnant mice might involve beneficial effects of immune stimulation on the placenta. In the present experiments, urethane treatment altered placental morphology and impaired placental function, the latter indicated by down-regulated activity of cell cycle genes and of genes encoding cytokines and growth factors. Maternal immune stimulation with either Freund's Complete Adjuvant (FCA) or interferon-gamma (IFNg) reduced morphologic damage to the placenta caused by urethane, and normalized expression of several genes that were down-regulated by urethane. Urethane treatment also shifted placental cytokine gene expression toward a T cell helper 1 (Th1) profile, while immunostimulation tended to restore a Th2 profile that may be more beneficial to pregnancy and fetal development. These data suggest that the beneficial effects of maternal immune stimulation on fetal development in teratogen-exposed mice may, in part, result from improved placental structure and function.

832 FUMONISIN-INDUCED NEURAL TUBE DEFECTS: DISRUPTION OF SPHINGOLIPIDS AND FOLATE TRANSPORT.

J. B. Gelineau-van Waes[1], R. Riley[2], K. Voss[2], J. Maddox[1], G. Bennett[1] and L. Starr[1]. *[1]Department of Genetics, Cell Biology & Anatomy, University of Nebraska Medical Center, Omaha, NE and [2]Toxicology & Mycotoxin Research Unit, Russell Research Center, USDA-ARS, Athens, GA.*

Fumonisin B1 (FB1), a mycotoxin produced by F. verticillioides, is a contaminant of corn involved in the etiology of various diseases in different species. FB1 disrupts sphingolipid biosynthesis by inhibiting the enzyme ceramide synthase, and has recently been implicated as a potential teratogen. Using a murine model, the current study investigates maternal FB1 exposure, sphingolipid alterations, and subsequent disruption of folate transport systems in the induction of neural tube defects (NTDs). FB1 exposure during early gestation caused an increase in apoptosis in the dorsal neuroepithelium and subsequent NTDs (exencephaly) in inbred LMBc mice. The timing of maternal FB1 exposure was critical, and the number of affected pups/litter increased in a dose-dependent manner. The ability of FB1 to cross the placenta was demonstrated by injecting pregnant dams with 14C-labeled FB1 and measuring radioactive uptake in embryos and maternal tissues. In addition, sphinganine levels were shown by HPLC analysis to be significantly elevated in both embryos and placentas following FB1 exposure. Maternal folinic acid supplementation by daily oral gavage reduced the incidence of FB1-induced NTDs by approximately 50%. However, co-administration of ganglioside GM1 during FB1 exposure was able to almost completely rescue the phenotype (95%). The impact of FB1 on folate transport was investigated *in vivo* by measuring 3H-folate uptake in control and FB1 embryos. 3H-folate uptake was significantly inhibited by FB1 exposure, but partially reversed by GM1 co-administration. Immunohistochemical staining for both the folate receptor and GM1 was decreased following FB1 exposure. Since GM1 is co-localized with the GPI-anchored folate receptor in lipid rafts, it is proposed that GM1 is an important component of the membrane microdomain necessary for proper folate receptor function, and adequate uptake of folate during development to protect against NTDs.

833 MICROARRAY ANALYSIS OF STRAIN-SPECIFIC RESPONSES TO ETHANOL.

K. Rozett Nemeth, J. H. Charlap and T. B. Knudsen. *Anatomy, Pathology and Cell Biology, Thomas Jefferson University, Philadelphia, PA.*

The striking parallelism possible with cDNA microarray analysis allows functional relationships in the genomic response to ethanol to be uncovered. Ethanol is a human teratogen that can act early in development to cause Fetal Alcohol Syndrome (FAS). In addition to craniofacial abnormalities and neurological deficiencies, FAS-like symptoms can include effects to the developing eye (microphthalmia and optic nerve hypoplasia). Whereas CD-1 mice are relatively less sensitive to the teratogenic effects of ethanol, C57BL/6 mice are susceptible. Strain differences imply a genetic basis to ethanol-related birth defects; therefore, the availability of a mouse model that exhibits differential susceptibility to acute ethanol exposure makes possible studies to elucidate the mechanism(s) related to these outcomes that are currently undefined. Pregnant mice were dosed with 2.9g/kg ethanol i.p. on gestation day 8. Embryonic headfold collected 3h post-exposure provided a source of RNA for microarray analysis. After checking QA/QC standards, the RNA from treated (ethanol) and control (vehicle) samples was labeled for competitive hybridization to MPS621 microchips followed by tyramide signal amplification and two-color fluorescent labeling (PerkinElmer Life Sciences). Data analysis used GeneSpring v 4.2 (Silicon Genetics). Genes were filtered for a 1.5-fold change and a consistent response between replicate arrays. Hierarchical clustering of the 383 genes (17% of those arrayed) meeting these criteria revealed distinct differences between the strains. Genes (240) related to transcription, stress response, and mitochondrial processes were found to change in C57BL/6 embryos whereas only 10% of these genes changed in CD-1 embryos, about half of them coding ribosomal proteins. Genes (121) related to chromosomal structure (HMG Y/1), protein synthesis, and cytoskeletal structure were found to change in CD-1 embryos. Organizing responsive genes into larger clusters should provide clues to mechanisms of differential susceptibility. (Supported by NIH grants AA13205 and ES07282)

834 THE PRESENCE OF XENOBIOTIC TRANSPORTERS IN RAT PLACENTA.

T. M. Leazer and C. D. Klaassen. *Pharmacology, Toxicology and Therapeutics, University of Kansas Medical Center, Kansas City, KS.*

Understanding the role of various transporters in placental handling of xenobiotics across the maternal-fetal interface is essential to evaluate the pharmacological and toxicological potential of therapeutic agents, drugs of abuse and other xenobiotics

to which the mother is exposed during pregnancy. Therefore, the purpose of this study was to assess mRNA levels of various transporters in placenta and to compare these to levels in maternal liver and kidney, the predominant organs of excretion, in an attempt to determine which transporters are most likely to have a role in xenobiotic transfer within the placenta. During late stage pregnancy, relative mRNA levels of three transporters of the multidrug resistance family (Mdr), six members of the multidrug resistance-associated protein family (Mrp), eight members of the organic anion transporting polypeptide family (Oatp), three members of the organic anion transporter family (Oat), five members of the organic cation transporter family (Oct), two bile acid transporters (Na+/taurocholate cotransporting polypeptide [Ntcp] and bile salt excretory protein [Bsep]), as well as four metal (ZnT1, DMT1, Menkes and Wilsons), a prostaglandin, two peptide, two sterolin, and four nucleoside transporters were assessed in placenta with respect to corresponding maternal liver and kidney mRNA levels. Of the 40 genes evaluated, the mRNA of 16 genes (Mdr1a and 1b, Mrp1 and 5, Oct3 and N1, Oatp3 and Oatp12, four metal, the prostaglandin, one sterolin [Abcg8], and two nucleoside transporters [ENT1 and ENT2]) was present in placenta at levels similar to or higher than those observed in maternal liver and kidney. The abundance of these transcripts in placenta suggests a role for these transporters in placental transport of xenobiotics. These data may further aid in the prediction of maternally-mediated developmental toxicities resulting from xenobiotic exposures. (Supported by NIH grants ES-03192, ES-09716, and ES-09649 and Training Grant ES-07079)

835 AN EMBRYO-FETAL DEVELOPMENT STUDY IN CYNOMOLGUS MONKEYS WITH RITUXIMAB, AN ANTI-CD20 ANTIBODY.

K. P. McKeever[1], J. Beyer[1], S. Ortega[2], D. Combs[3] and H. Tsusaki[4]. *[1]Safety Assessment, Genentech, Inc., San Francisco, CA, [2]Development Sciences Operations, Genentech, Inc., San Francisco, CA, [3]Clinical and Experimental Pharmacology, Genentech, Inc., San Francisco, CA and [4]Drug Safety Research Laboratories, SNBL, Kagoshima, Japan.*

Rituximab (Rituxan, Genentech, SSF, IDEC, San Diego) is approved by the USFDA for the treatment of CD20+, B-cell non-Hodgkin's lymphoma (NHL). This chimeric anti-CD20 antibody is being evaluated in non-oncologic indications, including immune thrombocytopenia purpura (ITP) and rheumatoid arthritis (RA). Although rituximab has been used to treat over 200, 000 oncology patients, it was not previously investigated for effects on reproduction. A study to investigate rituximab's effect on embryo-fetal development was undertaken. Forty-eight cynomolgus monkeys were divided into 4 groups (12/group). Rituximab was administered (IV) 1X/week during organogenesis (gestation days, GDs, 20-50). In order to provide consistent exposure during this period, loading doses were administered on GDs 20, 21 and 22. Rituximab was administered at doses of 0, 20, 50 and 100 mg/kg (loading doses were 0, 15, 37.5 and 75, respectively). Animals were monitored for clinical signs, pregnancy by ultrasound, body weight, food consumption, hematology, serum biochemistry, anti-drug antibody, and PK. Upon cesarean section at GD 100, fetal examinations included an external exam (viability, sex, body weight and placental weight), a visceral exam (gross observations of organs and tissues, with subsequent immunohistochemistry of spleen and lymph nodes), and a skeletal exam. There were 5 spontaneous abortions during the study; however, this is within the historical control data (10%) and does not appear to be treatment related. There were no effects of rituximab on any of the parameters measured, other than the expected pharmacologic effect of B-cell depletion. In addition, there were no unusual findings in the fetal examinations. Therefore, rituximab administration appears to have no adverse effect on embryo-fetal development in cynomolgus monkeys.

836 AMBIENT OXYGEN REGULATES INTRACELLULAR REDOX POTENTIAL AND TRANSCRIPTION FACTOR ACTIVITY IN CULTURE PRIMARY HUMAN MYOBLASTS.

J. M. Hansen[1], C. Harris[2] and M. Csete[1]. *[1]Anesthesiology, Emory University, Atlanta, GA and [2]Environmental Health Sciences, University of Michigan, Ann Arbor, MI.*

Muscle satellite cells are mononucleate stem cells that generate muscle or fat in an O2-dependent manner: High O2 (20%) in culture favors adipogenesis and low O2 (6%) promotes myogenesis. The free radical trap PBN reduces adipocyte differentiation by 50% in satellite cells cultured in 20% O2, suggesting that ROS produced as a function of environmental O2 concentrations play a pivotal role in the regulation of specific pathways in cultured mesenchymal-derived stem cells. Human skeletal myoblasts (hSKM) were loaded with a ROS indicator, DCF, and cultured in either 6% or 20% O2 for 24 hr. DCF fluorescence was significantly reduced in 6% O2, 40% less than at 20% O2. Intracellular redox potentials were calculated from GSH and GSSG concentrations, (determined by HPLC) following culture at either 6% or 20% O2 for 7 days. At 20% O2, hSKM GSH concentrations were 27% lower and GSSG concentrations were 6-fold higher, yielding a significant redox difference of +30 mV in 20% vs. 6% O2. Nuclear GSH was 78% lower in 20% O2 cultures as compared to 6% O2, suggesting that the nuclear environment is more oxidative than the cytosol. It is believed that +/-15 mV shift can modulate redox-sensitive transcription factors. Electromobility shift assays showed enhanced activity in the pro-adipogenic transcription factors C/EBP, CREB and RXR at 20% O2. These findings support environment-induced ROS increases and intracellular redox potential as key factors in regulatory pathways of both myogenic and adipogenic differentiation.

837 EXPRESSION OF MHC CASS II PROTEINS ON SPLENOCYTES AS A BIOMARKER FOR MODELING AND PREDICTING THE EFFECTS OF CHEMICAL STRESSORS.

S. B. Pruett, R. Fan and Q. Zheng. *Cell. Biol. & Anatomy, LSU Health Sciences. Center, Shreveport, LA.*

Previous studies have shown that the area under the corticosterone concentration vs. time curve (AUC) can be used as a quantitative measure of a chemical-induced stress response, allowing prediction of the effects of propanil on selected immunological parameters. The present study was designed to extend these findings using two additional chemical stressors (atrazine and ethanol) and to determine if a single immunological end point might serve as a predictive biomarker for chemical stressors. Ethanol (4, 5, 6, or 7 g/kg by gavage) and atrazine (100, 200, or 300 mg/kg i.p. in corn oil) increased serum corticosterone levels in female B6C3F1 mice 1-8 hr after dosing. Values for the corticosterone AUC were dose-responsive, and these values were related in a linear manner to changes in several immunological parameters including: splenic NK cell activity, IgG1 and IgG2a responses to keyhole limpet hemocyanin (KLH), spleen and thymus cellularity, B and T cell subpopulations in the spleen, CD4 and CD8-definsed subpopulations in the thymus, and expression of MHC class II proteins on splenocytes. Comparison of these results with previous results using exogenous corticosterone and restraint stress indicate that most of the linear models were more similar to those derived from restrained mice. As expected, there were a few immunological parameters (e.g., NK cell activity in ethanol-treated mice) that were affected more than predicted by stress models, suggesting chemical-specific immunotoxicity independent of the stress response. Finally, using the restraint models for each of these parameters and the chemical dosage at which 50% inhibition of MHC class II expression occurred, it was possible to accurately predict the quantitative change in almost all the other immunological parameters. This and other considerations suggest that MHC class II expression on splenocytes may be a useful biomarker and for chemical-induced stress and predictor or other immunological effects of this stress. This work was supported by a grant from NIEHS (ES09158).

838 MODELING AND PREDICTING IMMUNOSUPPRESSION BY CHEMICAL STRESSORS IN MICE USING BLOOD PARAMETERS.

C. Schwab, Q. Zheng, R. Fan, P. Hébert, P. Myers, L. Smart and S. B. Pruett. *Cell. Biol. & Anatomy, LSU Health Sciences. Center, Shreveport, LA.*

Previous studies have shown that the area under the corticosterone concentration vs. time curve (AUC) can be used to model and predict the effects of restraint stress and chemical stressors on a variety of immunological parameters in the mouse spleen and thymus. However, if this approach is to be used to complete a risk assessment parallelogram, similar data are needed with blood as the source of immune system cells, because this is the only tissue routinely available from human subjects. Therefore, studies were conducted using treatments for which the corticosterone AUC values are already known: Exogenous corticosterone, restraint, propanil, atrazine, and ethanol. The following immunological parameters were measured using peripheral blood from mice treated with a series of dosages of each of these agents: flow cytometry was used to quantify MHC II, B220, CD4, and CD8 cells, and leukocyte counts and differential counts were done. Cytokine (IL-2, IL-4, and IFN-g) production by isolated peripheral blood mononuclear cells was also measured. Spleen cell number and NK cell activity were evaluated (using a standard 4 hr 51Cr-relase assay with YAC-1 target cells) to confirm similarity to previous studies. Immune parameter data from mouse blood indicate that MHC II expression has consistent quantitative relationships to corticosterone AUC values, similar to those in the spleen. However other the immune parameters tended to have greater variability in the blood than observed in the spleen. The pattern observed in the spleen in which the chemical stressors generally produced very similar effects as noted for restraint stress (at the same corticosterone AUC values) was not observed using blood. Nevertheless, MHC class II expression seems to provide a consistent indication of stress exposure, regardless of the source of cells. The completed analysis of these two corners of a parallelogram has brought this predictive model one step closer to completion. This work was supported by a grant from NIEHS (R01 ES09158).

839 ETHANOL SUPPRESSES SIGNALING THROUGH TOLL-LIKE RECEPTOR 3 (TLR 3).

Q. Zheng, R. Fan and S. B. Pruett. *Cell. Biol. & Anatomy, LSU Health Sciences. Center, Shreveport, LA.*

Acute and chronic exposure to ethanol (EtOH) can be immunosuppressive, and cytokine responses to LPS, which acts through TLR 4, are suppressed by EtOH. However, it is not clear if suppression of signaling through other TLRs occurs or what components of the signaling pathways are affected. The purpose of the present study was to investigate these questions. Mice were treated with polyinosinic-polycytidylic acid (poly I:C), which induces cytokine production by acting on TLR 3, primarily on dendritic cells and macrophages. Some groups of mice were also treated by EtOH (6 g/kg) using our binge drinking model. The results indicate that EtOH profoundly suppresses poly I:C-induced cytokine production and accumulation of neutrophils in the peritoneal cavity (the site of poly I:C injection). This was associated with decreased activation of NF-kappa B in peritoneal macrophages (a late event in TLR signaling) and with decreased degradation of IRAK-1 in these same cells (an early event in TLR signaling). The results strongly suggest that EtOH acts to inhibit signaling through TLR 3 by acting at an early step in the signaling pathway. Further studies are needed to determine if decreased activation of NF-kappa B constitutes an additional effect of EtOH or is simply a consequence of inhibition of early steps in the TLR signaling pathway. To determine if IL-10 induced by poly I:C plus EtOH contributes to suppression of signaling, spleen cells from IL-10 knockout mice were stimulated *in vitro* with poly I:C or poly I:C plus EtOH (0.5% w/v). Similar experiments using normal mice indicated that EtOH significantly suppresess poly I:C-induced IL-12 production. In contrast, EtOH significantly enhanced IL-12 when splenocytes from IL-10 knockout mice were used. This suggests a possible role for IL-10 in suppression of poly I:C-induced signaling that leads to IL-12 production. This work was supported by a grant from NIAAA (R01 AA09505).

840 ETHANOL SUPPRESSES CYTOKINE PRODUCTION INDUCED BY LIGANDS FOR TOLL-LIKE RECEPTOR (TLR) 9 AND TLR 6.

K. Matthews, P. Thompson and S. B. Pruett. *Cell. Biol. & Anatomy, LSU Health Sciences. Center, Shreveport, LA.*

Oligodeoxynucleotides containing unmethylated CpG dinucleotides stimulate cells of the innate immune system, in part by inducing the production of several cytokines. Yeast polysaccharides such as zymosan also induce cytokine production, and both of these agents act through TLRs. Considering the prevalence of binge drinking and alcoholism, it seems appropriate to test the effects of ethanol (EtOH) on CpG DNA- and zymosan-induced cytokine production. The effect of acute EtOH exposure on the induction of IL-12 by CpG DNA was evaluated by ELISA. B6C3F1 mice were treated intraperitoneally with CpG DNA (40 μg/mouse) and given EtOH (6 g/kg by gavage in a 32% solution in water) at the same time. CpG DNA significantly increased IL-12 cytokine production *in vivo* compared to untreated mice, and EtOH significantly suppressed this increase (measured in the serum 2 hr after dosing). We also examined CpG DNA at lower dosages of 20 μg/mouse and 10 μg/mouse *in vivo* and observed dose-dependent production of IL-12, with near peak levels at 20 μg/ml. This indicates 20 μg/ml would be an appropriate dosage for future studies. Zymosan (5 mg/mouse, i.p.) induced the production of IL-12 (measured in serum 3 hr after dosing). Administration of EtOH (6 g/kg) at the same time as zymosan significantly decreased IL-12 production and significantly increased the production of the immunosuppressive cytokine IL-10. Previous studies by this and other laboratories indicate that EtOH suppresses cytokine production stimulated through TLR 3 and 4. The ligands examined here signal through TLR 9 (CpG DNA) and TLR 2/6 (zymosan). This strongly suggests that EtOH is a general inhibitor of TLRs. If confirmed in additional studies, this finding would have important implications as a mechanism for the well-characterized immunosuppressive effects of EtOH. This work was supported by a grant from NIAAA (R01 AA09505).

841 SUPPRESSION OF INFLAMMATORY CYTOKINE PRODUCTION BY CIGARETTE SMOKE IS MEDIATED BY ACROLEIN.

B. M. Freed[3], Y. Ouyang[3], T. G. Rosano[2], J. McCue[3], J. Zheng[1], Y. Yang[1], D. W. Pyatt[1], S. Lazis[3] and R. D. Irons[1]. *[1]Medicine, University Colorado Health Sciences Center, Denver, CO, [2]Pharmaceutical Sciences, University Colorado Health Sciences Center, Denver, CO and [3]Pathology and Laboratory Medicine, Albany Medical Center, Albany, NY.*

While cigarette smoking is known to inhibit T and B lymphocyte response in the lungs, little is known about the nature of the immunosuppressive compounds in cigarette smoke. We have found that pretreatment of human peripheral blood mononuclear cells with cigarette smoke extracts derived from a single high-tar (unfiltered *Camel*) or low-tar (*Carlton*) cigarette suppressed anti-CD3/PMA-stimulated IL-1β, IL 2, IFN-γ, and TNF-α production by >90%. The inhibitory effect of the cigarette smoke extract did not require direct contact with the cells. Rather, the effect carried over in the vapor phase to untreated cells in neighboring wells. Cells closest to the extracts exhibited >95% suppression of cytokine production, while cells further away on the plate exhibited progressively less inhibition. Using gas chromatography/mass spectrometry, we identified several aldehydes (acetaldehyde, acrolein, and propionaldehyde) and other volatile compounds (toluene, xylene, styrene, and limonene) in the vapor phase of the cigarette smoke extracts. Among these compounds, only the thiol-reactive acrolein exhibited significant inhibition of cytokine production. The effect of acrolein could be mimicked by another α, β-unsaturated aldehyde, crotonaldehyde, but not by the saturated acetaldehyde, butyraldehyde or propionaldehyde. Cigarette smoke extracts and acrolein blocked induction NF-κB and AP-1 DNA binding activity without affecting expression of p65, p50, Fos and Jun proteins. Finally, acrolein directly inhibited the binding of preformed NF-κ and AP-1 to their respective promoters, suggesting that it alkylates critical thiols in their DNA binding domains. All of these effects could be completely prevented by treating the cells or the extracts with the thiol protectant, N-acetylcysteine.

842 PARTICLE SIZE AND COMBINATION WITH ANTIGEN ARE IMPORTANT IN MACROPHAGE ACTIVATION BY PARTICULATE MATTER.

C. de Haar, D. Huttenhuis, I. Hassing, R. Bleumink and R. Pieters. *Immunotoxicology, IRAS, Utrecht, Utrecht, Netherlands.*

Various epidemiological and animal studies have shown a correlation between exposure to airborne particulate matter (APM) and airway hypersensitivity. Recently, we have shown that intranasal exposure of mice to carbon black (CB) as a model substance for APM enhanced the immune response to a co-exposed antigen (ovalbumin or OVA). Subsequent studies by others and us have indicated that alveolar macrophages might be important in these particle-induced adjuvant effects. In addition it became evident that certain particle characteristics, in particular charge and size, are crucial for the effect. Therefore, we have tested the effects of different model particles (CB, titanium dioxide (TiO2), polystyrene particles (PSP) of different sizes, and silica oxide (SiO2) on two different murine macrophage cell lines, the RAW 267.4 (monocyte/macrophage) and MH-S (alveolar macrophage). Effects of particles alone were compared with those of the antigen OVA or a combination of both. All particles were phagocytized, and most particles induced pro-inflammatory cytokines (TNF-a and IL-1b), and NO by the macrophages. SiO2 induced very high levels of TNF-a but was also the most toxic of all particles used. CB and TiO2 (1-200ug/ml) induced TNF-a release only at the highest concentrations. Using PSP of different size made it possible to determine the importance of particle size and surface area for the effects on macrophages. Whereas no difference in phagocytosis was observed, there is a correlation between total surface area and TNF-a release. Although exposure to OVA induced the release of both TNF-a and high levels of NO, the combined exposure to CB particles and antigen was even more effective. Results indicate that particulate matter, OVA and the combination of both have a stimulatory effect on macrophages. This effect depends on certain particle characteristics. Together, these data support the idea that macrophages may provide adjuvant-help to antigen-specific immune responses in the airways.

843 NEUROTOXICITY AND IMMUNOTOXICITY ASSESSMENT IN CBA/J MICE WITH CHRONIC *TOXOPLASMA GONDII* INFECTION AND MULTIPLE LOW DOSE EXPOSURES TO METHYLMERCURY.

M. D. King[2], D. S. Lindsay[1], S. D. Holladay[1] and M. Ehrich[1]. *[1]Virginia-Maryland Regional College of Veterinary Medicine, Virginia Tech, Blacksburg, VA and [2]USEPA, Washington, DC.*

The present study was conducted to determine the effect of multiple low doses of methylmercury (MeHg) on the course of a chronic Toxoplasma gondii infection. Four groups of six-week-old, female CBA/J mice were either fed 25 T. gondii tissue cysts of the ME-49 strain or vehicle control. Six weeks later, half of each group were orally gavaged with 8-mg/kg body weight doses of MeHg on days 0, 2, 4, 7, 10, 13. Mice were sacrificed on day 17 or 18 post MeHg exposure. Flow cytometric analysis of lymphocyte subpopulations in the thymus demonstrated a significant increase in the percentage of CD4-8+ T-cells in mice exposed to MeHg with a concurrent T. gondii infection. Groups of mice exposed to MeHg showed a decrease in total thymic cellularity and cellularity of all T-cell subpopulations when compared to control mice, but viability of these cells was unaffected. Splenic cell viability was decreased in mice exposed to MeHg, but alterations in T-cell subpopulations were not noted. These data indicate that multiple low doses of MeHg may not exacerbate

chronic toxoplasmosis but MeHg-induced effects on the immune system were evident. (The views expressed in this abstract are those of the authors and do not necessarily reflect the views and policies of the US Environmental Protection Agency.)

844 THE ROLE OF METABOLISM IN BENZO(*A*)PYRENE-INDUCED IMMUNOSUPPRESSION IN A FISH MODEL.

E. Carlson, Y. Li and J. T. Zelikoff. *Environmental Medicine, New York University School of Medicine, Tuxedo, NY.*

Benzo(a)pyrene (BaP) is a ubiquitous aquatic contaminant and mammalian immunosuppressant. Using Japanese medaka (*Oryzias latipes*) as the animal model, studies in this laboratory demonstrated that *in vivo* exposure to BaP (2 - 200 μ g/g BW) suppresses both innate and humoral-mediated immunity. Further studies examining the molecular mechanism(s) by which the observed effects on immune function may have occurred demonstrated that BaP activates biotransformation pathways both in the intact animal and within immune cells. Amelioration of BaP metabolism either by blocking CYP1A protein induction with the aryl hydrocarbon receptor (AhR) agonist alpha-napthaflavone or inhibiting CYP1A enzyme activity with ellipticine, resulted in the diminution of BaP-induced suppression of antibody production. In addition, IP injection of fish with the structurally-related weak AhR agonist, benzo(e)pyrene had no effect on immune function (compared to vehicle-treated control). To determine what role, if any, BaP metabolites may have played in the observed immunosuppression, non-adherent and adherent immune cells were treated *in vitro* with either BaP, benzo(a)pyrene-7, 8-dihydrodiol (BD), or benzo(a)pyrene-7, 8-dihydrodiol-9, 10-epoxide (BPDE). Although co-incubation of immune cells with CYP1A inhibitors alleviated the immunotoxicity of BaP and BD, BPDE-induced immunosuppression was unaffected. This suggests that BPDE represents the ultimate immunotoxicant in fish as appears to be true for mammals. Results of this study not only demonstrate that BaP-induced immunosuppression in fish proceeds *via* the AhR, but that CYP1A-mediated metabolism of BaP into its toxic metabolites is also necessary. These investigations have also revealed a plausible non-mammalian alternate species for assessing the immunotoxicity of PAHs - critical in light of intense social and political pressure for developing alternative animal models for scientific studies. US Army DAMD 60-1-8109/17-99-9011.

845 ALLERGEN-INDUCED GENE CHANGES IN MURINE LYMPH NODE CELLS.

C. J. Betts, R. J. Dearman, N. Ashraf and I. Kimber. *Syngenta CTL, Macclesfield, Cheshire, United Kingdom.*

Prolonged (13 day) topical exposure of BALB/c strain mice to the contact sensitizer 2, 4-dinitochlorobenzene (DNCB), or to the respiratory allergen trimellitic anhydride (TMA) results in the induction of preferential T helper (Th-) 1 and Th2 patterns of cytokine expression, respectively. In order to characterize gene expression changes occurring in the draining lymph node during the early stages of exposure we have employed a transcript profiling (microarray) approach. Groups of female BALB/c strain mice were exposed topically on the dorsum of both ears to 10% TMA or 1% DNCB, concentrations of these chemicals that are of equivalent immunogenicity with respect to lymphocyte activation. Seventy-two hours following initiation of exposure the draining lymph nodes were excised and mRNA isolated using oligo dT beads. Radiolabelled cDNA probes, generated by reverse transcription of sample mRNA in the presence of 33P ATP, were hybridized to nylon microarray filters comprising 588 known murine genes representing cellular mechanisms such as stress response, transcription factors and cell-cell communication including cytokines and associated receptors (Clontech). Differential gene changes were assessed by phosphorimager and ArrayVision software (Molecular Dynamics). Data were normalized for inter-membrane variation and stringent controls for background and duplicate spot variation were applied to exclude false positives. Changes of 1.5 fold or greater were considered significant. In two independent experiments the majority of genes on the array remained unchanged by exposure to chemical allergen. However, 13 genes were consistently up-regulated following exposure to TMA compared with DNCB and a further 7 genes were more highly expressed in DNCB-treated samples. Of the latter group, increased expression of interferon γ receptor (IFNγR) is consistent with the development of a Th1 profile and may play a role in polarization of the immune response.

846 EXAMINATION OF GENE EXPRESSION CHANGES IN PERIPHERAL BLOOD-DERIVED DENDRITIC CELLS FOLLOWING EXPOSURE TO A CONTACT ALLERGEN.

C. Ryan[1], B. C. Hulette[1], R. J. Dearman[2], I. Kimber[2] and F. Gerberick[1]. *[1]Procter & Gamble Company, Cincinnati, OH and [2]Syngenta CTL, Macclesfield, Cheshire, United Kingdom.*

An important step in the induction of allergic contact allergy is the activation and subsequent migration of Langerhans cells, the antigen presenting dendritic cells (DC) of the skin. Therefore, a possible approach for the development on an *in vitro* test for skin sensitization is to examine at the cellular and molecular levels the effects of exposure to contact allergens on DC. DC were generated from the adherent cell fraction of peripheral blood mononuclear cells by culture in the presence of granulocyte/macrophage-colony stimulating factor and interleukin-4 for 7 days. The resulting immature DC were treated with either 1 mM or 5 mM dinitrobenzene sulfonic acid (DNBS), the water soluble analog of the strong contact allergen dinitrochlorobenzene, for 24 hours. Total RNA was obtained and changes in gene expression were analyzed using Affymetrix U95Av2 Genechips®. Pairs plots indicated good correlation between the replicates for the treated and untreated groups. In the principal component (PC) analysis, a treatment related effect was clearly observed for the first PC (the component representing the highest source of variance). Comparison of mean signal values from the replicate cultures revealed 185 genes that were significantly different ($p < 0.001$) between DC treated with 1 mM DNBS versus control DC and 1340 significant gene changes between 5mM DNBS treated DC and untreated DC. It is our aim to utilize data achieved through this approach to develop endpoint measures that can be used as the basis of an *in vitro* approach for the identification of skin sensitizing chemicals.

847 DIVERGENT CYTOKINE RESPONSES ELICITED IN MICE BY PEANUT LECTIN AND PURIFIED PROTEIN DERIVATIVE (PPD).

B. F. Flanagan[2], C. J. Betts[1], H. T. Caddick[1], R. J. Dearman[1] and I. Kimber[1]. *[1]Syngenta CTL, Macclesfield, Cheshire, United Kingdom and [2]Department of Immunology, University of Liverpool, Liverpool, United Kingdom.*

The majority of food allergies are caused by a limited range of produce, including peanuts. Allergic sensitization is associated usually with high titer IgE antibody, consistent with the preferential induction of a T helper (Th) 2 cell population. Using C57BL/6 strain mice, a strain which displays a Th1 type phenotype in response to PPD (a bacterial protein extract that is associated in humans with a selective type 1 response), we have compared cytokine expression profiles induced following exposure to PPD with those provoked by peanut lectin, a minor allergenic constituent of peanuts. Groups (n=15) of mice were immunized with peanut lectin or PPD by intradermal injection on the dorsum of both ears on days 0 and 7. On day 14, the auricular lymph nodes draining the site of exposure were excised and a single cell suspension prepared for culture in the presence of peanut lectin, PPD, the T cell mitogen concanavalin A (con A) or medium alone. Following 24, 72 and 120 hours in culture, supernatants were harvested and total RNA isolated from the cultured cells. Cytokine gene expression was assessed by ribonuclease protection assay and protein secretion by enzyme-linked immunosorbent assay. Restimulation of peanut-primed cells *in vitro* with peanut lectin, but not with con A, PPD or medium alone, induced the selective expression of the Th2 cytokines interleukin (IL) -4, IL-5 and IL-13, with relatively low levels of interferon (IFN)-γ. In contrast, cells from mice both primed *in vivo* and restimulated *in vitro* with PPD exhibited high level expression of IFN-γ and IL-10. These patterns of mRNA expression were reflected by similar profiles of cytokine protein secretion. These data demonstrate the selective induction of a Th2 response following exposure to an allergenic protein.

848 BONE MARROW-DERIVED DENDRITIC CELLS UTILIZE DIFFERENT INTERNALIZATION PATHWAYS FOR UPTAKE OF THE NATIVE AND RECOMBINANT FORMS OF LACTOFERRIN.

M. Cumberbatch, R. J. Dearman and I. Kimber. *Immunology, Syngenta CTL, Macclesfield, Cheshire, United Kingdom.*

Lactoferrin (LF, 79.5kDa) is a member of the transferrin family of iron-binding proteins. The native (n) and recombinant (r) forms of human LF, available from breast milk and produced in *Aspergillus*, respectively, exhibit identical amino acid sequences and 3-D X-ray crystallographic structures. However, nLF and rLF differ with respect to their glycosylation patterns and their ability to provoke differential IgG and IgE antibody responses following systemic exposure to BALB/c strain mice. To investigate further the mechanistic basis for the differences observed in immune responses induced by nLF and rLF, we have examined the internalization pathways utilized by bone marrow-derived dendritic cells (BM-DC) for the uptake of LF. BM-DC, isolated from female BALB/c strain mice and harvested on day 8 of culture, were pulsed for 30 minutes at either 37°C or 4°C with various concentrations of nLF or rLF (0.1 to 1000μg/ml). LF uptake was visualized by flow cytometry using an anti-human LF antibody, which recognized both LF species equally when tested by Enzyme Linked Immunosorbent Assay. At all doses of LF examined, BM-DC exposed to rLF expressed 2-5 fold higher levels of internalized protein than did cells treated with nLF. Following pre-treatment of BM-DC with mannose, an inhibitor of the macrophage mannose receptor and other C-type lectins with mannose specificity, the active uptake of rLF at 37°C was inhibited by at least 80%. In contrast, uptake of nLF was compromised only partially (approximately

45%) by competition with mannose. These data suggest that whereas rLF is internalized almost entirely through a mannose-dependent pathway, uptake of nLF occurs *via* both mannose-dependent and independent routes; an observation that may ultimately impact upon the quality of immune response induced.

849 ANALYSIS OF DRAINING LYMPH NODE DENDRITIC CELL ACCUMULATION PROVOKED IN MICE BY CHEMICAL CONTACT AND RESPIRATORY ALLERGENS.

K. Clelland, M. Cumberbatch, R. J. Dearman and I. Kimber. *Immunology, Syngenta CTL, Macclesfield, Cheshire, United Kingdom.*

It has been reported previously that preferential activation of T helper (Th) 1 and Th2 cells is observed following repeated topical exposure of mice to chemical contact and respiratory allergens, and that only those chemicals that provoke respiratory allergy in humans induce IgE antibody responses. Temporal differences in the kinetics of Langerhans cell (LC) migration stimulated by these classes of chemical allergens have been reported recently. To explore further the dendritic cell (DC) response to such chemicals, we have performed kinetic and phenotypic analyses of DC accumulating in the draining lymph node (DLN) of BALB/c strain mice in response to the contact allergen 2, 4-dinitrochlorobenzene (DNCB) or the respiratory allergen trimellitic anhydride (TMA), at doses shown previously to be of equivalent immunogenicity. Excision of DLN 24 hours following exposure revealed increases in DC accumulation, enumerated by flow cytometry on the basis CD11c/Ia expression, that were significantly greater for DNCB ($p<0.05$, n=3) than for TMA; an observation that is in agreement with the delayed kinetics of LC migration observed for TMA. In DLN, DC numbers increased further 48 and 72 hours following exposure to both chemicals, such that values for DNCB- and TMA-treated mice were no longer significantly different. Flow cytometric analyses of lymph node cells revealed no difference between DNCB- and TMA-activated DC with respect to the expression of Ia, CD80, CD86, CD54, or CD8α. Although to date there has been no clear distinction between the phenotypic characteristics of DC isolated from DNCB- and TMA- sensitized mice, it is possible that the early kinetic differences in the accumulation of DC in DLN may ultimately influence the quality of response induced by these chemicals.

850 EVALUATION OF PROTEIN ALLERGENIC POTENTIAL IN MICE : INTER-LABORATORY COMPARISONS.

R. J. Dearman[1], C. Herouet[2], E. Debruyne[2] and I. Kimber[1]. *[1]Syngenta CTL, Macclesfield, Cheshire, United Kingdom and [2]Bayer CropScience, Sophia Antipolis, France.*

There is a growing interest in the development of methods for the evaluation of the allergenic potential of novel proteins. One approach is the measurement of specific IgE antibody production stimulated by systemic (intraperitoneal; ip) exposure of BALB/c strain mice. In the current investigations, inter-laboratory comparisons have been performed of the ability of various food proteins to induce IgE antibody. Female BALB/c strain mice (n = 5) were exposed to 0.1% peanut agglutinin, an allergenic constituent of peanuts, to 2% ovalbumin (OVA), a major allergenic constituent of hens' egg, or to a protein considered to lack significant allergenicity, potato agglutinin (5%). These doses were selected based on previous experience to induce similar levels of immunogenicity (specific IgG). Specific IgE antibody was measured by homologous passive cutaneous anaphylaxis assay. Two independent experiments were conducted in each laboratory. Administration of peanut agglutinin and OVA each stimulated marked IgE antibody responses in every experiment; titers ranging from 1 in 32 and 1 in 64, and 1 in 8 and 1 in 32, respectively, detected in both laboratories. In contrast, exposure to potato agglutinin failed to induce vigorous IgE production, with no detectable IgE (negative with neat serum) or titers of 1 (positive with neat serum only) recorded. These data demonstrate that the induction of IgE antibody by food proteins of differing allergenic potential is a relatively robust phenomenon and transferable between laboratories. Furthermore, these results suggest that the measurement of antibody (IgE) responses in BALB/c mice may allow discrimination between allergens and those materials that apparently lack allergenicity

851 NONRADIOISOTOPIC MEASUREMENT OF LYMPHOCYTE PROLIFERATION.

N. Humphreys, R. J. Dearman and I. Kimber. *Syngenta CTL, Macclesfield, Cheshire, United Kingdom.*

The murine local lymph node assay (LLNA) is a method for the prospective identification of chemical contact allergens. The current validated protocol assesses lymphocyte proliferation induced in the draining lymph node by in situ incorporation of radiolabelled thymidine. We have explored the possibility of using an alternative non-radioisotopic marker of cell division, the membrane-permeant cytoplasmic dye carboxyfluoresein succinimidyl ester (CSFE). When the cells divide, the CSFE-labelled cytoplasmic proteins are distributed equally between the daughter cells, thus the number of divisions each cell has undergone can be tracked. BALB/c strain mice were exposed topically to various concentrations of the contact allergen 2, 4-dinitrochlorobenzene (DNCB) or to the non-sensitizing skin irritant methyl salicylate (MS). Five days later, lymph node cells (LNC) were labelled with CSFE, cultured for 96 h, then incubated with fluorescently labelled anti-CD4 (T helper) and -CD8 (T cytotoxic) cell antibodies and proliferating CD4+ and CD8+ cells analyzed by flow cytometry. In LNC populations derived from vehicle-treated animals, less than 2% of either cell population had undergone one cell division or more. Topical exposure to MS (2.5% to 20%) did not increase the numbers of proliferating cells. Exposure to DNCB, however, resulted in a marked increase in the number of cells undergoing division, with between 5% and 9% of CD4+ cells and 9% to 16% of CD8+ cells proliferating in response to treatment with 0.25% and 0.5% DNCB, respectively. Cells derived from animals exposed to 0.1% DNCB also showed increased cell division in the CD8+ cell fraction. The threshold concentration for induction of proliferation by DNCB in the standard LLNA is approximately 0.05%, indicating that this method is somewhat less sensitive than is in situ incorporation of radiolabelled thymidine. However, these preliminary data suggest that this method may be applied to provide an alternative nonradioisotopic endpoint for the LLNA, particularly for the identification of potent contact allergens.

852 EVALUATION OF PROTEIN ALLERGENIC POTENTIAL IN MICE : DOSE RESPONSES.

S. Stone[1], R. J. Dearman[1], H. T. Caddick[1], D. A. Basketter[2] and I. Kimber[1]. *[1]Syngenta CTL, Macclesfield, Cheshire, United Kingdom and [2]SEAC Unilever Colworth Laboratory, Sharnbrook, United Kingdom.*

There is a growing need for the development of approaches for the characterization of the allergenic potential of proteins. Although immunogenicity is a common property of foreign proteins, few are significant dietary allergens with the capacity to provoke IgE antibody production and immediate type hypersensitivity responses. We have examined the induction of IgG and IgE antibody expression following systemic (intraperitoneal; ip) exposure of BALB/c strain mice. Mice were exposed to a range of concentrations (0.2% to 10%) of ovalbumin (OVA), a major allergenic constituent of hens' egg, or to the milk allergen bovine serum albumin (BSA), and to materials considered to lack allergenicity; a crude potato protein extract and a purified potato protein, potato agglutinin. Specific IgE antibody was measured by homologous passive cutaneous anaphylaxis assay and specific IgG antibody measured by enzyme-linked immunosorbant assay. Each of the 4 proteins induced IgG antibody responses at all doses tested, although there was some variation with respect to vigor of IgG responses. Marked differences in the capacity of these proteins to induce IgE responses was observed, with high titer IgE antibody provoked by OVA and BSA over the dose ranges examined whereas the potato proteins stimulated low titer IgE antibody at the highest dose (10%) only. Significant differences in the number of IgE responder animals were observed also. Importantly, differences in IgE antibody production were observed against a background of equivalent immunogenicity (IgG antibody responses). Thus, ip administration of OVA and potato agglutinin (0.5% to 10%) induced equivalent levels of IgG antibody but substantial (and statistically significant) differences in both the number of IgE responder mice and IgE titer were recorded. These data suggest that the measurement of antibody (IgE) responses in BALB/c mice may allow discrimination between allergens and those materials that apparently lack allergenicity

853 THE 90 KDA HEAT SHOCK PROTEIN ASSOCIATES WITH PPARα AND DIFFERENTIALLY REGULATES TRANSCRIPTIONAL ACTIVITY COMPARED WITH PPARβ OR PPARγ

W. K. Sumanasekera, E. Tien, G. H. Perdew and J. P. Vanden Heuvel. *Veterinary Science and Center for Molecular Toxicology and Carcinogenesis, Penn State University, State College, PA.*

The peroxisome proliferator-activated receptor α (PPARα), which belongs to the Type II steroid hormone receptor superfamily, may exist in a multimeric complex. One of the possible components of the PPAR complex is the 90 kDa heat shock protein (hsp90). In order to examine whether PPARα is associated with hsp90, liver cytosol from a C57BL/6N mouse was fractionated using a sucrose gradient. Co-migration of PPARα with hsp90 was observed. To further investigate the association between hsp90 and PPARα, hsp90 from C57BL/6N mouse liver cytosol was immunoprecipitated. A concomitant depletion of PPARα in hsp90-depleted mouse liver cytosol was detected. To test whether all three PPAR subtypes can bind to hsp90, a series of hsp90-GST fusion proteins were incubated with *in vitro* translated PPAR subtypes and GST pull-down assays were performed. The results indicate that both *in vitro* translated rat and mouse PPARα bind to the middle domain

of the hsp90, while mPPARβ or mPPARγ bind to a lesser extent. To further investigate the differential binding of PPARα to hsp90, mammalian 2 hybrid assay was conducted. While PPARα demonstrated a strong interaction with hsp90, the association between PPARβ and hsp90 was weak. In this assay, PPARγ was unable to interact with hsp90. In order to test the possible functional involvement of hsp90 in PPAR complexes, both COS-1 and HepG2 cells were co-transfected with PPARα and TPR domain of serine phosphatase 5. Co-transfection of TPR with PPARα resulted in an increased PPRE-driven reporter activity. Transcriptional activity of other isoforms of PPAR is unaffected by TPR co-transfection. The co-transfection of cells with the Hsc70-interacting protein (CHIP), a TPR containing E3 ubiquitin ligase that binds hsp90, increased PPARα transcriptional activity. Taken together, these results suggest that hsp90 is associated with PPARα as a transcriptional repressor. (Supported by NIH ES07799)

854 EVIDENCE THAT PPARα IS COMPLEXED WITH THE 90 KDA HEAT SHOCK PROTEIN AND THE HEPATITIS VIRUS B X-ASSOCIATED PROTEIN 2 (XAP2).

G. H. Perdew, W. K. Sumanasekera, E. Tien and J. P. Vanden Heuvel. *Veterinary Science and the Center for Molecular Toxicology and Carcinogenesis, Penn State University, University Park, PA.*

The perioxisome proliferator-activated receptor α(PPARα) is a ligand inducible transcription factor, which belongs to the nuclear receptor superfamily. PPARα mediates the carcinogenic effects of certain peroxisome proliferators in rodents. In addition, this receptor plays a fundamental role in regulating energy homeostasis *via* control of lipid metabolism. To study the possible role of chaperone proteins in the regulation of PPARα activity, a monoclonal antibody (mAb) was made against PPARα and designated as 3B6/PPAR. The specificity of mAb 3B6/PPAR in recognizing PPARα was tested in immunoprecipitations using *in vitro* translated PPAR subtypes. The mAb 3B6/PPAR recognized PPARα, failed to bind to PPAR β or PPARγ, and is efficient in both immunoprecipitating and visualizing the receptor on protein blots. The immunoprecipitation of PPARα in mouse liver cytosol using mAb 3B6/PPAR has resulted in the detection of two co-immunoprecipitated proteins, which are heat shock protein 90 (hsp90) and the hepatitis B virus X-associated protein 2 (XAP2). Complex formation between XAP2 and PPARα/FLAG was also demonstrated in an *in vitro* translation binding assay. Transient expression of XAP2 co-expressed with PPARα resulted in down regulation of a peroxisome proliferator response element (PPRE)-driven reporter gene activity. In mammalian one-hybrid assays XAP2 inhibited PPARα-driven transcriptional activity in the presence of ligand. Taken together, these results indicate that PPARα is in a complex with hsp90 and XAP2, and XAP2 appears to function as a repressor. This is the first demonstration that PPARα is stably associated with other proteins in tissue extracts and the first nuclear receptor shown to functionally interact with XAP2. (Supported by NIH ES07799)

855 PPARα-DEPENDENT REGULATION OF TUMOR SUPPRESSORS P19 AND C-ABL BY PEROXISOME PROLIFERATORS AND PHORBOL ESTERS.

J. P. Gray and J. P. Vanden Heuvel. *Center for Molecular Toxicology and Carcinogenesis, Pennsylvania State University, University Park, PA.*

Peroxisome proliferator-activated receptor α (PPARα) is a nuclear receptor responsible for the carcinogenic effects of peroxisome proliferators (PPs) in rodents. In addition to being activated by ligands such as Wy-14, 643, PPARα activity may be affected by phosphorylation events. Wy-14, 643 treatment of the rat hepatoma (FaO) cell line induces changes in the phosphorylation of Protein Kinase C (PKC), MAPK, and other kinases. Also, phorbol esters affect the transcriptional activity of PPARα in reporter assays. Both observations suggest a significant interaction between PKC and PPARα signaling. To investigate this crosstalk, we used liver cell lines generated from wild-type (wt) and PPARα-knockout animals (null). Although both cell types respond normally to phorbol ester (PMA)-induced mitogenesis, only wt cells respond to Wy-14, 643-induced mitogenesis. Gene expression arrays were used to find candidate genes differentially regulated by combinations of PMA and Wy-14, 643 treatment. A tumor suppressor, p19, was expressed constitutively higher in wt cells, but was repressed by Wy treatment only in that cell type. Both Wy and PMA treatment repressed the tumor suppressor c-Abl in wt cells, though neither had substantial effects in the null cells. Quantitative RT-PCR confirmed a substantially higher constitutive expression of c-Abl in wt cells. The regulation of these cell cycle genes in a PPARα-dependent manner helps to explain the carcinogenic effect of PPs in murine model systems. In addition, the fact that PMA regulates some gene expression in a PPARα-dependent manner suggests a significant amount of cross-talk with PKC signaling pathways. (Supported by NIH DK49009).

856 THE ROLE OF LIGAND INDUCED CONFORMATION CHANGES IN PEROXISOME PROLIFERATOR ACTIVATED RECEPTOR α COREGULATOR RECRUITMENT.

E. Tien and J. P. Vanden Heuvel. *Center for Molecular Toxicology and Carcinogenesis, Pennsylvania State University, University Park, PA.*

The peroxisome proliferator activated receptor α (PPARα) is a member of the nuclear receptor family and regulates genes that are involved in the metabolism of fatty acids in response to peroxisome proliferaters (PPs). In addition, numerous fatty acids and their metabolites are ligands for PPARα. PPs and endogenous ligands for PPARα have a wide variety of effects ranging from carcinogenesis to inhibition of cancer, often in a chemical-specific manner. One possible explanation for this varity of effect is specific conformational changes in the receptor induced by the ligand, similar to what has been observed with estrogen receptor (ER) and selective ER modulators (SERMs). In these studies, examination of these conformation changes was performed using cell culture based and *in vitro* based systems. The results indicate unique conformation changes in response to PPs with differing overall function. The possibility that these conformational changes will effect other aspects of the PP signaling cascade such as recruitment of coregulators is also being examined.

857 TRANS-ACTIVATION OF PXR BY PHTHALATE MONOESTERS.

C. H. Hurst and D. J. Waxman. *Biology, Boston University, Boston, MA.*

Phthalate esters, widely used as plasticizers in the manufacture of products made of polyvinyl chloride, are hepatocarcinogenic and induce reproductive/developmental toxicities in rodents. Recent studies demonstrate high human urinary levels of several phthalates, including monoethyl phthalate, monobenzyl phthalate (MBzP) and monobutyl phthalate (MBuP), raising the question of whether human environmental exposure to these chemicals is associated with adverse health effects. The present study investigates the effects of phthalates on the nuclear pregnane X receptor (PXR). PXR mediates the induction of CYP3A enzymes involved in the hydroxylation of steroids, bile acids and other lipophilic chemicals. PXR is activated by certain endogenous steroids (pregnanes, estrogens), as well as by endocrine disruptor chemicals, which interfere with the synthesis, secretion, transport, binding or elimination of hormones. Recently, several missense mutations in the ligand-binding domain of PXR leading to variant PXR proteins have been identified in human populations, suggesting these variants could contribute to individual differences in responsiveness to PXR-activating chemicals. To assay the effects of phthalate monoesters on PXR-mediated transcription, HepG2 cells were transiently transfected with mouse PXR and with wild-type or variant human PXR in a reporter gene assay. Treatment with mono-2-ethylhexyl phthalate (MEHP) increased the transcriptional activity of both mouse and human PXR with EC_{50} values of 3.6 and 4.4 μM, respectively. MEHP activated the human PXR variant A370T 5-fold, with an EC_{50} value of 2.7 μM. By contrast, the human PXR variant D163G was totally unresponsive to MEHP (500 μM). The transcriptional activity of mouse and human PXR (wild-type and variants A370T and V140M) was also activated 3-fold by MBzP. Thus, PXR-mediated transcription can be stimulated by phthalate monoesters, which could lead to disruption of endocrine function by altering PXR-regulated steroid hormone metabolism, with potential adverse health effects in exposed humans. [Supported in part by NIH/NIEHS grants ES07381 (DJW) and F32 ES11105 (CHH)].

858 EEECT OF CAR AND PXR ACTIVATORS ON TESTOSTERONE CLEARANCE IN CASTRATED MALE SPRAGUE-DAWLEY RATS.

M. Wyde[1], T. M. Baughman[2], Z. Zhao[2] and L. You[1]. *[1]CIIT Centers for Health Research, Research Triangle Park, NC and [2]GlaxoSmithKline, Research Triangle Park, NC.*

Cytochromes P450 (CYP) 3A1 and 2B1 are regulated by the nuclear receptors pregnane X receptor (PXR) and constitutive androstane receptor (CAR) and catalyze the hydroxylation of testosterone. CAR and PXR are promiscuous receptors for structurally diverse chemical ligands, including some environmental compounds. Potent induction of CYP 3A1 and 2B1 by the activators of CAR and PXR may affect testosterone homeostasis. The aim of the current study was to test the hypothesis that induction of CYP 3A1 and 2B1 by CAR and PXR activators increases the rate of clearance and alters the metabolism of testosterone. Castrated male Sprague-Dawley rats were exposed to DDE or phenobarbital (PB), CAR and PXR activators, or pregnenolone 16-α carbonitrile (PCN), a PXR activator, for 7 days prior to administration of exogenous C^{14}-labeled testosterone. Urine and feces were collected to determine whether chemical-induced changes in testosterone metabolism were reflected in the rate of testosterone clearance. Overall clearance of

testosterone was determined by the recovery of radioactivity in urine and fecal samples, and testosterone metabolites were analyzed by LC/MS. Exposure to DDE, PB, or PCN did not alter the overall rate of testosterone clearance. However, the amount of unmetabolized testosterone recovered was significantly lower in rats treated with DDE, PB, or PCN than in control rats. Unmetabolized urinary testosterone in DDE-, PB-, and PCN-treated rats was 28%, 38%, and 14% of controls, respectively. PCN exposure resulted in a decrease in radioactivity in the urine and an increase in the feces, suggesting treatment-mediated alteration in phase II conjugation. This study demonstrates a chemical-induced alteration in metabolism of testosterone, not of overall clearance, and suggests a treatment-induced change in the rate of metabolic inactivation of biologically active testosterone.

859 THE E3 UBIQUITIN LIGASE CARBOXYL TERMINUS OF HSC70-INTERACTING PROTEIN (CHIP) CAN MEDIATE HUMAN ARYL HYDROCARBON RECEPTOR PROTEIN TURNOVER.

J. L. Morales[1] and G. H. Perdew[2]. *[1]Graduate Program in Biochemistry and Molecular Biology, The Pennsylvania State University, University Park, PA and [2]Center for Molecular Toxicology and Carcinogenesis, The Pennsylvania State University, University Park, PA.*

Regulation of transcription factor levels relies often on protein degradation mechanisms. This report presents evidence that the human aryl hydrocarbon receptor (hAhR) and the 90KDa heat shock protein (hsp90) levels can be reduced dramatically by transient expression of the E3 ligase carboxyl terminus of hsc70-interacting protein (CHIP) in COS-1 cells. However, CHIP expression had no effect on the co-chaperones p23 and hepatitis B virus X associated protein-2 (XAP2) protein levels. A deletion construct of CHIP lacking its three tandem tetratricopeptide repeats did not affect hAhR levels while a construct lacking its University-box domain had minimal effects on the hAhR. Furthermore, CHIP reduces the amount of hAhR competent for transactivation, as determined in cell-based reporter assays. Immunoprecipitates of myc-tagged CHIP revealed the presence of hAhR and hsp90, suggesting that they associate directly in cells. XAP2 is known to enhance AhR levels when it is transiently expressed in COS-1 cells, while p23 is thought to modulate AhR ligand responsiveness. However, expression of XAP2 and p23 failed to inhibit CHIP-mediated hAhR turnover. In contrast, the heat-shock-protein organizing protein (HOP) was able to counteract the effects of CHIP on the hAhR, suggesting that a balance between HOP and CHIP protein levels may dictate whether the hAhR is degraded or not. Future studies may help determine whether the observed downregulation of the hAhR is in fact due to the ability of CHIP to target the hAhR for destruction directly or a consequential effect of CHIP-induced hsp90 degradation. It remains unknown whether CHIP plays a role in the ligand-induced downregulation of the AhR. (Supported by NIH, ES04869).

860 ESTABLISHMENT AND CHARACTERIZATION OF SIMIAN VIRUS 40 IMMORTALIZED AHR-NULL MOUSE HEPATOCYTES AND THEIR USE TO ASSESS THE ROLE OF THE AH RECEPTOR IN GENE REGULATION.

R. K. Reen[1], P. Ramadoss[1], P. M. Jeffrey[1], F. J. Gonzalez[2] and G. H. Perdew[1]. *[1]Centre for Molecular Toxicology and Carcinogenesis, Pennsylvania State University, State College, PA and [2]Laboratory of Metabolism, National Cancer Institute, Bethesda, MD.*

The aryl hydrocarbon receptor (AhR) is a ligand activated transcription factor that has been identified as a primary cellular target for 2, 3, 7, 8-tetrachlorodibenzo-p-dioxin (TCDD) and related compounds. There is a need for suitable models to gain insight into the AhR-signaling pathway. One potentially useful cell culture system is the establishment of immortalized Ahr-null hepatocytes from null (Ahr-/-) mice. Hepatocytes from Ahr-null (AhRKO) and wild-type (AhRWT) neonatal mice were immortalized by infecting with Simian virus 40 harboring temperature sensitive large T antigen gene. The AhRKO and AhRWT cell cultures grow at the permissive temperature of 34oC and at 37oC, however, at 39oC cellular growth declines after 24 h. Both AhRKO and AhRWT equally expressed albumin as well as proteins that participate in the AhR pathway such as Ah receptor nuclear translocator, 90 kDa heat-shock protein and hepatitis B virus X-associated protein 2. However, there was a complete absence of the AhR in AhRKO cells. RT-PCR studies revealed induction of CYP1A1 (200-fold) and CYP1B1 (8-fold) mRNA by TCDD in wild-type but not in the Ahr-null cell line. Both cell lines expressed CYP1B1, although the constitutive level in wild-type was higher than the null-cells. AhRKO cells also exhibited high transient transfection efficiency. Therefore utilization of this Ahr-null cell line with restored wild-type and mutant AhR signaling will provide a valuable tool for the elucidation of the mechanisms that underlie AhR mediated gene regulation. In addition, this study establishes the usefulness of immortalization of primary cells with SV40 virus from gene disrupted mice. AhRWT and AhRKO cells are being utilized in DNA microarray experiments to identify genes whose expression is altered due to TCDD-induced AhR signalling as well as the constitutive activity of the AhR.

861 ADRENERGIC RECEPTOR CROSSTALK DURING DEVELOPMENT: ADVERSE EFFECT OF TOCOLYTICS?

M. L. Kreider, F. J. Seidler and T. A. Slotkin. *Pharmacology & Cancer Biology, Duke University Med. Ctr, Durham, NC.*

Alpha-2 adrenergic receptors (A2ARs) are overexpressed throughout the fetus and are thought to play a role in cell proliferation. In most tissues, A2ARs decrease with the development of synaptic connections, coincident with the fall in mitotic activity. We evaluated whether the maturation of neural connections is responsible for the ontogenetic decline in A2ARs in the developing liver of newborn rats. Animals were sympathectomized on postnatal day (PN) 1 with 6-hydroxydopamine; A2AR expression (binding of 3H-rauwolscine) was decreased on PN6 but elevated on PN15. These results indicated that neural stimulation modulates the ontogenetic expression of A2ARs, with a positive trophic relationship early in development, followed by suppression of A2ARs once innervation becomes fully functional. The developing liver also contains high concentrations of beta-2 ARs (B2ARs), so we next determined if these receptors participated in the trophic effect. Animals were treated with terbutaline, a B2AR agonist that is commonly used to arrest preterm labor, using a regimen (10 mg/kg s.c. daily for four days) that produces biologic effects similar to those seen when used for maternal tocolysis. Terbutaline given on PN2-5 produced a significant decrement in A2AR receptors, and similar deficits were obtained with treatment on PN11-14, the period of rapid onset of sympathetic function. Isoproterenol, a mixed B1/B2-agonist, also elicited a decrease in hepatic A2ARs. Given the overexpression of A2ARs in many fetal or neonatal tissues, and their relationship to cell proliferation, the effects seen here may contribute to adverse effects of tocolytics. (Supported by NIH HD09713)

862 ADULT TO CHILD EXTRAPOLATION OF THE PHARMACOKINETICS OF ANAESTHETICS USING AGE-SPECIFIC PHYSIOLOGICAL MODELS.

G. Balagopal and K. Krishnan. *Occupational and Environmental Health, Universite de Montreal, Montreal, QC, Canada.*

The extrapolation of exposure concentrations from adults to children is a challenge to health risk assessors dealing with environmental contaminants. In this context, the data available and lessons learnt regarding the inhalation pharmacokinetics of anaesthetics might be useful. These data can be used to improve our understanding of adult-child extrapolation of exposure concentrations. The objectives of the present study were to develop a physiologically-based pharmacokinetic (PBPK) model for nitrous oxide and halothane in adults, and to apply this model for predicting the kinetics of these anaesthetics in children using age-specific physiological parameters. The PBPK model used in this study contained age-specific values of alveolar ventilation rate, cardiac output, tissue blood flow rates and tissue volumes, and facilitated the simulation of the ratio of exhaled to inhaled quantity (QE/QI) of anaesthetics during exposure. The PBPK model simulations in adults were consistent with the experimental data, which suggested a QE/QI value of 0.55 for halothane and 0.94 for nitrous oxide. Assuming the tissue:blood and blood:air partition coefficients to be the same in adults and children, the simulations for children (halothane: 2 months old; nitrous oxide: 3 years old) were obtained. The PBPK model simulations and experimental data indicate that, following a 20-min exposure to 5000 ppm, the QE/QI value in children is 0.75 for halothane and 0.96 for nitrous oxide. In general, for the anaesthetics investigated in this study, the QE/QI approached 1 in children and the adult-child difference in QE/QI could be explained by adult-child differences in alveolar ventilation rate and liver blood flow rate. These results suggest that the adult-child extrapolation factor for poorly metabolized anaesthetics and atmospheric contaminants is likely to be within a factor of two.

863 PHYSIOLOGICALLY-BASED PHARMACOKINETIC MODELING OF 1-PROPANOL (CAS # 71-23-8) IN HUMANS AND RATS.

L. M. Sweeney and M. L. Gargas. *The Sapphire Group, Dayton, OH.*

Physiologically based pharmacokinetic (PBPK) modeling is potentially a useful tool in minimization of animal experimentation mandated under various regulatory initiatives. A method that holds promise is the development of a "metabolic series approach" for developing toxicological information on compounds linked *via* steps in a metabolic pathway. Our effort to describe pharmacokinetic data for propyl series of compounds (propyl acetate, 1-propanol, propionaldehyde, and propionic acid)

in rats and humans has focused on 1-propanol. The existing human data consist of blood time courses of 1-propanol following iv injection in the presence and absence of ethanol, and for coingestion of 1-propanol and ethanol. Blood:air and tissue:air partition coefficients of 1-propanol are also available from the literature. These data were adequate for development, parameter fitting, and validation of a model for 1-propanol by the oral route or iv injection. The model structure includes metabolism of 1-propanol in the liver and in perfused tissues other than fat and urinary filtration of 1-propanol. The model predictions of the human data are generally very good to excellent. Sensitivity analysis indicates that the data are adequate to determine metabolic parameters. Preliminary models of 1-propanol inhalation and ingestion were developed, permitting sensitivity analysis and application of the rat model in experimental design.

864 MODELING THE INFLUENCE OF ALCOHOL DEHYDROGENASE GENETIC POLYMORPHISMS IN ETHANOL DISPOSITION IN HUMANS.

E. J. Flynn[1], G. M. Pastino[2] and L. G. Sultatos[1]. *[1]Pharmacology and Physiology, New Jersey Medical School, Newark, NJ and [2]Schering-Plough Research Institute, Lafayette, NJ.*

The family of cytosolic enzymes known as alcohol dehydrogenase (EC 1.1.1.1) catalyze the reversible oxidation of ethanol to acetaldehyde, with corresponding reduction of NAD^+ to NADH. Alcohol dehydrogenase in humans exists as multiple forms, including class and isozyme multiplicity, as well as allelic variations within several different isozyme forms. In the current study a continuous system model based on the Theorell-Chance mechanism for each isoform of alcohol dehydrogenase was incorporated into a physiologically based pharmacokinetic model for ethanol in humans. Models for the C_1 and C_2 homodimers, and the B_1 homodimer included the previously reported negative cooperativity and substrate inhibition, respectively, while heterodimers were modeled as the sum of the activity of the respective monomers. Association of dimers from monomers was assumed to occur randomly, and expression of various isoforms within a specific genotype were assumed to be equal. Simulations indicated that alcohol dehydrogenase genotype contributed significantly to the overall disposition of ethanol. For example, at an ethanol dose of 591 mg/kg, the elimination rate constant for ethanol was found to be 1.4275 mmol/L/h for a genotype of $B_3B_3C_1C_1$, while the same constant for the genotype $B_3B_3C_2C_2$ was 7.7803 mmol/L/h. These studies suggest that metabolic differences in alcohol dehydrogenase genetic polymorphisms are important contributors to the variability of ethanol disposition in a population, and that such variability can be described with biologically based models useful for risk assessment. (Supported by a grant from The American Chemistry Council).

865 ESTIMATING INTERINDIVIDUAL VARIATION IN PHYSIOLOGICALLY BASED PHARMACOKINETIC (PBPK) MODELING PARAMETERS FOR DICHLOROMETHANE METABOLISM IN HUMAN VOLUNTEERS.

C. R. Kirman[1], L. M. Sweeney[2], D. Morgott[3] and M. L. Gargas[2]. *[1]The Sapphire Group, Dayton, OH, [2]The Sapphire Group, Dayton, OH and [3]Health and Environment Laboratories, Eastman Kodak Company, Rochester, NY.*

The toxicokinetics of dichloromethane (DCM) are well understood in both laboratory animals and humans. DCM is metabolized by two enzyme systems: 1) mixed function oxidases, which follow Michaelis-Menten kinetics (Vmax, Km); and 2) glutathione-S-transferases, which can be described with a first-order rate constant (KFC). The latter pathway has been implicated as a key determinant of cancer risk in animals. This work includes a more detailed analysis of some previously published human kinetics data for DCM (DiVincenzo and Kaplan). In this study, a group of 14 volunteers (11 men, 3 women) were exposed to 1 of 4 concentrations of DCM (50, 100, 150, or 200 ppm) for 7.5 hours. Individual time-course data were collected for up to 40 hours post exposure for the following: 1) DCM concentrations in blood; 2) DCM concentrations in exhaled breath; 3) carboxyhemoglobin levels in blood; and 4) and carbon monoxide concentrations in exhaled breath. Variation in the tissue and exhaled breath concentrations was relatively small at the end of the exposure period (CV=0.02-0.44). Predictions for the time-course data were made using a validated PBPK model for DCM in humans. Individual values for body weight were used. Volume of adipose tissue was estimated based upon a consideration of age, height, and sex of the individual. Optimal fits for model predictions were obtained by adjusting Vmax and KFC for each individual, while all other values were held constant. Parameter distributions for Vmax and KFC were derived from the optimized parameter values generated from the individual data sets. The resulting distributions were compared graphically to several alternative distributions, including distributions from 1) OSHA, used in establishing a permissible exposure limit for DCM; 2) an expert elicitation effort; and 3) the published literature. The potential impact of these data on human health risk assessment for DCM is discussed.

866 PBPK MODEL ANALYSIS OF INTRATHYROIDAL IODIDE TRANSPORT IN HUMANS.

E. A. Merrill[2], R. A. Clewell[2], J. M. Gearhart[1] and P. J. Robinson[1]. *[1]Geo-Centers, Inc., Wright-Patterson AFB, OH and [2]ManTech Environ Technology, Inc., Wright-Patterson AFB, OH.*

An improved physiologically-based pharmacokinetic (PBPK) model for perchlorate (ClO4-) -induced inhibition of iodide (I-) uptake in adult humans was used to explore the influence of endogenous iodide on intersubject variability in radioiodide uptake measurements (RAIU) in the thyroid. The improved model thyroid includes four subcompartments for the stroma, follicle, colloid and bound iodide (ie., thyroid hormones). Both passive diffusion and active uptake were described between the stroma and follicular epithelium and between the follicular epithelium and colloid. First order rate constants, estimated from the literature, were used to simulate iodide organification and its secretion (thyroid hormones) to systemic circulation. Follicular maximum capacities, Vmax(s), were estimated from visual fits of thyroid RAIU measurements in human volunteers (Greer et al., 2002) and varied across subjects over an order of magnitude. However Vmax(s) did not vary within subjects (between RAIUs taken pre and post ClO4- exposure). Several factors are known to affect Vmax. Thyroid stimulating hormone (TSH), released during low levels of circulating thyroid hormone, increases sodium iodide symporters (NIS), thereby increasing the Vmax. Dietary iodide also affects Vmax, by altering intrathyroid levels of inorganic iodide. All subjects used had normal functioning thyroids and TSH levels (1.99+/-0.88 uU/mL). Even during two weeks of low perchlorate exposure (0.007 to 0.5 mg/kg/d), there was no observed effect on individual TSH and Vmax values. Therefore, dietary iodide was suspected to be the major contributor to individual variability in Vmax(s). Because alimentary restrictions were not implemented in the study, dietary iodide was estimated from predictions of endogenous serum and urinary iodine measurements. An inverse relationship was found between Vmax and both intrathyroidal iodide levels and dietary iodide.

867 PHYSIOLOGICALLY BASED PHARMACOKINETIC MODELING OF SPECIES-SPECIFIC EFFECTS OF PLASMA BINDING OF TRICHLOROACETIC ACID FROM TRICHLOROETHYLENE IN MICE, RATS, AND HUMANS.

M. H. Lumpkin[2,1], C. E. Dallas[1], J. V. Bruckner[1] and J. W. Fisher[1]. *[1]Interdisciplinary Toxicology Program, University of Georgia, Athens, GA and [2]Clayton Group Services, Inc., Kennesaw, GA.*

Recently, PBPK models have been used in the assessment of liver cancer risk from trichloroethylene (TCE) exposure, particularly to aid in the extrapolation of rodent bioassay data to human risk at environmental levels. The models were used to determine a range of human risks based on equivalent mouse exposures, using total plasma and liver area under the curve (AUC) for the metabolites trichloroacetic acid (TCA) and dichloroacetic acid (DCA) as dose metrics. Previous studies showed a significant difference in the ability of human and rodent plasma to bind TCA. From these results, we developed a PBPK model for TCE incorporating the plasma binding of TCA in mice, rats, and humans. This model included a Michaelis Menton expression within the blood compartment to determine free concentration of TCA in terms of total concentration. The expression for binding was governed by the parameters P (plasma albumin concentration), N (number of binding sites per protein molecule), and Kd (binding equilibrium dissociation constant). Species-specific physiological and metabolic parameters were used in the PBPK model. The proportion of free TCA in blood available for uptake into tissues was much less in humans than in rats or mice. Binding of TCA to proteins in human plasma dramatically affected the renal elimination rate compared to the rodents, explaining the long residence time of TCA in human blood. Our findings indicate that free TCA, as opposed to total TCA in the blood, is a more appropriate dose metric for extrapolation of TCE dosimetry from rodents to humans. Our model provides a quantitative framework to examine tissue uptake of free TCA over a wide range of TCE exposures. (This research was supported by DOE Cooperative Agreement # DE-FC02-02CH11109).

868 DEVELOPMENT OF A PBPK MODEL FOR PROPYLENE GLYCOL MONOMETHYL ETHER AND ITS ACETATE FOR RATS, MICE AND HUMANS.

R. A. Corley, R. A. Gies and H. Wu. *Pacific Northwest National Laboratory, Richland, WA.*

1-Methoxy-2-propanol (propylene glycol monomethyl ether, PGME) is the most widely used propylene glycol ether solvent. Commercial PGME consists of >99% 1-methoxy-2-propanol with less than 1% 2-methoxy-1-propanol. The major isomer of PGME is metabolized to either glucuronide or sulphate conjugates (minor) or propylene glycol (major). The major toxic effects of PGME in animals studies

includes sedation, very slight alpha 2u globulin-based nephropathy (male rats only) and hepatomegally at high exposures (typically >1000 ppm). Sedation in animal studies usually resolves within a few exposures to 3000 ppm (the highest concentration used in subchronic and chronic inhalation studies) due to the induction of metabolizing enzymes. Partition coefficients were determined and data from a variety of pharmacokinetic and mechanistic studies were incorporated into a PBPK model for PGME and its acetate in rats, mice and humans. Published controlled exposure and workplace biomonitoring studies were included for comparisons of internal dosimetry between laboratory animals and humans. PGME Acetate has a very short half-life (hydrolyzed to PGME) in humans (~36 min in blood and liver homogenates) and even shorter in rats (~15 min in blood and 30 min in liver homogenates). Thus, very little PGME Acetate is found *in vivo*. Regardless of the source for PGME (either PGME or its acetate), rats were predicted to have a higher Cmax and AUC for PGME in blood than humans, especially at concentrations >100 ppm. This would indicate that the major systemic effects of PGME would be expected to be less severe in humans than rats at comparable exposures.

869 COMPARISON OF THE DERMAL AND INHALATION ROUTES OF EXPOSURE ON THE ABSORPTION OF TOLUENE IN HUMAN VOLUNTEERS.

K. D. Thrall, K. K. Weitz and A. D. Woodstock. *Battelle, Pacific Northwest Laboratory, Richland, WA.*

Toluene can be present as a contaminant in both well and surface water. An assessment of the dermal contribution to total toluene uptake is useful for understanding human exposures. To evaluate the significance of these exposures, the dermal absorption of toluene was assessed in human volunteers using exhaled breath analysis and physiologically based pharmacokinetic (PBPK) modeling. Human volunteers were submerged in warm tap water to neck level in a stainless steel hydrotherapy tub containing an initial concentration of 0.5 mg/L toluene. Volunteers were provided breathing air to eliminate inhalation exposures, and exhaled breath was continually analyzed before, during, and post exposure to track the absorption of toluene in real time. A PBPK model was used to estimate the dermal permeability coefficient (Kp) to describe the exhaled breath data from n=6 volunteers. An average Kp value of 0.012 +/- 0.007 cm/hr was found to provide a good fit to all data sets. Volunteers also participated in a second study, in which the subject was allowed to breathe the room air during immersion, thus both dermal and inhalation exposures occurred. Exhaled breath analyses revealed that concurrent inhalation of volatilized toluene resulted in a transient 50% increase in peak exhaled breath levels compared to those observed in dermal only studies. For perspective, the total intake of toluene associated with oral consumption of 2 liters of water containing toluene at bath water concentrations were estimated to be more than 30 times greater than the dermal contribution due to bathing. (Supported by NIEHS grant 1-P42-ES10338-01).

870 INCORPORATION OF AGE-, GENDER-, AND SPECIES-SPECIFIC DATA ON THE METABOLISM, PROTEIN BINDING AND RENAL CLEARANCE OF 2-BUTOXYETHANOL AND ITS METABOLITE, BUTOXYACETIC ACID, INTO A PBPK MODEL.

J. J. Soelberg[1], D. M. Grant[2], E. Farris[1], K. K. Weitz[1], K. D. Thrall[1] and R. A. Corley[1]. *[1]Pacific Northwest National Laboratory, Richland, WA and [2]BIOGEN, Cambridge, MA.*

2-Butoxyethanol (BE) is the most widely used glycol ether solvent. BE's major metabolite, butoxyacetic acid (BAA), causes hemolysis with significant species differences in sensitivity. Several PBPK models have been developed over the past two decades to describe the disposition of BE and BAA in male rats and humans to refine health risk assessments. More recent efforts by Lee et al. (1999) to model the kinetics of BE in male and female F344 and B6C3F1 mice from the NTP chronic inhalation studies required the use of several assumptions to extrapolate model parameters from earlier PBPK models developed for young male rats. To replace these assumptions, a series of studies were conducted to determine the impact of age, gender and species on the metabolism of BE, and the tissue partitioning, renal acid transport and plasma protein binding of BAA. The Lee et al. PBPK model was updated and expanded to include metabolism of BAA by mice and humans and the salivary excretion of BE and BAA (mice) which may contribute to the forestomach irritation observed in the NTP study. The revised model was validated against several recent inhalation, oral gavage and intraperitoneal injection kinetic studies in rats and mice as well as the NTP chronic inhalation study. Peak blood concentrations of BAA have been used in several human health risk assessments that focused upon hemolysis. The revised model predicted that peak blood concentrations of BAA are greatest in female rats followed by female mice, male mice, male rats then humans at 6-hr inhalation exposure concentrations exceeding 100 ppm. At lower concentrations (i.e. <50 ppm), mice are predicted to have the lowest peak blood concentrations of BAA. The revised model serves as a quantitative tool for integrating an extensive pharmacokinetic and mechanistic database into a format that can readily be used to compare internal dosimetry across dose, route of exposure and species.

871 DEVELOPMENT OF A PRELIMINARY PHYSIOLOGICALLY BASED PHARMACOKINETIC MODEL FOR 1, 2-DIETHYLBENZENE IN THE F344 RAT.

K. E. Lewis[1], A. D. Woodstock[2] and K. D. Thrall[2]. *[1]Energy Pre-Service Teacher Research Fellowship, Washington State University, Pullman, WA and [2]Battelle, Pacific Northwest Laboratory, Richland, WA.*

1, 2-Diethylbenzene (1, 2-DEB) s a moderately volatile, colorless liquid used as an intermediate in the production of divinylbenzene, as a heat transfer fluid, and is found in gasoline, kerosene, and fuel oils. Environmental release of 1, 2-DEB may occur at sites where it is produced or used; 1, 2-DEB is listed as a contaminant found in drinking water supplies in some US cities. The most probable route of human exposure to 1, 2-DEB is by inhalation or dermal contact, mainly in occupational settings where the commercial grade mixture is used as a solvent. To better understand the kinetics of 1, 2-DEB, a preliminary physiologically based pharmacokinetic (PBPK) model to describe the absorption, distribution, metabolism and elimination of 1, 2-DEB in rats was developed. Partition coefficients were experimentally determined in rat tissues and blood samples using an *in vitro* vial equilibration technique. Both saturable Michaelis-Menten metabolic rate constants Km (affinity) and Vmax (capacity), and a first-order (Kfo) metabolic constant were derived from the optimization of a series of *in vivo* gas uptake curves conducted at various initial chamber concentrations. Pretreatment with pyrazole, an inhibitor of oxidative microsomal metabolism, did not impact the slope of the gas uptake curve, indicating that metabolism was not affected. The completed PBPK model was evaluated against real-time exhaled breath data collected from rats receiving an intraperitoneal (IP) injection of 1, 2-DEB. Exhaled breath profiles from animals treated with 1, 2-DEB by IP injection were evaluated and the absorption rate (Ka) determined using the PBPK model. Development of a PBPK model for 1, 2-DEB in rats is the first stop toward future extrapolations to understand the kinetics in humans. (Supported by NIEHS grant 1-P42-ES10338-01).

872 DEVELOPMENT OF A PHYSIOLOGICALLY-BASED PHARMACOKINETIC MODEL FOR THE STUDY OF 2-METHYLIMIDAZOLE KINETICS.

M. Easterling[1] and C. J. Portier[2]. *[1]Analytical Sciences, Inc., Durham, NC and [2]NIEHS, Research Triangle Park, NC.*

In support of the National Toxicology Program (NTP) bioassay for 2-Methylimidazole (2-MI), a model was developed to enhance the understanding of 2-MI kinetics. Earlier studies have identified thyroid as a possible target for 2-MI so the model included diffusion-limited delivery of 2-MI to a thyroid compartment, as well as diffusion-limited compartments representing muscle, skin, adipose, brain, liver, GI, kidney, and other aggregated tissues. The model included the administration of 2-MI orally and by IV. Elimination of 2-MI was from the feces, urine, or metabolism in the liver. Parameters not available from the literature were estimated with maximum likelihood methods by fitting the model predictions to data. Published data included 2-MI concentrations over time in tissues (adipose, brain, kidney, liver, muscle, skin, thyroid, venous blood) following oral and IV administration to male F344 rats, while the NTP toxicokinetic data included blood concentrations over time for IV and oral administration to F344 rats and B6C3F1 mice of both sexes. The model was able to adequately simulate the data across administration routes, species, and sexes. The model was used to evaluate, with formal statistical tests, differences in absorption, metabolism, and elimination rates between male and female F344 rats and B6C3F1 mice. These data and PBPK model permit a better mechanistic understanding of the relationship between exposure and target tissue dosimetry that will enhance the risk assessment process for 2-MI.

873 A PHYSIOLOGICALLY BASED PHARMACOKINETIC MODEL FOR GAVAGE AND I.V. ADMINISTRATION OF METHYLEUGENOL IN F344/N RATS AND B6C3F1 MICE.

S. Y. Whitaker, P. J. Koken and C. J. Portier. *Laboratory of Computational Biology and Risk Analysis, NIH/NIEHS, Research Triangle Park, NC.*

Methyleugenol is a flavoring and perfuming agent naturally found in nutmeg, mace, and foods and spices. Due to the structural similarity of methyleugenol to other known carcinogens, including safrole, isosafrole, and estragole, it has been tested for toxicity and carcinogenicity by the National Toxicology Program (NTP).

It was concluded that methyleugenol is toxic and carcinogenic in male and female rats and mice. As part of this toxicity testing, the NTP conducted single-dose intravenous and oral gavage toxicokinetic studies of methyleugenol in male and female rats and mice. A diffusion limited physiologically based pharmacokinetic (PBPK) model mathematically representing the absorption, distribution, metabolism, and elimination of methyleugenol in rats and mice was developed to quantitatively describe the process involved in methyleugenol toxicokinetics. The differential equations used in this model describe mass transfer of methyleugenol between tissue compartments and have parameters representing physiological quantities and chemical-specific parameters. The physiological parameters were chosen from literature values. The chemical-specific parameters were estimated from the plasma concentration time course data following intravenous and gavage administration of methyleugenol to the rodents. Absorption rates, metabolism rates, and permeability constants were estimated separately for rats and mice. Likelihood-based statistical methods were used to test hypotheses regarding the structure of the model and similarities across species. The analysis demonstrates that absorption of methyleugenol in rats and mice is rapid and complete, that the distribution of methyleugenol to tissues is not hindered by capillary permeability, that metabolism of methyleugenol is saturable, and that an extrahepatic site for metabolism is needed for both species.

874 UTILIZATION OF A PBPK MODEL TO PREDICT THE DISTRIBUTION OF 2, 3, 7, 8-TETRACHLORODIBENZO-P-DIOXIN (TCDD) IN HUMANS DURING CRITICAL WINDOWS OF DEVELOPMENT.

C. Emond[1], M. J. DeVito[2] and L. S. Birnbaum[2]. *[1]National Research Council PKB ETD NHEERL ORD, USEPA, Research Triangle Park, NC and [2]PKB ETD NHEERL ORD, USEPA, Research Triangle Park, NC.*

TCDD is a ubiquitous environmental contaminant that induces a wide spectrum of toxic responses, including developmental toxicity. Some of these developmental effects have different critical windows of sensitivity. The utilization of a PBPK model to predict maternal to fetal transfer of TCDD can be important for improving human health risk assessments for the developmental effects of TCDD. While, PBPK models for TCDD have been published for different species including, rat, mice, fish and humans, no PBPK models have described the distribution of TCDD during pregnancy. The aim of this work was the development of a PBPK model to predict the distribution and accumulation of TCDD between maternal and fetal compartments in humans. Previously validated in the rat, this model consisted of 4 maternal compartments (liver, fat, placenta and, rest of the body) and 1 fetal compartment corresponding to the whole fetus. The model described Ah receptor binding, CYP1A2 induction and binding, and physiological alterations occurring during gestation. The model assumed the distribution of TCDD was diffusion limited for fat and liver. This model focused on oral exposure because dietary exposures represented over 95% of the daily intake of TCDD. Different exposure scenarios were examined including chronic exposure and chronic exposure with intermittent periods of high exposures (i.e. meals containing higher than average concentration of TCDD). This model assumed a background exposure prior to the gestation period. Initial testing of this model provided reasonable fits to human exposure data. This model may be a useful tool for use in risk assessments as well as for understanding basic pharmacokinetic and pharmacodynamic processes during development. Acknowledgments: This project was funded by in part by a cooperative agreement (CR 828790) with NRC, NAS and performed at USEPA Research Triangle Park, NC, USA. (This abstract does not represent USEPA policy).

875 IMPROVED PBPK LACTATION/NEONATAL MODEL FOR PERCHLORATE-INDUCED INHIBITION OF ENDOGENOUS AND RADIOIODIDE UPTAKE IN THE RAT.

R. A. Clewell[1], E. A. Merrill[1], J. M. Gearhart[2] and P. J. Robinson[2]. *[1]Geo-Centers, Inc., Wright-Patterson AFB, OH and [2]ManTech Environmental Technology, Int., Wright-Patterson AFB, OH.*

Ongoing modeling efforts have resulted in predictive physiologically based pharmacokinetic (PBPK) models for perchlorate and radioiodide kinetics in the male, pregnant, lactating, fetal and neonatal rat, as well as in the adult human. The models successfully predict acute radioiodide control and inhibition data, and both acute and sub-chronic perchlorate data at several dose levels, and can be used to quantitatively determine estimates of both inter-species and intra-species (age, gender, perinatal) variability. However, to make these rat models more relevant to humans, they were expanded to simultaneously describe the kinetics of endogenous (dietary) iodinde and its incorporation into hormones (thyroxine, triiodothyronine, etc.), together with its effect on perchlorate-induced inhibition. Thyroid and serum compartments are divided into two sub-compartments describing incorporated iodine, which comprises 93% and 13% of the total iodine, respectively, and free iodide. Published total iodine levels were accurately simulated by the model in the maternal and neonatal gastro-intestinal tract and contents, skin, serum, and the maternal mammary gland and milk. By incorporating dietary and hormonal iodide, the models are able to address the physiological changes during development (e.g. increased serum binding) and environmental factors (e.g. iodine deficiency or iodine/hormone supplementation), in addition to the previously described susceptibility of the neonate to inhibition of iodide.

876 PHYSIOLOGICALLY BASED PHARMACOKINETIC (PBPK) MODELING OF GENISTEIN IN RATS.

P. M. Schlosser[1], S. J. Borghoff[1], N. G. Coldham[2], H. T. Tran[3], A. Upmeier[1] and M. G. Zager[1,3]. *[1]CIIT Centers for Health Research, Research Triangle Park, NC, [2]Department of Bacterial Diseases, Veterinary Laboratories Agency, Surrey, United Kingdom and [3]Department of Mathematics, NCSU, Raleigh, NC.*

Phytoestrogens are a class of endocrine-active compounds that occur naturally in some food crops, particularly soy products, with genistein being a significant component of these. High concentrations of genistein occur in tofu and soy infant formula. Genistein is associated with a range of effects from chemoprevention of breast and prostate cancer, cardiovascular disease, and postmenopausal ailments to observed reductions in weight and anogenital distances of rodents at birth. To estimate circulating levels of genistein during experimental health-effects studies, PBPK models for genistein in rats are being developed. A preliminary model was previously developed using published data, although those data rarely distinguished parent genistein from its glucuronide and other conjugates. Measurements of parent genistein and total radiolabel activity (including conjugates) in plasma have now been generated for rats, along with total radiolabel activity in a wide range of tissues. Binding of genistein and its conjugates to rat plasma protein has also been measured. The model is now being updated accordingly. However, the model did not fit the recently obtained data when using parameter values previously estimated for the same rat strain. Data from the literature shows that genistein undergoes enterohepatic circulation, but inclusion of this process without direct observation of biliary excretion rates also creates significant challenges in parameter identification. Despite those challenges, we concluded that a good description of genistein kinetics required two changes from the standard, perfusion-limited PBPK structure: description of transport through the gastrointestinal tissues as diffusion-limited and inclusion of binding of genistein to serum proteins. (Research supported in part by the American Chemistry Council and the Food Standards Agency, UK.)

877 INTERSPECIES PHYSIOLOGICALLY BASED PHARMACOKINETIC MODELING OF GENISTEIN.

J. F. Young[1], R. H. Luecke[2] and D. R. Doerge[3]. *[1]Biometry & Risk Assessment, NCTR, Jefferson, AR, [2]Chemical Engineering, University of Missouri - Columbia, Columbia, MO and [3]Biochemical Toxicology, NCTR, Jefferson, AR.* Sponsor: D. Hansen.

The evaluation of potential human health benefits from genistein, the principle soy isoflavone, often requires initial studies using experimental animals. Of particular value are metabolism and disposition studies that can permit extrapolation of animal blood and tissue measurements to human studies where only blood data are available. Genistein pharmacokinetic data obtained from laboratory animal experiments as well as literature reports of human exposures were simulated with a unique general purpose physiologically based pharmacokinetic (PBPK) model that was capable of simultaneously fitting data for both the active aglycone and inactive conjugated (primarily the glucuronide) forms. Single and multi-dose oral exposure as well as iv and ip injections were simulated using data obtained from mouse, rat, and human experiments. Metabolism and concurrent enterohepatic recirculation complicated the kinetics and prolonged the elimination of genistein in all three species. The interconversion between the aglycone and conjugate required the two PBPK models to be bidirectionally linked. Statistical and visually satisfactory fits were obtained for 10 sets of mouse data, four sets of rat data, and 19 sets of human data. Despite the extensive conjugation of circulating genistein, tissue levels of the aglycone after multi-dosing attained concentrations in all species that have been demonstrated to activate estrogen receptors α and β. This estrogen agonist activity is the likely basis for many of the putative beneficial effects and potential adverse effects of genistein and soy consumption

878 AGE-RELATED DIFFERENCES IN HEART RATE, BUT NOT BODY TEMPERATURE IN RATS PERFORMING OPERANT TASKS AT EQUIVALENT TRIAL RATES IN AIR AND WHILE INHALING TOLUENE.

W. M. Oshiro, T. E. Samsam, Q. T. Krantz, W. P. Watkinson and P. J. Bushnell. *NHEERL, USEPA, Research Triangle Park, NC.*

A physiologically-based pharmacokinetic (PBPK) model is being developed to estimate the dosimetry of inhaled toluene in rats under experimental conditions requiring varying degrees of physical activity. Heart rate was used as a surrogate index

to adjust the model input parameters for cardiac output and ventilation rate in active rats. Telemetered heart rate (HR) and core body temperature (Tco) were collected during performance of two operant tasks in young adult (7-8 mo, n=12) and old rats (20 mo, n=6) trained either on a signal detection task or a simple lever pressing task. HR and Tco were determined in 1-hr tests at rest and while performing the task at 4, 7, 10 and 13 trials per minute (tpm). HR increased by ~10% above sedentary rates at all trial rates in the old rats, whereas the HR of young rats increased from ~15% to 25% above sedentary rates, as a direct function of trial rate. Tco rose by 1.0 deg C during the first 10 min of performing the tasks in young and old rats under all conditions. Young rats were also exposed to toluene (0 and 2000 ppm) while performing either task at 5 and 10 tpm. Toluene elevated HR and attenuated the increase in Tco during performance of the tasks at both trial rates. These data indicate that activity-dependent increases in HR appear to be dampened in aged rats, but changes in Tco are not. Changes in activity level during exposure to volatile organic chemicals should be accounted for in the dosimetry of the chemical; in addition, the physiological effects of the chemical itself may impact its dosimetry. (This abstract does not necessarily reflect EPA policy.)

879 A PHYSIOLOGICAL PHARMACOKINETIC MODEL BASED ON CLEARANCE AND VOLUME OF DISTRIBUTION.

M. Beliveau and K. Krishnan. *Occupational and Environmental Health, Universite de Montreal, Montreal, QC, Canada.*

Clearance terms have been applied to describe certain physiological functions of organs such as kidney and liver. These organs remove chemical from the blood stream by metabolism or filtration. Clearance (CL) of chemicals in systemic circulation is expressed in units of blood volume per unit time. Volume of distribution (Vd), expressed in L blood, represents the apparent volume in which the chemical is distributed. Classical compartmental models frequently describe the pharmacokinetics of chemicals using Vd, CL and an elimination constant calculated as CL/Vd. These parameters are not directly used in physiologically-based pharmacokinetic (PBPK) descriptions. The aim of this study was to recast a conventional PBPK model in terms of clearances and effective volumes of distribution in tissues. In this study, the rate of change in the amount of chemical in tissues was computed as the difference between the input to tissue per unit time (mg/hr) and the product of the amount in tissue (mg) and the elimination constant (/hr). Whereas chemical input to tissue was calculated as influx clearance (L blood/hr) x arterial blood concentration (mg/L blood), the elimination constant was calculated as the ratio of tissue clearance (L blood/hr) to the effective volume of tissue distribution (L blood). Tissue clearance corresponded to the blood flow rate of tissues except liver for which intrinsic metabolic clearance capacity was also taken into account. In implementing the above modeling approach, there was no need to calculate the venous blood concentration exiting tissues (Cvt) for solving the mass balance differential equations. Further, the basic form of equations used in this study resembles that used in non-physiological pharmacokinetic models. The PBPK model based on CL and Vd was validated by simulating blood concentration of styrene following a 6-hr inhalation exposure to 80 ppm or 600 ppm. The simulations obtained were identical to that of the conventional PBPK model. The present study facilitates a better understanding of CL and Vd concepts as they relate to PBPK models.

880 A NOVEL APPROACH FOR PBPK MODELING OF METABOLIC INTERACTIONS IN CHEMICAL MIXTURES.

K. Krishnan and K. Price. *Occupational and Environmental Health, Universite de Montreal, Montreal, QC, Canada.*

Changes in tissue dose and toxicity during mixed exposures frequently occur due to metabolic interactions, which alter the hepatic extraction ratio (E) of mixture components. If the change in E during mixed exposure is known, then change in tissue dose of each component in a mixture can be predicted. The aim of this study was to develop an approach for calculating the change in E to facilitate the prediction of altered pharmacokinetics and tissue dose of chemicals during mixed exposures. The methodology involved the calculation of E based on the total exposure dose and pharmacokinetic equivalence of mixture components. The E value was then specified in an individual chemical PBPK model to simulate pharmacokinetics and tissue dose during mixed exposure. The proposed methodology was applied to model a mixture of three hydrocarbons, namely, toluene (TOL), m-xylene (XYL) and ethylbenzene (EBZ). The change in E value of these chemicals during mixed exposure to 100 ppm each was quantified by considering the mixture as the combination of different doses of a single chemical (on the basis of pharmacokinetic equivalence). In this study, the mixture was expressed in terms of TOL and TOL-equivalent doses of XYL and EBZ in order to determine the E value of TOL in the mixture. This method was then repeated for all components of the mixture. The E value of TOL, XYL and EBZ decreased between individual and mixed exposures from 0.30 to 0.05, 0.28 to 0.04 and 0.14 to 0.04, respectively. The calculated E values were identical to those obtained using an interaction-based PBPK model. Further, the use of these E values in individual chemical PBPK model provided simulations that were identical to those obtained using a mixture PBPK model. These results suggest that, when metabolic inhibition is the interaction mechanism, the change in E and pharmacokinetics of chemicals occurring during mixed exposures can be predicted with the knowledge of the total dose of the mixture and pharmacokinetic equivalence of components.

881 LOW-DOSE VALIDATION OF A PHYSIOLOGICALLY BASED PHARMACOKINETIC MODEL FOR TRICHLOROETHYLENE IN THE RAT.

D. A. Keys, J. V. Bruckner, S. Muralidhara and J. W. Fisher. *Interdisciplinary Toxicology Program, University of Georgia, Athens, GA.*

Trichloroethylene (TCE) is a volatile liquid used as a degreasing agent and is a common environmental pollutant. In 2001, the EPA published a draft risk assessment for TCE that incorporates dosimetry predictions of physiologically based pharmacokinetic (PBPK) models. The current modeling effort represents a lower dose validation of a PBPK model used for dosimetry predictions in the draft risk assessment. The pharmacokinetics of TCE in male Sprague-Dawley (SD) rats were characterized: (a) during inhalation exposure to 50 ppm TCE, (b) following gavage administration of 8 mg/kg TCE; and (c) following intraarterial injection of 8 mg/kg TCE. Blood and tissues (including liver, kidney, fat, muscle, heart, spleen, GI tract, brain) were collected at selected time-points from 5 minutes up to 24 hours post initial exposure. A PBPK model for TCE in rats had been developed previously (Fisher et al., 1991). Strain-specific physiological parameter values for the SD rat were used in the current work. Metabolism rates have been estimated from gas uptake studies in the Fisher-344 (F-344) (Andersen et al., 1987) and Long Evans (LE) (Simmons et al., 2002) rats, resulting in estimates of Vmaxc of 11.0 and 7.34 mg/hr/kg, respectively. The inhalation, gavage and intraarterial time-course data were better described by the LE rat specific value than the F-344 value. Blood and muscle concentrations were adequately predicted by the model. Concentrations of TCE in the fat were modestly overpredicted by the model, while concentrations in the liver were slightly underpredicted for inhalation, gavage and intraarterial exposures. To date, PBPK model validation for TCE in rat tissues has not been performed at inhalation doses lower than 200 ppm. This low dose validation increases our confidence about the use of the rat PBPK model for extrapolation to environmentally relevant doses. (Supported by DOE Coop. Agreement DE-FC02-02CH11109)

882 PBPK MODELING OF THE METABOLIC INTERACTIONS OF CARBON TETRACHLORIDE AND TETRACHLOROETHYLENE IN B6C3F1 MICE.

J. W. Fisher[1], M. Lumpkin[1], J. Boyd[1], D. Mahle[2], J. Bruckner[1] and H. El-Masri[3].
[1]*Interdisciplinary Toxicology Program, University of Georgia, Athens, GA,*
[2]*Operational Toxicology Branch, AFB, Dayton, OH and* [3]*Division of Toxicology, ATSDR, Atlanta, GA.*

Potential exists for widespread human exposure to low levels of carbon tetrachloride (CT) and tetrachloroethylene (TET). Both of these chlorinated hydrocarbons are metabolized by the cytochrome P450 system. The objective of this research was to examine the metabolic interactions between CT and TET using a physiologically based pharmacokinetic (PBPK) model in male B6C3F1 mice. CT was assumed to inhibit its own metabolism (suicide inhibition) directly by the formation of metabolically derived free radicals (CCl3 and OOCCl3) and indirectly by the formation of free radical products from lipid peroxidation. A CT PBPK mouse model was configured to describe suicide inhibition and competitive inhibition with TET. A TET model was configured to describe the metabolic formation of trichloroacetic acid (TCA), a cytochrome P450 mediated metabolite, with metabolism altered by competitive inhibition with CT and loss in metabolic capacity by CT induced suicide inhibition. Metabolic constants for CT were 1.0 mg/kg/hr for Vmaxc and 0.3 for Km (mg/L) and for TET (based in TCA production), 6.0 mg/kg/hr and 3.0 mg/L, respectively. The rate of enzyme loss (suicide inhibition, Vmaxloss) was describe as: Vmaxloss (mg/hr) = -KD * (RAM*RAM), where KD (hr/kg) is a second order rate constant, and RAM (mg/hr) is the Michaelis Menten description of the rate of metabolism of CT. CT caused dose-related depletion in available metabolic capacity for conversion of TET to TCA in animals orally dosed with 1 to 100 mg/kg CT followed one hour later by an oral bolus of 100 mg/kg of TET. Using a KD value of 450 hr/kg successfully described TCA serum levels in mice dosed with 1 to 100 mg/kg of CT. This project demonstrates the utility of PBPK modeling to better understand the metabolic and potential toxic consequences of chemical mixtures. (support by ATSDR #00001663931 and SERDP CU1073)

883 USE OF SENSITIVITY ANALYSIS ON A PHYSIOLOGICALLY BASED PHARMACOKINETIC (PBPK) MODEL FOR CHLOROFORM IN RATS TO DETERMINE AGE-RELATED TOXICITY.

C. R. Eklund[1], J. E. Simmons[1] and M. V. Evans[2]. *[1]ORD, NHEERL, ETD, PKB, USEPA, Research Triangle Park, NC and [2]ORD, NERL, HEASD, USEPA, Research Triangle Park, NC.*

Chloroform (CHCl3) is a disinfection byproduct for which several PBPK models are available. Since PBPK models account for physiological differences, they are well-suited to predict differences due to aging. We used a five compartment PBPK constant inhalation model for CHCl3 (Evans et al., 2002) to examine age differences and variation in input parameters. Model simulations were performed in MatLab running on Red Hat Linux. We calculated and compared sensitivity coefficients (SCs) for three model input parameters and four model outputs over three age groups (- 2, 3, and 24 months) and three chamber concentrations, 10, 100 and 500 ppm for 6 hours. We examined the effect of changing Vmax on rate of amount of CHCl3 metabolized (RAML) and amount of CHCl3 in liver (AL), cardiac output (QCC) on venous CHCl3 blood concentration (CV), and fat:blood partition coefficient (PCfat) on amount of CHCl3 in fat (AF). At 10 ppm CHCl3, changes in the 4 output parameters examined (RAML, AL, CV, and AF) were consistently much less than the changes applied to the input parameters. In contrast, at 500 ppm CHCl3, SCs for CV were greater than 1 for all 3 ages. At 500 ppm, the SCs for AF were greater than 1 for adult and old rats, but not young rats. At 500 ppm, the Scs for RAML approached 1, and for AL were much less than 1. Changes in Vmax produced opposite changes in RAML and AL. Increasing Vmax increased RAML and decreased AL. As the absolute magnitude of a SC serves as a measure of the impact of a change in a given input parameter on a model output of interest, SC results can be used to gauge the usefulness of further refinement of selected input parameters. Where SCs are large, increased parameter accuracy ma be needed; uniformly small SCs may indicate further refinement is not needed. This is an example of how modeling can suggest a reduction in the number of animals used. (This abstract does not necessarily reflect EPA policy.)

884 DOSE-RESPONSE ANALYSIS OF BETA-CHLOROPRENE INDUCED CARCINOGENICITY USING PBTK MODELING.

M. W. Himmelstein[1], P. M. Hinderliter[1], S. C. Carpenter[1] and R. Valentine[2]. *[1]Biochemical Molecular Toxicology, DuPont Haskell Laboratory, Newark, DE and [2]Inhalation Toxicology, DuPont Haskell Laboratory, Newark, DE.*

Beta-chloroprene (2-chloro-1, 3-butadiene, CD), used in the synthesis of polychloroprene, caused significant incidences of several tumor types in B6C3F1 mice and Fischer rats but not in Wistar rats or Syrian hamsters from two separate inhalation bioassays. This project investigated the relevance of bioassay tumor findings to potential human health risk. CD metabolism involves oxidation by cytochrome P450 to two epoxides metabolites, (1-chloroethenyl)oxirane (1-CEO) and (2-chloro-2-ethenyl)oxirane (instability of the latter metabolite precluded quantification for this project). A physiologically-based toxicokinetic (PBTK) model was developed that describes total CD metabolism and 1-CEO detoxification. Key project steps included identification of the plausible mode of action, completing quantification of tissue partition coefficients for the stable 1-CEO, finalizing *in vitro* parameters of CD and 1-CEO metabolism, refining the PBTK model structure, comparing the model with *in vivo* experimental gas uptake data, and selecting model-based values of rodent tissue dose for predicting a corresponding exposure concentration in humans. The most useful tissue dosimetric proved to be the total amount of CD metabolized daily by the lung; greater amounts of CD metabolism occurred in mouse lung compared with the other species. The internal dosimetrics and rodent lung tumor bioassay data were used to estimate an internal lung dose associated with 10% extra tumor incidence. Based on the human version of the PBTK model, the equivalent tissue dose in humans for 10% extra risk would be expected to occur from continuous exposure to 23 ppm CD. Concentrations associated with discontinuous occupational exposures such as 8 or 12 hr shift work were 90 and 100 ppm, respectively. This project demonstrates the applicability of PBTK modeling to quantitative risk assessment.

885 EVALUATING A PHYSIOLOGICALLY-BASED PHARMACOKINETIC MODEL FOR USE IN RISK ASSESSMENT.

L. H. Clark, H. A. Barton and R. W. Setzer. *USEPA, ORD, NHEERL, ETD, Research Triangle Park, NC.*

Physiologically-based pharmacokinetic (PBPK) models are increasingly being used in evaluation of the effects of chemical exposures on human health. Due to the increased use of PBPK models, it is becoming more evident in the biological modeling community that a universal set of criteria should be used to evaluate the quality of a model before it is used in a human health risk assessment. The objective of this study was to develop a set of important criteria that can be used to evaluate PBPK models. We present the criteria here and note that this is not an exhaustive list but one that can be used as a starting point for further discussion. Increased confidence in PBPK model predictions of human health risks can be attained if the following criteria are satisfied: 1) the model must be biologically plausible (i.e. known physiological and biochemical properties of a chemical must be accounted for in the model and the appropriate mathematical descriptions should be used); 2) the computer algorithms describing the mathematical equations in the model should be implemented properly; 3) a consistent set of parameters should be used to reproduce available experimental data, including data that were not used to estimate the parameters; and 4) the model should exhibit the appropriate sensitivity to changes in each parameter value. In our study, we used an existing PBPK model for isopropanol (Clewell et al., Toxicol Sciences, 63:160-172, 2001, Gentry et al., Regul Toxicol Pharmacol, in press) as a case study. This model has been proposed as a tool to perform the route-to-route and cross-species extrapolations, among other things, needed to evaluate the potential human health effects of isopropanol, based on studies in rats of systemic, developmental, reproductive, and neurobehavioral toxicities. The isopropanol model largely meets the above criteria and will be used here to illustrate the issues involved in evaluating the quality of a model. (This abstract does not reflect USEPA policy.)

886 USE OF PHYSICO-CHEMICAL PROPERTIES AND *IN VITRO*-DERIVED DATA IN PHYSIOLOGICALLY-BASED BIOKINETIC MODELING: MINIMUM DATA REQUIREMENTS.

B. J. Blaauboer. *Institute for Risk Assessment Sciences, Urecht University, Utrecht, Utrecht, Netherlands.* Sponsor: M. Vandenberg.

Physiologically-based biokinetic (PBBK) modeling is a useful tool in determining target tissue dose metrics. This information can play a role in the assessment of a compound's hazard or risk. Prerequisites are the availability of data on physico-chemical properties, basic knowledge on the mode of action and hence the target tissues, as well as the availability of the physiological parameters needed to build the PBBK model. Data requirements for the use of models will differ, depending on their complexity, which in turn is depending on the necessity to obtain an approximation rather than a detailed target tissue dose metric. An analysis was made of the requirements for data sets on the physico-chemical properties of chemicals. A determining factor appears to be the hydrophobicity of the compound. Highly water-soluble compounds will distribute over the body water and a first estimate of the volume of distribution will therefore be the body water volume, which is approximately 0.67*body volume. For more hydrophobic compounds it will be necessary to obtain blood-tissue partition coefficients. Approximations of these can be made, e.g. on the basis of partitioning between water and octanol. This allows a quantification of the partition coefficients in quantitative property-property relationships (QPPRs), describing the relationship between e.g. logPow and partitioning between blood and tissues. For both water-soluble and lipophilic compounds protein binding will have to be taken into account for a more accurate PBBK modeling of target tissue dose metrics. Absorption *via* the skin or in the g.i. tract and partitioning to a number of target tissues will involve active transport systems, that may either enhance or diminish the target tissue dose metric. It can be concluded that, depending on the precision of the required data, approximate as well as more precise PBBK models can be based on physico-chemical properties of compounds. Other parameters, e.g. protein binding and active barrier passage may be determined in *in vitro* models.

887 PHYSIOLOGICAL PARAMETERS IN DEVELOPING RATS AND MICE.

L. Haber[1], P. Gentry[2], Q. Zhao[1], T. McDonald[2], P. Nance[1], H. Bartow[2], C. VanLandingham[2], G. Foureman[3], H. A. Barton[4], R. S. DeWoskin[3] and J. C. Lipscomb[5]. *[1]TERA, Cincinnati, OH, [2]Environ, Princeton, NJ, [3]USEPA/NCEA, Research Triangle Park, NC, [4]USEPA/NHEERL, Research Triangle Park, NC and [5]USEPA/NCEA, Cincinnati, OH.*

The utility of PBPK models for addressing issues related to children's risk, and estimating tissue doses in young animals, is limited by the lack of published information on point estimates and population distributions of age-related changes in key physiological parameters. To address this issue, we have reviewed the published literature and compiled a database of physiological parameters in developing rats and mice related to tissue volumes, intake (food and water intake, alveolar ventilation), and flow rates (e.g., cardiac output, GFR). Data were collected for the early postnatal stages (birth through postnatal day 60), with some data through day 90 when time-series data were available. Chemical-specific parameters, such as partition co-

efficients and metabolic rate constants, were not included in the current work. To maximize the utility of the database for PBPK modeling, all data were associated with body weight, as well as animal age. To aid in prioritizing the large number of studies identified, emphasis was placed on studies providing data at multiple time points (or data for a given time point covering multiple endpoints). However, for data-poor parameters (e.g., GFR), all relevant data were entered into the database. The database was used to identify data gaps by age, sex, species, and strain. For example, few data are available for the mouse, compared with the rat, and more data are available on tissue volume than flow rates. The results of this analysis will be useful in (1) identifying key areas where additional data are needed in order to develop PBPK models for young animals; and (2) identifying parameters and parameter distributions for developing PBPK models for estimating tissue dose in neonates and young animals.

888 AN INTEGRATED MODEL OF LIFE STAGE-SPECIFIC CHANGES IN PHYSIOLOGICAL PARAMETERS OF FEMALE RATS.

K. Sokoloff and K. Krishnan. *Occupational and Environmental Health, Universite de Montreal, Montreal, QC, Canada.*

The pharmacokinetics and tissue dose of chemicals may vary from one life stage to another as a result of changes in physiology, biochemical processes and tissue composition. Some data and physiological models of specific life stages exist in the literature. The objective of this study was to interconnect the existing life-stage specific models to produce an integrated description of temporal changes in physiological parameters in female rats. The methodology involved the review of published literature to gather data on the rat physiological parameters such as body weight, organ weights, cardiac output and tissue blood flows for the different life stages and the development of regression equations for calculation of the age-dependent physiologic parameters. The following were the specific tissues for which weights and blood flows were investigated: brain, liver, adipose tissues, slowly perfused tissues, richly perfused tissues, mammary gland and placenta. The data and existing models for the following life-stages were obtained: gestation, lactation, embryo-fetal growth, nursing pup and post-lactational growth. For most life-stages, tissue-specific physiological parameters were found except for the embryo-fetus stage. The linkage of the five stages together needed some adjustments so as to have a real smooth continuum from the embryo-fetus to nursing pup to growing rat to the gestating dam and lactating dam. The data sources and regression equations identified in this study should be useful for constructing pharmacokinetic models to simulate the uptake and disposition of chemicals during prenatal and postnatal development.

889 EVALUATION OF TWO IMMUNOASSAYS FOR ANALYSIS OF METHAMPHETAMINE CONTAMINATION ON INDOOR SURFACES.

C. B. Salocks[1], M. J. Vona[2], R. A. Haas[3], R. R. Chang[4] and B. P. Simmons[4]. *[1]Office of Environmental Health Hazard Assessment, California Environmental Protection Agency, Sacramento, CA, [2]Department of Toxic Substances Control, California Environmental Protection Agency, Sacramento, CA, [3]Office of Environmental Health Hazard Assessment, California Environmental Protection Agency, Oakland, CA and [4]Department of Toxic Substances Control, California Environmental Protection Agency, Berkeley, CA.*

Illegal synthesis of methamphetamine is a major law enforcement and public health problem in California, where more than 2000 clandestine laboratories have been identified in each of the last three years. Methamphetamine is frequently produced in houses, apartments and mobile homes, and may result in widespread contamination of interior surfaces. Given the cost and delay associated with conventional analytical procedures, assessment of residual methamphetamine contamination is usually based solely on visual evidence, i.e., staining. To address the need for better assessment methods, two immunoassay methods, originally developed for detection of illicit drugs in biological fluids, were modified for detection of surface contamination. A microplate enzyme immunoassay (EIA) and a portable immunoassay utilizing a hand held reader were evaluated. In the validation study, standard solutions of illegally synthesized methamphetamine were prepared, applied to glass plates and allowed to dry. The plates were sampled using absorbent tabs, diluted in buffer, and analyzed using the microplate EIA, portable immunoassay, and GC/MS. Extraction (sampling) efficiency, precision, method bias, method detection limit, and quantitation range were determined. Both immunoassays are rapid and relatively inexpensive assessment tools that can be readily adopted by health officials to identify surfaces in former clandestine methamphetamine laboratories that require remediation and/or additional investigation.

890 AN ANALYTICAL METHOD FOR MEASURING DERMAL EXPOSURE TO HEXAMETHYLENE DIISOCYANATE.

C. B. Trent, A. Gold, H. Koc, L. M. Ball and L. A. Nylander-French. *Environmental Sciences and Engineering, University of North Carolina at Chapel Hill, Chapel Hill, NC.*

Occupational exposure to diisocyanates such as hexamethylene diisocyanate (HDI) is well documented as a cause of respiratory sensitization and occupational asthma. However, inhalation exposure may account for only part of the total body dose. Recent animal studies suggest that dermal exposure to diisocyanates is linked to respiratory sensitization; hence there is a need for dermal exposure assessment methods applicable in the workplace. We are developing a method to detect and quantitate dermal exposure to HDI. NIOSH Method 5521: "Isocyanates, Monomeric", originally developed for air sampling, was modified for use with our non-invasive dermal tape-stripping technique, whereby 2.5 by 4 cm rectangles of adhesive tape are applied to exposed skin surfaces, then removed, taking with them the outer layer of keratinocytes and any substances deposited thereon. The tape rectangles are immersed in toluene/1-(2-methoxyphenyl)piperazine solution; diisocyanates are recovered (after reaction with 1-(2-methoxyphenyl)piperazine) as their urea derivatives, and following extraction are ultimately detected and quantitated in that form by liquid chromatography-ion-trap mass spectrometry with electrospray ionization, operated in the positive mode. Compounds were identified by retention times and mass spectra. For quantitation of HDI, the protonated molecular ion of the urea derivative (HDIU; m/z 553.7) was monitored. Limits of detection and of quantitation were 1 pmol and 10 pmol injected, respectively. The urea derivative of octamethylene diisocyanate (ODIU) served as internal standard (1000 pmol per injection), and was detected as its protonated molecular ion (m/z 581.7). Response of HDIU relative to ODIU was linear from 0.01 to 1 mol/mol injected. Triplicate samples were reproducible within 10%. HDI was recovered at variable but detectable levels from paint droplets deposited onto tape, to mimic spray-painting operations. Supported by NIEHS P30-ES10126.

891 PERCHLOROETHYLENE EXPOSURE ASSESSMENT FOR GOVERNMENT INSPECTORS AT DRY-CLEANING FACILITIES.

B. D. Kerger[1], M. J. Fedoruk[2] and R. F. Bronstein[3]. *[1]HSRI, Inc., Tallahassee, FL, [2]Center for Occupational and Environmental Health, University of California, Irvine, Irvine, CA and [3]Safety Health West, Chino, CA.*

This study assessed occupational exposure to perchloroethylene (PERC) among government air quality inspectors at 16 dry-cleaning facilities selected to represent plausible high-end exposures based on historical air quality violation records. Inspectors normally assess airborne PERC levels using a photoionization detector (PID). They follow specific inspection procedures starting with measurements outdoors, at the facility entrance/lobby, in the equipment areas, and at specific locations around each piece of equipment (for leak detection at doors, seals, etc.). In addition to recording these usual measurements at each facility, each of the four inspectors who volunteered for the study was fitted with two personal air monitoring devices: a full-shift badge monitor (approx. 8 hrs.) and an active sorbent tube monitor (battery pump, on during inspections only, < 4 hrs.). Each of the personal samples demonstrated that time-weighted average $\pm$ std.dev. exposures for full-shift (1.3 ± 0.8 ppm, n = 8) and facility-only measurements (3.9 ± 3.7 ppm, n = 4, composite of 4 facilities each) were below occupational exposure limits. The exposure measurements (personal monitors and PID recordings) and inspector rankings of facility PERC exposures on a scale of 1-4 were also assessed for time-weighted exposure trends. Linear regression of full-shift and facility-only PERC levels showed direct correlation with an index of peak PID-minutes, but inverse correlations with entrance PID-minutes and inspector rank-minutes. Inspector rank-minutes was also directly correlated with entrance PID-minutes. These trends are possibly attributable to the observation that inspectors spent less time in completing their inspections in process areas of the facilities with higher ambient indoor PERC levels. The study suggests that trained inspectors utilize PID measurements and work habits to limit their own exposure to PERC at dry cleaning facilities with higher ambient indoor air levels.

892 AUTOMOBILE BRAKE MAINTENANCE AND AIRBORNE CHRYSOTILE FIBER EXPOSURES.

M. Banasik[1], D. R. Van Orden[2], C. Blake[3] and R. D. Harbison[1]. *[1]Department of Environmental and Occupational Health, University of South Florida, Tampa, FL, [2]RJ Lee Group, Inc., Monroeville, PA and [3]Clayton Group Services, Inc., Kennesaw, GA.*

The use, in the past and to a lesser extent today, of chrysotile asbestos causes health concerns among professional mechanics. Therefore, we conducted 4 separate tests in order to evaluate an auto mechanic's exposure to airborne chrysotile fibers while

performing routine brake maintenance. Four nearly identical Chevrolet Impalas from mid-1960s having 4 wheel drum braking systems were used. Each automobile was fitted with new replacement chrysotile-containing brake shoes and then driven over a predetermined public road course for about 1, 400 miles. Then, each car was separately brought into a repair facility; the brakes removed and replaced with new chrysotile-containing shoes. The test conditions, methods, and tools were as commonly used during the 1960s. The mechanic was experienced in brake maintenance, having worked in the automobile repair profession beginning in the 1960s. Effects of 3 independent variables, e.g., filing, sanding, and arc grinding of the replacement brake shoe elements, were tested. During each test, personal and area air samples were collected and analyzed for the presence of fibers, chrysotile fibers, total dust, and respirable dust. The results indicate airborne chrysotile fiber exposures for each test remained at or below currently applicable OSHA Permissible Exposure Limit of 0.1 fiber/cm^3, 8-h time-weighted average.

893 ARSENIC DRINKING WATER EXPOSURE AND URINARY EXCRETION AMONG ADULTS IN THE YAQUI VALLEY, SONORA, MEXICO.

M. M. Meza[1], M. J. Kopplin[2] and A. Gandolfi[2]. *[1]Department of Research and Graduate Studies, Institute Technological of Sonora, Cd. 0bregon, Sonora, Mexico and [2]Pharmacology and Toxicology, University of Arizona, Tucson, AZ.*

The drinking water standard As has been set at 10 ppb based primarily an epidemiology studies in Taiwan. However in the Southwest US and Northern Mexico, drinking water exposure to arsenic is primarily to Hispanic populations. Thus, this study was conducted in the Yaqui Valley, Sonora, Mexico, to explore arsenic exposure and urinary arsenic excretion in this Hispanic population. Forty-four adults residents from four towns (Esperanza, Cocorit, Pueblo Yaqui, and Col. Allende) who drank tube-well water for up to 23 years were examined. Arsenic concentrations in the wells were determined by ICP-MS as 43.3, 19.3, 9.7, and 5.5 μg As/l respectively. Urinary mean concentrations of the sum of As (III), As (V), MMA (V) and DMA(V) were between 79.7 and 31.2 μg/L. The average of arsenic urinary excretion only weakly correlated with the arsenic in drinking water. In contrast to previous studies we found low excretion of DMA V, (56-58 %, of total urinary As) and slight increase in inorganic arsenic As III and As V, 30-33 %, except in Cocorit. Genetic polymorphisms in As methylating enzymes may be responsible, for the different excretion of urinary arsenic metabolites, but further research is needed to identify genetic polymorphisms and altered gene expression in this population (NIEHS 04940).

894 DRINKING WATER ARSENIC EXPOSURE IS ASSOCIATED WITH DECREASED DNA REPAIR GENE EXPRESSION.

A. S. Andrew[1], M. R. Karagas[1], L. Klei[2] and J. W. Hamilton[2]. *[1]Community and Family Medicine, Dartmouth Medical School, Lebanon, NH and [2]Pharmacology and Toxicology, Dartmouth Medical School, Hanover, NH.*

Arsenic is well established as a human carcinogen, but its precise mechanism of action remains unknown. Arsenic does not directly damage DNA, but may act as a carcinogen through inhibition of DNA repair mechanisms, leading indirectly to increased mutations from other DNA damaging agents. The molecular mechanism underlying arsenic inhibition of nucleotide excision repair after UV irradiation is unknown, but could be due to decreased expression of critical genes involved in nucleotide excision repair of damaged DNA. This hypothesis was tested by isolating mRNA from cryopreserved lymphocytes taken from individuals enrolled in a population based case-control study investigating arsenic exposure and cancer risk in New Hampshire. Arsenic levels were determined in toenail clippings using instrumental neutron activation analysis and drinking water samples using high resolution ICP-MS with hydride generation. We previously measured expression of nucleotide excision repair genes by RT-PCR using mRNA from 16 individuals. In a linear regression analysis, toenail and drinking water arsenic levels were inversely correlated with expression of critical members of the nucleotide excision repair complex including, ERCC1, XPF, and XPB, but not XPG. Nucleotide excision repair gene expression was re-examined in mRNA isolated from 54 individuals by real-time PCR using Taqman primers and probes. Levels of nucleotide excision repair proteins in the lymphocytes were also compared by immunoblotting on a subset. Our findings, based on human exposure to arsenic in a US population, show an association between biomarkers of arsenic exposure and expression of DNA repair genes. These results are consistent with the hypothesis that inhibition of DNA repair capacity by arsenic in drinking water is a potential mechanism by which arsenic can contribute to increased cancer risk (supported by NIEHS ES07373, NCI CA57494).

895 HAZ-MAP: OCCUPATIONAL HEALTH INFORMATION FOR THE PUBLIC.

H. F. Chang, V. W. Hudson and G. F. Hazard. *National Library of Medicine, National Institute of Health, Bethesda, MD.* Sponsor: G. Fonger.

Haz-Map is an occupational toxicology database designed primarily for health and safety professionals, but also for consumers seeking information about the health effects of exposure to chemicals at work. It links jobs and hazardous tasks with occupational diseases and their symptoms. This relational database of chemicals, jobs, and diseases is part of the TOXNET system of databases on toxicology and environmental health provided by the National Library of Medicine (NLM) on the internet. The approximately 1000 chemicals and biological agents in the database are related to industrial processes and other activities such as hobbies. The linkage indicates the potential for exposure to the agents. The 180 occupational diseases and their symtpoms are associated with hazardous job tasks. This association indicates an increased risk for significant exposure and subsequent disease. NLM developed the Haz-Map Web interface which is accessible to the public *via* the internet. Main features of the Haz-Map Web interface include: text search capability, browsing by hierarchical categories, alphabetical listing of entries in all tables, searching hazardous agents by adverse effects, searching diseases by jobs and findings, and launching searches to NLM's TOXNET system of databases from Haz-Map. Users can easily find definitions of technical terms by clicking hyperlinks to the glossary. The purpose of the poster is to introduce users to the contents and sources of Haz-Map, and to demonstrate the features and navigation of this new occupational medicine resource.

896 HOUSEHOLD EXPOSURE TO PHTHALATES, PESTICIDES, ALKYLPHENOLS, PBDES, AND OTHER ENDOCRINE ACTIVE COMPOUNDS.

R. Rudel[1], D. Camann[2], J. D. Spengler[4], D. Barr[3] and J. G. Brody[1]. *[1]Silent Spring Institute, Newton, MA, [2]SWRI, San Antonio, TX, [3]HSPH, Boston, MA and [4]USCDC, Atlanta, GA.*

In order to characterize exposures to chemicals of interest for research on breast cancer and other hormonally mediated health outcomes, residential air and dust samples were analyzed for 93 target compounds that 1) have been identified as animal mammary carcinogens or endocrine active chemicals and 2) are used in commercial or consumer products. In data from 120 homes sampled on Cape Cod, MA, 64 of 93 target compounds were detected in indoor air and 72 of 92 were detected in house dust. Chemicals present at highest concentrations in air samples include: diethyl phthalate (DEP) (range 130-4, 300 ng/m3), dibutyl phthalate (DBP) (52-1, 100 ng/m3), o-phenyl phenol (oPP) (12-970 ng/m3), and nonylphenol (NP) (21-420 ng/m3). These concentrations are 2-3 orders of magnitude higher than indoor air concentrations of, for example, the ubiquitous PAH pyrene; suggesting that these chemicals may be important indoor air contaminants. Most abundant compounds in dust include DEHP (range 16.7-7, 700 microgram/g) and several other phthalates. Also commonly detected in dust were NP, OP and their ethoxylates, polybrominated diphenyl ethers, bisphenol A, benzo-a-pyrene, methyl paraben, and several pesticides. Pesticides detected in at least 50% of the homes include: oPP, permethrin, piperonyl butoxide, methoxychlor, DDT, pentachlorophenol, and chlordane. On average, 21 target compounds were detected in each indoor air sample and 28 in each dust sample. For 31 of the chemicals detected, no risk-based criteria are available for evaluating potential health effects, and risk based criteria that are available for the remaining chemicals generally do not consider their endocrine activity. This study identifies endocrine active chemicals that are widespread in indoor environments, making them priorities for future research and regulatory evaluation, for example Tier 2 testing as recommended by EDSTAC. It also provides new exposure assessment tools for the study of hormonally mediated health outcomes.

897 DIOXIN LEVELS IN HUMANS AND FOOD FROM AGENT ORANGE SPRAYED AND NON-SPRAYED AREAS OF LAOS AND VIETNAM COMPARED TO THE USA, GERMANY AND CANADA.

A. Schecter[1], M. Pavuk[1], R. Malisch[2], O. Paepke[3], J. Ryan[4], H. Phoupaseuth[5], L. Dai[6] and J. D. Constable[7]. *[1]Environmental Sciences, University of Texas School of Public Health, Dallas, TX, [2]State Institute for Chemical and Veterinary Analysis of Food, Freiburg, Germany, [3]ERGO Research, Hamburg, Germany, [4]Health Canada, Ottawa, AB, Canada, [5]Center for Laboratory and Epidemiology, Ministry of Public Health, Vientiane, Lao, [6]Vietnam Red Cross, Hanoi, Viet Nam and [7]Harvard Medical School, Boston, MA.*

Laos and Vietnam were countries sprayed with Agent Orange herbicide between 1962 and 1971. Agent Orange was contaminated with TCDD. High levels of TCDD have been reported in sprayed areas of Vietnam in human milk, up to 1,

850 ppt lipid, blood, up to 413 ppt, fish, up to 850 ppt, and soil, up to 1, 100, 000 ppt. Most Vietnam samples were lower. Dioxin studies in Laos have not previously been conducted. We report here the first dioxin measurements from Laos, in non-sprayed Vientiane and in sprayed Sepone City. Blood, human milk, and food were sampled and analyzed. Unlike Vietnam, levels of TCDD were always low in human milk, blood, and in food, from sprayed and non-sprayed areas examined. The highest blood TCDD was 4 ppt in a 55 year-old man from Sepone. Other values were not detectable or very low. Food was lower or similar in dioxin levels to American and European food. Exported Vietnamese food purchased in the USA was also very low in dioxins. Although generally lower, there was some overlap in dioxin levels in Laotian and exported Vietnamese food compared to US and European food. We speculate as to why Laotian human tissue and food levels in sprayed areas did not show elevation of TCDD: The persons sampled were relatively young and born after spraying ended. The defoliant sprayed may not have been Agent Orange, or if Agent Orange, may have been washed away over the years during yearly flooding. Further collaborative research in various locations in Laos is planned.

898 USING COTTON T-SHIRTS AS A SURROGATE FOR CHILDREN'S HOME EXPOSURE FROM FLEA CONTROL COLLARS CONTAINING CHLORPYRIFOS.

J. S. Boone, J. Tyler, K. Davis and J. E. Chambers. *CEHS, College of Veterinary Medicine, Mississippi State University, Mississippi State, MS.*

Twelve family units were chosen to determine the levels of insecticide that could be transferred to children from a flea control collar from a pet dog. One child (3 to 12 years) from each household wore t-shirts 5 different days before the application of the collar and for 5 consecutive days between days 14 and 20-post collar application (5 pre and 5 post). The dogs were petted to determine available transferable residues on days 14 and 20 using white cotton gloves. Commercially available flea control collars containing the organophosphate insecticide chlorpyrifos (8%) were applied to dogs as per package directions. Transferable residues were quantified by petting the dog for 5 minutes in 3 areas (neck with collar, neck, and back) and yielded averaged transferable residues of 136-974 µg, 68-622 µg, and 1-22 µg, respectively. The averaged t-shirt (100 in^2 front chest area) samples were 0.29 µg for the pre-application and 0.74 µg for the post-application. Most samples ranged from <2.5 pg to 2 µg with one sample at 12 µg (the 5th post-application sample of family 105 - 105post5). The remaining 105post5 shirt was analyzed for 9 additional regional sections and yielded residues of: 9.95, 7.84, 9.29, 4.99, 5.72, 6.80, 3.88, 7.17, and 4.85 µg. Since the other post-application t-shirts (1st, 2nd, 3rd, and 4th) for 105 were 0.69, 0.99, 0.76, and 0.62 µg, the 12 µg could be from another source. The average post application residue decreased to 0.52 µg without the 105post5 sample. The 109 household gave the next highest samples (0.78, 2.87, 2.44, 1.77, and 0.65 µg; post 1-5 respectively). The remaining 109post2 whole shirt yielded residues of: 0.99, 0.65, 0.66, 0.36, 0.72, 0.99, 1.38, 0.72, and 0.63 µg. The 109 household also gave the highest pre-application (1-5) samples (0.5, 1.94, 0.24, 2.02, and 0.33 µg, respectively). Introduction of flea control collars containing chlorpyrifos into homes may increase amounts of transferable residues, but variability is high. (Supported by EPA R-828017).

899 BIOMARKER MEASUREMENTS IN A FISH-EATING POPULATION EXPOSED TO ORGANOCHLORINES.

P. Ayotte[1,2], D. Pereg[2], C. Larochelle[2], E. Dewailly[1,2] and M. Feeley[3]. *[1]Social and Preventive Medicine, Laval University, Ste-Foy, QC, Canada, [2]Public Health Research Unit, CHUQ-Laval University Medical Centre, Ste-Foy, QC, Canada and [3]Health Canada, Ottawa, ON, Canada.*

The Lower North Shore region of the Gulf of St. Lawrence (Canada) is home to a fish-eating population that displays an unusually high body burden of several organochlorines, including polychlorinated biphenyls (PCBs), polychlorinated dibenzo-p-dioxins and dibenzofurans. In order to evaluate health risks due to this exposure, we recruited 40 participants for the assessment of biomarkers of exposure and effects. Concentrations of 14 PCB congeners and dioxin-like compounds (DLCs) in plasma were measured by high-resolution gas chromatography and the CALUX assay, respectively. Morning urine samples were collected for D-glucaric acid and porphyrin analyses. Cotinine concentration was also determined in urine samples to document smoking habits. The caffeine breath test (CBT) was performed on a subset of participants. The mean concentration for the sum of PCBs in plasma lipids was 2.9 mg/kg, with values ranging from 0.3 to 5.9 mg/kg (median=2.8 mg/kg). Plasma lipid concentrations of DLCs averaged 159 ng TEQ/kg and ranged from 55 to 469 ng/kg (median=133 ng/kg). Neither total DLCs nor total PCBs were correlated to biomarkers of effects. The rate of caffeine 3-N demethylation (CBT), which reflects liver CYP1A2 activity, was positively correlated to urinary cotinine concentration (Spearman's R=0.59, p=0.005, N=21) and negatively correlated to the PCB 118/PCB 153 congener ratio in plasma (R=-0.50, p=0.021, N=21). Urinary coproporhyrin concentrations were also negatively correlated to the PCB 118/PCB 153 congener ratio (R=-0.35, p=0.03, N=40). Hence, despite the relatively high body burden of PCBs and DLCs in this population, only smoking had a significant influence on biomarkers of effects. The negative correlation observed between caffeine N-3 demethylation and the PCB 118/PCB 153 congener ratio likely reflects an increased biotransformation rate of the mono-ortho PCB congener 118 in individuals with high CYP1A2 activity due to smoking.

900 CONCENTRATIONS OF PERSISTENT ORGANIC POLLUTANTS IN HUMAN MILK FROM NUNAVIK (ARCTIC QUEBEC, CANADA): CHANGES OBSERVED FROM 1989 TO 2001.

D. Pereg[1], P. Ayotte[1], G. Muckle[1], J. J. Ryan[2], S. Gingras[1] and É. Dewailly[1]. *[1]Public Health Research Unit, CHUQ-Laval University Medical Center, Ste-Foy, QC, Canada and [2]Health Canada, Ottawa, ON, Canada.*

Over the last decades, declining concentrations of organochlorines and increasing concentrations of polybrominated diphenyl ethers (PBDEs) have been reported in human milk collected worldwide. The objective of this study was to determine if similar changes could be observed in the Inuit population of Nunavik, which is particularly exposed to persistent organic pollutants through their traditional diet. Concentrations of 5 chlorinated pesticides, polychlorinated biphenyls (PCBs, 12 congeners), polychlorodibenzo-*p*-dioxins (PCDDs) and polychlorodibenzofurans (PCDFs) were determined in milk samples collected in this population between 1996-2000 (n = 46 to 55). These data were compared with those obtained in a human milk survey carried out in 1990 in the same region (n = 12 to 43). A similar comparison was carried out for PBDEs using 10 archived samples from each group. Concentrations were expressed on a lipid basis. TEQs were computed for dioxin-like compounds (DLCs: PCB congeners # 77, 126 and 169, PCDDs and PCDFs). Geometric means and confidence intervals ($CI_{95\%}$) were computed for concentrations of all contaminants (when detected) and compared (t-tests). Our results showed an 86% decrease ($p<0.0001$) in human milk concentrations of DLCs, from 43.26 ppt TEQs in 1990 ($CI_{95\%}$[34.27-54.60]) to 6.09 in 2000 ($CI_{95\%}$[4.07-9.12]). TEQs attributable to PCBs, PCDDs and PCDFs showed significant decreases of 90%, 87% and 76%, respectively. Ortho-substituted PCB congeners and organochlorine pesticides showed decreases averaging 66%. However, concentrations of PBDEs (sum of 9 congeners) showed a 70% increase ($p<0.0001$), rising from 5500 ppt in 1990 ($CI_{95\%}$[3240-9320]) to 9320 ppt in 2000 ($CI_{95\%}$[6570-13210]). The decline in organochlorine concentrations and the increase in PBDE concentrations in human milk from Nunavik are both consistent with results from other studies carried out worldwide.

901 ELEVATED BLOOD LEAD FROM GUNSHOT UP TO ONE YEAR AFTER INJURY.

J. L. McQuirter[1], S. J. Rothenberg[2,1], G. A. Dinkins[1], V. S. Kondrashov[1], M. Manalo[1] and A. C. Todd[3]. *[1]Oral and Maxillofacial Surgery, Drew University of Medicine & Science, Los Angeles, CA, CA, [2]Center for Research in Population Health, National Institute of Public Health, Cuernavaca, Morelos, Mexico and [3]Community and Preventive Medicine, Mt. Sinai School of Medicine, New York, NY.* Sponsor: M. Soliman.

There are no systematic studies of prevalence or antecedents of elevated blood lead concentration (BPb) in gunshot victims despite a century of published case studies. We studied patients with retained lead bullets for 12 months. We measured BPb (via AAS) from admission to one year, bone lead (KXRF) in the first six weeks and again at one year, patient and injury characteristics. Prevalence of BPb ≥20 µg/dl at mean of 0.3, 3, 18, 94, 188 and 363 days was 0.3, 2.0, 6.8, 9.8, 5.0 and 3.1%, respectively. Logit regression for BPb ≥20 µg/dl at 90 days after injury showed odds ratios (OR) (95% CI) of 6.5 (1.8-23.4) for patients shot in head, 3.1 (1.2-8.3) for patients shot in femur and 13.3 (4.4-40.3) for patients with bone fracture in torso. Every natural log increase in age was associated with an OR of 4.7 (1.2-17.9) and an OR of 1.6 (1.3-2.1) for every natural log increase in number of retained fragments. The logit model correctly predicted outcome in 79% of cases. In mixed model analysis for repeated measures over the first three months BPb increased 31% for every ln unit in number of retained fragments and increased 51% for every common log unit of days after injury. The effect of number of fragments on BPb increased significantly with time after injury; the effect of number of fragments on BPb was 28% greater in patients with bone fracture in torso than in those without such fracture. BPb increases with time in a majority of gunshot patients up to 90 days after injury. ~10% of patients have BPb approaching or exceeding CDC action limits at 90 days and a few patients show sustained elevations or increasing BPb out to 12 months after injury. These patients may go on to develop frank lead toxicity.

902 USEPA'S RESPONSE ACTIVITIES TO THE WORLD TRADE CENTER DISASTER.

A. Galizia. *USEPA, Edison, NJ.* Sponsor: S. Gavett.

The United States Environmental Protection Agency (USEPA) as well as other Federal, State and local agencies, responded promptly to the unprecedented attack on and subsequent collapse of the World Trade Center (WTC)towers. The USEPA's

response to address potential harm to human health and the environment associated with this catastrophic event included command, operational and monitoring activities. Command activities were coordinated by the Federal Emergency Management Agency (FEMA), with participation by Region 2 and other regional and national offices. Operational activities included dust suppression by HEPA vacuuming and power washing, set up of vehicle, personnel and landfill wash stations; distribution of appropriate protective equipment for the rescue workers; development of a database system and a website for the monitoring data; outreach to public officials, the public and community groups. The monitoring effort consisted of sampling at an extensive network of air monitoring stations, as well as targeted water and bulk dust sampling. The air monitoring network was established to address potential effects of demolition construction materials (PM, Asbestos, lead) and products of incomplete combustion (dioxins, VOCs, PCBs, PAHs). Much of the data from this monitoring effort can be obtained from the USEPA website, www.epa.gov under Response to September 11th. Results from the monitoring done at the World Trade Center and nearby surrounding areas show that: (1)there was no real impact to ambient, discharge and drinking water due to the WTC disaster; (2)there were some exceedences of benchmark air standards for the contaminants of concern, but they generally occurred soon after September 11. For example, a single PM2.5 exceedence of the Air Quality Index of 40 ug/m3 was reported in the days that follow September 11. Also, asbestos was found to exceed the AHERA standard of 70 s/mm2 in less than 1% of the samples taken in lower Manhattan. For lead, a few early samples were above the National Ambient Air Quality Standard (NAAQS) of 1.5ug/m3 but were well below the OSHA Permissible Exposure Limit (PEL) of 50 ug/m3.

903 PREDICTING RISK OF HOSPITAL ADMISSIONS USING AN AIR POLLUTION MODEL.

M. R. Francois[1], P. C. Grivas[1], J. Studnicki[2] and R. D. Harbison[1]. *[1]Center for Environmental/Occupational Risk Analysis and Management, College of Public Health, University of South Florida, Tampa, FL and [2]Center for Health Outcomes Research, College of Public Health, University of South Florida, Tampa, FL.*

A set of environmental indicators was constructed into a model in an attempt to predict respiratory-related hospital admissions. This model was subsequently tested on the sixty-seven counties in Florida. Government databases were reviewed to access the 1996-1999 estimates of environmental releases for the State of Florida by county. The environmental indicators selected included: carbon monoxide (CO), nitrogen dioxide (NO2), particulate matter less than 10 microns (PM10), particulate matter less than 2.5 microns (PM2.5), sulfur dioxide, volatile organic compounds, ammonia, and total industrial releases. In addition, a socio-economic indicator, an estimate of the percentage of adult smokers and the median age were obtained for each county. The second set of data was comprised of the Florida Agency for Health Care Administration's hospital discharge diagnosis data for each county in 1996-1999, for four respiratory diagnoses. Those admissions with the International Classification of Diseases (ICD-9) codes 506-519 encompassed respiratory conditions due to chemical and fumes, pneumonitis, emphysema, pleurisy, pneumothorax, and lung abscess. The ICD-9 codes 480-486 included diagnoses of pneumonia and influenza. The Chronic Obstructive Pulmonary Disease (COPD) category was represented by the ICD-9 codes 490-496. The diagnosis of asthma was extracted from the dataset by ICD-9 code 493. GB-Stat V8.0 and SAS were used to analyze the data. For these four years, the full model explained 92% to 95% of these admissions. Carbon monoxide was consistently one of the top five predictors, followed by PM2.5, PM10, hazardous air pollutants (HAP) and NO2. This model appears to be a valid tool for predicting respiratory-related hospital admissions in Florida.

904 BLOOD HOMOCYSTEINE (HCY) LEVELS IN NON-SMOKERS EXPOSED TO ENVIRONMENTAL TOBACCO SMOKE (ETS) AND THE EFFECT OF POLYMORPHISMS IN THE GLUTATHIONE-S-TRANSFERASE M (GSTM), GLUTATHIONE-S-TRANSFERASE T (GSTT) AND NAD(P)H QUINONE OXIDOREDUCTASE (NQO1) GENES.

N. J. Martin[2], L. A. Bowen[1], G. Cutter[3], S. Clodfelter[3] and C. A. Pritsos[1,2]. *[1]Nutrition, University of Nevada, Reno, NV, [2]Environmental Sciences and Engineering, University of Nevada, Reno, NV and [3]Department of Internal Medicine, University of Nevada, Reno, NV.*

Exposure to ETS may be a risk factor for cardiovascular disease (CVD). HCY is an independent risk factor for CVD whose mechanism of toxicity is thought to result from endothelial damage through oxidative processes. GST and NQO1 are Phase II detoxifying enzymes whose activities can prevent oxidative damage. As part of the Nevada Environmental Tobacco Smoke and Health Study funded by NIEHS, non-smokers, confirmed by serum cotinine, occupationally exposed to ETS and not living with a smoker were tested for plasma HCY levels as part of their baseline analysis and blood drawn with informed consent. Plasma HCY levels were assessed by HPLC with fluorescence detection at 385 nm excitation and 575 nm emission. GST polymorphisms were assessed in DNA from whole blood by multiplex PCR followed by separation on an agarose gel. NQO1 polymorphism (C-T transversion at 609 bp) was assessed with PCR followed by Hinf1 restriction endonuclease digest and separated by agarose gel electrophoresis. Preliminary findings based upon the analysis of 36 subjects indicates no relationship between plasma HCY levels and polymorphisms for any of the genes. Interestingly however, overall plasma HCY levels for males in the study population was 10.6 ± 2.7 μM and 9.6 ± 2.0 μM for females. These values are 13% and 23% higher than previously reported normal values for men and women respectively. A significant difference ($p<0.05$) in HCY levels between Caucasians and non-Caucasians was observed, with a value 2.6 μM higher in the Caucasian population. These preliminary results suggest that non-smokers exposed to workplace ETS exposure may have higher plasma HCY levels than the general population. These studies were funded in part by PHS NIEHS grant ESO0520 and the Fund for a Healthy Nevada.

905 SERUM OXIDIZED LDL LEVELS ARE INCREASED IN NONSMOKERS EXPOSED TO ENVIRONMENTAL TOBACCO SMOKE (ETS) AND ASSOCIATED WITH GENETIC POLYMORPHISMS IN GST-T, GST-M, AND NQO1.

L. D. Bowen[1], G. Cutter[3], S. Clodfelter[3] and C. A. Pritsos[1,2]. *[1]Nutrition, University of Nevada, Reno, NV, [2]Environmental Sciences and Engineering, University of Nevada, Reno, NV and [3]Internal Medicine, University of Nevada, Reno, NV.*

Exposure to ETS may be a risk factor for cardiovascular disease (CVD). Oxidized LDL (OxLDL) is considered to be an independent risk factor for CVD. In this study we looked at whether workplace exposure to ETS in non-smokers had an effect on serum OxLDL levels. Genetic polymorphisms to Phase II detoxification enzymes such as the glutathione-S-transferases and NAD(P)H quinine oxidoreductases (NQO1) could impact the extent to which ETS effects OxLDL levels. We tested whether genetic polymorphisms in glutathione-S-transferase-μ(GST-μ), glutathione-S-transferase-θ(GST-θ) or NQO1 affected OxLDL levels in these non-smoker, ETS exposed subjects. Blood samples were obtained from subjects in the Nevada ETS and Health Study. EIA was used to quantitatively measure serum autoantibodies against OxLDLs. Genetic polymorphisms were identified using DNA extracted from whole blood. GST- μ and GST- θ were qualitatively identified with multiplex PCR followed by agarose gel electrophoresis for null or wild type genotypes. A single nucleotide polymorphism of NQO1 was assessed with PCR and subsequent restriction digest and agarose gel electrophoresis. Preliminary findings suggest that our cohort of ETS exposed non-smokers had OxLDL values higher than previously reported OxLDL values for non-smokers. When stratifying these results for the GST and NQO1 polymorphisms, no difference was seen between the groups except for the group displaying the polymorphism in both GST-μ and GST-θ. These subjects had a significantly higher oxidized LDL ($p<.031$) than the other groups. These results suggest that non-smoker workplace exposure to ETS increases serum oxidized LDL and that the presence of a polymorphism in both GST-μ and GST-θ significantly increases serum oxidized LDLs and therefore may increase the risk for cardiovascular disease. This study was funded in part by PHS, NIEHS grant ESO9520 and the Trust Fund for a Healthy Nevada.

906 ASSOCIATION BETWEEN URINARY PORPHYRINS, MERCURY, SYMPTOMS, AND MOOD.

N. Heyer[1], D. Echeverria[1,2], J. S. Woods[1,2] and C. Garabedian[1]. *[1]Battelle CPHRE, Seattle, WA and [2]Environmental Health, University of Washington, Seattle, WA.*

Potential associations between urinary porphyrins and urinary mercury (Hg) (0-10 ug/l) with 68 self reported symptoms and 6 mood scales was conducted among 81 male dentists (DDs) and 97 female dental assistants (DAs) in Washington State. Symptoms were categorized as current (today), recent (past 3 months) and chronic (> one year). The Profile on Mood State measured 6 mood scales. Pooled copro-, precopro, and penta-carboxyl urinary porphyrins and mercury were measured at the time of the symptom and mood survey. Crude correlations were used to identify a set of potential determinants ($p<.05$) that were later tested in multiple regression models. Differences between sexes were sufficient to support separate analyses. Pooled copro-, precopro-, and penta-porphyrins were strongly associated (Beta =0.42 or 0.49) with urinary mercury at levels about 0-10 ug/l. Urinary Hg was associated with reported paresthesias among DDs (chronic only) and DAs (all 3 temporal categories), as well as with reports of chronic symptoms of muscular weakness and coordination among DDs. Urinary porphyrins were also associated with chronic muscular symptoms among DDs. Among DAs, urinary porphyrins were associated with recent and chronic symptoms involving memory and paresthesias,

as well as current anxiety and chronic skin symptoms. With respect to mood, urinary Hg was associated with mood among DAs while urinary porphyrins were associated with several dimensions of mood among DDs, however, these associations were in an unexpected direction. A number of self reported medical conditions and medication for these symptoms appeared as potential confounders, being associated with both porphyrin and Hg measures of exposure and the symptom and mood outcomes. This was particularly true for women with immune or endocrine conditions. In this study, porphyrin excretion levels were more closely associated with the outcomes generally attributed to Hg exposure, especially memory, and may be an important alternative measure of the effects of Hg exposure. Supported by ES04696 and ES07033.

907 ASSOCIATION OF TAMOXIFEN (TAM) AND TAM METABOLITE CONCENTRATIONS WITH SELF-REPORTED SIDE EFFECTS OF TAM IN WOMEN WITH BREAST CANCER.

L. Gallicchio[1], L. Lewis[1], K. Tkaczuk[2] and J. A. Flaws[1,2]. *[1]Epidemiology and Preventive Medicine, University of Maryland at Baltimore, Baltimore, MD and [2]The Greenebaum Cancer Center, University of Maryland School of Medicine, Baltimore, MD.*

The positive effects of tamoxifen (TAM) on breast cancer recurrence and survival as well as on overall mortality has led to its use as the predominant adjuvant therapy among women with breast cancer. However, the association of TAM intake with several undesirable side effects has been reported in numerous studies. This analysis was carried out to assess whether the concentrations of TAM or TAM metabolites, N-desmethyltamoxifen (N-DMT) and 4-hydroxytamoxifen (4-OHT), were associated with self-reported side effects of TAM in women diagnosed with breast cancer. Participants were 76 post-menopausal breast cancer patients who had been taking TAM for at least 30 days. Each participant completed a questionnaire that was used to ascertain whether she experienced certain specific symptoms while taking TAM. In addition, each woman provided a blood sample that was used to measure plasma concentrations of TAM, N-DMT, and 4-OHT by high pressure liquid chromatography. Results of the analysis showed that women who reported experiencing visual problems or fever had significantly higher levels of both TAM and N-DMT compared to those women who reported experiencing no visual problems or fever. In addition, women who reported experiencing nausea or migraines had significantly higher levels of N-DMT than women who did not experience these side effects. 4-OHT levels were not significantly associated with any TAM-related symptoms. The results of this study suggest that the self-reported occurrence of certain symptoms during TAM treatment is related to TAM metabolism. Future studies should assess subgroups of women with specific TAM and TAM metabolite profiles to determine whether alternate, equally effective therapies would decrease their risk of experiencing certain undesirable side effects. Supported by DOD Grant DAMD17-00-1-0321 and the University of Maryland, Maryland Statewide Health Network.

908 DIETARY EXPOSURE ASSESSMENT OF CADMIUM CLOSE TO THE CURRENT PROVISIONAL TOLERABLE WEEKLY INTAKE AND ITS EFFECTS ON RENAL BIOMARKERS AMONG FEMALE FARMERS IN JAPAN.

F. Kayama[2,1], H. Horiguchi[2,1], E. Oguma[2,1], S. Sasaki[3], K. Miyamoto[2], Y. Ikeda[2] and M. Machida[2]. *[1]Health Science, Jichi Medical School, Kawachi-Gun, Tochigi, Japan, [2]Nutrition, National Institute of Health and Nutrition, Tokyo, Tokyo, Japan and [3]CREST, JST, Kawaguchi, Saitama, Japan.* Sponsor: T. Yoshida.

Cadmium (Cd) is reported to induce renal tubular damage at higher oral exposures. However, few epidemiological studies with precise assessment of dietary Cd exposure have been undertaken to evaluate the effects on health of Cd in food. The present epidemiological study was undertaken to evaluate whether sustained low-dose dietary Cd exposure may increase prevalence of renal dysfunction among 1310 female farmers of 5 districts in Japan who consumed their own rice with various levels of Cd contamination. The geometric means of Cd concentrations in the rice (R-Cd) collected from study participants were 0.022, 0.061, 0.054, 0.113, and 0.154 microg/g in district A, B, C, D, and E, respectively. The estimates revealed that 0.5 - 2.5% of the participants in district A were exposed to a higher Cd dose than the current Provisional Tolerable Weekly Intake (PTWI), i.e. 4.5 - 20.3% in district B, 6.9 - 22.2% in district C, 24.0 -52.5% in district D, and 35.6 - 66.8% in district E. Creatinine-adjusted urinary Cd (U-Cd) and blood Cd (B-Cd) increased age-dependently, and correlated with the degree of Cd contamination in the districts. Both urinary alpha1-microglobulin and beta2-micoroglobulin, biomarkers of renal tubular dysfunction, showed statistically significant increases in an age-dependent manner in all the districts, but were correlated with neither University-Cd nor B-Cd, nor R-Cd. Multiple regression analysis depicted no significant increase in the prevalence of renal biomarkers in each district after adjustment for age. In conclusion, this study showed that the prevalence of renal tubular dysfunction remains the same among female farmers exposed to life-long dietary Cd close to or above the current PTWI. This research protocol was approved by the Committee on Medical Ethics in Jichi Medical School.

909 ISCHEMIC HEART DISEASE AMONG MINERS.

B. Sjögren[1], L. Barlow[2] and J. Weiner[3]. *[1]Work Environment Toxicology, Institute of Environmental Medicine, Karolinska Institutet, Stockholm, Sweden, [2]Centre for Epidemiology, National Board of Health and Welfare, Stockholm, Sweden and [3]Swedish Work Environment Authority, Solna, Sweden.* Sponsor: G. Johanson.

Miners are exposed to gases and respirable particles. Some previous studies have observed an increased mortality regarding ischemic heart disease (IHD) among miners and industrial sand workers. Objective: This study is a comparison of male miners with gainfully employed men in Sweden in order to investigate the occurrence of ischemic heart disease (IHD). Methods: Male miners were identified in the Swedish National Census. Miners with the same occupation in 1970 and 1980 were included. The referent group comprised all gainfully employed men with the same occupation in the 1970 and 1980 censuses. The cohort was followed from 1980 until December 31, 1995. All workers were identified and linked to the Cause of Death Register during the period of follow-up. Ischemic heart disease (IHD) was defined as code 410-414 of the International Classification of Diseases (ICD 7 and 8). The Standardized Mortality Ratio (SMR) has been calculated as the ratio between observed and expected numbers of deaths. Result: An increased risk due to IHD was observed among the miners, table 1. Conclusion: The increased risk of IHD is unlikely explained by smoking habits. Smoking habits were surveyed in the male population in 1963 and found to be almost identical between miners and the general male population. Shift work might explain some of the increased risk. Inhalation of air pollutants retained in the lungs will hypothetically create a low grade inflammation associated with an increase in plasma fibrinogen. The high concentration of fibrinogen will increase the likelihood for blood clotting and thereby the risk for myocardial infarction and IHD. Table 1. Standardized Mortality Ratios (SMR) of IHD among miners identified in the 1970 and 1980 Censuses and followed until the end of 1995.

Observed	Expected	SMR	95% confidence limits

910 USE OF THE GLOBAL ASSESSMENT SYSTEM FOR HUMANS IN MILITARY VETERANS TO DISCRIMINATE PERFORMANCE DEFICITS.

M. Y. Bekkedal[1], G. D. Ritchie[1], F. J. McDougle[1], S. M. McInturf[1], J. Rossi III[1] and . *[1]Neurobehavioral Effects Laboratory, Naval Health Research Center Detachment-Toxicology, Wright-Patterson AFB, OH and [2]Veterans Administration Medical Center, Dayton, OH.* Sponsor: E. Kimmel.

Acute and chronic exposures to neurotoxic compounds can compromise performance capabilities with effects ranging from minor to severe. The Global Assessment System for Humans (GASH) is a comprehensive set of neurobehavioral tests that is being developed to detect performance compromise resulting from exposure to neuroactive compounds and/or stressors. Last year we presented data using the GASH to identify performance deficits in military personnel exposed occupationally to jet fuel as part of our ongoing effort to systematically determine which neurobehavioral tests to include in the GASH. Tests are being selected based on ease of administration and sensitivity to detect and differentiate neurobehavioral deficits. In the current project 3 of the tests from the more comprehensive battery were used with military veterans in out-patient programs for either post-traumatic stress disorder (PTSD) or substance abuse (SA). They were evaluated by a clinical neuropsychologist prior to participation to confirm diagnosis. They were tested for performance on acoustic startle/prepulse inhibition (AS/PPI) with 3 different prepulse latencies (30, 60, & 120) to evaluate the integrity of a brainstem reflex gating mechanism for the response to loud bursts of sound, on eyeblink classical conditioning to assess a low level learning and memory system, and on a number of neuropsychological evaluation tasks from the computer-based Behavioral Assessment and Research System (BARS) where higher cognitive abilities were evaluated in tests of finger tapping, matching to sample, the Oregon dual task procedure, reaction time, symbol-digit matching, and serial digit learning. The results showed that acoustic startle and eyeblink conditioning were the tests that best discriminated between these groups. They demonstrated sufficient sensitivity to distinguish different aspects of neurobehavioral compromise in two separate groups of military veterans, and meet the criteria for inclusion in the final GASH product.

911 RISK FACTORS IN CARBON MONOXIDE POISONING.

D. D. Petersen[1] and D. Kobb[2]. [1]*Research & Development, USEPA, Cincinnati, OH and* [2]*Hyperbaric Medicine, University of Cincinnati, Cincinnati, OH.*

Carbon monoxide (CO) is a toxic by-product of the combustion of fossil fuels. In confined spaces, inefficient combustion sources, such as furnaces, stoves, kerosene heaters and automobiles can generate levels of CO that interrupt oxygen transport throughout the body, potentially resulting in death. CO interferes with oxygen transport primarily by avidly binding to the oxygen carrying pigment hemoglobin, rendering it incapable of its normal function of oxygen delivery to the tissues. CO also binds other iron-containing heme proteins like the cytochrome respiratory pigments in mitochondria, but these are secondary effects in the pathophysiology of CO. Emergency treatment for moderate to severely poisoned patients is primarily achieved through the use of hyperbaric oxygen treatment. At high pressure, sufficient oxygen dissolves in the blood plasma to provide oxygen to the tissues, making the poisoned hemoglobin irrelevant. During hyperbaric oxygen treatment, CO also dissociates from poisoned hemoglobin (carboxyhemoglobin) with a shorter half-time, leading to complete detoxification. In order to better prevent CO toxicity, we sought to understand the causal factors predisposing individuals to CO poisoning. We thus undertook a review of medical records from the Center for Hyperbaric Medicine in the University of Cincinnati Department of Emergency Medicine. We analyzed the records of patients by home address, age, gender, CO source, ethnicity, date of poisoning and educational status. We found that educational status was the strongest predictor of potential for CO poisoning. There was approximately a 50-fold difference in the poisoning rates between those with less than a grade-school education and those having a college degree. Clearly, education is a primary tool for the prevention of CO poisoning. These data illuminate the potential problem that the highest risk subpopulation is likely to have literacy problems, and may not be amenable to traditional public health education efforts.

912 ILLNESSES ASSOCIATED WITH A NOV. 1999 SPRINKLER APPLICATION OF METAM SODIUM IN EARLIMART, CA.

M. O'Malley[1], T. Barry[2], M. Verder-Carlos[1] and A. L. Rubin[3]. [1]*Worker Health & Safety Branch, Department of Pesticide Regulation, Cal-EPA, Sacramento, CA,* [2]*Environmental Monitoring Branch, Department of Pesticide Regulation, Cal-EPA, Sacramento, CA and* [3]*Medical Toxicology Branch, Department of Pesticide Regulation, Cal-EPA, Sacramento, CA.*

The pesticidal action of metam sodium (MS) is dependent on breakdown to gaseous methyl isothiocyanate (MITC). MITC and several other MS degradates (MIC, CS_2, H_2S) are ocular and respiratory irritants. On Nov. 13, 1999, an illegal MS sprinkler application to a field ~1/3 mile southeast of Earlimart, CA produced a plume of airborne degradation products that moved off-site over several neighborhoods. This movement was caused by a shift in wind direction and the development of a post-sundown atmospheric inversion layer. Eye or upper respiratory irritation was documented in 81% of 136 self-selected individuals in zone A (0-0.6 miles from the field), 61% of 18 in zone B (0.6-0.82 miles), 50% of 10 in zone C (0.82-1.08 miles), and 60% of 5 in zone D (>1.08 miles). Non-specific symptoms (headache, nausea, dizziness, shortness of breath, abdominal pain, vomiting, weakness) occurred in 61% of the 173 total individuals evaluated. 16% had respiratory complaints, including 2.9% with exacerbated asthma or other lower airway problems. MITC concentrations were estimated with a Gaussian air dispersion model (ISCST3), using data from a local weather station and prior MITC monitoring studies. Estimated 1-hr time weighted average concentrations in zone A fell between 0.5 and 1 ppm, with estimated peak 1-min concentrations as high as 7 ppm. These air concentration estimates and the corresponding symptoms were consistent with the regulatory values developed in DPR's recently released risk assessment of MITC following agricultural applications of MS (critical acute NOEL=220 ppb, based on eye irritation in humans at 800 ppb [REL=22 ppb]; critical subchronic NOEL=100 ppb, based on nasal epithelial atrophy in rats [REL=1 ppb]). This report highlights the potential health concerns surrounding sprinkler applications of MS.

913 COMPARATIVE ACUTE AND COMBINATIVE TOXICITY OF AFLATOXIN B1 AND FUMONISIN B1 IN ANIMALS AND HUMAN CELLS.

Y. Liu[1,2], L. Tang[1,2], M. Lian[1,2], C. McKean[1,2], H. Wu[1,2], H. Liu[1,2], C. W. Theodorakis[1,2], R. J. Kendall[1,2] and J. Wang[1,2]. [1]*Environmental Toxicology, Texas Tech University, Lubbock, TX and* [2]*The Institute of Environmental and Human Health, Texas Tech University, Lubbock, TX.*

Aflatoxin B1 (AFB1) and fumonisin B1 (FB1) are important food-borne mycotoxins that historically caused a variety of acute animals and human mycotoxicoses. Ubiquitous co-contamination of AFB1 and FB1 in human dietary components has been widely reported and is believed to play an important contributing role in high incidence of primary liver and esophageal cancers in certain areas of world. In this study, acute and combinative toxicity of AFB1 and FB1 were tested in F-344 rats and Mosquitofish (Gambusia affinis). Young male rats were randomly divided into five groups and were orally treated with 10.0, 4.64, 2.15, 1.0, and 0 mg/kg for AFB1 or 46.4, 10.0, 4.64, 2.15, and 0 mg/kg for FB1. The rats were observed for 7-days and lethality and toxic symptoms were recorded. The LD50 for AFB1 was calculated as 2.71 mg/kg with the 95% of confident limit (CI) at 2.00-3.69 mg/kg. No death was observed in FB1 treated groups although toxic symptoms in high dose groups are apparent. Healthy fish (half male and female) were randomly assigned to 6 groups and treated with 4.64, 2.15, 1.0, 0.464, 0.215, and 0 ppm of AFB1 or 10, 4.64, 2.15, 1.0, 0.464, and 0 ppm of FB1. The treated fish were observed for 5-days and death and toxic signs of fish were recorded. The LC50 for AFB1 was calculated to be 681 ppb with 95% CI at 420-800 ppb and LC50 for FB1 was 4.64 ppm with 95% CI at 2.15-10.0 ppm, respectively. Combinative studies used both biotoxins at doses of 1.0, 3/4, 1/2, 3/8, 1/4, and 1/8 LD50 or LC50 in both species. Additive toxic effects were observed in both species. Acute and combinative cytotoxicity of AFB1 and FB1 were also tested in human bronchial epithelial cells (BEAS-2B) and hepatoma cells (HepG2). These results will help for future studies on long-term combinative toxic and health effect of these mycotoxins and their mixtures. (Supported by the Soldier and Biological Chemical Command, US Army).

914 FOOD CONTAMINATION OF FUMONISIN B1 IN HIGH-RISK AREA OF ESOPHAGEAL AND LIVER CANCER.

J. wang[1,2], S. Wang[3], J. Su[5], T. Huang[5], X. Hu[4], J. Yu[5], Z. Wei[6], Y. Liang[6], Y. Liu[1,2], H. Luo[1,2] and G. Sun[3]. [1]*Environmental Toxicology, Texas Tech University, Lubbock, TX,* [2]*The Institute of Environmental and Human Health, Texas Tech University, Lubbock, TX,* [3]*Southeast University School of Public Health, Nanjing, China,* [4]*CDC Haian Branch, Huaian, China,* [5]*Guangxi Cancer Institute, Nanning, China and* [6]*Fusui Liver Cancer Institute, Fusui, China.*

Fumonisins (FNs), produced mainly by Fusarium moniliforme, are ubiquitous contaminants of cereal grains around the world. Fumonisin B1 (FB1), the representative toxin, was the causative agent for several animal mycotoxicoses, and has etiologically been linked to human esophageal and liver cancers in certain areas of South Africa and China. To study relationships between exposure to FNs and human cancer risks, we investigate current status of FB1 contamination in food samples in Huaian and Fusui. Both areas have among the highest incidence of esophageal and liver cancers in China. Corn samples were collected from individual households in Haian in December 2001 and from Fusui in May 2002. Corn samples were also collected in Zibo, Shangdong Province, an area with low incidence of both cancers. The enzyme-linked immunosorbent assay (ELISA) and immunoaffinity-HPLC methods were used for analysis of these samples. In corn samples collected from residents of Huaian, FB1 was detectable in 93.3% (70/75) of the samples with the medium at 3.2 ppm (range from 0.1 to 25.5 ppm). FB1 was also detected in 85.2% (52/61) of the Fusui samples with the medium at 0.6 ppm (range from 0.1 to 2.7 ppm). Nineteen out of 41 (46.3%) Zibo samples were also detected for FB1 with the medium at 0.9 ppm ranged from 0.1 to 5.7 ppm. Twenty-four out of 70 (34.3%) positive Huaian samples had level of FB1 larger than 2.0 ppm, as compared with the level been found only in 3/19 (15.8%) Zibo samples. The high contamination rates of FB1 found in food from these areas, along with other previous reports, suggest the possible contributing role of FNs in human esophageal- and hepato-carcinogenesis. (This work was supported by the NCI grant CA94683).

915 ANTIBODIES AGAINST MOLDS AND MYCOTOXINS AFTER EXPOSURE TO TOXIGENIC FUNGI IN A WATER-DAMAGED BUILDING.

A. Vojdani. *CEO, Immunosciences Lab. Inc., Beverly Hills, CA.*

Abstract Epidemiological studies have demonstrated an association between indoor fungal growth in water-damaged buildings and immunological symptoms. In relation to fungal antigens and allergens, there is significant emphasis on IgE mediated allergy. Since exposure to molds can cause IgE and non-IgE mediated allergy in humans, IgG and IgA antibody responses against different molds have been examined only in a few studies. The purpose of this study was to evaluate simultaneous measurements of IgG, IgM, IgA and IgE antibodies, as markers for fungal exposure, against the most common molds and their mycotoxins that have been cultured from water-damaged buildings as markers for fungal exposure. This study compared 40 patients occupationally exposed to molds with 40 control subjects without a history of exposure to indoor molds. Mold-exposed patients showed the highest levels of antibodies against one or more mold species. Most patients with high levels of antibodies against the antigens of molds exhibited elevated IgG, IgM, IgA or IgE antibodies against purified mycotoxins bound to human serum albumin (HSA), as well. This indicated patients' exposure to mold spores and mycotoxins.

These mold and mycotoxin antibodies were also detected in an insignificant percentage of healthy control subjects suggesting population exposure to environmental molds and mycotoxins. These antibodies against molds and mycotoxins are specific, since immune absorption studies demonstrated that only fungal specific antigens and mycotoxins could significantly reduce antibody levels. Detection of high cfu/m3 of molds, which strongly suggests the existence of a reservoir of spores at the time of sampling in the building along with a significant elevation in IgG, IgM or IgA antibodies against molds and mycotoxins, could be used as a marker for fungal exposure.

916 INHIBITION OF CERAMIDE SYNTHASE IN CORN SEEDLINGS INFECTED WITH *FUSARIUM VERTICILLIOIDES* OR EXPOSED DIRECTLY TO FUMONISIN B1 IN SOIL.

L. Williams[2,1], A. Glenn[2], C. Bacon[2], J. Showker[2] and R. Riley[2]. [1]*College of Agriculture and Environmental Sciences, University of Georgia, Athens, GA and* [2]*UDSA/ARS, Athens, GA.*

Fumonisins (FB) are water soluble mycotoxins produced by *F. verticillioides*, which is parasitic to corn plants. FBs are inhibitors of ceramide synthase. While FB1 is not known to cause plant disease, it is found in the ear, roots, and stalks of corn. FB1 in corn debris can be leached by rainfall and can move through soils intact. However, a large amount is bound in certain soils. In sandy loam soils, FB1 can be released under acid conditions. These data suggest that FB1 from corn debris, or produced by *F. verticillioides* in the soil, can accumulate in soil and under certain environmental conditions the FB1 could be released and become biologically available. The objectives of this study were to determine: i) can *F. verticillioides* produce FB1 in soil, ii) is the FB1 in soil biologically active, and iii) is FB1 in soil toxic to corn seedlings. Corn seeds were inoculated with spore suspensions from pathogenic or non-pathogenic strains of *F. verticillioides*. Seedlings were grown for 21 days in potting soil. The roots and soil were analyzed for sphingoid bases (a marker of ceramide synthase inhibition) and FB1, respectively. Only seedlings inoculated with the pathogenic strain had elevated levels of sphinganine and the degree of elevation was correlated with the severity of the pathology. FB1 was only detected in soil from the plants inoculated with the pathogenic strain. In a second experiment surface sterilized seeds were planted and watered for six days with of 1, 5, or 10 ppm FB1 and grown for 15 more days. The FB1 in soil and the sphinganine in roots were closely correlated with the FB1 dosage. Reduced root mass was noted at 10 ppm. These results show that under laboratory conditions i) FB1 can be produced by *F. verticillioides* in soil, ii) the soil FB1 taken up by plants is biologically active, and iii) FB1 in soil can have adverse effects on plants. Thus, providing proof in principle that FB1 in soil can cause corn seedling disease.

917 TRICLOSAN AS INHIBITOR OF THE SULFONATION AND GLUCRUONIDATION OF 3-HYDROXY-BENZO(a)PYRENE IN HUMAN LIVER.

L. Wang and M. O. James. *Department of Medicinal Chemistry, College of Pharmacy, University of Florida, Gainesville, FL.*

Triclosan (2, 3, 4'-trichloro-2'-hydroxydiphenyl ether) is a very common antibacterial agent used in a number of products as diverse as toothpaste, detergents, and clothing. Due to its similar structure to hydroxylated PCBs, which were recently demonstrated by our laboratory as potent inhibitors of sulfonation and glucuronidation of 3-hydroxy-benzo[a]pyrene (3-OH-BaP) in either fish or human, it is of interest and important that the health effects of triclosan be assessed. In this study, triclosan was shown to inhibit the sulfation and glucuronidation of 3-OH-BaP at low, environmentally relevant, micromolar concentrations (IC50, about 5/*mu*/M) in human liver. Second, kinetic studies suggested that the nature of the 3-OH-BaP sulfonation and glucuronidation inhibited by triclosan is non-competitive, similar to the inhibition of 3-OH-BaP sulfotransferase by hydroxylated PCBs in our previous research. Finally, the sulfonation and glucuronidation of triclosan were investigated. It was shown that triclosan was metabolized to the glucuronide (Vmax: 833 pmol/min/mg protein) more readily than sulfate (Vmax: 100 pmol/min/mg protein), as observed similarly in skin in previous study. These findings reveal that the commonly used, effective bactericide triclosan can create unwanted effects, and specifically may have important consequences for the biotransformation and toxicity of other phenolic xenobiotics.

918 SHORT TERM FEEDING OF 2, 4-HEXADIENAL (HX) ALTERS STOMACH GROWTH IN IMMEDIATE POST-NATAL SPRAGUE-DAWLEY RATS.

P. Lee[1,2] and C. Picchiottino[1]. [1]*Pediatrics, Medical College of Wisconsin, Milwaukee, WI and* [2]*Pharmacology & Toxicology, Medical College of Wisconsin, Milwaukee, WI.*

HX (an unsaturated aldehyde formed as the product of lipid peroxidation) is found naturally or as additives in many foods. Long term feeding of HX led to high incidence of forestomach cancers in mice and F344 rats. In F344 rats, short term feeding (10 days) also caused microscopic and macroscopic changes in their forestomach. We did short term feeding of HX to Sprague-Dawley rats to see whether it would change their gastric growth characteristics. HX (200 mg/kg/day) fed to ~26 day-old rats for 5 days led to an increase in total stomach weight (wt). Both fore and glandular stomach showed increases in their respective wts with the forestomach being more pronounced such that the ratio of fore/total stomach wts increased significantly. HX feeding did not affect the wt of the esophagus or kidney but decreased that of the liver. The increase in forestomach wt was dependent on the dose of HX and the duration of feeding. An increase in forestomach wt/100 gm body wt was evident even at 6.25 mg/kg of HX for 5 days but the total stomach wt/100 gm body wt did not attain significant difference from controls till the dose of HX reached 200 mg/kg for 5 days. At 200mg/kg of HX, a moderate increase in forestomach wt was found after 4 days of feeding. Further increase in forestomach wt was observed after 5 days. Changes in forestomach wt and fore/total stomach wt ratio were transient, as they returned to values comparable to controls 4 days after the cessation of HX feeding. HX seems to promote a selective growth in the stomach particularly the forestomach but not in other tissues studied. This suggests that HX targets the stomach, specifically the forestomach. How this growth promotion relates to cancer development in prolonged HX feeding is unknown at present.

919 EXPOSURE TO CARBON MONOXIDE AT ALTITUDE.

J. J. McGrath. *Physiology, Texas Tech University School of Medicine, Lubbock, TX.*

Over 35 million people live or visit at altitudes above 5, 000 ft in the United States; worldwide, the figure is closer to 80 million. Populations at altitude comprise residents, fully adapted to altitude, and short-term visitors or sojourners. It is the sojourner who is at greater risk from exposure to CO at altitude. The most prominent feature of the altitude environment, decreased oxygen tension (hypoxia) in the inspired air causes respiratory changes that affect the dosimetry and potential toxicity of CO. The NAAQS for carbon monoxide (CO) is 9 ppm for 8 hrs and 35 ppm for 1 hour exposure. These values are derived from studies in subjects with exercise-induced angina exposed to CO while exercising at sea level. Kleinman et al (1998) showed that time to onset of angina was reduced by both exposure to CO at sea-level (9%) or to clean-air exposures at high-altitude (11%), compared with clean air at sea level. However, joint exposure to CO at a high altitude reduced the time to onset of angina, relative to clean air, by 18%. Thus, CO presents a more significant threat to cardiac-impaired subjects at altitude. Moreover, emissions of CO from combustion sources are higher at altitude because of the lower oxygen tension in the atmosphere available for combustion. Accordingly, emissions from snowmobiles, older vehicles and vehicles whose emission controls have been altered by tampering, heating and cooking devices are all increased at altitude. CO measurements made along a snowmobiling trail in the Grand Teton National Park, WY were as high as 23 ppm with individual measurements as high as 45 ppm (Snook and Davis, 1997). Ambient CO concentrations in various microenvironments may also be elevated at altitude. Measurements made in diverse shelters (tents, igloos, snow caves) on Denali, AK usually exceeded 35 ppm and reached a maximum of 190 ppm (Turner et al, 1988). Therefore, CO presents a special hazard at altitude because of the altered physiological status of healthy individuals and cardiac-impaired subjects, the pathophysiological status of cardiac impaired subjects and its increased production by combustion sources.

920 MORPHOLOGICAL CHANGES AND METAL ACCUMULATION IN THE LUNG OF AGED DOGS.

A. Shimada[1], M. Oshima[1], M. Sawada[1], T. Morita[1], T. Hasegawa[2] and Y. Seko[2]. [1]*Department of Veterinary Pathology, Tottori University, Tottori, Japan and* [2]*Environmental Biochemistry, Yamanashi Institute of Environmental Sciences, Fujiyoshida, Yamanashi, Japan.*

Physiological function of the respiratory system is known to become less effective with advance of age. There have been, however, few pathological reports on the age-related pathological changes of lungs in humans as well as in animals. Reported changes include emphysema, thickening of the alveolar walls by increased volume of collagen and/or elastic fibers. Little is known of the mechanism of these changes. We examined 1) morphological changes and 2) accumulation of the inhaled suspended particulate matters (SPM) with the special emphasis on the metals in the lungs from dogs. Laminin immunohistochemistry and silver staining for the analysis of basement membrane, Prussian blue DAB and post DAB enhancement technique for the detection of iron and azan stain for the fibrosis were carried out as histological examination. Metals were determined using ICP-MS after wet digestion of the tissue samples. Lung and hilar lymph nodes from 7 young animals, ranging in age from 1 week to 4 years, and from 30 old animals, from 10 to 17 years, were used. Fibrosis and attenuated basement membrane were demonstrated in the alveolar walls of aged dog lungs. Intensity of SPM deposition in both lung tissue and hilar lymph nodes increased with age. Signs of tissue damage by the released reactive oxygen species were also shown with the use of 8-OHdG immunohistochemistry. Age-related increase of the level of metals (Fe) known to responsible for the

generation of the oxygen radicals was also demonstrated. Lung and hilar lymph nodes from the aged dogs may be good biological samples for the study of the effect of air pollution on the respiratory system.

921 DIESEL SOOT BINDS IL-8 IN A BIOACTIVE FORM.

J. Seagrave, C. Knall and J. L. Mauderly. *Lovelace Respiratory Research Institute, Albuquerque, NM.*

Exposure to air pollution particulate material (PM) has been implicated in health effects, including inflammatory responses in the lungs. To examine the direct effects of a surrogate air pollution PM on alveolar epithelial cells, we exposed monolayers of A549 cells to a wide range of concentrations of diesel PM (DPM: National Institute of Standards and Technology Standard Research Material 2975) and analyzed release of the neutrophil chemoattractant Interleukin-8 (IL-8) from these cells by ELISA. Low doses of DPM increased the concentration of IL-8 detected in the conditioned medium after 24 hours. Higher doses appeared to suppress the response, although this suppression was not related to acute DPM toxicity as determined by release of lactate dehydrogenase. In a cell-free system, incubation of IL-8 with DPM resulted in a loss of immunoreactive IL-8 in the supernatant of the reaction. In contrast, carbon black did not reduce the concentration of IL-8 in the mixture. The DPM-induced loss was only weakly blocked by a large excess of bovine serum albumin (BSA), indicating some specificity of the effect. When human blood neutrophils were exposed to DPM that had been pre-incubated with IL-8, then washed to remove free IL-8, they underwent morphological changes suggestive of orientation toward the particles. This orientation was not observed with either carbon black that had been incubated with IL-8 or with DPM alone. These results suggest that DPM binds IL-8 in a particle- and protein-selective manner, and that the resultant DPM-bound IL-8 is biologically active. Supported by Office of Heavy Vehicle Technology, US Department of Energy.

922 MECHANISMS OF NITROGEN DIOXIDE-MEDIATED CYTOTOXICITY.

V. N. Ayyagari, A. Januszkiewicz and J. Nath. *Respiratory Research, Walter Reed Army Institute of Research, Silver Spring, MD.* Sponsor: N. Gorbunov.

Nitrogen dioxide (NO_2) is a ubiquitous, pollutant gas that produces a broad range of patho-physiological changes in the lung. In our present study, we evaluated the mechanism(s)of NO_2- mediated cytotoxicity, using normal human bronchial epithelial (NHBE) cells as an *in vitro* experimental model. Cellular responses following brief exposure to high levels (45 ppm) of NO_2 in presence or absence of various cytokines, were monitored. At the end of 1, 6, 24 and 48 hours post exposure, levels of pro-inflammatory cytokines such as IL-8, TNF-α, IFN-γ & IL-β, were measured. Generation of NO, sICAM-1 and mICAM-1 were also monitored. Our results have shown a time-dependent increase in NO/nitrite levels (3-5 folds) in exposed NHBE cells. In order to ascertain the source of this high nitrite, iNOS and eNOS protein levels were checked at different time intervals. Increased expression of iNOS and to a smaller extent, of eNOS, were observed at 24 hrs post exposure. Also, lack of complete inhibition by addition of iNOS specific inhibitors indicated that a significant amount of the increased nitrite is formed *via* non-enzymatic reactions. Also, significantly elevated levels of IL-8 and IL-1β were observed during early time intervals(1-6 hr), suggesting the role of proinflammatory mediators in initiating NO_2-mediated cytotoxicity. In order to ascertain the role of cell-cell interactions in NO_2 - mediated cytotoxicity, we also checked for the levels of intercellular adhesion molecules (sICAM-1 & mICAM-1). Our initial experiments indicate an increased expression of both sICAM-1 & mICAM-1 proteins in NO_2 - exposed cells. Significant ICAM-1 induction was observed in presence of TNF-α and IFN-γ, either alone or in combination. N- [3-(amino methyl) benzyl] acetamidine (1400w), a highly specific iNOS inhibitor, inhibited ICAM-1 expression significantly. This suggests an involvement of NO in expression of ICAM-1. In conclusion, we suggest that proinflammatory mediators such as IL-8, IL-1β and NO may play important roles in NO_2 mediated cell injury, either directly or indirectly *via* induction of ICAM-1.

923 PHOTOCHEMCIAL REACTIONS OF URBAN AIR POLLUTION MIXTURES ENHANCE INFLAMMATORY RESPONSES IN LUNG CELLS.

I. Jaspers[1], H. E. Jeffries[2], K. G. Sexton[2], R. M. Kamens[2] and M. Doyle[2]. *[1]CEMALB, University of North Carolina, Chapel Hill, NC and [2]Env. Sciences. & Engineering, University of North Carolina, Chapel Hill, NC.*

There has been an increasing interest in examining complex urban air mixtures that realistically mimic urban smog rather than investigating the adverse health effects induced upon exposure to individual known components of urban smog. Smog chambers that has been used to conduct experiments for developing photochemical models for ambient ozone (O3) concentrations, were used to generate photochemical air mixtures. These photochemically altered air pollution mixtures were interfaced with an *in vitro* exposure system to compare the inflammatory effects of complex air pollutant mixtures with and without sunlight driven photochemistry. Briefly, two matched outdoor chambers capable of using real sunlight were utilized to generate two test atmospheres for simultaneous exposures to cultured lung cells. One chamber was used to produce a photochemical active system, which ran from sunrise to sunset, producing O3 and the associated secondary products. A few hours after sunset, NO was added to titrate and remove completely the O3, forming NO2. In the second chamber, an equal amount of NO2 was injected and the same amount of the 55-component hydrocarbon mixture used to setup the photochemical system in the first side. A549 cells, an alveolar type II-like cell line grown on membranous support were exposed to the photochemical mixture or the original NO2/hydrocarbon mixture for 5 hours and analyzed for IL-8 mRNA production 4 h post-exposure. In addition, a variation of this experiment was conducted to compare the photochemical system producing O3 and NO2, with a simple mixture of only the O3 and NO2. Our data suggest that the photochemically altered mixtures which produced secondary products induced an about 2-3 fold greater IL-8 mRNA production than the mixture of NO2 and hydrocarbons or O3. These results indicate that secondary products generated through the photochemical reactions of NOx and hydrocarbons significantly contribute to the inflammatory responses induced by exposure to urban smog.

924 GEOCHEMICAL SOLUBILITY OF ASBESTOS TOXICOLOGICAL STANDARDS IN SIMULATED LUNG FLUIDS.

T. L. Ziegler, T. K. Hinkley, P. J. Lamothe, G. P. Meeker, S. J. Sutley, H. Lowers, I. K. Brownfield and G. S. Plumlee. *USGS, Denver, CO.*

Asbestos mineral dust exposure is associated with lung diseases such as asbestosis, malignant mesothelioma, and bronchogenic carcinoma. Within the past decades, *in vitro* and *in vivo* studies have shown asbestos to be cytotoxic and mutagenic, yet the mechanisms responsible have escaped definitive identification. Asbestos-related diseases may be the result of two mechanisms, mechanical and intracellular, based on mineralogy, size, shape, chemistry, elemental speciation, and electral properties of the asbestos particles yet in the literature contradictions for specific asbestiform minerals can be found. Thus, the mechanistic questions may best be answered through increased collaborative research between the geochemistry and health-related communities. One key step in the research process is the mineralogical and geochemical characterization of commonly used asbestos toxicological standards. The USGS has analyzed 5 sets of asbestos standards (5 amosites, 4 anthophyllites, 6 chrysotiles, 5 crocidolites, 4 tremolites) by ICP-MS XRD, SEM, and EDS. The level of toxicity was determined as well. The initial analysis revealed mineralogical, geochemical and toxicological variations between the asbestos standards as well as within the sets of the same nominal asbestos mineral. To further characterize these standards, geochemical solubility studies in simulated lung fluids (SLF) were performed. Elemental solubility determined by ICP-MS analysis following sample incubation with SLF as compared to water revealed additional variations between the standards and within each standard set. Furthermore, SLF and water generated different solubility profiles for each of the individual asbestos standards. These variations between the asbestos standards, or variance within the sets of the same asbestiform mineral, may be responsible for conflicting toxicological results, ultimately inhibiting mechanistic identification. Differences in elemental solubility between the SLF and water indicate that the testing matrix may play a role in the toxicological response.

925 THE CHEMICAL COMPOSITION AND REACTIVITY OF DUSTS DEPOSITED BY THE 9/11/2001, WORLD TRADE CENTER COLLAPSE.

G. S. Plumlee, P. L. Hageman, G. P. Meeker, P. J. Lamothe, P. Theodorakos, S. J. Sutley, R. N. Clark, S. A. Wilson, G. A. Swayze, T. M. Hoefen, J. Taggart, M. Adams and T. L. Ziegler. *USGS, Denver, CO.*

As part of an environmental study of the WTC area after 9/11/2001 (http://greenwood.cr.usgs.gov/pub/open-file-reports/ofr-01-0429/), we characterized chemical composition and reactivity of dusts deposited in lower Manhattan. We analyzed sweep samples (2 indoor, 15 outdoor) collected within the first 2 weeks after 9/11. Major-element concentrations (Si, S, Mg, Al, Fe, C) of the dust samples reflect the contributions of glass fibers, concrete, gypsum wallboard, window glass, metals, paper, and other materials. Concentrations of some trace metals (Zn, Ba, Pb, Cu, Cr, Mo, Sb, Ti) are higher than in many natural soils, reflecting contributions from paints, lighting, electrical wires, pipes, fire retardant materials, computer equipment, electronics, and other diverse materials. Leach tests of the dust samples using water show the dusts are quite chemically reactive. Alkaline leachate solutions were

produced due to rapid partial dissolution of Ca(OH)2 from concrete particles. Indoor dust samples generated higher pH (11.8-12.4) than outdoor dust samples (8.2-10.4), indicating that the alkalinity of the outdoor dusts can be progressively neutralized by reactions with carbonic acid in rainwater. Although they generate caustic alkalinity, the indoor dusts are not as caustic as common drain cleaner or cement. Leach tests with simulated lung fluids (SLF) produced smaller pH shifts due to the buffering capacity of SLF components. Some metals in the dusts (Si, Al, Cr, Sb, Mo, Ba, Cu, Zn, Co., Ni) are quite soluble in water, and many are even more soluble in SLF due to chelation by chloride, citrate, and glycine. Leach tests with simulated gastric fluids are currently in progress. Information on the materials makeup, chemical composition, and chemical reactivity of the dusts may be useful in interpreting potential origins of some of the health problems that developed in individuals exposed to WTC dust after 9/11, such as WTC cough, bronchial hyperreactivity, and gastroesophageal reflux.

926 POLYCYCLIC AROMATIC HYDROCARBONS AND METALS IN SOILS OF TWO NEW ORLEANS COMMUNITIES.

H. W. Mielke[1], G. Wang[2], C. R. Gonzales[1], E. Powell[1], B. Le[2] and V. N. Quach[1]. *[1]College of Pharmacy, Xavier University, New Orleans, LA and [2]Department of Chemistry, Xavier University, New Orleans, LA.*

We evaluate 16 polycyclic aromatic hydrocarbons-PAHs (Naphthalene, Acenaphthylene, Acenaphthene, Fluorene, Phenanthrene, Anthracene, Fluoranthene, Pyrene, Benz(a)anthracene, Chrysene, Benzo[k]fluoranthene, Benzo[j]fluoranthene, Benzo(a)pyrene, Indeno[1, 2, 3-cd]pyrene, Dibenz[a, h]anthracene, and Benzo[g, h, i]perylene) and 8 metals (Pb, Zn, Cd, Mn, Ni, Cu, Cr, V) in soils of an inner city and an outlying suburban community of New Orleans. Surface (2.5 cm deep) samples were air-dried and sieved (2 mm). Accelerated solvent extraction was used for PAH analysis with gas chromatography-mass spectrometry. Metals were extracted at a 5:1 ratio of 1 mol nitric acid (room temperature) to soil, shaken 2 hours, centrifuged (1000 x g - 15 min.) and filtered for inductively coupled plasma-atomic emission spectrometry analysis. Pearson product moment correlation reveals that urban soils exhibit a correlation coefficient = 0.78, P = 10^{-6}, between PAHs and metals. Totals for PAHs and metals are summarized in Table 1 for the residential locations described above and indicate significant differences. Because children are so sensitive to contaminants, the data pose questions about toxic effects of chemical mixtures to human health in real-world settings. ACKNOWLEDGEMENTS: Metal research funded by ATSDR/MHPF cooperative agreement U50/ATU398948 and PAH research funded by DOD Grant # DSWA01-97-1-0028.

927 METALLOTHIONEIN AND GLUTAMATE-CYSTEINE LIGASE GENE EXPRESSION IN METAL-EXPOSED SMALL MAMMALS.

H. Barrus[1], S. Srinouanprachanh[1], M. J. Hooper[2], S. T. McMurry[2], G. P. Cobb[2] and T. J. Kavanagh[1]. *[1]University of Washington, Seattle, WA and [2]Texas Tech University, Lubbock, TX.*

Preliminary studies of small mammals at the Anaconda Smelter Site (Montana) have shown varying tissue concentrations of arsenic, lead, cadmium, copper, and zinc. This has provided a unique opportunity to study multi-species and multi-dose-responses for gene expression in tissues from wild rodent populations. Glutamate-cysteine ligase (GCL, the initiating enzyme in glutathione synthesis) and metallothionein (MT) levels are known to increase with heavy metal exposures in mammalian tissues. GCL (both the catalytic and modifying subunits) and MT mRNA expression have been studied in laboratory colonies of mice and rats after acute and semi-chronic individual heavy metal exposures. However, few field-based chronic-exposure studies of wild rodent populations have been conducted with these gene expression biomarkers. In this study, GCL and MT mRNA expression levels in the livers of *Peromyscus maniculatus* collected from the Anaconda Smelter site were measured with real-time quantitative PCR (RT-PCR). Post-transcriptional regulation will also be determined by Western blot analysis. Following these analyses, cDNA microarray analyses will be attempted to determine novel biomarkers. Preliminary analyses of RT-PCR data indicate significant correlations between transcriptional gene expression for GCLc and cadmium liver concentrations in both males (R^2=0.5732, p=0.004) and females (R^2=0.4857, p=0.046); and between both GCL subunits and copper concentrations in females only (GCLc R^2=0.6465, p=0.005; GCLm R^2=0.5483, p=0.002). However, no correlation was found for MT and liver concentrations of any of the metals. Interestingly, a correlation has also been found between GCLc and GCLm expression for males (R^2=0.6456, p⟨0.05) and females (R^2=0.5916, p=0.02), suggesting possible co-regulation. Sponsored by NIEHS grants P42ES04696 and P30ES007033.

928 EFFECTS OF CHROMATED COPPER ARSENIC (CCA) TREATED WOOD EFFLUENTS ON RATS.

L. Wilson[1], L. Ogden[1], T. Graham[2], L. Billups[2], F. Johnson[1], Q. Knight[1] and M. Hammersley[1]. *[1]Biomedical Sciences, Tuskegee University, Tuskegee Institute, AL and [2]Pathobiology, Tuskegee University, Tuskegee Institute, AL.* Sponsor: R. Dalvi.

CCA is the most commonly used chemical treatment of wood products. Humans are exposed to CCA when they contact treated wood which is used in fencing, playgrounds, decks, porches, utility posts, rafts, sound barriers, and building frames. Exposure can also occur when people contact water runoff from treated wood. CCA is a chemical mixture for which there is limited data, although there are several toxicity reports on the individual components of this mixture. The major objective of this study is to evaluate the effects of the CCA mixture (Type I) on rats. Adult rats were exposed to CCA by oral gavage. Some of these animals received various doses of CCA from wood soaked effluent. Other groups received various doses of a solution of the chemical mixture. Control groups received the vehicle alone. During the exposure, body weights, clinical signs, and feed consumption were monitored. Hematological and clinical chemistries were evaluated. Pathological and toxicological evaluations were conducted on various organs. Also, the mutagenic potential of the CCA mixtures was evaluated. There was a significant decrease in body weight gain among rats exposed to 40 mg/kg/day of CCA mixture. There was a trend toward increased feed consumption during the first and fourth weeks of exposure. Alkaline phosphatase and alanine transaminase were significantly higher than in the control rats. Based on these data the CCA mixture adversely affected rats by oral exposure.

929 UTILIZATION OF A HOMING PIGEON (*COLUMBA LIVIA*) MODEL TO ASSESS THE EFFECTS OF NON-LETHAL EXPOSURES TO MINE WASTES AND PESTICIDES IN MIGRATORY BIRDS.

J. M. Brasel[1,2], R. Cooper[1,2] and C. A. Pritsos[1,2]. *[1]Nutrition, University of Nevada, Reno, NV and [2]Environmental Sciences and Engineering, University of Nevada, Reno, NV.*

Other than the Migratory Bird Treaty Act, which is predicated upon no acceptable losses of migratory birds, there are no regulatory provisions that afford protection for health and survival of migratory bird species. Acute non-lethal exposures to mine wastes and pesticides including cyanide, arsenic, organophosphates and carbamates have been shown to have adverse biochemical effects on avian species, which could affect migration. It is unclear how these biochemical effects might impact these birds at a population level by affecting their ability to migrate. We previously showed that cyanide and arsenic exposure deplete intracellular ATP in these birds. Studies reported by this laboratory also suggested that homing pigeons could serve as a model to assess the impact of cyanide exposure on migratory birds. Preliminary results suggested an increase in flight time following non-lethal oral doses of cyanide. We have expanded these studies to demonstrate that this non-lethal exposure to cyanide results in a dose-dependent increase in flight time. The data also show that flight time increases with distance traveled. These studies are currently being expanded to test this homing pigeon model on arsenic and the acetylcholinesterase-inhibiting pesticides diazanon, methidathion, and aldicarb. Mitochondrial respiration, tissue ATP levels, and cholinesterase-inhibiting activity will provide information on biochemical effects as they are related to flight times. The purpose of these expanded studies will be to show the utility of this homing pigeon model for testing the biological impact of non-lethal exposure to various anthropometrically generated xenobiotic compounds on migratory birds. These studies were funded in part by USDA Hatch Grant NEV 00727.

930 REGIONAL, NOT TROPHIC, FORAGING PATTERNS SUBSTANTIATE DIFFERENCES IN CONTAMINANT LEVELS BETWEEN TWO NORTH PACIFIC ALBATROSS SPECIES.

M. E. Finkelstein[1], D. A. Croll[1], B. Tershy[1], B. S. Keitt[1], W. Jarman[2], T. Lowe[2], C. Bacon[2] and D. R. Smith[1]. *[1]Environmental Toxicology, University of California, Santa Cruz, Santa Cruz, CA and [2]Energy and Geoscience Institute, University of Utah, Salt Lake City, UT.*

Seabirds, due to their high trophic level and wide foraging ranges, are good indicators of contamination in the marine environment. We tested the hypothesis that seabird contaminant body burden is determined by 1) the trophic level at which they feed, and/or 2) the location in which they forage, by measuring contaminant loads (sum PCBs, sum DDTs) as well as carbon and nitrogen stable isotopes ($\delta^{15}N$, $\delta^{13}C$) in two closely related seabirds: Black-footed (*Phoebastria nigripes*) (BFAL) and Laysan (*P. immutabilis*) (LAAL) Albatross. Blood samples (~6mls) were collected from adult birds on Sand Island, Midway Atoll in May of 2000 and 2001. Samples were analyzed for PCBs and DDTs by gas chromatography. $\delta^{15}N$ and $\delta^{13}C$ values were measured by mass spectrometry. PCB and DDT levels for BFAL were 3 to 4-fold higher than for LAAL (PCBs and DDTs (ng/mL ± SD) for BFAL (n=25) = 161 ± 91 and 127 ± 146; for LAAL (n=16) = 46 ± 17 and 30 ± 15 respectively; $p \leq 0.001$, Mann-Whitney University). $\delta^{15}N$ values, used to ascertain trophic position, were marginally not significantly different between species (p=0.057, t-test, n=31 BFAL, 17 LAAL), however, $\delta^{13}C$ values, used to discriminate foraging areas, were highly significantly different ($p \leq 0.001$, t-test, n=31 BFAL, 17 LAAL). The $\delta^{15}N$ and $\delta^{13}C$ values suggest that differences observed in contaminant levels between BFAL and LAAL are driven primarily by differences in contaminant loads associated with different feeding locations, and less by trophic position. Furthermore, DDE levels for LAAL and BFAL show a 2- to 3-fold increase compared to levels reported from 1992-93 (Auman et al., 1997). When combined with albatross satellite foraging data and the observation that levels of contaminants, especially DDE, may not be diminishing over time in the environment, the results of this study help to elucidate regions of high marine contamination.

931 ESTROGEN RECEPTOR ALPHA, BUT NOT BETA OR GAMMA EXPRESSION IS INDUCED BY ESTRADIOL AND XENOESTROGENS IN FISH LIVER TISSUE.

T. L. Sabo-Attwood[1] and N. D. Denslow[2]. *[1]Pharmacology and Therapeutics, University of Florida, Gainesville, FL and [2]Biochemisry and Molecular Biology, University of Florida, Gainesville, FL.*

Estrogen receptors (ER) are nuclear transcription factors that control the expression of numerous genes involved in the reproductive process. We have obtained the entire coding regions of three distinct ER isotypes, alpha, beta, and gamma from Largemouth Bass (*Micropterus salmoides*) (LMB). The three ERs are most highly conserved in the DNA binding domain and show the most diversity in the trans-activation domains. ERs beta and gamma however share more sequence identity overall in comparison to ER alpha. The discovery of these multiple ER isotypes raises questions as to whether these receptors regulate gene expression similarly in response to 17β-estradiol (E2). One such gene that is induced *via* the ER pathway is vitellogenin (vtg). In order to determine the normal expression patterns of the ER isotypes and vtg during reproduction we measured mRNA levels by real-time PCR in females from October through April. The data show that maximal ER alpha induction correlates with peak vtg mRNA and plasma levels of vtg and E2. There was no correlation between the levels of vtg and ERs beta and gamma suggesting that the ER isotypes are not regulated in the same manner by E2. Male oviparous species do not normally produce vtg but the synthesis of this gene can be induced by E2. When male LMB were injected (ip) with E2 (2.5 mg/kg), ER alpha and vtg mRNAs were induced, with no significant increase in ER beta and gamma mRNAs. Similarly, exposure of LMB to nonylphenol (NP) produced the same response. We also investigated the induction of the ERs over time following a single injection of NP (50 mg/kg). ER alpha and vtg expression increased at 24 hours, peaked at 48 hours, and returned to basal levels by day 7 while no significant change in the expression levels of ERs beta and gamma occurred. This data indicates that NP affects ER mediated gene expression in a similar manner to E2 by inducing only the ER alpha isotype.

932 RELATIVE BINDING AFFINITY OF ENDOCRINE DISRUPTING CHEMICALS TO ESTROGEN RECEPTOR IN TWO SPECIES OF FRESHWATER FISH.

J. S. Denny[1] and T. R. Henry[2]. *[1]Mid-Continent Ecology Division, USEPA, Duluth, MN and [2]Experimental Toxicology Division, USEPA, Duluth, MN.*

The USEPA has been mandated to screen industrial chemicals and pesticides for potential endocrine activity. This study was designed to assess the plausibility of making inter-species extrapolations of affinity of chemicals to bind fish estrogen receptors (ER). Fifteen chemicals previously tested for binding affinity to rainbow trout liver ER (rtER) were tested for affinity to fathead minnow ER (fhmER). Liver tissue from 20 (male) to 50 (female) fish was the source of cytosolic ER. Binding affinity was measured by incubating liver cytosol (255 µl) with a saturating concentration (5nM) of ^{3}H-estradiol (^{3}H-E2) and a range of test chemical concentrations for 20hr at 4°C. Bound chemical was determined as the amount of ^{3}H-E2 displaced from the ER. RBA was calculated as: (IC_{50} of E2/IC_{50} of chemical)*100 (E2 = 100%). Chemicals tested included estradiol (E2), estrone (E1), estriol (E3), ethinylestradiol (EE), diethystilbestrol (DES), methylestradiol (MeE2), genistein (GEN), tamoxifen (TAM), testosterone (T), methyltestosterone (MT), α-trenbolone (ATren), β-trenbolone (BTren), p-tert-octylphenol (PTOP), p-nonylphenol (PNP) and methoxychlor (MXC). DES, EE, MeE2 and E1 bound with high affinity to the fhmER, having RBAs of 590, 170, 70 and 30%, respectively. E3, TAM and GEN yielded RBAs of 5, 4 and 1, respectively. The alkylphenols PNP and PTOP had weak affinity for the fhmER, with RBAs of 0.1 and 0.01, respectively. The androgens ATren (RBA = 0.002) and BTren (RBA = 0.02) fully displaced ^{3}H-E2, whereas T, MT, and MXC only partially displaced ^{3}H-E2;thus RBAs could not be calculated. This weak affinity of T, MT and MXC for the fhmER was also seen with the rtER. Comparison of binding affinities of the chemicals tested for fhmER and rtER shows that the rank order of RBAs are nearly identical across species. This abstract does not necessarily reflect EPA policy.

933 EFFECTS OF ATRAZINE ON REPRODUCTIVE SUCCESS IN THE MARINE FISH, CUNNER (Tautogolabrus adspersus).

L. J. Mills[1,2], R. E. Gutjahr-Gobell[1], D. Borsay Horowitz[1] and G. E. Zaroogian[1]. *[1]Atlantic Ecology Division, USEPA, NHEERL, Narragansett, RI and [2]Biomedical Sciences, University of Rhode Island, Kingston, RI.*

Atrazine, the most widely used herbicide in the world, leaches into ground water and surface runoff after agricultural and forestry applications. It has been detected in concentrations in the ppb range in ground water, surface waters, rivers, streams, and precipitation. Atrazine has also been reported to have endocrine disrupting activity, and is theorized to affect steroidogenesis in vertebrates by inducing aromatase, the enzyme complex that converts testosterone to estradiol. We tested the hypothesis that exposure to atrazine will affect reproductive success in a marine fish species, cunner (*Tautogolabrus adspersus*). During a one week pre-exposure period, cunner in spawning condition were monitored daily to determine egg production, egg fertility, and egg viability. Atrazine, mixed into a slow release matrix, was then implanted subcutaneously into each fish below the dorsal fin. Treatments were control (matrix only) and two nominal concentrations of atrazine, 0.5 and 5 mg/kg (500 and 5000 ppb, respectively). Each treatment consisted of four replicate tanks containing up to two male and three female fish. Eggs were collected daily and evaluated within 24 hours to determine total number, number fertile, and number developing normally (viable). At termination of the experiment, sperm motility was checked in males and blood was drawn from all fish. Fish were dissected to determine gonad and liver weights. Brain, gonad, liver and adipose samples were flash frozen and archived for later analysis. Results showed no significant differences between treatments or between pre- and post-exposure fish in daily female egg production, percent fertile eggs, and percent viable eggs. All males produced milt and had motile sperm. Likewise, there were no significant differences between treatments in average gonadosomatic and hepatosomatic indexes of female or male fish. These results indicate that this type of atrazine exposure does not affect the reproductive success of mature cunner.

934 LABORATORY FISH GONADAL SEX DIFFERENTIATION: A COMPARISON OF THE FATHEAD MINNOW (*PIMEPHALES PROMELAS*), SHEEPSHEAD MINNOW (*CYPRINODON VARIGATUS*) AND ZEBRA FISH (*DANIO RERIO*).

N. T. Wallis[1], F. M. Smith[1], T. Hutchinson[2] and G. Panter[2]. *[1]Research Pathology, Syngenta. Central Toxicology Laboratory, Macclesfield, Cheshire, United Kingdom and [2]Ecotoxicology, AstraZeneca, Brixam Environmenta Laboratory, Brixham, Devon, United Kingdom.* Sponsor: I. Kimber.

Due to their close interactions with the aquatic environment fish are regarded as a sentinal species for monitoring environmental endocrine disruption. Exposure of fish to endocrine modulating chemicals (EMCs) during the period of gonad development leads to skewing of the population sex distribution, intersex fish (i.e ovotestes) and abnormalities in the gonadal ducts. The study was performed to assess the maturity of the gonads at 30, 60 and 90 days post hatch to determine the optimal time-point for gonadal histopathological evaluation. 20 fish per species per time point were sectioned using methods developed in our laboratory that allowed evaluation of all gonadal zones and associated duct structures. Slides were evaluated histologically. Results: In all three species, the female gonad developed earlier than

the male, with ovarian follicles identifiable in a proportion of fish by 30 days and all females by 60 days post hatch. Male gonads were identifiable in some fish by 60 days, and in all male fish, in each of the three species, by day 90. Although gonadal sex was easily determined by day 90, reproductive maturity (as indicated by mature spermatid populations) was not detectable in fathead minnows at this time. Unlike some laboratory populations of zebra fish where males pass through an intersex phase during gonadal differntiation, the male fish we studied differentiated directly to the male phenotype, with no intersex phase. Sheepshead minnows, unlike the other species that have paired gonads, have a single central gonad. In conclusion by 90 days it is possible to definitively determine the gonadal sex of all three species allowing detection of EMCs affecting gonadal sex differentiation. This evaluation would not be possible at earlier time-points, as a proportion of the fish have indeterminate gonads. The technical processing allowed evaluation of the EMC sensitive accessory ducts.

935 ENDOCRINE DISRUPTION AND PERSISTENT BIOACCUMULATIVE CONTAMINANTS IN COLUMBIA RIVER WHITE STURGEON.

D. T. Gundersen[1], M. Plumlee[1], C. Wong[1], J. Paar[1], C. B. Schreck[2], G. W. Feist[2], M. A. Webb[2], A. G. Maule[3], E. Foster[4] and M. S. Fitzpatrick[4]. *[1]Environmental Science Program, Pacific University, Forest Grove, OR, [2]Oregon Cooperative Fishery Research Unit, Department of Fisheries & Wildlife, Oregon State University, Corvallis, OR, [3]Columbia River Research Laboratory, USGS-Biological Resources Division, Cook, WA and [4]Department of Environmental Quality, Portland, OR.*

Columbia River white sturgeon reproduction may be impaired due to loss of habitat and contaminant exposure. This is a report on research from a 3-year study looking at endocrine disruption and reproduction in Columbia River white sturgeon. Sturgeon were collected from the Columbia River estuary, and pools above Bonneville, The Dalles, and John Day dams. Condition factor (CF) and gonadosomatic index (GSI) were measured for all fish. Blood plasma samples were analyzed for 17β-estradiol, testosterone (T), and 11-ketotestosterone (KT), using RIA. Plasma vitellogenin (Vtg) was analyzed using ELISA. Livers and gonads were examined histologically and analyzed *via* GC-ECD for chlorinated pesticides and PCBs. Muscle tissue was analyzed for mercury using CVAA. The putative cytochrome P450 3A was measured in hepatic microsomes by western blotting. p, p'-DDE was the predominant contaminant found in gonad and liver tissues. Mercury was detected in all muscle samples, with >13% of the sample concentrations exceeding 0.5 ppm. CF was lower and incidence of histological gonad and liver abnormalities were higher in Bonneville fish versus fish from other sites. Liver and gonad p, p'-DDE was significantly higher in Bonneville fish. Male plasma T and KT levels and GSI were negatively correlated with liver p, p'-DDE. Hepatic cytochrome P450 3A in males was positively correlated with p, p'-DDE and negatively correlated with plasma androgens. Plasma Vtg was significantly higher in John Day and The Dalles males compared to fish from other sites. These data indicate that endocrine disruption is occurring in Columbia River white sturgeon, which may be contributing to poor reproductive success.

936 THE EFFECTS OF 2, 3, 7, 8-TETRACHLORODIBENZO-*P*-DIOXIN (TCDD) ON ORNITHINE DECARBOXYLASE (ODC) INDUCTION IN THE GONAD OF THE EASTERN OYSTER (*CRASSOSTREA virginica*).

M. L. Wintermyer and K. R. Cooper. *Toxicology, Rutgers University, New Brunswick, NJ.*

The naturally occurring polyamines putrescine, spermidine and spermine are present in all living cells, prokaryotes, eukaryotes, plants and animals. Ornithine decarboxylase (ODC) is the key enzyme of polyamine synthesis. The physiological activity of ODC is associated with cell proliferation. ODC is a highly inducible enzyme regulated by hormones, growth factors, xenobiotics carcinogens and tumor promoters. The environmental contaminant 2, 3, 7, 8-TCDD has been shown to be a tumor promoter as well as, cause adverse reproductive effects in several human and animals models. The effects of TCDD on ODC and tissue polyamine levels are controversial. Determination of TCDD induced changes in tissue polyamine levels may explain some of the degenerative processes seen in TCDD- treated animals. The rational for this study is based on the well documented reproductive toxicity of TCDD and the importance of ODC in regulating polyamine levels essential for cell growth and differentiation. Oysters (N=30) were adductor muscle injected with 10 pptr 2, 3, 7, 8-TCDD at day 1 and day 14. Oyster gonadal tissues (N=20) were sampled on day 30 for ODC activity and polyamine levels. In this study 2, 3, 7, 8-TCDD was shown to decrease ODC levels in the gonadal tissue of the eastern oyster (*Crassostrea virginica*) during gametogenesis. TCDD treated oysters showed a 10 fold decrease in gonadal ODC induction compared to control groups. Putrescine levels also showed a 10 fold decrease compared to control polyamine levels. Histologically, TCDD has been shown to cause delayed gonadal development and decreased egg size in the eastern oyster. Also, TCDD has been shown in egg fertilization assays to cause decreased egg viability and ultimately a decrease in egg fertilization in the oyster. Studies are on going to determine if 2, 3, 7, 8-TCDD exposure during gametogenesis interferes with normal reproductive development by altering the level of ODC induction resulting in delayed gonadal development, decreased egg viability, and egg fertilization.

937 MERCURY IN THE ENVIRONMENT OF NORTHWEST ALABAMA.

A. C. Nichols[1] and T. P. Murray[2]. *[1]Physical and Earth Sciences, Jacksonville State University, Jacksonville, AL and [2]Chemistry, University of North Alabama, Florence, AL.*

According to the USEPA (1998), approximately 51 tons of mercury (Hg) are emitted nationwide each year from coal-burning power plants. A large coal-burning power plant is located on the Tennessee River in the Shoals area of northwest Alabama. Catfish from local lakes and ponds were collected and analyzed for Hg. The appearance of Hg at similar levels in fish collected from widely separated sites in a local environment supports atmospheric deposition as a source. We analyzed wood from two trees for the presence of Hg. Tree ring dating could provide a means to examine Hg release over time. Blue catfish were harvested from lakes Pickwick and Wilson on the Tennessee River. Channel catfish were collected from six local ponds. The power plant is situated on the banks of Pickwick Lake. The ponds are located within a 30 km radius of Pickwick Lake. The wood samples, a red hickory and a shortleaf pine, were collected approximately 10 km from the power plant. Mercury concentrations in fish and wood were determined using USEPA Method 245.1, Cold Vapor Atomic Absorption. Mercury concentrations in fish from each location are reported as the mean in ug/g dry weight. Catfish from Lake Pickwick had muscle Hg concentrations of 0.03 and liver concentrations of 0.35 (n=6). Wilson Lake fish had muscle Hg concentrations of 0.10 and liver concentrations of 0.98 (n=13). Catfish collected from five ponds had mean muscle concentrations of 0.09 and liver concentrations of 0.67 (n=13). The sixth pond was constructed in 1999 and stocked with fingerling catfish in 2000. Two channel catfish were collected from this pond in April, 2002. They had Hg concentrations in muscle of 0.10 and 0.09 ug/g, and in liver of 0.95 and 0.65 ug/g. Wood collected from the outer circumference of the pine tree had a Hg concentration of 12.4 ng/g. Wood from the outer circumference of the hickory had a concentration of 7.4 ng/g. Atmospheric deposition of Hg generated by local coal-burning facilities ofers a plausible explanation for the Hg contamination observed in this study.

938 MERCURY DISTRIBUTION IN SEDIMENTS AND UPTAKE INTO THE AQUATIC FOOD WEB AT COTTAGE GROVE RESERVOIR, OREGON.

D. L. Morgans[1,2] and L. R. Curtis[2]. *[1]Environmental, CH2M HILL, Corvallis, OR and [2]Environmental and Molecular Toxicology, Oregon State University, Corvallis, OR.*

The Cottage Grove Reservoir in Lane County, Oregon has been impacted by a point source (Black Butte Mine), where mercury mining and processing has occurred within its watershed. To identify the extent of impact, total mercury concentrations [Hg-T] in sediments of the reservoir, tributary streams, and representative food web species were measured in 2002. The concentrations measured in 2002 were qualitatively compared to 1995 [Hg-T] to determine if [Hg-T] in sediments and tributaries have changed over time and if parallel changes have occurred in the food web. Sediment cores from both time periods were collected from the deepest areas of the reservoir. [Hg-T] from both sampling events increased from the surface to the bottom of the core, suggesting a gradual reduction in mercury loading since mercury production halted. Average [Hg-T] ranged from 1.4 mg/kg at the surface to a maximum of 3.7 mg/kg located 30 cm below the surface. [Hg-T] in transect samples collected from the center of the reservoir gradually increase from the inlet (0.7 mg/kg) to the dam (3.6 mg/kg). Transect and tributary samples collected during 1995 are spatially similar and concentrations trends generally agree with those collected in 2002. Mercury concentrations in largemouth bass (up to 2 mg/kg) are of concern for human health, and fish consumption advisories are posted at the Reservoir. Mercury concentrations were measured in organisms representing three trophic levels including benthic invertebrates, omnivorous amphibians/fish, and carnivorous fish. Average [Hg-T] measured in benthic organisms ranged from <0.02 mg/kg in snails to ~0.05 mg/kg in chironomids; average [Hg-T] measured in omnivorous amphibians and fish ranged from <0.02 mg/kg in bullfrog tadpoles to ~ 0.04 mg/kg in fingerling brown bullhead; and [Hg-T] were near or exceeded 1 mg/kg wet weight in largemouth bass (Micropterus salmonides). Food web results indicate substantial mercury biomagnification to higher tropic levels.

939 1, 1-DICHLOROETHYLENE-INDUCED MITOCHONDRIAL PERMEABILITY TRANSITION IN MURINE LIVER.

E. J. Martin[1], W. J. Racz[2] and P. Forkert[1]. *[1]Anatomy and Cell Biology, Queen's University, Kingston, ON, Canada and [2]Pharmacology and Toxicology, Queen's University, Kingston, ON, Canada.*

1, 1-Dichloroethylene (DCE) produces hepatotoxicity in mice. Our studies suggested that functional alterations in mitochondria initiate the toxic response. Here we provide evidence that DCE-mediated mitochondrial perturbations are a result of permeability transition pore (PTP) opening, an event that can result in both apoptotic and/or necrotic cell death. Liver mitochondria were isolated from 10 min to 12 h after DCE (125 mg/kg) treatment. Glutamate (complex I)- and succinate (complex II)-supported mitochondrial respiration was assessed by measurement of state-3 (ADP-stimulated) and state-4 (resting) rates of oxygen consumption, and respiratory control ratios (RCR: state-3/state-4) calculated. State-3 respiration rates and RCRs for glutamate-supported respiration were significantly decreased at 20 min after DCE treatment, and those for succinate-supported respiration at 90 min; however, all respiratory parameters returned to control levels by 6 h. A transient decrease in the mitochondrial membrane potential (Delta Psi(M)), measured spectrophotometrically, was concurrent with DCE-induced mitochondrial dysfunction. Additionally, Western blotting showed greater immunoreactivity for cytochrome c in cytosolic fractions from mice treated with DCE (125 and 225 mg/kg) than in control animals. All of these mitochondrial alterations were inhibited by pretreatment with cyclosporin A (CsA; 100 mg/kg), a specific inhibitor of the mitochondrial PTP, suggesting that DCE-mediated mitochondrial changes were the result of PTP opening. Liver toxicity, as assessed by serum alanine aminotransferase activity, was also temporally evaluated. Significant elevations observed as early as 1h after DCE treatment were inhibited by CsA. Collectively, these data suggest that DCE produces apoptotic cell death by inducing a transient mitochondrial permeability transition that causes loss of mitochondrial membrane potential and release of cytochrome c into the cytosol. (Supported by Grant MOP 11706 from the Canadian Institutes of Health Research).

940 MECHANISM OF PERFLUORINATED CARBOXYLIC ACID INDUCED MITOCHONDRIONOPATHY *IN VITRO*.

T. M. O'Brien and K. B. Wallace. *Biochemistry & Molecular Biology, Toxicology Graduate Program, University of Minnesota, Duluth, MN.*

Perfluorooctanesulfonate (PFOS), perfluorooctanoate (PFOA), and substituted perfluorooctanesulfonamides are widely used as surfactants on fabrics and papers, as anti-corrosion agents and fire retardants, as well as numerous other commercial applications. The sulfonamides include perfluorooctanesulfonamide (FOSA), perfluorooctanesulfonamidoacetate (FOSAA), N-ethylperfluorooctanesulfonamide (N-Et-FOSA), 2-(N-ethylperfluorooctanesulfonamido) ethyl alcohol (N-Et-FOSE), and N-ethylperfluorooctanesulfonamidoacetate (N-Et-FOSAA). Their broad application, global distribution and environmental persistence has generated interest in the metabolic and potentially toxic effects of these compounds. We have previously reported that perfluorinated carboxylic acids interfere with mitochondrial bioenergetics by inducing the mitochondrial permeability transition (MPT). The purpose of this investigation was to more thoroughly characterize the role of the MPT in the mechanism of toxicity associated with perfluorinated carboxylic acids. The carboxylated sulfonamides FOSAA and N-Et-FOSAA induced calcium-dependent mitochondrial swelling, inhibited uncoupled respiration, and induced ROS generation, all of which were inhibited by cyclosporin-A. Adding exogenous cytochrome c also restored uncoupled respiration. PFOA induced the MPT, however ROS generation was not detectable at the concentration tested. The non-carboxylated compounds PFOS, FOSA, N-Et-FOSA and N-Et-FOSE did not induce the MPT or ROS generation, nor did they inhibit uncoupled respiration. We conclude that induction of the MPT by perfluorinated carboxylic acids results in the release of cytochrome c and inhibition of respiration, leading to ROS generation, which may ultimately be responsible for any cytotoxicity associated with these compounds. (Supported by a grant from the 3M Company)

941 MITOCHONDRIAL-MEDIATED CELL KILLING BY BILE ACIDS.

C. M. Palmeira[1], A. P. Rolo[1] and K. B. Wallace[2]. *[1]Center for Neurosciences and Cell Biology of Coimbra, Department of Zoology, University of Coimbra, Coimbra, Coimbra, Portugal and [2]Department of Biochemistry and Molecular Biology, University of Minnesota School of Medicine, Duluth, MN.*

Cholestasis results from hepatocyte dysfunction due to the accumulation of bile acids in the cell. Ursodeoxycholate acid (UDCA) is used worldwide for treatment of chronic liver disease, but its therapeutic benefit remains to be substantiated. In the present study we determined if UDCA alters bile acid-induced cytotoxicity, and investigated the role of the mitochondrial permeability transition (MPT) in the mechanism of pathogenesis. Viability of Wistar rat hepatocytes in primary culture was measured by LDH leakage after exposure to bile acids alone or in combination. Mitochondrial membrane potential and ATP content were also evaluated. The percentage of cell killing increased in a time- and dose-dependent manner in cells exposed to unconjugated bile acids. Tauro- and glyco-conjugates of chenodeoxycholate (CDCA) and UDCA were less toxic than the corresponding unconjugated forms. Although relatively non-toxic, UDCA caused synergistic cell killing by lithocholate, CDCA, glyco-CDCA and tauro-CDCA. Furthermore, UDCA potentiated the mitochondrial depolarization, induction of the MPT, and ATP depletion caused by CDCA. Fructose maintained ATP levels and prevented bile acid-induced cell killing. Cyclosporine A (CyA), a potent inhibitor of the MPT, substantially reduced CDCA-induced cytotoxicity. Our results demonstrate that at cholestatic concentrations, cell death correlates with the degree of lipophilicity of individual bile acids. Additionally, induction of the MPT and impairment of cellular ATP generation appears to be associated with the final pathway leading to cell death after exposure to CDCA. In view of the wide implication of the MPT in chemical induced cell injury, these data draw into question the potential benefit of prescribing UDCA to treat cholestatic liver disease. (Supported by PRAXIS XXI/21454/99, FCT and the Luso-American Foundation)

942 ROLE OF MITOCHONDRIAL DYSFUNCTION IN COMBINED BILE ACID-INDUCED APOPTOSIS.

A. P. Rolo[1], C. M. Palmeira[1], J. M. Holy[2] and K. B. Chenodeoxycholic acid (CDCA), a hydrophobic bile acid, is toxic to hepatocytes by mechanisms involving mitochondrial dysfunction. It has been previously observed that ursodeoxycholate (UDCA) induces apoptosis in hepatocellular carcinoma cells and potentiates CDCA-induced necrosis in primary cultured hepatocytes due to induction of the mitochondrial permeability transition (MPT). Since UDCA has been used in the treatment for cholestatic liver disease in humans, the goal of this investigation was to evaluate whether CDCA-induced apoptosis is prevented by UDCA or tauroursodeoxycholic acid (TUDC) and to characterize the involvement of mitochondria in the process. Due to the interconnection between cell proliferation and programmed cell death, we also investigated the effects of bile acids on cell cycle. Cultured human HepG2 cells were treated in a dose- and time-dependent protocol in order to establish a low exposure to CDCA that causes apoptosis but not necrosis. Low dose CDCA induced a transient G1 and S phase block determined by flow cytometry. As a result, cell proliferation was prevented. UDCA or TUDC had no effect. CDCA-induced apoptosis, as determined by fluorescence microscopy of Hoescht 33342-stained nuclei, was strongly potentiated by UDCA, but not TUDC. Additionally, after exposure to UDCA plus CDCA, the cell membrane was permeable to fluorescent dyes, indicating that the combination caused both apoptosis and necrosis. The results suggest that UDCA potentiates CDCA cytotoxicity through both apoptotic and oncolytic cell death pathways, both of which may be initiated at the level of potentiation of induction of the MPT. 943 GALACTOSAMINE INDUCED ONCOTIC NECROSIS AND CASPASE-DEPENDENT APOPTOSIS IN RAT LIVER.

J. S. Gujral[1], A. Farhood[2] and H. Jaeschke[1]. *[1]Pharmacology and Toxicology, University of Arkansas for Medical Sciences, Little Rock, AR and [2]Pathology, University of Texas, Houston, TX.*

Galactosamine (Gal)-induced liver injury in rats is a well-recognized animal model resembling human viral hepatitis. Hepatocellular apoptosis and oncosis have been shown to occur after Gal treatment. However, it is yet unclear whether these two modes of cell death are sequential events or independent of each other. Female Sprague-Dawley rats received 500 mg/kg Gal and were observed for 3, 6 or 24 h. There was a time-dependent increase in plasma alanine transaminase (ALT) activities (24 h: 430 ± 122 University/L). Procaspase-3 processing and elevated levels of caspase-3 enzyme activity in the liver accompanied this. There was a 35-fold increase in the number of apoptotic hepatocytes after Gal (24 h: 5.4 ± 1.0 %) compared to untreated controls (0.14%). In addition to the apoptotic cells, cells with oncotic morphology were identified (24 h: 6.9 ± 0.8 %). Treatment with the pancaspase inhibitor IDN-7314 (2 doses of 10 mg/kg) or pretreatment with uridine (1 g/kg), reduced all parameters of apoptosis to baseline. However, there was no significant change in plasma ALT levels and oncotic necrosis at 6 h and only a 50% reduction at 24 h with the pancaspase inhibitor. Uridine, on the other hand, pre-

vented the increase in plasma ALT levels and reduced the number of apoptotic and oncotic cells by >80%. When animals were treated with a combination of Gal and Salmonella enteriditis endotoxin (0.1 mg/kg) (Gal/ET) for 6 h, plasma ALT levels, hepatic and plasma caspase-3 activities, and the number of cells undergoing apoptosis and oncosis, were higher compared to animals treated with Gal alone. Again, the pancaspase inhibitor reduced the parameters of apoptosis to control levels. However, plasma ALT levels and oncotic necrosis were only reduced by 50% and 30%, respectively. Conclusions: Galactosamine-induced hepatocellular apoptosis in rats is caspase-dependent. Although some of the apoptotic cells may undergo secondary necrosis, a significant number of hepatocytes die through oncotic necrosis as an independent mechanism of cell death.

944 MITOCHONDRIAL AUTOPHAGY DURING REMODELING OF CULTURED HEPATOCYTES.

S. Rodriguez and J. J. Lemasters. *Department of Cell and Developmental Biology, UNC at Chapel Hill, Chapel Hill, NC.*

BACKGROUND. Cultured hepatocytes de-differentiate, a phenomenon usually interpreted in terms of altered and suppressed gene expression. However, cellular remodeling (changes in cellular structure) also occurs during de-differentiation. **AIM.** To determine the role of autophagy and the mitochondrial permeability transition (MPT) in remodeling of cultured hepatocytes. **METHODS.** Isolated rat hepatocytes were cultured in Waymouth's medium. Mitochondria and acidic organelles (lysosomes and autophagosomes)were counted by confocal microscopy from the first to the fifth day of culture after labeling with 200 nM tetramethylrhodamine methylester and 150 nM LysoTracker Red (LTR), respectively. A LTR fluorescence assay was also used to quantify acidic organelle proliferation. To visualize movement of mitochondria into lysosomes, hepatocytes were co-loaded with 250 nM MitoTracker Green (MTG) followed by 150 nM LTR. **RESULTS.** Mitochondrial number decrease 55± 5% from 1000.4 ± 49 mitochondria per hepatocyte to 454 ± 52 ($p<0.0001$, n=30 cells) from the first to the fifth day of culture. Simultaneously, the number of acidic organelles increased per hepatocyte from 60 ± 6 to 204 ± 12 from the first to the third culture day, and decreased to 168 ± 18 on the fifth day ($p<0.0001$). The changes of LTR-labeled organelles observed by confocal microscopy correlated closely with measurements of total LTR fluorescence. Based on this assay, LTR fluorescence increased 250 ± 8% from the first to the third day of culture. CsA and NIM 811 (5 μM)), inhibitors of the MPT, blocked acidic organelle proliferation in the third day by 100 ±7 and 84 ± 10%. Tacrolimus (5 μM) an immunosuppressant that does not inhibit the MPT, was without effect. Confocal microscopy of hepatocytes on the first and second day of culture revealed movement of MTG-mitochondria into LTR-acid organelles as mitochondria disappeared from the cells. **CONCLUSIONS.** During remodeling of cultured hepatocytes, mitochondria undergo accelerated autophagy. This mitochondrial autophagy involves the MPT.

945 S-ADENOSYLMETHIONINE PROTECTS AGAINST ACUTE ALCOHOL INDUCED HEPATOTOXICITY.
